[1]'St Spiridon' Clinical Emergency Hospital, Department of Endocrinology, Iasi, Romania; [2]'Gr. T. Popa' University of Medicine and Pharmacy, Iasi, Romania; [3]'St Spiridon' Emergency Hospital, Department of Nuclear Medicine, Iasi, Romania; [4]'St Spiridon' Emergency Hospital, Department of General Surgery, Iasi, Romania.

Introduction
Although concomitant primary hyperparathyroidism (PHPT) and papillary thyroid carcinoma (PTC) has been repeatedly reported in medical literature with an incidence of 2.3–4.3%, no causal relationship has been elucidated. In most cases, diagnosis of PTC is mostly incidentally, while PHPT is usually the primary pathology. Recent literature supports the possible role of dual-phase ^{99m}Tc-MIBI parathyroid imaging in detecting PTC in patients with PHPT.
Case report
We present the case of a 47-year-old woman, recently diagnosed with nodular goiter and severe osteoporosis. Work up of the patient revealed increased levels of serum calcium and low level of phosphorus, high level of intact parathormone and hypercalciuria, consistent with primary hyperparathyroidism. Neck ultrasound identified a hypoechoic thyroid nodule, with macrocalcifications and intranodular vascularisation. The $^{99m}TcO_4$ -thyroid scan described no uptake of radiopharmaceutical in the left upper thyroid lobe. The ^{99m}Tc-MIBI scan revealed an increased uptake in the left lower thyroid lobe, and also in the left upper thyroid lobe. A diagnosis of PHPT and nodular goiter was established. The patient underwent parathyroidectomy and left thyroid lobectomy. After surgery, PHPT was biochemically cured. Histopathological examination revealed parathyroid adenoma in the left lower parathyroid gland, and papillary carcinoma in the suspect thyroid nodule. The completion of thyroidectomy was performed after 3 months. Patient underwent radioiodine ablation therapy, actually being on suppressive T4 treatment.
Conclusions
Even concurrent parathyroid adenoma and papillary thyroid carcinoma is rare, they may coexist. Prior to undergoing parathyroid surgery for PHPT, it's indicated to carefully screen for thyroid disease, to avoid a second surgery. Dual-phase 99mTc-MIBI parathyroid imaging may be useful in detecting both parathyroid adenoma and papillary thyroid carcinoma.

Multiple brown tumors inprimary hyperparathyroidismcaused by an adenoma mimicking metastatic bone disease with false positive results on computed tomography

Roma Pradhan[1,2], Prachi Shrimor[1] & Bikram Kharga[1]
[1]Sikkim Manipal Institute of Medical Sciences, Gangtok, India; [2]Dr Ram Manohar Lohia Institute of Medical Sciences, Lucknow, India.

Introduction
Brown tumors are bone lesions that arise due to osteoclastic activity and may mimic a true neoplasm. We encountered an unusual case of hyperparathyroidism with multiple brown tumors that mimicked metastatic bone tumor due to false positive results on computed tomography (CT).
Case
60 year old gentleman presented to the medicine out patient department with complains of fever, cough and right chest pain. Due to severe chest infection he was admitted, and CT scan was done. CT scan showed multiple lytic lesion in bilateral ribs with some areas of cortical breach suggestive of metastasis/multiple myeloma/enchondroma along with multiple calcifications in bilateral kidneys. With all the differentials in mind patient was evaluated. M Band was negative with high corrected calcium. Intact PTH was very high (3050 pg/ml: normal 9–55 pg/ml). On neck examination 3×2 cm nodule was palpable.With the report of high PTH and high calcium diagnosis of primary hyperparathyroidism was made with the doubt whether it's a palpable parathyroid carcinoma with bone metstasis. USG neck revealed hypoechoic lesion posterior to left inferior lobe of thyroid of 3.6 cm. As no MIBI scan was available in the vicinity, we went ahead with exploration. 4×3 cm lesion was found adherent to thyroid. Therefore enbloc excision was done with hemithyroidectomy. After resection, the patient's serum levels of calcium, alkaline phosphatase, and intact-PTH normalized Post-operatively patient developed clinical and biochemical hypocalcemia and managed with calcium infusion. Histopatholgy turned out to be parathyroid adenoma.
Conclusion
Palpable parathyroid tumor, advanced skeletal and very high serum calcium with parathyroid hormone levels are considered strong predictors of parathyroid carcinoma. Most of these features are common in Indian primary hyperparathyroidism (PHPT) patients although only few have Parathyroid carcinoma [1].

Regression of multipl brown tumors after surgical removal of mediastinal ectopic parathyroid adenoma

Sezin Dogan Cakir[1], Rumeysa Selvinaz Erol[1], Emre Sedar Saygılı[1], Seda Erem Basmaz[1], Adnan Batman[1], Feyza Yener Ozturk[1], Esra Cil Sen[1], Muhammed Masum Canat[1], Duygu Yildiz[1], Ezel Ersen[2] & Yuksel Altuntas[1]
[1]University Of Health Sciences, Sisli Hamidiye Etfal Training and Research Hospital, Department of Endocrinology and Metabolism, Istanbul, Turkey; [2]Istanbul University, Cerrahpasa Faculty Of Medicine, Department of Thoracic Surgery, Istanbul, Turkey.

Introduction
Parathyroid adenoma is the most common cause of primer hyperparathyroidism (PHPT). Mediastinal ectopic parathyroid adenomas constitute about 1–3% of the cases. Brown tumors ocur in less than 2% of the patients with PHPT. Moreover, those skeletal manifestations are even rarely demonstrated with maxillofacial bones involvement.
Case presentaton
Here we report a 36-years-old woman presented with approximately 30×26 mm mass growth in her mandible. She had been suspected for malignancy because of detected hypercalcemia and multipl lytic bone lesions. However, the biopsy of femur has been reported with no evidence of malignancy. Our laboratory findings revealed PTH dependent hypercalcemia (Calcium = 12.76 mg/dl (8.6–10.2), PTH = 1373 pg/ml (15–65), P = 1.8 (2.6–4.5), Mg = 1.93 mg/dl (1.6–2.6), creatinin = 0.73 mg/dl (0–0.95), ALP = 401 U/L (35–105), 24 h urinaryCa = 450 mg/24 h (100–300)). In bone scintigraphy, multipl foci of technetium-99 m uptake in calvarium, mandible, sternoclavicular joint, bilateral humerus, femur, sacroiliac joint, right iliac crest, costa and vertebra were detected. Maxillofacial CT scan identified multiple expansile lesions from 10×9 to 30×26 mm in frontal bone, hard palate, maxillary sinüs and mandible. Cervical sonography was unremarkable. Tc-99-m-MIBI scintigraphy revealed a 20 mm parathyroid lesion in the anterior mediastinum at subcarinal level. After intravenous hydration, loop diuretic, bisphosphonate and cinacalcet treatment, a thoracoscopic surgery was performed. The histopathology of the tissue was consisted with a parathyroid adenoma. Hungry bone syndrome occured following surgery and was treated with oral calcium and calcitriol for about 10 months. Over a year later, she has normal serum calcium and PTH levels. Control CT scan revealed a remarkable regression in Brown tumors and some of them did not even detected.
Conclusion
Brown tumors may mimic cancer metastasis therefore can be misdiagnosed. Physicians should always consider PHPT in the differential diagnosis. The most important way to distinguish these skeletal manifestations of PHPT from malignancy is by biochemical analysis with serum calcium and PTH levels. For localisation of PHPT, ectopic locations should also be evaluated if neck imagination reveals no lesion.

Multiple hormone resistance in a patient with follicular thyroid carcinoma and papillary microcarcinoma

Vlatka Pandzic Jaksic[1], Ivana Kraljevic[2], Petra Grbic Pavlovic[3] & Sanja Kusacic Kuna[2]
[1]Dubrava University Hospital, Zagreb, Croatia; [2]University Hospital Center Zagreb, Zagreb, Croatia; [3]Zadar General Hospital, Zadar, Croatia.

Pseudohypoparathyroidism and related hormone resistance disorders have very heterogeneous clinical course and might be recognized only in the adulthood, particularly with the development of hypocalcemia. We present a 41 years old male patient who underwent a neurological investigation because of progressive muscle weakness and elevated creatinine kinase. Very low serum calcium (1.46 mmol/l) with hyperphosphatemia, low magnesium and high normal PTH were measured. The patient also had slightly higher LH and high FSH with low normal free testosterone, 46 XY karyotype and testes of normal volume. Lumbar bone mineral density was increased. TSH was just over the reference range and thyroxine was normal. On the neck ultrasound 3 cm large suspicious nodule was found in the left thyroid lobe. FNA suggested follicular tumour and left thyroid lobectomy discovered follicular carcinoma with capsular invasion and papillary microcarcinoma. The patient was reoperated for right thyroid lobectomy and radioiodine ablation therapy was further performed. Postoperative PTH was low due to incidental parathyroidectomy. Malignant thyroid disease indicated the need for TSH suppression, but his TSH was persistently elevated despite increasing L-T4 dose up to 250 µg. Free T4 levels also rose and patient had thyrotoxic symptoms. High SHBG reflected tissue thyrotoxicosis. The combination of L-T4 and L-T3 therapy finally succeeded to decrease TSH to the middle of the normal reference range and SHBG was used as an additional marker for its optimization. We presumed that this patient has multiple hormone resistance associated with deficient G-protein α subunit signalling, involving at least PTH and gonadotropins. Low magnesium levels might have contributed to the breakdown of PTH and calcium balance that triggered hypocalcemia. Gonadotropin resistance did not interfere with male phenotype development and some physical features might appear as mild Albright's hereditary osteodystrophy. TSH resistance might also be found in such patients, but TSH is expected to fall promptly with L-T4 therapy. However, our patient showed inadequate responsiveness to L-T4 therapy suggesting a probable defect in thyroid hormone transport or deiodination. This was partially circumvented with L-T3 treatment, but uncertainties remain whether unsuppressed TSH might have negative impact on the risk for thyroid carcinoma recurrence. In this case we were faced with unexpected challenges of replacement therapy that could not be directly related with the primary disorder. Further genetic evaluation might contribute to our clinical assessment or even point to the common pathogenesis of this patient's clinical presentation.

Hypercalcemia not mediated by PTH: a case report

Yolanda Zambrano-Huerta, José Gregorio Oliva-García, Maria Teresa Herrera-Arranz, Pilar Olvera-Marquez, Elena Marquez-Mesa & Cristina Lorenzo-González
Hospital Nuestra Señora de La Candelaria, Santa Cruz de Tenerife, Spain.

Introduction
Hypercalcemia is a frequent hydroelectrolytic disorder, and primary hyperparathyroidism is the most common cause in oupatients. It is important to make an early diagnosis and adequate treatment in order to avoid possible complications such as nephrolithiasis, osteoporosis or the deterioration of glomerular filtration rate.
Clinical case
A 63-year-old female patient referred for hypercalcemia. Past medical history included stage IV chronic renal failure (with more marked deterioration of glomerular filtration in the last year) and recurrent bronchitis. She had polydipsia, polyuria, asthenia and 10 kg weight loss in the last year. Physical exam was normal except for mobile, soft bilateral supraclavicular, axillary and inguinal lymphadenopathies. Laboratory findings were as follow: Creatinine: 2.32 mg/dl (0.51–0.95), Corrected calcium:14.19 mg/dl (8.1–10.5), Phosphorus: 3.5 mg/dl (2.5–4.5), Angiotensin converting enzyme: 242 U/L (8.0–52), Parathormone related protein: <1.10 pmol /L (0.00–1.50); 1,25 hydroxyvitamin D: 99 pg/mL (16-56), intact PTH: 7.8 pg/mL (10.0–65.0), 25 hydroxyvitamin D: 18.3 ng/mL (Deficit: <20), Calcium/creatinine: 0.652, B2microglobulin: 11.06 mcg/ml (0.80–2.34), Leukocytes: 7750 10E3/µl (4.50–11.00), Erythrocyte sedimentation rate: 30 mm (1–20). No Monoclonal Component was evidenced. Bacilloscopy and mycobacterial culture: Negative, QuantiFERON-TB: Negative. Thorax radiography: Bilateral hilar adenopathies, without clear interstitial pattern. High resolution tomography: Supraclavicular, mediastinal, hilar, axillary, retrocrural, abdominopelvic, iliac and inguinal adenopathies; bilateral subpleural nodular lesions, focal splenic lesion of 0.8×0.70 mm. Biopsy of supraclavicular nodes showed non-necrotizing granulomas compatible with Sarcoidosis. Improvement of calcemia and renal function was obtained with intravenous hydration. After confirming the diagnosis of sarcoidosis, treatment with corticosteroids and hydroxychloroquine was initiated (current: corrected calcium 10.78 mg/dl; Cr 1.47 mg/dl)
Conclusion
Sarcoidosis is a rare cause of hypercalcemia, wich occurs as a result of the overexpression of the enzyme 1α-hydroxylase in the macrophages of granulomas (with the consequent increase of 1, 25-OH-vitamin D). It is essential to considered it in the differential diagnosis of non-PTH-dependent hypercalcemia.

Papillary thyroid cancer and primary hyperparathyroidism – a rare coincidence: case report

Entela Puca[1], Sonila Bitri[2], Kadir Burak Koza[3], Arben Dhima[4], Edmond Puca[5], Ema Lumi[6] & Blertina Olldashi[7]
[1]Service of Endocrinology, American Hospital, Tirana, Albania; [2]Service of Check-up and Toxicology, Tirana, Albania; [3]Service of General Surgery, American Hospital, Tirana, Albania; [4]Service of Radiology, American Hospital, Tirana, Albania; [5]Service of Infectious Diseases, UHC MOTHER TERESA, Tirana, Albania; [6]Regional hospital, Korce, Albania; [7]Neo style, Tirana, Albania.

Introduction
Although co-association between thyroid disease and parathyroid disease is rare, co-existence between parathyroid adenomas (HPPs) and papillary thyroid carcinomas (PTC) is rare. Perhaps this can be explained by the different embryological origins of the thyroids cells with the parathyroid cells.
Objectives
To report a case with parathyroid adenoma and multifocal papillary thyroid carcinoma.
Case presentation
A 62-year-old woman presented in the Endocrinology service due to a hypercalcemia 12.1 mg/dl (normal, 9.0–10.6 mg/dL), detected during routine biochemical evaluation for recidive kidney stone. High PTH value 280 pg/ml (normal range 10–69 pg/ml) confirmed primary hyperparathyroidism The neck ultrasound showed a potential parathyroid adenoma (nodule size 12×8 mm right lobe) as well as a nodule on the left lobe 24×10 mm. ^{99m}Tc-sestamibi parathyroid scintigraphy indicated an area with increased uptake at the aria of the nodule presented at ultrasonography. Because of the nodular aspect of the contralateral lobe: total thyroidectomy was performed and the histological examination the diagnosis of parathyroid adenoma and coincidence of invasive multifocal papillary thyroid carcinoma in the left thyroid lobe.). Hyperparathyroidism was cured with normal PTH and for the invasive PTC she received radioiodine therapy and now she is on suppressive LT4 treatment.
Conclusion
Careful evaluation of thyroid gland is advocated in all patients of primary hyperparathyroidism in order to prevent subsequent operations.

Role of Pro-inflammatory cytokines in Primary Hyperparathyroidism: A Prospective Study

M Venkateshwara Reddy[1], PRK Bhargav[2], B Ramesh[1], B Rajesh[1], B Chakrapani[3], D Vighnesh[1], A Rajkiran Reddy[4] & N Vimala Devi[2]
[1]VMC, Kurnool, India; [2]Endocare Hospital, Vijayawada, India; [3]Neuro Hospital, Nizamabad, India; [4]SMART Sunrise Hospital, Hyderabad, India.

Introduction
Primary Hyperparathyroidism (PHPT) is a frequent endocrine disease which requires surgical excision for definitive cure. Apart from genetic role in its pathogenesis, there are conflicting reports about role of immunomodulation in literature. In this context, we set out study the role of Pro- inflammatory cytokines in PHPT in South Indian population.
Material and methods
This prospective case-control study was conducted on surgically managed PHPT patients. Institutional ethical committee approval was obtained. Diagnosis of PHPT was based on biochemical confirmation, imaging, MIBI scanning and later confirmed by histopathology. Exclusion criteria were subjects with any systemic or chronic inflammatory disease or any medication which interferes with the normal function of the hypothalamic-pituitary-gonadal axis. Serum samples were collected from 21 PHPT subjects and 20 age matched healthy controls. Interleukin-6 (IL-6), Tumour necrosis factor-alpha (TNF-α) and high sensitive C reactive protein (hsCRP), leptin levels were measured in all serum samples. Statistical analysis was performed by one way ANOVA with Dunnet's test and Pearson correlation tests.
Results
The mean hSCRP level in PHPT and controls were 12.3 ± 3.6 mg/mL and 6.7 ± 1.3 mg/mL respectively. The mean TNF-α level and IL-6 level and Leptin levels were 189 ± 22.5 pg/mL, 16.4 ± 2.9 pg/mL and 3.1 ± 1.4 ng/mL respectively. Serum leptin level in controls was 3.7 ± 2.1 ng/mL. There was statistically significant difference of hsCRP and IL-6 level (P value < 0.05). There was no statistically significant difference of TNF-α and leptin between cases and controls (P value > 0.05).
Conclusions
This study shows raised titers of pro-inflammatory markers – IL-6 and hsCRP, while TNF-α and Leptin levels had neutral association with PHPT. But, the exact immuno-modulatory role and pathogenetic mechanism needs more investigational research.

Prevalence of kidney stones and osteoporosis in patients with primary hyperparathyroidism

Sherwin Criseno[1], Tarekegn Hiwot[1], Hyunseo Kim[2] & Neil Gittoes[1]
[1]Univeristy Hospitals Birmingham NHS Foudnation Trust, Birmingham, UK; [2]University of Birmingham, Birmingham, UK.

Aim
The main aim of this study was to evaluate the prevalence of kidney stones and osteoporosis in a cohort of patients with a confirmed diagnosis of primary hyperparathyroidism (PHPT).
Study design
This retrospective study reviewed the clinical records of patients with a confirmed diagnosis of PHPT in a single tertiary referral centre for metabolic bone disease over a period of 6 years (January 2010 – December 2015).
Patients
There were a total of 258 patients included in the study. 206 women (173 post-menopausal and 33 pre-menopausal) and 52 men with mean age of $63.5+14.84$ years.
Method
The clinical records of 258 patients were scrutinised to determine the prevalence of kidney stones (as identified by abdominal ultrasound or X-ray or computed tomography scan) and osteoporosis (defined as bone mineral density T-score of <-2.5 measured by dual-energy X-ray absorptiometry [DXA]). The prevalence of kidney stones and osteoporosis were compared between the symptomatic and asymptomatic PHPT patients.
Results
The prevalence of kidney stones in those who had undergone renal imaging was 13.86% (28 out of 202). There was no difference in the prevalence of kidney stones between the symptomatic and asymptomatic patients (15.45% versus 11.96%, $P=0.5428$). The prevalence of osteoporosis was found to be 43.62% (from 188 patients who had bone DXA scan). There was also no difference in the prevalence of osteoporosis between the symptomatic and asymptomatic patients (43.43% versus 43.82%, $P=1.0000$). Although only 27.13% of patients (70 out of 258) had urinary calcium excretion screening completed, symptomatic patients were found to have higher levels of urinary calcium compared with the asymptomatic patients (7.8 mmol/24 hours versus 4.4 mmol/24 hours, $P=0.0089$).
Conclusion
Kidney stones and osteoporosis are common in both symptomatic and asymptomatic PHPT patients. The results from this study provide further evidence of the need for a more rigorous and consistent evaluation of the kidneys and skeleton of patients diagnosed with PHPT in order to identify and manage these well- known end-organ complications appropriately.

Somatostatin receptors 1 and 5 are novel markers of parathyroid tumor aggressiveness

Sara Storvall[1], Helena Leijon[2], Eeva Ryhänen[1], Johanna Louhimo[3], Caj Haglund[3], Camilla Schalin-Jäntti[1] & Johanna Arola[2]
[1]Division of Endocrinology, Abdominal Center, University of Helsinki and Helsinki University Hospital, Helsinki, Finland; [2]Department of Pathology, Huslab and University of Helsinki, Helsinki, Finland; [3]Department of Surgery, Helsinki University Hospital and University of Helsinki, Helsinki, Finland.

Background
Parathyroid carcinoma (PC) is a rare cause of primary hyperparathyroidism (PHPT). Distinguishing PC from other tumours underlying PHPT can be difficult and sometimes malignant diagnosis can be made only after recurrence of the disease. Atypical parathyroid adenomas (APA) have similar histological features as PC but lack signs of invasive growth. The expression of somatostatin receptors (SSTR) 1–5 in parathyroid tumours, commonly expressed in other neuroendocrine tumors, is currently not known.
Aim
To examine immunohistochemical expression of SSTRs 1–5 in parathyroid tumours: parathyroid adenomas (PA), APAs and PCs.
Methods
Nationwide cohort of PC ($n=32$), age- and gender-matched PA ($n=72$) and APA ($n=28$) were used. TMA blocks were stained with antibodies for SSTR subtypes 1–5 and intensity (0–3) of cytoplasmic, nuclear and membrane expression was

scored. Correlations of SSTRs with parafibromin, Ki-67, fibrous septae and biochemical and clinical characteristics were also analysed.
Results
Membrane expression was negligible for all receptor subtypes. Expression of **SSTR 2-3** was negative. Nuclear **SSTR1**, nuclear and cytoplasmic **SSTR4** and nuclear **SSTR5** expression increased- and cytoplasmic SSTR5 decreased with tumour aggressiveness:

Receptors with statistical significance and their relative expression in the tumor groups

	PA	APA	PC	*p*-value
Nuclear **SSTR1**	1.5%	15%	41%	<0.001
Cytoplasmic **SSTR4**	29%	40%	56%	0.027
Nuclear **SSTR4**	31%	51%	62%	0.008
Nuclear **SSTR5**	15%	51%	69%	<0.001
Cytoplasmic **SSTR5**	85%	78%	56%	0.02

Expression of nuclear SSTR5 was related to decreased parafibromin expression ($P=0.002$). Serum calcium and parathyroid hormone concentrations correlated with expression of nuclear SSTR1 ($P<0.001$), inversely with nuclear SSTR5 ($P<0.001$) and positively with cytoplasmic SSTR5 ($P=0.045$). Tumor size, fibrous septae and Ki-67 were related to expression of nuclear SSTR1 ($P=0.029$, $P<0.001$, $P=0.005$) and SSTR5 ($P=0.023$, $P<0.001$, $P<0.001$)
Conclusion
SSTR1 and SSTR5 expression may have a role in parathyroid tumour pathogenesis.

Vitamin D and cancer of the prostate
Ifigenia Kostoglou-Athanassiou[1], Lambros Athnassiou[2], Nicolaos Mourmouras[3], Stefanos Topalidis[3], Athanasios Filios[3], Achilleas Karafotias[3], Olga Mascha[4] & Dimitrios Delakas[3]
[1]Department of Endocrinology, Asclepeion Hospital, Voula, Athens, Greece; [2]1st Department of Medicine, Asclepeion Hospital, Voula, Athens, Greece; [3]Department of Urology, Asclepeion Hospital, Voula, Athens, Greece; [4]Department of Microbiology and Biochemistry, Asclepeion Hospital, Voula, Athens, Greece.

Introduction
Vitamin D deficiency has been found to be associated with multiple chronic diseases, including diabetes mellitus type 1 and 2, rheumatoid arthritis and other autoimmune diseases. However, the relationship between vitamin D and cancer remains controversial. Vitamin D deficiency is widely prevalent in the general population. In accordance, vitamin D deficiency was found to be prevalent in Scotland. In a study performed in Scotland vitamin D deficiency was observed, however, no relationship with specific cancers was found. Additionally, relationship between vitamin D receptor mutations and cancer of the prostate has been observed.
Aim
The aim was to estimate the relationship between vitamin D and cancer of the prostate.
Methods
In a group of 31 patients suffering from prostate cancer $25(OH)D_3$ levels, PTH levels and calcium levels were measured. Observations were also performed in 31 patients, male, in the same age group serving as controls.
Results
Vitamin D, $25(OH)D_3$ levels, were found to be 25.32 ± 1.9 ng/ml and 20.21 ± 2.37 ng/ml in the group of prostate cancer patients and the control group, respectively, ($P<0.001$).
Conclusions
The relationship between vitamin D and cancer remains controversial. A relationship has been observed between mutations of the vitamin D receptor and cancer of the prostate. However, the relationship between vitamin D deficiency and cancer is controversial. In the present study higher vitamin D levels were observed in prostate cancer patients as compared to a control group of men within the same age group. Therefore, when administering vitamin supplementation as well as vitamin D treatment for osteoporosis or osteomalacia caution should be exercised in order to keep vitamin D levels within the normal range. It should also be noted, that $25(OH)D_3$ exerts its effects by binding to its receptor within the core of the cell, thereby exerting powerful, important and as yet unknown effects in the human organism.

Feasibility and efficacy in ultrasound guided percutaneous microwave ablation of primary hyperparathyrodism with parathyroid nodules
Lei Chen
Chinese PLA General Hospital, Beijing, China.

Purpose
To investigate the feasibility and efficacy of US-guided microwave ablation on primary hyperparathyrodism patients who were excluded from surgical treatment.
Materials and methods
From May 2014 to December 2017, 30 parathyroid nodules of 25 patients underwent percutaneous ultrasound-guided MWA in our department. Contrast enhanced ultrasonography, ^{99}Tmc-MIBI test, laboratory data and clinical symptoms were evaluated before therapy; 2 hours, 1, 3 days, 1 week and 1, 3, 6 and 12 months after treatment, and every 6-12 months thereafter.
Results
Twenty-two (88%) patients underwent successful ablation among total 25 patients, with 4 patients who underwent ablation of 2 nodules. Minor complications in 3 patients (12%) occurred, including transient fever and voice change.
Conclusions
MWA of hyperplastic parathyroid glands for treating primary HPT proved feasible and effective, while showing meaningful reduction in iPTH, calcium and phosphorus level, minor complications and satisfying clinical outcomes.

Association between age at onset of menopause and fracture risk: a systematic review and meta-analysis
Panagiotis Anagnostis[1,2], Pavlos Siolos[2], Nifon Gkekas[2], Nikoletta Kosmidou[2], Stavroula Paschou[3], Michael Potoupnis[4], Eleftherios Tsiridis[4] & Dimitrios Goulis[1]
[1]Unit of Reproductive Endocrinology, First Department of Obstetrics and Gynecology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Police Medical Center of Thessaloniki, Thessaloniki, Greece; [3]Division of Endocrinology and Diabetes, 'Aghia Sophia' Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [4]Academic Orthopaedic Unit, Aristotle University Medical School, General Hospital Papageorgiou, Thessaloniki, Greece.

Introduction
Early menopause (defined as age of menopause <45 years) and premature ovarian failure (defined as age of menopause <40 years) are associated with accelerated bone loss and increased risk of osteoporosis in later life. However, their association with increased fracture risk has not been established, with studies yielding conflicting results. The aim of this study was to systematically review and meta-analyze studies evaluating the effect of age at onset of menopause on fracture risk.
Methods
Search was conducted in three databases (PubMed, Central, Embase). Eligible for the review were studies that have reported fractures (total, vertebral, non-vertebral, hip) in women with premature ovarian failure or early menopause versus women with natural menopause. Data were expressed as odds ratio (OR) with 95% confidence intervals (CI) and combined by the Dersimonian/Laird method. The I^2 index was employed to indicate heterogeneity; publication bias was inspected by Funnel plots and tested by the Egger's test. Meta-analysis was performed using RStudio (Version 1.0.414, RStudio, Inc.) and the programming language R (version 3.4.3, 2017, The R Foundation for Statistical Computing).
Result
Twelve (four case-control and eight cohort) studies, including a total of 39,510 postmenopausal women (9,668 of which with fractures), were eligible for qualitative and quantitative analysis. Women with premature ovarian failure (age $<$ 40 years) had similar probability of experience a fracture (OR: 1.24, 95% CI: 0.77–1.99, I^2: 58%, 5 studies) compared to women with age of menopause $>$ 40 years. Women with early menopause (age $<$ 45 years) had similar probability of experience a fracture (OR: 1.43, 95% CI: 0.87–2.36, I^2: 94%, 9 studies) compared to women with age of menopause $>$ 45 years.
Conclusions
There is no evidence that women with premature ovarian failure or early menopause experience higher bone fracture risk in later life compared to women with natural menopause. More prospective cohort studies with adequate sample sizes and superior methodological characteristics are needed in order to estimate the effect of early age of menopause on bone fractures.

Hypoglycemia in non-diabetic patients: clinical features and causes

Imen Sakka, Ibtissem Oueslati, Melika Chihaoui, Meriem Yazidi, Fatma Chaker, Ons Rejeb & Hedia Slimane
Department of Endocrinology, La Rabta Hospital, Tunis, Tunisia.

Introduction
Hypoglycemia in non-diabetic patients is a rare condition. Because of the non-specificity of its symptoms and the multiplicity of its causes, hypoglycemia represents often a diagnostic challenge for general practitioners. The aim of our study was to assess the clinical features of hypoglycemia and to determine its causes in non-diabetic patients.
Methods
We conducted a retrospective analysis in 49 non-diabetic patients who were admitted to our endocrinology department between 2012 and 2017 with a clinical suspicion of hypoglycemia. The diagnosis of hypoglycemia was established using Whipple's triad. In patients with confirmed hypoglycemia, clinical and paraclinical features were analyzed.
Results
Among the 49 participants, Whipple's triad was documented in only 40 patients. In the other patients, symptoms were secondary to cardiac arrhythmia, anxiety attack, hysteria and dizziness. The mean age of patients with confirmed hypoglycemia was 43 ± 19.57 years [14–80 years] and the sex-ratio (F/M) was 2.14. Thirty nine percent of our patients were unemployed and 65% of patients have a diabetic family's member. Hypoglycemia was severe in 51% of cases. Neurogenic symptoms were present in 97% of cases (sweating, palpitations and shakiness in 90%, 73% and 61% of cases, respectively). Neuroglycopenic signs were reported in 70% of cases: seizure and coma were found in 17% and 36% of cases, respectively.The mean concomitant blood glucose concentration was 0.37 ± 0.1g/l. Etiological investigations revealed reactive hypoglycemia in 21% of cases and organic hypoglycemia in 79% of cases. Adrenal insufficiency was diagnosed in 29% of cases, factitious hypoglycemia in 24% of cases, drug induced hypoglycemia in 15%, paraneoplastic hypoglycemia secondary to gastrointestinal stromal tumor was diagnosed in one case. In three cases, the cause of hypoglycemia was unknown.
Conclusion
Although autonomic and neuroglycopenic symptoms are highly suggestive of hypoglycemia, the diagnosis of hypoglycemia should be established only in the presence of Whipple's triad.Then, appropriate evaluation should be conducted in order to set up the underlying cause.

First report of Gaucher disease in Montenegro: Genotype/phenotype correlations

Sanja Medenica[1], Snezana Vujosevic[1,2], Vesko Vujicic[3], Milena Dapcevic[3], Nikola Bakic[3], Yang Ruby[4], Jun Liu[4] & Pramod Mistry[4]
[1]Department of Endocrinology, Internal Medicine Clinic, Clinical Center of Montenegro, Podgorica, Montenegro; [2]School of Medicine, University of Montenegro, Podgorica, Montenegro; [3]Hematology Department, Internal Medicine Clinic, Clinical Center of Montenegro, Podgorica, Montenegro; [4]Yale Lysosomal Disease Center and Inherited Metabolic Liver Disease Clinic, Yale University School of Medicine, New Haven, Connecticut, USA.

Background
Gaucher disease (GD) is the most common lysosomal storage disorder. The defect is deficiency of lysosomal glucocerebrosidase (GBA), due to biallelic mutations in GBA gene, characterized by the deposition of GBA in cells of the macrophage-monocyte system.
Objective
To report clinical phenotypes of GD and correlate with GBA gene mutations, and to identify GBA gene mutation in patients diagnosed with GD in Montenegro.
Methods
Demographic and clinical phenotype was recorded for each patient in the study. The diagnosis was confirmed with low leucocyte acid beta glucosidase activity. GBA gene sequencing was performed after long range PCR for selective amplification of GBA active gene and analysis of the entire coding region.
Results
We report five patients (four male, one female) of type 1 GD. The age at diagnosis ranged from 7 to 40 years. Patients experienced delays of 1–12 years in diagnosis after onset of symptoms. Most common mode of presentation was variable degree of splenomegaly and thrombocytopenia; other symptoms included bone pain, hepatomegaly, abdominal pain and fatigue. Osteopenia was present in majority of the patients: 4/5. All patients had asymptomatic Erlenmeyer flask deformity of the distal femur. In one patient hepatitis B was diagnosed, one had Parkinsonism, and one low pulmonary diffusion capacity for carbon monoxide. On enzyme replacement therapy (ERT) the hematological and visceral parameters showed significant improvement, and no significant progression in bone mineral density was noticed. GBA gene sequencing revealed homozygosity for N370S mutation in one patient. Genotypes of other patients were N370S/55bp deletion, N370S/D409H (in two patients), and H255Q/N370S (one patient).
Conclusion
This is the first report of GD from Montenegro. N370S was the most common mutation occurred in all five patients, one patient was homozygous and others compound heterozygous. The phenotypes of GD1 encountered in Montenegro were severe but all responded well to ERT.

Hip axis length in women with type 1 diabetes mellitus

Volha Vadzianava[1], Alla Shepelkevich[2], Nadzeya Karytska[2] & Elvira Malevich[1]
[1]Belarusian Medical Academy of Post-Graduate Education, Minsk, Belarus; [2]Belarusian State Medical University, Minsk, Belarus.

Objective
In the early manifestation of type 1 diabetes (T1D) the process of bone mineralization is disrupted and the peak of bone mass is initially lower than in healthy individuals. In addition to low mineralization T1D may be a risk factor for a smaller bone size including the hip axis length (HAL). The aim of this study is to assess the HAL in women with T1D.
Materials and methods
We examined 68 T1D women, age: 31(25–37.6)yrs., duration of diabetes: 11(7–17)yrs., HbA1c: 8.5(6.9–10.4)%, BMI: 23.4(22.3–25.8 kg/m^2). The control group consisted of 53 healthy age- and BMI-matched females. Bone mineral density (BMD) was measured with dual X-ray absorptiometry. Hip axis length (HAL) was determined using the Advanced Hip Analysis program.
Results
BMD (Z-score) of the femoral neck in the group T1D women was significantly lower (T1D: -0.5 ($(-1.1)-0.2$) vs. controls: 0.1 ($(-0.6)-0.7$), $P=0.006$ respectively) compared to control group. Previous low-energy fractures occurred more frequently in female with T1D (T1D: $n=10$ (14.7%) vs. controls: $n=2$ (3.9%), $F=0.033$, $P=0.042$ respectively). In women with T1D HAL was statistically shorter than in the control group (T1D: 104.8(100–109.8) vs. controls: 107.3(103.8–110.1), $P=0.018$ right femur; T1D: 106(100.2–110.2) vs. controls: 107.5(105.2–110.8), $P=0.035$ left femur respectively).
Conclusions
In women with T1D HAL was statistically shorter than in the control group. The results of our own research potentially indicate the structural changes of the hip geometry in women with T1D.

P284

Vertebral fractures in patients with type 2 diabetes mellitus

Volha Vadzianava[1], Alla Shepelkevich[2], Nadzeya Karytska[2] & Natallia Vasilyeva[3]
[1]Belarusian Medical Academy of Post-Graduate Education, Minsk, Belarus; [2]Belarusian State Medical University, Minsk, Belarus; [3]Republican Medical Rehabilitation and Balneotherapy Centre, Minsk, Belarus.

The aim of study
Is to assess the frequency of occurrence of vertebral fractures (VFx) and their relationship with hip geometric parameters in type 2 diabetes mellitus (T2DM) postmenopausal women.
Materials and methods
We examined 94 T2DM women, age: 59.6(55.1–63.2)yrs., duration of DM: 7(4.5–11)yrs., duration of menopause 8.5(4–13)yrs., HbA1c:7.3(6.6–9.8)%). The comparison group consisted of 89 women without DM (age:58.3 (52.8–61.2)yrs., duration of menopause 8(3–11)yrs.). Bone mineral density (BMD) at lumbar spine and femoral neck and VFx were measured with dual X-ray absorptiometry. Geometric parameters were determined using Advanced Hip Analysis program. ISI-impact strength index was calculated using the formula of Karlamangla.
Results
It has been established that the BMD (T-score) of the lumbar spine (T2DM: $-1((-1.9)-0.1)$ vs. comparison gr.: $-0.8((-1.8)-0.1)$, $P=0.815$, respectively) and of the femoral neck (T2DM: $-0.7((-1.3)-0.2)$ vs. comparison gr.: $-0.7((-1.3)-0.1)$), $P=0.730$, respectively) in patients with T2DM is comparable with the comparison group, while the BMD of the proximal femur is higher in women with T2DM (T2DM: $0.3((-0.7)-1.4)$ vs. comparison gr.: $-0.1((-0.9)-0.7)$ $P=0.037$, respectively). VFx occur statistically significantly more often in patients with T2DM (T2DM:19.15%, $n=18$ vs. comparison gr.:7.87%, $n=7$, $X^2=4.935$, $P=0.026$). In patients with type 2 diabetes considering the OR and 95% of CI the high risk of VFx of 1, 2, and 3 degrees has been found in comparison with the women without DM (OR = 2.77, 95% CI = 1.098–7.012). T2D females with VFx had lower ISI (T2D with VFx: 0.22 (0.20–0.27) vs. T2D without VFx 0.25(0.23–0.28), $P=0.035$, respectively) and larger femoral neck diameter (T1D with VFx: 34.6(33.4–36) vs. T1D without VFx 32.9(31.5–34.8) $P=0.020$, respectively) compared with T1D females without VFx.
Conclusions
VFx statistically occur significantly more often in women with T2DM regardless of BMD. The obtained results testify to the lower ISI, larger femoral neck diameter in group T2DM with the presence of VFx.

P285

Vertebral fractures in women with type 1 diabetes mellitus

Volha Vadzianava[1], Alla Shepelkevich[2], Nadzeya Karytska[2] & Natallia Vasilyeva[3]
[1]Belarusian Medical Academy of Post-Graduate Education, Minsk, Belarus; [2]Belarusian State Medical University, Minsk, Belarus; [3]Republican Medical Rehabilitation and Balneotherapy Centre, Minsk, Belarus.

Research object
Since type 1 diabetic (T1D) patients are at higher fracture risk in comparison to general population the aim of study was to assess, whether femur geometric parameters are connected with Fx in T1D females.
Materials and methods
We examined 68 T1D 31 yrs. old (25–37.6) females with disease duration of 11 (7–17) yrs. and the average HbA1c equal to 8.5 (6.9–10.4) %. The control group consisted of 53 healthy age- and BMI-matched females. Bone mineral density (BMD) and VFx were measured with dual X-ray absorptiometry. Geometric parameters were determined using Advanced Hip Analysis program.
Results
T1D females had lower BMD at femoral neck (T1D: Z-score $-0.5((-1.1)-0.2)$ vs controls: Z-score 0.1 $((-0.6)-0.7)$, $P=0.006$, respectively), higher frequency of fragility Fx (T1D: $n=10$ vs controls: $n=2$, $P=0.042$, respectively), VFx (T1D: $n=12$ vs controls: $n=1$, $P<0.01$, respectively) compared to controls. Differences in the hip geometric parameter of CSA in women did not reach a statistically significant difference, however, there was a tendency to decrease this parameter in the group of T1D women. Age, diabetes duration, age of diabetes manifestation, and the prevalence of chronic complications were not different between type 1 diabetics with and without VFx. When comparing patients with VFx and without it it was found that in patients with type 1 diabetes with a VFx the BMD (Z-score) is lower both at spine $(-1.7((-2.3)-(-1.0))$ vs $-0.3((-1.1)-0.5)$, $P<0.001$, respectively) and at femoral neck $(-1.4\pm1.1$ vs -0.5 ± 1.05, $P=0.002$, respectively) and the daily insulin dose per kg is higher (0.89(0.76–1.25) vs. 0.69(0.54–0.9), $P=0{,}010$ respectively). T1D females with VFx had lower CSMI (cross-sectional moment of inertia) (T1D with VFx: 7836 (6533–10377) vs. T1D without VFx 10140(8770–12522), $P=0.035$, respectively) and CSA (cross-sectional area) (T1D with VFx: 122(104–137) vs. T1D without VFx 144(129–165) $P=0.006$, respectively) compared with T1D females without VFx. In the logit regression analysis VFx were associated with BMD spine, CSA and daily insulin dose.
Conclusions
Type 1 diabetic women have low BMD, higher prevalence of VFx. VFx were associated with BMD spine, CSA and daily insulin dose.

P286

Proximal femur structural geometry changes in women with type 2 diabetes mellitus

Volha Vadzianava
Belarusian Medical Academy of Post-Graduate Education, Minsk, Belarus.

Objective
The aim of this study is to assess the geometric parameters of the femur in patients with type 2 diabetes mellitus (T2DM) without osteoporosis.
Materials and methods
There were examined totally 97 type 2 diabetic females. We included in our study 60 type 2 diabetic females without osteoporosis (T-score more than – 2.5 in axial skeleton), age: 56.9(53.8–60.9) yrs., duration of DM: 6.5(5–11.5)yrs., HbA1c: 8.6(6.9–10.1)%, BMI: 33.2(29.3–36.8) kg/m^2). The control group consisted of 45 women age: 56.2 (51.4–59.2), BMI: 31.6(27–36). Bone mineral density (BMD) was measured with DXA. Geometric parameters were determined using Advanced Hip Analysis program including hip axis length (HAL), cross-sectional moment of inertia (CSMI), cross-sectional area CSA and the femur strength index (FSI).
Results
Age, height and weight were not different between T2DM and controls. In group T2DM duration of menopause (T2DM: 6.5(3–10)yrs. vs controls: 5(2–8) yrs., $P=$ 0.009 respectively) was longer than in the control group. It has been established that the BMD (T-score) of the lumbar spine in patients with type 2 diabetes mellitus was lower in comparison with the control group (T2DM: T-score $-0.4((-1.3)-0.3)$ vs controls: T-score -0.1 $((-0.7)-0.6)$, $P=0.023$ respectively). However, the BMD of the proximal femur (T2DM: T-score $0.5((-0.35)-1.6)$ vs controls: T-score 0.6 (0.2–1.2), $P=0.578$ respectively) and femoral neck (T2DM: T-score $-0.25((-1)-0.5)$ vs controls: T-score -0.1 $((-0.5)-0.6)$, $P=0.097$ respectively) was comparable in both groups. T2DM females had lower CSMI (T2DM: 10169 (8777–11482) vs. controls 11106(9951–12803), $P=0.012$ respectively) and CSA (T2DM: 145.5(128–162.5) vs. control 151(141–167) $P=0.044$ respectively) compared with the control group. The HAL, FSI and neck-shaft angle of the femoral neck in both groups were comparable. With comparable anthropometric parameters and BMD of the femur these changes may indicate an increased cortical porosity of bone and a poor bone quality.
Conclusions
In female with DM 2 type hip geometric parameters CSA and CSMI were lower in comparison to the control group. The results of our own research indicate that hip geometry structural changes might potentially predispose to higher fracture risk in T2D females.

Case report: male adult with autosomal-dominant osteopetrosis

Sebastian Schmidt[1], Gabriele Lehmann[2], Ullrich Alfons Müller[1] & Gunter Wolf[3]
[1]Clinic for Internal Medicine III, Endocrinology, University of Jena, Jena, Germany; [2]Clinic for Internal Medicine III, Rheumatology/Osteology, University of Jena, Jena, Germany; [3]Clinic for Internal Medicine, Nephrology, University of Jena, Jena, Germany.

Background
Osteopetrosis is a rare chronic bone disease with high bone mineral densitiy due to impaired osteoclast activity or development. Genetic mutations result in severe infantile (autosomal recessive, incidence 1:200,000) and less severe adult forms (autosomal-dominant osteopetrosis/ADO). The incidence is estimated at 1:20,000 for noninfantile forms. In adults osteopetrosis is often asymptomatic with increased risk for bone fracture. Treatment is symptom-based (e.g. calcium, cholecalciferol, calcitriol, red blood cell transfusion, interferon γ-1b, corticosteroids) since effective therapy is missing.
Case report
Twenty-seven year old male patient with a history of osteopetrosis for 9 years (self-employed photographer, working abroad, surfer/skater, smoker). Osteopetrosis was radiographically diagnosed in context with car accident and traumatic fracture of left clavicle. Further typical findings in spine ('sandwich vertebrae'), ribs, upper and lower limbs were detected in computertomography because of unclear abdominal pain and transient increased cervical lymph nodes 08/2017. Consultation of endocrinologist in 10/2017: No further bone fractures since 2008, slight pain of caudal left ribs after bruising, no routine medication. Diagnostic expert-based recommendations were taken from recent consensus guidelines from the osteopetrosis working group (Wu et al. 2017).
Results
Increased: tartrate-resistant acid phosphatase/TRAP5b: 54 U/l (1.4–6.1), BB isozyme of creatine kinase (CK-BB): 0.77 µkat/l (0.0 in healthy persons); bone mineral density (in g/cm^2: L1–L4 2.981; right femur 2.509; left femur 2.585) and T-score in DXA-scan (L1–L4 + 14.7; right femur + 10.9; left femur + 11.5 S.D.). Genetic analysis confirmed CLCN7 mutation (heterozygous) and thus autosomal dominant osteopetrosis type 2 (ADOII, Albers-Schönberg disease). MRI was cancelled due to metal near right orbita. Native computertomography of the brain excluded cranial (optic) nerve impingement but confirmed generalized thickening of the bone. Subspecial clinical complications (ophthalmology, hematology), pathologic alterations in renal ultrasonography and abnormal blood count (with differential), lactate dehydrogenase, serum calcium, intact parathyroid hormone, phosphorus, creatinine, 25-hydroxyvitamin D were not seen. Clinical controls and minimum laboratory (serum calcium, phosphorus, 25(OH)D, parathyroid hormone, blood count) were arranged half-yearly as recommended above (Wu et al. 2017). We clarified the patient of an increased risk of spontaneous and traumatic bone fracture with risky sports.
Conclusions
We established the patient's diagnosis ADO biochemically and genetically after first radiographic signs were confirmed one decade ago. Patients with osteopetrosis need to be monitored lifelong if appropriate in a multidisciplinary setting. Since epidemiological and clinical data is lacking publication of case reports is crucial.

P288

Fragility index in type 2 diabetes for identification of patients with risk of osteoporotic fracture or prevalent fracture

Antonia García-Martín[1,2], María Dolores Avilés-Pérez[1], Beatriz García-Fontana[1,2], María Teresa Márquez-Herández[1], María Hayón[1] & Manuel Muñoz-Torres[1,2]
[1]Bone Metabolic Unit. Endocrinology Division. Hospital Universitario Campus de la Salud., Granada, Spain; [2]RETICEF, Granada, Spain.

Introduction
Diabetes mellitus is associated with an increased risk of osteoporotic fractures, which leads to an increased risk of disability and frailty.
Aims
To assess the prevalence of frailty in type 2 diabetes and to analyze the relationship with bone mineral density (BMD) and Trabecular Bone Score (TBS), fracture risk and prevalent fractures.
Methods
We carried out a cross-sectional study of 75 diabetic patients (65 ± 7 years, 55.3% males). We collect data on clinical history, measured BMD and obtened trabecular bone score (TBS) by dual-energy X-ray absorptiometry (DXA) and software TBS InSight® respectively. We also estimated 10-year fractures risk using FRAX, FRAX adjusted with TBS and QFracture score. Finally, we conducted a validated fragility survey (Frail Scale).
Results
20% (*n*: 15) were considered fragile, 8% (n: 6) had densitometric osteoporosis and 13% (*n*: 10) had a history of fragility fractures. Frail scale was not related to the values of BMD or TBS. However, we found significant differences between fragile and non-fragile diabetic patients in the risk of major osteoporotic fracture (MOF) or hip fracture (HF) at 10 years in the FRAX score (MOF:: 4.7 4.2 vs 2.7 2.1 $P = 0.025$), FRAX score adjusted with TBS (MOF: 6.9 5.1 vs 3.8 3.1 $P = 0.015$; CF: 2 2.7 vs 0.7 1 $P = 0.009$) and QFracture score (MOF: 8.9 6.8 vs 4.9 3.8 $P = 0.012$; CF: 4.6 4.8 vs 2.3 2.3 $P = 0.018$). There were more patients with history of fractures in the group of fragile patients compared to non-fragile patients (35.7% vs. 8.2% $P = 0.006$).
Conclusion
Fragility index in type 2 diabetes mellitus is useful for identification of patients with risk of osteoporotic fracture or prevalent fracture.

Relationships between vitamins and lipids in the elderly

Asli Kilavuz[1], Sumru Savas[1], Pelin Tutuncuoglu[2], Fulden Sarac[1] & Fehmi Akcicek[1]
[1]Department of Geriatric Medicine, Ege University Medical Faculty, Izmir, Turkey; [2]Ataturk Training and Research Hospital, Department of Endocrinology and metabolism, Izmir, Turkey.

Objective
In recent years, many studies have been conducted on the beneficial effects of vitamin D. Vitamin D have many important effects on calcium metabolism, skeletal system and also on different systems. Low serum vitamin D levels are predictors of type 2 diabetes mellitus, cancer, cardiovascular diseases, immunological diseases and even mortality. The relationships between vitamin D and cardiovascular diseases can be explained by the lipid-lowering effect of vitamin D. In many studies, there is general agreement that high serum vitamin D levels are associated with a healthy serum lipid profile. The aim of this study was to investigate whether vitamin D levels are associated with lipid levels in outpatients, and to compare the patients above and below 60 years of age.
Material and methods
The medical records of patients who applied to outpatient clinic between January 2015 and August 2017 were reviewed. 236 outpatients aged 19–88 years who had serum 25-hydroxyvitamin D (25(OH)D) levels, total cholesterol, LDL-cholesterol, high density lipoprotein (HDL) cholesterol and triglyceride levels were included in the study. Patients' body mass index (BMI) was calculated. Overweight was defined as BMI (kg/m^2) between 25.0 and 29.9 and obesity was defined as BMI ≥30.0. Total cholesterol levels ≥200 mg/dl, LDL cholesterol levels ≥140 mg/dl and triglyceride levels ≥ 150 mg/dl were classified as high. HDL-cholesterol levels <40 mg/dl were defined as low. Serum 25(OH)D level <50 nmol/l, or <20 ng/ml, is an indication of vitamin D deficiency.
Results
This study was conducted with 236 outpatients aged 19–88 years. 46.2% of the study population were over 60 years old, 83.5% were female, 18.2% were normal weight, 50.4% were overweight and 31.4% were obese. 56.8% of the outpatients had high total cholesterol levels, 38.1% of had high LDL cholesterol levels and 30.1% of had high triglyceride levels. 14% of the outpatients had low HDL cholesterol levels. The prevalance of vitamin D deficiency was 49.6% (95% CI, 41–58%).
Conclusion
Patients with increased 25(OH)D levels in epidemiological studies; there was a significant decrease in total cholesterol, LDL cholesterol and triglyceride levels and an increase in HDL cholesterol levels (1–3). But, in our study, there was no statistically significant relationship between vitamin D deficiency and lipid profile in patients over 60 years and under 60 years of age. We planned to increase the number of patients.

Vitamin D and obesity

Lambros Athanassiou[1], Ifigenia Kostoglou-Athanassiou[2], Asimoula Koteli[3], Clio Mavragani[1], Panagiotis Athanassiou[4] & Michael Koutsilieris[1]
[1]Department of Physiology, Medical School, University of Athens, Athens, Greece; [2]Department of Endocrinology, Asclepeion Hospital, Voula, Athens, Greece; [3]Department of Biopathology, St. Paul's Hospital, Thessaloniki, Greece; [4]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece.

Introduction
Vitamin D has been found to be associated with multiple chronic diseases, including diabetes mellitus type 1 and 2, rheumatoid arthritis, systemic lupus erythematosus and other autoimmune diseases. Low vitamin D levels have also been observed in patients with obesity.
Aim
The aim was to study vitamin D levels in patients with morbid obesity.
Methods
In a group of 32 patients with morbid obesity, BMI 41.77 ± 1.15 (mean ± SEM), range 27.76–51.99, weight 112.05 ± 3.18 kg, range 85–150 kg, $25(OH)D_3$ levels were measured. Observations were also performed in a group of 32 patients with BMI and weight in the normal range, within the same age group, of the same sex, serving as controls.
Results
In the group of obese patients $25(OH)D_3$ levels were 10.77 ± 0.51 ng/ml as opposed to 24.51 ± 1.35 ng/ml in the control group, ($P < 0.001$, Student's t test). A negative correlation was observed between $25(OH)D_3$ levels and BMI, standardized beta coefficient −0.87, $P = 0.001$. A negative correlation was also observed between $25(OH)D_3$ levels and weight, standardized beta coefficient −0.345, $P < 0.001$.
Conclusions
Very low vitamin D levels were observed in a group of morbidly obese patients. A negative correlation was observed between $25(OH)D_3$ levels, BMI and weight, meaning that low vitamin D levels were correlated with high BMI and weight. Vitamin D has been found to be a negative index of the acute inflammatory response (Quraishi *et al*, Curr Opin Clin Nutr 2012). We propose that vitamin D is a negative indicator of the inflammatory environment which characterizes morbid obesity.

Vitamin D deficiency and risk of metabolic syndrome

Alena Andreeva[1], Olga Belyaeva[2], Anna Bystrova[2], Elena Bajenova[2] & Tatiana Karonova[1,2]
[1]Almazov National Medical Research Centre, St. Petersburg, Russian Federation; [2]First Pavlov State Medical University, St. Petersburg, Russian Federation.

Objective
Recent studies suggest that vitamin D deficiency could be a risk factor for metabolic abnormalities.
The aim of this study was to assess the relationship between 25(OH)D level and metabolic syndrome components.
Materials and methods
A total of 697 women from 30 to 55 y.o. were examined. Exclusion criteria were, clinically significant endocrine, renal, liver and GI diseases, regular insolation and intake of vitamin D and calcium supplementation. Anthropometric examination included height (m), weight (kg) and waist circumference (cm). Hemodynamic examination included systolic and diastolic blood pressure level (mmHg) measurement. Serum 25(OH)D level was performed using Abbott Architect 8000. Plasma glucose, serum lipids and insulin levels were performed using standard methods. Standard oral glucose tolerance test was performed if necessary. Insulin resistance index (HOMA-IR) were calculated. Metabolic syndrome diagnosed applying IDF criteria (2005).
Results
The study results showed that 90.7% of women had vitamin D deficiency or insufficiency, while 9.3% had normal vitamin D status. According to IDF criteria abdominal obesity was seen in 75.5%, impaired glucose tolerance (IGT) or type 2 diabetes in 33.3%, reduced HDL level in 32.2%, and hypertriglyceridemia in 23.4%. We found arterial hypertension in 26.6% of subjects. A total of 397 women were checked for metabolic syndrome, and it was diagnosed in 187 (47.1%) subjects. HOMA-IR was higher in subjects with metabolic syndrome (6.36 ± 0.81), in compared with subjects without metabolic syndrome (2.99 ± 0.13), ($P < 0.001$). Serum 25(OH)D level in women with or without metabolic syndrome did not differ (48.6 ± 1.8 & 51.1 ± 1.5 nmol/l, $P > 0.05$). We didn't find association between serum 25(OH)D level and HOMA-IR. Metabolic syndrome components risk was analyzed in women with different 25(OH)D level [OR, Cl95%]. We showed that vitamin D deficiency (25(OH)D < 50 nmol/l) was associated with an increased risk of abdominal obesity [2.23; 1.15–4.30] and low HDL [2.60; 1.04–6.49] compared to subjects with normal 25(OH)D level. IGT and type 2 diabetes risk was not significantly increased in women with vitamin D deficiency [1.07; 0.54–2.20]. Risk of metabolic syndrome did not differ in subjects with normal vitamin D status and insufficient/deficient women ($P > 0.05$).
Conclusions
Vitamin D deficiency could be associated with abdominal obesity, reduced HDL level and possibly increased risk of IGT or type 2 diabetes.

Effects of atorvastatin and ezetimibe therapy on LDL Cholesterol. A systematic review and meta-analysis of randomized controlled trial

Richard Buendia[1,2], Monica Zambrano[3,4], Andres Buendia[5], Tatiana Vargas[6], Alejandra Morales[6], Adriana Alejo[7], Santiago Cardenas[8], Heidy Mier[9], Diego Sanchez[10] & Johann Arrautt[11]
[1]Colsubsidio Centro De Especialistas, Bogota D.C, Colombia; [2]Hospital De La Policia, Bogota D.C, Colombia; [3]Hospital De La Samaritana, Bogota D.C, Colombia; [4]Colsubsidio, Bogota D.C, Colombia; [5]Fundación Universitaria de Ciencias de la Salud: Fucs, Bogota D.C, Colombia; [6]Universidad De La Sabana, Bogota D.C, Colombia; [7]Universidad El Rosario, Bogota D.C, Colombia; [8]Pontificia Universidad Javeriana, Bogota D.C, Colombia; [9]Universidad De Santander, Bogota D.C, Comoros; [10]Universidad El Bosque, Bogota D.C, Colombia; [11]Universidad Del Magdalena, Bogota D.C, Colombia.

Background
Evidence has shown that the use of high doses of statins is associated with lower levels of LDL cholesterol and a decrease in cardiovascular events. Likewise, the use of high doses of statins may increase the risk of myopathy, elevation of liver enzymes, renal failure and cognitive alterations. We conducted a systematic review with a meta-analysis of all RCTs investigating the impact of atorvastatin and ezetimibe therapy on levels of LDL cholesterol vs high doses of atorvastin.
Methods
We comprehensively searched the databases of MEDLINE, EMBASE, and Cochrane from their dates of inception through October 2017. The inclusion criteria were published RCTs comparing change in LDL cholesterol between Atorvastatin/Ezetimibe (10/10 mg and 20/10 mg) administration and Atorvastatin in high doses (40 and 80 mg/day). We used a random-effects model and calculated pooled standardized mean difference (SMD) with 95% confidence intervals (CI) comparing change in levels of LDL cholesterol (mg/dl) between the atorvastatin/ezetimibe and atorvastatin in high doses groups.
Results
Three studies were included in the meta-analysis. Atorvastain/ezetimibe 10/10 mg and 20/10 mg compared with atorvastian in high doses (40 and 80 mg) group; the atorvastatin/ezetimibe therapy group had lower cholesterol LDL (SMD = −14.00 mg/dl, 95% CI: −14.23 to −13.83, P-value heterogeneity = 0.60, $I^2 = 0\%$). The rank correlation test of funnel plot asymmetry was z = 1.56, P-value = 0,11.
Conclusion
This meta-analysis of randomized studies demonstrates how atorvastatin/ezetimibe at low doses such as 10/10 mg and 20/10 mg vs atorvastatin 40 mg and 80 mg, was superior in reducing LDL cholesterol levels by 14 mg/dl, statistically significantly, and without publication bias (determined by the test of funnel plot asymmetry).

Your patients say they do not tolerate statins? You can still lower their cardiovascular risk with red yeast rice supplementation

Agnieszka Kuzior[1], Ana Delia Santana-Suarez[1], Manuel Esteban Nivelo-Rivadeneira[1], Paula Fernandez-Trujillo-Comenge[1], Claudia Arnas-Leon[2], Carmen Acosta-Calero[2], Sara Quintana-Arroyo[2] & Francisco Javier Martinez-Martin[2]
[1]Endocrinology & Nutrition Department, Hospital Universitario de Gran Canaria Doctor Negrin, Las Palmas de Gran Canaria, Spain; [2]Endocrinology & Nutrition Department, Hospitales San Roque, Las Palmas de Gran Canaria, Spain.

Objectives
Main: To assess the effect on the 10-year risk of cardiovascular events (RCVE) of daily supplementation with a fixed combination of red yeast rice extract (250 mg), berberin 525 mg and coenzyme Q_{10} (50 mg) in patients with self-reported statin intolerance. Secondary: effects on anthropometric (BMI, SBP, DBP, HR) and laboratory (lipids, fasting glucose and HbA_{1C} in diabetic patients, eGFR, AST, ALT, GGT, CK); self-reported compliance and tolerance.
Methods
We recruited 30–75 year-old patients with LDL-cholesterol >130 mg/dl and triglycerides <300 mg/dl, without established coronary heart disease, cerebrovascular disease or heart failure, who had withdrawn statin therapy due to self-reported intolerance, without evidence of myolysis or hepatotoxicity. Data were obtained initially (>2 months after statin withdrawal) and after 3 months of therapy with the supplement. The study was open and uncontrolled. RCVE was estimated by the ASCVD Risk Estimator (AHA-ACC 2013). Statistical analysis were made with Kruskall-Wallis' H-test and Student's T-test.
Results
24 patients were recruited (age 59.2 ± 11.6, 17 women, 8 diabetic). 21 patients (87.5%) had adequate compliance ($>80\%$). No adverse effects were attributed to the supplement, and in no case AST, ALT or CK were >3xUNL.
RCVE: 12.4% → 9.3% (-25%, $P=0.0071$).
LDL-cholesterol (mg/dL): $166.3\pm31.2 \rightarrow 131.4\pm22.7$ (-21%, $P<0.0001$).
Total cholesterol (mg/dL): $248.6\pm48.4 \rightarrow 212.1\pm39.2$ (-15%, $P=0.0077$).
HDL-cholesterol (mg/dL): $41.4\pm8.3 \rightarrow 43.1\pm9.2$
Triglycerides (mg/dL): $204.5\pm69.8 \rightarrow 188.0\pm73.1$
AST (U/L): $39.7\pm11.7 \rightarrow 33.9\pm9.7$
ALT (U/L): $36.4\pm8.8 \rightarrow 32.7\pm9.2$
GGT (U/L): $67.6\pm18.7 \rightarrow 63.4\pm17.6$
CK (U/L): $87.4\pm16.8 \rightarrow 88.3\pm15.7$
BMI (kg/m^2): $29.6\pm5.2 \rightarrow 28.9\pm4.7$
SBP (mmHg): $144\pm11 \rightarrow 141\pm10$
DBP (mmHg): $83\pm9 \rightarrow 80\pm7$
HR (lpm): $78\pm8 \rightarrow 77\pm8$
Fasting glucose (mg/dL) in diabetic patients: $139\pm21 \rightarrow 132\pm17$
HbA_{1C} (%) in diabetic patients: $7.3\pm1.2 \rightarrow 6.9\pm1.0$
CKD-EPI eGFR (ml/min/1.73m^2): $68.5\pm11.3 \rightarrow 69.7\pm11.0$
Conclusions
The supplement was well tolerated in this group of hypercholesterolemic patients with self-diagnosed statin intolerance (without evidence of myopathy or liver disease); after 3 months the patients had marked reductions in total and LDL-cholesterol. and their RCVE was significantly reduced.

Lobeglitazone, a novel thiazolidinedione, improves hepatic steatosis in diet-induced obese mice

Sorim choung[1], Bo Ram You[2], Ji Min Kim[2], Kyong Hye Joung[2], Hyun Jin Kim[2] & Bon Jeong Ku[1,2]
[1]Department of Medical Science, Chungnam National University School of Medicine, Daejeon, Republic of Korea; [2]Department of Internal Medicine, Chungnam National University School of Medicine, Daejeon, Republic of Korea.

Although non-alcoholic fatty liver disease (NAFLD) patients are rapidly growing, there is not optimal therapy to improve NAFLD. NAFLD is strongly associated with insulin resistance. The peroxisome proliferator-activated receptor (PPAR) activator thiazolidinediones (TZD) is an insulin sensitizer, and have been focused as the drug for NAFLD. However, the TZD remain debate as drug of choice on NAFLD because of its conflicting results on the hepatic steatosis and fibrosis. Lobeglitazone could be more potent effects for improving insulin sensitivity in the T2DM patients. In the present study, we investigated the effects of new developed TZD, lobeglitazone on animal model with obesity-associated hepatic steatohepatitis, focusing on the lipid metabolism in liver. Lobeglitazone treatment for 4 weeks in high fat diet (HFD)-induced obese mice (HL group) improved the insulin resistance and glucose intolerance compared to HFD-induced obese mice (HU group). The gene related to hepatic gluconeogenesis also decreased by treatment of lobeglitazone. The liver of mice in HL group showed histologically reduced lipid accumulation with the lower plasma total cholesterol and triglyceride level. In addition, the HL group induced the significant decreases in the hepatic transcription levels of hepatic lipid synthesis, cholesterol biosynthesis and lipid droplet development genes, and the increase in the gene expressions of fatty acid β-oxidation. It suggested that lobeglitazone ameliorated the hepatic steatosis and recovered the hepatic lipid dysregulation. Liver with steatohepatitis increased not only the PPARγ, but also the phosphorylation of PPARγ at serine 273 (pS273) that leads to down-regulation of gene expression linked in insulin sensitivity. Lobeglitazone interestingly diminished the pS273 of PPARγ. It suggested that post-translational modification of PPARγ in liver by lobeglitazone might be one of underlying mechanisms for improvement of NAFLD. Collectively, lobeglitazone had potent beneficial effects on insulin sensitivity and hepatic steatosis through improvement of hepatic lipid metabolism. Our data revealed that the lobeglitazone shed the light on the novel therapy for the NAFLD.

B-type natriuretic peptide: a biomarker of cardiovascular risk in type 2 diabetes.

Ibtissem Oueslati[1], Nadia Khessairi[1], Emna Talbi[2], Meriem Yazidi[1], Fatma Chaker[1], Jaouida Abdelmoula[2], Melika Chihaoui[1] & Hedia Slimane[1]
[1]Department of Endocrinology, La Rabta Hospital, Tunis, Tunisia; [2]Laboratory of Biochemistry, Charles Nicolle Hospital, Tunis, Tunisia.

Background
Cardiovascular stratification and prevention in type 2 diabetic patients represent a major public health preoccupation in order to reduce their mortality. Several methods of detecting atherosclerosis have been developed such as biomarkers. The aim of this study was to evaluate the association between B-type natriuretic peptide (BNP) and cardiovascular risk (CVR) in type 2 diabetic patients.
Methods
We conducted a cross-sectional study in 71 type 2 diabetic patients (38 patients with at least one cardiovascular disease (CVD) and 33 patients without any CVD). Their CVR level was estimated using Framingham score (FS). All patients had BNP and high-sensitivity C-reactive protein (hs-CRP) measurements. BNP threshold was 10 pg/ml.
Results
The average level of BNP was 27.65 ± 31.95 pg/ml. It was significantly correlated with body weight ($r=0.3$, $P=0.01$), waist circumference ($r=0.2$, $P=0.03$), low HDL cholesterol ($r=-0.26$; $P=0.02$) and the number of CVR factors ($r=0.38$, $P=0.001$). It was significantly higher in patients with hypertension ($P<0.001$), dyslipidemia ($P=0.02$), metabolic syndrome ($P=0.009$), high CVR level ($P=0.04$), coronary heart disease (CHD) ($P=0.004$) and microangiopathy ($P=0.03$). High level of BNP was associated with an age ≥ 45 years for men and ≥ 55 years for women (hazard ratio [HR] 9.36, $P=0.03$), hypertension (HR = 7.27, $P<0.001$), metabolic syndrome ((HR = 3.64; $P=0.03$), high CVR level (HR = 6.6, $P=0.01$), CHD (HR = 2.8, $P=0.04$), diabetic retinopathy (HR = 3.14, $P=0.03$) and diabetic nephropathy (HR = 3.12, $P=0.03$). BNP had higher sensibilities (se) and specificities (sp) than Hs-CRP as a marker of high CVR level (se: 62.3% vs 41.7%; sp: 80% vs 52.6%, respectively).
Conclusion
Our results demonstrated significant associations between BNP, high CVR level, CHD and microangiopathy in type 2 diabetic patients. However, prospective controlled studies including a large population are needed to confirm these results.

Relationship between the triglyceride glucose index and the presence and fibrosis of nonalcoholic fatty liver disease in Korean adults

Min Kyung Kim[1], Doo Man Kim[1], Sang Bae Lee[2], Shinae Kang[2], Ji Sun Nam[2], Jong Suk Park[2] & Chul Woo Ahn[2]
[1]Hallym University Kangdong Sacred Heart Hospital, Division of Endocrinology, Seoul, Republic of Korea; [2]Gangnam Severance Hospital, Division of Endocrinology, Seoul, Republic of Korea.

Background
Recently, the triglyceride glucose (TyG) index has been considered a surrogate marker of insulin resistance. Insulin resistance is a well known pathogenic factor in nonalcoholic fatty liver disease (NAFLD). However, few studies have investigated the relationship between the TyG index and liver fibrosis in subjects with NAFLD. Thus, we investigated the relationship between the TyG index and liver fibrosis in Korean adults.
Methods
In total, 5158 participants who underwent ultrasonography in a health promotion center were enrolled. Anthropometric profiles and multiple metabolic risk factors were measured. The TyG index was calculated as ln [fasting triglycerides (mg/dl) $\times$ fasting glucose (mg/dl)/2], and the insulin resistance index of homeostasis model assessment (HOMA-IR) was estimated. NAFLD was diagnosed by ultrasonography, and degree of liver fibrosis was assessed by NAFLD fibrosis score (NFS). Significant liver fibrosis was defined as NFS ≥ -1.5.
Results
All subjects were stratified into four groups based on their TyG indices. Significant differences were observed in metabolic parameters among the groups, and the prevalence of NAFLD and liver fibrosis by NFS significantly increased with increasing TyG index. When classifying the severity of NAFLD into three groups, there was a significant correlation between the severity of NAFLD and the TyG index. In the logistic regression analysis after adjustment for multiple risk factors, the odds ratio for the prevalence of liver fibrosis, when comparing the highest and lowest quartiles of the TyG index was 1.92 (95% CI: 1.46–2.53; *P* for trend < 0.01); the odds ratio for the prevalence of liver fibrosis, when comparing the highest and lowest quartiles of HOMA-IR was 2.92 (95% CI: 1.12–2.40; *P* for trend <0.01).
Conclusion
There is a significant association between the TyG index and liver fibrosis of NAFLD, but HOMA-IR was superior to TyG index for predicting liver fibrosis in NAFLD patients.

Adropin concentration correlates with selected anthropometric and biochemical parameters – preliminary report

Justyna Nowak[1], Karolina Kulik-Kupka[1], Iwona Zieleń-Zynek[1], Joanna Kowalska[1], Bartosz Hudzik[1,2], Agnieszka Będkowska-Szczepańska[3], Anna Żyła[4] & Barbara Zubelewicz-Szkodzińska[1,3]
[1]Department of Nutrition-Related Disease Prevention, School of Public Health in Bytom, Medical University of Silesia, Katowice, Bytom, Poland; [2]3rd Department of Cardiology, School of Medicine with the Division of Dentistry in Zabrze, Medical University of Silesia in Katowice, Silesian Center for Heart Disease, Zabrze, Poland; [3]Department of Endocrinology, Piekary Medical Center, St. Luke's Local Hospital in Piekary Śląskie, Piekary Śląskie, Poland; [4]Department of Laboratory Diagnostics, Mazovian Specialist Hospital in Radom, Radom, Poland.

Adropin, hormone playing an important role in carbohydrates and lipids metabolism, improves mainly the glucose homeostasis. It could also play a protective role in pathogenesis and development of cardiovascular diseases. The purpose of the study was to assess the adropin concentration and some parameters of nutritional status (BMI, WHtR, BAI, VAI) as well as biochemical parameters (fasting glucose and insulin, and lipid profile). 25 patients (84% of group was women, $n=21$) without any carbohydrate metabolism disorders, diagnosed at endocrinology department because of other reasons were included to the study. The exclusion criteria were any glucose metabolism disorders (diabetes mellitus, insulin resistance, glucose intolerance, fasting glucose impairment) or medications influence glucose concentration and metabolism (glucocorticosteroids, hypoglycaemic drugs, etc.). The data were statistically analyzed by STATISTICA. $\alpha=0.05$. The median serum levels of adropin concentration was 1387.9 pg/ml (1187.4–1655.7 pg/ml). There was observed a negative correlation between WHtR index and adropin concentration ($R=-0.41$, $P=0.0385$) and a positive correlation between adropin level and HDL cholesterol ($R=0.41$, $P=0.04$). In the next step the examined group was divided into two subgroups concerning the cardiovascular risk defined by WHtR index (above 5 – high risk and below 5 – low risk). At that step there was no significant differences observed between serum concentration of adropin concerning into two groups defined by WHtR index (respectively 1413.1 vs 1512.2, $P=0.4598$). Concerning glucose metabolism parameters there was no correlation observed between adropin level in relation to fasting glucose and fasting insulin ($P>0.05$). The following step was to compare adropin concentration to the certain parameters of nutritional status. There was observed no correlation between BMI, BAI, VAI indexes and adropin levels ($P>0.05$). Adropin via regulation fat accumulation, lipid metabolism and HDL -cholesterol concentration could present a protective role in cardiovascular diseases. To strengthen the results an enlargement of study group is required.

Silent myocardial ischemia in type 2 diabetes patients with ischemic heart disease

Alena Naumenka[1] & Igar Adzeriho[2]
[1]The Republican Research Center for Radiation Medicine and Human Ecology, Gomel, Belarus; [2]State Educational Establishment 'Belarusian Medical Academy of Postgraduate Education', Minsk, Belarus.

Objective
The prevalence of silent myocardial ischemia (SMI) is more frequent in diabetic patients and is associated with a worse prognosis. It has been known that diabetes is a major cardiovascular risk factor; it often leads to severe cardiovascular complications, and coronary artery disease (CAD) is the main cause of death in diabetic patients. The aim was to examine the prevalence and duration of SMI in type 2 diabetes (DT2) patients with ischemic heart disease (IHD).
Materials and methods
180 patients both sexes with type 2 diabetes aged 56.56 ± 11.07 years were studied. All patients were divided into 4 groups: 1 – 50 (27.8%) patients with stable angina pectoris (SAP), 2 – 50 (27.8%) patients with SAP and DT2, 3 – 50 (27.8%) DT2 patients and 4 – 30 (16.6%) healthy control group. In all patients 24-h ECG Holter monitoring was carried out.
Results
We found significant differences in duration of episodes of painful and silent myocardial ischemia between groups. Patients with SAP and DT2 had a long duration of SMI than patients with SAP without DT2 ($P=0.019$). There were not significant differences between 1 and 2 groups in the number of patients with painful myocardial ischemia (PMI) ($P=0.06$). Episodes of PMI were not recorded among patients of group 3.
Conclusions
Silent myocardial ischemia is more often in patients with DT2 and IHD due to autonomic neuropathy.

PCSK9 inhibitors as an add on for the treatment of dislipemia in real clinical practice

Carmen Hernández García, Cristina María Díaz Perdigones, Miguel Damas Fuentes, Clara Estaún Martínez, Andrea Sánchez Ramos, Ana Molina Ramos & Francisco Tinahones Madueño
Hospital Clínico Universitario Virgen de la Victoria, Málaga, Spain.

Introduction and objectives
The treatment with monoclonal antibodies that inhibit proprotein convertase subtilisin-kexin type 9 (PCSK9) is a new group of drugs that allows us to reach the therapeutic targets of low density cholesterol (LDL-c) in patients intolerant to statins or those who despite treatment with maximum doses of them do not obtain a proper lipid control.
Material and methods
We performed a descriptive observational study. We include all patients with hypercholesterolemia who started treatment with iPCSK9 at the Virgen de la Victoria Hospital of Malaga. We analyzed the clinical characteristics, indication

for iPCSK9 treatment and changes in LDL-c levels at the first visit and after 6 months of treatment. The diagnoses included are: Heterozygous Familial Hypercholesterolemia, 23 patients (66%); Mixed Dyslipidemia, 8 patients (23%); and Polygenic Hypercholesterolemia, 4 patients (11%).
Results
We analyzed data from 35 patients with mean age 60 years (±10 years), 57% males. They had associated comorbidities: 20% were active smokers, 63% had high blood pressure, 11% had diabetes mellitus, 49% were obese and 63% have had a cardiovascular event. Regarding the treatment prior to the addition of iPCSK9: 77% were on statins plus ezetimibe at maximum doses; 3% were only statins, 11% were on ezetimibe and 9% were without treatment because of intolerance. Before starting iPCSK9 treatment: Total cholesterol was 256 mg/dl (±90), LDL-C was 161 mg/dl (±47), was HDL-C 51 mg/dl (±14) and triglycerides 165 mg/dl (±105). 48% ($n=17$) of patients presented intolerance to maximum doses of statins (myalgias and gastrointestinal symptoms). They received iPCSK9 as follows: Evolocumab 140 mg 13 patients (34%) and Alirocumab 22 patients (63%); 14% Alirocumab 75 mg and 48.6% Alirocumab 150 mg. The mean LDL-C levels after the first six months of treatment was 74±40 mg/dl (55% reduction compared to the initial LDL-C, $P=0.000$). In the analysis by subgroups: Alirocumab reduced 46% and Evolocumab 65%, this reduction was statistically significant with respect to the initial parameters but without finding differences between the two drugs ($P=0.092$). Two patients presented mild adverse reactions and other three were hyper responders, None had to suspend the treatment for these reasons or presented new cardiovascular event.
Conclusions
The iPCSK9 are an effective and safe treatment in patients with high cardiovascular risk and high levels of c-LDL, at least in the first 6 months after administration without differences between both options.

Treatment adherence through an Integral Care Program for patients with Metabolic Syndrome in Central Mexico

Daniela Beatriz Muñoz-López[1], David Ramos-Borja[2], Marisol Espino-Reyes[1], Verónica Reyes-Pérez[1], Mónica del Carmen Preciado-Puga[1], Ana Lilia González-Yebra[1] & Silvia Quintana-Vargas[3]
[1]Universidad de Guanajuato, Campus León, Mexico; [2]IMSS, Irapuato, Mexico; [3]HRAEB, Leon, Gto, Mexico.

Introduction
The Metabolic Syndrome (MS) is a cluster of risk factors that are related to cardiovascular disease. In Mexico, the prevalence of MS in adults according to the ENSANUT 2012 is 41%, and it has become a public health problem making it necessary to implement strategies for its management at the lowest cost possible that could encourage adherence to treatment.
Objective
To evaluate the effectiveness of a comprehensive care program to achieve an increase in the adherence to treatment through the change of behaviors in lifestyles.
Methods
Prospective and experimental study involving 34 adults (32 women – 94% and 2 men – 6%) with MS using the armonized criteria, from rural areas of central Mexico who had public health services, age of 54.5+10.5 years, 4 years of average schooling, occupation as housewives (60%) and farmers (40%). They underwent a comprehensive care program which included a workshop on food preparation, aerobic exercise and strength training (180 min/week), guidance on the disease and its complications for six months. Adherence to treatment was evaluated in 5 domains: diet, exercise, pharmacological consumption, prevention of complications and social support through the Transtheoretical Model. Descriptive statistics and χ^2 were used to evaluate the differences in the percentages of the 5 domains, with the Statistica V13 software. The protocol was approved by the institutional ethics committee.
Results and discussion
Statistically significant difference in the percentages of treatment adherence was found in the 5 domains evaluated comparing the beginning versus the end of the maneuver as follows: diet 5.8% to 39.7% ($\chi^2=31.3$, $P=0.0000$), exercise 25% to 50% ($\chi^2=22.6$, $P=0.0000$), pharmacological use 41.1% to 48.5% ($\chi^2=3.98$, $P=0.04$), prevention of complications 12.1% to 24.4% ($\chi^2=4.99$, $P=0.02$) and social support 13% to 26% ($\chi^2=10.1$, $P=0.001$). Despite the increase in the observed percentage of attachment, treatment adherence was not found to an optimum degree in the group studied; is necessary to reinforce the acquired behaviors by supporting the health system that the population has, since changes in lifestyle were encouraged.
Conclusion
The Comprehensive Care Program was effective in increasing treatment adherence in patients with MS residing in central Mexico. This low-cost maneuver encourages the actions of the public health system in the treatment of this pathology.

Searching the best feeding habits to improve atherogenic dyslipidemia and inflammatory activity in patients with psoriatic arthritis

Manuel Cayón-Blanco, Carolina García-Figueras-Mateos & Raúl Menor-Almagro
Hospital SAS Jerez de la Frontera, Jerez de la Frontera, Spain.

Introduction
There is solid epidemiologic evidence linking psoriasis and psoriatic arthritis (PsA) to cardiovascular risk factors and an increased risk for developing cardiovascular diseases. Despite this, dietetic advice is not routinely performed in clinical practice in patients with inflammatory arthropathies and the potential effect of diet on metabolic profile and inflammatory activity is few studied in these patients. This research aims to describe dietetic habits of a cohort of patients with PsA and to investigate the potential influence of these habits on metabolic profile, particularly on atherogenic dyslipidemia, and inflammatory activity.
Methods/design
In this cross-sectional study, forty out-patients with PsA were included. Qualitative and quantitative characteristics of food intake were recorded in all patients. According to characteristics of diet, patients were classified in three groups: High protein, balanced or high carbohydrate diet. Demographic data and metabolic profile were collected. Atherogenic index was calculated as marker of cardiovascular disease. Inflammatory activity was measured by erythrocyte sedimentation rate (ESR), reactive C protein (RPC) and disease activity score (DAS 28).
Results
Balanced, high carbohydrate and high protein diet were followed by 54%, 30% and 17% of the cohort respectively. Patients with high protein diet had lower total cholesterol levels when compared to those with a balanced or a high carbohydrate diet (177.1±31.6 mg/dl vs 215.8±37 mg/dl vs 200.5±27.2 mg/dl respectively; $P=0.037$). Atherogenic index was lower in these patients (1.8±1.3 vs 2.4±1.1 vs 2.6±1.3; $P=0.032$). Fish was the main source of proteins in high protein diet group. With regard to inflammatory indexes, ESR and RCP were lower in patients with high protein diet, but DAS 28 score was lower in high carbohydrate diet group, but significant differences were not reached.
Conclusions
Metabolic benefits, at least on lipid profile, are more likely to be found in patients with PsA that follow a high protein diet when fish is the main source of protein intake, resulting in potential cardiovascular benefits linked to a lower prevalence of atherogenic dyslipidemia. However, diet habits were not linked to lower inflammatory activity. Further prospective studies are needed to verify our observation.

Worse MELD score is linked to a higher rate of metabolic syndrome in HIV/HCV co-infected patients on highly active antiretroviral therapy

Carolina García-Figueras-Mateos & Manuel Cayón-Blanco
Hospital SAS Jerez de la Frontera, Jerez de la Frontera, Spain.

Introduction
The prevalence of metabolic syndrome (MetS) is increasing in patients with HIV infection on highly active antiretroviral therapy (HAART). Additionally, HCV coinfection is common among HIV patients in our area. It is widely known MetS impacts on the liver in different ways but relationship between both MetS and liver function is few studied in HIV/HVC co-infected population.

Methods/design
Cross-sectional study including 35 HIV/HVC co-infected patients. Patients with significant ascites were excluded for analysis. All patients were screened for visceral obesity, dyslipidemia, hyperglycemia, and hypertension. Abdominal circumference was also measured. NCEP-ATP III criteria were used to define MetS and Model for End-Stage Liver Disease (MELD) score was calculated for every patient. Patients were divided into two groups according to median MELD score. Continuous variables are presented as mean and standard deviation or as median and interquartile range based on data distribution. Categorical variables are presented as frequencies.
Results
Prevalence of MetS was higher among patients with higher MELD score (100% vs 27.6%; $P=0.002$). When every individual component of MetS was analyzed, high abdominal circumference was more prevalent among patients with higher MELD score (54.5% vs 14.3%; $P=0.003$) but no other showed significant difference between groups. Patients with higher MELD score also had lower levels of HDLc (38 (33–45) vs 46 (39–58) mg/dl; $P=0.032$). Among patients with higher MELD score, no significant differences were observed according to LDLc (89.9±25.8 vs 107.2±37.2 mg/dl; $P=0.08$) tryglicerides levels (114 (83.2–198.2) vs 129 (93–185) mg/dl; $P=0.37$), systolic blood pressure (121 (113.2–130) vs 120 (107–130) mm Hg; $P=0.20$) or dyastolic blood pressure (80 (74–82) vs 77 (70–80) mm Hg; $P=0.08$).
Conclusions
A worse liver function is linked to development of MetS in HIV/HCV co-infected patients on HAART and therefore, related to higher cardiovascular risk. Abdominal circumference and lipid profile are major determinants for the higher rate of MetS observed in these patients. Due to the cross-sectional nature of our observation, further follow-up studies are needed to delucidate cause-effect.

Improved lipid profile and cardiovascular risk factors after bariatric surgery

Elena González, Ana Urioste, David Barajas, Paula Fernández, Tania Ramos, Mirian Alejo, Ana Hernández, Sara García, Begoña Pintor, Luis González, Isidoro Cano & María Ballesteros
Complejo Hospitalario León, León, Spain.

Background
Bariatric Surgery (BS) is an effective treatment for the metabolic control of obese patients. One of its purposes is to improve the lipid profile and reduce cardiovascular risk.
Aims
• To determine the changes in lipid profile and other cardiovascular risk factors before and one year after BS.
• To assess differences in lipid parameters depending on the surgical procedure used.
• To assess pre and post BS admissions in the cardiology ward.
Methods
Retrospective observational study of 418 patients who underwent BS from 1998 to 2017. Registered variables were gender, age, BMI, type of surgery, total cholesterol, HDL, triglycerides, blood pressure, blood glucose and HbA1c, baseline and one year after surgery (expressed as median and interquartile range) and compared according to the surgical procedure. The number and reasons for admission in cardiology before and after BS for patients in our health area was also recorded.
Results
Of the 418 patients, 76.3% were women. 88% underwent malabsorptive-restrictive procedures and 12% underwent pure restrictive procedures. Median age and BMI were 44.98 (16.33) years and 46.94 (8.97) kg. Levels of cholesterol, HDL, triglycerides, systolic blood pressure, diastolic blood pressure, blood glucose and HbA1c were 192 (148.5) mg/dl, 45 (15.75) mg/dl, 119 (80.75) mg/dl, 140 (18.75) mmHg, 90 (14.75) mmHg, 98.5 (29, 75) mg/dl, 5.8 (1.08)% respectively, and were reduced significantly one year after BS ($P<0.001$) to: 142.5 (46.75) mg/dl, 48.5 (16,75) mg/dl, 97 (61) mg/dl, 90 (14.75) mmHg, 75.5 (18.75) mmHg, 82.5 (12) mg/dl, 5.05 (0.5)%. Improvement in cholesterol, diastolic blood pressure and Glu/HbA1c was higher for malabsorptive procedures ($P<0.05$). Among patients in the area of León, 2% had an admission in the cardiology ward before BS (50% were ischemic). 4% were admitted after BS: 8.3% due to ischemic causes and 66.6% because of arrhythmias.
Conclusions
Bariatric surgery significantly improves lipid parameters and cardiovascular risk factors in one year, especially with malabsorptive procedures. The rate of admission for ischemic heart disease is lower than the reported to general population in our community (5.7/10000 population vs 8.25/10000 inhabitants in 2014 in the community of Castilla y León).

Efficacy and safety of proprotein convertase subtilisin/kexintype nine inhibitors in real life experience

Clara Navarro-Hoyas[1], Raquel Miralles Moragrega[1], Laura Delegido-Gómez[1], Beatriz López-Muñoz[1], Óscar Moreno-Pérez[1,2], Antonio Picó-Alfonso[1,2] & Víctor González-Sánchez[1]
[1]Endocrinology and Nutrition Department, Alicante University General Hospital, ISABIAL-FISABIO, Alicante, Spain; [2]Miguel Hernández University, Alicante, Spain.

Introduction
PCSK9 inhibitors (iPCSK9) have previously been evaluated through controlled clinical trials showing up to 60% reduction in LDL cholesterol concentrations. However, we still do not have enough data regarding the real life experience of the treatment.
Objectives
1) Describe patients with hypercholesterolemia treated with iPCSK9 in clinical practice.
2) Evaluate treatment efficacy and safety.
Methods
Retrospective observational study. Inclusion criteria: patients treated with iPCSK9 at the Alicante University General Hospital. Primary end point: changes in LDL cholesterol 3 and 6 months after the start of iPCSK9. Secondary end point: changes in total cholesterol (TC), HDL cholesterol and triglycerides (TG). Other variables: Occurrence of adverse events. Statistical analysis: descriptive (mean ± S.D., median [P25–P75]), Wilcoxon; $P<0.05$; SPSS v22.0.
Results
24 patients (50% women, age 60±12 years, BMI 27±3 kg/m^2). 62.5% heterozygous familial hypercholesterolemia, 58% onset cardiovascular disease, 21% both. At baseline 66% patients were taking combination ezetimibe-statins therapy (21% rosuvastatin 20 mg/d, 4% rosuvastatin 10 mg/d, 13% rosuvastatin 40 mg/d, 21% atorvastatin 80 mg/d), 21% statin therapy (8% rosuvastatin 20 mg/d, 8% atorvastatin 80 mg/d), 4% monotherapy with ezetimibe 10 mg/d. Evolocumab 140 mg was prescribed in 62.5% of cases and alirocumab 75 mg in 37.5%. Primary end point: 50% reduction in LDL [16–61%] at 3 months, 55% [42–74%] at 6 months ($P<0.01$). Secondary end point: 38% reduction in TC [21–44%] at 3 months, 41% [21–44%] at 6 months ($P<0.01$). Non-significant 7% decrease in TG at 3 months, 3% at 6 months. There were also no significant changes in HDL. 5 of the 24 patients (21%) presented mild adverse events: 1 recurrent respiratory tract infections, 2 flu-like syndrome, 1 hypertransaminasemia, 1 pruritus. None of them demonstrated increase in plasma glucosa levels, or showed neurocognitive symptoms.
Conclusion
In short-term real life studies, the addition of PCSK9 inhibitors to their previous treatment leads to improvement in metabolic control with an adequate safety profile.

Plasma insulin levels in patients with the different severity of atherosclerotic lesions of coronary arteries

Georgiy Mankovsky[1] & Olena Stepura[2,3]
[1]Scientific and Practical Medical Center of Pediatric Cardiology and Cardiac Surgery, Kiev, Ukraine; [2]National Medical Academy for Postgraduate Education, Kiev, Ukraine; [3]Center of Medical Innovations, Kiev, Ukraine.

Introduction
There is growing body of evidence that insulin resistance and hyperinsulinemia can contribute to development and accelerate the progression of atherogenesis of large arteries. However, an association between the severity of angiographically

confirmed atherosclerotic lesions of coronary arteries and the levels of insulin in the plasma in patients with ischemic heart disease (IHD) without history of diabetes mellitus or dysglycemia was not properly examined. The aim of the study was to investigate the plasma insulin levels in patients with clinically and angiographically confirmed IHD and different severity of atherosclerotic lesions of coronary arteries.

Materials and methods

We examined 78 patients with IHD without history of diabetes mellitus or impaired glucose tolerance (aged 61.5 + 9.2 years, BMI – 29.5 + 5.1 kg/m^2). All studied patients underwent stress test, coronaroventriculography and oral glucose tolerance test. The blood was collected at fasting and 2 h after glucose ingestion. Insulin levels were determined in all blood samples by radioimmunosorbent method (ELISA) along with plasma glucose measurements.

Results

All studied patients with IHD were divided to three groups according to the number of occluded coronary arteries (with atherosclerotic lesions located in 1, 2 and 3 coronary arteries, respectively). None of the studied patients had type 2 diabetes mellitus or impaired glucose tolerance based on the results of oral glucose tolerance test. The mean plasma glucose levels were not significantly different between all three groups of patients studied either at fasting or 2 h after ingestion of glucose during oral glucose tolerance test. Also, there was no elevation of glycated hemoglobin levels in all patients studied. It was found that fasting plasma insulin levels were significantly elevated in patients with IHD and multiple atherosclerotic lesions which expanded to 2 or 3 coronary arteries compared to patients with 1 occluded artery. The insulin levels at fasting were 19.1 + 1.16, 24.1 + 2.28, 25.0 + 1.64 μMU/ml in patients with 1, 2 or 3 occluded coronary arteries, respectively, $P < 0.05$ for comparisons between insulin levels in subjects with 2 and 3 damaged arteries compared to 1 artery. The similar trend was found in plasma insulin levels 2 h after administration of glucose.

Conclusions

Hyperinsulinemia as the reflection of insulin resistance is related to the more severe angiographically documented atherosclerotic lesions of coronary arteries in patients with IHD. We may speculate that hyperinsulinemia can play a role in the progression of atherosclerosis of coronary arteries.

A multi-disciplinary approach to the management of NAFLD improves both liver and metabolic health and is cost effective

Ahmad Moolla[1], Kenzo Motohashi[1], Amelia Shard[2], Tom Marjot[1], Mark Ainsworth[2], Jeremy Tomlinson[1] & Jeremy Cobbold[2]
[1]Oxford Centre for Diabetes, Endocrinology and Metabolism (OCDEM), and National Institutes of Health Research (NIHR) Oxford Biomedical Research Centre, University of Oxford, Oxford, UK; [2]Department of Gastroenterology and Hepatology, Oxford University Hospitals NHS Foundation Trust, Oxford, UK.

Introduction

Non-alcoholic fatty liver disease (NAFLD) is the hepatic manifestation of metabolic syndrome and is tightly associated with type 2 diabetes (T2DM), the principal risk factor for disease progression, liver failure and cardiovascular complications. At present there are no licensed therapies and management aims to optimise metabolic risk factors through weight loss, and pharmacological interventions for diabetes and cardiovascular disease. A multidisciplinary approach involving hepatologists and diabetologists working alongside allied health professionals providing structured lifestyle advice is advocated, although objective evaluations of this approach are currently limited.

Objective

We have undertaken a retrospective study to determine the impact of a large, tertiary centre, multidisciplinary metabolic hepatology clinic. Detailed liver, cardio-metabolic and related health parameters including surrogate markers of metabolic syndrome, cardiovascular risk and liver disease were evaluated in addition to a pilot health economic analysis.

Results:

165 patients with NAFLD without hepatic co-morbidities and excluding those undergoing bariatric surgery, were followed from referral until latest review. All patients attended ≥2 times between 2014 and 2017. Median follow-up period was 13 months (2–34). At baseline, 29% had liver cirrhosis and 59% had T2DM. At follow-up, weight decreased by 3.3 kg (3.4%, $P = 0.0005$) and was associated with significant improvements in liver chemistry (alanine aminotransferase, ALT: −11 IU/l, 21%, $P < 0.0001$), and total cholesterol (−0.7 mmol/l; 14%, $P = 0.0023$). Median HbA1c fell (1.5 mmol/mol, 3.1%, $P = 0.0045$), with reduction most marked in those with poorly controlled T2DM (HbA1c >58 mmol/mol at baseline: −14 mmol/mol, 18%, $P < 0.0001$). Overall, there was a 6.4% reduction in 10-year cardiovascular risk (QRISK3, aged-match, $P = 0.0085$). Finally, median liver stiffness, measured using transient elastography as a surrogate of fibrosis, decreased by 1.3 kPa (14%, $P = 0.0097$). Preliminary economic analysis of our multidisciplinary approach using the UKPDS Outcomes Model indicated an improvement in quality adjusted life expectancy alongside a reduction of costs of diabetes complications if health improvements were maintained. Importantly, these costs fell well below the accepted UK cost-per-QALY (quality adjusted life year) threshold of £20,000 for commissioning of health interventions, suggesting a cost-effective clinical management strategy.

Conclusion

Our results demonstrate that patients with NAFLD managed through a multidisciplinary approach derive significant clinical improvements in liver and cardio-metabolic health. Patients with poorly controlled T2DM, demonstrated the largest improvement in HbA1c of a magnitude known to reduce complications which may potentially confer good benefit to patients in slowing NAFLD progression. Furthermore, our pilot economic data suggest that this approach may also be cost-effective.

A case of combined dyslipidemia with two different defined genetic alterations

Aydın Tuncer Sel[1], Müjde Aktürk[1], Muzaffer Serdar Deniz[1], Başak Bolayır[1], Fatih Süheyl Ezgü[2], Alev Altınova[1], Füsun Töruner[1] & İlhan Yetkin[1]
[1]Department of Endocrinology and Metabolism, Gazi University Faculty of Medicine, Ankara, Turkey; [2]Department of Pediatric Metabolism, Gazi University Faculty of Medicine, Ankara, Turkey.

Background

There are plenty of primary genetic or secondary causes for both hypercholesterolemia and hypertriglyceridemia. Two different genetic causes in one patient does not generally come to mind in first place.

Aim

We report a case who has two genetic alterations as a cause of hypercholesterolemia and hypertriglyceridemia.

Case report

62 year-old male referred because of high serum lipid levels. He had no active complaint. There were type 2 DM, hypertension for 15 years and an ischemic cerebrovascular event 10 years ago in his medical story. His medications included metformin, valsartan and ASA. Statin therapy was started 5 years ago but has not been using it for two years. He had no family history for pancreatitis, early-onset coronary heart disease and cerebrovascular disease. Tendon or tuberous xanthoma, xanthelesmas were not present in his physical exam. Laboratory analysis showed that LDL-C: 248 mg/dl (60–130) Total Cholesterol: 393 mg/dl (110–200) HDL-C: 63 mg/dl (40–60) Triglyceride: 506 mg/dl (<150). Fasting blood glucose was 98 mg/dl, HbA1c: 5.9%. His kidney, liver and thyroid function tests were normal. ECG, echocardigram and carotid arterial doppler USG revealed no pathology. Abdominal USG showed grade 2 hepatosteatosis. According to genetic testing for familial causes for hypercholesterolemia and hypertriglyceridemia; we found a heterozygous change in LDLR gene (c.1706-10G>A) which is accepted as a mutation for familial hypercholesterolemia. We also found a heterozygous change in APOA5 gene p.Ser19Trp (c.56 C>G) which is suggested for an increasing in tendency for hypertriglyceridemia.

Conclusions

Although very rare, different genetic alterations can be together in patients with high LDL-C and high triglyceride levels.

Soluble ST2, a promising cardiovascular biomarker, is associated with parameters of glucose and bone metabolism in subjects at cardiovascular risk

Vito Francic[1], Martin Gaksch[2], Verena Schwetz[1], Christian Trummer[1], Marlene Pandis[1], Felix Aberer[1], Martin Grübler[1], Nicolas D Verheyen[3], Winfried März[4], Thomas R Pieber[1], Andreas Tomaschitz[3], Stefan Pilz[1] & Barbara Obermayer-Pietsch[1]
[1]Division of Endocrinology and Diabetology, Medical University of Graz, Graz, Austria; [2]Department of Laboratory Medicine, Paracelsus Medical University, Salzburg, Austria; [3]Division of Cardiology, Medical University of Graz, Graz, Austria; [4]Synlab Holding Germany GmbH, Mannheim, Germany.

Introduction
Soluble ST2 (sST2) is the truncated soluble form of the ST2 receptor in the circulation. It is a decoy receptor of IL-33 and thereby inhibits the effects of IL-33/ST2 signaling. Elevated levels of sST2 have been associated with various adverse cardiovascular outcomes. Recently, potential associations of sST2 with obesity and type 2 diabetes mellitus (T2DM) have been described in the general population. In this study, we determined possible cross-sectional associations of sST2 with surrogate parameters of cardiovascular and metabolic risk in vitamin D-deficient subjects with and without T2DM.
Methods
Serum sST2 levels were measured (by Human St2/IL-33 R Quantikine ELISA Kit; R&D Systems) in 174 hypertensive, vitamin D deficient [25(OH)D $<$ 30 ng/ml] participants of the Styrian Vitamin D Hypertension Trial (NCT02136771). After assigning cardiovascular characteristics and parameters of bone and glucose metabolism to the respective quartiles according to sST2 concentrations, we used ANOVA, Jonckheere-Terpstra tests and chi-square tests to determine the presence of significant trends. In addition, a multiple regression model was constructed after adjusting each of the parameters for age and gender.
Results
We found significant trends across quartiles of sST2 concentrations for (BMI; $P=0.024$), plasma glucose ($P < 0.001$), insulin ($P < 0.001$), haemoglobin A1c (HbA1c; $P=0.001$), HOMA-IR ($P < 0.001$), T2DM prevalence ($P=0.007$), gender ($P < 0.001$), gamma-glutamyl transferase (GGT; $P < 0.001$), mean 24-h systolic blood pressure ($P=0.016$), total cholesterol ($P=0.001$), HDL ($P=0.002$), LDL ($P=0.004$) and osteocalcin (OC; $P=0.001$), while C-reactive protein, pulse wave velocity, mean 24-h diastolic blood pressure, NT-proBNP, eGFR, triglycerides and time since T2DM onset showed no significant association. In a multiple regression model we found HOMA-IR to be the only significant predictor of sST2 concentrations (adj. $R^2 = 0.124$, $\beta=0.359$, $P<0.001$) among the parameters included in the study.
Discussion
We found higher concentrations of sST2 positively associated with parameters of glucose and bone metabolism in vitamin D deficient subjects at cardiovascular risk, with HOMA-IR showing the strongest association. The findings of our study provide additional information on the emerging role of sST2 in obesity and T2DM, while uncovering a possible link to bone metabolism via osteocalcin.

P309

Comparison of inflamatory parameters, lipid profile and clinical values in patients with clinical and subclinical hypothyroidism

Musa Faruk Altan & Ahmet Kaya
Necmettin Erbakan University, Meram Medical Faculty, Konya, Turkey.

Aim
In this study, we aimed to perform a comparative evaluation of lipid profile, inflamatory markers, clinical parameters, which are related to cardiovascular diseases, and measurements of carotid intima media thickness (CIMT), which is considered to be an indicator of cardiovascular diseases, in patients with overt and subclinical hypothyroidism, all of which have been studied separately in differen studies.
Methods
Patients older than 18 years old, who admitted to the Endocrinology outpatient clinic, with the diagnosis of hypothyroidism (overt and subclinical) were enrolled into the study. Antropometric and serum lipid, hs-CRP, ESR and CIMT of the patients were studied.
Results
Totally 63 patients were included in the study. 55 (87%) of them were females and 8 (13%) of them were males. Mean ages of patients were 34.4 ± 11.9 years. 51 (81%) of patients were diagnosed as subclinical hypothyroidism, and 12 (19%) of them were diagnosed as overt hypothyroidism. Mean BMI was 27.1 ± 5.6 kg/m^2. Systolic and diastolic blood pressures were within normal limits.Mean, ESR was 12.6 ± 9.1 mm/h, hs-CRP was 4.3 ± 1.5 mg/l, total cholesterol was 195 ± 43 mg/dl, LDL cholesterol was 115.3 ± 36.1 mg/dl, Lp (a) was 17.8 ± 20.3 mg/dl and CIMT was 0.66 ± 0.17 mm. Patients were divided into two groups as subclinical and overt hypothyroidism which were similar in terms of age, gender. Mean CIMT measurement was higher in the overt hypothyroidism group than the subclinical group ($P=0.11$). Mean CIMT of both groups were higher than age-sex matched healthy population.
Conclusion
Our study group is at risk for early atherosclerosis and cardiovascular diseases because our patients are overweight and their levels of LDL cholesterol and hs-CRP and CIMT values are higher. This risk is higher in the overt hypothyroid group.

High levels of sclerostin are related to cardiovascular mortality

Cristina Novo-Rodríguez[1,2], Beatriz García-Fontana[2,3], Verónica Ávila-Rubio[2,4], Juan De Dios Luna-Del Castillo[5], Francisco Andújar-Vera[2], Cristina García-Fontana[2], Sonia Morales-Santana[2,6], Pedro Rozas-Moreno[7], Antonia García-Martín[2,4] & Manuel Muñoz-Torres[2,3,4,8]
[1]Endocrinology and Nutrition Unit, Hospital Universitario Virgen de las Nieves, Granada, Spain; [2]Instituto de Investigación Biosanitaria de Granada (Ibs.GRANADA), Granada, Spain; [3]CIBERFES. Instituto de Salud Carlos III, Madrid, Spain; [4]Endocrinology and Nutrition Unit, Hospital Universitario Campus de la Salud, Granada, Spain; [5]Department of Biostatistical, University of Granada, Granada, Spain; [6]Proteomic Research Service, Fundación para la Investigación Biosanitaria de Andalucía Oriental- Alejandro Otero, Granada, Spain; [7]Endocrinology Division, Hospital General de Ciudad Real, Ciudad Real, Spain; [8]Department of Medicine. University of Granada, Granada, Spain.

Introduction
Cardiovascular disease (CVD) is a health issue, worldwide, particularly in individuals with diabetes. The identification of CVD biomarkers can improve risk stratification. Sclerostin is a modulator of the Wnt/β-catenin signalling pathway in different tissues, and has recently been linked to vascular biology.
Objectives
Our objective was to evaluate the relationship between circulating sclerostin levels and cardiovascular and non-cardiovascular mortality in individuals with and without type 2 diabetes.
Material and methods
A cohort of 130 participants (mean age 56.8 years; 75 with type 2 diabetes; 46 with prevalent CVD), were followed-up for 7 years. Time to death (both of cardiovascular and non-cardiovascular causes) was assessed to establish the relationship between sclerostin and mortality. Serum sclerostin levels were measured at the baseline.
Results
Serum sclerostin concentrations were significantly higher in patients with prevalent CVD ($P<0.001$), and independently associated with cardiovascular mortality ($P=0.008$), showing sclerostin to be a stronger predictor of mortality than other classical risk factors (area under the curve = 0.849 vs 0.823). The survival analysis showed that an increase of 10 pmol/l in the serum sclerostin level resulted in a 31% increase in cardiovascular mortality. No significant association was observed between sclerostin levels and non-cardiovascular mortality ($P=0.346$).
Conclusions
High sclerostin levels are related to mortality due to cardiovascular causes. The clinical implication of these findings is based on the possible use of serum sclerostin as a new biomarker of cardiovascular mortality risk in order to establish preventive strategies.

Lipid profile after pregnancy in women with gestational diabetes mellitus

Sebai Imen, Ounaissa Kamilia, Ben Cheikh Marwa, Stambouli Islem, Abdessalem Haifa, Ben Brahim Asma, Yahiaoui Rym & Amrouche Chiraz
National Institute of Nutrition, Tunis, Tunisia.

Aim
The aim of our study was to describe the lipid profile of Tunisian women after pregnancy with gestational diabetes mellitus (GDM) and to analyze the influence of maternal age, insulin requirement and postpartum glycemic status on lipoproteins changes after pregnancy.
Methods
We conducted a cross-sectional study among pregnant women who were referred to the national institute of nutrition for management of GDM. The lipid profile included total cholesterol (TC), HDL-C (High density lipoprotein-C) and triglycerides (TG). Pregnant women with prior diabetes or prior known dyslipidemia or thyroid disorders were excluded. Subgroups analyses were performed according to categories of maternal age (<35 years versus ≥ 35 years), insulin requirement (yes versus no) and postpartum glycemic status (normal HGPO, abnormal HGPO).
Results
After pregnancy (23 ± 7.5 Weeks post-partum), mean triglyceride, total cholesterol and HDL cholesterol levels were 1.02 ± 0.68 mmol/l, 1.3 ± 0.23 mmol/l and 5 ± 1.18 mmol/l respectively. An average significant decrease of $43.4 \pm 40.8\%$ in triglycerides levels ($P=0.002$), of $15.4 \pm 14.9\%$ in total cholesterol ($P=0.001$) and of $14 \pm 26.6\%$ in HDL cholesterol ($P=0.016$) was observed. After pregnancy, no woman had isolated hypertriglyceridemia (higher than 1.7 mmol/L), 15% had isolated hypercholesterolemia (higher than 5.2 mmol/L), 30% had mixed hyperlipidemia and 45% had low HDL-C (lower than 1.7 mmol/L). No significant differences in lipids variation were observed according to postpartum glycemic status neither according to maternal age. Insulin-treated patients showed a significant lower decrease of total cholesterol ($P=0.035$).
Conclusions
Dyslipidemia is a persistent problem in women with gestational diabetes mellitus after pregnancy. Insulin requirement affected the variation of total cholesterol in women with GDM. The development of GDM may be a predict factor of possible future cardiovascular or metabolic disease. The control of the lipid profile after gestational diabetes mellitus can be an interesting opportunity to screen women with dyslipidemia and to institute effective management strategies to reduce this cardiovascular risk factor.

Secondary diabetes associated with principal endocrinopathies (about 161 cases)

Fatima Zahra Iftahy[1,2,3], Siham El Aziz[1,2,3] & Asma Chadli[1,2,3]
[1]Endocrinology, Diabetology and Metabolic Diseases Department Ibn Rochd University Hospital of Casablanca, Morocco, Casablanca, Morocco; [2]Neurosciences and Mental Health Laboratory, Casablanca, Morocco; [3]Faculty of Medicine and Pharmacy- University Hassan II- Casablanca-Morocco, Casablanca, Morocco.

Background
Many endocrine diseases can be complicated by diabetes, due to hyperglycemic hormones and insulinresistance. The aim of the work was to analyze prevalence, therapeutic and progressive aspects of secondary diabetes as well as carbohydrate intolerance (CHI) in patients with an endocrinopathy.
Materials and methods
A retrospective study was conducted in the endocrinology and diabetology department including 161 patients followed for diabetes or CHI and endocrinopathy (hyperthyroidism, acromegaly, pheochromocytoma and hypercorticism) between 2005 and 2017 among all endocrinopathies (365 cases). Variables studied in these patients were imbalance degree, degenerative complications, treatment and evolution.
Results
Mean age was 33.5(18-71) years with a female predominance. The etiologies were represented by hypercorticismin 57 patients, acromegaly in 38 patients, pheochromocytoma in 27 patients and hyperthyroidism in 39 patients. General diabetes prevalence was 44%. Concerning etiology, diabete prevalence of acromegaly was 34%, for hypercorticism (63%), for hyperthyroidism (33.3%) and for pheochromocytoma (38%).The prevalence of IHC was 18,6%. Diabetes revealed the endocrinopathy in 30 patients. The mean HbA1c was 9.3%. The degenerative assessment had objectified a diabetic retinopathy (16%), a nephropathy (12%), a neuropathy (7%) and hypertension (50%). Therapeutic management consisted of treatment with ADO (32%) and insulintherapy (52%). Among the patients treated and cured of their endocrinopathy (69%) we noted a diabetes regression in 78% of cases and diabetes persistence with therapeutic needs regression in 22% of cases.
Conclusion
The prevalence of secondary diabetes varies according to endocrinopathy. It can reveal the disease and associated with other metabolic disorders. Adequate screening and management is recommended in the presence of endocrinopathy.

Metabolic syndrome and triglyceride-rich lipoproteins

Silvia Paredes[1], Liliana Fonseca[2], José Carlos Oliveira[2], Helena Ramos[2] & Isabel Palma[2]
[1]Hospital de Braga, Braga, Portugal; [2]Centro Hospitalar e Universitário do Porto, Porto, Portugal.

Introduction
Hypertriglyceridemia, a cardinal feature of metabolic syndrome (MS), is associated with cardiovascular disease and abnormal metabolism of apolipoproteins which may form the basis for this relationship. The aim of this study is to evaluate triglyceride-rich lipoproteins profile in MS patients.
Material and methods
A retrospective study was performed, including patients evaluated in a tertiary hospital. Patients with thyroid dysfunction, neoplastic disease, HIV, severe hepatic or renal disease, genetic dyslipidemia or under treatment with corticosteroids, fibrates or ezetimibe were excluded. MS was classified using the American Heart Association/National Heart, Lung and Blood Institute definition.
Results
We included 75 patients with MS, mean age 55.05 ± 11.5 years, body mass index (BMI) 29.72 ± 4.5 kg/m^2, waist circumference (WC) 102.28 ± 10.8 cm, 44% female and 72 patients without MS, mean age 42.74 ± 16.3 years, BMI 25.81 ± 4.5 kg/m^2, WC 92.24 ± 14.7 cm, 59.7% female. Patients with MS presented significantly elevated levels of triglycerides (200.68 ± 129.5 vs 98.14 ± 46.6 $P<0.001$) and ApoCII (7.80 ± 4.3 vs 4.88 ± 4.2 $P=0.006$) and lower levels of ApoA1 (140.80 ± 27.6 vs 165.50 ± 35.1 $P<0.001$). Only 16.7% of MS patients had ApoCIII levels within normal range, the remaining 83.3% presented elevated levels whereas in patients without MS, only 46.2% had elevated ApoCIII levels ($X^2=0.001$). We found no correlation between ApoCII, ApoCIII or ApoA1 and age, BMI, WC or blood pressure.
Conclusion
Increased apoC-II and ApoCIII and decreased ApoA1 levels are common in the MS phenotype. ApoCIII is thought to have a direct role in atherogenesis, and their elevated levels in MS patients may further aggravate their cardiovascular risk. Understanding ApoC lipoproteins metabolism can contribute to develop new therapeutic targets for MS.

Specificity of mathematical indexes versus histopathological findings in the diagnosis of nonalcoholic fatty liver disease in mexican population

Mónica del Carmen Preciado-Puga[1], Juana-Rosalba García-Ramírez[2], Lorena del Rocío Ibarra-Reynoso[1], Karen-Ivette Gutiérrez-Aguirre[1], Marion Velázquez-Villafaña[1], Maria-Luisa Lazo-de-la-Vega-Monroy[1], Yeniley Ruiz-Noa[1], Benjamín Jordán-Pérez[2] & Serafin Garnelo-Cabañas[2]
[1]Universidad de Guanajuato, Campus León, Mexico; [2]Hospital General León, León,Gto, Mexico.

Introduction
Non-alcoholic fatty liver disease (NAFLD) is an emerging disease in Mexico and it could become in a public health problem, this one understands a spectrum of

histopathological findings ranging from simple steatosis to steatohepatitis and cirrhosis. The gold standard continues to be the liver biopsy, but several mathematical indexes have been proposed, such as non-invasive techniques, however there are very few studies in our population. This study aims to compare the specificity of mathematical indexes and histopathological findings for the detection of NAFLD in Mexican population.
Methods
A cross-sectional study was performed at the 'Hospital General Regional de León'. Patients aged 18 years or above that underwent laparoscopic cholecystectomy were recruited. No history of alcohol consumption habit or hepatic diseases characterized the patients. The fatty liver index (FLI) and the lipid accumulation product (LAP) were calculated. Demographics, blood samples, and a liver biopsy were obtained. Results between FLI, LAP and livery biopsy were compared. The area under de curve (AUC) was calculated for each mathematical index SPSS V21 was used for statistics analysis.
Results
A total of 152 patients were included (84.9% women and 15.1% men). The mean age was 38.7±12 years, BMI 28.8±5.3 kg/m^2. The FLI identified 80 patients with NAFLD of whom 60% were corroborated with biopsy, whereas the LAP identified 87 patients of whom 55.2% were corroborated with biopsy. From the patients with FLI negative index (n=72), a total of 26% has a histopathological diagnosis of steatosis. For LAP, 65 patients were negative, of which 29.2% presented positive biopsy for the presence of NAFLD. The AUC for FLI was 0.69 whereas the AUC for was LAP 0.68 using ROC curve.
Conclusion
According to our results, the efficiency of these two mathematical indexes are regular for the diagnosis of NAFLD due their specificity at least our population, so liver biopsy remains to be the gold standard for the detection of NAFLD in our population. Future studies should be performed in order to continue looking for other non-invasive markers for NAFLD.

What changes does pregnancy bring to the lipid parameters of diabetic patients?

Chaima Jemai, Nadia Ben Amor, Nadia Khessairi, Bourguiba Rim, Aroua Temessek, Hajer Tertek & Faika Ben Mami
Institut National De Nutrition De Tunis, Tunis, Tunisia.

Objective
The objective of our study is to describe the lipid parameters of pregnant women with diabetes during the three trimesters of pregnancy.
Materials and methods
This is a retrospective study that looked at 44 diabetic pregnant women. Clinical biological data were collected from medical records. The personal history of dyslipidemia, pathologies, and medications that may interfere with lipid parameters have been eliminated.
Results
Patients in the first trimester of pregnancy had a mean age of 33.5 years +/−6.3 (33.4+/−5.8 in T2 and 33.1+/−5.5 in T3). Diabetes was type 1 in almost 100% of cases (it was type 2 in 62.5% of patients in T2 and in 60% of patients in T3). The average pre-perceptible body mass index was 27.4 kg / m2+/−4.5 (29.2 kg / m^2+/−5 in T2 and 28 kg / m^2+/−3.3 in T3). on average 10.7 years +/−2.1 (7.2 years +/−5.4 in T2 and 6.6 years +/−4.6 in Q3) with an average HbA1C of 9.1%+/−1, 1 (7.9%+/−0.3 in T2 and 8.1%+/−0.4 in T3). The average triglyceride level was 1.1 mmol / L+/−0.3 (1.6 mmol / L+/−0.5 in T2 and 1.7 mmol / L+/−0.4 in T3). Mean cholesterolemia was 4.5 mmol / L+/−0.7 (4.9 mmol / L+/−0.7 in T2 and 5.2 mmol / L+/−0.6 in T3). Hypercholesterolemia was noted in only one patient (18.7% in T2 and 60% in T3). Hypertriglyceridemia was also noted in one patient (in 50% of patients in T2 and in 60% of patients in T3). All patients had normal HDL-CT regardless of the trimester of pregnancy. All patients, except two in T1, were outside the LDL-CT goal, which averaged 1.03g / L+/−0.2, in T1, 1.05g / L+/−0.2 in T2 and 1.1g / L+/−0.2 in T3.
Conclusion
In our population, it has been noted that hypercholesterolemia and hypertriglyceridemia are lipid abnormalities whose frequency increases with the evolution of pregnancy. A larger sample of diabetic patients is needed to better characterize changes in lipid parameters during pregnancy.

Identifying metabolic unhealthy obesity using the product of triglycerides and glucose

Liliana Fonseca[1], Sílvia Paredes[2], José Carlos Olivera[1], Helena Ramos[1] & Isabel Palma[1]
[1]Centro Hospitalar e Universitário do Porto, Porto, Portugal; [2]Hospital de Braga, Braga, Portugal.

Introduction
There are significant physiologically and clinically differences in profiles between metabolic healthy and metabolic unhealthy obese individuals. Several markers are on study in order to better characterize the metabolic profile of metabolic unhealthy obese individuals. The aim of this work was to determine whether the triglycerides/glucose (TyG) index may be a valuable marker for identifying metabolically unhealthy obesity.
Methodology
Metabolic unhealthy obesity was defined as the presence of ≥3 of the following: blood pressure ≥130 and/or ≥85 mmHg or anti-hypertensive drug use; triglycerides ≥150 mg/dL or anti-dyslipidemic drug use; high-density-lipoprotein <40 mg/dL in males and <50mg/dL in females; fasting glucose ≥110 mg/dL or anti-diabetic drug use and waist circumference (WC) ≥102 cm in males and ≥88 cm in females. The TyG index was calculated as ln[fasting triglycerides (mg/dl) x fasting glucose (mg/dl)/2].
Results
We included 84 individuals, mean age 53.3±12.4 years, mean body mass index (BMI) 33.55±3.4 kg/m^2, mean WC 108.6±8.7 cm, 50% female. 88.1% (n=74) were classified as metabolic unhealthy obese individuals. These patients presented a superior TyG index compared to patients with metabolic healthy obesity (9.38±0.7 vs 8.54±0.7 P=0.001). Patients with metabolic unhealthy obesity also presented a significant larger WC and significantly low levels of HDL cholesterol and elevate levels of oxidized LDL-cholesterol. We did not find differences in respect to LDL cholesterol, uric acid and ultra-sensitive-PCR between the two groups of patients. ROC curves evidenced that a cut-off point of TyG index >8.94 identifies patients with a greater probability of having a metabolic unhealthy obesity (Sensitivity: 71.9%; Specificity 80.0%; AUC 0.822; P< 0.001).
Conclusion
We found that individuals with metabolic unhealthy obesity presented a higher TyG index compared to those with metabolic healthy obesity and that this index has a good specificity and sensitivity in identifying this type of obese individuals. Larger studies are necessary to validate this marker in our clinical practice, nevertheless, these data highlight the value of the TyG index in discriminating those obese subjects with metabolic dysregulation.

Diabetic ketoacidosis occurring in the patient whom newly started insulin glargine U300: a case report

Cem Onur Kirac, Suleyman Ipekci & Levent Kebapcilar
Selcuk University, Faculty of Medicine, Konya, Turkey.

Basal insulin secretion is essential for the maintenance of fasting glucose levels, especially through inhibition of excessive hepatic glucose output. Insulin glargine U300 is a novel long acting basal insulin formulation that provides more stable effect than glargine U100. Because of the pharmacokinetic properties of glargine U300, the expected plasma insulin concentration is not achieved during the first 4 days of treatment. We report a case of diabetic ketoacidosis in the first day of glargine U300 treatment due to low plasma insulin concentration. A 62 year old female patient with diagnosis of type 2 diabetes mellitus (DM) for 25 years. Her medications include insulin aspart 12 unit three times daily, insulin detemir 22 unit once daily, metformin 1000 mg twice daily, linagliptin 5 mg. According to the patient's anamnesis, it has been noticed that in addition to the especially night hypoglycemia, the blood glucose levels of fasting and postprandial in the evening were high and she said that did not adhere to her diet. Physical examination revealed that her BMI is 33 kg/m^2. Laboratory findings were as follows; HbA1c: 10.3%, c-peptide: 0.07 µg/L, Hb: 9.2 g/L, MCV: 89 fL, ferritin: 7.93 µg/L. The patient was hospitalized to regulate her blood glucose and to investigate anemia etiology. Insulin detemir, used by the patient were replaced by insulin glargine U300 U/mL, 30 units once daily because of the hypoglycemia at night and the high blood sugar levels in the evening. On the second day of treatment, abdominal

ultrasound examination is demanded from the patient to research anemia etiology in the morning and as fasting. Blood glucose was measured 450 mg/dL after returning from the ultrasound when she had not eaten breakfast. It was detected that the ketone in the urine and pH: 7.29, hCO3: 14 mmol/L in the blood gas of the patient with complaints of nausea and fatigue. Insulin infusion was initiated by considering mild diabetic ketoacidosis in the patient. For treatment of insulin glargine U300 U/mL to be stable, 4 days must pass. For the first 4 days, it may be seen the diabetic ketoacidosis on the patients who have type 1 DM and, as in this case, long-term type 2 DM with decreased insulin reserve, that are treated with newly started insulin glargine U300 due to inadequate plasma basal insulin.

A female patient with diabetic ketoacidosis who had hyperthyroidism and acute appendicitis

Aşkin Güngüneş[1], Şenay Arikan Durmaz[1], Ridvan Erdin[2], Faruk Pehlivanli[3] & Oktay Aydin[3]
[1]Department of Endocrinology of School of Medcine, Kırıkkale, Turkey; [2]Department of Internal Medicine of School of Medcine, Kırıkkale, Turkey; [3] Department of General Surgery of School of Medcine, Kırıkkale, Turkey.

Introduction
Hyperthyroidism is defined as thyroid hyperfunction due to overproduction of thyroid hormones. Graves disease is the most common cause of hyperthyroidism. Hyperthyroidism may be associated with glycemic dysregulation. We are presenting a case with diabetic ketoacidosis who had Graves disease and acute appendicitis.
Case presentation
A nineteen years old female patient wtih Graves disease who had hyperthyroidism despite high dose antithyroid medication. She applied with diabetic ketoacidosis and acut appendicitis. Respiratory arrest developed and she was intubated. Hydration, electrolyte replacement, HCO3 replacement and intravenous insulin started due to diabetic ketoacidosis. Surgical treatment was planned for acut appendicitis. Potassium iodide, anti- thyroid theraphy and beta-blocker was started. Appendectomy was performed under spinal anesthesia after diabetic ketoacidosis had partially improved. Post-operative propylthiouracil 20tb / day, beta-blocker and cholestyramine treatment was given. Free thyroid hormones were normal after these treatment and total thyroidectomy was planned.
Conclusion
Hyperthyroid patients have an higher risk to develop hyperglycemia. Possible mechanisms are increased hepatic glucose output, rapid glucose absorption from the intestine, increased gluconeogenesis and insulin resistance. Patients presenting with diabetic ketoacidosis should be carefully evaluated in terms of precipitating factors such as hyperthyroidism.

Factitious hypoglycemia; Case report

Şenay Arikan Durmaz[1], Aşkin Güngüneş[1] & Selim Yalçin[2]
[1]Department of Endocrinology of School of Medcine, Kırıkkale, Turkey; [2]Department of Oncology of School of Medcine, Kırıkkale, Turkey.

Introduction
Hypoglycemia is defined as a reduction in plasma glucose concentration to a level that may induce symptoms such as sweating, shaking, palpitation, headache, *blurry vision*, loss of consciousness, *seizure*, *coma*. We present a case with hypoglycemia which is due to the use of exogenous insulin.
Case presentation
A 72-years-old patient with Alzheimer disease who was admitted to the emergency clinic because of unconsciousness.Plasma glucose was 25 mg/dl at this time and concurrently measured insulin and C-peptide value were >1000 uU/ml and 0.31 ng/ml, respectively.The patient's plasma glucose was increased and consciousness was improved by intravenous dextrose. Injection areas were observed in the skin of the abdomen on physical examination.Present findings supported hypoglycemia which was associated with the use of exogenous insülin. However, patient's relatives denied the use of exogenous insülin.Insulin antibody was screened to exclude autoimmune hypoglycemia. Insulin antibody was not detected. The patient was followed up, insulin and C-peptide levels returned to normal 10 days later (insulin 11.22 and C-peptide 4.41 ng/ml)
Conclusion
Exogenous administration of insulin results an increase on insulin levels without a concomitant increase in the C-peptide level.Factitious hypoglycemia should be kept in mind especially in elderly patients in need of care for others.

Development of fatal lactic acidosis after inadvertent use of metformin in a non-diabetic hemodialysis patient

Suat Akgür[1], Ayşegül Oruç[1], Abdülmecit Yıldız[1], Canan Ersoy[2], Mustafa Güllülü[1] & Alparslan Ersoy[1]
[1]Uludag University Medical Faculty, Department of Nephrology, Bursa, Turkey; [2]Uludağ University Medical Faculty, Department of Endocrinology and Metabolism, Bursa, Turkey.

Metformin is considered to be the first choice in the treatment of type 2 diabetes mellitus. Lactic acidosis is a rare life-threatening complication of metformin with approximately 50% overall mortality. Metformin is contraindicated in patients with factors predisposing to lactic acidosis such as impaired renal function (eGFR <30 mL/min). Herein, we present a hemodialysis patient who developed lactic acidosis after inadvertent usage of metformin.
Case report
A 77-year-old woman was admitted to the emergency department with complaints of nausea, vomiting, black stools, weakness and deterioration in general condition. The patient underwent regular hemodialysis twice a week for 1.5 years due to hypertension and end-stage kidney disease. She was anuric for one year. The last dialysis session was performed 3 days ago. Her family said she had inadvertently received six metformin tablets resembling calcium acetate pills, three in the morning and three in the evening, two days ago. Metformin belonged to one of the family members. She was afebrile, tachypneic, agitated and confused. Heart rate was 145 b/min, blood pressure 70/30 mmHg and oxygen saturation in the room air 75%. There was no significant cardiovascular and pulmonary findings. Laboratory tests showed glucose 88 mg/dl, urea 199 mg/dl, creatinine 10.1 mg/dl, sodium 134 mmol/l, potassium 6.3 mmol/l, white blood cell 42.7 K/mm^3 and hemoglobin 10.5 g/dL. Her liver function tests were normal. Wide-anion gap metabolic acidosis without ketonemia was detected. The pH was 6.9, bicarbonate (HCO_3^-) 6 mmol/L, and lactate 140 mmol/L. Metformin-induced lactic acidosis was diagnosed. She was treated with positive inotropic support and bicarbonate infusion. Hemodialysis with bicarbonate buffered replacement fluid was started to remove metformin and correct lactic acidosis. After dialysis, control blood gas values were mildly improved (pH 7.16, lactate 108 mg/dL and HCO_3^- 13.8 mmol/L). Then, despite the dialysis treatment, acidosis deepened (pH 6.8, HCO_3^- 6 mmol/L and lactate 170 mg/dL) and she died with sudden cardiac arrest.
Conclusion
Lactic acidosis and/or hypoglycemia have been reported after inadvertent metformin overdose in diabetic hemodialysis patients. Our case was the first non-diabetic patient who developed lactic acidosis after accidentally metformin use. Significant lactic acidosis occurs only in the presence of comorbid conditions including kidney failure. Drug use should be controlled in elderly dialysis patients.

Effect of hemoglobin J variant on HbA1c values as measured by HPLC (high-perfomance liquid chromatography)

Jessica Ares Blanco, Angel Bernardo Gutiérrez, Alicia Martín-Nieto, Silvia González-Martínez, Elías Delgado-Álvarez & Edelmiro Menéndez-Torre
Hospital Universitario Central de Asturias, Oviedo, Spain.

Hemoglobin A1c (HbA1c) is used for the long-term management of patients with diabetes mellitus (DM). Hemoglobin variants other than HbA1c and e-N-lysine-glycated HbA0 may cause analytical interference in determinations of HbA1c.

Hemoglobin J is an abnormal hemoglobin, an alpha globin gene variant and present in various geographic locations. Hemoglobin J (depending on its type) has different characteristics and functions. For example hemoglobin J Capetown (α2 92Gln β2), the most commonly seen Hb J variant (CGG->CAG), is associated in the heterozygous state with increased oxygen affinity and polycythemia. Other variants like Hb J Sardegna will show a completely unremarkable clinical picture in the heterozygote. Hemoglobin J Bancock (beta 56 Gly->Asp) and J Baltimore (beta 16 Gly->Asp) have been described in combination with sickle hemoglobin. Recently, Valencia Clinical Hospital discovered a new variant named Hemoglobin J Valencia; it was discovered after routine glycemic testing was carried out on a person with Diabetes, with the results of the test coming back abnormally low within the parameters. We describe the case of a 39-year-old caucasian male with history of HIV who presented to our institution for elevated HbA1c, with normal fasting glycemia. He was first diagnosed with HIV two years ago, when infectious disease specialist determined HbA1c for the first time (as a protocol), obtaining 12%. Our patient was also receiving treatment with Efavirenz, Tenofovir and Emtricitabine (HIV therapy). Fasting glycemias were always normal, so the doctor recommended metformin 850 mg twice daily. No hemoglobinopathy was known or suspected, as the blood count was normal; {red blood cells =5.89 million/mm^3 [reference interval (RI) =4.5-6 million/mm^3}; hemoglobin =17.2 g/dl (RI =13-18 g/dl); hematocrit =51.4% (RI =40%-55%). Previous values of HbA1c were: 12.0% (29/04/2015), 11.5% (27/01/2016) and 11.8% (28/06/2016); and fasting plasma glucose concentrations were 89 mg/dL, 96 mg/dL and 93 mg/dL, respectively. As these results did not correlate between them, we gave him a continuous glucose monitoring system; he worn it for one week. Time in target was 95%; glucose trend, 93 mg/dL, and no low glucose event was detected. Taking all these data into account, we performed a test for identification of hemoglobin variants using HPLC, which presented: HbA0=56.2%; HbA2=3.3%; and the presence of probable HbJ =39.2%. As a result, real HbA1c was lower than we could first determine.

Performance-enhancing drugs and adverse endocrine effects

Diana Oliveira, Adriana Lages, Isabel Paiva, Mara Ventura, Nelson Cunha, Lúcia Fadiga, Diana Catarino, Sandra Paiva & Francisco Carrilho
Endocrinology, Diabetes and Metabolism Department, Coimbra Hospital and University Center, Coimbra, Portugal.

Introduction
Performance-enhancing drug (PED) use is currently a common practice both inside and outside the sports competition scenario, and its adverse health effects remain underappreciated.
Case report
We report the case of a 26-year-old man, bodybuilding practitioner, no relevant medical history, family history of autoimmune disorders. Referred to the emergency room with polydipsia, polyuria, blurred vision associated with a post-prandial capillary blood glucose of 422 mg/dl. Initial testing revealed glucose 281 mg/dl, normal liver tests and renal function, no acidosis, no significant ketonemia. He had participated in a bodybuilding competition four days before and used the following PED (6 weeks cycle before the competition): androgenic-anabolic steroids – testosterone cypionate 500 mg/wk, trenbolone 100 mg every other day, stanozolol 40 mg id, boldenone 1200 mg/wk, sustanon® 250 mg twice weekly, testosterone enanthate 250 mg id, drostanolone propionate 100 mg every other day, mesterolone 25 mg 4-6id, fluoxymesterone 75 mg id; dopaminergic agonist – cabergoline 0.25 mg every other day; aromatase inhibitor – anastrozole 1 mg id; beta 2-adrenergic receptor agonist – clenbuterol tid; thyroid hormones – levothyroxine 100 mcg id, liothyronine 25 mcg bid; non-specified multivitamins. On the day of the competition, he took diuretics (altizide + spironolactone). He had done similar cycles since he was 21 years old. Hospitalized for suspected diabetes Mellitus (DM). Body mass index 21.1 kg/m^2, with fat mass 2.7 kg (5.5–13.7) and lean mass 61.8 kg (52–60.2). He maintained blood glucose 70–130 mg/dl. Hematocrit was increased (53%). A posterior analytic evaluation revealed oral glucose tolerance test with impaired glucose tolerance, positive diabetes autoimmunity, A1c 5.8%, C peptide 1.7 ng/ml (1.0–7.6). Autoimmune thyroiditis was also detected, with mild subclinical hypothyroidism. Pituitary function assessment showed hypogonadotropic hypogonadism (total testosterone 0.9 ng/dl), without evident signs or symptoms. He maintains irregular follow-up.
Discussion
A wide range of endocrine adverse effects of PED use are described. Altered glucose homeostasis can occur through increasing insulin resistance, which can accelerate DM natural history in individuals with positive autoimmunity. Anabolic steroid-induced hypogonadism is caused mainly by feedback suppression of the hypothalamic-pituitary-gonadal axis and can be irreversible, leading to infertility. Although complications related to PED use are known, there is scant scientific evidence regarding the long-term consequences and complex endocrine disruption likely caused by the stacking and cycling of multiple high-dose synthetic androgens and other classes of PED. Clinical and hormonal function evaluation of these athletes is difficult, as they are using unregulated or non-authorized drugs and can have a low level of trust in the medical community.

Maturity – onset diabetes in the young and non-alcoholic fatty liver disease: a case report

Agne Kadusauskiene[1,2], Raimonda Klimaite[1] & Neli Jakuboniene[1,3]
[1]Department of Endocrinology, Hospital of Lithuanian University of Health Sciences Kauno klinikos, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction
Maturity-onset diabetes of the young (MODY) is a form of diabetes mellitus transmitted by an autosomal dominant mode of inheritance, usually diagnosed before the age of 25 years. Non-alcoholic fatty liver disease (NAFLD) is a chronic liver disease, particularly closely related with insulin resistance and type 2 diabetes mellitus. MODY and NAFLD combination has rarely been described in the literature.
Case
A 25-year-old women was admitted to the Hospital of Lithuanian University of Health Sciences, Kauno klinikos to verify diabetes type. She has been diagnosed with type 1 diabetes a year ago. Despite dietary control and a basal-bolus insulin therapy, her glycaemic control was inadequate with glycosylated haemoglobin (HbA1c) 8.8%. Blood tests for islet-cell antibodies and glutamic acid decarboxylase autoantibodies were negative (anti GAD65 0.25 IU/ml (normal range 0–1), anti IA2 0.05 U/ml (0–1), anti-insulin 4.5% (<6.4), with enough insulin secretion (C-peptide before eating 1.49 nmol/l (0.36–1.09)). A missense GCK gene mutations were confirmed by genetic (NM_000162.3(GCK):c.[679+38T>C]); [679+38T>C]), suggesting diagnosis of MODY 2 diabetes. The insulin therapy was gradually withdrawn and sulfonylurea was introduced. Patient had no history or risk factors of liver disease, with body mass index (BMI) 27.6 kg/m^2 and minor dyslipidaemia. Her liver function tests showed moderate elevations of liver enzymes (aspartate aminotransferase (AST) 147 U/l (0–35), alanine aminotransferase (ALT) 143 U/l (0–45), γ-glutamyl transferase (GGT) 168 U/l (0–55)), with normal bilirubin's levels. Serum hepatitis markers, autoantibody screenings were negative, ceruloplasmin was normal (0.36 g/l (0.22–0.58)). There was a moderate increase in ferritin (354.4 μg/l (20–275)) with normal saturation (34% (15–45)). A liver ultrasound showed increased echogenicity with diffuse fatty infiltration confirming diagnosis of NAFLD. Despite 3 months of treatment by 280 mg silymarin and statins, her liver enzymes remained elevated. Finally, insulin therapy was resumed, because with dietary control and 120 mg of gliclazide, glycaemic control persisted to be inadequate. After 6 months, liver enzymes decreased and glycaemic control improved.
Conclusions
Coexistence of MODY and NAFLD is rare and it is hard to distinguish a causative relationship. Therefore, research and new management strategies for this pathology are urgently needed.

Dapagliflozin and Atkins Diet in a patient with type 2 Diabetes Mellitus: A combination that should be avoided

Maria Grammatiki[1], Eleni Rapti[1], Despina Dina[1], Theocharis Koufakis[1], Vasiliki Antonopoulou[1], Xanthippi Tsekmekidou[1], Maria Yavropoulou[1], Spyridon Karras[1], Pantelis Zebekakis[2] & Kalliopi Kotsa[1]
[1]Diabetes Center, Department of Endocrinology and Metabolism, 1st Department of Internal Medicine, AHEPA University Hospital, Thessaloniki, Greece; [2]1st Department of Internal Medicine, AHEPA University Hospital, Thessaloniki, Greece.

Introduction
Prevalence of type 2 diabetes mellitus (T2DM) rises rapidly worldwide and most patients with T2DM are obese. All treatment algorithms advocate lifestyle modification and weight loss in combination with various therapeutic categories available for the treatment of T2DM, resulting in diet-antidiabetic drug combinations that are not always proper or safe for the patients.
Case presentation
A 73-year-old Caucasian man presented to the emergency department of our hospital with weakness and malaise gradually deteriorating over the previous 3 days, accompanied by anorexia, nausea and vomit tendency over the last 24 hours. He had a previous history of hypertension, diagnosed 15 years ago, currently treated with felodipine and metoprolol. He also had a history of T2DM diagnosed 10 years ago, currently treated with metformin, sitagliptin and dapagliflozin. Despite his poor general condition and his reduced food intake he continued all his medications. The patient was obese, struggling with several weight loss efforts over the last ten years. The week before admission to the hospital he had started an Atkins diet. Physical examination at the time of admission revealed signs of dehydration. Patient vitals were within normal range. His point-of-care blood glucose value was 143 mg/dl. He had moderate tenderness to palpation in the upper abdomen, while the remainder of the clinical examination was normal. On admission serum creatinine and uric acid were increased while the rest of the biochemical tests were normal. Estimated serum osmolality was 308 mOsm/kg. His arterial blood gas showed a pH 7.19, PCO2 of 34 mmHg, PO2 of 103 mmHg, bicarbonate of 13.5 mmol/l and an anion gap of 24 mEq/l. He had increased blood β-hydroxybutyric acid and urine ketones in the urine analysis. The diagnosis of euglycemic diabetic ketoacidosis (euDKA) was established and he was treated with intravenous fluids, glucose and insulin.
Conclusions
Sodium-glucose cotransporter-2 (SGLT2) inhibitors lower plasma glucose and favour weight loss by promoting glycosuria and inhibiting glucose reabsorption. Low carbohydrate diets force the body into ketogenesis, causing a state of relative metabolic acidosis even in non-diabetic patients. This case indicates that these diets should be avoided in T2DM patients on SGLT2 inhibitor treatment, since both SGLT2 inhibitors and low carbohydrate diets (such as Atkins diet) can induce ketogenesis or even ketoacidosis in the presence of a triggering factor, reflecting a life-threatening ketogenic combination.

A rare cause of hypoglycemia: insulin autoimmune syndrome in a Turkish patient taking Alpha lipoic acid

Basak Bolayir[1], Mehmet Ayhan Karakoc[1], Muzaffer Serdar Deniz[1], Alev Altinova[1], Mujde Akturk[1], Busra Yurumez[2], Fusun Toruner[1] & Ilhan Yetkin[1]
[1]Department of Endocrinology and Metabolism, Gazi University Faculty of Medicine, Ankara, Turkey; [2]Department of Internal Medicine, Gazi University Faculty of Medicine, Ankara, Turkey.

Insulin autoimmune syndrome (IAS) is a rare cause of hypoglycemia and characterized with autoantibodies to insulin in a patient without prior exposure to exogenous insulin. Medications with sulfydryl group and autoimmune diseases are known to be associated with this syndrome. Nearly 90% of the cases were reported in Japanese patients. We presented a Turkish patient with insülin autoimmune syndrome possibly caused by α-lipoic acid. A 62-year-old woman was admitted to our clinic recurrent episodes of sweating, weariness, heart palpitations and anxiety occurring both fasting and postprandial. The first episode was two weeks before admission and the capillary glucose was measured as 40 mg/dl during episode. She had been diagnosed with hypertension and hyperlipidemia for ten years and treated with indapamid, nebivolol and atorvastatin. She had never been diagnosed as diabetes mellitus and never injected insulin before. She had no family history of diabetes or autoimmune disease. She had been taken multivitamin preparation which contained α-lipoic acid until three weeks prior to her hospitalization. Laboratory investigations revealed normal renal and liver functions. During hypoglycemic event, serum glucose was 46 mg/dl; serum insulin was 1890 μIU/ml (normal: 1.9-23) and C-peptide was 11.9 ng/mL (normal value 0.9–7.1). Proinsulin levels was 33.8 pmol/l (normal: <8). An oral glucose tolerance test showed hypoglycemia with inappropriately high insulin levels at 300 min. The 72-h fasting test, abdominal computed tomography (CT) and magnetic resonance imaging (MRI) were normal. Insulin recovery was 6.6% after polyethylene glycol precipitation. No interference was detected with heterophile blocking tubes. Insulin antibodies was measured as 79% (normal: <8.2) and the patient was diagnosed as insulin autoimmune syndrome. Patient was instructed not to use the suspected medication again. Diet with low carbonhydrate and frequent small meals was planned. Her symptoms resolved and no hypoglycemic event was recorded. Insulin levels have decreased from 1890 μIU/ml to 76 μIU/ml (normal: 1.9-23) during follow-up. In all hyperinsulinemic hypoglycemic cases, especially in patients taking medications known to be associated with the syndrome and having very high insulin levels, the diagnosis of insülin autoimmun syndrome should be kept in mind.

Post bariatric surgery malabsorption and vitamin D deficiency

Paraskevi Potamousi[1], Charilaos Samaras[1], Styliani Gerakari[1], Anastasia Fambri[1], Panagiotis Bouras[1], Lambros Athanassiou[1], Dimitra Fasfali[1], Evangelos Siarkos[1] & Ifigenia Kostoglou-Athanassiou[2]
[1]1st Department of Medicine, Asclepeion Hospital, Voula, Athens, Greece; [2]Department of Endocrinology, Asclepeion Hospital, Voula, Athens, Greece.

Introduction
Bariatric surgery is a revolutionary method for the treatment of morbid obesity. It is effective as far as weight control is concerned, for the prevention and treatment of diabetes mellitus and the metabolic syndrome. However, bariatric surgery may be accompanied by adverse effects if postoperatively dietary instructions are not adhered to.
Aim
The aim was to present a case of a patient who underwent sleeve gastrectomy for the treatment of morbid obesity and postoperatively developed severe malabsorption and vitamin D deficiency.
Methods
The case of a patient, female, aged 50 is described, who suffered from morbid obesity, body weight being 250 kg, BMI 91.83. The patient underwent sleeve gastrectomy, the treatment being effective as far as weight loss is concerned, as she lost weight. However, in the course of the disease the patient did not comply with dietary instructions. She developed diarrhea, severe malabsorption, severe vitamin D deficiency and spontaneous rib fractures. Additionally, she developed hidradenitis suppurativa.
Results
An intestinal biopsy was performed which showed non-specific intestinal inflammation. However, the syndrome of diarrhea was so severe, that mesalazine was administered. Mesalazine administration improved diarrhea. A month ago, the patient presented with generalized bone and muscle pain, cardiac insufficiency and respiratory insufficiency. Plasma $25(OH)D_3$ was 3 ng/ml (normal range >30 ng/ml), PTH 280 pg/ml (normal range 10–65 pg/ml) and plasma calcium 8.4 mg/dl. Cholecalciferol was administered in high dosage and generalized pain improved.
Conclusions
Morbid obesity may be a manifestation of severe depression, which affects dietary behavior and may manifest as bulimia. Surgical treatment of obesity improves body weight however it does not improve depression. Dietary behavior may persist with destructive effects on the gastrointestinal system and the organism, such as premature ageing, diarrhea and malabsorption with vitamin and micronutrient deficiency. In particular vitamin D deficiency may induce osteomalacia and generalized bone and muscle pain. In the case described, the patient developed hidradenitis suppurativa, which, being an autoimmune disorder, may have been partially induced by vitamin D deficiency.

Diabetes and bulimia – a dangerous combination

Daniel Tudor Cosma[1], Cristina Alina Silaghi[2], Horatiu Silaghi[3], Carmen Emanuela Georgescu[2] & Ioan Andrei Veresiu[4]
[1]Center for Diabetes, Nutrition and Metabolic diseases, Cluj-Napoca, Romania; [2]Department of Endocrinology, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania; [3]Vth Department of Surgery, "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania; [4]Department of Diabetes, Nutrition and Metabolic diseases, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania.

Introduction
Bulimia is an eating disorder characterized by constant preoccupation with food, irresistible cravings for food and binge eating episodes. The data regarding the incidence of bulimia in people with diabetes are contradictory. The glycemic variations subsequent to binging and vomiting leads to complications like retinopathy, kidney or liver failure, hypoglycemic comas and electrolyte imbalances.
Case presentation
A 57-year-old female, diagnosed with type 2 diabetes at the age of 33, complicated by diabetic polyneuropathy and under treatment with Metformin (2 g/day), glargine (96 IU/day) and glulisine (32 IU/day) was admitted to our center for persistent hyperglycemia (Gl max = 430 mg/dl), polyuria, polydipsia, nocturnal enuresis, xerostomia and nocturnal paresthesia in the upper and lower limbs. Despite her associated disorders (recurrent depression and bulimia) untreated properly, she underwent a gastric plication procedure with an initial weight loss of 20 kg regained after a period of 2 years. At admission: depressive facial affect, BMI = 42.87 kg/m^2, distended abdomen due to fat tissue with multiple surgical scars, psoriatic lesion on the posterior thorax, elbows and lower limbs and acanthosis nigricans on the neck. Labs exams revealed: Gl = 304 mg/dl, hypertriglyceridemia, low calcium and magnesium levels, glycosuria and poor glycemic control in the last 3 months (A1c = 11.4%). The 24-hour weighed food diary showed a caloric intake higher than her daily requirements with 3 main meals and 4 snacks (consisting of fruits, sweets, bread and yogurt). To improve the glycemic and weight control the prandial insulin was stopped and Exenatide 10 μg bid was initiated, alongside with a low caloric diet of 1200 Kcal/day and resumed therapeutic education with a favorable outcome. The psychological and psychiatric consults confirmed the previous diagnoses and recommended increasing the Fluoxetine to 40 mg/day, monthly reevaluation and cognitive behavioral therapy. The hormonal profile excluded other secondary causes of obesity. The neuropathic symptoms diminished significantly under i.v treatment with α-lipoic acid. The Doppler exam displayed decreased values of the ankle-brachial index.
Conclusions
The data regarding the incidence of bulimia in people with diabetes are contradictory and the factors which may underlie the link between diabetes and bulimia have not been systematically investigated. The screening for bulimia and other eating disorders may be an efficient tool for detection and implementation of the multidisciplinary approach in order to obtain the therapeutic success.

P328

Prolonged hyperglycemia in a type 1 diabetic futsal player after a single betamethasone injection for pain in the groin area

Daniel Tudor Cosma[1], Cristina Alina Silaghi[2], Horatiu Silaghi[3], Carmen Emanuela Georgescu[2] & Ioan Andrei Veresiu[4]
[1]Center for Diabetes, Nutrition and Metabolic diseases, Cluj-Napoca, Romania; [2]Department of Endocrinology, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania; [3]Vth Department of Surgery, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania; [4]Department of Diabetes, Nutrition and Metabolic diseases, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania.

Introduction
Pain in the groin area is frequently encountered in football players, the cause being a sport hernia, muscle tears, avulsions, sacroiliac joint pathology, etc. Local corticosteroid injections (LCIs) are often used as one of the first-line treatments in the conservative management because of their ease of delivery, low cost and efficacy.
Case presentation
A 32-year-old amateur futsal player (goalkeeper) diagnosed with type 1 diabetes at the age of 18, complicated by mild peripheral polyneuropathy, treated with aspart insulin through an insulin pump (basal rate = 25.7 IU/day and boluses = 35 IU/day) was admitted to the Clinical Recovery Hospital for an intense pain in the left groin area (9/10 on VAS), located profound and aggravated by any physical activity. The patient was previously treated with Celecoxib 90 mg/day in 2 cycles of 7 days at one month's interval. At admission: BMI = 26 kg/m^2, BP = 120/80 mmHg, Pulse = 70/min, flat feet, bilateral hallux valgus, cracking sounds on knees mobilization, lipohypertrophy due to insulin therapy under umbilical area. Labs exams revealed: Gl = 173 mg/dl, A_1c = 6.7% and negative inflammatory markers. The X-rays displayed an avulsion of the antero-inferior iliac spine (AIIS) confirmed by CT scan which also revealed the preservation of the muscle tendon insertion and a partial tear of the left rectus femoris. Under treatment with Celecoxib (30 mg/day), Tramadol + Acetaminophen 37.5/325 mg (bid) and local Ketoprofenum 2.5% applications the pain intensity decreased slightly (6/10 on VAS). In order to optimize the pain management a Betamethasone injection 1 ml (7 mg) in the groin area was administered in the 4th day of hospitalization. In order to maintain an optimal glycemic control significant increases of both basal rate (120% - 140% - 160%) and prandial boluses (with 2, 4 and 5 IU) were necessary. The highest glycemic value was 456 mg/dl and was documented in the 4th day after LCI. The patient returned to his initial insulin doses in the 9th day after LCI. The improvement in pain symptoms lasted for almost 6 months.
Conclusions
This case report demonstrated that a single injection of Betamethasone can cause a significant rise in the average daily insulin requirements needed to control blood glucose levels. The medical practitioners should warn type 1 diabetic patients about this possible side effect and must advise a more frequent monitoring in order to detect and correct the hyperglycemic events.

Glucose, lipids, and insulin in cord blood of neonates and their association with birth weight

Jingya Wang[1,2], Yashu Kuang[1], Malcolm Price[2], Jinhua Lu[1], Songying Shen[1], Huimin Xia[1], Xiu Qiu[1], Kar Keung Cheng[2] & Krishnarajah Niratharakumar[2]
[1]Division of Birth Cohort Study, Guangzhou Women and Children's Medical Centre, Guangzhou Medical University, Guangzhou, China; [2]Institute of Applied Health Research, University of Birmingham, Birmingham, UK.

Background
Low and high birth weight (BW) has been linked to the increased risk of infant mortality, obesity, diabetes, and cardiovascular diseases. Metabolic biomarkers, glucose, lipids and insulin in human umbilical cord blood could potentially reflect the new-born metabolic status. This study aims to assess the concentration of glucose, lipids and insulin in cord blood, and to investigate the association between these metabolic parameters and BW.
Methods
A total number of 1522 mother-baby pairs from the Born in Guangzhou Cohort Study (delivered during January 2015–June 2016) were included into this analysis. Data on cord maternal gestational metabolic characteristics, delivery information, cord blood metabolic parameters (glucose, lipids and insulin concentrations) and BW were prospectively collected. Associations between cord blood metabolic parameter z-scores and BW z-score were assessed using multivariable linear regression, adjusted for maternal age, gestational age, parity, gender, delivery mode, maternal metabolic characteristics (2nd trimester glycaemic status and triglycerides level) and sample storage duration.
Results
Other than insulin (median[IQR]: 7.43[4.34, 12.61]) μU/ml) and triglycerides (TG, median[IQR]: 0.33[0.27, 0.41] mmol/l), the concentrate distribution of glucose, total cholesterol (TC, mean ± s.d.: 1.72 ± 0.42 mmol/l), high-density lipoprotein cholesterol (HDL, mean ± s.d.: 0.91 ± 0.28 mmol/l), low-density lipoprotein cholesterol (LDL, mean ± s.d.: 0.61 ± 0.24 mmol/l) in the cord blood were normal distributed. Z-score of glucose concentration in the cord blood was not associated with BW ($P = 0.81$) z-score. Z-score of cord blood TC (β[95%CI]: 0.05[0.01, 0.09]), HDL (β[95%CI]: 0.08[0.04, 0.12]), and insulin (β[95%CI]: 0.21[0.17, 0.25]) were positively associated with BW z-score, while TG z-score was inversely associated with BW z-score (β[95%CI]: −0.22[−0.27, −0.18]).
Conclusion
Our findings suggest new-borns with higher BW centile might have increased risk of insulin insensitivity and high TG consumption rate. Insulin and TG concentrations in cord blood potentially reflect new-born metabolic status.

Association of RS1170806 polymorphism in *ADCY5* and RS7754840 polymorphism in *CDKAL1* with birth weight, neonatal glucose, insulin and insulin resistance.

Ivette Guadalupe Aguilera Venegas[1], Julia Mora Peña[1], Martha Isabel Gonzalez Dominguez[2], Hector Manuel Gomez Zapata[3], Gloria Barbosa Sabanero[1] & Maria Luisa Lazo de la Vega Monroy[1]
[1]Department of Medical Sciences, University of Guanajuato, Campus León, Leon, Guanajuato, Mexico; [2]State University of Cienega Michoacan, Sahuayo Michoacan, Mexico; [3]UMAE No. 48, IMSS, Leon, Guanajuato, Mexico.

Background
The fetal insulin hypothesis proposes that low birth weight, insulin resistance, and decreased insulin secretion in adulthood are genetically mediated. Babies with low birth weight have higher morbidity and mortality risk in adulthood. However, this situation could also occur in children with adequate weight at birth with genetic risk factors. The polymorphisms rs11708067 in *ADCY5* and rs7754840 in *CDKAL1* have been associated with low birth weight, risk of DM2, and lower insulin secretion in adults. However, it remains to be proven if they are related to fetal-neonatal insulin secretion or insulin resistance.
Methods
Genotyping for rs11708067 in *ADCY5* was performed by RFLPS and for rs7754840 in *CDKAL1* by qPCR with TaqMan probe in genomic DNA from 218 healthy neonates recruited in Guanajuato. Neonatal C-peptide and insulin concentrations were measured by ELISA. The difference between genotypes was evaluated using ANOVA. The association of polymorphisms with insulin and C-peptide was evaluated by multiple regression.
Results
Differences were found in the concentrations of insulin ($P=0.010$) and C-peptide ($P=0.004$) between rs11708067genotypes, with lower concentrations of both variables on allele A carriers. We found an inverse association of the A allele of rs11718067 with insulin ($P=0.016$) and neonatal C-peptide ($P<0.001$). No differences were found between genotypes and birth weight, glucose, or HOMA-IR. For rs7754840 no difference was found between genotypes for any variable, nor association with insulin concentrations or C-peptide.
Conclusions
The risk allele A in rs11708067 ADCY5 could be related to fetal/neonatal insulin secretion. This is the first study to evaluate neonatal insulin associated with the rs11708067 genotype. This proyect was supported by CONACYT (CB-2013-222563) and UG-DAIP 2016-2017 (1089/2016).

Evaluation of community pharmacy-based services for type-2 diabetes in an Albanian setting: pharmacist survey

Edmond Pistja & Alba Themeli
Medical Training center Santa Maria, Lezhe, Albania.

Background
Diabetes type II is an emerging chronic disease in developing countries. Currently the management of diabetes in developing countries is mainly hospital or clinic based. With burgeoning numbers of patients with diabetes, other models need to be evaluated for service delivery in developing countries. Community pharmacists are an important option for provision of diabetes care. Currently, data regarding practices of community pharmacists in diabetes care in Albania are limited.
Objectives
To evaluate current community pharmacy-based services and perceived roles of pharmacists in type 2 diabetes care, and characteristics (pharmacist and pharmacy) associated with current practice.
Setting
Community pharmacies in several cities in Albania.
Methods
A questionnaire was administered to pharmacists managing a random sample of 30 community pharmacies in different cities in Albania. Current practice and pharmacists' perceived roles were rated using Likert scales, whilst an open-ended question was used to identify priority roles. Logistic regression models determined characteristics associated with current practice.
Results
A response rate of 60% was achieved. Dispensing (100%) and education on how to use medications (72.6%) were common current pharmacy practices. More than 50% of pharmacists were supportive towards providing additional services beyond dispensing. The highest priorities for services beyond dispensing were education on medications [i.e. directions for use (58.6%) and common/important adverse effects (25.7%)], education on exercise (36.5%), education on diet (47.7%), and monitoring medication compliance (27.9%). Facilitators identified were: being perceived as part of a pharmacist's role (for all priority services), pharmacies with more than 50 diabetes customers per month (for diet education), and pharmacists' involvement in diabetes training (for compliance monitoring). The key barrier identified was lower pharmacist availability (for diet education as well as compliance monitoring).
Conclusions
Most community pharmacies in Albania have only provided a basic service of dispensing for type 2 diabetes patients. Many pharmacists believed that they should extend their roles particularly regarding patient education and monitoring. The development of pharmacist professional roles would assist in managing the burgeoning burden of diabetes. The identified facilitators/barriers provide baseline data to support the development of community pharmacy-based diabetes services.

P332

Estimation of HbA1c in hospitalized patients with bronchial asthma

Bayar Qasim[1], Safer Haj[1] & Herish Ahmed[2]
[1]Department of Medicine, University of Duhok, Duhok, Iraq; [2]Directorate of Health of Duhok, Duhok, Iraq.

Background
Asthma is a chronic inflammatory respiratory disease. Stress hormones may increase in asthma and expected to induce hyperglycemia. Some anti-asthma medications increase blood glucose levels e.g. Beta-agonist, while others are known hyperglycemic agent's e.g. steroids. People who have experienced stress hyperglycemia during severe illness have a threefold risk of developing diabetes in subsequent years, and it may be appropriate to screen for diabetes in survivors of critical illness.
Aim
The aim of this study is to assess hyperglycemia patients with bronchial asthma, to the best of our knowledge; this is the first study to assess serum level of HbA1c among patients with bronchial asthma in Duhok, Iraq.
Methods
A case-control study conducted at the medical ward, department of internal medicine at Azadi Teaching Hospital in Duhok Governorate, Kurdistan Region, Iraq from 1st June 2016 to 30th January 2017. Seventy five patients and seventy five controls were enrolled in this study. HbA1c measurements were performed on blood samples of patients and controls.
Results
The study revealed that the rate of hyperglycaemia was higher in cases of bronchial asthma in comparison to healthy controls ($P=0.001$). Our data suggest that the HbA1c level were elevated in 26(34.6%) of patients and in 4(5.3%) of controls. Levels of HbA1c was not significant in chronic use of corticosteroid both inhaler and oral type, salbutamol inhaler, current use of corticosteroid both intravenously and orally, and duration of bronchial asthma ($P>0.009$).
Conclusion and recommendations
Hyperglycemic control might improve risk assessment in those patients with bronchial asthma. Measurement of RBS besides HbA1c in asthmatic patients is essential. Hyperglycemia more probably is associated with bronchial asthma itself rather than its treatments. In patients admitted to a medical ward with acute bronchial asthma, glucose levels should be monitored closely.

DOI: 10.1530/endoabs.56.P332

P333

Inpatient diabetes management service, 30-day readmissions and length of stayof patients with diabetes

Samantha Mandel[1], Nestoras Mathioudakis[2], Sherita Hill Golden[2] & Mihail Zilbermint[2,3,4]
[1]New York University, New York, NY, USA; [2]Division of Endocrinology, Diabetes, and Metabolism, Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, MA, USA; [3]Johns Hopkins Community Physicians, Suburban Hospital, Bethesda, MA, USA; [4]Johns Hopkins University Carey Business School, Baltimore, MA, USA.

Context
Diabetes mellitus (DM) is common among hospitalized patents. An inpatient diabetes management service (IDMS) has been implemented to provide better glycemic control. The impact on length of stay (LOS) and 30-day readmission rates is unknown.
Objective
We retrospectively analyzed LOS and 30-day readmission rate of patients with known DM admitted to a 240-bed community hospital in suburban Maryland between January 2016 and May 2017.
Methods
International Classification of Diseases 10 codes were used to identify patients with diabetes. LOS and 30-day readmissions were analyzed using Quality Advisor (SM) software. Data were compared by two-sample t-test and simple linear regression analysis.
Results
4654 patients with DM (71.32±13.95 years, 48.3% female) were admitted to a community hospital during the data collection period. IDMS team was consulted on 22.3% of the patients, while the remainder of patients with DM were cared for by other medical and surgical teams. Average LOS and 30-day-readmission rate in all patients decreased by 0.87 days and 10.52%, respectively, from January 2016 to May 2017. Average LOS of patients cared by IDMS team was higher, than control group (6.49 vs 4.72 days, $P=0.000000035$). There was no difference in 30-day readmission rates between the groups. Similarly, there was no difference in LOS trends between the two groups ($P=0.88$).
Conclusions
Since the implementation of IDMS team, LOS and 30-day readmission rate significantly decreased in all patients with diabetes at the community hospital. We speculate that patients with diabetes cared for by the IDMS team may have overall longer LOS, likely due to higher complexity and severity of illness. Limitation of this study includes confounding variables (e.g. mortality index), and a short time frame during which this study was conducted. Further studies are needed, including a formal cost effectiveness analysis, to better assess the economic impact of the IDMS team model in community hospitals.

Evolution of the degree of glycemic control in a cohort of patients with type 2 diabetes mellitus. study to 26 weeks

Sandra Herranz-Antolín, Visitación Álvarez-de Frutos & Miguel Torralba
University Hospital of Guadalajara, Guadalajara, Spain.

Objective
To evaluate the evolution of glycemic control in a cohort of patients with type 2 diabetes mellitus (T2DM) after its assessment in endocrinology.
Methods
Prospective cohort study. 465 patients with T2DM who were not followed up at an endocrinology clinic were included. This study was approved by the Ethics and Clinical Research Committee of the University Hospital of Guadalajara.
Results
Mean age was 63.4±12.5 years; 61.5% males. Time of evolution of T2DM was <5 years in 30.1% of cases and ≥5 years in 69.9%. At the beginning of the study, 7.5% of patients did not receive hypoglycaemic treatment, 60.9% received oral antidiabetics (OA) (including glucagon-like peptide-1 receptor agonists), and 31.6% received insulin therapy (with or without OA). Initial body mass index was 33.2±7.4 kg/m^2 and at 26 weeks follow up was 32.4±6.8 kg/m^2 ($P<0.0001$). Initially, 1.3% of the patients presented some episode of severe hypoglycaemia in the year prior to their inclusion in the study, while after 26 weeks of follow-up, 1.4% of the patients presented some episode ($P=0.7$).
Evolution of glycated hemoglobin (HbA1c) according to the characteristics of the patients. Initial HbA1c; HbA1c at 26 weeks of follow up; Difference of means; 95%CI; p.
– Entire cohort: 8.3±1.8; 6.6±0.9; 1.7; 1.4–1.9; <0.0001
– Male: 8.4±1.7; 6.6±1; 1.8; 1.6–2.1; <0.0001
– Female: 7.9±1.9; 6.6±1; 1.3; 1–1.8; <0.0001
– <65 years: 8.6±1.9; 6.5±1.1; 2.1; 1.7–2.4; <0.0001
– ≥ 65 years: 7.9±1.6; 6.7±0.9; 1.2; 1–1.5; <0.0001
– <5 years of evolution of T2DM: 8.2±2.1; 6.2±0.8; 2; 1.5–2.5; <0.0001
– ≥5 years of evolution of T2DM: 8.3±1.7; 6.8±1; 1.5; 1.3–1.8; <0.0001
– Initial HbA1c ≥7%: 9.1±1.6; 6.8±1; 2.3; 2.1–2.6; <0.0001
– Initial HbA1c <7%: 6.4±0.4; 6.2±0.8; 0.2; −0.002–0.3; 0.098
– Initial treatment with OA; 8.1±1.8; 6.5±0.9; 1.6; 1.3–1.9; <0.0001
– Initial treatment with insulin: 8.7±1.8; 6.9±1.1; 1.7; 1.3–2.1; <0.0001
Conclusions
– There is an improvement in glycemic control without weight gain or increase of severe hypoglycaemia episodes.
– The improvement is independent of the characteristics of the patients, although it is not achieved in patients with initial HbA1c <7%.

Study of the association of transcription factor 7 like 2 gene polymorphism with type 2 diabetes mellitus and diabetic nephropathy in the Egyptian population

Alshaimaa Rezk Alnaggar[1], Randa Fayez Abd El-salam[1], Normeen Hany Rady[2], Marianne Fathy Ishak[2] & Soha Hamed Ammar[2]
[1]Internal Medicine department, Cairo University, Cairo, Egypt; [2]Clinical Pathology, Cairo University, Cairo, Egypt.

Background
Studies from different parts of the world have given controversial results regarding the association of transcription factor 7like 2 (*TCF7L2*) gene polymorphism with Type 2 diabetes mellitus (T2DM) and diabetic nephropathy (DN). Aim: This study aimed to investigate if *TCF7L2* gene polymorphism, rs12255372(G>T) is a risk factor for the development of T2DM and DN in type 2 Egyptian diabetic patients. PATIENTS AND METHODS: This study was conducted on 150 subjects, divided into three groups (50 type-2 diabetic patients without nephropathy, 50 type-2 diabetic patients with nephropathy (DN) and 50 age and sex matched normal subjects). Genotyping for the rs 12255372(G>T) polymorphism in *TCF7L2* gene was performed by real time PCR. RESULTS: There was statistically significant association between *TCF7L2* gene polymorphism rs 12255372 and type 2 diabetic patients & DN, P=0.005, the allelic frequency differed significantly between the three studied groups P=0.005, denoting that the G allele was the risky allele for developing T2DM & DN. CONCLUSION: The present study indicates a strong association between *TCF7L2* variants and the risk of developing T2DM & DN and suggests a role of ethnicity and genetic background for susceptibility to diabetes and its complications.
Keywords: Type-2 diabetes mellitus – diabetic nephropathy – TCF7L2 Gene – single nucleotide polymorphism – real time PCR.

Relationship between serum zinc, glycemic status and HOMA2 parameters in a regional Australian hospital population

Sarah Lim[1], Abul Hasnat Milton[2], Vasudha Iyengar[1,3,4,5] & Md Rafiqul Islam[1,3,4,5]
[1]Goulburn Valley Health, Shepparton, Australia; [2]Hunter Medical Research Institute, The University of Newcastle, New Lambton, Australia; [3]Department of Rural Health, The University of Melbourne, Shepparton, Australia; [4]School of Health and Social Development, Deakin University, Burwood, Australia; [5]Rumbalara Aboriginal Cooperative Liited, Shepparton, Australia.

Aim
Previous studies demonstrated lower serum zinc among prediabetics and diabetics, compared to normoglycaemics. There is no current epidemiological data available in regional Australia examining the association between serum zinc and glycaemic status. This study was conducted to determine the relationship between serum zinc, glycaemic status and Homeostasis Model Assessment (HOMA-2) parameters in a regional Australian hospital population.
Methods
A retrospective review was conducted among all adult patients who presented to a regional Australian hospital between June 2004 and April 2017. Patients were included if they had either fasting blood glucose (FBG) and serum zinc; or FBG,

serum zinc and fasting insulin done. Serum zinc, FBG, fasting insulin, lipid profile, vitamin D and other demographic information were collected. Beta-cell function, insulin resistance and insulin sensitivity were calculated using the HOMA-2 calculator. All data were analysed using Stata 11.
Results
A total of 313 patients' record was retrieved. According to American Diabetic Association classification, 74.8% (234) were normoglycaemics, 18.8% (59) prediabetics and 6.4% (20) diabetics. Data for 84 patients were available tosarah calculate HOMA-2 parameters. Mean serum zinc was found to be lower in prediabetics than normoglycaemics (14.68 ± 3.05 vs 14.96 ± 4.01 uMol/l). In simple linear regression among all participants, higher serum zinc was associated with an increased insulin sensitivity (coefficient 2.67, 95% CI: -1.3 and 6.7), decreased insulin resistance (coefficient -0.03, 95% CI: -0.12 and 0.57) and decreased beta-cell function (coefficient -3.2, 95% CI: -6.2 and -0.2).
Conclusion
Consistent with the current literature, we observed lower serum zinc in prediabetics than normoglycaemics. Higher zinc levels are associated with greater insulin sensitivity and lower insulin resistance. Low serum zinc may have a role in the pathogenesis of insulin resistance. Further evaluations are warranted regarding zinc supplementation in prediabetics to prevent or delay the progression to Type 2 Diabetes.

The role of polysomnography for detection of OSA in patients with type 2 diabetes in the Uzbek population

Sitorakhon Muminova[1], Lola Daminova[2] & Dina Esimova[3]
[1]Tashkent Medical Pediatric Institute, Tashkent, Uzbekistan; [2]Tashkent State Dental Institute, Tashkent, Uzbekistan; [3]Republican Specialized Scientific and Practical Medical Center of Endocrinology, Tashkent, Uzbekistan.

Actuality
According to the International Classification of Sleep Disorders in type 2 diabetes, the risk of obstructive sleep apnea (OSA) in middle-aged people ranges from 18% to 36%. In a report by S. D. West et al. the incidence of sleep apnea in patients with diabetes is estimated at 23% compared with 6% in the general population. In a recent study, AS Peltier et al. it was found that 79.2% of patients with OSA had a violation of glucose tolerance and 25% were first diagnosed with diabetes mellitus. There is a high prevalence of type 2 diabetes and related metabolic disorders among patients with obstructive sleep apnea syndrome (OSAS). Sleep apnea has a negative effect on the function of the beta cells of the pancreas and insulin sensitivity.
Purpose
Detection of OSA by results of the Stop-bang questionnaire in patients with type 2 diabetes using polysomnography.
Material and methods
We interviewed 150 women on the Stop Bang questionnaire, 40 women had a high risk of developing OSA, patients underwent polysomnography for confirmation of OSA: average of age 52.7; IAG 56.4; BMI-32.4; Hb1C-7.9%; Desaturation-80.The same is divided by the severity of the course of OSA: low $5 \leq$ IAG, average < 15, $15 \leq$ IAG, high < 30 IAG ≥ 30.
Results
According to the results, low degree of OSA-11 (27%) in women, an average severity of OSA-12 (30%), a severe degree of 17 (42.5%) in patients with type 2 diabetes, OSA revealed obesity of grade 3 and a high level of Hb1C (8.1%). The results of the study show that OSA is independently linked to insulin resistance of glucose, thus can lead to increased blood sugar levels. The Stop Bang questionnaire is one of the promising methods for detecting OSA and direction patients for polysomnography. Patients were recommended to comply with HLS, the use of intraoral devices and CPAP therapy.

Transcription Factor 7 Like2 Gene Polymorphisms and Susceptibility to Type 2 Diabetes Mellitus in a cohort of Egyptian diabetic patients, a pilot study

Iman Mandour, Rania Darwish, Randa Salam, Merva Naguib & Sarah El-Sayegh
Cairo University, Cairo, Egypt.

Purpose
Transcription factor 7-like 2 (*TCF7L2*) variants are known risk factors of type 2 diabetes (T2DM).However; this association is not consistent among different populations. The current study aimed at investigating the relationship between rs 7903146, rs 12255372 variants of *TCF7L2* and susceptibility to T2DM.
Patients and methods
This case control study included 60 diabetic patients and 60 matched unrelated healthy controls. Genotyping was performed by using Real Time-PCR. The frequency of genotypes and alleles, anthropometric measures, glycemic indices, HOMA-IR and lipid profile were evaluated in patients and control.
Results
Regarding rs 7903146, TT genotype was more frequent in healthy controls (43.3%) than diabetic patients (20%) (OR = 0.291, 95% CI = 0.108–0.788, $P = 0.015$). T allele was more frequent in healthy control (61.7%) than diabetic patients (44.2%) and it was associated with lower risk of diabetes (OR = 0.492, 95% CI = 0.294–0.823, $P = 0.007$). In contrast, T allele of rs12255372 had no significant relation to diabetes risk (OR = 0.602, 95% CI = 0.361–1.005, $P = 0.052$). There was no statistically significant difference of frequency of any rs12255372 genotypes between cases and controls.
Conclusion
The study confirmed the association of *TCF7L2* (rs 7903146) and T2DM, while failed to detect any association between *TCF7L2* (rs 12255372) and susceptibility to T2DM.

Undiagnosed diabetes and related risk factors in postmenopausal women: the 2011–2012 Korean National Health and Nutrition Examination Survey

Sang-Yong Kim & Jin-Hwa Kim
Division of Endocrinology, Chosun University, Gwangju, Republic of Korea.

Aims
Postmenopause is associated with unfavorable metabolic disturbances and might be related to increase the risk of diabetes. Identification of undiagnosed diabetes and at-risk individuals may allow to initiate earlier management and to prevent diabetic complication. The objective of the present study was to determine the prevalence of undiagnosed diabetes and related risk factors in postmenopausal women.
Methods
This study was based on data from the Korean National Health and Nutrition Examination Survey (KNHANES), conducted during 2011-2012 by the Korean Ministry of Health and Welfare. This survey is a cross-sectional and nationally representative study of noninstitutionalized civilians using a stratified, multistage, clustered probability sampling design. From the 16,576 participants, data for 2,210 postmenopausal women were included in the analysis.
Results
The prevalence of undiagnosed diabetes in Korean postmenopausal women was 6.8%. They were older, more obese, under educated and the prevalence of hypertension and dyslipidemia was higher than the women without diabetes. The menarche age was later, but the age at menopause, breast feeding, oral contraceptive did not show significant difference. The multivariate logistic regression analysis showed that waist circumference over 80 cm (odds ratio [OR] 2.623 [95% CI 1.517-4.534]), hypertension(1.847 [1.120-3.045]), dyslipidemia(2.109 [1.314-3.383]) significantly increased the risk of undiagnosed diabetes. Moreover, women who had a two, or three components of metabolic syndrome were significantly associated with the risk of undiagnosed diabetes.
Conclusion
The prevalence of undiagnosed diabetes in Korean postmenopausal women was 6.8%. The components of metabolic syndrome were significantly associated with the risk of undiagnosed diabetes. Therefore individualized approach to postmenopausal women with components of metabolic syndrome is needed to early diagnose and manage diabetes.

Comparison of quality of life and symptoms of depression in diabetes combined with gastroparesis and without it

Marina Orlova, Arina Frolova & Tatiana Rodionova
Saratov State Medical University Named V.I. Razumovsky, Saratov, Russian Federation.

Objective
To assess the quality of life, the presence and severity of depressive symptoms in patients with diabetes combined with gastroparesis and without it
Methods
Forty three patients with diabetes were included in the study. The presence and severity of gastrointestinal symptoms, as well as the intensity and frequency of symptoms over the last 2 weeks, were measured with the Patient Assessment of the upper gastrointestinal symptom severity index (PAGI-SYM), the Patient Assessment of the upper gastrointestinal disorders-quality of life (PAGI-QOL). To assess the emotional sphere and cognitive functions, questionnaires were used: 36-item Short Form Health Survey and Beck Depression Inventory.
Results
In our study, a significant prevalence of GI symptoms among patients with diabetes was found: 24 patients had gastrointestinal symptoms (55.8%), 19 patients had no such symptoms (44%). In our study, we compared the prevalence of depression in a group of patients with GI symptoms and without them: in both groups there was a mild degree of depression (10–15 points in the assessment of the Beck Depression Inventory), in 8 patients with GI symptoms (33%) there was a moderate degree of depression (16–19 points), the severity of gastrointestinal disorders in patients with diabetes did not correlate with the severity of depression in these patients. In the analysis of the SF-36 QoL questionnaire, the median QoL in patients with diabetes without GI symptoms ranged from 50 (general health) to 100 (role-related emotional functioning). In the group of patients with GI symptoms, the median of quality of life scores on 8 scales ranged from 45 (general health) to 70 (physical functioning, social functioning). When comparing groups of patients, significant differences in glycemic control were not revealed, and according to the results of testing, lower values of the quality of life in the group with GI symptoms were noted. Both groups reported deterioration in the quality of life, but the severity of the symptoms of depression was greater in the group with GI symptoms.
Conclusions
Patients with diabetes and symptoms of gastroparesis suffer from deterioration in the quality of life and the severity of depressive symptoms.

Predictors of anxiety development at diabetes mellitus type 1

Yana Navmenova[1], Irina Savasteeva[1], Elena Makhlina[1] & Tatiana Mokhort[2]
[1]The Republican Research Center for Radiation Medicine and Human Ecology, Gomel, Belarus; [2]Belarusian State Medical University, Minsk, Belarus.

Objective
To assess possible predictors of anxiety disorder development at Diabetes Mellitus type 1.
Materials and methods
There were examined 164 patients (93 males and 71 females) with diabetes mellitus type 1 (DM) at the age from 18 to 60 years old. The level of anxiety was assessed with the use of the Hospital Anxiety and Depression Scale (HADS), blood glucose level was determined in the fasted state and 2 hours after the meal. Also there was monitored average daily glucose in blood during 3 days at fourfold detection of glycemia; there were detected glycated hemoglobin level (HbA_{1C}), total cholesterol (TC), triglycerides (TG), very low-density lipoprotein cholesterol (VLDL cholesterol), low-density lipoprotein cholesterol (LDL cholesterol), high-density lipoprotein cholesterol (HDL cholesterol), blood homocysteine level.
Results
1. There were determined anxiety disorders within 30,48% patients with DM type 1.
2. The growth of average glycemia significantly increased the risk of development of anxiety disorders (b = 0,16) (Exp (b) = 1,18; 95% CI – 1,03 ÷ 1,34; $P < 0,02$).
3. The risk of anxiety disorder development is not associated with levels of total cholesterol (b = 0.20) (Exp (b) = 1.23; 95% CI – 0.93 ÷ 1.60; $P = 0.09$), level of total VLDL cholesterol (b = 0.55) (Exp (b) = 1.73; 95% CI – 0.87 ÷ 3.46; $P < 0.10$), level of AC (b = 0.20) (Exp (b) = 1.22; 95% CI – 0.92 ÷ 1.62; $P < 0.10$) and level of homocysteine (b = 0.64) (Exp (b) = 1.07; 95% CI – 0.99 ÷ 1.15; $P = 0.08$).

Comparative analysis of the prevalence of type 2 diabetes according to the screening and register data in Uzbekistan

Nilufar Ibragimova[1], Raisa Tregulova[2], Nargiza Normatova[3] & Sherzod Djalalov[1]
[1]'UMID' Charity Association of Persons with Disabilities and People with Diabetes Mellitus, Tashkent, Uzbekistan; [2]Republican Specialized Center of Cardiology, Tashkent, Uzbekistan; [3]Tashkent Institute for Advanced Training of Doctors, Department of Ophthalmology, Tashkent, Uzbekistan.

Purpose of the study
To carry out the comparative analysis of the prevalence of Type 2 Diabetes (T2DM) according to the screening and register data in Uzbekistan.
Material and methods
Within the framework of WDF international project 'Prevention of diabetes in rural population of Uzbekistan', with the support of the Ministry of Health of the Republic of Uzbekistan, the screening campaign was conducted in 6 rural regions to actively identify diabetes and IGT among 6189 people at high risk. A questionnaire chart (developed on the basis of FINDRISS map, taking into account the mentality of the Uzbek people) included the following risk factors: age; Excess weight or obesity; Arterial Hypertension; Myocardial infarction; Stroke; Birth of a child weighing >4 kg. The average age is 59.39 ± 10.22 years, 62% of women and 38% of men. 6189 people passed the GTT and HbA1c tests. Statistical data processing was made using the program Statistica 10, Excel (2007).
Results of the study
Following the results of fasting glycemia (venous blood) and OGTT, T2DM was detected in 823 people (13.3%), including 548 women, 275 men (ratio 2:1). Newly diagnosed peoples with diabetes have already HbA1c level such as: HbA1c >6.5–23.4%; between 8–9% and >9%–12.7%, that indicating long-term hyperglycemia and an advanced stage of the disease which can lead to the further development of diabetes complications. The IGT was found in 26.7%, IFG in 1040 people accordingly. The frequency of T2DM in the peoples at high risk was 16,3% which is significantly higher than the officially registered prevalence of diabetes in Uzbekistan (5–6%). It demonstrates once again low level of diabetes diagnosis and duly treatment at the primary healthcare link. The prevailing risk factors for diabetes development among the rural population were: Arterial Hypertension-78.6%; Obesity (BMI >30) – 43.3%, Gestational diabetes –42%, hereditary predisposition –35.2%.
Conclusion
The screening undertaken in 6 regions identified a high level of the high prevalence of T2DM in the high-risk group (13.3%) compared with the national register of 5–6%. These figures reveal the importance of screening to actively detect the people with diabetes, IGT and IFG in order to provide the appropriate treatment and prevent the development of serious complications. The prevailing risk factors for diabetes development among the rural population aged over 40 years in Uzbekistan were: arterial hypertension – 78.6%; obesity (BMI >30) – 43.3%, gestational diabetes – 42%, hereditary predisposition – 35.2%.

Nutrition of non-fasting patients with diabetes during the month of Ramadan

Najoua Lassoued, Neila Abid, Faten HadjKacem, Nadia Charfi & Mohamed Abid
Endocrinology Department, Hedi Chaker University Hospital, Sfax, Tunisia.

Introduction
Fasting during the month of Ramadan is the most observed religious practice by Muslims. Diabetes is one of the condition that exempt Muslims from fasting because of the risk of complications. The International Diabetes Federation states that high-risk patients 'should not fast'. The objective of this study was therefore to evaluate the daily food intake during the month of Ramadan in non-fasting patients with diabetes in order to detect diet mistakes made during this month.
Patients and methods
Descriptive study conducted in 66 patients with diabetes.
Results
The average age was 51,33 years with a sex ratio of 0,5. Twenty-two patients had type 1 diabetes and 44 patients had insulin-requiring type 2 diabetes. During the month of Ramadan the average daily intake in Kcal increased by 6,7% ($P = NS$). There was a significant increase in protein intake at the expense of animal protein

($P=0.019$); a significant increase in lipid intake with increased cholesterol intake ($P=0.002$) and a decrease in carbohydrate intake despite a significant increase in sucrose consumption ($P=0.008$). The diet was low in fiber, iron, magnesium and folic acid with a significant increase in calcium intake ($P=0.005$). In addition, there was a poor distribution of meals, with a decrease in breakfast and lunch, in favor of dinner, which corresponded to '*el iftar*' (*P* respectively 0.027, 0.001 and 0.024).

Conclusion

The results of our study reflect the nutritional errors made by our patients during Ramadan. These data testify to the complexity of diabetes management which is difficult even in normal times. A preparation before Ramadan and a continuous educational approach are recommended, with an educational support adapted to the local context during the holy month.

Evaluation of procalcitonin levels in diabetic and diabetic nephropathic patients

Murat Dağdeviren[1], Esin Beyan[2], Tanyel Sema Dağdeviren[3], Esra Çopuroğlu[2], Yavuz Çağır[2], Özlem Doğan[4], Derun Taner Ertuğrul[1] & Mustafa Altay[1]

[1]Sağlık Bilimleri University, Keçiören Health Administration and Research Center, Endocrinology and Metabolism, Ankara, Turkey; [2]Sağlık Bilimleri University, Keçiören Health Administration and Research Center, Internal Medicine, Ankara, Turkey; [3]Sağlık Bilimleri University, Keçiören Health Administration and Research Center, Family Practice, Ankara, Turkey; [4]Ankara University, Medical Biochemistry, Ankara, Turkey.

Aim

To determine how serum procalcitonin (PCT) levels are affected in diabetic and diabetic nephropathic patients, it is important to determine whether PCT is indicative of an inflammation in these patients.

Materials and methods

The study included 175 patients (75 diabetic nephropathy (group 1), 75 diabetic (group 2) and 25 non-diabetic nephropathy (group 3)) and 75 healthy volunteers. Serum and urine creatinine, serum high sensitive C- reactive protein (HsCRP), procalcitonin, white blood cell, neutrophil, HbA1c and urinary protein values of patient and control groups were obtained. Urinary protein / creatinine ratio and eGFR were calculated.

Results

There was no significant difference between groups 1, 2, 3 and control group of the PCT values (0.20, 0.19, 0.23 and 0.19, respectively) ($P>$ 0,05). HsCRP levels of all 3 patient groups were higher than the control group ($P<0.001$). There was a negative correlation between eGFR values of nephropathy patients (diabetic and non-diabetic) and PCT ($P<0.001$; $r=-0.475$) and HsCRP ($P<0.001$; $r=-0.415$) values. When diabetic nephropathy patients were compared with those below eGFR 60 and those above eGFR 60, When the eGFR values were lower than 60, the HsCRP values were higher ($P<0.05$); There was no difference between the PCT values ($P>0.05$).

Conclusion

There was no significant increase in PCT values of diabetic and diabetic nephropathy patients. However, there was a negative correlation between PCT level and eGFR.

Telmisartan increases gluconeogenesis by inducing PKCζ-Thr^{410} phosphorylation in hyperglycemia-treated HepG2 cells and high-fat diet-fed mouse liver

Du-Hyong Cho[1], Kae Won Cho[2] & Kee-Ho Song[3]

[1]Department of Pharmacology, School of Medicine, Eulji University, Daejeon, Republic of Korea; [2]Soonchunhyang Institute of Medi-bio Science, Soonchunhyang University, Cheonan, Republic of Korea; [3]Division of Endocrinology and Metabolism, Department of Internal Medicine, Konkuk University School of Medicine, Seoul, Republic of Korea.

Telmisartan, an angiotensin II type 1 receptor blocker (ARB), is widely prescribed for the treatment of hypertensive patients with simultaneous diabetes mellitus (DM). Unlike other ARBs, telmisartan is reported to have various ancillary effects as well as common blood pressure-lowering effect. In this regard, telmisartan improves endothelial dysfunction and cardiovascular complications in DM patients and is recently reported to reduce new-onset DM incidence. However, effects and mechanism of telmisartan on gluconeogenesis in hepatocytes and liver remain elusive. Here, we investigated effects and a molecular mechanism of telmisartan on gluconeogenesis in hyperglycemia-treated HepG2 cells and high-fat diet (HFD)-fed mouse liver. Telmisartan dose-dependently increased gluconeogenesis in hyperglycemia-treated HepG2 cells and accompanied an increase of phosphoenolpyruvate carboxykinase (PEPCK) expression without change of glucose-6-phosphatase (G6Pase) expression. Furthermore, telmisartan dose-dependently increased insulin receptor substrate-1 (IRS-1)-Ser^{302} phosphorylation and decreased IRS-1-Tyr^{632} phosphorylation, indicating that telmisartan impairs insulin action in HepG2 cells. Because protein kinase C ζ (PKCζ) is reported to reduce insulin action by inducing IRS-1 serine phosphorylations, we assessed its phosphorylation and found that telmisartan dose-dependently increased PKCζ-Thr^{410} phosphorylation. Ectopic expression of dominant-negative PKCζ constructs significantly attenuated the telmisartan-induced gluconeogenesis and the telmisartan-induced IRS-1-Ser^{302} phosphorylation and -inhibited IRS-1-Tyr^{632} phosphorylation, although it did not alter PEPCK expression, showing that gluconeogenesis, when insulin is acutely treated, is largely regulated by changes of IRS-1 phosphorylations. Among ARBs, including losartan and fimasartan, only telmisartan induced IRS-1-Ser^{302} phosphorylation and decreased IRS-1-Tyr^{632} phosphorylation. Furthermore, effects of telmisartan on IRS-1 phosphorylations were not altered by pretreatment with GW9662, a specific and irreversible peroxisome proliferator-activated receptor γ antagonist. Finally, in the liver from HFD-fed mice, telmisartan increased PEPCK and G6Pase expressions and PKCζ-Thr^{410} phosphorylation, and accompanied an increase and a decrease of IRS-1-Ser^{302} and -Tyr^{632} phosphorylations, respectively. Taken together, our findings suggest that telmisartan increases gluconeogenesis by inducing PKCζ-Thr^{410} phosphorylation that leads to increased phosphorylation of IRS-1-Ser^{302} and decreased phosphorylation of IRS-1-Tyr^{632}, and consequently impairs insulin action in hepatocytes.

Diabetes complications and comorbidities in patients newly diagnosed with diabetes in newfoundland and labrador (NL): gender differences

Richa Parihar[1,2] & Shabnam Asghari[2]

[1]Dalhousie University, Halifax, Canada; [2]Memorial University of Newfoundland, St John's, Canada.

Introduction

Diabetic patients are known to develop complications and co-morbidities as a result of the disease. Determining gender susceptibility to diabetic complications can lead to improved patient-centered care for patients.

Objectives

To examine the gender differences on complications and comorbidities in patients newly diagnosed with diabetes in NL.

Methods

A retrospective cohort study, patients were followed for 5 years from the date of diagnosis, between 1998 to 2003, till their deaths or end of study (2008), whichever came first. The study included individuals who were newly diagnosed with diabetes aged 20 years and older that were identified using provincial medico-administrative data. Gestational diabetes was excluded. Diabetes complications and comorbidities were defined as any record for cardiovascular disease, renal failure, end stage renal disease and lower-extremity amputation during the study period. Late diagnosis was identified as any record for complications at the time of diagnosis. Other variables included healthcare utilization and place of residence. Healthcare utilization was defined as number of visits with family physicians, specialists as well as number of hospitalizations per year. Descriptive analyses as well as multiple logistic regressions were performed.

Results

There were 20,292 patients, mean age 60($\pm$15); 50% were women. Majority of the patients (63%) belonged to urban areas. Approximately, 17% of the men and 13% of the women had a late diagnosis ($P<0.000$). Five year after diagnosis, 27% and 18% of men and women respectively had at least one complication, while 18% of men and 16% of women had died during the study period. Men were more likely to develop diabetic complications than women (OR = 1.63, CI 1.51–1.75) after being accounted for age, late diagnosis, place of residence and healthcare utilization.

Conclusion
Men are prone to late diagnosis and developing more diabetic co-morbidities than women in NL. The differences in the healthcare utilization and the susceptibility to late diagnose in males can account for the differences observed between gender. Therefore, the gender differences in health and healthcare should be taken into account in diabetes management. Further research is required to determine the biological and healthcare factors.

Visfatin concentration and anthropometric/biochemical parameters in healthy individuals-preliminary study

Justyna Nowak[1], Karolina Kulik-Kupka[1], Joanna Kowalska[1], Iwona Zieleń-Zynek[1], Bartosz Hudzik[1,2], Anna Żyła[3], Beata Stanuch[1] & Barbara Zubelewicz-Szkodzińska[1,4]
[1]Department of Nutrition-Related Disease Prevention, School of Public Health in Bytom, Medical University of Silesia, Katowice, Bytom, Poland; [2]3rd Department of Cardiology, School of Medicine with the Division of Dentistry in Zabrze, Medical University of Silesia in Katowice, Silesian Center for Heart Disease, Zabrze, Poland; [3]Department of Laboratory Diagnostics, Mazovian Specialist Hospital in Radom, Radom, Poland; [4]Department of Endocrinology, Piekary Medical Center, St. Luke's Local Hospital in Piekary Śląskie, Piekary Śląskie, Poland.

Visfatin (pre-B cell colonyenhancing factor) is a adipocytokine playing an important role in glucose homeostasis. High concentrations of visfatin are observed in obese people. Previous studies suggest that estimation of visfatin concentration could be a promising tool for predicting obesity or its metabolic consequences. The aim of the study was to evaluate the correlation between visfatin concentration, selected anthropometric parameters (BMI, WHR, BAI, VAI index) and biochemical parameters (glucose metabolism parameters). 39 patients without carbohydrate metabolism disorders, diagnosed at endocrinology department because of other reasons were included to the study. The exclusion criteria were any glucose metabolism disorders (diabetes mellitus, insulin resistance, glucose intolerance, fasting glucose impairment) or medications influence glucose concentration and metabolism (glucocorticosteroids, hypoglycaemic drugs, etc.). The data were statistically analyzed by STATISTICA. $\alpha=0.05$. The median age was 33 years (26–38 years). 69% patients with normal weight (n = 27), 21% patients overweight ($n=8$) and 10% obese ($n=4$). The median BMI was 23.7 kg/m^2 (21.1–26.5 kg/m^2); WHR 0.8 (0.75-0.85); BAI 29% (25-32%); VAI 0.87 (0.61–1.29). The median serum visfatin was 0.7 ng/ml (0.4–5.6 ng/ml); fasting insulin 6.7 μU/ml (5.5–9.1 μU/ml); fasting glucose 88 mg/dl (84–93 mg/dl). There were no correlation observed among differences in visfatin concentration (0.7 vs 0.8 vs 0.9, $P=0.8$) was found between patients of examined groups (respectively patients with normal weight, overweight and obesity) as well as no correlation between visfatin concentration in relation to fasting glucose ($R=-0.1$, $P=0.5564$); fasting insulin ($R=-0.09$, $P=0.5662$) was observed. Moreover, not significant correlation of BMI and visfatin levels ($R=0.06$, $P=0.7192$), WHR index and visfatin levels ($R=0.11$, $P=0.5071$), BAI index and visfatin levels ($R=0.01$, $P=0.9571$) as well as VAI index and visfatin ($R=-0.09$; $P=0.5913$) were observed. Visfatin concentration in healthy individual does not correlate with anthropometric parameters and glucose parameters.

Serum soluble vascular adhesion molecules and highly sensitive C: reactive protein in elderly type 2 diabetic patients with mild cognitive impairment

Salwa Hosny[1], Meram Bekhet[1], Mohamed Khater[2], Ahmed bahaaeldin[1] & Ghada Hasanin[1]
[1]Department of Internal Medicine, and Endocrinology, Faculty of Medicine – Ain Shams University, Cairo, Egypt; [2]Department of Geriatric, Faculty of Medicine – Ain Shams University, Cairo, Egypt.

Background
T2DM is a metabolic disorder characterized by high blood glucose in the context of insulin resistance and relative insulin deficiency with disturbances of carbohydrate, fat, and protein metabolism.T2DM is a risk factor for Alzheimer's disease and mild cognitive impairment. The etiology of cognitive impairment in people with T2DM is uncertain, but it is most likely multi factorial. Chronic hyperglycemia, cerebral micro vascular disease, severe hypoglycemia, and increased prevalence of macro vascular disease are implicated.
Aim of the work
To determine the serum levels of soluble vascular adhesion molecule (sVCAM-1) and highly sensitive C-reactive protein (hs-CRP) in elderly type 2 diabetics with mild cognitive impairment (MCI).
Patient and methods
Our study was conducted on 90 elderly subjects (aged 60 years old or more). They were divided into Group I, 30 patients with T2DM and mild cognitive impairment, group II, 30 patients with T2DM without cognitive impairment and group III, 30 healthy subjects as a control group. All participants were subjected to history taking, full clinical examination, anthropometric measurement, the Addenbrooke's Cognitive Examination III (ACE–III 2012) and laboratory investigations including Fasting plasma glucose, 2 hours plasma glucose, HbA1c, serum cholesterol, triglycerides, LDL-c, HDL-c, protein/creatinine ratio, serum sVCAM-1 and hs-CRP.
Results
Serum levels of sVCAM-1 in diabetic elderly patients with MCI were significantly higher (946.7 ± 162.01 ng/ml) than diabetic elderly patients without cognitive impairment (479.06 ± 65.27 ng/ml) and control (263.7 ± 72.05 ng/ml) with ($F=0.652$ and $P=0.002$). Serum levels of Hs-CRP in diabetic elderly patients with MCI were significantly higher (7.9 ± 1.09 ng/ml) as compared to diabetic elderly patients without cognitive impairment (4.3 ± 0.96 ng/ml) and control (2 ± 0.74 ng/ml) with ($F=1.033$ and $P=0.005$).
Conclusion
Elderly diabetic patients with mild cognitive impairment, have higher levels of soluble adhesion molecules and markers of low-grade systemic inflammation than other groups. Inflammatory mediators play a role in the development of mild cognitive impairment in diabetic elderly patients.

Evaluating quality of diabetic care in patients with severe mental illness (SMI) in an academic primary care clinic

Rujuta Katkar, Gregory Gudleski & Smita Bakhai
University at Buffalo, Buffalo, USA.

Background
Higher prevalence of type 2 Diabetes Mellitus (DM II) has been reported in patients with SMI (serious mental illness). SMI patients get suboptimal diabetes care as compare to non- SMI patients.
Methods
We tested the hypothesis that SMI patients get suboptimal diabetes care as compare to non- SMI patients. We did a retrospective cohort study in an academic, primary care clinic for underserved,urban population.SMI patients included schizophrenia and bipolar disorder diagnosed by psychiatrist. We created electronic database of variables of interest for eligible patient population. Inclusion criteria included patients ages 18–75, and have been seen by a primary care provider for at least 1 year with at least 2 visits and at least 2 HbA1c levels between the study period. 184 SMI patients met the inclusion criteria; and were compared to 184 patients of non-SMI patients. Patients being treated by an endocrinologist for DMII were excluded from the study. Outcomes measures including HbA1c, blood pressure, LDL, eye and foot exam, nephropathy assessment and smoking status; and process measures such as alcohol and substance abuse, medications, pneumonia vaccine and health care utilization measures were measured and compared between two groups.
Results
Data analysis was done using logistic regression. After controlling for possible confounders such as gender, Race, BMI and Insulin use, there was no significant difference in HbA1C control of <7 between SMI and non-SMI groups ($P=0.115$). Patients who were on insulin therapy were less likely to achieve HbA1c <7 without any significant difference between SMI and non-SMI groups (12.5% vs 11.8%). However SMI patients who were not on insulin were more likely than non-SMI patients to achieve HbA1C <7 (75.3% vs 63.2%, OR = 3.26, 95% CI: 2.05–5.19, $P<0.001$). No significant between group difference was observed in remaining parameters of nephropathy assessment, blood pressure, foot exam, smoking cessation treatment offered except for eye exam (OR = 1.90, 95% CI: 1.08–3.34; $P=0.027$). There was no significant difference

in above parameters after adjusting for Antipsychotics use. There was no significant difference between the groups for number of clinic visits or continuity of primary care provided.
Conclusion
Diabetes care of SMI patients is not suboptimal to non- SMI patients in primary care clinic. Further study is needed to evaluate whether living in a supervised group home facility of SMI patients contributes improved care of SMI patients observed in our clinic.

Prorenin and secreted frizzled-related protein-4 levels in women with gestational diabetes mellitus

Suleyman Ipekci[1], Suleyman Baldane[1], Ayse Gul Kebapcilar[2], Sedat Abusoglu[3], Hasan Beyhekim[2], Tolgay Tuyan Ilhan[2], Ali Unlu[3] & Levent Kebapcilar[1]
[1]Selcuk University, Faculty of Medicine, Division of Endocrinology and Metabolism, Konya, Turkey; [2]Selcuk University, Faculty of Medicine, Department of Gynecology and Obstetrics, Konya, Turkey; [3]Selcuk University, Faculty of Medicine, Department of Biochemistry, Konya, Turkey.

Background
This study was designed to investigate prorenin and secreted frizzled-related protein-4 (SFRP-4) levels in pregnancies with or without gestational diabetes mellitus (GDM).
Materials and methods
A total of 76 pregnant women were included in the study. Thirty-five of the pregnant women were included in the GDM group according to the results of oral glucose tolerance tests (OGTT) and 41 pregnant women were included in the control group.
Results
In the group with GDM, SFRP-4 value was found to be significantly higher than that of the control group (5.59 ± 3.32 ng/ml vs 4.05 ± 2.15 ng/ml; $P = 0.017$). Women with GDM had significantly higher serum prorenin levels compared with control group (737 (427–1339) pg/ml vs. 535 (376–725) pg/ml, $P = 0.009$). There was a significant positive association between prorenin and SFRP-4 levels in the GDM ($r = 0.91$, $P < 0.001$) and control group ($r = 0.42$, $P = 0.002$) and whole pregnancies ($r = 0.75$, $P = 0.002$).
Conclusions
We have shown that prorenin and SFRP4 were significantly elevated in GDM patients when compared to healthy control group. Furthermore, we found that there was a positive correlation between prorenin and SFRP-4.

Novel inflammatory pathways in monocytes of type 2 diabetes patients are modulated by vitamin D

Nojan Nejatian, Marissa Penna-Martinez & Klaus Badenhoop
Department of endocrinology and diabetology Medical clinic 1, Frankfurt am Main, Germany.

Type 2 diabetes (T2D) patients have a high cardiovascular risk due to vascular inflammation and dyslipidaemia. Furthermore vitamin D (VD) deficiency is highly prevalent. Our aim was to elucidate the role of fatty acid receptors in inflammatory pathways and their regulation by VD. We therefore examined the VD effect on gene expression of Arachidonate 5-lipoxygenase (ALOX-5) and Sphingosine-1-phospate receptors (S1PR1 and S1PR2) in primary isolated monocytes of T2D patients and healthy controls (HC). $CD14^+$ monocytes (Mo) were isolated from 20 healthy controls (HC) and 20 T2D patients and were treated for 24 h with / without 10^{-8} M calcitriol. Interleukin-1β as an inflammatory stimulant served as IL-$1\beta_{control\text{-}cells}$. CD14, ALOX-5, $S1PR_1$ and $S1PR_2$ mRNA expression levels were measured by TaqMan™ analyses. 18s rRNA served as a house keeping gene. Gene expressions were defined as $2^{-[Ct\ (target)-Ct\ (18srRNA)]}$. Calcitriol treatment significantly increased the CD14 gene expression in both HC ($CD14_{calcitriol}$: 5059 vs. 2104; $P = 0.05$) and T2D ($CD14_{calcitriol}$: 12176 vs. 6712; $P = 0.001$) compared to the IL-$1\beta_{control\text{-}cells}$. The CD14 gene expression was noticeable increased in T2D patients compared to HC ($P = 0.002$). Moreover ALOX-5 mRNA-levels were also increased by calcitriol compared to the IL-$1\beta_{control\text{-}cells}$ in HC ($ALOX\text{-}5_{calcitriol}$: 1686 vs. 1004; $P = 0.02$) and in T2D ($ALOX\text{-}5_{calcitriol}$: 2744 vs. 1372; $P = 9.1 \times 10^{-5}$). By comparing HC vs. T2D, it stands out that ALOX-5 mRNA-levels were higher in T2D patients compared to HC ($P = 0.01$). Furthermore, the mRNA levels of $S1PR_2$ were significantly reduced in both HC ($S1PR_{2calcitriol}$: 5.75 vs. 25; $P = 10^{-6}$) and T2D ($S1PR_{2calcitriol}$: 5.96 vs. 36; $P = 0.001$) compared to the IL-$1\beta_{control\text{-}cells}$. Interestingly, T2D patients mRNA levels of $S1PR_2$ of IL-$1\beta_{control\text{-}cells}$ compared to HC were significantly higher ($P = 0.03$). Calcitriol treatment did not change the mRNA levels of $S1PR_2$ by comparing HC vs. T2D. No significant changes of the $S1PR_1$ mRNA expression were observed in calcitriol treated Mo from HC and T2D patients. *In vitro* calcitriol increased the CD14 and ALOX-5 gene expression in HC and T2D-patients.However, the increase of CD14 and ALOX-5 gene expression in T2D appears to be disease specific. Further calcitriol had no impact on $S1PR_1$ -but on $S1PR_2$ mRNA expression. Although calcitriol reduced the gene expression of $S1PR_2$ both in T2D-patients and HC this was not discriminatory. These results provide novel insights into potential anti-inflammatory mechanisms of VD in type 2 diabetes.

Serum adiponectin in male type 2 diabetic patients exposed to ionizing radiation in early years

Natalia Dombrovska, Oleksii Kaminskyi, Dmitryi Afanasyev, Oksana Pleskach & Dmitryi Bazyka
State Institution 'National Research Center for Radiation Medicine of the National Academy of Medical Sciences of Ukraine', Kyiv, Ukraine.

Prevalence of diabetes mellitus in the world is constantly increasing and today the type 2 diabetes pandemic is the point of issue. The type 2 diabetes incidence in exposed individuals i.e. the participants of the Chernobyl Nuclear Power Plant accident consequences clean-up works (ChNPP ACUW) in Ukraine in the post-accident years was about 15-21%, which was significantly higher ($p < 0.0001$) than in the non-irradiated persons (3-9%). The adipose tissue is actively involved in regulation of the energy metabolism being the endocrine and paracrine organ producing a wide spectrum of adipocytokines. Adiponectin is the main adipotocytokine with cardioprotective effect but its role in the development of type 2 diabetes has not been studied in subjects exposed to ionizing radiation. The 66 male diabetic patients who were exposed to ionizing radiation after the Chernobyl catastrophe, 45 irradiated subjects having no diabetes, and a control group of 20 healthy persons were examined. Concentrations of the total adiponectin were significantly lower ($p < 0.05$) in blood serum of irradiated persons, namely in the ChNPP ACUW of the iodine period (first months upon the accident in 1986) who had the established diagnosis of type 2 diabetes being of a normal body weight, overweight or obese compared to the concentrations in the almost healthy subjects and the clean-up workers with normal glycemic control. Concentration of the total adiponectin decreased with increasing body weight, and there was a correlation of average strength between the concentration and obesity ($t = -0.367$, $p < 0.05$). With deterioration of glycemic control the concentration of total adiponectin decreased. With increase in disease duration from 5 to 20 years there is a slow decrease in total adiponectin concentration in blood serum in the ChNPP ACUW and in the control group. However, in disease duration over the 20 years there is an increase in the total adiponectin level. There were no significant differences in total adiponectin concentration with increasing the external exposure doses in the range of 10.0-860.0 mSv.
Conclusion
In men exposed at a young age due to the Chernobyl Nuclear Power Plant accident, which were the clean-up workers suffering diabetes mellitus a marked decrease in adiponectin concentration was observed in comparison with the same workers having no diabetes and with non-irradiated subjects. The adiponectin level depended on disorders of carbohydrate metabolism, body weight increase, and prolonged course of diabetes mellitus.

Decreased spexin levels in patients with type 1 diabetes

Anara Karaca[1], Filiz Bakar[2] & Nese Ersoz Gulcelik[3]
[1]Department of Endocrinology, Ankara Trainig Hospital, ankara, Turkey; [2]Department of Biochemistry, School of Pharmacy, Ankara University, Ankara, Turkey; [3]Department of Endocrinology, Ankara Gulhane Medical Schhol, Ankara, Turkey.

Spexin is a novel peptide which has a potential role as a biomarker of insulin resistance, diabetes and obesity. We aimed to investigate spexin levels in lean type 1 diabetes patients and spexin's role on glycemic parameters without the presence of obesity or insulin resistance.
Patients and methods
This cross-sectional study included 29 type 1 diabetic patients and a control group of 23 healthy subjects adjusted for age, sex and body mass index (BMI). Height and weight for every patient were measured using standard techniques. Glucose levels triglycerides, total cholesterol, HDL cholesterol, LDL cholesterol, serum cortisol levels and spexin levels were measured for each patient.
Results
Serum spexin levels were significantly lower in patients with type 1 diabetes than control subjects ($P=0.008$). Spexin levels were not correlated with glycemic parameters, lipids, BMI, cortisol levels and TSH ($P>0.05$). Only age was turned out to be correlated with spexin levels in patients with type 1 diabetes when groups are analyzed separately. Regression models including age and diabetes duration revealed no association between age and spexin levels. Regression models including cortisol, BMI, HbA1c revealed no association with spexin levels within each group.
Conclusion
In conclusion presence of type 1 diabetes results in lower spexin levels independent of glucose, lipid parameters and BMI. Its expression from pancreas apart from current glycemic control of the patients may be the main determinant of spexin levels in type 1 diabetic patients.

Increase in C-peptide levels after short term glycemic control in patients with type 2 diabetes mellitus: myths or facts?

Ömercan Topaloğlu, Bahri Evren & İbrahim Şahin
Inonu University Medical Faculty, Department of Endocrinology, Malatya, Turkey.

Introduction
Long term control of glucotoxicity has been shown to increase the secretion of insulin and C-peptide (Cp) from beta cells. However, there is limited data concerning the effect of short term glycemic control and reversal of glucotoxicity on basal Cp. We aimed to investigate the change in serum Cp levels after short term glycemic control in patients with uncontrolled type 2 diabetes mellitus (DM).
Materials and methods
A total of 123 patients with type 2 DM admitted and hospitalized to our clinics with uncontrolled hyperglycemia were included. Demographic and clinical data, and basic laboratory parameters were recorded and analyzed. Basal fasting Cp levels were measured both at admission (Cp-admission) and after control of hyperglycemia just prior to discharge (Cp-discharge). Cp-difference was calculated as (Cp-discharge)-(Cp-admission). The patients were divided into 2 groups: group 1 with positive Cp-difference; group 2 with negative Cp-difference.
Results
Of the patients, 61.8% had positive Cp-difference, and Cp-differences were 0.16 ($\pm$1.59) ng/mL in all patients, 0.96 ($\pm$1.03) in group 1, and $-$1.11 ($\pm$1.51) in group 2 ($P=0.001$). Mean body weight, creatinine and Cp-discharge were significantly higher in group 1 ($P=0.045$, $P=0.013$, $P=0.00$; respectively). However, mean age, body mass index (BMI), diabetes duration, hospitalization duration, proteinuria, fasting and postprandial glucose, HbA1c, lipids, TSH, free T4, Cp-admission were similar in both groups. The patients were further subgrouped according to age ($65<$ or ≥ 65), BMI(<30 or $\geq 30 kg/m^2$), diabetes duration, use of secretagogue, diabetic ketaoacidosis history, HbA1c (<10 or $\geq 10\%$), hyperlipidemia or hypertriglyceridemia, presence of any microvascular complication. There were no significant differences between subgroups as regards to Cp-difference. Cp-admission was positively correlated with triglyceride, body weight and Cp-discharge ($P=0.004$, $P=0.025$, $P=0.00$; respectively); and negatively correlated with diabetes duration, HbA1c, and Cp-difference ($P=0.009$, $P=0.043$, $P=0.00$; respectively). Cp-discharge was positively correlated with triglyceride, body weight, Cp-admission and Cp-difference ($P=0.001$, $P=0.00$, $P=0.00$, $P=0.00$; respectively). Cp-difference was correlated positively with Cp-discharge ($P=0.00$), negatively with Cp-admission ($P=0.00$). Positive predictors of having positive Cp-difference were history of cardiovascular disease ($P=0.004$; Odds Ratio (OR)$=3$), and higher Cp-discharge ($P=0.00$; OR$=6.42$).
Conclusion
Our results indicate that short-term glycemic control has little but significant positive effect on basal Cp. Having cardiovascular disease was found as a strong predictor for positive Cp-difference. Presence or absence of microvascular complications, HbA1c level, and diabetes duration did not affect Cp-difference.

Incidence of glucocorticoid-induced hyperglycemia among hospitalized nondiabetic patients

Afif Nakhleh, Naim Shehadeh & Irit Hochberg
Institute of Endocrinology, Diabetes and Metabolism, Rambam Health Care Campus, Haifa, Israel.

Introduction
High-dose glucocorticoid therapy is a recognized cause of hyperglycemia. Given the paucity of literature regarding the incidence of glucocorticoid-induced hyperglycemia among nondiabetic patients, we commenced this study in order to assess its incidence and to identify risk factors.
Design
A retrospective longitudinal cohort study.
Methods
We retrieved patients over 18 years old, without prior diabetes diagnosis or treatment who were hospitalized in Rambam Health Care Campus between 1.1.2012 – 31.3.2017, and received $\geq$10 mg oral prednisone or equivalent intravenous hydrocortisone or intravenous dexamethasone, for at least 2 days. Demographic and laboratory values of patients who developed hyperglycemia (defined by $\geq$ 1 capillary blood glucose $\geq$ 180 mg/dl during the first 4 days of glucocorticoid treatment) were compared to those of patients who did not develop hyperglycemia.
Results
There were 671 patients who filled the inclusion criteria: 355 received oral prednisone, 164 received intravenous dexamethasone, and 152 received intravenous hydrocortisone. The incidence of glucocorticoid-induced hyperglycemia among all patients was 22.6%. Patients who developed glucocorticoid-induced hyperglycemia were older and had a higher creatinine, BUN and WBC count. Using multivariate regression analysis, age over 80 years (OR: 6.27, 95% CI 3.02-13.05), hospitalization in non-surgical wards (OR: 3.08, 95% CI 1.64–5.81), and a 4-day cumulative prednisone dose $>$ 240 mg (OR: 1.78, 95% CI 1.2–2.64), were identified as independent risk factors for hyperglycemia.
Conclusion
Older patients without prior diabetes receiving high doses of glucocorticoids should be monitored closely for the development of glucocorticoid-induced hyperglycemia. Special attention should be paid to patients receiving over 60 mg prednisone/day and patients hospitalized in non-surgical departments.

Diabetes after liver transplantation

Paloma Moreno-Moreno, Ana Barrera-Martín, Concepción Muñoz-Jiménez, María Rosa Alhambra-Expósito & María Ángeles Gálvez-Moreno
Hospital Universitario Reina Sofía, Córdoba, Spain.

Objective
Diagnosis of diabetes after transplantation (NODAT) has been described in up to 25% of cases. NODAT is a metabolically complex disorder, similar to type 2 diabetes. Factors that influence the development of NODAT are: BMI, HCV and immunosuppression. Objective: to know the prevalence and incidence of diabetes mellitus (DM) in liver transplant patients of our hospital.
Patients and methods
Retrospective descriptive study of liver transplant patients. Variables analyzed: age, sex, cause of liver disease, BMI, pretransplant DM, NODAT according to

ADA criteria and death. Statistical analysis: comparison of means with Student's T and proportions using chi-square statistics, statistical program SPSS v.18 for Windows.
Results
Liver transplantation in 73 patients (85% men). Age: 54.5±7.1 years. Liver disease: alcoholic cirrhosis 44.4%; cirrhosis HCV 22.2%; cirrhosis HBV 6.3%; alcoholic cirrhosis and HCV 12.7%; alcoholic cirrhosis and HBV 4.8%; another 9.6%. BMI: women 23.7±5.2 vs men 27.4±4.3 Kg/m^2 ($P=0.3$). BMI higher in group of alcoholic cirrhosis (28.5±5.2 Kg/m^2, $P=0.4$). Prevalence of pretransplant DM was 32% (alcoholic cirrhosis 40%, cirrhosis HCV 30%, alcoholic cirrhosis and HCV 10%, $P=0.9$). Prevalence of NODAT was 38% (alcoholic cirrhosis 45.8%, cirrhosis HCV 29.2%, alcoholic cirrhosis and HCV 8.3%, $P=0.9$). No remission of pretransplant DM. Incidence of NODAT was 11.6%, lower than that described in other series ($P=0.05$). 33.3% hepatocarcinoma in transplanted patients, 47.6% with DM (NODAT 20%). Transplanted deceased 22.6%, 36.5% had DM (NODAT 7.9%).
Conclusions
Prevalence of pretransplant DM and NODAT is higher in alcoholic cirrhosis and HCV. BMI has a tendency to be higher in alcoholic cirrhosis. Incidence of NODAT is lower than that described in the literature.

Distribution of Korean obese patients based on National Health Insurance Claim Data in 2016

Ryungwoo Kang[1], YounSue Lee[1] & Deborah Chee[1,2]
[1]Korea National Enterprise for Clinical Trials (KoNECT), Seoul, Republic of Korea; [2]The Korean Society for Clinical Pharmacology and Therapeutics (KSCPT), Seoul, Republic of Korea.

South Korea has a universal health coverage system that the National Health Insurance covers approximately 98% of the overall Korean population. The claims data of HIRA contains 46 million patients per year that account for 90% of the total population in Korea and include claims from almost 80,000 healthcare service providers across South Korea as of 2011. National Health Insurance (NHI) reimbursement coverage continues to expand and there will be full reimbursement of cancer, cardiovascular, cerebrovascular and rare diseases by 2017. The proportion of GDP spent on healthcare will keep growing from the current 7.5%, driven by the ageing population. The claims data of HIRA is collected when healthcare service providers in South Korea seek reimbursements for healthcare services that the National Health Insurance Corporation agrees to cover. The annual number of Korean patients that submitted health insurance claims is approximately 46 million. The claims data of HIRA is a national data compiled from healthcare providers across the country that corresponds to the number of claims submitted by patients. In addition, the claims from patients with medical aid program, government expenditures, and veteran patients are also included in the claims data. According to the National Health Statistics 2015: National Health and Nutrition Survey, conducted by Ministry of Health and Welfare, Prevalence and trends in obesity among Korean adults were incresed since 1998. Percent of adults aged 20 years and over with obesity was 25.1% in 1998 and 39.7% in 2015.

Table 1 Annual numbers of patients.

	2011	2012	2013	2014	2015	2016
Total Patients	20,330	18,143	18,371	18,047	17,549	16,613

Think insulin: a prospective study of the knowledge of insulin preparations and administration in a Cohort of nurses in district general hospital

Emma Jade Shepherd, Surya Ashotush, Sian Jones, Julie Jones, Beth Mumford, Gaynor Harrison & Hussam Abusahmin
Prince Charles Hospital, Merthyr Tydfil, UK.

Introduction
Blood glucose control in insulin-dependent diabetes is heavily influenced by compliance, and how insulin is administered, which is emphasised to those with diabetes. However, when a patient is admitted to hospital, the administration of insulin is often by a nurse. The aim of this study was therefore to assess the knowledge of nurses around this subject, and to identify if there was a need for further training.
Method
We conducted a prospective audit with questionnaires, which were distributed among nursing staff from varying specialties and backgrounds, over a 40-day period in a district general hospital. 136 nurses returned their questionnaire.
Results
We found that within our cohort, more than half learnt about insulin administration from another colleague and had no formal training. The majority recognised of appropriate injection sites, however a small percentage would consider administration in the calf muscle. Around 97% of the nurses were aware

to rotate these injection sites, however awareness that areas of lipohypertrophy should be avoided for the appropriate time was answered correctly in approximately quarter of the cohort. Nearly 80% of them had knowledge about the timing that different preparations of insulin should be administered in relation to meals, however fewer percentage were not aware that the preparation before administration of insulin varies, and therefore may prepare insulin incorrectly.
Conclusion
This study suggests that whilst most areas of knowledge about insulin and insulin administration are sound, there are significant gaps, which could have adverse effects on patients. We therefore suggest that all registered nurses have adequate and continued formal education about all aspects of insulin.

Association between NK cell activity and glucose regulation in type 2 diabetes patients

Jung Hye Kim, Kahui Park, Sang Bae Lee, Ji Sun Nam, Shinae Kang, Jong Suk Park, Chul Woo Ahn & Yu-Sik Kim
Yonsei University College of Medicine, Gangnam Severance Hospital, Seoul, Republic of Korea.

Introduction
NK cells are cytotoxic lymphocytes critical to innate immunity. The purpose of this study is to find out the difference in NK cell activity between type 2 diabetes patients and controls, and to investigate the association between NK cell activity and glucose control.
Methods
Forty-nine subjects were enrolled in this study, with 23 type 2 diabetes patients and 26 normal glucose tolerant controls. Anthropometric and biochemical parameters were assessed. Homeostatic model assessment (HOMA) was calculated for insulin resistance. NK cell activity was measured using a newly developed NK Vue® Kit (ATgen, Seoul), which is a method of detecting and comparing interferon-gamma level from NK cells.
Results
NK cell activity was lower in type 2 diabetes patients compared to control subjects. There was a significant inverse linear relationship between NK cell activity and fasting plasma glucose after adjusting for age and gender ($r=-0.346$, $P=0.045$). Postprandial glucose and HbA1c showed a similar tendency with NK cell activity ($r=-0.313$ and -0.241, and $P=0.072$ and 0.17, respectively). Regression analysis showed HbA1c, fasting glucose and postprandial glucose to be independent predictors of NK cell activity (beta $=-0.303$, -0.360, -0.356, and $P=0.034$, 0.011, 0.033). There was no relationship between NK cell activity and HOMA-IR.
Conclusions
NK cell activity was lower in type 2 diabetes compared to controls, and it was significantly related to degree of hyperglycemia. A further, larger population study is warranted to confirm the possible correlation.

The effects of Korean red ginseng on diabetic complications and glucose modulation in type 2 diabetic patients

Chul Woo Ahn, Jung Hye Kim, Kahui Park, Sang Bae Lee, Ji Sun Nam, Shinae Kang, Jong Suk Park & Yu-Sik Kim
Yonsei University College of Medicine, Gangnam Severance Hospital, Seoul, Republic of Korea.

Background
Korean red ginseng (KRG) has been shown to improve glucose tolerance and insulin resistance in several human studies. However, human studies on the effects of KRG on diabetic complications are lacking. We performed this study to investigate the effects of KRG administration on glucose metabolism and chronic diabetic complications in type 2 diabetes patients.
Methods
This study was a randomized, double-blind, placebo-controlled trial. 83 type 2 diabetes patients were randomly allocated to two groups assigned to consume either the placebo or KRG twice a day for 24 weeks. (taking total 2 grams a day) The primary outcomes were changes of diabetic microvascular complication markers at week 24 (serum creatinine, urinary albumin to creatinine ratio, laminin-P1 and Neurometer). The secondary outcome was change in fasting plasma glucose and HbA1c at week 24.
Results
Total of 61 patients (32 patients in the KRG group and 29 in the placebo group) completed the study. In the first 12 weeks, serum eGFR and creatinine levels deteriorated (P 0.04, P 0.01 respectively), but in the second 12 weeks, the statistically significant improvement was observed (P 0.03, P 0.01 respectively). Laminin-P1, an indicator of diabetic retinopathy, improved after 24 weeks of KRG administration but was statistically insignificant (P 0.08). At week 24, the neurometer grade was not statistically significant but showed a tendency to improve. The grade of the right arm improved from 2.38 to 1.30, the left arm from 1.81 to 0.71, the right leg from 0.99 to 0.69, and the left leg from 0.84 to 0.75 (P 0.16, P 0.12, P 0.58, P 0.86 respectively). Changes in fasting plasma glucose and HbA1c were not significant after 24 weeks of KRG administration (P 0.21, P 0.12 respectively).
Conclusions
Twenty-four week administration of Korean red ginseng in type 2 diabetic patients showed a gradual improvement in diabetic nephropathy after a transient deterioration and a tendency to improve diabetic polyneuropathy.

Phenotypic and autoimmunity analysis of patients with type 1 diabetes mellitus onset

Cristina María Díaz Perdigones, Carmen Hern, Miguel Damas Fuentes, María José Picón César, José Luis Pinzón Martín, María Molina Vega & Francisco Tinahones Madueño
Hospital Clínico Universitario Virgen de la Victoria, Málaga, Spain.

Introduction
Type 1 diabetes mellitus (T1DM) is considered, in general, a disease of children and young adults with normal body mass index (BMI), linked to a genetic susceptibility based on autoimmunity. However, we know that it can be diagnosed at any age and we must differentiate it from type 2 diabetes mellitus.
Objetives
To investigate the phenotypic characteristics and the presence of specific autoimmunity in T1DM patients diagnosed in our hospital.
Material and methods
We performed a descriptive observational study, including patients first diagnosed with T1DM between 2013 and 2017. They have been followed during the last year, in the Diabetes Onset clinic at Virgen de la Victoria Hospital in Málaga. We analyzed the clinical features and autoimmunity, pancreatic reserve and glicated haemoglobin (HbA1c) at onset of diabetes.
Results
We analyzed data from 69 patients with mean age 26 ($\pm$10.8 years), 61% males; IMC 23.6$\pm$3.8. 47.8% had a family history of diabetes: 24.6% T1DM and 23.2% type 2 diabetes (T2DM). Only 1.4% had autoimmune thyroid disease prior to the diagnosis of diabetes. The presentation onset of the disease was: 17.4% diagnosed casually without symptoms; 59.4% presented cardinal symptoms of diabetes; 21.7% suffered ketoacidosis and, only 7.2% required hospital admission. None of the patients died in that initial event. The autoimmunity at debut was analyzed: 47.8% had positive anti-IA2 antibodies and 92.8% positive anti-GAD antibodies. 4% had negative autoimmunity. All patients presented a decreased pancreatic reserve with C peptide values at diagnosis 1.2$\pm$0.9 ng/mL and insulin values 5$\pm$3.4 μU/mL. They had poor metabolic control (HbA1c 13.2%) that precipitated the diagnosis.
Conclusions
Nowadays we have a major difficulty to identify T1DM after 30 years due to the increasing prevalence of DM2 background. It requires the determination of autoimmunity as a useful marker to demonstrate the presence of disease. Failure to diagnose late-onset T1DM could have serious consequences due to early development of insulin dependence.

Is it useful the O'Sullivan test ≥200 to diagnose gestational diabetes mellitus (GDM)?

María Molina-Vega, María José Picón-Cesar, Carmen Hernández-García, Miguel Damas-Fuentes, Cristina Díaz-Perdigones & Francisco Tinahones-Madueño
Virgen de la Victoria Hospital, Málaga, Spain.

Introduction
A two-step approach is usually used to diagnose GDM. At 24–28 weeks of pregnancy, a 50 g 1-hour glucose or O'Sullivan test is performed. If it is positive (≥140 mg/dl), it is followed by a 100 g-3 hours-Oral Glucose Tolerance Test (OGTT) which is considered positive if at least two or more values are ≥ of reference values (105-190-165-145 mg/dl). Despite it is not include in any clinical practice guideline, sometimes the 100 g OGTT is obviated if O'Sullivan is ≥200 mg/dl.
Objective
To evaluate the usefulness of O'Sullivan≥200 for diagnosis of GDM.
Material and methods
We analyzed data from 2774 patients presenting O'Sullivan test positive, who were carried out the 100g-OGTT at Virgen de la Victoria Hospital from 2015 to 2017 in order to compare 100g-OGTT vs O'Sullivan≥200 for diagnosis of GDM. In addition, we compared maternal and perinatal characteristics of 3 groups of patients: O'Sullivan<200 and non-pathological 100g-OGTT (A), O'Sullivan≥200 and non-pathological 100g-OGTT (B) and O'Sullivan≥200 and pathological 100g-OGTT (C).
Results
From 2774 patients with O'Sullivan test positive, 523 (18.9%) presented pathological 100g-OGTT and 2251 (81.1%) non-pathological. From 140 patients with O'Sullivan≥200, 83 (59.3%) presented pathological 100g-OGTT and 57 (40.7%) non-pathological. Therefore, the parameters of internal validity of O'Sullivan≥200 were: sensitivity 15.8%, specificity 97.4%, positive predictive value 59.2%, negative predictive value 83.3%, false-positive rate 2.5%, false-negative rate 84.1%. Comparison between groups: table 1. We only observed patients from group A to be significantly younger than those from groups B and C.

	A	B	C	*p* value
Pre-pregnancy BMI (kg/m^2)	26±5.3	26.7±5.5	27.1±5.6	0.624
Age (years)	30.8±5.6	34.1±4.5	33.3±5.5	**0.020**
Weight increase during pregnancy (kg)	7.9±5.1	11.2±6	9.1±5.9	0.310
Gestational age (weeks)	39.7±1.1	39.5±1.4	39.2±1.1	0.255
Newborn weight (gr)	3395.3±336.1	3442.9±516.3	3230.4±455.3	0.186
Type of childbirth (%)				
Eutocic	52.5	51.3	70	0.435
Instrumental	22.5	20.5	15	
Cesarean	25	28.2	15	

Conclusions
- If O'Sullivan ≥200 is considered as diagnosis of GDM, in order to avoid the 100g OGTT, 4.1 in every 10 pregnant women would be falsely diagnosed of GDM, causing unnecessary concern in patients and, probably, and an increase in GDM prevalence probably unacceptable by gestational diabetes units.
- O'Sullivan ≥200 is not useful to identify pregnant women with a higher obstetric risk.

Study on sphingolipids in tissues of animals with the diet-induced obesity

Talat Saatov, Bakhodyr Zainutdinov, Sanobar Irgasheva, Mukhammadjon Mustafakulov, Tokhir Ishankhodjaev & Elvira Ibragimova
Institute of Bioorganic Chemistry, Uzbekistan Academy of Sciences, Tashkent, Uzbekistan.

Disturbance in insulin signaling under effect of sphingolipids is thought to be the mechanism underlying the obesity-mediated insulin resistance. The work was initiated to study sphingolipid metabolism in tissues of rats with obesity induced by a prolonged high-calorie diet. The lipid extraction and purification was performed by Folch's method; concentrations of sphingosine and ceramide were measured by Lauter *et al*. method. In obesity, the levels of total gangliosides in tissues of experimental animals were found to reduce by 16.5% and 35% in the liver and in the skeletal muscles, respectively. This was found to cause changes in cell surface properties and a decline in the glucose transport. In obesity, ratios of some ganglioside fractions were established to be abnormal, as well; thus, in particular, concentrations of GM_3 ganglioside were found to increase by 1.5 and 1.8 times in the liver and skeletal muscles of animals with diet-induced obesity, respectively. A significant increase in GM_3 in obesity could facilitate the insulin resistance onset by blocking insulin signaling on the initial stages of the hormone signal pathway. An imbalance between metabolites of sphingomyelin cycle, a decline in sphingomyelin and accumulation of sphingomyelin metabolites, such as ceramide and sphingosine, were established to take place in the liver and skeletal muscles of obese experimental animals. Ceramide/sphingosine ratios in the liver and skeletal muscles were found to be 1.17 and 1.5, respectively. This is consistent with the findings from studies on stimulation of activity of neutral sphingomyelinase, a key enzyme of sphingomyelin cycle, by 1.25 and 1.45 times in the liver and skeletal muscles, respectively. The activation of sphingomyelin cycle is thought to be an element of metabolic rearrangements in obesity. The increase in ceramide concentrations in tissues of animals with diet-induced obesity appeared to provoke the insulin resistance and type 2 diabetes mellitus onset.

Influence of HLA pattern on the age at onset of type 1 diabetes mellitus

Pedro González Fernández[1], Elsa Fernández Rubio[1], Inés Urrutia Etxebarria[2], Teba González Frutos[2], Natalia Maruri Machado[1], Luis Castaño González[2] & Sonia Gaztambide Sáenz[1]
[1]Cruces University Hospital, Barakaldo, Spain; [2]BioCruces Health Research Institute, Barakaldo, Spain.

Aim
To determine, in type 1 diabetes mellitus (T1DM) patients, if there is any relationship between the age at onset and the number of HLA risk alleles for T1DM (DRB1*03 and DRB1*04).
Methods
Retrospective study. We selected patients with T1DM diagnosis (pancreatic autoimmunity and insulin-dependent diabetes) and age at onset >15 years, identifying 275 subjects (59.6% men and 40.4% women), with a median age at onset of 31 years (interquartile range -IQR- 13 years). We registered the following data at the time of diagnosis: presence of ketoacidosis, glycemia, HbA1c, BMI, pancreatic autoantibodies GAD, IA2 and IAA (measured by radioimmunoassay with recombinant antigen) and HLA-DRB1 typing (determined by PCR-SSO). We compared the age at diagnosis between patients with 0, 1 or 2 HLA risk alleles. Also, we compared our sample's HLA pattern with the one from a pediatric group (patients with onset before 15 years of age), obtained from a previous study from the same population and with identical diagnostic criteria *(Urrutia I, et al. (2017) Lower Frequency of HLA-DRB1 Type 1 Diabetes Risk Alleles in Pediatric Patients with MODY. PLoS ONE 12(1): e0169389).*
Results
26.7% of patients had ketoacidosis at onset. Median glycemia at diagnosis was 359 mg/dL (IQR 150), being mean HbA1c 11.95% (SD 2.52) and median BMI 22.48 kg/m^2 (IQR 4,72). 91.6% of patients had positive anti-GAD antibodies, 39.0% anti-IA2 antibodies and 29.1% anti-IAA antibodies. Median age at onset (IQR) was 31 (15) years in patients without risk alleles; 32 (13) years in patients with 1 risk allele and 27 (12) years in patients with 2 risk alleles. Statistically significant difference and decreasing trend (Kruskal-Wallis $P=0.037$; Jonckheere-Terpstra $P=0.046$). The distribution of risk alleles between the 2 groups of age was as follows, with statistically significant differences (Pearson's chi-squared test $P=0.01$).

	Number of HLA risk alleles			
Age	0 Alleles	1 Allele	2 Alleles	Total
Under 15 years	12 (7.5%)	71 (44.4%)	77 (48.1%)	160 (100%)
Over 15 years	55 (20.0%)	119 (43.3%)	101 (36.7%)	275 (100%)
Total	67 (15.4%)	190 (43.7%)	178 (40.9%)	435 (100%)

Conclusions
In type 1 diabetes patients, the presence of two HLA-DRB1 risk alleles is associated with a disease onset at a younger age.

Lipoatrophic Diabetes Mellitus: a rare special type!

Shaimaa A Fathy, Aasem Seif, Heba Sherif & Dina Farouk
Internal Medicine, Diabetes and Endocrinology, Faculty Of Medicine, Cairo University, Cairo, Egypt.

Introduction
Lipodystrophic syndromes are a heterogeneous group of congenital or acquired disorders characterized by either complete or partial lack of adipose tissue. Other prominent abnormalities of these disorders include Diabetes Mellitus and acanthosis nigricans due to the associated insulin resistance. Liver affection is common due to fatty infiltration of the liver, which can lead to cirrhosis and its complications.
Clinical case
A 31 years old single female presented to our emergency department multiple times due to hematemesis, hepatic coma and uncontrolled Diabetes Mellitus. She was diagnosed with Diabetes since the age of 15 and was on insulin therapy but always uncontrolled. She also reported history of 2ry amenorrhea. Her clinical examination revealed a BMI of 17 (normal range: 18.5–24.9), obvious loss of subcutaneous fat all over her body, pallor, acromegaloid features, acanthosis nigricans, hepatosplenomegaly, ascites and her fundus examination showed proliferative diabetic retinopathy. Her laboratory investigations showed microcytic hypochromic anemia (Hb: 11 g/dl; *n*: 12–15.5 g/dl), impaired coagulation profile (INR: 1.2; n: 1) and hypoalbumineamia (Alb: 2.4 g/dl; n: 3.5–5.5 g/dl). Her FBG was 250 mg/dl, OGTT 380 mg/dl and HbA1C 9%. Her lipid profile was normal apart from HDL of 28 mg/dl ($n > 50$ mg/dl). Liver and kidney function tests, hepatitis markers and autoimmune hepatitis markers were normal. Her TSH was normal, but her FSH was 1.4 mIU/ml (n: 1.5–9 mIU/ml), LH: 0.2 mIU/ml (*n*: 1–11.4 mIU/ml), estradiol was 20 pg/ml (n: 44–211 pg/ml). Her upper endoscopy showed grade III oesophageal varices and band ligation was done. Her Child-Pugh score was 9 (Child B).
Conclusion
Although lipodystrophy syndromes usually present with dyslipidemia, a normal lipid profile can be found in those patients with late stage disease associated liver cirrhosis. Lipodystrophy syndromes usually present early in life and the associated Diabetes Mellitus is mainly due to insulin resistance and shouldn't be misdiagnosed as T1DM. Medications such as Thiozolidines and Metformin can improve insulin resistance in the early disease before the onset of liver cirrhosis. Later on Insulin and leptin remain the only treatment lines.
Key words: Lipodystrophy, Insulin resistance, Diabetes Mellitus, fatty liver, liver cirrhosis.

Does gender-affirming hormone therapy alter insulin resistance in transgender persons?

Kessewa Abosi-Appeadu*, Anne-Sophie De Maertelaere*, Samyah Shadid, Justine Defreyne & Guy T'Sjoen
University Hospital, Ghent, Belgium.
*Both authors contributed equally to this work.

Background
Gender-affirming hormone therapy in transgender persons induces secondary characteristics of the experienced gender. However, androgens and estrogens are also thought to be involved in insulin sensitivity and research suggests a dose-dependent risk for developing insulin resistance when administrated in supraphysiological doses.
Aims
To assess the influence of gender-affirming hormone therapy on glucose metabolism in transgender persons.
Methods
In 90 transgender persons (35 transgender men and 55 transgender women) an OGTT was performed at baseline and one year after the introduction of gender-affirming hormone therapy as part of the ENIGI study (European Network for the Investigation of Gender Incongruence). HOMA-IR and AUC glucose during OGTT were used to quantify insulin resistance (IR).
Results
AUC glucose did not change significantly in either sex. In transgender women, we observed an increase in the median-calculated HOMA-IR, from 1.58 [1.08–1.97] to 2.06 [1.49–2.76] ($P < 0.001$) indicating higher IR after administration of estrogens and anti-androgens, an increase in total fat percentage from 18.60% ± 5.3 to 24.50% ± 10.11 ($P < 0.001$), and a decrease in the waist-to-hip ratio (WHR) from 0.87 ± 0.068 to 0.84 ± 0.084 ($P = 0.001$). In transgender men, there was no significant difference in the median-calculated HOMA-IR, but we observed a decrease in total fat percentage from 28.49% ± 5.92 at baseline to 24.30% ± 7.17 after one year ($P < 0.001$) and an increase in total activity score from 7.30 ± 2.56 to 9.05 ± 2.46 ($P < 0.001$). In transgender women, we observed a positive correlation ($R = 0.273$, $P = 0.045$) between change in WHR and change in HOMA-IR and a positive correlation ($Rs = 0.287$, $P = 0.034$) between change in HOMA-IR and change in cholesterol. In trans men, these correlations were not significant.
Conclusions
This study has identified significant changes in glucose metabolism in transgender women after one year of gender-affirming hormone therapy; IR increased, which is in line with the observed change in body composition. In transgender men, no change in IR was proven, despite a decrease in fat percentage and an increase in total activity scores.

Diagnosis and optimal medical management of patients with maternally inherited diabetes and deafness (MIDD)

Nicholas Ng, Begonia Sanchez, CJ McCarrick, Cian Mangan & Maria Byrne
Mater Misericordiae University Hospital, Dublin, Ireland.

Background
Maternally inherited diabetes and deafness (MIDD) is a rare disease affecting approximately 1% of all diabetics. The most common mutation involved is a single base mutation (A-G) at position 3243 within the $tRNA^{LEU(UUR)}$ gene. The clinical characteristics normally associated with this disease include sensorineural hearing loss, macular pattern dystrophy, cardiomyopathy, and diabetes. This study aims to identify clinical phenotype and insulin secretory response to glucose.
Methods
We prospectively studied 33 patients from 23 different pedigrees with MIDD, all of which were identified from the Mater-MODY cohort database. Audiograms, ECHO's and biochemical markers including Hba1c, Lactate, Creatinine Kinase (CK) were performed. 2-hr OGTT's were performed to determine the degree of glucose tolerance, C-peptide and insulin secretory response. Clinical and metabolic data outcomes were analysed.
Results
23 (72%) patients have diabetes with 1 pre-diabetic and 9 non-diabetics. The mean age was 49.7(±12.8)y/o and BMI is 23.5(±3.2)kg/m^2. 6 (18.2%)patients were misidentified as Type 1 Diabetics while 14 (42.4%) as type 2 Diabetics. 31 patients (93.9%) had the mtDNA 3243A > G mutation. 1 had Kearns-Sayre syndrome. 1 had the m.12258C > A mutation. Heteroplasmy was determined in 24 patients (69.7%) using blood leucocytes with ranges of 3–41%. 28 patients (84.8%) were found to have sensorineural hearing loss. 8 patients (24.2%) developed cardiomyopathy. Only 1 (3.0%) patient had maculopathy and 5 patients (16.1%) developed MELAS. 8 (24.2%) patients had ophthalmopathy. 14 (42.4%) patients had 2-hr OGTT's which showed glucose (mmol/L), insulin (pmol/L) and C peptide (pmol/L) mean level at baseline/120 mins as follows: 7.8 (±4.3)/13.3 (±7.7), 63.3 (±25.8)/297.3 (±170.8), and 570.6 (±201.4)/2318.7 (±1224.8). 31 (93.9%) patients had HBa1c with mean of 66.4 (±18.6) mmol/mol. 13(39%) patients had metformin discontinued. 14(42.4%) patients are on insulin alone. 5(35.7%) are on insulin and OHA's. 4 (12.1%) are on sulphonylurea alone.
Conclusion
There is a wide phenotypic variability seen in MIDD which can lead to misdiagnosis and induction of inappropriate therapy. Patients with diabetes and

deafness should arouse suspicion of mitochondrial diabetes as well as those who are young and lean diabetics with rapid progression to insulin. These patients also have a good insulin secretory response seen on OGTT. However, 54% of patients have ended up on insulin with mean HBa1c of 66.4 mmol/mol indicating diabetic control remains brittle.

Predictors of non-alcoholic fatty liver disease in metabolic syndrome

Irina Savasteeva, Alexander Rozhko, Veronica Selkina, Yana Navmenova & Maria Rusalenko
Epablican Scientific Center for Radiation Medicine and Human Ecology, Gomel, Belarus.

The results of a survey of 209 patients with Diabetes mellitus type 2 (DM 2) and 94 patients with X-syndrome were analyzed. Non-alcoholic fatty liver disease (NAFLD) is verified in 91.9% of cases with DM 2 and 83.0% with X-syndrome. Predictors that significantly influenced the development of NAFLD in X-syndrome have been identified: age (b = 0.07; Exp (b) = 1.07(1.02 ÷ 1.14); $P < 0.02$); body mass index (b = 0.37, Exp(b) = 1.45 (1.16 ÷ 1.81), $P < 0.001$), total cholesterol (b = 0.52, Exp (b) = 1.68 (1.03 ÷ 21.75), $P < 0.04$), triglycerides (b = 1.34; Exp (b) = 3.81 (1.32 ÷ 11.02); $P < 0.02$) and very low density lipoproteins b = 2.60; Exp (b) = 13.14 (1.31 ÷ 137.18), $P < 0.03$). In patients with X-syndrome over the age of 30, the relative risk of developing RR (NAFLD) = 4.00 and was statistically significant (95%CI = 1.27 ÷ 12.60). In patients with X-syndrome and BMI above 28.08 kg/m^2, the OR of the development of NAFLD – 9.54 (2.54 ÷ 35.75), with total cholesterol above 5.3 mmol/l OR – 4.08 (1.28 ÷ 13.05) The level of triglycerides is higher than 1.03 mmol/l OR – 11.37 (1.27 ÷ 12.60). If the VLDL level is above 0.47 mmol/l OR – 10.14 (1.27 ÷ 12.60). In the presence of diabetes 2, there were no significant critical values of laboratory and clinical predictors of the development of NAFLD. Therefore, patients at the time of manifestation of diabetes 2 already have severe metabolic disorders, such as NAFLD. The data cited indicate that the presence of NAFLD in the background of X-syndrome should be regarded as din from the predictors of development of diabetes 2, and the critical points of clinical and laboratory indicators, perhaps significantly below the generally accepted.

Carbohydrate metabolism indicators in athletes who stopped using anabolic androgenic steroids

Mykola Lykhonosov
The Federal State Budget Educational Institution of Higher Education The first St. Petersburg State Medical University named after academician I.P. Pavlova of the Ministry of Health of the Russian Federation, St. Petersburg, Russian Federation.

Introduction
The use of steroids for the formation of a sports figure is widespread. Anabolic androgenic steroids (AAS) are used in large doses than in therapeutic practice. Studies of the side effects of AAS on carbohydrate metabolism are hampered due to the self-over-the-counter use of AAS.
Hypothesis
We hypothesized that with the abolition of AAS, the effect of elevated doses of testosterone (Ts) and nandrolone (ND) decanoate on the utilization of glucose is reduced.
Methods
After the informational lectures among the visitors of the sports clubs of St. Petersburg on the impact of the AAS application on health, the expressed desire is included in the study. The inclusion criterion was the use of preparations of 19-nortestosterone with a course of 6 to 8 weeks in a weekly dosage of 300 to 700 mg in combination with Ts propionate and Ts enanthate, as well as the rejection of the subsequent use of anabolic steroids. BMI, HbA1c, immuno-reactive insulin (IRI) and fasting plasma glucose (FG), and HOMA-IR insulin resistance index were compared before and after 3 months after the abolition of all AAS, while maintaining the previous exercise and dietary habits.
Results
Twenty-four athletes (18M), age 27 ± 3.6 were examined. The average period of use of AAS is 7.3 weeks. After the abolition of the AAS, the IMB increased (mean difference = 4.7 kg, $P = 0.012$). The metabolism of glucose has changed in the direction of increasing all the indicators considered: FG (mean difference = 1.02 mmol/l, $P = 0.047$), IRI (mean difference = 9.83, $P = 0.023$), HOMA-IR (mean difference = 7.31, $P = 0.015$) and HbA1c (mean difference = 0.25%, $P = 0.031$). However, no violations of glucose metabolism were detected in any case.
Conclusions
The abolition of AAS in athletes caused an increase in body weight and a shift in all glucose metabolism rates closer to the upper normal values. This trend deserves further study.

DOI: 10.1530/endoabs.56.P369

P370

Carbohydrate metabolism disorders in patients with Graves treated with systemic corticosteroid regimen

Joanna Rutkowska, Elżbieta Bandurska-Stankiewicz, Katarzyna Myszka-Podgórska, Wojciech Matuszewski, Magdalena Szychlińska & Magdalena Stefanowicz-Rutkowska
University of Warmia and Mazury School of Medicine, Olsztyn, Poland.

In patients with Graves disease and Graves' orbitopathy (GO), the diagnosis was based on clinical activity score (CAS), TSH-receptor antibodies, orbital MRI assesment. Thyreometabolic status was assessed by TSH, FT4, FT3. Before the administration of high-dose intravenous glucocorticoids oral glucose tolerance test (OGTT) was performed obligatory. The patient with confirmed diabetes were excluded form the study. Acute hyperglycaemia was diagnosed at the glucose concentration ≥ 180 mg/dL, and required insulin therapy.
Results
The study group included 62 euthyroid patients with GO (85.5% women). 32 persons (51.6%) were treated with thiamazole, 16 (25.8%) after 131I, 10 (16.1%) after thyreoidectomy. Carbohydrate metabolism disorders in OGTT were found in 20 (32.2%) of the stoudy group: impaired fastig glucose (IFG) was found in 17 (27.4%); impaired glucose tolerance (IGT) in 2 (3.2%); IFG + IGT in 1 (1.6%) cases. Normal OGTT was found in 42 (67.8%) patients. A cumulative average dose of metylprednisolone was 4.5–6 g. Acute hyperglycaemia requiring insulin therapy was found in 56 (90.32%) patients, mainly at lunch and dinner time.
Conclusions
1. In euthyroid patient with Graves disease and GO disturbances in carbohydrate metabolism are more common comparing to general population.
2. OGTT should be perfomed routinely in patients with GO before systemic corticosteroid therapy.
3. Acute hyperglycaemia is observed in patient treated with systemic corticosteroid mainly at lunch and dinner time.
4. The administration of short acting insulin analogs at the meal time helps to reduce acute hyperglycaemia.

A difficult synchronous diagnosis; Type 2 Diabetes and insulinoma

Okan Sefa Bakiner, Emre Bozkirli, Filiz Eksi Haydardedeoglu, Gulay Simsek Bagir & Melek Eda Ertorer
Baskent University, School of Medicine, Department of Endocrinology and Metabolic Disorders, Adana, Turkey.

Background
In the literature there are rare cases of patients with known Type 2 Diabetes Mellitus whom are diagnosed as insulinoma. However a synchronous diagnosis with insulinoma and diabetes for a patient presenting with hypoglycemia symptoms is not an expected condition.
Case
A 79 years-old female patient was sent to our Endocrinology outpatient clinic because of repeating minor and major hypoglycemia attacks. She had no important finding in her background except a history of autoimmune thyroiditis which is held in control with levothyroxine replacement. Her renal and liver function tests were normal in her initial laboratory tests. A prolonged fasting test was performed after hospitalization. At the third hour of fasting she presented hypoglycemia symptoms and her blood sugar was found as 40 mg/dl. Blood

samples for plasma c-peptide, insulin and cortisol level measurement were obtained. Her plasma c-peptide was 3 nmol/L and plasma insulin was 101.6 μU/mL, compatible with insulinoma diagnosis while her cortisol levels were high in a manner excluding a possible adrenocortical defficiency. The patient's urine ketone was negative during this period. Urinary sulfonylurea metabolites were unmeasured because of laboratory inability for the patient who has endogenous hyperinsulinemia and hypoglycemia at the same time. A sudden spontaneous hyperglicema reaching up to 350 mg/dL was observed in the blood sugar controls while the patient was waiting for pancreatic imaging. Insulin infusion therapy was iniated to control blood sugar levels. During that stage HbA1c and anti-insulin autobodies were studied. Her HbA1c was 5.2% and her anti-insulin autoantibodies were negative. In her follow-ups; repeating hypoglycemia attacks were observed despite the interruption of insulin infusion therapy. Her control laboratory tests were again compatible with hypoglycemia accompanied by endogenous hyperinsulinemia. Her pancreas diffusion magnetic resonance imaging revealed a 12 mm hypervascular mass in the tail region suggesting a possible insulinoma. No local invasion signs were observed. After that, pancreatic mass enucleation was performed. Pathological diagnosis was insulinoma (1.1 cm, pStage I, chromogranin (+), synaptophysin (+), insulin (+), mitoses 3/10 HPF and Ki-67 index: 2%). Multiple subcutaneous insulin injection therapy was initiated after the surgical intervention because of high blood sugar results in the follow-ups. Six months after the surgery, the patient is still using basal insulin and metformin, and her last HbA1c level was 7.2%. She does not report any hypoglycemia attacks since surgery.

Conclusion

In the present case we report a rare situation in which the underlying diabetes seem to remain secret possibly because of the variable secretory pattern of insulinomas.

Immunoglobulin G4 related pancreatitis; can it be a rare cause of secondary diabetes?

Emre Bozkirli, Okan Sefa Bakiner, Gulay Simsek Bagir, Filiz Eksi Haydardedeoglu & Melek Eda Ertorer
Department of Endocrinology and Metabolic Disorders, Baskent University, School of Medicine, Adana, Turkey.

Background

Autoimmune pancreatitis (AIP) is a relatively new entity in which the exocrine pancreas shows lymphocytic infiltration. There are two subtypes of AIP; Type 1 related with Immunoglobulin G4 (IgG4) as the pancreatic manifestation of IgG4-related disease (IgG4-RD), and Type 2 related with granulocytic infiltration. The characteristic features of Type 1 AIP are increased serum IgG4 levels, lymphoplasmacytic sclerosing pancreatitis (infiltration of IgG4+ plasmacytes and lymphocytes, storiform fibrosis, and obliterative phlebitis), extra-pancreatic manifestations of IgG4-RD (e.g. sclerosing cholangitis, sclerosing sialadenitis, retroperitoneal fibrosis), and steroid responsiveness.

Case

A 60 years-old male was sent to our Endocrinology outpatient clinic because of elevated fasting blood sugar levels found during his Chest Diaseases Department follow-ups due to bronchiectasis and multiple lung cysts. His initial fasting blood glucose was 123 mg/dl. A 75-gr oral glucose tolerance test was performed and second hour glucose level was found as 246 mg/dl. Subsequent HbA1c measurement was 8.62%. In his background he had undergone lung surgery for cyst excision and tuberculosis treatment for a year. He had no first degree relative with diabetes in his family history. He had weakness, remarkable weight loss and serious postprandial dyspeptic symptoms. In his physical examination his BMİ was 22.4 kg/m^2 and no conspicuous finding except of abdominal tenderness was found. A diffusion magnetic resonance imaging of pancreas was performed according to negative family history for diabetes, weight loss and sudden presentation of diabetes in advanced age to rule out a possible pancreatic neoplasm. Pancreas MRI revealed a diffuse thickened and edematous pancreas with loss of lobulated appearance and an evident pancreatic duct. These findings were interpreted in favor of autoimmune pancreatitis. Afterwards the patient was examined for autoimmune diabetes. Anti glutamic acid decarboxylase, islet cell and insulin autoantibodies were all negative. Serum IgG4 levels were elevated (150 mg/dl), suggesting a possible IgG4-RD since the actual criteria for IgG4-RD implies a cut-off value of serum IgG4 > 135 mg/dl. We presumably thought that cystic lung disease and autoimmune pancreatitis could be manifestations of IgG4-RD and consequently IgG4 related pancreatitis can be the cause of deterioration of both exocrine and endocrine funtions of pancreas for this patient. On this basis we thought that diabetic condition of the patient could be secondary to IgG4 related AIP.

Conclusion

The concomitant onset of autoimmune pancreatitis and autoantibody positive type 1 diabetes has been described among IgG4-RD. But our case is suggesting a unique immune disturbance that compromises the pancreatic endocrine and exocrine functions.

Evaluation of glycemia correction during sleeping on the somnological indicators in type 1 diabetes patients

Ina Darashkevich[1], Tatiana Mokhort[2], Lola Nikanava[1] & Serhey Tishkovsky[1]
[1]Grodno State Medical University, Grodno, Belarus; [2]Belarus State Medical University, Minsk, Belarus.

Fluctuations of glycemia, the rate of glycemia decreasing, the chronic decompensation type 1 diabetes adversely influenceon diabetic complications development. Increased glycemia during sleep leads to a change in the structure of sleep and a decrease in its functions.

The aim of the study was to assess the effect of glycemic values and it's correction during sleep on somnological indicators.

Materials and methods

The study included 7 type 1 diabetes patients who received insulin therapy in a basal-bolus regime. All participants were assessed for glycated hemoglobin (HbA1c) (Architectc8000, Abbott, USA), polysomnographic study "SOMNO-lab2, Weinmann R&K" with continuous glucose monitoring (CGM) "CGMSGold" Medtronic Mini Med USA) for two diagnostic nights. CGM was performed in parallel with the PSS in the second diagnostic night.In case of detecting hyperglycemia during sleeping according to CGM (glucose level (GL) > 7.0 mmol/l) the correction of insulin therapy was performed, with repeated implementation of the complex study (PSS and CGM) with an interval of 5–7 days (Table 1). All patients were in type 1 diabetes decompensation stage (HbA1c 8.95%). Before the insulin therapy correction, fluctuations in glycemia at night were recorded in the range 8.2–13.8 mmol/l, after correction of insulin therapy - 5.50–6.50 mmol/l. Achievement of normoglycemia was accompanied by an increase in the coefficient of sleep efficiency to 86.7% vs 70.0% before correction. The duration of WASO was maximal for patients with fluctuations in glycaemia from 8.20 to 13.80 mmol/l (71 min vs 31 min). Similar results were obtained from the evaluation of the proportion of REM sleep reduction from 39.9 to 35.4%, and an increasing of N3 (2.80 vs 5.10) and N4 (1.20 vs 3.70) stages.

Conclusions

Achievement of glycemia 5.5–5.6 mmol/l for type 1 diabetes in decompension (HbA1c 8.95%) improves the structural parameters of sleep: reduces REM phase, prolongs the deep stages of slow sleep (N3, N4), and improves sleep efficiency, reduces the duration of WASO.

Table 1 Comparative characteristics of the results.

Indicator	Before correction of insulin therapy Me[25;75]	After correction of insulin therapy Me[25;75]
HbA1C (%)	8,95 [7,50;9,30]	8,95 [7,50;9,30]
The minimum glucose level during sleep (mmol/l)	8,20 [7,50;9,50]*	5,50 [5,50;6,50]
The maximum glucose level during sleep (mmol/l)	13,80 [10,50;15,00]*	6,50 [6,00;7,00]
Sleep Efficiency Ratio (%)	70,00 [69;00;73,00]*	86,70 [84,90;87,00]
WASO (wake after sleep onset)(min)	71,00 [35,00;94,00]*	31,00 [25,00;47,00]
REM (%)	39,90 [35,70;41,40]*	35,37 [24,51;37,10]

Insulin resistance and β-cell function in patients with cystic fibrosis

Ángel Rebollo Román, Paloma Moreno Moreno, Ana Barrera Martín, María Rosa Alhambra Expósito, María Dolores Alcántara Laguna, José Manuel Vaquero Barrios, Alfonso Calañas Continente & María Ángeles Gálvez Moreno
Hospital Universitario Reina Sofía, Córdoba, Spain.

Introduction
Recent studies defend the measurements of insulin resistance and β-cell function to assess the endocrine pancreatic function in patients with cystic fibrosis (CF). HOMA-IR indexes greater than 1 translate insulin resistance and HOMA-%β values lower than 100% imply an altered β-cell function.
Aim
To describe insulin resistance and β-cell function using HOMA-IR and HOMA-%β indexes in patients with CF and compare them according to their glucose tolerance.
Methods
Observational, cross-sectional, clinical research on patients with CF evaluated at Hospital Universitario Reina Sofía (Córdoba). Statistical analysis performed with SPSS software.
Results
31 patients were included in our study. The mean age was 32.25 ± 8.89 years, with a mean CF evolution time of 23.45 ± 10.21 years. 61.3% of the patients were women. After the oral 75g-glucose test (OGTT) 13.8% patients were diagnosed with cystic-fibrosis related diabetes (CFRD), 25.1% with impaired glucose tolerance (IGT) and 51.7% showed a normal glucose tolerance. 50% of patients with IGT or CFRD had an HOMA-IR > 1 compared to the 18.2% of patients with normal tolerance who had an index greater than 1. The difference was not statistically significant ($P = 0.208$). 57.1% of patients with IGT or CFRD had an HOMA-%b $< 100\%$ in comparison to the 36.4% of patients with normal glucose tolerance who had an HOMA-%b $< 100\%$ ($P = 0.302$).
Conclusions
- In our series, half of the patients with IGT or CFRD showed abnormal insulin resistance indexes but there are not statistically significant differences with the indexes of those patients with normal glucose tolerance.
- Most of the patients (57.1%) with CF and abnormal glucose tolerance in our study presented with an impaired β-pancreatic cell function. This proportion is smaller in patient with normal glucose tolerance (36.4%) but the difference was not statistically significative.

HNF-1β maturity-onset diabetes of the young (MODY 5): defining diabetes etiology in a family with different diabetes phenotypes

Carlos Silva[1], Elena García[1], Gema Villa[1], David Males[1], Juan Carlos Romero[1,2], Guillermo Martinez[1] & Miguel León[1]
[1]Hospital Universitario 12 de Octubre, Madrid, Spain; [2]Instituto Ecuatoriano de Seguridad Social, Cuenca, Ecuador.

Introduction
HNF-1β maturity-onset diabetes of the young (MODY5) is uncommon, nevertheless accurate diagnosis guides individualized management and informs prognosis in probands and relatives.
Objective
To emphasize the importance of the appropriate use of clinical, biochemical and genetic investigations for the correct classification of diabetes etiology.
Case-report
A 35-year-old overweight Latin-American male was diagnosed with ketosis-prone A-β+ diabetes mellitus, however, due to a strong family history of diabetes with an autosomal dominant inheritance pattern, a niece with polycystic kidney disease during childhood, negativity for pancreatic β-Cell antibodies, and a C-peptide of 237 ng/ml, HNF-1β- MODY was suspected, further investigation revealed aplasia of the dorsal pancreas. The diagnosis was confirmed by the identification of a missense mutation (M_000458.2:c.884G>A (p.R295H) in the DNA-binding homeodomain of the HNF-1b gene (1).
Methods
Systematic clinical, biochemical characterization and HNF-1β mutational analysis were implemented to determine the diabetes etiology in four relatives.
Results
Identification of the p.R295H mutation in the proband's maternal half brother and sister confirmed the diagnosis of HNF-1β-MODY, they were previously misclassified as having type 1 and type 2 diabetes respectively. A mutation analysis of his two sons, who did not meet diabetes criteria at the time of evaluation, revealed the p.R295H mutation, a diminished glomerular filtration rate with renal cysts, and aplasia of the dorsal pancreas only in the elder son. The proband's other sister and adolescent niece had a diagnosis of diabetes mellitus and polycystic kidney disease but they were not able for testing nor his mother with diabetes but already deceased.
Conclusions
Two previously misclassified family members were shown to have HNF-1β-MODY, whereas another was shown to have clinical features associated with the mutation (pancreatic atrophy and chronic kidney failure with renal cysts) but no diabetes yet. This family exemplifies the importance of careful phenotyping and systematic evaluation of relatives after discovering monogenic diabetes in an individual since it has unique management, prognostic and genetic counseling implications.

Habitual dietary intake in response to futsal-based exercise in people with type 1 diabetes

Daniel Tudor Cosma[1], Cristina Alina Silaghi[2], Horatiu Silaghi[3], Carmen Emanuela Georgescu[2], Ioan Andrei Veresiu[4] & Matthew D Campbell[5]
[1]Center for Diabetes, Nutrition and Metabolic Diseases, Cluj-Napoca, Romania; [2]Department of Endocrinology, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania; [3]Vth Department of Surgery, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania; [4]Department of Diabetes, Nutrition and Metabolic diseases, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania; [5]Carnegie Research Institute, Institute for Sport Physical activity and Leisure, Leeds Beckett University, Leeds, UK.

Background
Adequate and appropriate nutrition in type 1 diabetic athletes is essential not only to increase the physical performance but also to prevent the hypoglycemic events. Detailed nutrition history represents the initial step in developing a proper meal plan according to the specific characteristics of the physical activity performed.
Purpose
This study assessed changes in habitual dietary intake and macronutrient distribution in response to intermittent-type futsal-based exercise under free-living conditions in people with type 1 diabetes who have not previously received structured nutritional diabetes education.
Methods
Nine people with type 1 diabetes (HbA_{1c} $7.6 \pm 0.9\%$; Age 28 ± 5 years; BMI 23.7 ± 1.8 kg/m^2; Diabetes duration 11.3 ± 6.4 years) completed a 24-hour weighed food diary on two separate occasions: 1) on a day containing exercise (EX), and 2) a non-exercise day (CON). The exercise day consisted of performing a standardized 80-minute intermittent-type typical futsal-based training session. All participants were competing at an international-level in futsal. Participants had not previously received dietary education as part of their diabetes care. Food frequency and dietary intake were subsequently analyzed.
Results
EX resulted in 78% of participants experiencing hypoglycemia, whereas this was limited to 45% under CON. Meal frequency and meal-time energy intake was similar between conditions ($P \geq 0.050$), however all participants under EX consumed additional carbohydrate-based snacks, whereas this was limited to 56% under CON. Correspondingly, total kcal intake was on average 31% greater under EX (EX 2470 ± 783 vs. CON 1888 ± 601 kcal.day^{-1}; $P = 0.047$), with more carbohydrate (EX 287.7 ± 81.5 vs. CON 238.4 ± 92.6 g.day^{-1}; $P = 0.044$), fat (EX 94.6 ± 50.3 vs. CON 60.9 ± 22.0 g.day^{-1}; $P = 0.013$), and protein (EX 128.2 ± 68.2g vs. CON 99.2 ± 44.2 g.day^{-1}; $P = 0.039$) consumed.
Discussion
This is the first investigation to show that people with type 1 diabetes with no prior structured nutritional diabetes education performing intermittent-type futsal-based exercise rely predominantly on carbohydrate-based snacks to prevent exercise-induced hypoglycemia rather than adjust meal frequency, meal-macronutrient distribution, or meal-macronutrient amount.

TWEAK levels in patients with prediabetes and diabetes mellitus

Yildiz Okuturlar[1], Hakan Kocoglu[1], Sibel Ocak Serin[2], Tarik Ercan[1], Mehmet Hursitoglu[1], Meral Mert[1], Bahar Ozdemir[1], Betul Erismis[1], Asuman Gedikbasi[1] & Ozlem Harmankaya[1]
[1]University of Health Sciences, Bakirkoy Dr. Sadi Konuk Education and Research Hospital, Istanbul, Turkey; [2]University of Health Sciences, Umraniye Education and Research Hospital, Istanbul, Turkey.

Introduction
Tumor necrosis factor-like weak inducer of apoptosis (TWEAK) belongs to TNF family and is released from inflammatory cells. It has been reported that TWEAK has several biological actions ranging from cell proliferation to stimulation of apoptosis. In *in vitro* studies, it was reported that TWEAK has alleviating effect on insulin resistance in hepatocytes. TWEAK decreases insulin resistance induced by TNF-a through activation of phosphatase 2A pathway in adipocytes. In our study, the relationship between TWEAK levels and biochemical parameters was assessed in patients with prediabetes and diabetes mellitus.
Material and method
The study recruited overall 90 patients including 32 patients with diabetes mellitus (17 men, 15 women), 32 patients with prediabetes (14 men, 18 women) and 26 controls (12 men, 14 women). The diagnosis of prediabetes was made according to fasting blood glucose measurement (100–126 mg/dl) and 75-gr OGTT (2 h glucose: 140–199). Diabetes group included patients with newly diagnosed type II diabetes mellitus. Biochemical evaluations were performed in all patients. Homeostasis Model Assessment (HOMA) was calculated by using following formula: HOMA-IR = Fasting Blood Glucose (mg/dl) × Fasting Insulin (uIU/ml)/405. Spearman's correlation analysis was used to assess correlations.
Findings
There were significant differences in TWEAK among three groups ($P = 0.001$). There was no significant difference between prediabetes and diabetes groups ($P = 0.867$) while there was significant difference in controls when compared to prediabetes or diabetes groups ($P = 0.001$).
Discussion
In our study, the finding presence of significant difference between controls and prediabetes or diabetes groups but not between prediabetes and diabetes groups suggests that TWEAK levels can be affected even at early phase of insulin resistance. The negative correlation between TWEAK and insulin resistance or inflammation markers may be a clue indicating that TWEAK levels can be used as a novel, early marker for metabolic syndrome. The decreased TWEAK levels by increasing insulin resistance and inflammation raises the likelihood of using TWEAK as an early marker for metabolic syndrome which is now considered as a common public health issue.

Description of clinical, biochemical and radiological variability of Hepatocyte Nuclear Factor-1βeta (HNF1β) Mutations

Matilde Bettina Mijares Zamuner, Nicholas Khay Jin Ng, Nadia Siddique, Marie Burke & Maria Byrne
Department of Endocrinology, Mater Misericordiae University Hospital, Dublin, Ireland.

Background
HNF1β mutations are one of the commonly identified genetic causes of renal malformations, but one of the less common forms of MODY. HNF1β is involved in the development of kidneys, liver, pancreas, intestine and urogenital tract. Patients can present with distinctive but highly variable clinical features. The aim of this study is to evaluate the clinical, biochemical and radiological variability of HNF1β variants and the challenge of management on the basis of the insulin secretory response to glucose.
Methods
11 HNF1β mutation positive subjects underwent phenotyping with a 2-h OGTT to determine their degree of glucose tolerance and insulin secretory response. Biochemical testing included magnesium, urate, faecal elastase (FE). Abdominal and pelvic ultrasound (US), Magnetic Resonance Imaging (MRI) of pancreas and liver were performed.
Results
Diabetes was present 9/11 patients. Diabetes was diagnosed at 29 ± 16 years of age, BMI 23.4 ± 2.5 kg/m^2, mean HbA1c was 67 ± 15 mmol/mol. 5/9 on insulin (MDI) and 3/9 started on oral hypoglycaemic agents (OHAs-Metformin and Gliclazide MR) after OGTT and HNF1β mutation positive, with a significant reduction of insulin doses. 2/9 on OHAs required basal insulin after 10 years of diabetes diagnosis, 1/9 on OHA and 1/9 diet controlled. The insulin secretory response to glucose was variable but present in all the patients. Glucose (mmol/l), Insulin (mU/l) and C-Peptide (μg/l) mean at 0 min/120 min: 9.3(±4.8)/19.3(±8.3), 56.2(±65.8)/150.0(±77.3), 363.7(±219.5)/1364.6(±1031.7) respectively. 6/11 had mild asymptomatic hypomagnesaemia 0.64 ± 0.09 mmol/l. 3/11 had hyperuricemia and 2 had early onset gout. 5/11 had deranged LFT's. 3/11 had sub-clinical pancreas exocrine insufficiency (FE 52 ± 40 μg/g). 7 patients have undergone for MRI demonstrating pancreas malformation in 4 subjects (atrophic pancreas, agenesis of the body and tail, partial pancreatic divisum), female genital tract abnormalities in 2 cases (uterus didelphys) and one patient with seminal vesical cysts as part of infertility investigation. 5/11 had renal cysts. 1 patient with CKD stage 3. 7 different mutations were identified; p.Gly83Ser (p.G83S) has been described as a novel mutation.
Conclusion
This case series highlights the spectrum of clinical manifestations of HNF1β variants. Genetic diagnosis enables the physician to screen for hypomagnesaemia, gout, pancreatic insufficiency and pancreatic/hepatic/genital malformations. The patients could benefit from insulin and/or OHA for treatment on the basis of insulin secretory response.

Maternally inherited diabetes and deafness (MIDD): the many faces of the same disease in a Spanish family

Carlos Silva, Elena García, Gema Villa, Alba Martín, David Males, Guillermo Martinez & Miguel León
Hospital Universitario 12 de Octubre, Madrid, Spain.

Introduction
Maternally inherited diabetes and deafness (MIDD), is a rare entity. Most commonly, it is related to a point mutation in the mitochondrial DNA (mtDNA) at position 3243 (m.3243A > G) encoding the gene for tRNA. A high index of suspicion is required for the diagnosis due to a wide heterogeneity in its clinical presentation which reflects different levels of mutated mtDNA among mitochondria in a given tissue (heteroplasmy). Thyroid cancer risk has never been specifically assessed in this population.
Case-report
We report a 39-year-old male diagnosed with type 2 diabetes mellitus (T2DM) at the age of 29 when he presented with polyuria. His body mass index at diagnosis was 22.6 kg/m^2 and pancreatic autoimmunity was negative. After the presumed T2DM diagnosis he was started on oral hypoglycemic agents. He was added on insulin after 4 years of diagnosis because of poor glycemic control. He had never experienced any episodes of diabetic ketoacidosis (DKA). He had a subcapsular cataract of the left eye but there was no evidence of retinopathy, neuropathy, kidney disease, muscular weakness or cardiac disease at the time of presentation. His past medical history included a sensorineural hearing loss at 25 years of age. His family history revealed a bilateral hearing loss at the age of 50 in his mother who had also been diagnosed with T2DM and multinodular goiter in the last year. His sister was diagnosed with type 1 diabetes mellitus when she was 15 years of age and on physical examination she also had a multinodular goiter. The patient, his mother and sister underwent genetic testing which confirmed the m.3243A > G mutation with a level of heteroplasmy of 90%, 61% and 5% respectively. During the follow up the patient showed a thyroid papillary microcarcinoma with BRAF-V600E-K mutation. He was referred for thyroidectomy.
Conclusions
This family exemplifies the clinical heterogeneity of MIDD linked to the degree of heteroplasmy in the mitochondria of affected tissues. Probands commonly show high levels of heteroplasmy, they prompt the diagnosis as they are usually the most affected members of their families. Careful phenotyping and systematic evaluation of relatives after the diagnosis of the index case is mandatory due to unique management, prognostic and genetic counseling issues. The distribution of thyroid disease and thyroid cancer risk in this population is elusive. To our current knowledge this is the first reported case of MIDD and concurrent differentiated thyroid carcinoma.

The detection of disordered eating risk in patients with type 2 diabetes mellitus

Veranika Labashova[1], Alla Shepelkevich[2], Yulia Dydyshka[2] & Alena Kozlova[3]
[1]Republic Centre of Medical Rehabilitation and Balneotherapy, Minsk, Belarus; [2]Belarussian State Medical University, Minsk, Belarus; [3]14 central Minsk-city polyclinic, Minsk, Belarus.

Background and aims
Type 2 diabetes is strongly associated with obesity as the major potentially modifiable risk factor. Apart from total caloric intake, certain eating patterns have been associated with the risk of diabetes and insulinoresistance. Researchers have found that specific groups in the community may be at increased risk of eating disorders, including people with diabetes and those who are obese. The aim of the study was to detect the risk of disordered eating in patients with T2DM using EAT-26 questionnaire.
Materials and methods
We studied 107 patients with type 2 diabetes mellitus (20 men and 87 women) recruited from clinical and community settings. The mean age of the participants was 61.75 + 9.32 years; the mean BMI was 34.39 + 6.72 kg/m^2. The most widely used standardized measure of eating disorders symptoms the Eating Attitudes Test (EAT-26) was used for the purposes of the present study. Questions are scored on a Likert scale from 0 (never, seldom, or sometimes) to 3 (always). A score greater than 20 represents a risk for developing a eating disorder, and participants are categorised as being at risk of disordered eating.
Results
The analysis showed that 49 patients with T2DM (45,7%) have score more than 20 on EAT-26; 58 patients (54, 37%) scored less than 20. Among the subgroup of men the value 20 and more was revealed in 7 questionnaires (35%), the score less 20 – in 13 ones (65%). In the subgroup of women 42 females (48,7%) were 'positive' on their cut-offs, 45 females (51,3%) account less 20. The significantly higher mean value (2,01) was received on the question 'I avoid foods with sugar in them': 52 persons (48,6%) answered 'always', 26 persons – 'usually', 9 persons (8.4%) – 'often', 20 persons (18.7%) – 'never, seldom, or sometimes'. The higher rate on this question maybe associated with the specifity of diabetes and could influence the total score rate on the scale. Future research efforts are required to strengthen the present findings.
Conclusion
Our findings showed a high risk of disordered eating among patients with T2DM according to EAT-26 questionnaire. More research is needed to understand the role of eating disorders in T2DM.

Gestational diabetes and weight gain in outpatient practice

Lina Zabuliene[1,2], Ruta Einikyte[1], Daiva Kersulyte[2], Jelena Kutkauskiene[2] & Jurgita Urboniene[3]
[1]Vilnius University Faculty of Medicine, Vilnius, Lithuania; [2]Karoliniskiu Clinic, Vilnius, Lithuania; [3]Vilnius University Hospital 'Santaros clinic', Vilnius, Lithuania.

Hyperglycaemia is one of the most common medical conditions women encounter during pregnancy. The occurrence of gestational diabetes mellitus (GDM) is rising and it represents an important modifiable risk factor for adverse pregnancy outcomes. Similar to GDM, excessive weight gain is associated with a number of undesirable consequences for both the mother and neonate. The aim of this study was to evaluate prevalence of GDM in outpatient practice and investigate associations between glucose metabolism and gestational weight gain (GWG) during pregnancy.
Methods
We analysed retrospective data of all adult pregnant women who were followed up in Vilnius Karoliniskiu clinic, Lithuania and gave birth in 2016. GDM was diagnosed using the UK National Institute for Health Care Excellence (NICE) criteria. GWG was categorized as low, appropriate and excessive according to Institute of Medicine Guidelines.
Results
Data of 415 women were analysed. Mean age at delivery was 30.14 ± 5.13 years. The first antenatal visit was at 11.64 ± 4.47 gestational week. Oral glucose tolerance test was performed at 26.62 ± 4.14 gestational week. A total of 86 women (21%) were diagnosed with GDM and 4 (1%) had overt diabetes in pregnancy. 15.1% of women having GDM were normal weight, 33.3% – overweight, 51.6% – obese. Overweight and obese women had 3.68 (95% CI 2.21–6.11) times higher odds ratio for developing GDM comparing with underweight or normal weight women ($P < 0.0001$). Mean total GWG was higher in underweight and normal weight women group than that in overweight and obese women group (13.87 ± 4.85 vs 11.59 ± 5.88 kg ($P = 0.001$)). Mean total GWG was higher in normal glucose tolerance group compared to GDM group (13.73 ± 4.84 vs 12.15 ± 6.09 kg ($P = 0.03$)). Excessive GWG have had one-third (33.1%) of all women. Excessive GWG was more frequent in GDM group than in healthy women (45.9% vs 30.1%, $P = 0.009$).
Conclusions
This audit presents a relatively high prevalence of GDM in everyday outpatient practice. Overweight and obesity significantly increases risk of GDM. Compliance with lifestyle guidelines helps women with GDM to control weight gain during pregnancy, nevertheless excessive gestational weight gain is still more frequent in women with GDM.

Oral glucose tolerance test in reclassification of gestational diabetes after delivery – results from portuguese national registry

Nelson Cunha[1], Leonor Gomes[1,2], Sandra Paiva[1], Luisa Ruas[1], Diana Oliveira[1,2], Adriana Lages[1], Mara Ventura[1], Lúcia Fadiga[1], Diana Catarino[1], Maria Ceu Almeida[3] & Francisco Carrilho[1]
[1]Serviço de Endocrinologia Diabetes e Metabolismo, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [2]Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal; [3]Serviço de Obstetrícia, Maternidade Bissaya Barreto - Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal.

Introduction
Gestational diabetes (DG) is associated with higher risk of diabetes mellitus (DM), and it's recommended to perform an oral glucose tolerance test (OGTT) with 75 g after delivery to its reclassification. However, not all scientific societies recommend it.
Aim
To evaluate glucose tolerance with OGTT after delivery in women with DG and the risk factors to glucose intolerance in glycaemia at 120′.
Methods
Retrospective cohort study that included women with DG who performed OGTT after deliver between 2012 and 2015, from national register of diabetes and pregnancy of Portuguese Society of Diabetes. The WHO diagnostic criteria were considered.
Results
7435 women were included: 92.2% ($n = 6857$) had a normal response; 0.8% ($n = 60$) presented DM criteria (43% ($n = 26$) at 0' and 57% ($n = 34$) at 120′), 1.1% ($n = 84$) had impaired fasting glucose (IFG) and 5.9% ($n = 434$) had impaired glucose tolerance (IGT). Women with DM criteria at reclassification presented higher values at fasting glycaemia (FG) in 1st trimester (119.7 ± 35.0 vs 97.3 ± 7.1 mg/dl; $P < 0.001$), at glycaemia at 60′ at OGTT in 2nd trimester (211.3 ± 42.3 vs 175.5 ± 30.1 mg/dl; $P < 0.001$), daily dose of insulin (31.4 ± 20.5 vs 21.7 ± 16.9 U; $P < 0.001$) and $n°$ of injections (2.9 ± 1.6 vs 2.2 ± 1.3; $P < 0.001$), and earlier diagnosis (16.4 ± 8.4 vs 19.7 ± 8.5weeks; $P = 0.004$) and delivery (37.5 ± 2.2 vs 38.4 ± 1.6; $P < 0.001$). Of 32 women with FG in 1st trimester ≥126 mg/dl, 34.4% had DM criteria, 18.8% IFG and 12.5% IGT at reclassification. At reclassification, women with DM criteria at 120′, were associated with IFG after delivery (OR = 24.17; IC95% 11.32–51.60), insulin therapy (OR = 7.40; IC95% 3.14–17.44), DG diagnosis at 60′ in 2nd trimester OGTT (OR = 3.85; IC 95% 1.30–11.40), newborn large for gestational age (LGA) (OR = 3.20; IC95% 1.59–6.46) and DG in previous pregnancy (OR = 2.59; IC95% 1.36–4.95). Women with IGT were associated with these risk factors and also age ≥35years (OR = 1.54; IC 95% 1.27–1.87).
Conclusion
The prevalence of glucose intolerance after delivery was 7.8%, with the majority of women (5.9%) being diagnosed with IGT, a condition with increased cardiovascular risk. DM was diagnosed in 0.8% of women, exclusively by glycaemia at 120′ in 57%. DM diagnosis at 120′ was associated with DG in previous pregnancy, DG diagnosis at 60′ in 2nd trimester OGTT, insulin therapy during pregnancy, newborn LGA and IFG after delivery. These data reinforces the importance of OGTT for correct reclassification of DG, with increased relevance in women with risk factors.

Relationship between circulating 25-hydroxyvitamin D and glucose homeostasis in women with postmenopausal osteoporosis

Verónica Ávila-Rubio[1], Beatriz García-Fontana[1,2], Cristina Novo-Rodriguez[1], Jesús Cantero-Hinojosa[3,4] & Manuel Muñoz-Torres[1,2,4]
[1]Bone Metabolic Unit, Endocrinology and Nutrition Division, Hospital Universitario San Cecilio, Instituto de Investigación Biosanitaria de Granada (Ibs.GRANADA), Granada, Spain; [2]CIBERFES, Instituto de Salud Carlos III, Madrid, Spain; [3]Unit of Internal Medicine, Hospital Universitario San Cecilio de Granada, Granada, Spain; [4]Department of Medicine, University of Granada, Granada, Spain.

Context
Postmenopausal osteoporosis (PMO) is associated with other comorbidities such as cardiovascular disease and impaired glucose homeostasis. Vitamin D insufficiency is highly prevalent, and may be a common link between these disorders. Recently, it has been shown that vitamin D may be involved in insulin resistance; however, this relationship has not been well evaluated in women with PMO.
Objective
To assess the relationship between circulating levels of 25-hydroxyvitamin D (25OHD) with parameters of glucose homeostasis in a cohort of women with PMO. Additionally, the threshold of 25OHD serum concentration was determined, from which influence at glucose homeostasis were observed in our study population.
Design and methods
Cross sectional study including 40 non obese women with PMO belonging to the coverage area of San Cecilio University Hospital in Granada (Spain). Clinical, anthropometric, bone mineral density and, biochemical parameters related to glucose metabolism (HbA1c, insulin, glucose homeostasis model [HOMA2-Calculator]) and mineral metabolism (25OHD, infracarboxylated osteocalcin [ucOC]) were determined. A descriptive analysis and a multiple linear regression analysis (significance <0.10) was performed.
Results
Mean values of the characteristics of the study population: age 62 ± 8.5 years; BMI 25.4 ± 3.9 kg/m^2; percentage of body fat (PBF) 33.9 ± 6.9%; lumbar spine T-score -2.9 ± 0.6 SD; femoral neck T-score -1.8 ± 0.7 S.D.; 25OHD 42.9 ± 19.8 ng/dl; HbA1c 5.4 ± 0.3%; ucOC 8.3 ± 10 ng/ml. Circulating levels of 25OHD were related to glucose metabolism parameters: negatively with HOMA2-IR ($R=-0.314$, $P=0.07$), HOMA2-%B ($R=-0.468$, $P=0.003$) and insulin levels ($R=-0.332$, $P=0.06$); and positively with HOMA2-%S ($R=0.368$, $P=0.02$); resulting in an indicator of insulin resistance independently of age, BMI, PBF and ucOC. The patients with serum 25OHD ≥45 ng/ml showed lower values on HOMA2-IR and HOMA2-%B indexes, lower insulinemia, and greater HOMA2-%S index.
Conclusions
Our results support the hypothesis that circulating 25OHD levels are related to glucose homeostasis and therefore constitute a modifiable cardiovascular risk factor in women with PMO.

Demographic and clinical factors associated with having ischemic heart disease as a multiple contributing causes of death among diabetes mellitus deaths in the United States and Brazil

Maaya Kita Sugai[1], Shuhei Nomura[1], Stuart Gilmour[1], Gretchen A Stevens[2] & Kenji Shibuya[1]
[1]The University of Tokyo, Tokyo, Japan; [2]World Health Organization, Geneva, Switzerland.

Introduction
Between-country comparability and validity of mortality statistics is a global public health challenge, especially for cause-of-death assignment of diabetes mellitus (here after diabetes) in relation to cardiovascular disease. The multiple contributing causes of death (MCD) representing comorbidity are not used to classify mortality cause, as the underlying cause of death (UCD) becomes the cause-of-death. Diabetes increases risk of ischemic heart disease (IHD). To aid in policy making for preventing IHD deaths as comorbidity of diabetes, this study determines demographic and clinical factors on having IHD as a MCD among deaths with diabetes as the UCD.
Methods
Death records including causes of death were obtained through the World Health Organization, which are originally from the Centers for Disease Control and Prevention (CDC) in the US for years 2012–2015, and from Sistema de Informação sobre Mortalidade in Brazil for years 2006-2009 and 2011-2013. A logistic regression analysis was conducted to identify factors associated with having IHD as a MCD among diabetes deaths.
Results
IHD appeared as the MCD in 38% and 16% of 305,885 deaths in the U.S and 367,717 deaths in Brazil that were deaths with diabetes as the UCD, respectively. Marital status, smoking, age, place of death, high cholesterol, and existence of autopsy were significantly associated to having IHD as a MCD in the two countries. In the U.S., in addition, race was significantly associated to having IHD as a MCD. In Brazil, significant factors also included assistance of medical staff, education, having hypertension, and obesity (P-values <0.05).
Conclusion
MCD could play a large role in better characterizing diabetes mortality estimates. Differences in existence of IHD as comorbidity of diabetes deaths were observed between the U.S. and Brazil. Factors identified in this study could help detect population subgroups with masked IHD among diabetes deaths. Representation of IHD comorbidity among diabetes deaths is needed for adequate public health measures to be taken, leading to lower mortality through a more target-specific intervention for non-communicable disease.

Gestational diabetes – association of lipid profile in pregnancy with post-partum dysglycemia

Sílvia Paredes, Aline Fernandes & Maria Lopes Pereira
Hospital de Braga, Braga, Portugal.

Introduction
Lipid profile characterization in women with gestational diabetes mellitus (GDM) and its impact on post-partum dysglycemia remains to elucidate. The aim of this study was to evaluate lipid profile in women with GDM during pregnancy and 8 weeks after and to study its correlation with glycemic control.
Methods
This study was carried out in a central hospital in Portugal. All women with GDM diagnosed from January/2014 to December/2015 were enrolled. A lipid profile was recorded during pregnancy and at post-partum reclassification and was later accessed. GDM diagnosis was made through fasting glucose or through OGTT glucose accordingly to international guidelines (IADPSG consensus panel, 2010).
Results
We included 448 women, mean age 33.49 ± 5.0 years, mean pre-pregnancy weight 68.61 ± 14.7 kg, mean BMI 26.35 ± 5.6 kg/m^2 and mean pregnancy weight gain 8.73 ± 5.5 kg. Post-partum, there was a statistically significant decrease of total (254.12 ± 50.7 vs 189.16 ± 36.4), LDL (LDL-c) (157.39 ± 44.6 vs 115.97 ± 33.3) and HDL (HDL-c) (67.52 ± 5.2 vs 55.12 ± 12.9) cholesterol and triglycerides (195.79 ± 62.1 vs 83.73 ± 46.9). In respect to lipid profile at pregnancy, we found a statistically significant correlation between c-HDL and OGTT glucose at 60′ ($r=-0.175$) and 120′ ($r=-0.343$) and between triglycerides and OGTT glucose at 120′ ($r=0.164$). In respect to post-partum, we found a statistically significant correlation between total and LDL-c and pre-pregnancy weight ($r=0.143$. $r=0.154$, respectively). LDL-c was also found to have a statistically significant correlation with OGTT glucose at 120′ ($r=0.178$), while HDL-c was found to have a statistically significant correlation with fasting glucose at the diagnosis ($r=-0.184$). Triglycerides presented a statistically significant correlation with fasting glucose at diagnosis ($r=0.460$) and with glucose at 120′ in the reclassification test ($r=0.169$).
Conclusion
There is a close relation between lipid and glycemic profile in women with GDM. Elevated glucose levels at the diagnosis of GDM seem to correlate with lower HDL-c and higher triglycerides in the post-partum period. Elevated 3rd trimester triglycerides correlate with a higher glucose levels at reclassification test, thus maternal hypertriglyceridemia during pregnancy can negatively influence glycemic control in the post-partum period.

Changes in the glutathione system in patients with impaired carbohydrate metabolism

Volha Shyshko[1], Tatjana Mokhort[1], Inna Buko[2], Elena Konstantinova[3], Natalia Tsapaeva[1] & Alena Sazonava[4]
[1]Belarussian State Medical University, Minsk, Belarus; [2]Center of Hygiene and Epidemiology, Minsk, Belarus; [3]Institute of Heat and Mass Transfer of the National Academy of Sciences of Belarus, Minsk, Belarus; [4]City Endocrinology Dispensary, Minsk, Belarus.

Introduction
Many studies have found that markers of oxidative stress (OS) are significantly increased in diabetes mellitus, but only a limited number of studies describe the disturbance of OS in pre-diabetes.
Objective
To study the state of the glutathione system in patients with disorders of carbohydrate metabolism and concomitant diseases of the cardiovascular system (CVS).
Materials and methods
181 patients were included under the age of 55 years: group 1–27 patients with newly diagnosed pre-diabetes without concomitant CVS diseases, group 2–28 patients with newly diagnosed pre-diabetes and the presence of concomitant IHD, group 3–20 patients with newly diagnosed pre-diabetes and the presence of concomitant IHD and peripheral vessels atherosclerosis, group 4–47 patients with type 2 diabetes (T2D), group 5–59 practically healthy persons. The total glutathione (GSHt) and glutathione in the oxidized form (GSSG) contained in the erythrocytes were measured by a glutathione reductase reaction. The redox potential of glutathione (Eh) of erythrocytes was determined by the Nernst equation.
Results
In group 1 GSHt and GSH were significantly lower, compared with group 3 ($p_{1\text{-}3}=0.012$, $p_{1\text{-}3}=0.053$, respectively). When compared with the group group 4, a significantly higher GSH content was detected ($p_{1\text{-}4}=0.068$). In the group 4 there was a significant decrease in GSH and 2GSH + GSSG, and an increase in GSSG, compared to group 2, group 3 and group 5 ($p_{4\text{-}2}=0.006$, $p_{4\text{-}3}=0.006$, $p_{4\text{-}5}=0.003$, $p_{4\text{-}2}=0.005$, $p_{4\text{-}3}=0.009$, $p_{4\text{-}5}=0.014$, respectively, and $p_{4\text{-}2}=0.005$, $p_{4\text{-}3}=0.016$, $p_{4\text{-}5}=0.001$, respectively). According to the results of the study, the highest concentration of glutathione (5.11 [1.98, 5.78]) was in the group 2. The presence of concomitant IHD decreases the ability of glutathione to recover, as evidenced by the significantly lower values of GSH and GSHt in group 4, compared to group 1 ($p_{4\text{-}1}=0.004$, $p_{4\text{-}1}=0.016$, respectively), and an increase GSSG ($p_{4\text{-}1}=0.004$). Eh was significantly higher in group 4 than in groups of 1,2,5 ($p_{4\text{-}1}=0.035$, $p_{4\text{-}2}=0.013$, and $p_{4\text{-}5}=0.055$).
The conclusion
The state of the glutathione system can be considered as one of the markers of vascular lesion in patients with prediabetes. At the stage of pre-diabetes, the patient rarely has complaints typical of cardiovascular diseases. However, at this stage, the mechanisms that lead to the development of complications in the subsequent already type 2 diabetes mellitus begin to form.

The effect of the dopamine agonist cabergoline on insulin sensitivity in the skeletal muscle: an *in vitro* study in a mouse cell model demonstrating mediation by serotoninergic receptors

Mariarosaria Negri, Claudia Pivonello, Gilda Di Gennaro, Cristina de Angelis, Chiara Simeoli, Davide Iacuaniello, Immacolata Cristina Nettore, Paolo Emidio Macchia, Giovanna Muscogiuri, Annamaria Colao & Rosario Pivonello
Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Università Federico II di Napoli, Naples, Italy.

Insulin resistance (IR), characterized by an impairment of target tissues to insulin responsiveness, is the core defect preceding diabetes. Preclinical and clinical data have suggested a role for the dopaminergic system in glucose homeostasis control. The aim of the current study was to investigate the role of the dopamine agonist cabergoline (CAB), displaying high affinity for dopamine type 2 (DR2) receptor and low affinity for serotonin receptors (5-HTRs), in the regulation of muscle IR. An *in vitro* model of mouse skeletal muscle (C2C12) has been used in baseline and IR palmitate (1 mM for 16 h)-induced conditions. DRs and 5-HTRs messenger and protein levels have been evaluated by RT-qPCR and WB, respectively. DR2 protein expression has been analyzed also through liquid chromatography tandem-mass spectrometry (LC-MS/MS). The effect of escalating doses of CAB (10^{-10} M, 10^{-8} M, 10^{-6} M) alone or combined with $2*10^{-8}$M insulin on glucose uptake (GU) was evaluated by a colorimetric assay, while intracellular signaling has been investigated by WB. To evaluate GLUTs translocation, membrane proteins have been isolated from cytoplasmic proteins and analyzed by WB. As revealed by RT-qPCR and WB, C2C12 did not express DRs but expressed messenger and protein levels of 5-HT2RA and B. LC-MS/MS confirmed the complete absence of D2 protein. In C2C12 at baseline condition, the percentage (%) of GU was significantly stimulated by 10^{-10} M and 10^{-8} M CAB, either alone or combined with insulin. A significant increase of IRS-1 Tyr608 and Akt Ser473 phosphorylation levels as well as membrane GLUT4 translocation were shown after the 10^{-8} M CAB combined with insulin exposure, suggesting that CAB might stimulate GU by activating insulin receptor (INS-R) signaling. In condition of IR, C2C12 exposed to 10^{-6} M CAB with insulin showed a significant increase of % GU as well as GLUT1 membrane translocation after 10^{-6} M CAB alone. Moreover, 10^{-6} M CAB either alone or combined with insulin triggered a significant increase of pAMPK Thr172 and a significant decrease of pERK Thr202/Tyr204, suggesting that in IR state, CAB might stimulate glucose internalization through AMPK pathway independently from INS-R signaling activation. Pre-treatment with 5-HT2RA (altanserin) and 5-HT2RB (Ly272015) antagonists inhibited CAB-regulated intracellular signaling and GU suggesting that CAB acts through 5-HTRs. In conclusion, these data show that CAB induces muscle GU both at baseline and IR conditions by improving insulin and AMPK pathways respectively, through the serotoninergic pathway.

Eating habits, food choices and physical activity in adult patients with type 1 diabetes mellitus

Eleftheria Barmpa, Christina Tsiouma & Alexandra Bargiota
Department of Endocrinology and Metabolic Diseases, University of Thessaly, Larissa, Greece.

Introduction
Eating habits, food choices and exercise affect glycaemic control in patients with Type 1 Diabetes Mellitus (T1DM). The purpose of this study was to evaluate eating behaviors, food choices and the level of physical activity in patients with T1DM.
Methods/design
A random sample of 84 patients (M/F: 31/53) with T1DM, aged 34 + 11.9 years, living in central Greece, were individually interviewed. Food consumption was assessed by a semi-quantitative food-frequency questionnaire and adherence to the Mediterranean diet (MedDiet) was evaluated using the KIDMED questionnaire. Physical activity also assessed by validated questionnaires. Information was collected regarding self-perceived body size, dietary knowledge, control for eating, meal and snack frequency and eating out of home. Height, weight, BMI and waist circumference (WC) were also measured. Glycemic control was assessed by glycated hemoglobin.
Results
Mean BMI was 24.5 + 5.3 kg/m^2 and about half patients (48.9%) were overweight or obese (BMI >25 kg/m^2). Mean WC was 92.7 + 11.2 cm (M: 98.5 + 12.2 cm and F: 89 + 9.2 cm) and HbA1c was 7.7 + 1.7%. Body image concerns, education about food, personal control for eating and the presence of diabetes are factors found to affect food choices. Regular meals at home were frequent, 75% reported to have breakfast daily, 58% have a midmorning snack, 99% eat lunch and dinner daily and 46.4% have a snack before bed. Eating out with friends and/or family and eating at work was related to higher consumption of 'junk type of food'. Only 33.3% of patients reported high adherence to MedDiet (KIDMED index >8), 54.8% reported moderate (KIDMED index 4–7) and 11.9% reported low (KIDMED index ≤ 3) adherence to MedDiet. 13.1% of patients reported a high physical activity level and 22.6% reported moderate levels at least three times per week. The great majority (64.3%) of patients had low levels or no regular physical activity. No correlation was found between HbA1c levels and adherence to MedDiet ($r=0.432$, $P=0.298$). HbA1c levels were negatively correlated with the level of physical activity ($r=-0.233$, $P=0.00$).
Conclusion
The presence of diabetes, personal issues, peers and family affect food choices in patients with T1DM. As physical activity remains low and the prevalence of obesity is increasing in this group of patients, implementation of multilevel strategies is necessary for improving glycaemic control and avoiding weight gain.

Preconception management in type 2 diabetes mellitus (T2DM): there is still much work to do

Irene Berges-Raso[1], Lara Albert[1], Ismael Capel[1], Albert Cano-Palomares[1], Laia Casamijana[1], Isabel Mazarico[1], Maria Florencia Luchtenberg[1], Jordi Costa[2] & Mercedes Rigla[1]
[1]Department of Endocrinology and Nutrition, Parc Taulí Hospital Universitari, Institutd'InvestigacióiInnovació Parc Taulí I3PT, Universitat Autònoma de Barcelona, Sabadell, Spain; [2]Department of Obstetrics and Gynecology, Parc Taulí Hospital Universitari, Institutd' Investigació iInnovació Parc Taulí I3PT, Universitat Autònoma de Barcelona, Sabadell, Spain.

Background
Preconception planning is essential for a successful pregnancy in women with pregestational diabetes,although many women still do not plan their pregnancies. The rapid outbreak of T2DM among the general population, including women of childbearing age, is one of the largest public health issues. The aim of this study is to describe time trends in preconception planning, obstetric and perinatal outcomesduring the past 8 years in ourpregestational care unit, focusing on T2DM.
Material and methods
We performed a retrospective case study of all deliveries of pregnant T2DM or T1DM women followed in our unit from 2009 to 2016 ($n=114$). Wedescribed clinical data, preconception care, pregnancy and neonatal outcomes, comparing the results: 1) among T1DM ($n=68$) and T2DM ($n=46$) and 2) T2DM pregnancies between different periods of time (2009–2012 vs. 2013–2016). We analyzeddata, evaluating differences using χ^2 test, Student' *t*-test or Mann–Whitney test.
Results
As compared with T1DM pregnant, T2DM pregnant wereolder (age: 33.9 ± 4.9 vs. 31.0 ± 4.5 years [mean ± S.D.]; *P* 0.002) and had less duration of diabetes (2 (1–5) vs. 14 (6–20.8) years [median (P25–P75)]; *P* 0.000). T2DM had less preconception care (15.2 vs 54.4%; *P* 0.000) and higher parity (nulliparous: 15.2 vs 42.6%; *P*0.002). 40% of T2DM pregnantwere obese (17.9% of T1DM; *P* 0.01) but had less total pregnancy weight gain (4.9 (2.6–10.1) vs. 11.2 (5.1–14.3) kg; *P* 0.001). No differences between HbA1c levels at pregnancy diagnosis (6.7% (6.1–7.4)) or during 1rst trimester (6.5% (6.0–7.2)) were detected, butduring 2nd and 3rd trimester T2DM were more likely to achieve lower glucose levels (HbA1c: 5.7%(5.6–6.1) and 5.9% (5.6–6.2) vs. 6.2% (5.8–6.5) and 6.3% (5.9–6.5);*P* 0.000 and *P* 0.001). There were no differences in obstetric and perinatal outcomes between T1DM and T2DM (risk of preeclampsia (PE): 8.8%, preterm delivery: 16.7%, cesarean section: 45.6%, newbornlarge for gestational age: 33.3%, neonatal hypoglycemia: 23%, congenital malformations: 20.2%, newborn's admission to intensive care unit (ICU): 24.8%, perinatal mortality: 1.8%). Between 2013 and 2016, compared to the preceding 4 years, T2DM had more total pregnancy weight gain (7.2 (4.3–10.7) vs 2.9(1.3–5.1) kg; *P* 0.008) and a tendency of less pregnancy preparation (8.3 vs 22.7%; *P* 0.175). There was less proportion of PE (2.2 vs 15.6%; *P* 0.016) and less neonatal hypoglycemia (2.2% vs 15.6%; *P* 0.016) with no statistically significant differences in other outcomes, although a trend towards improvement was detected regarding preterm birth (8.3% vs 22.7%), c-section (25% vs 50%), newborn's admission to ICU (13% vs 22.7%), and malformations (12.5% vs 18.2%).
Conclusion
Risk of pregnancy outcomes in T2DM pregnant are as high as in T1DM. Lately only 8.3% of T2DM had preconception management. It is crucial to enhance the need for pre-pregnancy preparation in this group to improve health outcomes.

Kinky and sparse hair as an associated finding inmaternally inherited diabetes and deafness

Gülay Karagüzel[1], Alper Han Çebi[2] & Elif Sağ[3]
[1]Karadeniz Technical University, School of Medicine, Department of Pediatric Endocrinology, Trabzon, Turkey; [2]Karadeniz Technical University, School of Medicine, Department of Genetics, Trabzon, Turkey; [3]Karadeniz Technical University, School of Medicine, Department of Pediatric Gastroenterology, Trabzon, Turkey.

Background
Maternally inherited diabetes and deafness (MIDD) is a rare form of diabetes due to defects in mitochondrial DNA (mtDNA). Maternal transmission of diabetes and neurosensorial deafness are the main clinical features of MIDD followed by other mitochondrial disorders, myopathies, and macular dystrophy. 3243 A > G is the mutation most frequently associated with this condition, but also other mtDNA variants have been linked with MIDD. We describe the case presenting with hyperglycemia and hair findings diagnosed as MIDD.
Case report
A 9-year-old boy was referred to our clinic for hyperglycemia. He was the third child of consanguineous healthy parents. He had previously diagnosed bilateral neurosensorial deafness and he was wearing a conventional hearing aid. His weight was 24 kg (3–10.p), height 132 cm (50.p), and BMI 13.8 kg/m^2. He had kinky, sparse, and ivory hairs. Fundus examination was normal, maculopathy was not detected. There was no hepatomegaly or splenomegaly. On laboratory; his glycated hemoglobin (HbA1c) was 6.6%, hemogram, thyroid, hepatic and renal function tests were normal. Celiac and diabetes-related (islet cell antibody, anti-glutamate decarboxylase, insulin auto antibody) antibodies were negative. Serum copper and zinc levels were normal. Electromyogram was normal. The whole mtDNA analysis was revealed TRNL1 gene the mutation.
Conclusions
Determination of the mitochondrial origin of diabetes is important for genetic counseling and clinical care. The whole mtDNA should be screened because the 3243A > G variant is not as frequent in children as in adults for MIDD our patient's hair features was suspected Menkes Kinky hair disease and zinc deficiency. The brittle, tangled, sparse, steely or kinky hairs that are often white, ivory, or gray in color with easy pluckability are main findings for Menkes Kinky hair disease is an X-linked recessive trait caused by mutations in the ATP7A gene leading to disturbed copper metabolism. However, our patient's serum copper and zinc levels were normal.

P391

Stiff - person syndrome in an old woman with late onset type 1 diabetes mellitus

María Florencia Luchtenberg, Ismael Capel, Isabel Mazarico, Albert Cano, Lara Albert, Laia Casamitjana, David Subías, Jose Miguel Martinez, Assumpta Caixàs & Mercedes Rigla
Hospital Parc Taulí, Sabadell, Spain.

Introduction
Stiff person syndrome (SPS) is a rare neurological disease resulting in stiffness and spasm of muscles and, as a consequence, severely impaired ambulation. Pathophysiology of the disease is based on an increased muscle activity caused by the decreased level of the inhibitory neurotransmitter gamma-aminobutyric acid (GABA) due to an autoimmune attack against glutamic acid decarboxylase (GAD); enzyme which is also one of the main autoantigens of type 1 diabetes mellitus (DM). SPS is often associated with autoimmune disorders and it may rarely occur as a paraneoplastic syndrome. We present a singular case of SPS in a woman with late onset type 1 DM.
Case report
A 74 years old woman had been recently diagnosed with type 2 diabetes due to a mild hyperglycemia. Treatment with metformin was started but few months later she developed polyuria, polydipsia and weight loss (BMI 24.5 kg/m^2). She was referred to our center and insulin therapy was initiated as well as autoimmunity study was requested. Blood test showed anti GAD level of 3701.9 U/ml (normal range: 0–3.9) with a very low C peptide (0.21 ng/ml, normal range: 0.9–4) so, she was diagnosed with type 1 DM. Two years later she presented with progressive gait disturbance and rigidity of lower limbs. Neurological examination revealed dystonia and tremors in lower extremities as well as areflexia in both Achilles tendons. Routine laboratory tests including complete blood count, chemistry profile, creatinine kinase, C-reactive protein and thyroid function were in the normal range. Brain and cervical spine MRIs were unremarkable but electromyography (EMG) observed continuous motor unit discharge and simultaneous co-contraction in lower extremities. SPS diagnostic was made based on the clinical findings, EMG results and a positive therapeutic response to diazepam. Treatment with benzodiazepines, gabapentin, intravenous immunoglobulin and mycophenolate was started with significant improvement observed in the follow-up.

Conclusions
SPS is a rare condition but it should be considered in any patient with bizarre gait disorder and autoimmune disease, especially type 1 DM, in order to prevent delay in diagnosis and long-term neurologic disability.

Autoimmune hypoglycemia in a patient with slow type 1 diabetes

Bouizammarne Ilham, El Mghari Ghizlane & El Ansari Nawal
Department of endocrinology, Diabetes and metabolic diseases, Marrakesh, Morocco.

Introduction
Hypoglycemia is rarely due to an auto-immune etiology, which is the presence in the serum of the patient of anti-insulin or anti-insulin receptor antibodies. The present case is of a slow type 1 diabetic patient in whom the autoimmune origin of repeated hypoglycemia was found.
Case
A 58 years old female patient, Who is a slow type 1 diabetes carrier, and has been on premixed human insulin for 4 years, the patient presented repeated episodes of hypoglycemia: both nocturnal and late postprandial. She also denied skipping meals or having any drug intake that is likely to cause hypoglycemia, the search for signs in favor of gastroparesis was negative, and no family history of Autoimmune disease was found. Physical Examination revealed a conscious patient, glucose blood level was 0,6 g/l, No lipodystrophy was found. Blood tests showed normal liver and kidney function, Cortisol level at 8 AM was 15 µg / dl; after stimulation (Synacthen test): 26 µg / dl, Anti-transglutaminase IgA antibody detection was negative with absence of IgA deficiency), High levels of anti-insulin antibodies was discovered; it returned higher than 50 IU/ml, The diagnosis of autoimmune hypoglycemia was confirmed by the high level of the Anti-insulin antibodies. The indication for corticosteroid therapy was made alongside the use of the insulin analogue.
Conclusion
Autoimmune hypoglycemia is considered a rare etiology of hypoglycemia, human insulin remains as an immunogenic product that induces the secretion of specific antibodies, especially among patients with autoimmune diseases.

Insulin resistance in diabetes mellitus type 1, and its association with cardiovascular disease, sex hormones

Diana Simoniene[1], Dzilda Velickiene[1,2] & Aksana Platukiene[2]
[1]The Hospital of Lithuanian University of Health Sciences Kauno Klinikos, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Kaunas, Lithuania.

Objective
The aim of the study was to determine frequency of insulin resistance, in individuals with type 1 diabetes mellitus and the link between insulin resistance and cardiovascular disease, sex hormones. The task of the research is to determine the frequency of insulin resistance among people with diabetes mellitus type 1. To determine association between eGDR and age, sex, cardiovascular disease, chronic complications of diabetes and sex hormones. To determine association between insulin resistance and duration of disease, body mass index, chronic complications of diabetes mellitus. To determine eGDR cutoff value when chronic complications of diabetes are more frequent. To find the association between insulin resistance and cardiovascular disease among people with diabetes mellitus type 1.
Research design and methods
The study is a part of an international research 'Litdiane'. The study involved 200 people, with type 1 diabetes mellitus, over the age of 18 years. With reference to survey and information from medical records, performed the data analysis. Insulin resistance is associated with eGDR. It was calculated by the following formula eGDR = 24.31- 2.22(LKS)-3.29 (AH)-0.57 (HbA1c%). Estimated glucose disposal rate was divided into tertiles. One – way ANOVA were used to contrast means between eGDR groups. To determine the influence of factors multinomial logistic regression method was applied. The data was considered statistically significant at $P < 0.05$.
Results
Cutoff value of eGDR which shows resistance of insulin is <6.4 mg/kg/min. When eGDR is <6.4 mg/kg/min, diabetic complications were more common. eGDR is statistically significantly lower for patients with chronic complications of diabetes mellitus ($P < 0.001$), and for patients with cardiovascular diseases (5.5 ± 2.4 mg/kg/min ($P < 0.001$)). eGDR has the highest influence on cardiovascular diseases occurrence ($P = 0.004$). SHBG concentration is positively associated with higher eGDR. Testosterone levels are related with resistance of insulin in type 1 diabetes patients.
Conclusions
Diabetic complications are more common when eGDR is <6.4 mg/kg/min. Insulin resistance was found for 33.5% of patients. The resistance of insulin is statistically significantly associated with micro- and macro-vascular complications. Insulin resistance statistically significantly affects progression of cardiovascular disease. Smoking, male gender, low testosterone level, duration of disease were associated with resistance of insulin.

Mitochondrial diabetes in 40 patients belonging to 30 Tunisian families: phenotypic and genotypic heterogeneity

Wajdi Safi[1], Mouna Tabbabi[2], Faten Hadj Kacem[1], Imene Gargouri[1], Mouna Elleuch[1], Salwa Sassi[1], Mouna Mnif Feki[1], Faiza Fakhfakh[2] & Mohamed Abid[1]
[1]Endocrinology Department, Hedi Chaker Hospital, Sfax, Tunisia; [2]Laboratory of Molecular and Functional Genetics, Faculty of Sciences of Sfax, Sfax, Tunisia.

Introduction
Mitochondrial diabetes (MD) is characterized by a broad spectrum of phenotypic and genotypic involvement. Through a cohort study of 40 patients with DM, we tried to correlate this diversity of phenotypic expression with the biomolecular substratum of the mitochondrial genome in the Tunisian population.
Results
Epidemiologically and anthropometrically, our series fits the literature data with age at 31.6 years (5–52), female predominance (82.5%) and normal BMI in 60% of cases. Diabetes was MIDD2 in ¾ cases, with a significantly higher incidence of diabetic retinopathy 42.5% versus 8-13% in the literature. Regarding the extra-pancreatic manifestations, reticular macular dystrophy, very characteristic of DM, was absent in all our patients; as well as retinitis pigmentosa (15% of cases versus 57–86%). Perceptive deafness, classically almost constant, was only present in half of the cases. A dilated cardiomyopathy was found in only 1 case versus 18 to 34% in the literature. The biomolecular study of the mitochondrial genome revealed the absence of the most frequently described mutation associated with DM: m.3243A > G (tRNA Leu). This led us to look for the mutation m.14709T > C (tRNA Glu), found in 6 patients belonging to three different families, however the study of the heteroplasmic rate in 2 families did not reveal a correlation with the spectrum of phenotypic involvement. In addition, sequencing of the entire mitochondrial genome has revealed other polymorphisms not described in the literature and having a key role in the functioning of the mitochondrial respiratory chain.
Conclusion
Our cohort is characterized by a phenotypic and genotypic heterogeneity. It seems that the m.3243A > G mutation is not specific to our Tunisian population and that the m.14709T > C mutation was more frequent. A larger scale study is needed to determine the impact of heteroplasmic rate on the spectrum of phenotypic involvement.

DOI: 10.1530/endoabs.56.P394

Hyperandrogenaemia in women with type 1 diabetes mellitus; associations with lipids and lipoprotein particle size, and early vascular disease

Anjuli Gunness[1], Agnieszka Pazderska[1], Mohamed Ahmed[1], Anne McGowan[1], Niamh Phelan[1], Gerard Boran[1], Angela Taylor[2], Michael O'Reilly[2], Wiebke Arlt[2], Kevin Moore[1], Lucy Ann Behan[1], Mark Sherlock[1] & James Gibney[1]
[1]Department of Endocrinology, Adelaide and Meath Hospital, Tallaght, Dublin 24, Ireland; [2]Institute of Metabolism and Systems Research (IMSR), University of Birmingham, Edgbaston, Birmingham, UK.

Hyperandrogenaemia and polycystic ovary syndrome (PCOS) are common in women with Type 1 diabetes, but it is not known if they contribute to increased cardiovascular risk. We aimed to compare associations between androgen levels, lipid variables and early atherosclerosis in reproductive-age women with and without T1DM. 87 (16 with PCOS) women with T1DM (mean $\pm$ SD; age 28.7 $\pm$ 6.1yrs, BMI 25.4 $\pm$ 4.4kg/m^2), and 87 (16 PCOS) nondiabetic women (mean $\pm$ SD; age 31.8 $\pm$ 5.9yrs, BMI 28.3 $\pm$ 4.01kg/m^2), were studied. Androgens (LCMS), plasma lipids and lipoprotein subclasses (polyacrylamide-gel-tube-electrophoresis) and carotid-intima-media-thickness (CIMT), a validated marker of atherosclerosis were measured. In non-diabetic women SHBG correlated negatively and free testosterone positively with VLDL($r=-0.37$/$r=0.32$), triglyceride (TG) ($r=-0.26$/$r=0.28$) and TG/HDL-C ratio($r=-0.28$/$r=0.29$) while DHEAS correlated negatively with LDL-C($r=-0.29$) ($P<0.05$ for all). In T1DM, SHBG correlated negatively($r=-0.26$) and free testosterone positively($r=0.22$) with TG and TG/HDL-C ratio($r=0.24$) while androstenedione correlated positively with TC($r=0.24$), VLDL ($r=0.32$) and LDL-C($r=0.32$) ($P<0.05$ for all). TC, LDL-C and TG were not associated with CIMT in either group, but VLDL($r=0.59$, $P<0.0001$) and the proportion of atherogenic small-dense LDL (sdLDL, $r=0.24$, $P=0.04$) correlated with CIMT only in women with T1DM. Androgens did not correlate with CIMT in either group. In summary, in T1DM and nondiabetic women, SHBG and free testosterone correlated with lipid and inflammatory markers characteristic of insulin resistance, but did not correlate with CIMT. VLDL and sdLDL were associated with CIMT in T1DM only. These results do not support a role of hyperandrogenaemia in atherogenesis in T1DM. The role of VLDL and sdLDL in early atherogenesis in T1DM requires further exploration.

Association of the FTO gene rs9939609 polymorphism with carbohydrate metabolism disorders in the Republic of Tatarstan

Farida Valeeva, Ildus Ahmetov, Tatyana Kiseleva, Kamilya Khasanova, Elizaveta Sozinova & Elena Valeeva
Kazan State Medical University, Kazan, Russian Federation.

Aim
To investigate the possible association of the FTO gene rs9939609 polymorphism with different disorders of carbohydrate metabolism in residents of the Republic of Tatarstan.
Materials and methods
A total of 237 patients with a single history of hyperglycemia were examined. They underwent an oral glucose tolerance test on a BS-200E Mindray analyzer. 198 patients from the whole cohort had various disorders of carbohydrate metabolism, so they were included in the study. The patients were divided into several groups: 110 people with type 2 diabetes mellitus (DM2), 46 with hyperinsulinism, 29 with impaired glucose tolerance, and 13 with impaired fasting glycemia. DNA was isolated from whole blood, followed by analysis of gene polymorphisms with real time polymerase chain reaction (TestGen). The distribution of patient's genotypes and alleles was compared with the control group consisting of residents of the Republic of Tatarstan without carbohydrate metabolism disorders ($n=851$).
Results
The frequency of alleles and distribution of genotypes of the A/T polymorphism of the FTO gene in the control and study groups corresponded to the Hardy-Weinberg distribution ($\chi^2=1.13$, $P=0.29$ and $\chi^2=0.72$, $P=0.4$, respectively). The distribution of genotypes (AA - 33%, AT - 50%, TT - 17%) and alleles (A - 58%, T - 42%) in individuals with DM2 significantly differed from the control group (AA - 14%, AT - 44.5%, TT - 41.5%, A allele - 36.3%, T allele - 63.8%, OR = 2.38, $p<0.0001$). Significant differences from controls have also been noticed in distribution of genotypes of patients with other disorders of carbohydrate metabolism: with hyperinsulinism (AA - 47.8%, AT - 34.8%, TT - 17.4%, A allele - 65.2%, T allele - 34.8%, OR = 3.3, $P<0.0001$); with impaired glucose tolerance (AA - 55.2%, AT - 34.5%, TT - 10.3%, A allele - 72.4%, T allele - 27.6% OR = 4.62, $P<0.0001$); with impaired fasting glycemia (AA - 30.8%, AT - 53.9%, TT - 15.4%, A allele - 57.7%, T allele - 42.3%, OR = 2.38, $P=0.04$).
Conclusion
The association of the FTO gene with the risk of developing DM2 in Republic of Tatarstan has been proved, which is also confirmed by the results of other studies. The positive correlation of the FTO gene A allele with early carbohydrate metabolism disorders was revealed, which allows to identify groups of increased risk for violations of carbohydrate metabolism. Apparently, the A/T polymorphism of the FTO gene is mostly associated with the secretory function of pancreatic beta cells.

Reactive hypoglycaemia – a debilitating condition

Bonnie Grant, Caoimhe Bonner, Yun-ni Lee, Augustine William, Raj Tanday, Anna Hawkins, Edel Casey & Khash Nikookam
Department of Endocrinology, Barking Havering and Redbridge University NHS Trust, Greater London, UK.

Although there are no formal diagnostic criteria, reactive hypoglycaemia is a term generally used to describe hypoglycaemia occurring within a few hours after meal intake where other causes of hypoglycaemia such as medications, cortisol deficiency and insulinoma have been excluded. Although this is considered a benign, easily managed condition here we present three cases of reactive hypoglycaemia with significant debilitating symptoms. The first case is a 26-year-old man who was referred to the Endocrine clinic following an episode of complete loss of consciousness after two pints of beer and another episode where he was found to be unrousable in the morning with a capillary blood glucose of 3.1mmol/l. He described a history of one stone weight loss over six months alongside symptoms of headache, dizziness, nausea and lethargy occurring 2–5 h after meals. An oral glucose tolerance test arranged by the general practitioner found capillary blood glucose of 2.7 mmol/l at 2 h. Subsequent extended oral glucose tolerance test over 5 h revealed symptomatic hypoglycaemia with serum glucose levels as low as 1.6 mmol/l at 2.5 h. The second case is a 58-year-old lady referred after having a pre-syncopal episode while driving and was found to have a capillary blood glucose of 3.0mmol/l in the Emergency Department. She also described episodes of feeling unsteady on her feet and her legs giving way associated with a craving for sweet foods a few hours after oral intake. There was nothing of note on her past medical history. She experienced symptomatic hypoglycaemia with a serum glucose of 3.9 mmol/l at 3 h following extended oral glucose tolerance test. The third case is a 44-year-old lady who presented with symptoms of dizziness and unsteadiness on her feet occurring around 3.5 h after eating lunch which resolved after having a sugary drink or food. Following an extended oral glucose tolerance test she experienced moderate hypoglycaemia with serum glucose of 2.3 mmol/l at 3 h with sweatiness and light-headedness.
Conclusion
The above three cases highlight the significant morbidity and potentially severe symptomatology associated with reactive hypoglycaemia. This should be considered in patients presenting with multiple symptomatology in particular syncope and pre-syncope following a meal as awareness of the same enables us to manage and control reactive hypoglycaemia by less but more frequent intake of a balanced diet.

Metabolic syndrome in patients with latent autoimmune diabetes of adults (LADA)

Fatima Zahra Zaher, Ghizlane Elmghari & Nawal Elansari
Department of Endocrinology, Diabetes, Metabolic Diseases and Nutrition, Mohammed VI University Hospital, Marrakech, Morocco.

Introduction
Latent autoimmune diabetes in adults (LADA) is an endocrine disorder characterized by a progressive destruction of pancreatic beta cells by an autoimmune mechanism leading to absolute insulin deficiency. However, recent studies have shown the presence of a certain degree of insulin resistance in LADA patients, hence the possibility of the existence of a metabolic syndrome in these patients. The purpose of our work is to evaluate the presence of metabolic syndrome among our LADA patients.
Patients and methods
Our study has included 27 patients followed for LADA. Anthropometric measures, measurement of blood pressure and lipid status were ordered in all patients. Metabolic syndrome was diagnosed on IDF criteria.
Results
The mean age of patients was 47.6 years and the mean age of discovery was 39.7 years. The sex ratio was 1.4 with a female predominance. 50% of our patients have normal BMI, 15.3% are thin, 15.3% are overweight and 19.2% are obese. Waist circumference was pathological in 57% of patients and 19.2% had hypertension. Hypertriglyceridemia was present in 14.8% of patients and hypo HDLemia in 22.2%. Metabolic syndrome was found in 22.2% of patients according to WHO or IDF criteria.
Conclusion
Our study showed that LADA patients may have a metabolic syndrome, and that the presence of the latter does not exclude the diagnosis of LADA. One could also think of the benefit of insulin sensitizers in the management of LADA diabetes.

Gestational diabetes and postpartum follow up

Yasmine Driouich, Siham El Aziz, Salma Bensbaa & Asma Chadli
Endocrinology, Diabetology and Metabolic Diseases – Department Ibn Rochd University Hospital, Casablanca, Morocco.

Introduction
Gestational diabetes mellitus (GDM) is an important public health issue because of its frequency and its risk of progression to T2DM. Risk of subsequent type 2 diabetes is associated with quality screening and to certain risk factors.
Objective
The aim of our study was to assess the evolving risk of GDM to type 2 diabetes, and to find its significant predictive factors.
Methods
We report a retrospective study from January 2016, aboutpatients followed at the Ibn Rochd University Hospital of Casablanca's Endocrinology – Diabetology department for gestational diabetes. The parameters studied were age, GDM's recurrence, family history of diabetes, pre-gestational BMI, pregnancy term at GDM's discovery, initial fasting glucose, treatment adopted, taking weight during pregnancy, delay of postpartum screening, and means of screening. Statistical analysis was univariate for all the variables using SPSS version 22.0.0.
Results
Mean age of our patients was 32.4 ± 6.5 years. Two thirds of the patients were between the ages of 30 and 40. The average gestational diabetes' term diagnostic was 20.2 ± 0.45 weeks of gestation. Family history of Diabetes was found in 68% of cases. During pregnancy, insulin therapy was required in 59% of the patients. Screening for dysglycemia was 1.5 to 16 months post-partum (average 6 months). An OGTT 75g was made in 47 patients (62.7%). In contrast, 9.3% of the study population benefited only from fasting blood glucose and HbA1c. We noted that 21% were lost to follow-up. Type 2 diabetes was diagnosed in 22 patients (25.5%), moderate fasting hyperglycemia in 8 patients (9.5%), carbohydrate intolerance in 12 patients (14%). The only factor significantly associated with development of diabetes has been the use of insulin during pregnancy ($P=0.02$). The FPG and HbA1c initially high were frequently associated, without having a significant impact.
Discussion
Consistent with the literature, our results reflected a high incidence of postpartum dysglycemia in our population, hence the importance of an initial awareness and extended follow-up, with a particular attention for use of insulin during pregnancy.

Glycemic variability and diabetes-related antibodies titer at diagnose in type 1 diabetic patients: is there a correlation?

Adriana De Sousa Lages[1,2], Luís Cardoso[1,2], Carla Baptista[1], Luísa Barros[1], Patrícia Oliveira[1], Diana Oliveira[1,2], Mara Ventura[1,2], Nelson Cunha[1], Diana Catarino[1], Lúcia Fadiga[1] & Francisco Carrilho[1]
[1]Coimbra Hospital and University Center, Coimbra, Portugal; [2]Faculty of Medicine, Coimbra University, Coimbra, Portugal.

Introduction
Type 1 Diabetes (DM1) is associated with a destructive autoimmune process of pancreatic b-cells. The presence of anti-islet cells (ICA) antibodies (Ab), as well as for distinctive antigens – GAD65, IA2 or Insulin (IAA) - is related to the disease development.
Aim
To evaluate the effect of DM1 antibodies on the measures of glycemic variability (GV) obtain through continuous glucose monitoring (CGM).
Materials and methods
Were included 41 patients with DM1 who performed CGM, corresponding to 7872 h of CGM. Analytic and clinical data were obtained through patient's individual process and hospital's electronic process consultation. Data from the CGM was obtained using iPro2 Medtronic®. Statistical analysis was performed on SPSS Statistics v.25®. We included as measures of GV: Mean Tissue Glucose, Standard-Deviation (SD), *CONGA, LI, JINDEX, LBGI, HBGI, GRADE, MODD, MAGE, ADDR, M-value* e *MAG*.
Results
Patients were stratified in two groups (1: patients with £2 different classes of positive Ab ($n=28$) *vs* 2: patients with >2 different classes of positive Ab ($n=13$)). We found significant differences between groups regarding disease duration 17.03 ± 8.6 vs. 14.15 ± 8.9; $P=0.004$), age (32.39 ± 10.6 vs. 25.15 ± 7.17; $P=0.000$) and HbA1c (7.93 ± 0.93 vs. 7.58 ± 1.02; $P=0.013$) at the MCG date. Concerning different measures of GV, we also found significant differences related to mean tissue glucose (8.88 ± 2.3 vs. 8.23 ± 2.2; $P=0.021$), *CONGA* (7.68 ± 2.2 vs 7.13 ± 2.1; $P=0.036$), JINDEX (48.78 ± 23.2 vs 43.42 ± 24.5; $P=0.02$), HBGI (10.44 ± 6.6 vs 8.97 ± 6.5; $P=0.037$), GRADE (8.05 ± 4.7 vs 6.89 ± 4.5; $P=0.042$), MODD (4.01 ± 1.1 vs 3.41 ± 1.1; $P<0.001$) and ADDR (30.22 ± 9.8 vs. 26.02 ± 10.5; $P=0.006$). We established a significant correlation between Ab anti-GAD65 ($r_s=-0.137$; $P=0.031$) and Ab anti-IA2 ($r_s=0.23$; $P=0.017$) and GRADE measure. When the model was adjusted for potential confounding variables, namely disease duration, we still observed an inverse correlation between variability and presence of Ab and ADDR measure ($P=0.003$).
Conclusions
In our sample, we found significant differences between the number of Abs and several measures of GV (Mean, *CONGA, JINDEX, HBGI, GRADE, MODD, ADDR*). However, after adjusting the data for the duration of disease, only the differences on ADDR were still observed, highlighting the importance of the clinical data and disease evolution for the interpretation of GV.

Major adverse cardiovascular events and in-hospital outcomes in patients with diabetes

Celestino Neves[1,2], João Sérgio Neves[1,3], Sofia Castro Oliveira[1,2], Miguel Pereira[1], Ana Oliveira[1] & Davide Carvalho[1,2]
[1]Department of Endocrinology, Diabetes and Metabolism, São João Hospital Center, Porto, Portugal; [2]Instituto de Investigação e Inovação em Saúde da Universidade do Porto, Porto, Portugal; [3]Department of Surgery and Physiology, Cardiovascular Research Center, Faculty of Medicine, University of Porto, Porto, Portugal.

Background
Diabetes is an important risk factor for major adverse cardiovascular events (MACE). Although the increased risk for MACE is well known, the impact on the in-hospital outcomes remains incompletely understood. Our aim was to evaluate the interrelation between diabetes and MACE in a central hospital in the North of Portugal between 2009 and 2015.
Methods
We evaluated retrospectively the hospitalizations due to MACE including stroke or transient ischemic attack (TIA), acute coronary syndrome (ACS) and heart failure from the Hospital Coding Centre. We have studied the distribution by age, sex, causes and duration of admissions. Statistical analysis was performed with Student's *t*-test and chi-squared test. A two-tailed P value <0.05 was considered significant.
Results
A total of 124150 hospitalizations were registered during the studied period, with a total of 13425 MACE. The proportion of MACE admissions among all admissions was significantly higher in patients with diabetes (13.4% vs 9.7%, $P<0.001$). Patients with diabetes presented a higher proportion of stroke or TIA (3.9% vs 3.5%, $P<0.001$), acute coronary syndrome (5.3% vs 3.8%, $P<0.001$) and heart failure (4.2% vs 2.4%, $P<0.001$) compared with patients without diabetes. Among individuals with MACE, the group with diabetes was older (71.6 ± 10.8 vs 69.4 ± 15.3 years, $P<0.001$) and presented a higher proportion of women (46.0% vs 41.6%, $P<0.001$). There were no significant differences regarding in-hospital mortality among patients with diabetes compared with patients without diabetes (5.4% vs 5.3%, $P=0.737$). On the other hand, patients with diabetes presented a longer duration of MACE hospitalization (9.9 ± 9.6 vs 8.8 ± 8.5 days, $P<0.001$).
Conclusions
We observed a higher proportion of admissions for MACE among patients with diabetes. Furthermore, a longer duration of MACE hospitalization was observed among patients with diabetes. The higher incidence of MACE in patients with diabetes highlight the importance of improving the prevention and treatment of cardiovascular complications in this population.

Screening for autoimmune endocrinopathiesAt 300 insulin-dependent diabetics type1

FZ Kaidi[1], S. El Aziz[1], A. Mjabber[1], A. Chadli[1] & Fatima Zahra Kaidi[2]
[1]Endocrinology, Diabetology and Metabolic Diseases Department.Ibn Rochd University Hospital of Casablanca, Morocco, Neurosciences and Mental Health Laboratory, Faculty of Medicine and Pharmacy- University Hassan II- Casablanca-Morocco, Casablanca, Morocco; [2]Endocrinology, Diabetology and Metabolic Diseases Department. Ibn Rochd University Hospital of Casablanca, Morocco., Casablanca, Morocco.

Introduction
Type 1 diabetes is an autoimmune disease that can be associated with other autoimmune endocrinopathies. Occurrence of these autoimmune endocrinopathies increases the management of diabetes and affects the quality of life of patients. The aim of our study was to clarify the prevalence of endocrine autoimmune diseases associated with diabetes type 1 and their clinical characteristics.
Patients and methods
A descriptive analytical and retrospective study was conducted in Endocrinology, Diabetes and Metabolism Department, Ibn Rochd University Hospital of Casablanca, extended over a period of 7 years (January 2007 - December 2016) including 300 T1Ds. All patients had benefited from thyroid hormone assessment; 104 patients, had benefited from early morning cortisol assessment. Statistical analysis was univariate for all the variables using SPSS version 22.0.0
Result
We found 32 patients (10.66%), including 28 women and 4 men, of mean age 28.6 years (15-53 years) had a polyendocrinopathy, type T1D-hypothyroidism in 12 patients, T1D-hyperthyroidism in 11 patients, T1D- adrenal insufficiency (AI) in 5 patients, T1D-AI-hypothyroidism in 3 patients, and T1D-AI-hypoparathyroidism in one patient. Weight loss motivated the thyroid hormones assessment in 76% of cases, hypoglycemia in 62%, palpable thyroid in 37%, and palpitation in 28%. Hypoglycemia's motived the early morning cortisol assessmentin 98% of the cases, asthenia in 82%, and Weight loss in 77% and the melanodermia in 20%. Diabetes preceded endocrinopathy in 18 patients, with a difference in age of 3 years 3 months. Endocrinopathy preceded diabetes in 6 patients; with a difference of 3 years 9 monthsand they were concomitant in 8 patients. Anti-TPO ABs was positive in 12 patients, anti-TSH receptors in 09 patients and anti-21 hydroxylases in 4 patients.
Conclusion
The thyropathies are the most autoimmune endocrinopathies associated with T1D, essentially in young women. Timing and circumstances of discovery are variable, hence the importance of regular biological testing.

Mortality related to diabetes in orthopedic surgery patients

María Molina Vega[1], Pilar Losada Mora[2], Alfonso M Garrido Castro[3] & Juan Luis Carrillo Linares[3]
[1]Endocrinology, Hospital Virgen de la Victoria, Malaga, Spain; [2]Cardiology, Hospital Virgen de la Victoria, Malaga, Spain; [3]Internal Medicine, Hospital Virgen de la Victoria, Malaga, Spain.

Introduction
Episodes of poorly controlled diabetes (DM) are one of the most frequent medical complications during hospitalization in the elderly population.
Goals
To analyze the mortality rate (M) in patients with DM who undergo some medical decompensation during an admission to Orthopedic Surgery and Traumatology (OST).
Material and methods
Descriptive analysis of patients admitted to OST who suffered some type of medical decompensation that needed to notify an team of Internal Medicine, Endocrinology and Cardiology. We analyze the patients with known DM and their M.
Results
From June 2008 to December 2014, 1486 consultations were sent to Internal Medicine, Cardiology, Nephrology and Endocrinology regarding patients admitted to the OST area who had undergone some type of medical decompensation during admission. Of these patients, 437 (29.4%) had a documented history of DM. Their M was 11.21% (49 patients), with the M of the decompensated 10.3%.
Conclusions
DM is a cause of medical decompensation in 8.3% of patients admitted to OST. One in four known diabetics had abnormal blood glucose levels. Patients with a history of DM, decompensated or not, present a slightly higher M than the global number of decompensated patients in this area. We suggest that an early evaluation of blood glucose levels by Cardiology, Nephrology, Endocrinology or Internal Medicine could be beneficial in terms of morbidity and mortality.

Mortality related to diabetes in vascular surgery patients

María Molina Vega[1], Pilar Losada Mora[2], Alfonso M Garrido Castro[3] & Juan Luis Carrillo Linares[4]
[1]Endocrinology, Hospital Virgen de la Victoria, Málaga, Spain; [2]Cardiology, Hospital Virgen de la Victoria, Málaga, Spain; [3]Internal Medicine, Hospital Virgen de la Victoria, Málaga, Spain; [4]Internal Medicine, Hospital Virgen de la Victoria, Malaga, Spain.

Introduction
Episodes of poorly controlled diabetes (DM) are one of the most frequent medical complications during hospitalization in the elderly population.

Goals
To analyze the mortality rate (M) in patients with DM who undergo some medical decompensation during admission to Vascular Surgery and Angiology (VS).
Material and methods
Descriptive analysis of patients admitted to VS who suffered some type of medical decompensation that needed to notify a team of Internal Medicine, Endocrinology and Cardiology. We analyze the patients with known DM and their M.
Results
From February 2011 to December 2014, 173 consultations for Internal Medicine, Endocrinology, Nephrology or Cardiology were carried out regarding patients admitted to the VS area who had suffered any medical decompensation during admission. Of these patients, 94 (49.1%) had a documented history of DM. Its M was 23.4% (22 patients), with the M of the decompensated patients being 16.76%.
Conclusions
DM is a single cause of medical decompensation in 4.6% of patients admitted to the VS. However, associated with decompensation of other vascular risk factors, one out of four known diabetics had abnormal blood glucose levels. Patients with a history of DM, decompensated or not, present a M that is much higher than the overall M of decompensated patients in this area. We suggest that an early assessment of glycemia and strict monitoring of diabetic patients suffering from some medical decompensation in VS, by Cardiology, Nephrology, Endocrinology or Internal Medicine could be beneficial in terms of morbidity and mortality.

Diabetes and other frequent clinical problems in patients admitted in orthopaedic surgery

Maria Molina Vega[1], Pilar Losada Mora[2], Alfonso Garrido Castro[3] & Juan L Carrillo Linares[3]
[1]Hospital Virgen de la Victoria, Endocrinology, Malaga, Spain; [2]Hospital Virgen de la Victoria, Cardiology, Malaga, Spain; [3]Hospital Virgen de la Victoria, Internal Medicine, Malaga, Spain.

Objectives
To analyze the most frequent consultations on patients admitted to Orthopedic Surgery and Traumatology (OST) unit asked to medical physicians.
Material and methods
Descriptive analysis of consultations on patients admitted to OST who suffered any medical decompensation that needed to be notified.
Results
From June 2008 to November 2014, 1486 consultations were sent from OST to a medical team (Internal Medicine + Cardiology + Endocrinology + Pneumology + Nephrology) assigned to control of medical pathologies in surgical areas. The most common consultations were: dyspnea 371 (25%), pluripathology control 163 (11%), diabetes control 124 (8.3%) and high blood pressure 123 (8.3%). Digestive pathology was 10.5% (specified according to the disease: diarrhea, nausea-vomiting or abdominal pain). Analytic alterations 4%. Dyspnea was analized as it was considered too nonspecific. 48.7% were of respiratory origin: pneumonia (32%, of which 56% nosocomial), noncondensing respiratory infection (26%), exacerbation of COPD (18%), bronchospasm (16%) and pulmonary thromboembolism (2%). 41% of dyspnea had a cardiological origin; 66% the main factor inducing heart failure was not clearly identified; 13.6% presented excessive intravenous fluid therapy, 11.3% anemia secondary to the intervention, 11.3% uncontrolled atrial fibrillation. Then anxiety (4.7%). In 3,7% no dyspnea was observed. The reason for consultation was poorly controlled DM in 124 patients (8.3%), with 111 patients (89.5%) presenting hyperglycemia and 13 (10.5%) presenting hypoglycaemia. However, since the consultations were made by the Orthopedic Surgeon who requested it, after the initial evaluation of all these patients, the diagnosis of poorly controlled DM was only considered in 108 patients (7.4% of the total decompensated patients), since the rest, despite presenting glycemia above 125 on fasting, were considered controlled taking into account their particular clinical situation. This implies an actual decompensation of 24.7% of patients with known DM.
Conclusions
25% of consultations for medical decompensation in OST patients correspond to dyspnea, almost half from respiratory origin and somewhat less from cardiological. An important percentage are due to intrahospital processes (nosocomial pneumonia and excessive intravenous therapy). DM is a cause of medical decompensation in 7.4% of patients admitted to OST. One in four known diabetics had abnormal blood glucose levels. An early examination of patients with personal history of medical problems such as diabetes, performed before the surgery, could be beneficial in terms of morbidity.

DOI: 10.1530/endoabs.56.P406

P407

A novel lipid tetrad index as predictor of premature coronary artery disease in diabetic patients

Saswati Das
Maulana Azad Medical College, New Delhi, India. QDI, NE, India.

Background
The prevalence of premature coronary artery disease (CAD) has increased steadily in diabetic patients in the recent years. The aim of this study was to explore if evaluation of lipid risk factors like Lipoprotein(a) [Lp(a)] and conventional lipid profile parameters can be a efficient predictor of the cardiovascular risk in the patients of Diabetes.
Methods
Sixty individuals with angiographically proven premature CAD and 30 healthy individuals matched for age & sex were studied a tertiary health care center, New Delhi,India, over a period of 18 months. CAD patients were divided into two groups based on presence ($n=30$) [Group I] and absence ($n=30$) [group II] of type 2 diabetes mellitus (DM). The serum levels of Lipoprotein(a) were measured by ELISA and routine lipid profile (serum triglyceride, total cholesterol, HDL-C and LDL-C) was measured by automated analyzer. Angiographic clinical vessel scoring was also done for all the patients.
Results
Lipoprotein (a) levels for Group I was 40.26 ± 8.23 mg/dl, Group II was 40.81 ± 11.16 mg/dl respectively which was significantly (i.e. $P<0.01$) higher than the levels in healthy controls[Lp(a) $= 16.39 \pm 5.71$ mg/dl]. We found a significant increase in mean levels of Total cholesterol (TC), Low Density Lipoprotein-Cholesterol (LDL-C) and Triglyceride (TG) in cases than controls($P<0.01$). In contrast High Density Lipoprotein-Cholesterol (HDL-C) values decreased. Non HDL-C was calculated using the equation = [Total Cholesterol(TC) - LDL-C]. Lipid Tetrad Index (LTI) and Atherogenic Index were also calculated for all patients. LTI was calculated using the equations LTI = [total cholesterol x triglycerides x lipoprotein(a) / HDL-C] and the Modified Lipid Tetrad Index that we propose was calculated using the equation MLTI = [non HDL-C x triglycerides x lipoprotein(a) / HDL-C]. On analyzing by cumulative probability plot the new modified Lipid Tetrad Index defined by us is able to discriminate case and control populations more precisely than the existing LTI and Atherogenic Index. The Modified Lipid Tetrad Index has a better sensitivity and specificity than the existing LTI and also has a better correlation with the angiographic vessel score in all patients.
Conclusion
The new proposed Modified Lipid Tetrad Index is a better indicator of premature CAD diabetic patients from India, than the exsisting Lipid Tetrad Index and Atherogenic Index. The new proposed Modified Lipid Tetrad Index appears to be a predictor of the severity of premature CAD in diabetes patients.

P408

Oral health care behaviors among Tunisian patients with diabetes mellitus.

Sebai Imen, Chelly Aida, Temessek Aroua, Tertek Hajer & Ben Mami Faika
National Institute of Nutrition, Tunis, Tunisia.

Aim
The aim of our study was to describe oral health care behaviors among diabetic patients in Tunisia.
Method
This was a cross-sectional study involving diabetic patients hospitalised in the C department of the national institute of nutrition of Tunis between August and October 2016. A questionnaire contained a combination of open and close ended questions was specifically developed for this study. Patients were asked to answer questions related to their socio-demographic characteristics and their oral health behaviors (tooth brushing, mouth rinse and frequency of dental visits). Data about medical history, comorbidities and biology results were collected from medical file of patients.
Results
The mean age for the 101 diabetes recruited was 54.8 ± 14.9 years old, females comprised 57% of the population and the majority were having type 2 diabetes (83%). The mean number of years since diagnosis of diabetes was 12.8 ± 9.5 years. More than two thirds (70%) of participants were taking insulin. The average HbA1c was 10.4 ± 2.1%. The proportion of participants who had seen a dentist within the last year was 48%. Most of them (45%) visited their dentist mainly when urgent treatment was needed or because of pain. Only 12% visited a

dentist for check-up. Approximately 19% didn't visit a dentist at least 5 years ago and 8% did never consult a dentist. The higher the A1C was, the more recent was the dentist visit ($P=0.020$). Regarding tooth brushing, 34% admitted to brushing their teeth once a day or less, 45% brushed their teeth at least two times daily and 21% skipped tooth brushing altogether. We observed that women were more likely than men to brush twice daily ($P<0.0001$). Miswak use was reported by 33.7% of subjects. A minority (8%) reported using a mouth rinse. Tooth brushing frequency was negatively associated with tooth loss ($r^2=0.342$; $P=0.001$).
Conclusion:
Despite the greater risk for the development of periodontal disease, the oral self-care was poor among Tunisian diabetes. Promotion of oral self-care and regular dental check-ups are needed.

Clinical evaluation of erectile dysfunction in diabetic patients by IIEF5 Score

Taieb Ach, Yosra Hasni, Asma Ben Abdelkarim, Amel Maaroufi, Maha Kacem, Molka Chaieb & Koussay Ach
Endocrinology and diabetology, University hospital Farhat Hached de Sousse., sousse, Tunisia.

Introduction
The management of diabetes goes through the education but also the management of acute and chronic complications. Among the complications, erectile dysfunction are too often forgotten as they actually affect the quality of life. The repercussions of this complication incite the clinician to look for it among the other complications of diabetes. The aim of our study is to evaluate the prevalence of erectile dysfunction in a diabetic population and to evaluate its clinical severity.
Patients and methods
This is a prospective study of diabetic patients hospitalized for diabetes from January 2017 to April 2017. The types of diabetes included were type 1 and type 2 diabetes. Diagnosis of dysfunction Erectile was done at the time of hospitalization and the degree of severity was assessed by Urological Score IIEF5 Simplified International Index of Erectile Function interpreted as: Severe erectile dysfunction (score of 5–10), moderate (11–15), mild (16–20), normal erectile function (21–25) and uninterpretable (1–4).
Results
There were 114 patients with a mean age of 53.77 ± 10.8 years. The family history was type 2 diabetes in 78.9%, hyperrtension in 43.9%, and ischemic stroke in 16.1% of cases. Of the patients, 30.1% were hypertensive, 32.5% were dyslipidemic all under statins, 71.9% were smokers. Type 2 was predominant in patients in 91.2%. Treatment of diabetes was insulin-only in 48.1% of cases, oral antidiabetic alone in 18.4% and 32.5% in combination. Degenerative complications were present in 51.4%, with diabetic retinopathy in 51.4% of cases, diabetic neuropathy in 44.2% of cases and diabetic nephropathy in 18.2% of cases. The mean BMI of patients was $=26\pm5.6$ kg/m^2 with overweight in 28.4% of cases and obesity in 19.7% of cases. Erectile dysfunction affected 91.2% of the study population. The mean IIEF5 score was 11 ± 3, with 22.8% mild degree dysfunction, 55.7% moderate, and 20.3% dysfunction considered severe. The hormonal profile showed mean testosterone levels $=4.02\pm1.53$ ng/ml with a decreased levels in 61.1% of cases.
Conclusions
In addition to the high prevalence of erectile dysfunction in diabetics, this study also shows that it is important to rate the degree of severity of the dysfunction to better match the treatment. This is why erectile difficulties must be systematically detected at least annually, in the same way as another complication.

DOI: 10.1530/endoabs.56.P409

P410

Variability of glycemia and cognitive function in patients with type 1 diabetes mellitus

Mariia Matveeva, Julia Samoilova, Oxana Oleynik & Mariya Rotkank
Siberian State Medical University, Tomsk, Russian Federation.

Objective
To determine the effect of glycemic variability on cognitive function in patients with type 1 diabetes mellitus.
Materials
Thirty patients with type 1 diabetes mellitus were examined at the age of 29.7 (27.45–30.4) years, the duration of the disease was 19 (15.1–20.3) years. Patients were divided into 2 groups: 1st group ($n=15$) – patients with cognitive impairment, 2nd group ($n=15$) – without.
Methods
All patients were evaluated for cognitive status using the Montreal Cognitive Scale. The content of HbA1c was determined on DS5 Glycomat (Drew Scientific, The Netherlands). For the diagnosis of fluctuations in glycemia, continuous monitoring of glycemia was conducted using the iPro-2 (Medtronic, USA) and CareLink iProTM software. EasyGV calculator (2011) was used to analyze the variability of glycemia. The following indices were studied: mean glycemic mean (MEAN), standard deviation (S.D.), mean amplitude of glycemic fluctuations (MAGE), long-term glycemic index (CONGA), glycemia lability index (LI), hypoglycemia risk index (LBGI), hyperglycemia risk index (HBGI), mean hourly rate of change in glycemia (MAG). Statistical processing of the obtained data was carried out using the application software package R-system
Results
As a result of the study, patients with type 1 diabetes of the main group were diagnosed with cognitive impairment, the mean score was 23.8 ± 0.66, when in the control group it was 26.4 ± 0.13 ($t=3.6$, $P=0.001$). In the study of HbA1c in blood plasma, it was determined that the mean level in the main group was $10.5\pm1.3\%$, and in the control group it was 6.7 ± 0.23. % ($t=-2.5$, $P=0.015$). Significant difference in MEAN, S.D., CONGA, LBGI, HBGI, MAGE and MAG values between the groups is recorded. When performing the correlation analysis, it was shown that the level of HbA1c ($\chi2=-0.450$, $P=0.014$), as well as the parameters of the variability of glycemia-MEAN ($\chi2=-0.584$, $P=0.001$), S.D. ($\chi2$), affects the cognitive functions in type 1 diabetes. $=0.022$, $P=0.022$), CONGA ($\chi2=-0.853$, $P=0.001$), LBGI ($\chi2=-0.451$, $P=0.014$), HBGI ($\chi2=-0.053$, $P=0.003$), MAGE ($\chi2=-0.480$, $P=0.008$), MAG ($\chi2=-0.573$, $P=0.001$).
Conclusion
In patients with type 1 diabetes mellitus, hyperglycemia and hypoglycaemia, the duration of the increase in glycemia and the average fluctuation in glycemia may lead to a decrease in cognitive functions.

Septicemia in diabetics in Tunisia: Study of 43 cases

Mouna Elleuch[1], Rihab Ben Abdallah[2], Boulbaba Kolsi[1], Dorra Lahiani[3], Faten Haj Kacem[1], Nabila Rekik[1], Mounir Ben Jemaa[3] & Mohamed Abid[1]
[1]CHU Hedi Chaker Sfax Service Endocrinology Tunisia, Sfax, Tunisia; [2]Faculty of Sciences Sfax Tunisia, Sfax, Tunisia; [3]Infectious Diseases Service CHU Hedi Chaker Sfax Tunisia, Sfax, TUNISIA, Sfax, Tunisia.

Diabetes is a factor favoring infections. Among which, the sepsis that becomes formidable and serious on this ground. The purpose of our work is to study the clinical, therapeutic and evolutionary features of sepsis in diabetics. A retrospective study of 43 cases of septicemia in diabetic patients collected at the service of Sfax Infectious Diseases. There were 22 men and 21 women, mean age 59 (20–78) years. Community origin was present in 88.4% of cases and nosocomial in 11.6% of cases. urinary symptomatology in 13 cases (30%), digestive in 8 cases (18.6%) and cutaneous in 12 cases (27.9%) The table was severe from the outset (sepsis or shock) in 13 cases. were gram-negative bacilli in 52% (including Escherichia coli in 31.8% of cases) and Gram-positive cocci in 49% (including Staphylococcus aureus in 62% of cases). The portal of entry was certain in 34 case (79%) and probable in 9 cases (21%): urinary (46.5%), cutaneous (39.5%) and endovascular (14%) One or more secondary locations were found in 14 patients (33%): osteo-articular (4 cases), renal (3 cases), pulmonary (3 cases), cutaneous (2 cases), cardiac (1 case) and abdominal (1 case). Treatment was adapted to the isolated germ in 76.7% d The average duration of effective treatment was 22 (10–60) days. The septicemia of the diabetic individualized by their greater frequency compared to the non-diabetic population. The germs in question are gram-negative bacilli as well as gram-positive cocci.

An association of non-alcoholic fatty liver disease and autonomic neuropathy parameters in patients with type 2 diabetes

Yu Ji Kim, Kyung Ae Lee, Heung Yong Jin & Tae Sun Park
Department of Internal Medicine, Division of Endocrinology and Metabolism, Medical School, Research Institute of Clinical Medicine of Chonbuk National University – Biomedical Research Institute of Chonbuk National University Hospital, Jeonju, Republic of Korea.

Background
Non-alcoholic fatty liver disease (NAFLD) is metabolic disorder of the liver that is associated with type 2 diabetes.The relationship between NAFLD and diabetic neuropathy was still poorly understood. This study aimed to investigate whether the NAFLD is associated with the autonomic neuropathy parameters in patients with type 2 diabetes.
Methods
A total of 174 patients with type 2 diabetes were included in this study. Patients were divided into two groups based on the presence of NAFLD: 87 type 2 diabetes with NAFLD and 87 type 2 diabetes without NAFLD. The presence of NAFLD was determined in patients using abdominal ultrasonography. Anthropometric measurements, glycated hemoglobin, lipid profile, liver function test were assessed. Autonomic neuropathy testing was performed according to the ADA guidelines. They consists of the valsalva ratio, lying standing heart rate, R-R interval variation, postural hypotension, and sustained handgrip.
Results
Comparing to NAFLD group, mean age of non-NAFLD group was significantly higher (62.84 ± 11.93 vs 54.16 ± 12.93, $P < 0.05$). BMI, ALT and LDL levels were higher in NAFLD group than non-NAFLD group ($P < 0.05$). There was no difference of HbA1c level between two groups. In each autonomic function test parameter, there was no significant difference according to presence of NAFLD in type 2 diabetes patients, except BP response to sustained handgrip. Changes of autonomic function test parameters according to severity of fatty liver were only significantly different in heart rate response to Valsalva. Patients with severe fatty liver were higher in Valsalva ratio than mild and moderate severity groups ($P < 0.05$).
Conclusion
Our study showed that autonomic neuropathy parameters of type 2 diabetes did not demonstrate significantly consistent result according to presence of NAFLD. Further prospective studies are needed to elucidate the association of NAFLD and diabetic autonomic neuropathy.

Characteristics of cardiovascular autonomic neuropathy depending on the type of diabetes and importanace of cardiovascular tests in diagnostics

Snjezana Popovic-Pejicic[1,2] & Nina Pejicic[2]
[1]Internal Clinic – Department of endocrinology, University Clinical Centre of the Republic of Srpska, Bosnia and Herzegovina, Banja Luka, Bosnia and Herzegovina; [2]Faculty of Medicine, University of Banja Luka, Republic of Srpska, Bosnia and Herzegovina, Banja Luka, Bosnia and Herzegovina.

Purpose
The goal of the study was to determine: existence and degree of diabetic cardiovascular autonomic neuropathy (DCAN) depending on the type of diabetes; influence on systolic and diastolic function of myocardium and correlation with coronary disease and cardiovascular risk factors; possibility of early detection and diagnostic value of cardiovascular tests (CVT).
Methods
The study involved 90 participants: 30 patients with type 1 diabetes (T1DM), 30 patients with type 2 diabetes (T2DM) and 30 participants in the control group. Electrocardiogram, cardiac stress test and echocardiography has been done to all participants. Function of the autonomic nervous system was evaluated using 5 CVT: Valsalve maneuver, deep breathing, stand-up after lying position, orthostatic hypotension and Hand grip tests.
Results
The results showed that DCAN occurred significantly more often in patients with T2DM ($P < 0.001$). In patients with T1DM and T2DM with DCAN cardiac stress test was positive significantly more often ($P < 0.05$), i.e. correlation with coronary disease. Concerning coronary disease risk factors most common correlation was found with obesity and hypertension. Diastolic function of the left ventricle was significantly often impaired in patients with DCAN ($P < 0.001$), especially in T2DM. The most common pathological CVT in T1DM (71,4%), T2DM (83,3%) $P < 0.001$, was standup from lying position test.
Conclusion
Significant correlation between impaired diastolic function of the left ventricle and abnormal cardiac stress test results with DCAN indicates its significance in etiopathogenesis of diabetic cardiomyopathy and coronary disease. CVTs enable early detection of DCAN and objective cardiovascular evaluation.

Importance of HBA1C level and BMI in patients with chronic kidney disease

Snjezana Popovic-Pejicic[1,2] & Andreja Figurek[3,2]
[1]Internal Clinic – Department of endocrinology, University Clinical Centre of the Republic of Srpska,Bosnia and Herzegovina, Banja Luka, Bosnia and Herzegovina; [2]Faculty of Medicine, University of Banja Luka, Republic of Srpska, Bosnia and Herzegovina, Banja Luka, Bosnia and Herzegovina; [3]Department of Nephrology, University Clinical Centre of the Republic of Srpska,Bosnia and Herzegovina, Banja Luka, Bosnia and Herzegovina.

Purpose
Diabetic nephropathy is one of the leading causes of chronic kidney disease (CKD). Poor regulated glycemic control can result in progression of CKD. As diabetes mellitus (DM) and obesity can participate in development of atherosclerosis, the aim of this study was to assess the association of HbA1c and BMI in patients with CKD with intima-media thickness (IMT) as the early marker of atherosclerosis.
Methods
This cross-sectional study included 88 patients of all stages of CKD. Patients' average age was 62.84 ± 11.37 years. There were 56% female patients. 40% of patients had DM and 91% hypertension (HTA). HbA1c level, BMI, lipid and mineral status, kidney function and IMT were analyzed.
Results
DM cause CKD in 35.63% patients and HTA in 15%. Mean HbA1c level was 7.80 ± 1.28 and BMI 27.19 ± 3.59 kg/m^2. Average value of IMT was 1.09 ± 0.25 mm and mean estimated glomerular filtration rate 40.59 ± 31.15 μmol/l. HbA1c level positively correlated with serum calcium and phosphate product (CaxP) level ($r = 0.4$, $P < 0.05$), whereas BMI with IMT level ($r = 0.28$, $P < 0.01$). Binary logistic regression showed patients' age as the independent predictor of pathological IMT value. HTA and CaxP level were the best predictors of the occurrence of carotid plaque.
Conclusions
Our study showed that HbA1c level is associated with the CaxP in patients with CKD. BMI was associated with early signs of atherosclerosis. Glycemic control and nutritional status in patients with CKD should be carefully monitored and tailored to each individual patient.

The results of questionnaire by comprehensive symptom profile diabetes mellitus hypoglycemia nodule in type 2 diabetes patients

Said Ismailov & Alexandra Vodovskaya
Tashkent Paediatric Medical Institute, Tashkent, Uzbekistan.

The aim
To evaluate the results of Questionnaire by Comprehensive Symptom Profile Diabetes Mellitus hypoglycemia (CSP-DM-HypoGl) nodule in type 2 diabetes patients
Material and methods
Under our supervision in the departments of the Center of Endocrinology of PH Ministry of RUz in the period from September 2016 for December, to 2017, 20 patients were observed with DM 2, men – 9, women-11; 54.5 ± 1.5 m/$61,6 \pm 1.8$ w years old. The remoteness of disease hesitated in limits from 7 to 9 years. All patients were observed by standard rules.
Results
Patients were distributed on 2 groups: 1 gr – 10 patients (5/5), which received IIT, 2 gr – 10 patients (4/6) on CT (insulin + Metformin, SM, etc). We studied results of CSP-DM-HypoGl in all patients, which has 28 questions. On the data of interpretation of CSP-DM-HypoGl, if patients results achieve 1–4 in middle: this is lower degree of hypoglycemia, if 5-6 – middle degree of hypoglycemia and 7 >: higher degree of hypoglycemia. In 1 st group of patients we found of CSP-DM-HypoGl in range of 7 ± 0.3, which submit higher degree of episodes of hypoglycemia in this group. Patients had such symptoms as weakness, headache,

disorders of sleep. In the 2 nd group of patients we found middle range of CSP-DM-HypoGl 5,5 ± 0.4, which submit middle degree of episodes of hypoglycemia in this group.
Conclusions
The using of CSP-DM-HypoGl gives possibility to evaluate the degree of symptomatic hypoglycemia in patients with DM 2

Comparitive angiographic profile in diabetic and non-diabetic patient (retrospective study)

Blertina Dyrmishi, Taulant Olldashi, Ema Lumi[2], Entela Puca[3] & Dorina YLLI[3]
[1]Hygeia Hospital Tirana, Tirana, Albania; [2]Regional Korca Hospital, Korca, Albania; [3]UHC 'Mother Teresa', Tirana, Albania.

Background
Diabetes is one of the risk factor for coronary disease. Patient with diabetes have a increased prevalence and incidence of coronary vessels disease compare with the people without diabetes in the general population.
Aim and objectives
To compare the study of angiographic coronary results in the patient with and without diabetes.
Materials and methods
172 pacients; 66 with diabetes and 106 without diabetes was admitted to our hospital. In a retrospective study we evaluated the results of coronary angiography examination. The examination was performed to the patients with acute coronary syndrome or in patients with positive cardiac stress test.
Results
38% (66) of the patients was with diabetes or prediabetes compare with 62% (106), without diabetes. In diabetes patients: 74% (49) males and 26% (17) females. Average ages in diabetes patients was 63.1 ± 9 years old and average HbA1c values was 7.8 ± 1.5%. Angiography results in patients with diabetes: 42.5% (28) with triple multi vessel; 24.5% (16) two vessel; 21% (14) one vessel and 12% (8) without significant stenosis. Angiography results in patient without diabetes: 23% (24) triple multi vessel; 18% (20) two vessel; 26% (28) one vessel and 25% (26) without significant stenosis.
Conclusions
The incidence of multi vessel coronary artery disease was higher in diabetes patients compare to non diabetes patient. The majority cases in patients with diabetes have two or three vessel coronary artery disease.

Thiol-disulfide homeostasis, total antioxidant capacity and advanced oxidant protein products in patients with diabetic peripheral neuropathy

Derya Ustun Eroglu[1], Sinem Kiyici[2], Yasemin Ustundag[3], Deniz Sigirli[4], Nilufer Buyukkoyuncu Pekel[5], Gamze Emlek[1] & Gurcan Kisakol[1]
[1]University of Health Sciences, Bursa Yuksek Ihtisas Education and Research Hospital, Department of Internal Medicine, Bursa, Turkey; [2]University of Health Sciences, Bursa Yuksek Ihtisas Education and Research Hospital, Department of Endocrinology and Metabolism, Bursa, Turkey; [3]University of Health Sciences, Bursa Yuksek Ihtisas Education and Research Hospital, Department of Biochemistry, Bursa, Turkey; [4]Uludag University, Medical Faculty, Department of Biostatistics, Bursa, Turkey; [5]University of Health Sciences, Bursa Yuksek Ihtisas Education and Research Hospital, Department of Neurology, Bursa, Turkey.

Aim
In our study, we aimed to evaluate the relationship between oxidative stress markers such as total antioxidant capacity (TAC), advanced oxidant protein products (AOPP) and thiol-disulfide homeostasis parameters and diabetic peripheral neuropathy (PNP), an important microvascular complication of diabetes mellitus (DM).
Material and methods
80 (male/female = 34/46) patients with type 2 DM and 19 healthy controls were included in the study. All patients were assessed for PNP by Michigan Neuropathy Screening Test (MNTT) and Electroneuromyography (EMG). TAC, AOPP and total thiols, native thiols and disulfide levels of thiol-disulfide homeostasis parameters were studied in serum samples of patients and controls.
Results
There was no statistically significant difference between serum TAC, AOPP levels and thiol-disulfide homeostasis parameters when patients were grouped as those with and without PNP according to EMG or MNTT results. Regrouping was made and the patients were classified as having PNP if both EMG and MNTT results were positive. If both EMG and MNTT results were negative, they were classified as patients without PNP. Patients with discordant results were excluded. According to the regrouping, serum HbA1c (9.5 ± 2.0% vs 8.0 ± 1.8%; $P = 0.019$) and triglyceride levels (204.4 ± 77.0 vs 151.7 ± 58.5 mg/dl, $P = 0.014$) were significantly higher while serum total thiol levels (540.4 ± 9.9 vs 566.7 ± 2.6 μmol/l, $P = 0.038$) were lower in diabetic patients with PNP compared to diabetic patients without PNP. There was no difference between serum TAC, AOPP, native thiol and disulfide levels in patients with and without PNP. However, when compared with the control group, serum CRP, AOPP, total thiol and native thiol levels were found higher in patients with type 2 DM ($P = 0.001$, $P = 0.002$, $P = 0.02$ and $P = 0.03$; respectively).
Conclusions
In our study, there was no significant increase in serum TAC, AOPP, and thiol-disulfide homeostasis parameters, which are indicative of oxidative stress, in diabetic patients with PNP compared to those without PNP. These results suggest that the oxidative stress parameters assessed in our study are more closely related to the presence of diabetes rather than the presence of PNP.

Association of dislipidemia and glycemic control in patients with type 1 diabetes mellitus

Elena Makhlina[1], Tatiana Mokhort[2], Yana Navmenova[3], Marina Kaplieva[1] & Irina Savosteeva[3]
[1]Gomel State Medical University, Gomel, Belarus; [2]Belarusian State Medical University, Minsk, Belarus; [3]SI Republican Research Centre for Radiation Medicine and Human Ecology, Gomel, Belarus.

Objective
Assessment of the association of dyslipidemia and glycemic control in patients with type 1 diabetes mellitus
Materials and methods
200 patients with DM 1 were examined (mean age 29.14 ± 7.33 years, duration of DM 1 10.00 ± 7.33 years). The study of daily glucose dynamics was carried out by the continuous glucose monitoring system (CGMS) of Medtronic MINIMED, USA. HbA1c and lipid metabolism parameters were determined by the biochemical analyzer ARCHITECT c8000, Abbott.
Results
The correlation analysis revealed a direct relationship between the level of HbA1C and the level of total cholesterol ($rs = 0.21$; $P < 0.05$), triglycerides ($rs = 0.23$; $P < 0.05$), VLDL ($rs = 0.23$; $P < 0,05$) and between the duration of hyperglycemia and the level of TG ($rs = 0.16$; $P < 0.05$), VLDL ($rs = 0.19$; $P < 0.05$), total cholesterol ($rs = 0.15$; $P < 0.05$). The duration of hypoglycemia is negatively associated with the atherogenic index ($rs = -0.32$; $P < 0.05$). The minimum level of glucose directly depends on the level of TG ($rs = 0.14$; $P < 0.05$), VLDL ($rs = 0.17$; $P < 0.05$), total cholesterol ($rs = 0.17$; $P < 0.05$), the atherogenic index ($rs = 0.23$; $P < 0.05$) (Table 1).
Conclusion
The association of atherogenic lipid profile with an increase in the level of HbA1c and the presence of hypoglycemic states has been proved.

Table 1 Laboratory characteristics of glycemic control and lipid metabolism.

Indicator	Me (25;75)
HbA1c, %	9,00 (7,70; 10,60)
The minimum level of glucose, mmol/l	2,70 (2,20; 4,10)
The average level of glucose, mmol/l	10,10 (8,30; 12,20)
Duration of hypoglycemia, %	5,00 (2,00; 10,00)
Duration of hyperglycemia, %	50,00 (32,00; 68,00)
Total cholesterol, mmol/l	4,60 (4,00; 5,20)
Triglycerides, mmol/l	0,92 (0,68; 1,37)
HDL (high-density lipoproteins), mmol/l	2,08 (1,55; 2,89)
LDL (low-density lipoproteins), mmol/l	1,73 (1,34; 2,42)
VLDL (very low density lipoproteins), mmol/l	0,40 (0,30; 0,62)
Atherogenic index	2,10 (1,60; 2,70)

Urinary neutrophil gelatinase-associated lipocalin (NGAL) as a marker of diabetic nephropathy in type 1 diabetic patients

Pinar Sisman[1], Ozen Oz Gul[2], Melahat Dirican[3], Ahmet Selim Bal[3], Soner Cander[2] & Erdinc Erturk[2]
[1]Medicana Hospital, Endocrinology and Metabolism Clinic, Bursa, Turkey; [2]Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey; [3]Uludag University Medical School, Department of Biochemistry, Bursa, Turkey.

Aims
Glomerular and tubulointerstitial damage plays a role in renal function failure in diabetic patients. While both serum and urine levels of neutrophil gelatinase-associated lipocalin (NGAL) show significantly increased levels in acute renal pathologies, the NGAL increase in active phase indicates a reversible condition in chronic cases. In this study, we determined if urinary excretion of NGAL can be used as an early indicator of diabetic nephropathy, which causes chronic renal damage. We compared urinary NGAL excretions both between type 1 diabetic patients and the healthy control group and between the patients with and without albuminuria within the type 1 diabetic group. The goal of this study was to investigate if NGAL excretion is sensitive enough for clinical use as an early indicator of nephropathy in diabetic patients.
Methods
Fifty-two type 1 diabetic patients and 30 healthy volunteers participated in the study. The diabetic participants were separated into two groups as follows: a normoalbuminuria group consisting of those with an albumin/creatinine ratio less than 30 mg/g and an albuminuria group consisting of those with an albumin/creatinine ratio equal or greater than 30 mg/g. Albumin, creatinine and NGAL were measured in the morning spot urine samples of both the patient and the control group.
Results
The median NGAL level of diabetes patients was 21.1 ng/ml, which was significantly higher than the corresponding value of 11.9 ng/ml in controls. When diabetic patients were compared as those with and without albuminuria, the median urinary NGAL levels of normoalbuminuria and albuminuria were 24.7 and 16.1 ng/ml, respectively, but the difference was not statistically significant.
Conclusion
In type 1 diabetic patients, urinary NGAL excretion was increased but was not significantly correlated with urinary albumin excretion. The greater amount of NGAL excretion among diabetic patients may be due to diabetic nephropathy with possible tubulointerstitial damage pathologies. In this regard, urinary NGAL excretion should not be used as an alternative to microalbuminuria in detecting diabetic nephropathy. There is a need for further studies examining the long-term changes in NGAL excretion levels and renal functions.

APOB/APOA1 ratio is associated with metabolic syndrome in type 2 diabetes mellitus women with ischemic cardiomiopathy

Gabriela Lyzet Reynoso-Villalpando[1], Cristina Sevillano-Collantes[2], Yeminia Valle[1], Inmaculada Moreno-Ruiz[2], Jorge Ramon Padilla-Gutiérrez[1] & Francisco Javier del Cañizo-Gómez[2]
[1]Instituto de Investigación en Ciencias Biomédicas, Centro Universitario de Ciencias de la Salud (CUCS), Universidad de Guadalajara (UdG), Guadalajara, Mexico; [2]Hospital Universitario Infanta Leonor, Madrid, Spain.

Background
Retrospective, transversal and analytical study was designed to determine the relationship between ApoB/ApoA1 ratio, Non-HDL-Cholesterol/HDL-Cholesterol ratio and Metabolic Syndrome (MetS) in type 2 diabetes mellitus (T2DM) patients attending routine follow-up in outpatient clinic from Madrid.
Methods
The study was performed at the University Hospital Infanta Leonor, a public health center, and specialized secondary referal, which provides services to the 31 urban district of Madrid, Spain (Vallecas district, 300 000 people). 100 T2DM and high cardiovascular risk subjects, who attended the clinic between January of 2014 and June of 2017 for a routine follow-up were enrolled in this study. A blood sample was taken every 6 months in all patients and an average of 4-5 values prior to analysis were performed. Diagnosis of MetS was made according to definition of modified NCEP-ATPIII (National Cholesterol Education Program's Adult Treatment Panel III) 2. The following variables were measured in serum or plasma samples: Colesterol, HDL-Cholesterol, ApoB, ApoA1, triglycerides, high-sensitivity C Reactive Protein, ferritin, and transferrin. LDL-Cholesterol was calculated (Friedewald). Median comparisons were done with the Mann Whitney U test. Relationships between variables were measured with Spearman correlation test. Multivariate regression analysis was performed with ApoB/ApoA1 and Non-HDL-Cholesterol/HDL-Cholesterol ratios as dependent variables and age, gender and other cardiovascular risk factors as independent variables, after an outlier identification. A level of $P<0.05$ was considered statistically significant (SPSS, v. 21.0).
Results
We found associations, that remain after adjusting comorbidities and risk factors, between MetS and ApoA1 ($R^2=0.164$, $P=0.028$), ApoB/ApoA1 ratio ($R^2=0.187$, $P=0.001$); and Non-HDL-Cholesterol/HDL-Cholesterol ratio ($R^2=0.269$, $P=0.0001$). Moreover, there is an association between women with MetS and ApoB/ApoA1 ratio and ischemic cardiomyopathy that remain also after adjusting comorbidities and risk factors ($R^2=0.160$, $P=0.032$).
Conclusions
We found that both lipidic ratios are adequate for predicting MetS in T2DM patients of the population studied. ApoB/ApoA1 ratio shows to be a better cardiovascular risk marker, in women with MetS than in men. New studies should be carried out to confirm this finding.

Soluble dipeptidyl peptidase-4 activity is associated with decreased renal function in patients with type 2 diabetes

Eun-Hee Cho[1], Ji Yun Jeong[2], Mi Young Lee[3], Jung Min Kim[4] & Mi-Seon Shin[5]
[1]School of Medicine, Kangwon National University, Chuncheon, Republic of Korea; [2]Soonchunhyang University, Gumi, Republic of Korea; [3]Yonsei University Wonju College of Medicine, Wonju, Republic of Korea; [4]Sanggye Paik Hospital, Inje University College of Medicine, Seoul, Republic of Korea; [5]Hanil General Hospital, Seoul, Republic of Korea.

Objective
Dipeptidyl peptidase (DPP)-4 is highly abundant in the kidney. In various chronic inflammatory diseases, soluble DPP-4 activity is used as a marker for diabetes, coronary artery disease and cancer. This study examined the association between serum soluble DPP-4 levels and renal function or cardiovascular risk in patients with type 2 diabetes mellitus.
Research design and methods
Soluble DPP-4 activities were measured retrospectively in a total of 120 patients with type 2 diabetes in the preserved samples from our previous coronary artery calcium score study.
Results
The mean soluble DPP-4 level was 645 ± 152 ng/ml. Univariate analyses revealed that soluble DPP-4 activities were significantly correlated with total cholesterol ($r=0.214$; $P=0.019$), serum creatinine ($r=-0.315$; $P<0.001$), and estimated glomerular filtration rate by the modification of diet in renal disease (MDRD) ($r=0.303$; $P=0.001$). Associations between soluble DPP-4 with serum creatinine and GFR by the MDRD equation remained significant after adjustment for body mass index, age, and duration of diabetes. However, there was no association between soluble DPP-4 levels and body mass index, waist circumference, or coronary artery calcium score (CACs).
Conclusions
These data suggest that soluble serum DPP-4 activity might be used as a potential biomarker of deteriorated renal function in patients with T2D.

Predictors of the development of androgen deficiency in men with type 1 diabetes mellitus

Elena Vaschenko[1], Irina Savasteeva[1] & Tatjana Mokhort[2]
[1]The republican Research Centre for Radiation Medicine and Human Ecology, Gomel, Belarus; [2]The Belarussian State Medical University, Minsk, Belarus.

The aim of the study is the search of predictors of the development of androgen deficiency in men with 1 diabetes mellitus type 1. The study included 211 men

with type 1 diabetes mellitus aged 18–55 years. The median age of men was 39.00 (30.00; 45,00) years, the median duration of diabetes mellitus type 1 was 12,00 (7,00; 22,00) years. As a result of the research, it was found that an increase in the patient's age significantly increased the risk of developing androgen deficiency (b = 0.07, Exp (b) = 1.08 (1.00 ÷ 1.16), $P < 0.05$). The age of smoking experience also had a significant effect on the risk of developing androgen deficiency (b = 0.06; Exp (b) = 1.07 (1.10–1.13), $P < 0$, 04). The relative risk of developing (RR) androgen deficiency in men with a smoking experience of more than 7 years was 3.76 and was statistically significant (95% CI = 1.07 ÷ 13.25). With an increase in the level of glycated hemoglobin, the risk of developing androgen deficiency also increased significantly (b = 0.08; Exp (b) = 1.01 (1.00 ÷ 1.02), $P < 0.04$). The exceeding of the glycated hemoglobin level above 7.5% demonstrated a statistically significant RR = 6.71 (95% CI = 1.19 ÷ 37.86). The reduction of LDL decreased the risk of developing androgen deficiency in the men surveyed at the level of a stable trend (b = −0.45; Exp (b) = 0.64 (0.35 ÷ 1.18), $P < 0.10$). At an LDL level of less than 3.50 mmol / l, the RR of androgen deficiency was 0.29 and was statistically significant (95% CI = 0.09–0.97). The rise in VLDL significantly increased the risk of androgen deficiency (b = 0.71; Exp (b) = 2.04 (1.11 ÷ 3.76), $P < 0.02$). At a VLDL level of 0.42 mmol/L, the RR was 2.58 (95% CI = 1.38–3.29). As can be seen from the data provided, unsatisfactory compensation of type 1 diabetes mellitus increases the risk of developing androgen deficiency in men.

Relationship between serum levels of HDL cholesterol subclasses and carotid intima media thickness in patients with type 1 diabetes mellitus

Gamze Emlek[1], Sinem Kiyici[2], Yasemin Ustundag[3], Deniz Sigirli[4], Erhan Ozhan[5], Derya Ustun Eroglu[1], Metin Guclu[2] & Gurcan Kisakol[1]
[1]University of Health Sciences, Bursa Yuksek Ihtisas Education and Research Hospital, Department of Internal Medicine, Bursa, Turkey; [2]University of Health Sciences, Bursa Yuksek Ihtisas Education and Research Hospital, Department of Endocrinology and Metabolism, Bursa, Turkey; [3]University of Health Sciences, Bursa Yuksek Ihtisas Education and Research Hospital, Department of Biochemistry, Bursa, Turkey; [4]Uludag University, Medical Faculty, Department of Biostatistics, Bursa, Turkey; [5]University of Health Sciences, Bursa Yuksek Ihtisas Education and Research Hospital, Department of Radiology, Bursa, Turkey.

Aim
We aimed to investigate the possible relationship between HDL cholesterol subclasses and carotid intima media thickness (CIMT) in patients with type 1 diabetes mellitus (DM).
Material and methods
Sixty-two (female/male: 33/29, mean age: 33.3 ± 8.5 years) patients with type 1 DM at least 5 years and 20 (female/male: 10/10, mean age: 30.4 ± 5.6 years) healthy controls were included in the study. After physical examination and anthropometric measurements of all volunteers were performed, HDL2 and HDL3 cholesterol levels were studied from the serum samples which were taken following an 8–10 hour fasting period. CIMT measurements were performed to evaluate the existence of subclinical atherosclerosis by an experienced radiologist.
Results
There was no statistically significant difference between the two groups in terms of age, gender distribution, blood pressure control, anthropometric data, serum total cholesterol, LDL cholesterol, triglyceride, HDL cholesterol, ALT and creatinine levels. The mean HbA1c level was 8.1 ± 1.1% in patients with type 1 DM. The mean serum HDL2 cholesterol level was 17.3 ± 10.7 mg/dl in the patient group and 18.3 ± 7.2 mg/dl in the control group. The mean serum HDL3 cholesterol level was 27.5 ± 11.8 mg/dl in the patient group and 28.8 ± 8.6 mg/dl in the control group. No statistically significant difference was found between the groups in terms of serum HDL2 and HDL3 cholesterol levels ($P = 0.22$ and $P = 0.4$, respectively). The CIMT measurements were not different between the patient and the control groups (0.5 ± 0.2 mm vs 0.4 ± 0.1 mm; respectively) ($P = 0.23$). When both groups were evaluated together, there was no statistically significant correlation between serum HDL2 cholesterol levels and CIMT, but there was a negative correlation between serum HDL2 cholesterol levels and body mass index and waist circumferences ($r = -0.352$; $P = 0.001$ and $r = -0.236$; $P = 0.033$, respectively). There was no correlation between serum HDL3 cholesterol levels and any other study parameter including the measurement of CIMT. While serum HDL3 cholesterol levels in female patients with type 1 DM were higher than the male patients, serum HDL2 cholesterol levels were higher in females compared with the males in the control group ($P = 0.019$ and $P = 0.026$).
Conclusions
In our study, there was no relationship between serum HDL2 and HDL3 cholesterol levels and CIMT measurements in patients with type 1 DM. There is a need for additional prospective studies to demonstrate possible antiatherosclerotic effects of HDL cholesterol subclasses.

Dyslipidemia: type 1 diabetes vs. type 2 diabetes

Marwa Khiari, Sabrine Zribi, Hager Zahra, Ramla Mizouri, Mahjoub Faten, Berriche Olfa & Henda Jamoussi
National Institute of Nutrition of Tunis, Tunis, Tunisia.

Lipid abnormalities are common in diabetic patients, increasing their cardiovascular risk. The aim of our study is to compare the lipid profile between type 1 and type 2 diabetics. This is a retrospective study of 100 patients, half of them have type 1 diabetes (group 1) and the other half have type 2 diabetes (group 2), hospitalized in department A of the National Institute of Nutrition of Tunis between January 2017 and June 2017. Type 2 diabetics were older than type 1 diabetics. The sex ratio was 0.67 in the first group and 1.17 in the second group. Diabetes evolved from an average of 8.55 years in the 1st group and 11.78 years in the 2nd. It was poorly balanced in both groups with the averages of HbA1c and fasting glucose respectively at 10.72% and 12.54 mmol/l in the 1st group and 10.46% and 10.81 mmol/l in the 2nd group. It was noticed that, for the 2nd group, the triglycerides levels were statistically higher (1.92 mmol/l vs 1 mmol/l; P value < 0.001) and the HDL cholesterol levels were lower (1.09 mmol/l vs 1.27 mmol/l; P value = 0.009). We did not find a statistically significant difference in LDL cholesterol levels between the two groups (1.01 g/l in the 1st group and 1.20 g/l in the second group). Our results are in line with the literature. In fact, our type 2 diabetics had a higher triglyceride level and a lower HDL-c level compared with type 1 diabetics. However, the LDL-c level, the most atherogenic fraction of cholesterol, does not seem to be influenced by the type of diabetes.

The comparison of serum cerebellin and catecholamine levelsin patients with newly diagnosed hypertension and type 2 diabetic whose had newly diagnosed hypertension

Sedat Çiçek[1], Kader Uğur[2], Meltem Yardım[3], İbrahim Şahin[4], Ahmet Karataş[5], Faruk Kılınç[2] & Süleyman Aydın[3]
[1]Firat Universty, Deparment of Internal Medicine, Elazig, Turkey; [2]Firat Universty, Deparment of Endocrınology and Metabolism, Elazig, Turkey; [3]Deparment of Biochemistry, Elazig, Turkey; [4]Erzincan University, Department of Histology and Embryology, Erzincan, Turkey; [5]Firat Universty, Deparment of Rheumatology, Elazig, Turkey.

Background/purpose
The combination of DM and HT accelerates vascular complications and increases the risk of mortality and morbidity. Hypertension is seen in half of diabetic patients. HT can be detected in approximately 40% of newly diagnosed diabetic patients. DM frequency increased 2.5 times in hypertensive patients. The association of HT and DM is due to the common mechanism responsible for the pathogenesis of both diseases. There is a limited number of studies investigating the association of HT and DM with catecholamines and the molecule called cerebellin, which is involved in the synthesis of catecholamines, has not yet been studied. Therefore, in this study, we aimed to determine how catecholamine and cerebelline levels were affected both before and after treatment in urine and blood of patients with HT and HT + DM.
Method
This study included 30 patients with newly diagnosed hypertension, 30 patients with previously diagnosed diabetes mellitus and new hypertension, and 30 healthy volunteer were included to the study. Both before and after treatment,

urine and blood samples were taken. Cerebelline, adrenaline, noradrenalin, metanephrine and normetanephrine levels were measured by ELISA. Other biochemical parameters (FBG, HbA1c, LDL, TG) were measured by autoanalyzer. In addition, the clinical characteristics of the collected patients were also recorded including age, gender, blood pressure and BMI.
Result
The BMI profile was similar among control, HT and HT + DM groups ($P > 0.05$). There was a significant decrease in blood and urine cerebellin, metanephrine and normethanephrine levels in the study patients compared with the control group, both before and after treatment ($P < 0.05$). When compared with the control group, the adrenaline levels in both urine and blood were increased in HT and HT + DM groups ($P < 0.05$). When compared with the control group, a significant increase in blood noradrenalin level was observed in HT group but decreased in HT + DM group. In addition to, when compared with control group, the urine noradrenaline level was increased in both HT and HT + DM groups ($P < 0.05$).
Conclusion
This result suggest that there is a relationship between cerebellin, catecholamine and catecholamine metabolites in HT and HT + DM patients. In the future, there is a need for further studies on the possibility that these biomarkers can give an idea about the etiopathogenesis of diseases such as HT, DM.
Key Words: Hypertension, diabetes mellitus, cerebellin, catecholamines

The prevalence of microvascular complications in the adults with type 1 diabetes and the glycemic control in the Republic of Belarus

Marina Mantachik[1], Alla Shepelkevich[1], Yuliya Dydyshka[1] & Veranika Lobashova[2]
[1]Belarusian State Medical University, Minsk, Belarus; [2]Republic Medical Rehabilitation and Balneotreatmentcenter, Minsk, Belarus.

According to the current expert recommendations it is advisable to screen microvascular complications: diabetic peripheral polyneuropathy (DPN), diabetic retinopathy (DR), diabetic nephropathy (DN) in all patients with type 1 diabetes mellitus (T1D) and disease duration of 5 years. Therefore, the aim of the study was to assess the clinical and laboratory parameters of patients with type 1 diabetes at the age of 30−45 years with duration of the disease 5–15 years, taking into account adherence to the implementation of recommendations for the control of glycemia.
Materials and methods
360 T1D patients, 196 (54.4%) men and 164 (45.6%) women were examined. The average age of the patients was 37.9 ± 4.5 (37.4−38.4) years, the age of diabetes onset – 28.1 ± 6.2 (27.5−28.8) years, duration of the disease – 9.0 (7.0−12.0) years, body mass index – 24.8 ± 3.95 (23.6−25.2) kg/m^2. The study carried out a detailed clinical examination of patients with medical record analysis. The study was conducted within the framework of the nationwide action 'Early Detection of Chronic Complications of Type 1 Diabetes Mellitus in Adults'. Patients completed questionnaires of adherence to the implementation of recommendations for the glycemic control, the results of which were divided into two groups: 1st group (Gr1) − 257 (71.4%) people − predominantly compliant patients, 2nd (Gr2) − 103 (28.6%) people − mostly not committed to the control of glycemia. To verify the DPN the Vibratip device also used.
Results
In 36.9% cases DPN was diagnosed; DR – in 21.7%, DN − in 40.6%, albuminuria – in 38.1% cases. Microvascular diabetic complications were in 270 (75%) patients. The level of $Hb_{A1c,}$ used to estimate the compensation of glycemia, averaged 8.37 ± 1.83 (8.18−8.56), while in Gr1 the index was significantly lower than in Gr2: 8.20 ± 1, 83 vs 8.80 ± 1.75%, however, in both groups, the target values were not achieved. There were significant differences in groups in the presence of DPN − 33.5 vs 45.6% ($\chi^2 = 4.67$, $P = 0.030$), microvascular complication − 71.6 vs 83.5% ($\chi^2 = 5.55$, $P = 0.018$). However, there were no differences in the prevalence groups of DN − 62.6 vs 51.5% ($\chi^2 = 4.67$, $P = 0.051$), albuminuria 35.4 vs 44.7% ($\chi^2 = 4.67$, $P = 0.030$), DR − 51.4 vs 54.4% ($\chi^2 = 2.66$, $P = 0.102$).
Conclusions
In 75% cases of T1D fixed microvascular complications. Adherence to the control of glycemia without reaching the target values is associated with the diabetic neuropathy, but does not affect the development of diabetic retinopathy and nephropathy.
DOI: 10.1530/endoabs.56.P426

P427

Inflammation in patients with diabetic nephropathy receiving different classes of glucose-lowering medications: serum levels of interferon gamma

Ivan Pchelin[1], Volha Vasilkova[2], Alexander Shishkin[1], Valentina Bayrasheva[1] & Natalia Hudiakova[1]
[1]Saint Petersburg State University, Saint Petersburg, Russian Federation; [2]Gomel State Medical University, Gomel, Belarus; [3]Almazov National Medical Research Centre, Saint Petersburg, Russian Federation.

Proinflammmatory cytokines including interferon gamma (IFNg) are known to be involved in the pathogenesis of diabetic nephropathy. The aim of this study was to assess serum level of IFNg and its clinical correlates in patients with type 2 diabetes and early CKD receiving different types of treatment. We investigated 64 patients with type 2 diabetes and CKD stages 1-3. Group 1 included 20 patients on insulin therapy. Group 2 included 44 patients on metformin or combined oral hypoglycemic therapy. Groups were comparable on the basis of sex, age, body mass index and eGFR. In addition to routine clinical tests, we measured serum levels of ferritin, homocysteine, interleukin-6 and IFNg. Mann-Whitney *U*-test and Spearmen's correlation coefficient (rs) were used for statistical analysis. Serum level of IFNg was elevated in 20.0% patients from group 1 and 31.8% patients from group 2. Mean level of this cytokine was significantly higher in group 2 as compared to group 1 (14.6 ± 2.4 pg/ml vs. 6.5 ± 1.7 pg/ml, respectively, $P = 0.018$). In both groups serum concentration of IFNg had no significant correlations with age, body mass index, eGFR (CKD-EPI), albuminuria, hemoglobin, homocysteine, total cholesterol, lipid fractions, and interleukin-6. Only in group 1 (but not in group 2) the level of IFNg correlated with serum ferritin level (rs = −0.629, $P = 0.003$) and platelets count (rs = 0.547, $P = 0.013$). The results of the study suggest that insulin therapy is associated with lower serum level of IFNg in patients with type 2 diabetes and early CKD after adjustment for sex, age, body mass index and eGFR. This could be related to anti-inflammatory effects of insulin. In insulin-treated patients, serum level of IFNg correlates negatively with serum ferritin level and positively – with platelets count.

The relationship between morbidity and mortality and HbA1c level in major surgery applied with diabetic patients

Begüm Şeyda Avci[1], Tayyibe Saler[1], Akkan Avci[2], Mehmet Bankir[1], Zeynep Tüzün[1] & Hakan Nazik[3]
[1]Science Health University, Adana City Research and Traning Hospital, Internal Medicine, Adana, Turkey; [2]Science Health University, Adana City Research and Traning Hospital, Emergency Medicine, Adana, Turkey; [3]Science Health University, Adana Numune Research and Training Hospital, Gynecology, Adana, Turkey.

Background
Diabetes Mellitus (DM) is a disease that increasing in prevalence rapidly in our country and in the world with the increase of sedentary life and unhealthy nutrition. The risks of surgery applied in diabetic patients differ according to other patients.
Aim
We aimed to investigate the relationship between the preoperative HbA1c levels and the complications and mortality rates in the postoperative period in patients with diabetes diagnosis and was applied major surgical treatment.
Method
We included patients who underwent major surgery between January 1, 2015 and December 31, 2016 in our hospital and who had been diagnosed with type 2 diabetes and had been looked at HbA1c levels preoperatively. A total of 1013 patients whose file data were completely accessed, were included in the study. Preoperative HbA1c levels of the patients and complications seen within the first 7 and first 30 days postoperatively were recorded.
Results
Forty nine (4.8%) of the patients were exitus in the hospital while 964 (95.2%) of patients were discharged. Preoperative HbA1c levels of the patients were found to be predictive marker of mortality in the first 7 and 30 days postoperatively ($P < 0.05$). Preoperative HbA1c value was found to be very significant in predicting the complication, wound infection, total infection risk within the first 7 and 30 days postoperatively ($P < 0.001$).
Discussion
It is very important to base HbA1c levels on preoperative surgical risk assessment in diabetic patients. Better provision of long-term glycemic control in patients

planned elective surgery and have high HbA1c levels may significantly reduce postoperative mortality and complications.

The relationship between intertemporal choice and blood glucose control in type 2 diabetes

Hyun Ju Lee[1], Mi-Kyung Kim[2], Yang Tae Kim[1], Hye soon Kim[1] & Nan Hee Cho[1]
[1]Department of Psychiatry, Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Department of Internal Medicine, Keimyung University School of Medicine, Daegu, Republic of Korea.

The objectives of this study were to investigate intertemporal choice in patients with type 2 Diabetes and whether blood glucose control is related to intertemporal choice. Ninety seven diabetes patients (41 inpatients and 56 outpatients) were recruited. All patients were subjected to the following tests: DM Distress Scale (DDS), Beck Anxiety Inventory (BAI), the Center for Epidemiologic Studies Depression Scale (CES-D) and the Big Five Inventory-K-10 (BFI-K-10). 73 of recruited patients performed the delay discounting task (DDT). Compared to the outpatient group, the inpatient group showed higher delayed reward discounting rate in DDT. Outpatient group showed higher score in the agreeableness than inpatient group. And Inpatient group scored higher than outpatient group in the score of the Beck-anxiety inventory. The anxiety score and DDT were negatively correlated, and anxiety score and HbA1c were positively correlated. In addition, anxiety scores were positively correlated with neuroticism, diabetes distress scores, depression scores and negatively correlated with agreeableness scores. Agreeableness showed a negative correlation with HbA1c and 180days′ indifferent points, respectively. Agreeableness was also significantly associated with diabetic stress, anxiety, depression and there was a positive correlation with conscientiousness. In this study, we found that there is a difference in intertemporal choice between inpatient and outpatient groups. In addition, it was confirmed that the difference of personality traits and negative emotions between the two groups was related to the selection of intertemporal choice and related to the control of blood glucose.

Characteristics of diabetic foot patients admitted to department of endocrinology and metabolic diseases at ankara university, faculty of medicine

Şule Canlar, Murat Cinel, Adile Begüm Bahçecioğlu Mutlu, Rıfat Emral, Dilek Bayram, Nuran Metinarıkan, Birgül Yurdakul, Özgür Demir & Demet Çorapçıoğlu
Ankara University Faculty of Medicine, Department of Endocrinology and Metabolic Diseases, Ankara, Turkey.

Introduction
Diabetic foot is one of the important and destructive complications of diabetes. During the life time of a diabetic patient, the risk of developing foot ulcers is around 5–15%, and about 20–25% of the causes of hospitalization in diabetic patients are due to foot ulcers. 40–80% of foot ulcers can be infected and resulted in osteomyelitis. Hospitalization due to osteomyelitis is 12 times more in diabetic patients than in non-diabetic population.
Objective
It is aimed to evaluate retrospectively, the patients admitted due to diabetic foot to the Department of Endocrinology and Metabolic Diseases at Ankara University, Faculty of Medicine in the last 1 year.
Method
Information from the data processing system and file records about patient age, gender; smoking habbits, diabetes education, diet compliance; duration of diabetes; presence of other micro/macrovascular diabetic complications, diabetic foot development and progression, and HbA1c levels were obtained. Fifty four diabetic foot patients were evaluate eighteen of whom were outpatient, and thirty six of whom were inpatient.
Results
The majority of patients were suffering from type 2 diabetes melltus (96%). All chronic micro/macrovascular complications especially peripheral arterial disease were detected at high rates in diabetic foot patients. Trauma and burns (respectively, 34% and 10.6% of patients) were detected as major triggering factors. The mean duration of diabetic foot development was determined as 150 days at inpatients and 60 days at outpatients. Most of outpatients (55.6%) were presented with Wagner 1 diabetic foot ulcers and 50% of the inpatients were presented with Wagner 3-4-5 diabetic foot ulcers.
Conclusions
Diabetic foot evaluation, treatment and follow-up requires a multidisciplinary approach. In terms of diabetic foot development, it is very important to identify high-risk patients and determine the appropriate treatment plan.

Atherosclerosis in women of reproductive age with type 2 diabetes mellitus and polycystic ovary syndrome

Stavroula A Paschou[1,2], Nikolaos Kalogeris[1], Stella Proikaki[1], Vasiliki Loi[1], Panagiotis Anagnostis[3] & Andromachi Vryonidou[1]
[1]Department of Endocrinology and Diabetes, Hellenic Red Cross Hospital, Athens, Greece; [2]Division of Endocrinology and Diabetes, 'Aghia Sophia' Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [3]Unit of Reproductive Endocrinology, First Department of Obstetrics and Gynecology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece.

Introduction
The aim of this study was to investigate the degree of atherosclerosis in women of reproductive age with type 2 diabetes mellitus (T2DM), with and without polycystic ovary syndrome (PCOS).
Patients and Methods
71 women (mean age 43.2 y) with T2DM treated with diet or oral anti-diabetic medications and 36 controls were studied. According to menstrual cycle and clinical hyperandrogenism, patients with T2DM were classified into two subgroups, 53 without PCOS (T2DM+PCOS-) and 18 with PCOS (T2DM+PCOS+). After overnight fast in the first phase of menstrual cycle, hormonal and biochemical measurements were recorded, while the carotid intima-media thickness (IMT) was measured.
Results
Women with T2DM presented significantly higher BMI (34.5 ± 6.39 vs 27.9 ± 6.1, $P<0.001$), waist circumference (105.3 ± 14 vs 86.9 ± 11.2, $P<0.001$), hirsutism (1.78 ± 0.9 vs 1.15 ± 0.3, $P<0.01$) and family history of T2DM (82.5% vs. 34.6%, $P<0.002$). They also had significantly higher total testosterone (0.62 ± 0.21 vs 0.45 ± 0.11, $P<0.001$), insulin (17.8 ± 11.9 vs 9.8 ± 3.6, $P<0.002$), triglycerides (131 ± 23 vs 95 ± 67, $P=0.02$) and LDL cholesterol levels (132 ± 31 vs 114 ± 23, $P=0.025$), while lower SHBG (34.3 ± 16.2 vs 53.9 ± 18.7, $P<0.001$) and HDL cholesterol levels (47.1 ± 12.8 vs. 57 ± 10.9, $P<0.001$) compared to controls. T2DM+PCOS+ patients reported a significantly higher rate of gestational diabetes (37.5% vs. 8.3%, $P<0.05$), younger age of diagnosis of T2DM (32.8 ± 5.7 vs. 39.7 ± 6.1, $P<0.001$) and presented significantly higher waist circumference (115 ± 12.8 vs. 99 ± 11.1, $P<0.01$) compared to T2DM+PCOS- patients. They also had higher levels of total testosterone (0.75 0.22 vs 0.54 ± 0.16, $P=0.01$) and insulin levels (24 ± 15.8 vs 14.4 ± 7.5, $P<0.05$), lower SHBG (26.1 ± 9.5 vs 39.8 ± 17.6, $P<0.001$) and HDL-cholesterol levels (41.4 ± 11.2 vs 50.8 ± 12.6, $P<0.001$). The degree of atherosclerosis as assessed by IMT was significantly higher in patients with T2DM compared to controls (0.065 ± 0.007 vs 0.056 ± 0.008, $P<0.001$), but did not differ significantly between the two subgroups of patients with T2DM.
Conclusion
The results of this study provided evidence that women of reproductive age with T2DM present early atherosclerosis compared to healthy controls, but the

coexistence of PCOS does not seem to additionally deteriorate the degree of clinical atherosclerosis.

Association of adverse pregnancy outcomes with glycemic cut-offs stated by the IADPSG, POGS and WHO diagnostic criteria for gestational diabetes mellitus in De La Salle University Medical Center (DLSUMC), Cavite, Philippines from January 2012 to December 2015

Danica Francisco[1,2] & Aimee Andag-Silva[1]
[1]De La Salle University Medical Center, Dasmarinas, Philippines; [2]The Medical City, Pasig, Philippines.

Objectives
To determine the association between adverse pregnancy outcomes with each of the 75 g OGTT cut-off values prescribed by the World Health Organization (WHO), Philippine Obstetrical and Gynecological Society (POGS), and the International Association of Diabetes in Pregnancy Study group (IASDPG) criteria to help define more appropriate glycemic cut-off levels for Filipinas.
Methodology
Retrospective Cohort study of pregnancy deliveries in De La Salle University Medical Center (DLSUMC), Cavite, Philippines from January 2012 to December 2015. Subjects were >18 years old with a singleton pregnancy, a 75-g OGTT result, and complete medical record without other existing comorbidities or illnesses that may affect outcomes. Maternal and neonatal outcomes were recorded and their association with the different glycemic cut-offs stated by the WHO, POGS and IADPSG were analyzed.
Results
Total of 195 subjects were included. Patients with an FBS >126 mg/dl were 5.7 folds more likely to have pre-eclampsia ($P=0.020$) and 3.2 folds likely to have preterm delivery ($P=0.44$), however, there is a significant number of GDM patients (22.3%) not diagnosed by this higher FBS cut-off. Maternal outcomes showed 2.9 folds increased risk for preterm delivery with the 1-hour OGTT of >180 mg/dl ($P=0.021$) and 6.7 times likely to have gestational hypertension with the 2-hour OGTT of > 140 mg/dl ($P=0.011$).
Conclusion
It is recommended to utilize the IADPSG criteria, but the usage of 2 h OGTT of >140 mg/dl instead of >153 mg/dl showed added advantage for the Filipino population.

Ankle-brachial index values in diabetic patients with and without claudication

Savas Bayrak[1], Yildiz Okuturlar[2], Denis Bozer[2], Sogol Sadri[2], Isil Ozbas Tevetoglu[2], Banu Boyuk[3] & Meral Mert[4]
[1]Bakirkoy Dr. Sadi Konuk Education and Research Hospital, Department of General Surgery, Istanbul, Turkey; [2]Bakırkoy Dr. Sadi Konuk Education and Research Hospital, Department of Internal Medicine, Istanbul, Turkey; [3]Taksim GOP Education and Research Hospital, Istanbul, Turkey; [4]Bakırkoy Dr. Sadi Konuk Training and Research Hospital, Endocrinology and Metabolism, Istanbul, Turkey, Istanbul, Turkey.

Aim
The ankle-brachial index (ABI) shows the existence of peripheral arterial disease and is also related to cardiovascular mortality in diabetic patients, even in those with coronary artery disease at an early stage. Normal levels are considered to be an ABI of 0.9 – 1.3; ABI thresholds of less than 0.9 and more than 1.3 are highly suspicious for PAD and high CV risk in diabetic patients. In this study, we planned to investigate the ankle-brachial index values in diabetic patients with and without claudication.
Materials and methods
Hundred patients were enrolled in this study. 16 patients with coronary artery disease or cerebrovascular disease were excluded. All of 84 patients were underwent ankle-brachial index (ABI) measurements in the out-patient department of internal medicine.
Results
Forty-four patients with claudication and 40 patients without claudication were included in the study. We couldn't palpate tibial artery in three patients and dorsal artery in three patients. These six patients were reffered cardiovascular surgery due to complete obstruction. There was no significant difference between age, a1c, body mass index (BMI), waist circumference, duration of diabetes mellitus (DM) of these two groups. The right ABI was found to be higher in patients with claudiation (1.18 ± 0.19) than patients without claudication (1.06 ± 0.18) ($P=0.003$). Also the left ABI was found to be higher in patients with claudiation (1.11 ± 0.2) than patients without claudication (1.05 ± 0.18) (p: 0.012) (table 1). However, patients with normal and abnormal ABI levels (0.9-1.3) were not found to be related to claudication complaint. Cigarette, family history, antihypertensive drug, statin, metformin, sulfonylurea, dpp4, glitazone or insulin use were not found to be related with claudication complaint. There was a significant relationship between neuropathy ($P=0.023$), sex ($P=0.039$) and claudication complaint. In the analysis of correlation, left and right ABI measurements were not found to be correlated with age, a1c, BMI, duration of DM.
Conclusion
Early diagnosis of PAD in diabetic patients without coronary artery disease or cerebrovascular disease can be done with ABI measurments. It is especially important to take ABI measurement in our everyday practice for diabetic patients with neuropathy and claudication complaint before yet developed macrovascular complications.

Analysis of kidney biopsy findings in diabetic patients

Suat Akgür[1], Ayşegül Oruç[1], Abdülmecit Yıldız[1], Canan Ersoy[2], Berna Aytaç Vuruşkan[3], Mustafa Güllülü[1] & Alparslan Ersoy[1]
[1]Uludag University Medical Faculty, Department of Nephrology, Bursa, Turkey; [2]Uludağ University Medical Faculty, Department of Endocrinology and Metabolism, Bursa, Turkey; [3]Uludağ University Medical Faculty, Department of Pathology, Bursa, Turkey.

Kidney disease occurs in diabetic patients during disease course in time. Diabetes duration, co-morbid diseases, presence of retinopathy, family history of diabetic nephropathy (DN) predict kidney involvement. Although DN is the initial diagnosis in diabetics with proteinuria, other diseases like primary glomerulonephritis (GN) could be the reason of kidney involvement. DN is increasing in proportion with the increase in diabetes prevalence, and it has been predicted to continue to increase in the future. We aimed to analyze the biopsy findings of diabetic patients who presented with renal findings apart from DN.
Methods
The study included 47 (30 males, 17 females) diabetic patients who performed kidney biopsy between 2002 and 2016. Biopsy indications were atypical presentation, like hematuria, proteinuria without retinopathy, acceleration in proteinuria, and unexpected deterioration of kidney function.
Results
The mean age of patients was 56.2 ± 11 years, diabetes duration was 6 ± 4 years. Serum creatinine levels were 2.24 ± 1.6 mg/dL, albumin 3.16 ± 0.77 g/dL, urinary protein excretion 7.52 ± 6.9 g/day, HbA1C 6.0 ± 0.81%, CRP 2.83 ± 5.2 mg/dL, total cholesterol 242 ± 102 mg/dL, triglyceride 225 ± 101 mg/dL and LDL cholesterol 160 ± 92 mg/dL. The biopsy indications were nephrotic syndrome (74.5%), asymptomatic urinary abnormality (17%), rapidly progressive kidney disease (6.4%) and nephritic syndrome (2.1%). DN was diagnosed in 18 diabetic patients (38.3%). Others were focal segmental glomerulosclerosis in 5 patients, AA amyloidosis in 5, IgA nephropathy in 4, membranous GN in 3, AL amyloidosis in 3, ANCA-associated GN in 2, membranoproliferative GN in 1, post-infectious GN in 1, hypertensive nephrosclerosis in 1, thrombotic microangiopathy in 1 and nonspecific changes in 3. The patients were divided into two groups as DN and non-DN. There was no significant difference between characteristics of both groups. Only the ratio of diabetic retinopathy in DN group was higher than that of non-DN group (44 vs. 6.9%, $P=0.003$).
Conclusion
The present study suggests that non-diabetic kidney pathologies may be common in diabetic patients. Therefore, a kidney biopsy may be useful in diabetic patients with atypical presentation. Although diabetic retinopathy was found to be an important predictor for DN, it is not known whether it's presence can completely differentiate DN from non-diabetic etiologies.

Hypomagnesemia as a marker of diabetic nephropathy

Mohamed Mashaheet[1], Ahmed Hammad[1], Shahira Elshafee[2] & Basma Abdelsamad[1]
[1]Department of Internal Medicine, Faculty of Medicine, Fayoum University, Egypt; [2]Department of Clinical pathology, Faculty of Medicine, Fayoum University, Egypt.

Magnesium is an essential element and has a fundamental role in carbohydrate metabolism in general and in the insulin action in particular. Magnesium is involved in multiple levels in insulin secretion, binding and activity. Cellular magnesium deficiency can alter the activity of the membrane bound Na + K + ATPase, which is involved in the maintenance of gradients of sodium and potassium and in glucose transport. Magnesium depletion has a negative impact on glucose homeostasis and insulin sensitivity in patients with type 2 diabetes as well as on the evolution of complications such as retinopathy, arterial atherosclerosis and nephropathy. Moreover, low serum magnesium is a strong, independent predictor of development of type 2 diabetes. A cross sectional study included 105 type 2 diabetic patients. Twenty nine were males (27.6%) and seventy six were females (72.4%).Their ages ranged from 30 to 77 with a mean of 49.7 ± 10.6. All patients were subjected to full clinical examination, and investigations which included: serum creatinine, HbA1c, albumin creatinine ratio and serum magnesium. Their mean BMI was 23 kg/m^2 and mean waist/hip ratio was 0.9.Their mean HbA1c was 8.55%. Of all patients, 13 of them had normal level of A/C ratio (control group) and 92 were albuminuric with a mean A/C ratio 238.26 ± 727.9 with a range of 33.7 (0.09–4700), mean s.creatinine was 1.29 ± 1.16 and their mean s.magnesium level was 2.04 ± 0.49 with a range of 1.9 (0.8–3.9). We observed significant negative correlation between A/C ratio and serum creatinine with a P-value of <0.0001. The study shows negative correlation between serum magnesium and A/C ratio($r = -0.202$, $P = 0.039$).

Keywords: Type 2 diabetes, diabetic nephropathy, albuminura, hypomagnesemia.

Association cystatin C with the presence of carotid atherosclerosis in patients with diabetes type 2 and chronic kidney diseaseassociation cystatin C with the presence of carotid atherosclerosis in patients with diabetes type 2 and chronic kidney disease

Volha Vasilkova[1,2], Tatiana Mokhort[3], Ivan Pchelin[4], Valentina Bayrasheva[5] & Natallia Filiptsova[2]
[1]Gomel State Medical University, Gomel, Belarus; [2]The Republican Research Center for Radiation Medicine and Human Ecology, Gomel, Belarus; [3]Belarusian State Medical University, Minsk, Belarus; [4]Saint Petersburg State University, Saint Petersburg, Russian Federation; [5]Laboratory of Diabetology of Institute of Endocrinology, Federal Almazov North-West medical research centre, Saint Petersburg, Russian Federation.

Objective
Cystatin C has been proposed as a novel marker of renal function and as a predictor of the severity of coronary atherosclerosis and future cardiovascular events. The aim was to evaluate the possible role of chronic kidney disease and particularly CysC on the characteristics of carotid atherosclerosis in patients with type 2 diabetes (DT2).
Materials and methods
We investigated 195 patients both sexes with DT2 aged 56.54 ± 4.17 years. Control group included 84 healthy subjects the same age. The intima-media thickness (IMT) was measured as the distance between the lumen-intima interface and the media-adventitia interface. Atherosclerotic plaque was defined as a focal structure encroaching into the arterial lumen of 0.5 mm or 50% of the surrounding IMT value. Total plaque area (TPA) was calculated as the sum of all plaque areas. GFR was estimated using the modification of diet in renal disease (MDRD) equation.
Results
Patients were divided into 2 groups by CysC levels tertiles. Patients in the high CysC tertile ($n = 76$) had significantly higher mean carotid IMT (0.88 ± 0.12 mm vs. 0.76 ± 0.07 mm, $P = 0.03$), and TPA (4.69 ± 2.03 mm^2 vs. 2.71 ± 0.57 mm^2, $P = 0.02$) compared to patients in the lower tertiles ($n = 119$). CysC levels demonstrated significant positive correlation with the mean carotid IMT ($r = 0.35$, $P = 0.011$). In multivariate analyses adjusted for cardiovascular risk factors, the association between CysC and IMT remained significant ($P = 0.037$). In contrast, neither serum creatinine nor estimated GFR were associated with IMT ($P = 0.17$).
Conclusions
Our study demonstrated a significant association of increased CysC levels with characteristics of carotid atherosclerosis in patients with type 2 diabetes and chronic kidney disease.

Diabetic ketoacidosis among SGLT2i-treated patients: insight from a single medical center located in the region with the highest diabetes mellitus mortality rate in Israel

Anat Jaffe, Naomi Dafni & Galith Haran
Hille Yaffe Medical Center, Hadera, Israel.

SGLT2i drugs have been funded by the Israeli health basket since 2017 for patients with type-2-diabetes and previous cardiovascular disease, as a result of the EMPA-REG outcome studies documenting 34% reduction in all-cause mortality. In 2015 the FDA warned that SGLT2i may result in diabetic-ketoacidosis (DKA). The reported DKA cases were not typical because many had type-2-diabetes and their blood glucose was slightly increased.
Objective
To describe DKA cases among patients treated with SGLT2i hospitalized in the Hadera region.
Methods
The electronic files of all hospitalized patients with DKA diagnosis (codes 250.10-13) during 2015-2017 were reviewed. Patients on SGLT2i treatment were analyzed.
Results
No cases were documented in 2015, two in 2016 and nine in 2017. DKA diagnosis and treatment within the hospital was delayed in 2(18%), length of hospital stay was 5.3 ± 1.9 days, 10 (91%) were diagnosed in the community as type-2-diabetes. Antidiabetic treatment: insulin 7(64%), metformin 7(64%), DPP-IVi 5(45%), GLP-1 agonist 3(27%) and sulfonylureas 2(18%). Mean blood glucose was 280 ± 84. Precipitating factors: 2(18%) had infection, 1(9%) drinking alcohol, 6(86%) stopped insulin. Four (40%) had pre-hospitalization clinical signs suggestive of LADA, of these: 3 were insulin treated, and 2 had recurrent DKA. Severity score was: 2(18%)-mild, 4(36%)-moderate and 5(45%)-severe; one died. Two restarted SGLT2i treatment after hospitalization, one recurred with DKA.
Conclusion
Patients with obvious insulin deficiency are being treated with SGLT2i, including some with previous DKA. Community and the medical center physicians and nurses should be aware of the a-typical presentation of DKA among patients with diabetes and SGLT2i.

Investigation of serum SCUBE-1 level in relation to microvascular complications in patients with type 2 diabetes mellitus

Umut Bingöl, Ayşe Kevser Demir, Faruk Kutlutürk, Zeliha Cansel Özmen & Osman Demir
Gaziosmanpaşa University, Tokat, Turkey.

Objective
The aim of this study was to investigate the association between serum level of signal peptide-CUB-EGF domain-containing protein 1 (SCUBE-1) and both type 2 diabetes mellitus and its related microvascular complications.
Material and methods
The study was included 50 type 2 diabetic patients with complications (group 1), 50 diabetic patients without complications (group 2) and 50 healthy individuals as control group (group 3). Anthropometry and blood pressure measurements were performed in all participants. Serum SCUBE-1 level was measured by ELISA method. Blood levels of fasting glucose, BUN, creatinine, liver function tests, prothrombin time, active partial thromboplastin time, hemoglobin, platelet count, serum lipid parameters, and HbA1c values of participants were recorded. The diagnosis of diabetic retinopathy was performed by indirect fundus examination

following pupil dilatation. The diagnosis of diabetic nephropathy was determined by microalbuminuria that measured by a 24-hour urine collection.
Results
The groups were similar in terms of age and gender ($P>0.05$). The median SCUBE-1 serum levels were 5.2 (2.35–9.55) ng/ml, 3.68 (1.47–6.42) ng/ml, and 3.87 (2.13–6.69) ng/ml in group 1, group 2, and group 3, respectively ($P=0.365$). There was not any significant difference between the groups according to SCUBE-1 serum level if diabetic subjects were divided into two groups according to their HbA1c levels as >7% or <7% ($P=0.913$). When all subjects were divided into two groups according to their fasting blood glucose levels as <200mg/dl or >200 mg/dl, median serum SCUBE-1 levels were 3.57 (1.79–6.72) ng/ml and 5.63 (2.45–9.88) ng/ml, respectively ($P=0.030$).
Conclusion
There was a positive correlation between serum SCUBE-1 level and fasting blood glucose level. However, there was not any meaningful change between serum SCUBE-1 level and diabetic microvascular complications such as diabetic retinopathy or nephropathy.

Hyperlipidemia during gestational diabetes: maternal and offspring complications

Aura D. Herrera-Martínez[1], Rafael Palomares Ortega[1], Rodrigo Bahamondes Opazo[2], Paloma Moreno Moreno[3] & María A. Gálvez Moreno[3]
[1]Reina Sofía University Hospital, Córdoba, Spain; [2]Reina S, Córdoba, Spain; [3]Reina Sofia University Hospital, Córdoba, Spain.

Lipid profile suffers adaptive changes during pregnancy due to estrogen stimulation and insulin resistance. Several relations have been suggested between maternal lipid profile, glucose tolerance, endothelial cell dysfunction and long-term cardiovascular risk; the effects of maternal lipid profile metabolism in fetal growth are also inconclusive. Since a regular evaluation and follow-up of lipid profile during pregnancy has not been stablished yet, we aimed to evaluate the incidence of dyslipidemia in patients with gestational diabetes (GDM) and analyze some putative relations with pregnancy, offspring complications and maternal metabolic syndrome parameters determined three and twelve months after delivery.
Patients and methods
Two hundred and fifty patients with GDM were included. Full medical history, offspring characteristics, lipid profile and maternal variables of metabolic syndrome were evaluated during pregnancy, three- and twelve-months after delivery, the incidence of dyslipidemia during pregnancy was determined using two different classifications.
Results
Lower plasma HDL and hypertriglyceridemia were the most current disorder; prematurity or birth weight were not correlated with dyslipidemia; during pregnancy the lipid-related parameter that better predicted the risk of offspring macrosomia was triglycerides (TG); high TG three months after delivery were correlated to macrosomia and metabolic syndrome characteristics before and after pregnancy (three and twelve months).
Conclusions
TG during pregnancy is the parameter that best predicts the risk of macrosomia and is related to increased metabolic risk after delivery, the evaluation of lipid profile and other metabolic variables during pregnancy and after delivery are required to early diagnose cardiovascular risk factors especially in high risk population.

Osteopontin levels in plasma, muscles and bone in patient with non-healing diabetic foot ulcers: a new player in wound healing process?

Marina Shargorodsky[1,2], Zeev Feldbrin[1,2] & Elena Omelchenko[1]
[1]Wolfson Medical Center, Holon, Israel; [2]Sackler Faculty of Medicine, Tel Aviv University, Tel AVIV, Jamaica.

Background
The present study was designed to investigate the impact of osteopontin (OPN) in different tissue (e.g., plasma, muscles and bone) on amputation rate (in-hospital and during one year follow-up) for non-healing diabetic foot ulcers (DFUs).
Methods
This pilot study consisted of 30 diabetic patients, hospitalized due to non-healing DFUs. Patients were divided into two groups: Group 1 included 14 patients who underwent limb-preserved debridement procedure; Group 2 included 16 subjects who underwent amputation. Additionally, the study participants were divided into two groups according reccurent amputation rate during 1 year follow-up.
Results
Plasma OPN was higher and bone OPN was lower in Group 2 compare to Group 1 ($P=0.016$ and $P=0.004$, respectively). In the logistic regression analysis, bone OPN emerged as a significant independent predictor of amputation (OR=0.042, 95% CI 0.003–0.699, $P=0.027$). Plasma OPN was also associated with amputation such that each unit increase in plasma OPN was associated with increase in odds of amputation of 17.7% (95% CI 0.997–1.388, $P=0.054$). The study participants were divided into two groups according amputation during 1 year follow-up: Group 1 included 11 patients who underwent amputation; Group 2 included 19 patients who did not need amputation at one year follow-up. Plasma OPN were higher and bone osteopontin was lower in Group 1than in Group 2. However, in GLM analysis bone OPN was marginally associated with one year amputation.
Conclusions
Decreased levels of OPN in bone and increased plasma OPN are independently associated with in-hospital amputation in patient with non-healing diabetic foot ulcers.

Impaired awareness of hypoglycaemia does not affect the prevalence of diabetes-related distress in people with diabetes type 1

Damianos Tsitlakidis, Nadine Kuniss, Ulrich Alfons Müller, Nicolle Müller, Christof Kloos & Guido Kramer
Endocrinology and Metabolic Diseases, Department for Internal Medicine III, Jena University Hospital, Jena, Germany.

Objective
The aim of this study was to assess prevalence of impaired awareness of hypoglycaemia (IAH) by the Gold method in people with type 1 diabetes and to compare people with and with IAH regarding metabolic control.
Methods
In a cross-sectional study, we assessed IAH in 139 people with type 1 diabetes (54.1y, diabetes duration 24.0y, HbA1c 7.1%) attending the University outpatient department for endocrinology and metabolic diseases. IAH was assessed using the Gold method by asking the question "Do you know when your hypos are commencing?" while scoring on a Lickert scale from 1 ("always") to 7 ("never"). A Gold score ≥ 4 is considered as IAH.
Results
Impaired awareness of hypoglycaemia had 25.2% (n=35/139) of the participants. Individuals with IAH had a longer diabetes duration (56.5 ± 13.3 vs. 53.2 ± 14.4 years, $P=0.001$) and lower threshold of blood glucose level when noticing first symptoms of hypoglycaemia (3.0 ± 1.2 vs. 3.7 ± 0.6 mmol/l, $P=0.006$) than people with normal awareness. Furthermore, people with IAH had more episodes of hypoglycaemia without symptoms (1-3 events per month: 31.4 vs. 17.5%, 1-3 per week: 37.2 vs. 17.5%). We did not find a difference of PAID Score in patients with and without IAH had (score 19.1 vs. 17.8 out of 100). There were also no differences regarding number of non severe an severe hypoglycaemia, satisfaction of diabetes treatment social status and HbA1c (7.0% vs. 7.2%, $P=0.363$), in individuals with IAH compared to normal awareness.
Conclusions
One out of four individuals with type 1 diabetes showed IAH. Risk of hypoglycaemia without symptoms is higher in people with IAH despite HbA1c is comparable between patients with IAH and normal awareness. To reduce risk of hypoglycaemia, glucose targets should be adjusted in people with IAH.

The comparison of the fate of arteriovenous fistula in diabetic and non-diabetic recipients following kidneytransplantation

Alparslan Ersoy[1], Hikmet Utku Odman[1], Atıf Yolgösteren[2], Ayşegül Oruç[1], Suat Akgür[1], Abdülmecit Yıldız[1] & Canan Ersoy[3]
[1]Uludag University Medical Faculty, Department of Nephrology, Bursa, Turkey; [2]Uludag University Medical Faculty, Department of Cardiovascular Surgery, Bursa, Turkey; [3]Uludağ University Medical Faculty, Department of Endocrinology and Metabolism, Bursa, Turkey.

Native arteriovenous fistula (AVF) represents the best vascular approach for chronic hemodialysis. It is difficult to create an AVF in diabetic hemodialysis patients due to atherosclerotic changes in the arteries. Although AVF becomes useless after a successful kidney transplant, there is no accepted policy for preserving or ligating AVF. The aim of this study was to compare the fate of AVFs in diabetic and non-diabetic patients after kidney transplantation.
Methods
The study included 129 (66 males, 63 females) consecutive kidney transplant recipients with AVF. Our cohort excluded patients with vascular access problems and/or permanent catheter placement prior to transplantation. The patients were divided into two groups: diabetics ($n=25$) and non-diabetics ($n=104$). Features and fates of AVF in both groups were evaluated.
Results
The female ratio, mean age and body mass index of diabetic patients were higher than those of non-diabetics (72% vs 43%, $P<0.01$; 51 ± 8 vs 44 ± 10 years, $P=0.004$ and 29.9 ± 5.1 vs 26.9 ± 7.8 kg/m^2, $P=0.001$, respectively). The renal replacement type, donor type, donor age, systolic and diastolic blood pressures, pulse beat and hemoglobin levels were comparable between two groups. The ratio of brachiocephalic AVF was higher in the diabetics (68% vs 43%, $P=0.017$). There was no significant difference between history of dialysis catheter (72% vs 86.5%) and the ratio of functioned AVF (36% vs 54.4%) in diabetic and non-diabetic groups, respectively. Symptoms and findings did not differ between two groups. The ratio of aneurysm in non-diabetic groups was higher (28.8% vs 8%, $P=0.030$). In both groups, cosmetic and esthetic concerns were not different. The ratio of steal syndrome was higher in diabetics (12% vs 2.9%, $P=0.052$). After transplantation, AVFs were closed in 6 diabetic patients and 31 non-diabetic patients ($P>0.05$). The causes of fistula closure were similar (infection in 7, pain in 4, edema in 9, cardiac in 13, own choice in 2 and aneurysm in 1 patient). The ratios of ejection fraction, left ventricular hypertrophy, pulmonary hypertension and valvular disease in the patients were similar in both groups. Mean serum creatinine levels in non-diabetics and diabetics were 1.33 ± 0.59 and 1.48 ± 0.65 mg/dl at the last visit, respectively ($P=0.139$).
Conclusion
Our study showed that the presence of diabetes mellitus did not significantly affect fistula-associated symptoms and findings, fistula fate and graft survival after kidney transplantation.

DOI: 10.1530/endoabs.56.P442

TSH and adiponectin levels in patients with diabetic kidney disease after renal transplantation

Alena Sazonava[1,2], Tatiana Mokhort[2], Natalia Karlovich[2], Volha Shyshko[2] & Anna Dolgolikova[3]
[1]City Endocrinological Dispensary, Minsk, Belarus; [2]Belarusian State Medical University, Minsk, Belarus; [3]Republican Scientific and Practical Center for Organ and Tissue Transplantation, Minsk, Belarus.

Aims
Diabetic nephropathy (DN) is a leading cause of chronic kidney disease (DKD). Various hormonal disturbances are not rare among DKD patients. Adipose tissue as an active endocrine organ with multiple metabolic effects may play an extra important role in hormonal disbalance during progressive kidney function decline. The purpose of the study was to investigate potential relationship between thyroid status and adiponectin levels in patients with type 1 diabetes (T1D) and DKD after renal transplantation (RT).
Materials and methods
We recruited 121 patients (43 m; 78 f; age 42.26 ± 11.670 yrs; duration of T1D 23.07 ± 9.95 yrs) with T1D. Hypertension was observed in 84(69.42%) patients, 62(51.24%) patients took ACE inhibitors. Dyslipidemia was found in 107(88.43%) patients, and only 34(28.10%) of them received statins. GFR was estimated by CKD-MDRD formula. Kidney injury was assessed using NGAL. All patients were divided into 2 groups: the group 1 comprised 105 patients at stages 2–4 of DKD (GFR 64.0[49.00; 75.00] ml/min); group 2–16 patients with DKD after renal transplantation (GFR 42.5[27.95; 51.15] ml/min). In group 1–21 patients received replacement therapy with levothyroxin, in group 2 only 1 (mean dosage 106.55 ± 37.84 mcg vs 25.00 mcg). Biochemical parameters, HbA1c, thyroid hormones, NGAL, adiponectin levels were measured. Nonparametric statistical methods were used. A P-value <0.05 was considered significant.
Results
Groups were matched by age, gender, HbA1c, diabetes duration, blood pressure, LDLc levels. Comparative analysis of patients in the subgroups revealed reliable differences in BMI ($P=0.028$), adiponectin ($P=0.034$), NGAL ($P=0.009$), TSH ($P=0.048$), AbTSH-R ($P=0.002$). Mean BMI in group 1(25.53[22.54; 28.74]) was higher than those after RT(23.17 [20.87; 24.71]). Adiponectin levels were higher in patients after RT(26.65[16.73; 69.31]) vs DKD(14.18[10.46; 23.60]). Mean TSH levels were higher in patients after RT(3.16[2.39; 4.41] vs 2.27[1.61; 3.55]). AbTSH-R were much lower in patients after RT(0.33 ± 0.08 vs 0.545[0.3; 1.21]). NGAL levels were significantly higher in patients after RT 3.49[3.27; 6.69] vs 0.88[0.48; 1.75]. Correlation of adiponectin and TSH was observed in group 2($r=0.812$). In patients after RT TSH levels correlate with BMI ($r=0.579$). In group 1 inverse correlations of adiponectin and BMI was revealed ($r=-0.273$).
Conclusion
Patients with T1D after RT have reliably higher levels of TSH and adiponectin than patients with stages 2–4 of DKD, which may represent deeper metabolic disorders than in patients before transplantation.

Knowledge and Attitudes of Trainee Doctors in the Management of DKA and Compliance with current Protocol in a large University Teaching Hospital

Carmel Kennedy[1], Tara McDonnell[1], Kennedy Cormac[2], Salmaan Bholah[1], Valerie Julius[1], Agnieszka Pazderska[1], Marie Louise Healy[1] & Niamh Phelan[1]
[1]Endocrinology Department, St James' Hospital, Dublin, Ireland; [2]Pharmacology Department, St James' Hospital, Dublin, Ireland.

Diabetic Ketoacidosis (DKA) is a diabetic emergency with associated morbidity and mortality. Current evidence supports a protocol-based approach to its management. Our survey was conducted in a tertiary university hospital, where patients with DKA are initially managed as part of unselected general medical take.
Objectives
To assess knowledge and confidence of trainee doctors in DKA management. To review adherence to DKA protocol and identify areas for future intervention and improvement.
Methods
Using diabetes consultation records, we identified 30 patients admitted with DKA to our hospital between October 2016 and October 2017. We audited adherence to the current DKA protocol. Concurrently, a survey was circulated to medical trainees to identify knowledge and attitudes towards DKA.
Results
Suboptimal compliance with DKA protocol was identified with respect to fluid resuscitation and adequate monitoring of potassium, with subsequent development of hypokalemia in eight patients. 33.33% of patients developed hypoglycaemia during intravenous insulin infusion, most commonly due to delayed cessation of fixed, weight-based doses of insulin infusion once ketonemia had resolved. 55 (29%) of medical trainees working in the hospital responded to our survey. 60% of respondees demonstrated poor knowledge of appropriate fluid resuscitation. 75% reported that checking potassium at the advised intervals was only achievable on wards where nursing staff perform phlebotomy. Only 45% of those surveyed recognised the need to switch to variable rate insulin when DKA resolved. Only 20% expressed confidence in performing the switch from IV to subcutaneous insulin.
Discussion
Fidelity to DKA protocols is often poor. Prior research on interventions to improve compliance is primarily from the ICU setting. We show that deviations mirror areas where physicians lack confidence. A multifactorial educational intervention has been proven to be effective at improving guideline compliance in DKA.

The association between glycemic markers and variability with plasma adipocytokine levels and markers of endothelium dysfunction in women with pregestational diabetes mellitus

Seher Tanrikulu[1], Sakin Tekin[1], Gulsah Yenidunya Yalin[1], Elif Bagdemir[1], Cemile Idiz[1], Elmire Dervisoglu[2], Songul Hatiboglu[2], Sema Genc[2] & Nevin Dinccag[1]
[1]Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Endocrinology and Metabolism, Istanbul, Turkey; [2]Istanbul University, Istanbul Medical Faculty, Department of Biochemistry, Istanbul, Turkey.

Introduction
Pregnant women with pre-existing diabetes are at greater risk of perinatal morbidity and diabetic complications. Glycemic control is the greatest impotance for both mothers and infants due to the risk of congenital anomalies, perinatal mortality and significant morbidity in the short and long term. Continuous glucose monitoring system (CGMS) is a novel tool to assess 24-h glucose fluctuations. In pregestational diabetes, CGMS may have an important role for excellent glucose control and treatment adjustments in conjunction with other glycemic status markers. Aim of this study was to assess relationship between these glycemic markers and CGMS parameters and their correlations with adipocytokine visfatin, 8-isoprostane, a marker of oxidative stress, and endogenous NOS inhibitor - asymmetric dimethylarginine (ADMA).
Material and methods
Twenty pregnant women (mean age 32.2±5) with pregestational diabetes mellitus (14 with type 1DM, 6 with type 2 DM with history of diabetes for 9.5 years) who admitted to our gestational diabetes mellitus outpatient clinics, were included in this study. All patients used insulin during pregnancy. CGMS profiles for >5 day in the 32 week of gestation were compared with glycemic markers-HbA1c and 1,5-anhydro-D-glucitol (1,5-AG). Visfatin, 8-isoprostane and ADMA levels were determined by ELISA.
Results
Seven of patient were primipar and 6 of them give more than 3 births. BMI before pregnancy was 25.8±3.3 kg/m^2, weight gain during pregnancy was 12.3±5.1 kg. Mean values of HbA1c, 1,5-AG were 6.5±0.6 and 0.5±03 ng/ml respectively. The number of glycemic excursions were 16.2±7.3 which was consist of high (11.6±6) and low excurtions (4.5±3.5). Mean absolute difference percentage (MAD%) was 12.5±6.6. Mean levels of visfatin, 8-isoprostane and ADMA were 6.4±3.8 ng/ml, 463.4±120 ng/L and 0.53±0.06 µmol/l respectively. HbA1c, fructosamine and ADMA levels were not associated with glycemic markers or other cytokine levels. Visfatin levels were correlated with 1,5 AG ($r=0.979$, $P=0.000$). 8-isoprostane levels were inversely related to the lowest value in CGMS data ($r=-0.649$, $P=0.002$). There were no significant interactions between cytokines and MAD%, glycemic excurtions in CGMS.
Conclusion
Including 1,5-AG, glycemic markers do not reflect glycemic variability. CGMS can be used to assess hypoglycaemia and glucose variability in conjunction with HbA1c. It is also important for treatment adjustment in all patients with type1 diabetes and patients with type 2 diabetes treated with insulin therapy.

Acoustic Radiation Force Impulse Elastography and Ultrasonographic Findings of Achilles Tendon in Patients with and without diabetic peripheral neuropathy: a cross-sectional study

Ozlem Turhan Iyidir[1], Feride Kural Rahatlı[2], Yusuf Bozkuş[1], Lala Ramazanova[1], Hale Turnaoğlu[2], Aslı Nar[1] & Neslihan Başçıl Tütüncü[1]
[1]Başkent University, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Başkent University, Department of Radiology, Ankara, Turkey.

Diabetic foot is one of the most feared complication of diabetes. The tendons and ligaments' stiffness and elasticity are known to be altered in diabetic foot. Achilles tendon (AT) plays an important for foot biomechanics and the altered stiffness of AT may have a role in pathogenesis of diabetic foot. Determination of the early changes in AT may help to identify the risky patients for diabetic foot. Acoustic Radiation Force Impulse (ARFI) Elastography is an elastography measures the shear wave velocity (SWV) of the target region inside the region of interest without external compression. Here we aimed to evaluate the elastographic features of AT with ARFI in patients with and without diabetic neuropathy. Forty five patients with type 2 diabetes recruited from the outpatient clinics served as the study group and were divided in two subgroups according to presence of peripheral neuropathy. Those with peripheral neuropathy were defined as group I (22 patients) and those without peripheral neuropathy were defined as group II (23 patients) Thirty age-, gender-, and body mass index (BMI)-matched healthy individuals were served as controls. The middle portion of Achilles tendon which is nearly 2-6 cm proximal to the calcaneus insertion is chosen for both ultrasonographic and ARFI elastographic examination. There was no statistically significant difference between the groups in terms of gender, age, BMI, height, and weight. HbA1c levels and fasting plasma glucose were similar between group I and group II. Achilles tendon thicknesses (ATT) were similar between group I and II $P=0.991$). Both patient group's ATT were significantly higher than controls. (group I vs control $P=0.01$; group II vs control $P=0.006$). Stiffness of AT as represented as SWV was similar between patients without neruopathy and control group ($P=0.993$). SWV was significantly lower in patients with neuropathy compared with patients without neuropathy and control group ($P<0.001$).

	Group I	Group II	Control Group
SVW of right AT (m/s)	4.0±1.1	5.4±1.0	5.4±1.1
SVW of left AT (m/s)	4.0±1.1	5.5±1.1	5.4±1.2

To the best of our knowledge this is the first study evaluating stiffness of AT with ARFI. In conclusion diabetic patients with neuropathy have thicker and softer AT however elasticity of AT of diabetic patients without neuropathy was similar with healthy controls. Softening of AT may be an early sign of diabetic foot and may indicate risky patients for diabetic foot.

Impact of systemic and local cytokine status in diabetic foot syndrome on ulcers healing rate

Maryia Mashkova[1], Tatiana Mokhort[1], Vitaliy Goranovb[1], Alena Shyshko[1], Liliya Chvatova[1], Inessa Pukita[2] & Volha Symantovich[1]
[1]Belarusian State Medical University, Minsk, Belarus; [2]Endocrinology Medical City Center, Minsk, Belarus.

Aim
To study the relationship of cytokines level in patients with diabetic foot syndrome (SDS) with a healing rate of ulcerative defect and diabetes compensation.
Materials and methods
Twenty-four patients with DFS (DFS group) and 24 diabetic patients without foot ulcers (control group) (both groups comparable in age and other clinical and general laboratory characteristics, ongoing treatment, offloading mode). All DFS patients had chronic non-infected foot ulcers Wagner 2. Cytokine levels (IL-6,8,1,4) in the blood serum (both groups) and ulcers exudate (DFS group) were determined. Ulcer area was calculated at the first visit and in 8 weeks (if not healed).
Results
In the DFS group IL-1 and IL-6 level was significantly higher than in the control group – 94.53±3.2 vs. 34.95±1.36 and 16.33±1.02 vs. 9.27±0.27 ($P<0.05$) accordingly. In the DFS group IL-8 level in ulcer exudate was much higher than in the blood serum 35.56±2.5 vs. 9.76±1.84 ($P<0.05$). The correlation analysis revealed positive correlation between HbA1c and serum IL-1 ($r=0.634$, $P<0.05$) and IL-6 ($r=0.521$, $P<0.05$) level and IL-8 level in ulcers exudate ($r=0.654$, $P<0.05$) in the DFS group. Significant negative correlation was revealed between IL-4 level in ulcer exudate and wound healing rate in DFS group ($r=-0.620$, $P<0.05$) but no such correlation was revealed for HbA1c level.
Conclusion
Thus, the study of the local cytokine status (in ulcer exudate) in patients with DFS can help to identify new mechanisms that determine ulceration, limit and predict the course of the wound healing process.

The relationship between cardiovascular autonomic neuropathy and the severity of coronary atherosclerosis

Olena Stepura[1] & Georgiy Mankovskiy[2]
[1]P.L.Shupyk National Medical Academy of Postgraduate Education, Department of Diabetology, Center for Innovative Medical Technologies, Kyiv, Ukraine; [2]Scientific and Practical Medical Center of Pediatric Cardiology and Cardiac Surgery, Kyiv, Ukraine.

Introduction
Cardiovascular autonomic neuropathy (CAN) is a significant risk factor for cardiovascular morbidity and mortality in patients with diabetes mellitus. However, an association between CAN and severity of coronary atherosclerosis in patients with ischemic heart disease (IHD) was not investigated.
Objectives
The aim of this study was to investigate the relationship of CAN and coronary stenosis in patients with clinical signs of IHD.
Materials and methods
We examined 63 patients, 48 men and 15 women with clinical symptoms of IHD (aged 61.79 ± 1.18 years, BMI – 30.39 ± 0.61 kg/m^2) (data are presented everywhere as mean ± SEM). All patients were performed coronaroventriculography, oral glucose tolerance test and 5 standart tests to diagnose CAN by Ewing. The diagnosis of CAN was confirmed in patients with 3 positive tests. The data analysis by SPSS statistical package version 23.0 for Windows.
Results
CAN was diagnosed in 52.4% patients, diabetes mellitus type 2 was diagnosed in 17.5% patients. All patients were divided for 3 groups depending on the number of occluded coronary arteries – with lesions in 1, 2 or 3 arteries. We found positive correlation between the number of the coronary arteries with atherosclerotic lesions and impaired results of Valsalva maneuver reflecting parasympathetic dysfunction ($OR = -0.27$, $P < 0.05$) and with the changes of diastolic blood pressure to isometric exercise (handgrip test) reflecting sympathetic dysfunction ($OR = -0.44$, $P < 0.05$).
Conclusion
We found some relationship between the severity of coronary arteries stenosis and sympathetic and parasympathetic dysfunction in patients with IHD with and without diabetes mellitus. These data can suggest the pathogenetic role of the impairment of cardiovascular autonomic regulation in the progression of atherosclerosis of coronary arteries.

Type 1 diabetes is associated with a differential pattern of carotid atherosclerotic plaque types

Esmeralda Castelblanco[1,2], Anna Ramírez-Morros[1], Marta Hernandez[3,4], Minerva Granado[1,4], Angels Betriu[4], Manel Puig-Domingo[1,2], Nuria Alonso[1,2,5] & Didac Mauricio[1,2,4]
[1]Department of Endocrinology and Nutrition, University Hospital & Health Sciences Research Institute Germans Trias y Pujol, Badalona, Spain; [2]Centro de Investigación Biomédica sobre Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), ISCIII, Barcelona, Spain; [3]Department of Endocrinology and Nutrition, University Hospital Arnau de Vilanova, Lleida, Spain; [4]Biomedical Research Institute of Lleida, Lleida, Spain; [5]Biomedical Research Institute of Lleida, Lleida, Spain.

Introduction
The presence and type of atherosclerotic plaque is associated with future cardiovascular events (CVE). We previously described that increased frequency of plaques is associated with specific features in type 1 diabetes. The aim of the present study was to investigate the characteristics of atherosclerotic plaques in patients with type 1 diabetes mellitus (T1D).
Methods
A cross-sectional study of 174 subjects with carotid atherosclerotic plaques (46.6% women; mean age 53.6 ± 9.6 years; 107 with T1D, 61.5%) with normal renal function, and without history of CVE. All patients underwent: 1) carotid ultrasound (mode B) to assess the type of plaque, 2) collection of clinical variables.
Results
There was a differential pattern of atherosclerotic plaque types in patients with T1D compared with non-diabetic controls ($P = 0.001$): hypoechoic 48.6% vs. 73.1%; hyperechoic 25.2% vs. 7.5%; hypoechoic/hyperechoic 16.8% vs. 17.9%, and calcified with or without other plaque types 9.4% vs. 1.5%, respectively. In addition, hyperechoic plaques were more frequent in T1D compared to non-diabetic controls (49.5% vs. 26.9% $P = 0.005$). In the multivariate analysis, the risk of having a hyperechoic plaque was higher in T1D subjects (OR 2.64; $P = 0.008$), and lower the higher the creatinine value (OR 0.04, $P = 0.029$), and also in female subjects (OR 0.33, $P = 0.019$). There was a significant interaction between sex and age, with age being a risk factor only in men ($OR = 1.12$, $P < 0.001$).
Conclusions
Patients with T1D show a differential pattern of atherosclerotic plaque type, with a higher frequency of hyperechoic and calcified plaques than in non-diabetic subjects.

Neurosensorial hearing loss in type 2 diabetic patients

Ersida Golemi[1], Anjeza Kuci[2], Elira Myrtaj[3] & Agron Ylli[4]
[1]Endocrinologist Main Policlinic of the Specialities Nr3, Tirana, Albania; [2]Otorinolaringologist, Main Policlinic of the Specialities Nr3, Tirana, Albania; [3]Endocrinologist, Hospital of Gjirokastra, Gjirokaster, Albania; [4]Endocrinologist, Mother Teresa Hospital of Tirana, Tirane, Albania.

Introduction
There is a connection between neurosensorial hearing loss and tipe 2 diabetes. Diabetes is a systemic chronic disease that affects the vessels and nerves. There are 415 million people all over the world that suffer from diabetes. There is not a clear mechanism of how diabetes is related to hearing loss but it s possible that the high blood glucose levels associated with diabetes cause damage to the small blood vessels in the inner ear, similar to the way in wich diabetes can damage the eyes and the kidneys.
Aim
The role of tipe 2 diabetes in neurosensorial hearing loss in patient without any other systemic disease like HTA and without any other risk of hearing loss like loud noise proffesions, genetics, asthma and other chronic diseases of the middle ear: chronic otitis media, otosclerosis. Obtaining a normal glucose level in diabetic patients (HbA1C < 7%) prevents early RNS hearing loss.
Method and patients
We have taken in our study 2 groups: one group of 100 patients with tipe 2 diabetes without any other systemic diseases and the other is the control group of 100 healthy people from 45–65 years old, from 2015–2017. We performed: blood count cells, biochemical balance, HbA1c, urine test from the endocrinologist and otoscopy, audiometry, tympanometry from the ent doctor
Results
The average of HbA1C was 9.2%. Some of them had other diabetic complications such as diabetic nephropathy, retinopathy and neuropathy. We found normal otoscopy and tympanometry, bilateral RNS hearing in the higher tones in 60 patients, in wich in those with higher HbA1C with grave RNS hearing loss and in the others with medial RNS hearing loss.
Conclusions
There is a strong connection between poor control diabetes and RNS hearing loss. In those with grave RNS hearing loss it was irreversible and needed acoustic prosthesis. We recommended good control of diabetes and performe an audiograme in every patient detected with diabetes.

Serum level of the autophagy biomarker beclin-1 in patients with diabetic nephropathy

Mervat Hussin & Laila Rashed
Cairo Univresity, Cairo, Egypt.

Introduction
Autophagy is a major clearance mechanism that destroys organelles and damaged proteins to keep cellular survival and homeostasis. Previous experimental studies have showed that autophagy has crucial role in the progression of diabetes and kidney diseases.
Aim
This pilot cross-sectional study aimed to investigate the association between serum concentrations of beclin-1, a key regulator of autophagy, and diabetic nephropathy.
Methods
The study included 70 patients with type 2 diabetes and diabetic nephropathy (group 1; 35 patients with eGFR > 30 ml/min/1.73 m^2 and group 2; 35 patients with with eGFR < 30 ml/min/1.73 m^2) and 20 age- and sex-matched healthy subjects as controls. Laboratory work up included; glycated hemoglobin (HbA1c), serum creatinine, estimated glomerular filtration rate (eGFR) using modification

of diet in renal disease (MDRD) formula, urine albumin to creatinine ratio (ACR), and serum beclin-1 measurement using an enzyme-linked immunosorbent assay.
Results
Patients with DN had significantly lower beclin-1 levels (2.38 ± 1.46 ng/mL) compared with control group (6.03 ± 1.94 ng/mL; $P < 0.001$). Moreover, patients in group 1 had significantly higher beclin-1 level (3.36 ± 1.30 ng/mL) than group 2 (1.43 ± .83 ng/mL; $P < 0.001$). In univariate analysis, the concentration of beclin-1 correlated well with eGFR ($r = .64$, $P < 0.001$), ACR ($r = -.63$, $P < 0.001$),and duration of diabetes ($r = -0.43$, $P < 0.001$) but didn't correlate HbA1c ($r = -.17$, $P = .15$).
Conclusion
This data suggest that low levels of serum beclin-1 could be a biomarker of DN in type 2 diabetic patients. Furthermore, it correlates well with the indicators of kidney function and renal damage.

The comparison of longevity of arteriovenous fistula in hemodialysis patients with or without diabetes mellitus

Atıf Yolgösteren[1], Abdülmecit Yıldız[2], Canan Ersoy[3] & Alparslan Ersoy[2]
[1]Department of Cardiovascular Surgery, Uludag University Medical Faculty, Bursa, Turkey; [2]Department of Nephrology, Uludağ University Medical Faculty, Bursa, Turkey; [3]Department of Endocrinology and Metabolism, Uludağ University Medical Faculty, Bursa, Turkey.

Vascular access remains both a life line and a 'weak link for patients receiving hemodialysis (HD) therapy. It difficult to create an arteriovenous fistula (AVF) in diabetic hemodialysis patients due to atherosclerotic changes in arteries. This study investigated the fate of AVFs in diabetic and non-diabetic HD patients.
Methods
The study included 306 patients (142 females, 164 males) on regular HD treatment with AVF. We excluded patients dialyzed with permanent catheter placement or arteriovenous graft. The patients were divided into two groups: diabetics ($n = 131$, 66 females) and non-diabetics ($n = 175$, 76 females). The history of cardiovascular diseases and AVF survival were evaluated.
Results
The dialysis features of both groups were comparable. The mean age and body mass index of diabetic patients were higher than those of non-diabetics (64 ± 10 vs 60 ± 15 years, $P < 0.014$, and 27.8 ± 5.3 vs 24.2 ± 4.1 kg/m^2, $P < 0.001$, respectively). There was no significant difference between the ratios of smoking and dyslipidemia in diabetic and non-diabetic groups (16.8% vs 21.7% and 7.6% vs 5.1%, respectively, $P > 0.05$). The ratios of coronary artery, peripheral and cerebral artery diseases were higher in diabetic patients than non-diabetics (6.2% vs 18.3%, $P = 0.002$; 2.3% vs 7.6%, $P = 0.049$; 2.1% vs 7%, $P = 0.004$, respectively). The longevity of AVFs was 26 months (range 0-1349) in diabetics and 30 months (range 0–-294) in non-diabetics ($P = 0.334$). The ratios of nonfunctioned AVF in diabetic group did not differ from non-diabetic group (26.7% vs 20.6%, $P = 0.220$).
Conclusion
Inadequate arterial inflow in diabetic HD patients have been increasingly recognized as the major cause of fistular malfunction. However, our study showed that the presence of diabetes mellitus in HD patients did not adversely affect longevity of AVF despite increased prevalence of arterial disease.

Endothelial dysfunction in the diabetic foot

Edward Jude[1,2,3], Janice Mascarenhas[1,3], Deepak Bhatnagar[2], R Weston[1], Fiona Wilkinson[1] & Yvonne Alexander[1]
[1]Manchester Metropolitan University, Manchester, UK; [2]University of Manchester, Manchester, UK; [3]Tameside Hospital NSH Foundation Trust, Ashton under Lyne, UK.

Endothelial dysfunction (ED) is common in type 2 diabetes mellitus (T2DM) and can lead to microvascular and macrovascular complications. The aim of our study was to assess ED in patients with T2DM ($n = 21$; 13 with diabetic neuropathy (DN), 8 without DN) and compare them with non-diabetic controls ($n = 10$).
Methods
ED was assessed by skin microcirculation (SM) and biochemical markers (BM) of endothelial function. SM was measured on the dorsum of the foot by laser Doppler (LD) iontophoresis using the Perimed Laser Doppler Imager. Endothelial-mediated vasodilation (EMV) was measured by the iontophoresis of acetylcholine (Ach), while sodium nitroprusside (SNP) was used to study endothelium-independent vasodilation (EIV). Fasting blood samples were collected at baseline for markers of endothelial activation (ICAM, VCAM and inflammatory molecules like IL-6).
Results
Patients in the control group were younger and had lower BMI and HbA1c. There was no difference in skin microcirculation between groups, for both EMV and EIV. There was also no difference in biochemical markers of ED including ICAM, VCAM, however, there was a significant up-regulation of IL-6 in T2DM ($P = 0.006$)
Conclusions
In this small study we found no difference in skin microcirculation and biochemical markers of ED. Of note, the inflammatory marker IL-6 was raised in diabetic patients and whether this influences the endothelial dysfunction observed in this patient group remains to be corroborated in larger studies.

Polyglandular Autoimmune Syndrome Type III(PAS) onset with diabetic ketosis caused by the insulin analog induced anti-insulin antibody: successful treatment with human insulin

Fatma Tugba Catan Erdekli[1], Alev Selek[2], Berrin Cetinarslan[2], Zeynep Canturk[2] & Ilhan Tarkun[2]
[1]Department of Internal Medicine, Kocaeli University, Kocaeli, Turkey; [2]Department of Endocrinology, Kocaeli University, Kocaeli, Turkey.

Type III PAS is defined as autoimmune thyroiditis occurs with another organ-specific autoimmune disease. Further PAS IIIA is subclassified as autoimmune thyroiditis with immune-mediated diabetes mellitus. Circulating organ-specific autoantibodies can be detected in these patients. We report a patient with Hashimoto Thyroiditis since five years on levothyroxine treatment with normal TSH levels and new onset insulin dependent Type I DM for 3 months. The patient was admitted Recurrent Diabetic Ketosis and succesfully treated by switching Analog insulin to Human Insulin. Analog–insulin Induced Anti-InsulinAntibody was thought to be the cause. 43-year-old female patient admitted to our hospital with diabetic ketoacidosis. She was treated with four times daily insulin injections with insulin aspart before meals and insulin detemir at bedtime. She did not miss any dose or there were no identified underlying cause for ketosis. She weighed 48.3 kg with BMI: 20.63 kg/m^2 and physical examination revealed no pathologic findings. Laboratory evaluation showed markedly increased HbA1c (10,5) levels together with decreased C-peptide levels (0.51 ng/ml). An autoimmunity screening was performed: antiGAD (51.27 IU/ml) and antiICA(+1) have positive results as suggesting the Type I DM. We started to insulin infusion with reguler insulin untill plasma ketones were negative. Insulin detemir and aspart were initiated as intensive treatment. Dose titration performed according to 7 point daily glucose monitorisation for a week. She has been treated with five daily insulin injections: 75 units of aspart and 60 units of detemir daily. Nevertheless her blood glucose levels were 200–310 mg/dl with this treatment. Consequently we started to insulin infusion with reguler insulin again. In the first hours of the regular infusion hypoglycemia developed with 4units/hour dosage. Anti-insulin antibody level was markedly elevated. (15U/ml; normal, <10 U/ml). We switched the treatment to regular and NPH insulin. Afterwards, her blood glucose quickly normalized and daily insulin need was decreased significantly to 50–55 units. She was discharged with regular insulin and NPH treatment. HbA1c level was 7.5% on third month follow-up. Immunological insulin resistance, which is characterized by a requirement for an insulin dosage over 120 U/day due to anti-insulin antibodies has since become quite rare. In the few reported cases, patients were treated with glucocorticoids or plasmapheresis Recently we succesfully treated a patient with severe immunological insulin resistance due to antibodies by modification of insulin administration; Analog insulin to Human Insulin.

Bone markers and bone integrity in type 2 diabetes

Edward Jude[1,2,3], Janice Mascarenhas[1], Deepak Bhatnagar[2], R Weston[1], Fiona Wilkinson[1] & Yvonne Alexander[1]
[1]Manchester Metropolitan University, Manchester, UK; [2]University of Manchester, Manchester, UK; [3]Tameside Hospital NHS Foundation Trust, Ashton under Lyne, UK.

Type 2 diabetes mellitus (T2DM) and obesity are linked to osteoporosis, making these patients at increased risk of developing fractures. In this study we aimed to investigate bone biochemical markers and bone structure in diabetic patients to compare with non-diabetic controls.
Methods
We recruited 21 type 2 diabetic patients and 10 non-diabetic controls. Fasting blood samples were collected for markers of bone turnover (Sclerostin (SCL), RANKL, OPG, OPN, OCN, BMP4 and TGF-1β and the inflammatory marker IL-6. Calcaneal bone mineral density (BMD) was measured using a quantitative ultrasound device called Sahara Clinical Bone Sonometer, in which the bare heel is placed in the device and the BMD is calculated within 30 seconds and where the *T*-score, projected by the device, was used as an indicator of calcaneal BMD.
Results
Patients in the control group were younger and had lower BMI and HbA1c. There was no difference in BMD between groups. OCN was higher in control group, whereas SCL, OPG and IL-6 were raised in the type 2 diabetic group. Furthermore, the type 2 diabetic cohort showed a strong positive correlation between Sclerostin and OPG and IL-6 and RANKL; and a negative correlation between RANKL and OCN and IL-6 and BMP-4.
Conclusions
Fracture risk in diabetes may be mediated by modulation of bone-related proteins. Although BMD showed no difference in bone structure between diabetic patients and controls, the alteration detected in osteogenic factors could reflect the increased risk of vascular calcification present in diabetic patients. This will be investigated in future studies.

Levels of scerostostin in serum and femoral vascular tissue and its relationship with atherosclerosis and cardiovascular mortality in patients with and without type 2 diabetes

Beatriz García-Fontana[1,2], Cristina Novo-Rodríguez[1], Francisco Andújar-Vera[1], Cristina García-Fontana[1], Sheila González-Salvatierra[1,3], Teresa Márquez-Hernández[1,3], Silvia Lozano-Alonso[4], Sonia Morales-Santana[5], Pedro Rozas-Moreno[6], Antonia García-Martín[1,2], Francisco O'valle-Ravassa[7], Juan De Dios Luna-Del Castillo[8] & Manuel Muñoz-Torres[1,2,3]
[1]Endocrinology and Nutrition Unit, Hospital Universitario Campus de la Salud, Instituto de Investigación Biosanitaria de Granada (Ibs.GRANADA), Granada, Spain; [2]CIBERFES. Instituto de Salud Carlos III, Madrid, Spain; [3]Department of Medicine, University of Granada, Granada, Spain; [4]Service of Angiology and Vascular Surgery, Universitario Campus de la Salud, Granada, Spain; [5]Proteomic Research Service, Fundación para la Investigación Biosanitaria de Andalucía Oriental-Alejandro Otero, Instituto de Investigación Biosanitaria de Granada (Ibs.GRANADA), Granada, Spain; [6]Endocrinology Division, Hospital General de Ciudad Real, Granada, Spain; [7]Department of Pathological Anatomy, University of Granada, Granada, Spain; [8]Department of Biostatistical, University of Granada, Granada, Spain.

Introduction
Sclerostin is a glycoprotein expressed mainly by osteocytes, which acts as inhibitor of bone formation. However, several studies have shown an increase in serum levels of sclerostin in subjects with type 2 diabetes (T2D) and cardiovascular disease (CVD) suggesting an additional role of this protein at the vascular level. The hypothesis that sclerostin could be expressed by vascular smooth muscle cells (VSMCs) under calcifying conditions could justify this elevation. However, there are few data at the tissue level.
Objectives
Determination of serum sclerostin levels in non-diabetic and T2D subjects with CVD and a at the transcriptional and immunohistochemical levels in femoral vascular tissue of patients with DM2 with atherosclerosis and non-atherosclerotic vascular tissue from healthy controls. Evaluation of the relationship between circulating sclerostin levels and cardiovascular mortality in subjects with and without T2D.
Material and methods
Serum sclerostin levels were determined in 75 T2D subjects with and without CVD and in 55 non-diabetic controls by commercial ELISA kit (Biomedica). Sclerostin expression was determined by RT-qPCR from 400 ng of total RNA from 45 sections of atherosclerotic femoral arterial tissue from subjects with T2D as well as from a healthy control. The gene expression was normalized according to the expression of two constitutive genes (GAPDH and ubiquitin). Immunohistochemical detection of sclerostin was performed on sections of paraffined vascular tissue using 1:50 antiesclerostin-specific antibody (Sigma Aldrich) and chromogenic detection. The relationship between sclerostin and cardiovascular mortality was assessed by a competitive risk analysis (Fine & Gray) after the 7-year follow-up of the cohort of diabetic and non-diabetic subjects with and without CVD.
Results
Serum sclerostin levels were significantly higher in T2D subjects with CVD compared to controls (58.29 ± 26.36 vs 39.27 ± 12.71 pmol/l, $P < 0.001$). Increased expression of sclerostin at the transcriptional and immunohistochemical level was observed in atherosclerotic femoral artery of T2D patients compared with the femoral artery of healthy control. Serum sclerostin levels were independently associated with cardiovascular mortality ($P = 0.008$).
Conclusions
The increase in serum sclerostin associated with CVD in T2D could be associated with an increased expression of this protein by vascular tissue. This suggests the involvement of sclerostin in the atherosclerotic process. In addition, high levels of sclerostin are associated with increased cardiovascular mortality, and it could act as new biomarker of cardiovascular mortality risk.

Serum lipid changes during pregnancy and after delivery in women with previous gestational diabetes

Montserrat Prados[1,2], Juana A Flores-Le Roux[2,3], David Benaiges[2,3], Gemma Llaurado[2,3], Juan José Chillarón[2,3], Verónica Amador[2], Cristina Bosch[3], Antoni Paya[4] & Juan Pedro-Botet[3,2]
[1]Hospital Sant Joan de Deu de Martorell, Martorell, Spain; [2]Departament of Medicine, Universitat Autonoma de Barcelona, Barcelona, Spain; [3]Endocrinology and Nutrition Department, Hospital del Mar, Barcelona, Spain; [4]Obstetrics and Gynecology Department, Hospital del Mar, Barcelona, Spain.

Background
Women with a history of gestational diabetes mellitus (GDM) are at increased risk for diabetes and lipid alterations.
Objective
In a cohort of women with previous GDM, we aimed to ascertain whether women with abnormal glucose tolerance one year post-delivery had a more atherogenic lipid profile after pregnancy than those with normal glucose tolerance.
Design and patients
A descriptive study of GDM women who underwent pre and postnatal follow-up at the Hospital del Mar, Barcelona between January 2004 and March 2016 was conducted.
Results
Three hundred and six (56.8%) of 537 women diagnosed of GDM during the studied period, attended a control visit during the first year after delivery. The incidence of type 2 diabetes mellitus (T2DM) and prediabetes in these patients was 5.2% and 36.6%, respectively. High-density lipoprotein (HDL) cholesterol remained significantly lower in women with T2DM (48 ± 11 mg/dl vs 59 ± 12 mg/dl; $P = 0.009$) and the prediabetes group (54 ± 13 mg/dl vs 59 ± 12 mg/dl; $P = 0.029$) at the first year postpartum than in those with normal glucose tolerance. Additionally, triglycerides were higher in the T2DM group compared with the normal glucose tolerance group (128 ± 60 mg/dl vs 89 ± 41 mg/dl; $P = 0.009$). There were no differences in LDL cholesterol levels within the three groups.
Conclusions
Women with previous GDM who develop T2DM or prediabetes one year post-delivery have lower HDL cholesterol concentrations than those with normal glucose tolerance. Moreover, those who develop T2DM have higher triglyceride concentrations than those with normal glucose tolerance.

The relationship between oxidative stress markers and carotis intima media thickness in patients with diabetic microvascular complications

Dilek Tuzun[1], Tugba Yilmaz[2], Ayten Oguz[1] & Kamile Gul[1]
[1]Department of Endocrinology and Metabolic Disease, Kahramanmaras Sutcu Imam University Faculty of Medicine, Kahramanmaras, Turkey; [2]Department of Internal Medicine, Kahramanmaras Sutcu Imam University Faculty of Medicine, Kahramanmaras, Turkey.

Aim
To investigate the relationship between oxidative stres markers and carotis intima media thickness in diabetic patients with microvascular complications.
Material and methods
112 patients with type 2 diabetes mellitus and 44 healthy control subjects were included in the study. The presence of diabetic retinopathy was investigated by ocular examination. Neurological examinations were performed for neuropathy. In addition, catalase (CAT), superoxide dismutase (SOD), glutathione peroxidase (GPx), malondialdehyde (MDA), nitric oxide (NO) and serum prolidase activity were measured for oxidative stress in the morning blood samples of all patients. Carotis intima media thickness (CIMT) was measured.
Results
Of the patients with type 2 diabetes mellitus, 80 (71.42%) had complications and 41 (28.58%) had no complications. When the groups were compared in terms of biochemical data; CRP levels in diabetic complication group were significantly higher than the other groups ($P<0.001$). Creatinine levels in diabetic complication group were significantly higher than the other groups ($P<0.001$). Protein levels in spot urine in diabetic complication group were significantly higher than the other groups ($P<0.001$). LDL levels in the diabetic complication group were significantly higher tham the others group ($P=0.018$). Triglyceride levels in the diabetic complication group were significantly higher than the others groups ($P<0.001$). There was no statistically significant difference between the groups in terms of TSH and fT4 levels. When the groups were compared in terms of oxidative stress markers; the antioxidant stress markers (CAT, SOD, GPx) were found to be lower in the diabetic complication group than the other groups ($P<0.001$, $P<0.001$, $P<0.001$, respectively), while oxidative stress markers (MDA and NO) were found to be higher in the diabetic complicated group. When the groups were compared in terms of CIMT; the CIMT was significantly higher in diabetic patients than in the healthy control group ($P<0.001$). There was statistically significant negative correlation between CIMK and antioxidant stress markers (CAT, SOD, GPx) while there was statistically significant positive correlation between CIMK and oxidant stress markers (MDA, NO).
Conclusion
In our study, serum oxidative stress parameters were found to be statistically significantly higher in diabetic patients with complications than the healthy control and diabetic patients without complications. Also we found there is positive correlation between carotis intima media thickness and oxidant stress markers.

Predictors of perinatal complications in pregnant women with gestacional diabetes

Filipe Manuel Cunha[1], José João Eira[2], Vanessa Pires[2], Sónia Carvalho[2] & Cláudia Nogueira[1]
[1]Serviço de Endocrinologia do Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, Portugal; [2]Serviço de Medicina Interna do Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, Portugal.

Background
Pregnant women with gestational diabetes (GD) have a higher risk of perinatal complication compared to women without. Nevertheless, in women with GD, predictors of perinatal complication are not well established. We aimed to compare, in women with GD, those with and without perinatal complications and to study predictors of perinatal complications in women with GD.
Methods
Retrospective study of pregnant women followed in the Endocrinology clinic of Centro Hospitalar de Trás-os-Montes e Alto Douro who had a childbirth in 2016. GD diabetes defined as fasting glycaemia $\geq$92 mg/dl in the first trimester or a 7g-OGTT at 24–28 weeks with at least one abnormal value ($\geq$92; $\geq$180 or $\geq$153 mg/dl at 0, 60 or 120 min, respectively). HbA1c used was the closest to the end of pregnancy available. Perinatal complications defined as a combination of preeclampsia, polyhydramnios, fetal macrosomia, preterm labour ($\leq$37 weeks), neonatal hypoglycemia, neonatal hyperbilirubinemia, neonatal distress respiratory syndrome, or trauma during delivery. We compared women with and without perinatal complications: χ^2 test, student t test and Mann Whitney U test. A multivariate logistic regression analysis was built to study predictors of perinatal complications.
Results
We studied 104 women, 27 with perinatal complications. Mean age was 34 years, 37.5% had a college degree. Mean body mass index before pregnancy was 26.2$\pm$5.3 kg/m^2 with a mean weight gain at the first appointment and at delivery of 8.2 kg and 11.1 kg, respectively. Median time between diagnosis and first appointment was 5 (3–9) weeks and the diagnosis of GD was made in the first trimester in 39.4%. Mean HbA1c was 5.2$\pm$0.4% and 44.2% needed treatment with metformin and/or insulin. Cesarean delivery rate was 37.5%. There were no significant differences between pregnant women with and without perinatal complications except in the birth weight that was lower in those with complications (2896$\pm$628 vs 3188$\pm$390; $P=0.03$). In the multivariate logistic regression analysis (variables included: age; college degree; time to fist appointment; GD diagnosed in the first trimester; metformin and/or insulin treatment, and HbA1c), only a college degree was an independent predictor of perinatal complications, OR 3.35 (95% IC: 1.23–9.12), $P=0.02$.
Conclusions
Pregnant women with GD with and without perinatal complications have similar social, anthropometric and clinical characteristics. The only variable associated with perinatal complications was having a college degree. Pregnant women with a college degree had more than three times the risk of perinatal complications.

Role of the lipid profile as a predictive factor in the development of diabetic retinopathy in patients with type 1 diabetes

Juan Manuel Zubiría[1], María José Goñi[1], Nerea Eguílaz[1], Ana Irigaray[1], Joaquín De Carlos[1], Lluis Forga[1] & Ibai Tamayo[2]
[1]Complejo Hospitalario de Navarra, Pamplona, Spain; [2]Navarra Biomed, Pamplona, Spain.

Introduction
Diabetic retinopathy (DR) is the most common microvascular complication in patients with type 1 diabetes (T1D), and the role of lipids in the development of this complication is still controversial. In this study we have analyzed the association between lipid levels at onset and during the follow-up and the subsequent development of DR.
Methods
The cohort consists of 1132 patients with T1D who were diagnosed in Navarra between 1/1/1990 and 12/21/2016. Information on their LDL-cholesterol, HDL-cholesterol and triglycerides levels was collected at onset and during the follow-up, and the diagnosis of DR was accomplished according to the criteria of the American Academy of Ophthalmology. The results were analyzed using Student-Fisher t test, univariate regression and Cox multivariate regression model.
Results
Comparing the group of patients with T1D who developed DR in relation to those who did not develop it, we observed significantly higher LDL-cholesterol at onset (117.0$\pm$60.5 mg/dl vs 109.0$\pm$45.8 mg/dl, $P=0.002$), higher triglycerides (90.5$\pm$67.8 mg/dl vs 79.0$\pm$60.0 mg/dl, $P=0.02$); and significantly lower HDL-cholesterol at onset (45.5$\pm$22.2 mg/dl vs 49.0$\pm$20.0 mg/dl, $P=0.05$). In the univariate analysis, adjusting for other factors such as age, gender, BMI, smoking habit, blood pressure, and HbA1c or C-peptide levels, we observed that LDL-cholesterol, triglycerides and HDL-cholesterol were significantly associated with the risk of DR throughout follow-up. The multivariate analysis confirmed the results observed in the univariate results in terms of triglycerides: an increase of 10 mg/dl in triglycerides during the follow-up raises the risk of developing DR by 2.9% (HR 1.029 (CI95%: 1.01–1.05), $P=0.003$). However, the association between HDL-cholesterol and DR in multivariate analysis was only marginally significant (HR 0.91 (CI95%: 0.83–1.00), $P=0.058$); and the association of LDL-cholesterol with DR development was not significant.
Conclusions
1) In patients with T1D, lipid profile at onset is a predictor of DR development; 2) high levels of triglycerides can be considered as a risk factor for development of DR in T1D.

Markers of nitrosative stress, angiogenesis and inflammation linked to severity of complications in type 1 diabetes

Jelizaveta Sokolovska[1,2], Kristīne Ošina[1], Alise Dekante[1,2], Gita Krievina[3], Pēteris Tretjakovs[3], Valdis Pīrāgs[1,2] & Nikolajs Sjakste[1]
[1]University of Latvia, Riga, Latvia; [2]Pauls Stradins Clinical University Hospital, Riga, Latvia; [3]Riga Stradins University, Riga, Latvia.

Background
Hypoxia, oxidative stress and inflammation induced by hyperglycaemia are 'key players' in development of diabetic complications.
Aim
To analyze differences in levels of nitric oxide (NO) and its metabolites nitrate and nitrite (NO2/NO3) and well as angiopoietin 2 (Ang2) and neuropeptide Y (NPY) in patients with type 1 diabetes and different complications status; to analyze associations between these markers.
Methods
Samples of 315 of LatDiane study patients with type 1 diabetes duration more than 1 year were analyzed. Albuminuria was estimated *via* morning spot urine albumin/creatinine ratio. eGFR was calculated with CKD-EPI equation. Ang2 and NPY in serum were measured by for Luminex xMAP Technology and ELISA respectively. Added concentration of NO2/NO3 in serum and urine was measured by Griess reaction. Production of NO in the whole blood was detected by means of ESP spectroscopy of Fe-DETC-NO complex.
Results
NO2/NO3 in serum was higher and in urine - lower in patients with macroalbuminuria and ESRD compared to normo- and microalbuminuric patients (serum: 50.054 ± 38.00 μM vs 32.35 ± 22.41 μM, $P=0.02$; urine: 550.63 ± 550.77 μM vs 917.84 ± 813.19 μM, $P=0.018$). Similarly, patients with proliferative retinopathy had lower NO2/NO3 levels in urine compared to earlier stages of retinopathy (701.26 ± 620.04 μM vs 961.35 ± 848.79 μM; $P=0.02$). Significantly lower levels of NO2/NO3 in urine were found also in patients with diabetic polyneuropathy. Ang2 levels were higher in patients with macroalbuminuria/ESRD (1696.7 ± 1379.88 pg/ml vs 785.0 ± 450.7 pg/ml, $P=0.001$), proliferative retinopathy (1015 ± 845.28 pg/ml vs 808.68 ± 538.09 pg/ml, $P=0.017$), history if CVD (1381.38 ± 1256.51 pg/ml vs 823.36 ± 548 pg/ml, $P=0.000$) compared to patients without these determinants. Higher NPY levels were found in patients with macroalbuminuria and ESRD compared to normo- and microalbuminuric patients (19.91 ± 7.14 ng/ml vs 14.52 ± 7.57 ng/ml, $P=0.001$). NO, NO2/NO3 in urine and serum as well as Ang2 and NPY correlated with eGFR ($P<0.05$). Serum NPY correlated with blood NO and serum Ang2 levels ($P<0.05$).
Conclusions
Differences in levels of nitric oxide metabolites, Ang2 and NPY levels are observed in biological fluids of patients with different stages of diabetic complications. Data on association between these markers provide new knowledge about links between hypoxia, inflammation and oxidative stress in type 1 diabetes.

Nonalcoholic fatty liver disease in men with type 2 diabetes mellitus and androgen deficiency

Yanina Allakhverdieva, Irina Khripun, Sergey Vorobyev & Nikolay Mineev
Rostov State Medical University, Rostov-on-Don, Russian Federation.

Background
Nonalcoholic fatty liver disease (NAFLD) is the most common cause of liver diseases, and the presence of type 2 diabetes mellitus (T2DM) increases its incidence up to 90%. To date, the effect of androgen deficiency in men with T2DM on the development of NAFLD has not been studied.
Aim
To assess the effect of the endogenous testosterone (T) level on the incidence of NAFLD in men with T2DM.
Materials and methods
The study included 50 men with T2DM (mean age 53.6 ± 5.9 years) who were divided into 2 groups: the 1st one included 20 patients with T level ≥ 12.1 nmol/l, the 2nd - 30 men with T level <12.1 nmol/l. Patients underwent clinical examinations, such as: assess of anthropometric data (weight, BMI, waist circumference (WC), hip circumference (HC)), evaluation of parameters of carbohydrate and lipid metabolism, liver transaminases, total T level, immunoreactive insulin (IRI) and leptin concentrations. Also, all patients underwent magnetic resonance imaging (MRI) of the liver by the Dickson method with a double gradient echo into the phase and antiphase to quantify the liver fat fraction (FF), which allowed to determine the presence and severity of NAFLD. For statistical data processing, the STATISTICA software package (StatSoft 10) was used. The statistical analysis was carried out using the Mann-Whitney U test, a critical significance level was taken to be $P<0.05$. For statistical data processing, the STATISTICA software package (StatSoft 10) was used.
Results
The severity of obesity according to BMI, WC, HC was significantly higher in patients of the 2nd group. This was accompanied by a significantly higher level of IRI by 30% ($P=0.049$) and twice higher leptin level ($P=0.0008$) in patients with androgen deficiency, compared to the control group. In addition, in the 2nd group, the level of ALT was significantly ($P=0.034$) higher by 25% compared to patients of group 1. In men with a low level of endogenous T, the liver fat fraction was significantly ($P=0.0002$) 2.5-fold higher than in men without androgen deficiency (10.96 (7.78; 14.44) vs 4.2 (2.25; 5.86)%). These findings demonstrate the higher severity of NAFLD in men with late onset hypogonadism compared to patients not having T deficiency.
Conclusion
T deficiency in men with T2DM promotes the development and aggravation of the already existing NAFLD.

Influence of ethnicity on gestational diabetes mellitus in the center of Israel: a retrospective cohort study

Yuval Hochman[1,2], Yifat Wiener[2,3], Shlomit Koren[2,4] & Ronit Koren[1,2,3]
[1]Department of Internal Medicine A, Assaf Harofeh Medical Center, Zerifin, Israel; [2]Sackler Faculty of Medicine, Tel-Aviv University, Tel-aviv, Israel; [3]Division of Maternal Fetal Medicine, Department of Obstetrics and Gynecology, Zerifin, Israel; [4]Diabetes Unit, Assaf Harofeh Medical Center, Zerifin, Israel.

Aim
The aim of this study was to compare maternal and neonatal outcomes between Israeli Arab and Jewish women with GDM not controlled with lifestyle modification.
Methods
We conducted a retrospective cohort study of women with GDM who were not controlled with lifestyle modification and were followed and gave birth in a university affiliated medical center between 2005 and 2015.
Results
The study included 343 women, 45 (11.8%) of them Arabs. There were no differences in the baseline characteristics between the two ethnic groups including age, gravidity, parity or pre-pregnancy body mass index. There were 41.85% Jewish women with good glycemic control compared to 31.4% of the Arab women ($P=0.197$). A similar fraction gave birth by caesarian section or assisted labor (%17.8 of the Arab versus 15.1% of the Jewish women, $P=0.669$). There were no differences in composite outcome comprised of pre-eclampsia, caesarian section due to diabetes, macrosomia and neonatal hypoglycemia (68.9% for the Arabs vs. 62.4% for the Jewish women $P=0.42$).
Conclusions
Our study did not find differences in maternal and neonatal outcomes of Arab and Jewish population of women with GDM controlled with glucose lowering agents. These results are not consistent with previous published data. It is possible that the Arab population in our study shares comparable socioeconomic elements with the Jewish one and has access to similar medical care. Other possible explanation is a small sample size of this study.

Subclinical atheromatous disease detection improves cardiovascular event prediction in chronic kidney disease with and without diabetes

Ana Palanca[1,2], Esmeralda Castelblanco[3,4], Angels Betriu[5], José M Valdivielso[5], Hèctor Perpiñan[5], Manel Puig-Domingo[1,2,3], Elvira Fernández[5], Didac Mauricio[1,2,3,4] & Nuria Alonso[1,2,3,4]
[1]Department of Endocrinology and Nutrition, Germans Trias i Pujol University Hospital, Badalona, Spain; [2]Department of Medicine, Universitat Autonoma de Barcelona, Barcelona, Spain; [3]Germans Trias i Pujol Health Research Institute, Badalona, Spain; [4]Diabetes and Associated Metabolic Diseases Networking Biomedical Research Centre, Madrid, Spain; [5]Lleida Biomedical Research Institute, Lleida, Spain.

Background
Cardiovascular disease (CVD) is the leading cause of morbidity and mortality in chronic kidney disease (CKD) patients with and without diabetes mellitus (DM). Traditional cardiovascular risk factors fail to fully account for the increase in cardiovascular risk in these patients. The NEFRONA study is a large, multicentre, prospective, observational study that evaluated atheromatous disease (AD) in the carotid and femoral territories in a large cohort of Spanish CKD patients without previous CVD.
Objectives
To analyse the prognostic value of subclinical AD in CKD patients with and without DM on the incidence of cardiovascular events (CVE).
Materials and methods
NEFRONA cohort data from CKD patients with DM ($n=698$) and without DM ($n=1747$) were analysed. Patients underwent baseline carotid and femoral ultrasound examinations and were followed-up for 4 years. All the CVE during the follow-up period were registered. Bivariate analysis and Fine-Gray competing risks models were used to perform the statistical analysis. Hazard ratios and 95% confidence intervals were reported.
Results
Among patients with DM, 96 CVE (13.75%) were reported during follow-up. Male gender, renal replacement therapy (RRT) and insulin treatment were more frequent in DM patients with CVE compared to those without CVE. Among CKD patients without DM, 107 CVE (6.12%) were reported. Being older, RRT and decreased serum concentrations of HDL-cholesterol were more frequent among non-DM patients with CVE. Presence of plaque, number of plaques and having more than two vascular territories affected with plaque at baseline were more frequent among CKD patients with CVE (with and without DM). Following competing risks models, the variable predicting CVE among CKD patients with DM was number of territories with plaque at baseline (1.78 (1.39, 2.28)). The variables predicting CVE in CKD patients without DM were age (1.03 (1.00, 1.05)), number of territories with plaque at baseline (1.86 (1.43, 2.42)) and serum concentrations of 25OH-vitaminD (0.96 (0.93, 0.99)).
Conclusion
Presence and burden of subclinical AD is the most potent factor to influence CVE in CKD patients with DM whereas, in CKD patients without DM, other risk factors such as age and decreased serum concentrations of 25OH-vitaminD are also associated with an increased risk of CVE. Early detection of subclinical AD and identification of AD burden through arterial ultrasound, performed at different vascular territories, could improve prediction of CVE in these patients.

Wrist and ankle measurements in patients with and without diabetes-related macrovascular disease

Yildiz Okuturlar, Isil Ozbas Tevetoglu, Denis Bozer, Gamzegul Cicek, Sogol Sadri, Gamze Ugur, Bahar Ozdemir, Hamide Piskinpasa, Pinar Karakaya, Ozgur Okuturlar & Meral Mert
Bakirkoy Dr. Sadi Konuk Education and Research Hospital, Istanbul, Turkey.

Aim
We aimed to evaluate wrist and ankle measurements in patients with and without diabetes-related macrovascular disease.
Material and method
151 consecutive patients with type 2 diabetes who came to our diabetic outpatient clinic were included. We have divided the patients into two groups. Group 1 (patients with diabetes related macrovascular complications) and group 2 (patients without diabetes related macrovascular complications). Group 1 (*n*:45) includes diabetic patients with complete occlusion of one of the lower extremity arteries (right and left leg, dorsal and tibial arteries), cerebrovascular disease, coronary stenting, history of myocardial infarction (MI), coronary artery bypass graft (CABG) and diabetic foot. Group 2 (*n*:106) includes diabetic patients without macrovascular complications.
Results
In Group 1 there were 14 patients with complete occlusion of one of the lower extremity arteries, 10 patients with cerebrovascular disease, 20 patients with coronary stenting, 13 patients with history of myocardial infarction (MI), nine patients with coronary artery bypass graft (CABG) and one patient with right leg amputation due to diabetic foot disease. Wrist circumference was found to be statistically significantly thicker in group 1 (18.17 ± 1.46) than group 2 (17.53 ± 1.73) ($P=0.042$). Statistical analyzes with chi-square test revealed a significant relationship between the presence of macrovascular complications and sex ($P=0.003$) (odds ratio(OR) 2.891, 95% confidence interval (CI) 1.405–5.952), antihypertensive drug use ($P=0.0001$) (OR 12.553, 95% CI 4.191–37.596), statin use ($P=0.018$) (OR 2.426, 95% CI 1.156–5.093), metformin use ($P=0.008$) (OR 0.379, 95% CI 0.184–0.781), presence of diabetic foot (OR 7.714% 95% CI 0.780–76.259), presence of neuropathy ($P=0.035$) (OR 2.246, 95% CI 1.049–4.806). In the analysis of correlation, positive correlations were found between wrist circumference and age ($r=0.192$, $P=0.018$), height ($r=0.273$, $P=0.001$), weight ($r=0.388$, $P=0.0001$), body mass index (BMI) ($r=0.187$, $P=0.021$), waist circumference ($r=0.382$, $P=0.0001$), ankle circumference ($r=0.362$, $P=0.0001$. Positive correlations were found between ankle circumference and BMI ($R=0.331$; $P=0.0001$), waist circumference ($r=0.365$; $P=0.0001$), wirst circumference ($r=0.241$; $P=0.003$).
Conclusion
In diabetic patients, the relation between waist/hip ratio and macrovascular complications has been shown in many studies. In this sudy, we have demonstrated that the wrist is thicker in patients with diabetic-related macrovascular complications. This study shows that wrist circumference measurement in diabetic patients may be an important predictive anthropometric measurement for macrovasular complications as waist/hip ratio.

Prevalence and risk factors of diabetes in chronic viral hepatitis B and C: about a retrospective study

Fatma Boukhayatia, Dhilel Aissaoui, Hela Kchir, Abdelwaheb Nakhli, Haythem Yacoub, Nedia Maamouri & Nabil Ben Mami
Gastroenterology Department, La Rabta Hospital, Tunis, Tunisia.

Introduction
Carbohydrate metabolism disorders are common in chronic liver diseases, from glucose intolerance to proven diabetes. The presence of diabetes during chronic liver disease is a factor of poor prognosis. The purpose of our study is to assess the prevalence of diabetes in chronic hepatitis B and C and to determine the risk factors.
Patients and methods
This is a retrospective study that collects all cases of chronic hepatitis hospitalized in the Gastroenterology department from January to December 2016. The search for an association with diabetes or glucose intolerance has been carried out systematically.
Results
133 cases of chronic viral hepatitis have been identified. The origin is viral C ($N=102$) and viral B ($N=31$). The average age of patients was 59.25 (range 26–83 years) with a sex ratio of 0.7. The fibrosis stage evaluated by fibrotest or liver biopsy was as follows: F0 ($N=13$), F1 ($N=6$), F2 ($N=21$), F3 ($N=12$), F4 ($N=81$). 42.1% of patients were suffering from diabetes (56 patients). A metabolic syndrome was noted in 46 patients. Diabetes was anterior to the diagnosis of cirrhosis in 19 patients, after the diagnosis of cirrhosis in 14 patients. Both diagnoses were recognized simultaneously in 8 cases. Diabetes was significantly correlated with: age $>$ 50 years ($P=0.001$), fibrosis $>$ F3 ($P=0.005$) and the presence of a metabolic syndrome ($P<0.001$), mainly in case of viral hepatitis C. In patients who received antiviral treatment, diabetes was a factor of poor therapeutic response ($P=0.03$).
Conclusion
In our series, the prevalence of diabetes in chronic viral hepatitis B and C is high and found in more than 40% of cases. Diabetes was associated with age >50 years, fibrosis $>$ F3 and the presence of a metabolic syndrome, mainly with viral hepatitis C.

Hypoglycemia in patients with type 2 diabetes mellitus in geriatric population

Damla Okay[1], Alev Eroglu Altinova[2], Basak Bolayir[2], Olgun Deniz[3], Ayse Kaya[1], Mujde Akturk[2], Berna Goker[3] & Fusun Balos Toruner[2]
[1]Gazi University Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey; [2]Gazi University Faculty of Medicine, Division of Endocrinology and Metabolism, Ankara, Turkey; [3]Gazi University Faculty of Medicine, Division of Geriatric Medicine, Ankara, Turkey.

Introduction
Hypoglycemia is a complication of diabetes mellitus (DM) with high morbidity and mortality. Risk of hypoglycemia is affected by the type and duration of DM, use of insulin or oral antidiabetic agents, dietary habits and comorbidities. In this study, we aimed to understand frequency and causes of hypoglycemia in patients with type 2 DM in Turkish population and especially collect data about hypoglycemia in geriatric population.
Methods
Between May and August 2017, one hundred and eigthy three patients who applied to Endocrinology and Metabolism and Geriatric Medicine Policlinics of Gazi University Faculty of Medicine were included in this study. These patients answered the questionnaire which had multiple choice questions about their hypoglycemia experiences. Also clinical information of these patients taken in last 3 months was achieved from digital archive.
Results
In this study, hypoglycemia frequency was 59.2% in non-geriatric population ($n=142$), and 46.3% in geriatric population ($n=41$). However, frequency of nocturnal hypoglycemia was 22.0% in geriatric population and 2.4% of this was severe; whereas, in non-geriatric patients, frequency of nocturnal hypoglycemia was 13.4% and none was severe. In geriatric patients who had duration of diabetes less than ten years, frequency of hypoglycemia was 23.5% and more than ten years was 62.5%. In 50.0% of geriatric patients who were on intensive insulin treatment had mild-moderate nocturnal hypoglycemia. Hypoglycemia frequency in non-geriatric patients with diabetic complications was 1.5%, but in geriatric patients it was 10.0%. 37.5% of geriatric patients with atherosclerotic heart disease were experiencing hypoglycemia and 12.5% of them were experiencing hypoglycemia every day.
Conclusion
In this study, hypoglycemia was detected in approximately half of the patients with type 2 DM and geriatric patients had more nocturnal hypoglycemia episodes. We should take measures for prevention of hypoglycemia and its detrimental effects especially in geriatric patients.
Keywords: Hypoglycemia, nocturnal hypoglycemia, geriatric population

Predictors for low bone mineral density assessed with DXA and trabecular bone score in patients with diabetes mellitus

Madalina Dragne[1,2], Roxana Dusceac[1,2], Bogdan Sorohan[2,3] & Catalina Poiana[1,2]
[1]CI Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Fundeni Clinical Institute, Nephrology Department, Bucharest, Romania.

Background
Diabetes mellitus is a metabolic disease associated with an increased risk of fracture, despite normal or increased bone mineral density (BMD), especially type 2 diabetes mellitus (T2DM). Trabecular bone score (TBS) is an imaging investigation that measures the grayscale variations on the lumbar spine performed on the DXA machine. The aim of this study was to evaluate the determinants associated with low BMD and TBS in patients with type 1 and type 2 diabetes mellitus.
Methods
We retrospectively analyzed 47 patients with T1DM and T2DM from our clinic between 2015 and 2017. The exclusion criteria were: absence of diabetes, secondary causes for diabetes and age <18 years. We divided the group by T/Z score and TBS and evaluated the predictors for bone structure. To identify the predictors, we performed binary logistic regression. In the multivariate analysis were introduced all the variable with $P<0.2$ in group comparison. Predictive performances of significant variables were evaluated.
Results
Among the 47 patients, 76.6% had a TBS compatible with altered bone structure, while only 31.9% had a T/Z score diagnostic for osteopenia or osteoporosis. The predominant gender was female (83%), median age was 63 years (IQR: 54–68) and the study group was characterized by overweight (mean BMI $=30.5\pm4.9$). The mean duration of DM was 10.9 ± 7.4 years. The majority of patients had type 2 DM (89.4%). By multivariate analysis, β-crosslaps (CTX) was independently associated with a low T/Z score (adjusted OR $=1.02$; 95% CI: 1.010–1.029, $P=0.001$). The cut-off value of CTX $=0.2915$ ng/ml had a sensitivity of 86.7% (95% CI: 59.54–98.34%), specificity of 78.1% (95% CI: 60.03–90.72%) and an AUC of 0.85 (95% CI: 0.72–0.98, $P<0.0001$) to predict osteopenia or osteoporosis. Also, in multivariate analysis age was independently associated with low TBS (adjusted OR $=1.08$, 95% CI: 1.01–1.14, $P=0.02$). The cut-off value of age of 61.5 years had the best predictive performance for altered bone structure, with a sensitivity of 69.4% (95% CI: 51.9–83.6%), a specificity of 72.7% (95% CI: 39–93.98%) and an AUC of 0.73 (95% CI: 0.54–0.91, $P=0.02$).
Conclusions
Patients with diabetes mellitus showed a more altered bone quality using TBS than DXA and β-crosslaps is an independent predictor for low BMD using DXA, while age is an independent predictor for low spine TBS.

Is-it safe for diabetic patients to fast during Ramadan?

Marwa Ben Cheikh, Olfa Laajili, Taghrid Naceri, Hana Bel Hadj Hassen, Henda Jamoussi, Faika Ben Mami, Ines Kamoun & Leila Ben Salem
Endocrinology and Nutrition Departement, National Nutrition Institute, Tunis, Tunisia.

Introduction
As Ramadan fasting is one of the five pillars of Islam, more than one billion muslims fast simultaneously worldwide. Patients with diabetes especially those with type 1 diabetes who fast during Ramadan, are at increased risk of diabetic ketoacidosis, particularly if their diabetes is poorly controlled before Ramadan. The aim of our study was to compare the incidences of diabetic Ketosis or ketoacidosis during in the month of Ramadan, the preceding month (Shaaban), and the following month (Shawal).
Methods
We performed a prospective study that included all known diabetic patients admitted with diabetic ketosis or ketoacidosis in the different departments of the National Nutrition Institute of Tunis during the pre-Ramadan month, Ramadan and post Ramadan month of 2 years 2015 and 2016. Demographics, clinical, and laboratory indices were collected.
Results
Total number of patients who were admitted with diabetic ketosis or ketoacidosis was 136 patients, 42 during Shaaban, 38 during Ramadan and 56 during Shaawal. There was no significant difference in the number of patients admitted with ketosis or keto acidosis during the three periods ($P=0.425$). The duration of acidosis during Ramadan (19 ± 24 h) was slightly higher than the others periods (17 ± 18 hours before and 15 ± 10 hours after) ($P=0.906$). During Ramadan, 58% of patients were with type 1 diabetes, 43% before Ramadan and 48% after Ramadan ($P=0.013$). The mean age of patients during Ramadan was significantly lower than during the two other periods ($P=0.027$). Non-compliance was the main precipitating factor during in the whole study periods.
Conclusion
Our study showed no significant difference in the incidence of ketosis or ketoacidosis during Ramadan compared to preceding and later months (Shaaban and Shaawal). Structured education seems to be important to avoid these diabetic complications during Ramadan.

Risk factors for delay gastric emptying in patients with type 2 diabites

Iryna Kostitska[1], Boris Mankovsky[2], Oksana Shapoval[1], Nadiya Zherdova[2], Roman Grunevych[1], Oleksandr Babenko[1] & Oksana Marysyn[1]
[1]Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine; [2]National Medical Academy of Postgraduate Education, Kiev, Ukraine.

Introduction
The objective of the research was to determine the predictive value of the most probable etiopathogenetic factors contributing to the development and progression of gastric dysfunction in patients with type 2 diabetes. Only 5% of type 1 and 1% of type 2 diabetic combine the delay of gastric emptying (DGE) with typical gastroparesis symptoms. Systematic review of risk factors of development and progression symptoms of diabetic gastroparesis (DG). Results

presented from searches undertaken to ascertain predictors to early diagnostic of gastric dysfunction. It is associated with marked glycemic lability and it has significant morbidity.
Materials and methods
We have studied 170 patients with type 2 diabetes and disease duration of 10.3 ± 0.4 years; the patients' average age was 57.8 ± 0.9 years; there were 85 males and 85 females. The BMI – 33.1 ± 0.8 kg/m^2; the neurological symptoms score (NSS) – 18.1 ± 0.2 points; HbA_1C – 8.7 ± 0.2%, fasting glucose – 7.9 ± 0.4 mmol/l. The patients completed the gastroparesis cardinal symptom index (GCSI). To assess the severity of diabetic polyneuropathy (DPN) symptoms, a generally accepted scale measuring neurological symptoms and objective signs included into the NDS – the NSS was used. The stomach function was determined using the ^{13}C-octanoate breath test (^{13}C-OBT) No subjects studied have had the signs of other disorders of dysfunction in gastrointestinal motility.
Results
According to the questionnaire results, physical examination data as well as additional laboratory and instrumental investigations, mild DG was found in 17.7% subjects, moderate DG was observed in 19.3% patients and the signs of severe DGE were present in 8.0% patients only. Thus, the proportion of patients with gastric dysfunction among patients with diabetes was 45.0% which slightly exceeded the results of epidemiological studies. According to the linear regression analysis, in patients with type 2 diabetes, there was a positive correlation between the degree of DGE and the duration of the underlying medical condition, DPN manifestations, cigarette smoking and the severity of hypoglycemic episodes. The 95% confidence interval for the unstandardized B coefficient was as follows: the GCSI and the NDS RR = 0.83, 95% CI = 0.56–1.09, P = 0.000; whereas the ^{13}C-OBT and the NDS RR = 2.20, 95% CI = 1.13–3.27; P = 0.000.
Conclusions
Diabetes duration of more than 10 years, severe manifestations of DPN, the increase in the incidence of hypoglycemic episodes as well as smoking should be considered as major risk factors for DGE in patients with type 2 diabetes.

DOI: 10.1530/endoabs.56.P470

Clinical and laboratory predictors of positive renal effects of vildagliptin

Valentina Bayrasheva[1], Ivan Pchelin[2], Alina Babenko[1,3], Svetlana Chefu[1,3] & Elena Grineva[1,3]
[1]Almazov National Medical Research Centre, Saint Petersburg, Russian Federation; [2]Saint Petersburg State University, Saint Petersburg, Russian Federation; [3]Pavlov First Saint Petersburg State Medical University, Saint Petersburg, Russian Federation.

Accumulating facts show that incretin-modulating therapy could be beneficial in both glycemic control and nephroprotection in type 2 diabetes (DM2). Clinical evidence for nephroprotective potential of DPP-4 inhibitors is limited and predictive determinants are unknown. The study conducted with DM2 patients aimed to assess renal effects of vildagliptin addition and identify their clinical and laboratory predictors. The study enrolled 44 insulin-treated male and female type 2 diabetic patients, aged 49–70 years with satisfactory glycemic and blood pressure (BP) control, without overt chronic kidney disease, severe micro- and macrovascular diabetic complications, and non-diabetic renal impairment. Patients were randomized either to continue insulin therapy (control, n = 21), or to receive vildagliptin (50 mg/daily) added-on insulin therapy (Vgroup, n = 23). At baseline and after 6 months of treatment we assessed eGFR using serum creatinine (eGFRcr), cystatin C (eGFRcys), and both (eGFRcr-cys), and creatinine-adjusted urinary markers (albuminuria (UACR), and collagen type IV (uColIV). Groups were comparable on the basis of sex and age. A2 category of CKD was detected in 47.6% of control patients and in 52.2% – in Vgroup, P = 0.76. At baseline there were no significant differences in assessed parameters. In the control group none of them changed significantly after 6 months of the treatment. Patients from Vgroup demonstrated significant decrease in HbA1c, insulin requirement along with the frequency of hypoglycemic episodes. Significant reduction in diastolic BP, serum cystatin C and excretion of uColIV was documented in Vgroup as well as the increase of eGFRcys and eGFRcr-cys. Correlation analysis showed that neither changes of serum cystatin C, eGFRcys and eGFRcr-cys nor changes of uColIV in Vgroup were significantly related to the dynamics of HbA1c (r = −0.31, 0.21, 0.19, and 0.13, respectively, P > 0.05 each). We found inverse association between the changes of systolic BP and eGFRcr-cys (β = −0.47, R^2 = 0.22, R^2 = 0.02) suggesting that hemodynamic mechanisms at least partially contribute to vildagliptin renal action. Stepwise regression analysis showed that lower levels of baseline eGFRcys were independent predictors of both eGFRcys and eGFRcr-cys increase (β = −0.61, R^2 = 0.37, and β = −0.45, R^2 = 0.20, respectively, P < 0.05 each). Reduction of uColIV excretion was more pronounced in older patients (β = −0.74) with lower levels of diastolic BP (β = 0.57), R^2 = 0.46, P = 0.002. In conclusion, vildagliptin administration was associated with reduction of uColIV excretion along with the increase of eGFRcreat-cys and eGFRcys, independent of glycemic control. Older age and lower baseline values of diastolic BP were predictive of better uColIV-response in patients receiving vildagliptin.

An assessment of abnormal liver function tests in a cohort of unselected diabetic patients

Stephen Ludgate, Sara Naimimohasses, Mostafa Redha, Vivian Crowley, Suzanne Norris & Marie-Louise Healy
St. James's Hospital, Dublin, Ireland.

Introduction
The prevalence of abnormal liver function tests (LFTs) in the general population has been estimated to be 8.1–9.8%. Abnormal LFTs are common in diabetes although there are still few studies describing the exact prevalence. AST-to-platelet-ratio-index (APRI) and Fibrosis-4-score (FIB4) are scoring systems which can be used to estimate the degree of liver fibrosis. An APRI score > 1 has a sensitivity of 76% and a specificity of 72% for predicting cirrhosis while a score > 0.7 has a sensitivity of 77% and a specificity of 72% for predicting significant fibrosis. A FIB4 score > 3.25 has a 97% specificity and a positive predictive value of 65% for advanced fibrosis. A score < 1.45 has a negative predictive value of 90% for advanced fibrosis.
Aims/Background
The aim of this retrospective study was to evaluate the prevalence of abnormal LFTs in patients attending a tertiary referral centre with diabetes. We also aimed to calculate APRI and FIB4 scores in this population.
Method
Electronic records were used to review all patients with who had LFTs processed in 2016. APRI and FIB-4 scores were calculated for each patient where the required variables (age, AST, ALT, and platelet count) were available.
Results
1777 patients were included in the study, of whom 1077 were male and 700 were female. 212 had type 1, and 1565 type 2 diabetes (T2DM). 600 (33.76%) patients had at least one abnormal LFT. ALT was the most commonly elevated enzyme, 410 (23.1%) having an abnormal result. APRI and FIB4 scores could not be calculated in 734 (41.3%) patients, mostly due to unavailable platelet counts. Of the remaining 1043 (58.69%), 30 (2.88%, 30 = T2DM) had an APRI score > 0.7 while 17 (1.63%, 17 = T2DM) had a score ≥ 1. 265 (25.41%) had FIB4 ≥ 1.45 and < 3.25, and 18 (1.73%) patients had a score ≥ 3.25.
Conclusion
The results of this study demonstrate a high prevalence of raised LFTs in the diabetic population. ALT was the most commonly raised liver enzyme. A small but significant cohort of patients had APRI and FIB4 scores suggestive of cirrhosis and liver fibrosis, although the accuracy of these estimates will need to be histologically validated in diabetes. APRI and FIB-4 scores are potentially useful as routine screening tools for liver disease in diabetes in conjunction with history and clinical examination, but require addition of platelet count to the panel of routinely measured blood tests.

The effect of glutathione S-transferase M1 and T1 polymorphisms on ascorbic acid plasma levels in diabetic patients

Ana Valente[1,2,3], Manuel Bicho[3,4], Ana Carolina Santos[3,4], Andreia Matos[3,4], Rui Duarte[5], João F Raposo[5] & Helena S Costa[1,6]
[1]Departamento de Alimentação e Nutrição, Instituto Nacional de Saúde Doutor Ricardo Jorge, I.P., Av. Padre Cruz, 1649-016 Lisboa, Portugal, Lisboa, Portugal; [2]Atlântica - Escola Universitária de Ciências Empresariais, Saúde, Tecnologias e Engenharia, Oeiras, Portugal; [3]Laboratório de Genética, Instituto de Saúde Ambiental, Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal; [4]Instituto de Investigação Científica Bento da Rocha Cabral, Lisboa, Portugal; [5]Associação Protectora dos Diabéticos de Portugal, Lisboa, Portugal; [6]REQUIMTE/LAQV, Faculdade de Farmácia da Universidade do Porto, Porto, Portugal.

Introduction
Type 2 diabetes mellitus have been associated with excessive production of reactive oxygen species. Glutathione S-transferase (GST) polymorphisms result

in decreased or absent enzyme activity and altered oxidative stress. Meta-analyses have indicated that deletion of either GSTM1 or GSTT1 is associated with a significant increased risk of coronary heart disease. The aim of this study was to evaluated if ascorbic acid (AA) plasma levels differ by GST genotype in diabetic patients with and without angiopathy.
Methods
An observational analytical case-control study in 123 Caucasians type 2 diabetic patients was performed. GI - 65 diabetics with angiopathy, GII - 58 diabetics without angiopathy. Plasma levels of AA were measured by a validated HPLC method. The genotyping of GSTT1 and GSTM1 it was determined simultaneously by PCR-Multiplex technique.
Results
The frequency of GSTM1 and GSTT1 single-null genotypes was 42.9% and 30.8% in group I and 43.9% and 31.0% among in group II. The percentage of diabetics patients who had both GSTM1 and GSTT1 functional genotypes was GI:46.0% and GII:42.9%, who had one of the present genotypes was GI:33.4% and GII:37.5% and who had both null genotypes was GI:20.6% and GII:19.6%. Plasma AA concentrations were lower in those with the GSTT1 null genotype than in those with the GSTT1 functional genotype. GSTM1 null genotypes had higher plasma AA levels than those with functional GSTM1 allele. Suboptimal AA plasma concentrations (<4.93 µmol/L) were more frequent in GSTT1 deletion genotype (76.3%) compared to GSTT1-1 (69.4%). Inversely, the percentage of patients with functional GSTM1 allele (72.1%) was higher than null genotype (67.3%).
Conclusion
Plasmatic levels of AA differ by GSTM1 and GSTT1 polymorphisms in Caucasians diabetic patients with or without angiopathy. The upper and lower regulation of AA plasma levels in subjects with nonfunctional GSTT1 or GSTM1 could be partially understood to compensate the lack of functionality.

Maternofetal complications of diabetic pregnancy: about 293 cases

Sara Atraki, Siham EL Aziz, Selma Bensbaa & Asmaa Chadli
Endocrinology, Diabetology and Metabolic Diseases Department Ibn Rochd University Hospital of Casablanca, Morocco; Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy- University Hassan II, Casablanca, Morocco.

Introduction
Pregnancy in women with diabetes is considered high risk because of potentially serious maternal and fetal complications that can put in to risk the maternal and fetal prognosis.
Objective
Describe and analyze risks associated with diabetic pregnancies and compare maternal fetal prognosis of pregnancies with pregestational diabetes (T1D and T2D) with gestational diabetes mellitus (GDM).
Patients and methods
It was a descriptive retrospective study including 293 diabetic pregnant women, hospitalized in Endocrinology and Diabetology department of Ibn Rochd University Hospital of Casablanca, over a period from January 2013 to December 2016. Data collection was done from medical records. The statistical analysis was done by SPSS.
Results
The middle-aged of patients was 31.6-year-old, 50.5% had T2D, 24.5% T1D and 25.5% had GDM. 38% of patients had a history of miscarriage, 20.3% fetal death in utero (FDIU) and 38% had macrosomia. Regarding maternal complications: 41.5% of patients delivered by Caesarean section which 30.6% had pregestational diabetes and 9.6% had GDM (p: 0.02), the threat of premature birth was 22%, 15% for preeclampsia, Urinary tract infection was significantly associated with patients with GDM ($P<0.001$) in the order of 22%. For fetal complications: 33% had macrosomia, 14.2%, neonatal jaundice, 9.5% were premature, polyhydramnios has been objectified in 13%, the FDIU in 16.2% of patients, neonatal mortality was of the order of 5.9%, 1.8% had shoulder dystocia and 6.3% of new borns were transferred to intensive care. Only macrosomia and shoulder dystocia were significantly associated with patients with GDM compared to those with pregestational diabetes (p: 0.008 and p: 0.001).
Discussion
We see a high rate of complications in diabetic pregnancies without prior followed with a high rate of miscarriages, fetal death, shoulder dystocia, and macrosomia, more frequent in cases of GDM.

Bacterial lower limb dermo-hypodermitisin diabetic patients: what epidemiological, clinical and therapeutic particularities? About 134 cases

FZ Kaidi, S El Aziz, A Mjabber & A Chadli
Endocrinology, Diabetology and Metabolic Diseases Department, Ibn Rochd University Hospital, Casablanca, Morocco; Neurosciences and Mental Health Laboratory, Faculty of Medicine and Pharmacy- University Hassan II- Casablanca-Morocco.

Introduction
The uncontrolled diabetics are led to develop severe infections like severe forms of acute bacterial dermo-hypodermitis. The aim of our study was to clarify the epidemiological, clinical and therapeutic characteristics of BDH in diabetic patients.
Patients and methods
A prospective, descriptive and analytical study was conducted in the Diabetology, Endocrinology and Metabolism Department, Ibn Rochd University Hospital of Casablanca, from January 2016 to December 2017, including all diabetic patients with BDH. Necrotizing fasciitis are excluded from the study. Statistical analysis was univariate for all the variables using SPSS version 22.0.0.
Result
Were included 134 diabetics, 57% had a T2D, their middle-aged was 53, and average HbA1c was 9.8%. 37% of patients were hypertensive, 32% dyslipidemic, 18% with ischemic cardiomyopathy, 37.5% had diabetic retinopathy, 61% diabetic nephropathy, 46% peripheral neuropathy and 23% autonomic neuropathy. Risk factors for BDH were a lower extremity edema in 38%, obesity in 30%, age greater than 65 years in 23%, inadequate hygiene in 22%, *obliterating arteriopathy of lower limbs* in 20%, active smoking in 16% and previous history of BDH in 11%. Average duration of consultation was 6 days. Localization was the leg in 67% of cases and the foot in 47%. Entry point was a fungal interdigital in 31% of cases, a perforating ulcer of the foot in 29%, and anarterial ulceration in 10%. BDH was accompanied by local signs of severity in 28% of cases, complicated in 14%. Fever was present in 43% of patients, with general signs in 37%. Infection was moderate involving the member in 34%, severe involving the lives of patients in 23%. Third-generation cephalosporins were used in 43% of cases, a monotherapy in 43% and dual therapy in 28%, initially, intravenously in all patients. Evolution was good in the majority of cases, 4 patients had presented a necrotizing fasciitis and 6 patients had presented a necrotizing bacterial dermo-hypodermitis without necrotizing fasciitis.
Conclusions
The diabetic is a subject at high risk of developing severe forms of BDH. Perforating ulcer of the foot and arterial ulceration are frequently the entry points.

Analysis of safety and efficacy of liraglutide compared with dulaglutide in patients with type 2 diabetes mellitus

Arina Frolova, Marina Orlova & Tatiana Rodionova
Saratov State Medical University, Saratov, Russian Federation.

Background
Was performed an open study in 2 parallel groups to compare the efficacy and safety of dulaglutide and liraglutide in combination with Metformin in patients with type 2 diabetes mellitus.
Methods
Thirty-two patients (13 men and 19 women) with type 2 diabetes mellitus with unsatisfactory glycemic control on Metformin monotherapy were examined. The median age was 52 [44; 61] years old, the duration of diabetes was 4.6 [2,5; 9,0] years, median of glycated hemoglobin initially was 8.3 [7,7; 8,6] %; 14 patients were treated with dulaglutide 1.5 mg once a week, 18 patients – with liraglutide 1.2 mg every day.
Results
The duration of the observation was 26 weeks, after this period at the therapy with dulaglutide 1.5 mg/week the glycated hemoglobin descension was -1.09 [0.82, 1.21] %, which was comparable to the results in the group of patients on liraglutide 1.2 mg /day – 1.12 [0.90; 1.25] % ($P=0.78$). Weight loss was more significant on liraglutide – 5.2 [3.5; 6.0] kg. vs. 4.3 [2.5; 5.3] kg. on dulaglutide ($P\leq0.05$). Side effects included nausea (35.7% for dulaglutide and 33.3% for liraglutide ($P=0.9$)), dyspepsia (7.1% for dulaglutide and 11.1% for liraglutide ($P=0.81$)), diarrhea (14.3% for dulaglutide and 11.1% for liraglutide ($P=0.85$)) and decreased appetite (28.6% for dulaglutide and 33.3% for liraglutide ($P=0.9$)). The amount of hypoglycemia was comparable in both groups and no severe hypoglycaemia was reported.

Conclusions
According to the results obtained, dulaglutide and liraglutide were comparable in effectiveness with respect to the reduction of glycated hemoglobin, while the number of side effects was comparable, but the decrease in weight on liraglutide was significantly higher than on dulaglutide.

A localized painfull rash induced by linagliptin in a patient with type 2 diabetes

Ismail Yildiz[1,2], Ramazan Gen[2], Leyla Batmaz[2], Kerem Sezer[2], Esen Akbay[2] & Yasemin Yuyucu Karabulut[3]
[1]Namık Kemal University, Faculty of Medicine, Department of Endocrinology and Metabolism, Tekirdag, Turkey; [2]Mersin University, Faculty of Medicine, Department of Endocrinology and Metabolism, Mersin, Turkey; [3]Mersin University, Faculty of Medicine, Department of Patology, Mersin, Turkey.

Introduction
Although dipeptidyl peptidase-4 (DPP-4) inhibitores are generally safe and are associated with less side effects compared to other oral antidiabetic medications, they could also be associated with some side effects including skin rash. Herein we report the first case of a type 2 diabetes patient who developed a painfull maculopapular rash induced by linagliptin, a widely used DPP-4 inhibitor.
Case presentation
A-54-year old female patient with newly diognesed Tip 2 diabetes admitted to our outpatient clinic due to nausea, vomiting, polyuria and polydipsia. Physical examination was normal except for a reduced skin turgor and tonus. On biochemical analysis, her fasting plasma glucose (FPG), HbA1c, white blood cell count (WBC), serum creatinin, BUN and C-reactive protein levels were 300 mg/dL, %9.8, 17.000 (%70 neutrophil), 1.7 mg/dL, 60 mg/dL and 3 mg/L (<5 mg/L), respectively. She didn't have ketonuria or acidosis and the serum potassium level was normal. One day after starting rehydration with isotonic saline infusion and intensive insulin therapy for acute renal injury and hyperglycemia, the skin turgor and tonus, FPG, serum creatinin, BUN and white blood cells count returned to normal. On the 3th day after admission, treatment with metformin was started, however, she developed dyspeptic complaints and watery diarrhea. Therefore,metformin was stopped and treatment with linagliptin was started. However, one day later, the patient developed a painfull, maculopapular rash without itching, on the palmar sides of the both hands. The linagliptin treatment was stopped. A skin biopsy revealed an eosinophilic superficial dermatitis. So, a diagnosis of an allergic skin reaction due to linagliptin was made.Treatment with bethametasone ointment was started. Four days after cesation of linagliptin and starting treatment with bethametasone oinment, the pain and maculopapular rash were completely dissapeared.
Conclusion
The present case suggests that like other DPP-4 inhibitores such as sitagliptin and vildagliptin, linagliptin may also cause skin reactions. Therefore, attention should be paid to patient receiving this class of drugs and treament should be stopped after appearance of skin reactions. However, it is not well known whether cross reaction would develop after switching to another DPP-4 inhibitor in patients with skin rash developed after starting a DPP-4 inhibitore. However, close follow-up of patients with skin reactions after a DPP-4 inhibitor is necessary to prevent serious skin reactions.

Preservation of residual β-insulin function in a patient with a type 1 diabetes treated early by fingolimod for multiple sclerosis

Hamza Benderradji[1,2], Maxime Kwapich[1], Samira Bouzaib[1], Hubert Ythier[3], Helene Zephir[4] & Clara Leroy[1,5]
[1]Department of Endocrinology and Diabetology, Hôpital Huriez, Lille University Hospital, Lille, France; [2]Jean Pierre Aubert Research Center, INSERM U 1172, Lille, France; [3]Department of Pediatrics, VICTOR PROVO Hospital, Roubaix, France; [4]Department of Neurology, Hôpital Salengro, Lille University Hospital, Lille, France; [5]Department of Pediatric Endocrinology, Lille University Hospital, Lille, France.

Introduction
Type 1 diabetes (T1D) and multiple sclerosis (MS) are autoimmune diseases with common immunological mechanisms. Type 1 diabetics have an increased risk of MS. The aim of this work is to report a clinical observation of a partial preservation of β-cell function in a type 1 diabetic patient treated early by Fingolimod for MS.
Observation
A polyuro-polydipsic syndrome and a weight loss of 10 kg led to the diagnosis of T1D (typing HLA DR4/DR3, Anti-GAD and anti-IA2 antibodies positive: 3.7 and 3.2 IU/ml respectively, C-fasting peptide: 0.41 ng/ml and HbA1c: 14%) in a 15-year-old patient treated by a basal-bolus insulin. 4 weeks later, the majoration of old balance disorders and the onset of an epileptic seizure (without hypoglycemia), revealed a relapsing-remitting MS, justifying the introduction of an immuno-modulatory treatment by Fingolimod (a sphingosine 1-phosphate receptor modulator which causes a redistribution of T lymphocytes to lymphoid organs, reducing the circulation of auto-aggressive lymphocytes) 11 weeks after discovery of T1D. After 31 months under Fingolimod, glycemic balance is perfect (HbA1c between 5.8 and 7%) with partially preserved insulin reserves (fasting C-peptide around 0.50 ng/ml). According to results of studies on mouse models, Fingolimod preserves β-cell function by modulating the immune response and inhibiting apoptosis (Hosik M Diabetes Metab Res Rev 2013). At 33 months post-diagnosis of T1D, insulin boluses were replaced by Repaglinide at mealtime (before change: fasting C-peptide at 0.5 ng/ml and postprandial at 1.5 ng/ml, glycemia respectively at 1.93 g/l and 2.67 g/l. 4 months after change: fasting C-peptide at 0.51 ng/ml and postprandial at 1.85 ng/ml, glycemia respectively at 1.11 g/l and 1.66 g/l). Metformin has been introduced to reduce insulin resistance in a context of overweight, combined with a GLP-1 analogue. The glycemic balance remains correct with HbA1c between 7 and 8.1% without glycemic fluctuations. The insulin reserves remained stable (12 months after change the fasting C-peptide remains around 0.50 ng/ml).
Discussion
Although slow-type 1 diabetes or a protective effect of the GLP 1 analogue can not be excluded, the early introduction of Fingolimod probably helped to preserve the residual β-cell function, which is consistent with results of work on murine models. This opens new therapeutic hope for management or prevention of T1D as well as the use of Fingolimod in diabetes cell therapy (Bowers J Biomed Mater Res 2017).

Treating depression in insulin dependant diabetics improves glucoregulation

Jana Radojkovic[1], Sanja Ilic Mijailovic[1], Natasa Sikanic[2] & Katarina Lalic[3]
[1]Clinical Hospital Center 'Dr Dragisa Misovic', Belgrade, Serbia; [2]Pro Anima Psychiatric Clinic, Belgrade, Serbia; [3]Clinic for Endocrinology, Diabete and Diseases of Metabolism, Belgrade, Serbia.

Bacground
It is disputable whether negative effects of comorbid depression in patients with type 2 diabetes can be diminished by treatment of depression. The primary aim of this study was to assess whether addition of antidepressants to existing insulin therapy would further improve glycemic control in these patients. A secondary objective was to assess whether such treatment impairs their lipid and inflammatory status.
Material/methods
Total of 50 patients with poorly controlled diabetes (defined as HbA1c $>8\%$) and BDI-II >14 and psychiatric confirmation of depression, in the abscence of any uncontrolled medical condition, entered the 6 month interventional phase with SSRI class antidepressants.
Results
During the interventional phase HbA1c dropped from $8.5\% \pm 1.2\%$ to $7.7\% \pm 0.7\%$ ($P<0.001$). BDI-II scores improved significantly from 30.4 ± 13.2 to 23.5 ± 11.0 ($P=0.02$) during the interventional phase. A positive linear correlation between improvement in depression scale and improvement in glycemic control was observed ($R^2=0.139$, $P=0.008$). Lipid profile and inflammatory status did not change significantly during interventional phase.
Conclusion
Patients with poorly controlled diabetes and comorbid depression might benefit from screening and treatment of depression with SSRI antidepressants by achieving an incremental effect on glycoregulation. This therapy did not have any adverse effects on lipid profile or inflammatory status.

Comparative analisis of multiple daily injection of insulin and continuous subcutaneous insulin infusion regimes in children and adolescents with type 1 DM in Uzbekistan

Khilola Gulyamova[1], Ismailov Said[1], Alimova Nasiba[2] & Feruza Suleymanova[2]
[1]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan; [2]Republican Specialized Scientific-Practical Medical Center of Endocrinology, Tashkent, Uzbekistan.

Background
Insulin pumps, devices for continuous subcutaneous insulin infusion have become fundamentally new and progressive step in the treatment of diabetes. To date, there has been no experience with the use of insulin pumps in Uzbekistan
Aims and objectives
To evaluate the effectiveness of insulin pump therapy in comparison with the regime of multiple daily injections (MDI) of insulin.
Materials and methods
Forty children and adolescents with type 1 diabetes from 5 to 17 years (28 girls and 12 boys) were examined. All patients were divided into 2 groups. Group 1 consisted of patients who were transferred from the baseline bolus scheme of insulin therapy with human insulin to MDI with combination of a human insulin analog and a short-acting insulin. Group 2 includes patients who were transferred to pump insulin therapy and received ultrashort acting insulins. Glycemia and glycated hemoglobin were monitored Within 12 months,
Results
The comparative analysis showed a significant decrease in glycated hemoglobin ($7.9+0.3$) by 2.3% in group 2, compared with children and adolescents on the MDI regime (HbA1c $7.8+0.3$%, decrease by 1.5%). The proportion of patients with a HbA1c level of less than 7.5% on MDI increased from 20% to 50%, and in the group receiving insulin pump therapy increased from 15% to 50%. Target values of HbA1c <7.5% reached 50% of patients in groups 1 and 2.
Conclusion
On insulin pump therapy HbA1c decreased by 2.3%. The target values of HbA1c reached 50% of the patients in both groups.

Perinatal outcomes in Mexican women with mild gestational diabetes mellitus without treatment diagnosed by the international association of diabetes and pregnancy study groups criteria

Nayeli Martinez Cruz, Enrique Reyes Muñoz, Karla P. Soriano Ortega, Lidia Arce Sanchez, Carlos Ortega Gonzalez, Ursula Torres Herrera, Salvador Espino y Sosa & Aracely Montoya Estrada
Instituto Nacional de Perinatología, Ciudad de Mexico, Mexico.

Aims
To compare the risk of adverse perinatal outcomes (APO) between pregnant women with mild gestational diabetes mellitus (GDM) by International Association of Diabetes and Pregnancy Study Groups (IADPSG) criteria without treatment versus women without GDM.
Methods
A retrospective cohort study. We included pregnant women with prenatal care and delivery at our Institution. Group 1, women with mild GDM defined by one abnormal glucose value according to IADPSG criteria; fasting: 5.1–5.2 mmol/l (92–94 mg/dl) or 2 h 8.5–8.56 mmol/l (153–154 mg/dl), which did not receive treatment for GDM. Group 2, women without GDM matched by maternal age and pre-gestational body mass index (BMI). We excluded women with pregestacional diabetes, any chronic disease, and multiple pregnancies.
Results
282 women were included in each group. There were not significant differences in basal characteristics between groups. The newborn weight was significantly higher in group 1 (3042.4 ± 499 g) vs group 2 (2910 ± 565 g) $P=0.003$, however the incidence of neonates large for gestational age (LGA) and macrosomic were similar in both groups 6 vs 5.7% and 2.1 vs 2.2% respectively. There were no differences in the risk of APO such as; preeclampsia, gestational hypertension, cesarean, preterm delivery and premature rupture of membranes. In a sub-analysis we showed that LGA was significantly higher in women with pre-gestational BMI ≥ 30 kg/m^2 in both groups.
Conclusions
The risk of APO is similar in Mexican women with mild GDM diagnosed by IADPSG criteria without treatment compared to pregnant women without GDM. The pre-gestational BMI is an independent risk factor for neonates LGA.

Meta-analysis of clinical efficacy of traditional chinese medicine formula (Simiao Yong'an Decoction) in treatment of diabetic foot meta-analysis of clinical efficacy of traditional chinese medicine formula (Simiao Yong'an Decoction) in treatment of diabetic foot

Suping Huang, Yongjin Liu & Bowei Huang
Fujian University of Traditional Chinese Medicine, Fuzhou, China.

Objective
To evaluate the efficacy and safety of Traditional Chinese medicine formula (Simiao Yong'an Decoction) in the treatment of Diabetic foot (DF).
Methods
A comprehensive retrieval was made in PubMed, EMRS, EMbase, The Cochrane Library, CNKI, WanFang and other databases to collect randomized controlled trials (RCTs) on the treatment of DF with Simiao Yong'an Decoction (from the establishment of databases to Dec 2017). Two reviewers independently screened literature, extracted data and assessed the risk of bias. RevMan 5.3 software was used to perform Meta-analysis. The control groups was treated by conventional Western therapy (anti-infectives, anticoagulant, promote the blood circulation), while the intervention groups was treated by Simiao Yong'an Decoction. There was no statistically significant on the levels of blood glucose between these two groups. The curative effect was measured by clinical curative effect, the blood flow in the dorsalis pedis, ankle brachial index, side effects. The therapy was sustained at 8 weeks.
Results
Seven RCTs were enrolled in the study, with a total of 485 patients. The Meta-analysis results showed that compared with the conventional therapy, Simiao Yong'an Decoction had advantages in improving clinical curative effect (OR = 1.15, 95% CI = [1.07, 1.24], $P=0.000\ 2$), and enhance the blood flow in the dorsalis pedis (WMD = 1.40, 95% CI = [0.94, 1.86], $P<0.000\ 01$) and increase the ankle brachial index (WMD = 0.07, 95% CI = [0.02, 0.12], $P=0.005$). While there was no statistically significant on adverse events.
Conclusion
Simiao Yong'an Decoction may have advantages over Western medicine in the treatment of DF, and it is a form of recommendable adjuvant therapy for DF. In view of the limited quantity and quality of the included studies, it is needed to verify with more high quality randomized controlled trials.

Maculopapular rash developed after initiation of U-300 glargine insulin in a patient with type 1 diabetes mellitus

Ömecan Topaloğlu, Bahri Evren, Mehmet Akif Bilgiç, Mahmut Kara & İbrahim Şahin
Inonu University Medical Faculty, Department of Endocrinology, Malatya, Turkey.

Introduction
U-300 insulin glargine has been used as a concentrated form of glargine. Skin and subcutaneous tissue disorders (eg, rash, pruritus, and urticaria) have been reported with insulin glargine. But to our knowledge, maculopapular rash has not been reported with use of U-300 insulin glargine. We present a patient with type 1 diabetes mellitus(DM) developing maculopapular rash after initiation of U-300 glargine insulin.
Case Report
37 year-old female patient followed up with type 1 DM for 8 years was referred to our clinics with the signs of hypoglycemia including intermittent palpitation, sweating and tremor. She had neuropathic complaints as "stocking glove" paresthesia. She had been taking multiple daily insulin injection (3*10 unit regular, 1*12 unit U-100 glargine insulin). On physical examination; vital signs were stable and systemic examination was unremarkable. Serum biochemistry and hormonal analysis revealed as fasting blood glucose(FBG) (159 mg/dL), postprandial blood glucose(PPBG) (231 mg/dL), HbA1c (6.6%), C-peptide (<0.10 ng/mL), creatinine (0.65 mg/dL), ALT (12U/L), Na (136 mmol/L), K (4.27 mmol/L), TSH (1.28 IU/mL) and free T4 (0.79 ng/mL). Due to frequent hypoglycemic attacks, the patient was accepted as "Brittle diabetes". Insulin dosage was titrated according to monitorization of blood glucose. However, due to persistent increased morning fasting glucose levels, U-100 insulin glargine was increased to a dose of 22 unit. Nocturnal hypoglycemia occured after this adjustment; therefore, U-300 insulin glargine was initiated instead of U-100 insulin glargine. The frequency of nocturnal and daytime hypoglycemia, and glycemic variability decreased, and glycemic regulation was maintained with

U-300 insulin glargine of 9 units. 3 weeks later, we detected maculopapular rash on her anterior chest, left arm and deltoid (Photograph-1). Then, U-300 insulin glargine was cessated, and rash was regressed.
Conclusion
We report a case with maculopapular rash developed in a diabetic patient after initiation of U-300 insulin glargine for a first time. Timely cessation of U-300 insulin glargine was resulted in resolution of the rash. Our case highlights rare and lesser known side effect of U-300 insulin glargine.

Dapagliflozin after liraglutide in patients with type 2 diabetes

Paloma Moreno-Moreno, Concepción Muñoz-Jiménez, María Rosa Alhambra-Expósito & María Ángeles Gálvez-Moreno
Hospital Universitario Reina Sofía, Córdoba, Spain.

Objective
To evaluate the efficacy of dapagliflozin for glycemic control and progression of weight loss after stabilization with liraglutide 1.8 mg.
Patients and methods
Descriptive study: patients with tipo 2 diabetes (DM-2) in treatment with metformin and liraglutide 1.8 mg, optimal metabolic control, which after stabilization in weight loss, liraglutide is suspended and dapagliflozin is added. Variables analyzed baseline and at 6 months after treatment change: age, sex, time of diabetes evolution, Body mass index (BMI), abdominal perimeter (BP), systolic blood pressure (SBP), diastolic blood pressure (DBP), LDL, HDL, triglycerides (TG), uric acid (UA). Statistical analysis: comparing means with Student's test.
Results
15 patients with DM-2 treated with metformin 1000 mg/12 h and liraglutide 1.8 mg with optimal glycemic control and stabilized weight loss. 60% women Age: 56±7.5 years. Time of diabetes evolution: 8±4.1 years. Weight loss achieved 6 months after the change of treatment was 9.7±11 Kg. No side effects were recorded. The treatment change was satisfactory for all patients.

	Basal (mean ± SD)	6 months (mean ± SD)	P
Weight (Kg)	96.3±11	89.5±11	0.1
BMI (kg/m^2)	34±2.7	31.5±2.8	0.02
BP (cm)	109.5±9.5	105.3±9	0.2
SBP (mmHg)	137.6±10.5	130.3±9	0.05
DBP (mmHg)	86.6±14.5	72.8±8.1	0.003
HbA1c (%)	7±0.2	6.5±0.3	0.001
LDL (mg/dl)	95±115.7	80.5±11.6	0.01
HDL (mg/dl)	45.3±7.4	48.6±4.8	0.2
TG (mg/dl)	178.6±69.8	124.6±37.3	0.01
UA (mg/dl)	7.1±0.8	6.3±1.1	0.002

Conclusions
The change of treatment of liraglutide 1.8 mg to dapagliflozin in patients with optimal glycemic control and stabilization weight loss, achieves a progression in weight loss and improves the metabolic control of the patient with DM-2. The change of treatment was satisfactory for all patients.

Canagliflozin after liraglutide in patients with type 2 diabetes

Paloma Moreno-Moreno, María Rosa Alhambra-Expósito, Concepción Muñoz-Jiménez & María Ángeles Gálvez-Moreno
Hospital Universitario Reina Sofía, Córdoba, Spain.

Objective
To evaluate the efficacy of canagliflozin 100 mg for glycemic control and progression of weight loss after stabilization with liraglutide 1.8 mg.
Patients and methods
Descriptive study: patients with type 2 diabetes (DM-2) in treatment with metformin and liraglutide 1.8 mg, optimal metabolic control, which after stabilization in weight loss, liraglutide is suspended and canagliflozin 100 mg is added. Variables analyzed baseline and at 6 months after treatment change: age, sex, time of diabetes evolution, Body mass index (BMI), abdominal perimeter (BP), systolic blood pressure (SBP), diastolic blood pressure (DBP), LDL, HDL, triglycerides (TG), uric acid (UA). Statistical analysis: comparing means with Student's test.
Results
Eighteen patients. 50% women Age: 55.61±7.1 years. Time of diabetes evolution: 7.7±5 years. Weight loss achieved 6 months after the change of treatment was 6±2.5 Kg. No side effects were recorded. The treatment change was satisfactory for all patients.

	Basal (mean ± SD)	6 months (mean ± SD)	P
Weight (Kg)	97.5±10.8	91±10.9	0.1
BMI (kg/m^2)	35.2±2.3	33.1±2.2	0.01
BP (cm)	110.3±9.4	105.7±8.6	0.1
SBP (mmHg)	137.5±8.5	128.9±7.1	0.002
DBP (mmHg)	84.6±14.4	75.5±7.1	0.02
HbA1c (%)	7±0.2	6.5±0.3	0.000
LDL (mg/dl)	104.5±32.1	89.3±22	0.11
HDL (mg/dl)	46.8±8	49.5±6.7	0.3
TG (mg/dl)	164.5±74.2	125.8±44.4	0.06
UA (mg/dl)	7.2±0.9	6.5±1.2	0.05

Conclusions
The change of treatment of liraglutide 1.8 mg to canagliflozin 100 mg in patients with optimal glycemic control and stabilization weight loss, achieves a progression in weight loss and improves the metabolic control of the patient with DM-2. The change of treatment was satisfactory for all patients. No side effects were recorded.

Inhibitors SGLT2 after liraglutide in patients with type 2 diabetes

Paloma Moreno-Moreno, Concepción Muñoz-Jiménez, María Rosa Alhambra-Expósito & María Ángeles Gálvez-Moreno
Hospital Universitario Reina Sofía, Córdoba, Spain.

Objetive
The change of treatment of liraglutide 1.8 mg to dapagliflozin or canaglifonzin 100 mg in patients with optimal glycemic control and stabilization weight loss, achieves progression in weight loss and improves the metabolic control of the patient with tipo 2 diabetes (DM-2). Our objective is to evaluate if there are differences in metabolic control and progression of weight loss in patients treated with canagliflozin 100 mg or dapagliflozin.
Patients and methods
Retrospective descriptive study: patients with DM-2 treated with metformin and liraglutide 1.8 mg, optimal metabolic control which after weight stabilization, liraglutide is suspended and treatment with canagliflozin 100 mg (group 1) or dapagliflozin (group 2) is initiated. Variables analyzed baseline and at 6 months after treatment change: age, sex, time of diabetes evolution, Body mass index (BMI), abdominal perimeter (BP), systolic blood pressure (SBP), diastolic blood pressure (DBP), lipid profile and uric acid (UA). Statistical analysis: comparing proportions with the chi-squared and comparing means with Student's test.
Results
Thirty-three patients (group 1: 18; group 2: 15). Baseline characteristics were similar in both groups. Results at 6 months of treatment change:

	Group 1 (mean ± SD)	Group 2 (mean ± SD)	P
Weight (Kg)	9.1±10.9	89.5±11	0.7
BMI (kg/m2)	33.1±2.2	31.5±2.8	0.08
BP (cm)	105.7±8.6	105.3±9	0.9
SBP (mmHg)	128.9±7.1	130.3±9	0.6
DBP (mmHg)	75.5±7.1	72.8±8.1	0.3
HbA1c (%)	6.5±0.3	6.5±0.3	1
LDL (mg/dl)	89.3±22	80.5±11.6	0.2
HDL (mg/dl)	49.5±6.7	48.6±4.8	0.9
TG (mg/dl)	125.8±44.4	124.6±37.3	0.06
UA (mg/dl)	6.5±1.2	6.3±1.1	0.6

Conclusions
We did not find differences in metabolic control and progression of weight loss in patients treated with canagliflozin 100 mg or dapagliflozin after stabilization with liraglutide 1.8 mg.

Second setp in type 2 diabetes, what to choose?

María Rosa Alhambra Expósito, Paloma Moreno Moreno, Ana Barrera Martín, Inmaculada Prior Sánchez & María Ángeles Gálvez Moreno
Hu Reina Sofía, Córdoba, Spain.

Introduction
In type 2 diabetes the choice of the second drug after metformina is marked by the basic characteristics of the patient.
Objetive
To analyze in real clinical practice the effectiveness of different antidiabetics.
Material and methods
Observational study including patients with type 2 diabetes, in which we added to metformina different antidiabetics. We revised them 3-6 months from change.
Results
Seventy-three patients were included, 40 were added SGLT2, 21 DDP4, 12 GLP1 agonist. There were not found different between groups in basal or 3-6 month characteristics except on BMI. 3-6 month after the change (table1), triglycerides, glucose, HbA1c and TAS were significantly lower on SGLT-2 group. On IDPP-4, only HbA1c levels were significantly lower than basal. On GLP-1, HbA1c and TAD were significantly lower.

		BASAL	FINAL	P-value

Short term adherence with discharge recommendation for insulin treatment among patients with type 2 diabetes

Shlomit Koren[1], Orel Hemo[2], Michael Yoshpe[2], Ronit Koren[3], Dror Cantrell[2] & Micha J. Rapoport[2]
[1]Diabetes Unit, Assaf Harofeh Medical Center, zerifin, Israel; [2]Department of Internal Medicine C, Assaf Harofeh Medical Center, zerifin, Israel; [3]Department of Internal Medicine A, Assaf Harofeh Medical Center, zerifin, Israel.

Background
Basal-Bolus (BB) insulin treatment is increasingly used in uncontrolled diabetes patients during hospitalization and is commonly recommended on their discharge. However, the extent of adherence with this recommendation is unknown.
Aim
To determine the short term adherence of type 2 diabetes mellitus (T2DM) patients discharged from internal medicine wards with recommendation for BB insulin treatment.
Methods
Prescription (primary-physician adherence) and purchase (patient-adherence) of long acting and short acting insulins during the 1st month following discharge from internal medicine wards was determined in 336 T2DM patients. Adherence was defined as "full" if prescription/purchase of both basal (long acting) and bolus (short acting) insulin was made and as "partial" if only one kind of insulin was prescribed/purchased. Association between demographic and clinical parameters and adherence was determined.
Results
Primary-physicians' full adherence with discharge instructions was higher than patients' full adherence)76% vs. 62.2% respectively, $P=0.01$). Pre-hospitalization HbA1c was significantly associated with both patient's and physicians' adherence ($9.0\% \pm 2.1\%$ in the full adherence group and $7.7\% \pm 1.3\%$ in the no adherence group, $P<0.01$). Age was negatively associated with adherence of primary-physicians (73 ± 11.2 years in the full adherence group and 65.4 ± 15.5 years in the no adherence group, $P<0.01$). A negative correlation between patients and physicians' adherence and Length of hospitalization was found. When the sole cause of admission was diabetes, close to 100% adherence of both primary-physicians and patients was found.
Conclusion
Short term adherence with discharge recommendation for BB insulin treatment is associated with pre-hospitalization patient characteristics and length of hospitalization

Dulaglutide; effectiveness in a real world population with type 2 diabetes

Lidia Urbón López de Linares[1] & Cristina Crespo Soto[2]
[1]Hospitales Recoletas, Valadolid, Spain; [2]Hospital Rio Hortega Valladolid, Valladolid, Spain.

Diabetes is a chronic disease that is often accompanied by multiple comorbidities and health complications such as overweight/obesity. In the late years therapies improving glycemic control while reducing body weight have become a convenient choice to treat diabetes. One of those therapies are GLP 1 receptor agonists. Dulaglutide allows for a once weekly dosing which might improve compliance; moreover its new application device ease the injection. We show the results of HbA1c and weight evolution after starting dulaglutide 1.5 mg weekly in 60 patients (all of them were on metformin and a second drug). Women represented the 42% and the medium age was 59 ± 7 years. We show data after 6 months on dulaglutide. Initial Hba1c was 8.3% (± 1.2). After 6 months it was 7.2% (± 1). Initial weight was 107.7 kg (± 12). After 6 months it was 101.5 kg (± 16). Our results showed an average reduction of HbA1c of 1.1% and average reduction of weight of 6.2 kg. 25% of the patients showed sickness and only a 5% vomits. Only 2 patients had to stop the therapy. There were no other side effects. None of the patients complained about pain or inconvenience related to the injection and all of them found it painless. All the patients rated positively the one weekly dosing. Dulaglutide added to the previous treatment improved glycaemic control in DM2 patients. Dulaglutide added to the previous treatment produced weight loss in DM2 patients. The main side effect was sickness, but it was well tolerated in most of the patients and the therapy was not discontinued. The one weekly dosing and the painless administration was positively rated by all the patients.

Experience in clinical practice with new long-acting insulins in type 2 diabetes (T2D)

María Molina Vega, Araceli Muñoz Garach, Miguel Damas Fuentes, Carmen Hernandez García, Cristina Díaz Perdigones, Isabel Cornejo Pareja & Francisco Tinahones Madueño
Virgen de la Victoria Hospital, Málaga, Spain.

Introduction
New long-acting insulin analogues (insulin degludec –ID- and insulin glargine 300 U/ml –IG300-) have proved, in clinical trials, that improve metabolic control with lower hypoglycemia rate in T2D.
Objective
To assess characteristics of T2D patients who were given ID and IG300 and to evaluate their effect on metabolic control, weight and insulin dose.
Material and methods
We studied T2D patients whose treatment had been modified. We analyzed weight, HbA1c and insulin dose at baseline and 3-6 months after treatment initiation.
Results
Forty-four patients: 61.4% women, mean age 60,5 ± 10.2 years. T2D evolution time: 15.4 ± 8.6 years. Mean BMI: 31 ± 4.4 kg/m^2. Mean HbA1c: 9.2 ± 1.7%. At baseline, 16% not insulin-treated (4.6% oral antidiabetic drugs –OADs-, 11.4% OADs + GLP1 agonists); 84% treated with long-acting insulin (34.1% insulin glargine, 31.8% insulin detemir, 6.8% pre-mixed insulin, 11.4% insulin NPH) + other therapies (61.4% OADs, 31.8% GLP1 agonists, 25% short-acting insulin). Reason to change: IG300: 91% poor metabolic control, 4.5% twice-daily basal insulin, 4.5% hypoglycemia; ID: 54.5% poor metabolic control, 27.3% twice-daily basal insulin, 18.2% hypoglycemia (*P* 0.025). Baseline: no differences in age, T2D evolution time, BMI or HbA1c. ID group had higher dose of basal insulin –BI- (50.7 ± 31.7 vs 29.4 ± 19.8; p 0.033), total daily dose –TDD- (59 ± 30.3 vs 37.7 ± 44.9, *P* 0.036) and units per kg –U/kg- (0.8 ± 0.4 vs 0.4 ± 0.5; *P* 0.031) vs IG300 group. 3–6 months after: no differences between groups. ID: significant drop in HbA1c (1 ± 1.3%; *P* 0.003), BI dose (7.7 ± 14.5 U; *P* 0.008), TDD (8.9 ± 13.3; *P* 0.016) and U/kg (0.8 ± 0.4 vs 0.6 ± 0.3; *P* 0.02), maintaining weight. IG300: significant drop in HbA1c (0.8 ± 1.7%; 0.037), maintaining BI dose, TDD, U/kg and weight. Patients switching from other insulin to ID required a significantly lower dose of IB and U/kg, unlike to those switching to IG300 (−7.7 ± 14.5 vs 5.5 ± 14.2; *P* 0.003 and 0.13 ± 0.1 vs 1.7 ± 0.2 U/kg; *P* 0.011 respectively).
Conclusions
ID was chosen in patients with high insulin requirements, not only to improve metabolic control, but also to reduce hypoglycemia and insulin dose, while IG300 was mainly used in not insulin-treated patients and in those with poor metabolic control.
A lower dose of insulin is required with ID vs IG300.

Six months of retrospective glycemic control and anthropometric outcomes in type 2 diabetic patients with new dapagliflozin treatment; actual clinical experience data from single center

Soner Cander, Murat Calapkulu, Ozen Oz Gul & Canan Ersoy
Uludag University, Bursa, Turkey.

Introduction
SGLT2 inhibitors have been an important step in the treatment of diabetes. With numerous controlled experimental studies of these antidiabetic drugs, evaluation of real-life data after entry into clinical practice is an important condition. In our study, it was aimed to evaluate short-term results on glycemic control and weight loss in a narrow group of patients in the single tertiary medical center.
Methods
The study was retrospectively designed and 20 type 2 diabetic patients who had started dapagliflozin in the last 1 year and who had anthropometric and glycemic control data at 3-6th months were included in the study. Data of the patients who did not undergo non-routine administration and whose other antidiabetic treatments were not changed were collected from medical hospital records.
Results
The mean age of the twenty patients was 54.95 years, 25% male and 75% female, mean duration of diabetes was 10.8 years. The mean HbA1c level before dapagliflozin was 8.42%, while it was 7.57 in third and 7.85 in sixth months. Fasting blood glucose levels were found 186.8, 141.6 and 142.2 mg/dl and postprandial glucose levels were found 262.1, 183.9 and 187.1 mg/dl at the 0-3-6th months respectively. Weights were reduced from 87.8 to 84.1 and 83.4 kg, BMI from 33.3 to 31.3 and 31.5 kg/m^2. There was a corresponding decline (107.7 → 106.2 → 106.1 cm) in the waist circumferences. In patients using insulin (n = 5, 25%) weight reduction was slightly lower (average −5.1 to −2.4 kg) but glycemic control was better (HbA1c in the insulin using; 9.54% → 7.70% → 8.30%, non-using; 8.02% → 7.53% → 7.69%). Improvement in glycemic control was more pronounced when diabetes age < 10 years (n = 9, 45%) compared with those of ≥ 10 years.
Discussion
It has been shown that SGLT2 inhibitors provide glycemic control without increasing the risk of hypoglycemia by causing glycosuria with the effect on the glucose reabsorption in the proximal tubules and dependent on serum glucose level. Studies have shown that they reduce HbA1c levels by between 0.5-1% on average and cause weight loss around 5%. The data on our study were found to be consistent with these findings. In addition, indicate that SGLT2 inhibitors are more effective for glycemic control in patients with diabetes mellitus less than 10 years and using insulin, and better in terms of weight control in the patients who do not use insulin.

Can patient profile influence on GLP1 analogues prescription among physicians?: patient selection and perspectives

Manuel Cayón-Blanco & Carolina García-Figueras-Mateos
Hospital SAS Jerez de la Frontera, Jerez de la Frontera, Spain.

Introduction
The use of glucagon like peptide 1 analogues (GLP1a) for the treatment of type 2 diabetes mellitus (T2DM) is growing. After a decade-long effort to improve the pharmacokinetics of GLP1, a number of GLP1a are currently available on the market. With a view to identifying patient characteristics that could influence physicians' prescription of different GLP1a we carried out this observational study in routine clinical practice conditions. Outcomes after add-on these drugs were described as well.
Methods/design
The study was based on a retrospective design and the following variables were collected to identify potential influencing factors in patient profile at baseline: gender, age, time of evolution of T2DM, body mass index (BMI), HbA1c level and treatment with insulin. To measure outcomes, changes in HbA1c and BMI at 6 months after add-on, were assessed.
Results
75 poorly controlled patients with T2DM who received any GLP1a as add-on therapy were analysed. There was a homogeneus distribution of patients according to the drugs evaluated (one-third of sample for each one: exenatide-LAR [EL], dulaglutide [D] and liraglutide [L]). At baseline, patients on D were older as compared to other GLP1a (D: 60.8 ± 10.8 vs EL: 51.8 ± 10 vs L: 54.2 ± 10.2 years; P = 0.008). There was a nonsignificant trend to prescribe EL in patients with higher BMI ([Kg/m^2]: EL: 41.8 ± 8.8 vs L: 40.7 ± 7.3 vs D: 37.8 ± 6.9; P = 0.17) and D to patients with higher level of HbA1c ([%]: D: 9.2 ± 1.4 vs EL: 8.7 ± 1.7 vs L: 8.5 ± 1.1; P = 0.23). No significant changes in HbA1c and BMI reductions were detected among drugs at 6 months. The highest HbA1c reductions were reached with D (−1.9 ± 1.5% vs EL: −1.2 ± 1.1% vs L: −1.5 ± 1%; P = 0.13). BMI reductions were also equivalent among groups.
Conclusions
According to the trends of use of GLP1a, we can conclude that there is a nonsignificant perception of a higher HbA1c-lowering effect and better security profile for D and a higher weight-lowering effect for EL among physicians. Nevertheless, HbA1c and BMI reductions are equivalent among different types of GLP1a in our routine clinical practice.

SGLT-2 inhibitors or GLP-1 receptor agonists as add-on to insulin therapy in patients with type 2 diabetes: comparative analysis

Carolina García-Figueras-Mateos & Manuel Cayón-Blanco
Hospital SAS Jerez de la Frontera, Jerez de la Frontera, Spain.

Introduction
Multiple studies have evaluated the efficacy of SGLT-2 inhibitors (SGLT2i) and GLP-1 receptor agonists (GLP1ra) in patients with type 2 diabetes mellitus

(T2DM). However, their efficacy in clinical practice is less known in patients receiving insulin and few are the studies that compare use of SGLT2i vs GLP1ra as add-on therapy to insulin. This study aims to assess clinical efficacy of both treatments in a cohort of patients with T2DM on insulin and poor glycemic control under routine clinical practice conditions.
Methods/desing
An observational and retrospective study was carried out including 77 T2DM patients on insulin who were added either SGLT2i or GLP1ra to their treatment because of poor glycemic control. Demographic, anthropometric, clinical and therapeutical variables were recorded and compared between groups at baseline and at 24 weeks after add-on. Continuous variables are presented as mean and standard deviation or as median and interquartile range [Q1-Q3] based on data distribution. Categorical variables are presented as frequencies.
Results
SGLT2i was prescribed in 46 patients and 31 patients received GLP1ra. At baseline, both groups were equivalent respect to age, body mass index, weight, time of T2DM duration, dose and regimen of insulin treatment. Female gender rate was higher in GLP1ra group (74.2% vs 30.4%; $P<0.001$). Differences related to HbA1c-lowering effects and weight loss weren't observed between groups at 24 weeks after add-on: HbA1c (SGLT2i vs GLP1ra): $-1.8\pm0.3\%$ vs $-1.7\pm0.3\%$; $P=0.73$; weight loss (SGLT2i vs GLP1ra): -3 ± 0.7 vs -2.6 ± 0.6 kg; $P=0.67$. Moreover, no differences were observed neither in rate of patients who lowered insulin dose nor insulin units according to insulin regimen (basal or basal-bolus): Basal régimen (SGLT2i vs GLP1ra): rate of patients who required any decrease in insulin dose (54.5% vs 43.7%; $P=0.51$), median dose decrease (7 [4–12.5] vs 20 [8–28] IU; $P=0.22$); basal-bolus or basal-plus (SGLT2i vs GLP1ra): rate of patients who required any decrease in insulin dose (33.3% vs 53.8%; $P=0.51$), dose decrease (15.5 [7.5–29.5] vs 14 [8–24] IU; $P=0.96$).
Conclusions
Both SGLT2i and GLP1ra as add-on therapy to insulin result in equivalent HbA1c-lowering effects, weight loss and insulin dose reductions. We didn't find solid arguments focusing on metabolic control, weight-lowering effects or insuline dose reductions to recommend one or another treatment to optimize outcomes in these patients. Further studies exploring patients preferences and adverse events are needed.

Clinical predictors of therapeutic response to SGLT-2 inhibitors

Carolina García-Figueras-Mateos & Manuel Cayón-Blanco
Hospital SAS Jerez de la Frontera, Jerez de la Frontera, Spain.

Introduction
Predictors for therapeutical response of SGLT-2 inhibitors (SGLT2i) is scarcely studied. The aim of the study was to retrospectively analyse the clinical parameters that contribute to the therapeutic outcomes of SGLT2i.
Methods/design
We enrolled 75 patients with type 2 diabetes mellitus (T2DM), treated with SGLT2i for longer than three months. The patients were divided into two groups: good responders (if HbA1c-lowering effects were $\geq 0.5\%$) and poor responders (if $<0.5\%$), based on pretreatment and post-treatment differences in HbA1c levels. Good responders were also divided into three groups according to decreases of HbA1c: intermediate responders (0.5–0.9%) high responders (1–1.9%), very high responders ($\geq 2\%$). Patients receiving GLP-1 analogues, with glomerular filtration rate below 60 ml/min/1.73 m^2 or any contraindication for the use of SGLT2i were excluded. We used univariate and multivariate analyses to assess pretreatment parameters between the two groups and to identify predictors for response.
Results
78.7% of the patients were good responders. According to decreases of HbA1c, 21.3% were classified as poor responders, 18.7% as intermediate responders, 28% as high responders and 32% as very high responders. Responders had a higher HbA1c at baseline ($9.2\pm1.3\%$ vs $7.5\pm1\%$; $P<0.001$) but no differences according to age, gender, time of evolution of T2DM, body mass index, weight, weight loss, use of other antidiabetic oral agents or insulin were found as compared to poor responders in an univariate analyses. Very high responders had significant ($P<0.001$) higher HbA1c at baseline ($10.4\pm1.1\%$) as compared to high ($8.5\pm0.7\%$) and intermediate responders ($8.3\pm0.6\%$). Multivariate analyses showed that HbA1c at baseline was the only independent predictor for good response to SGLT2i (OR 5.3; 95%CI: 2.1 – 13.1).
Conclusions
Our study showed that level of HbA1c at baseline, but no other parameter, is linked to the therapeutic effect of SGLT2i on T2DM patients and also, related to the magnitude of the response.

Improvement control rate of blood glucose/blood pressure/blood lipid in diabetes patients by hospital-community integrated management in Shanghai

Li Wei, Yuanyuan Zeng, Chaoyu Zhu, Yuanyuan Xiao & Qingge Gao
Department of Endocrinology and Metabolism, Shanghai Jiao Tong University Affiliated 6th People's Hospital Shanghai, Shanghai, China.

Background
Diabetes prevalence and mortality are increasing rapidly and glycemic goals (hemoglobin A1c $< 7\%$) are often not achieved in patients with type 2 diabetes in China, The low control rate of diabetes has become a global problem. The management of community diabetes is the most effective choice to prevent and control chronic diseases.
Objective
To improve the management of diabetes mellitus in community, we analyze the effect of hospital-community integrated management.
Method
541 cases diabetic patients in a suburb community of shanghai from April 2014 to April 2015 were cared with hospital-community integrated management, Include community blood glucose monitoring and regular diabetes education, hospital experts guide the treatment of community doctors etc, and the clinical and laboratory data before and after management was collected, and the control rate of HbAlc, blood pressure, blood lipids and related factors were analyzed.
Results
After one year management, patients with diabetes compared to baseline HbA (%), FPG, 2hPG, HOMA-IR, SBP, DBP, TG, LDL-C, Waist indexes have significant decline ($P<0.05$). the control rates of HbA, blood pressure, blood lipid were increased from 63.40%, 9.98%, 50.46% respectively to 72.27%, 22.18%, 58.96% ($P<0.05$), and the control rates of single, two, three indexes of HbA, blood pressure, blood lipid were all increased from 62.84%, 2.49%, 3.18% respectively to 69.13%, 12.93%, 33% ($P<0.05$).Multivariate Logistic regression analysis shows lack of exercise and control of diets, lower frequency of monitoring blood glucose in community and high systolic blood pressure and triglyceride levels are risk factors of reduction the target rate of HbA to diabetic patients; Age, persons with a lower educational level and high HbA and triglyceride levels are risk factors of decreasing the target rate of hypertension to diabetic patients; Lack of exercise and regular pharmacologic treatment and lower frequency of monitoring blood glucose in community are risk factors of decreasing the target rate of blood lipids to diabetic patients.
Conclusion
The integrated management of hospital and community can improve the control rate of blood glucose, blood pressure and blood lipid in shanghai community, strengthening the blood glucose monitoring in community is an effective method of chronic diseases management of diabetes mellitus

A case with metformin overdose associated acidosis

Merve Yilmaz[1], Adnan Karatas[2] & Demet Yalcin Kehribar[2]
[1]Endocrinology Department, Samsun Gazi Governmental Hospital, Samsun, Turkey; [2]Internal Medicine Department, Samsun Gazi Governmental Hospital, Samsun, Turkey.

Introduction
Metformin-induced lactic acidosis (MALA) is one of the most important drug toxicities with high morbidity and mortality rates. Nonspecific symptoms such as nausea, vomiting, epigastric pain, hypotension, tachycardia, tachypnea, arrhythmia, renal insufficiency, coma and cardiac arrest can be seen. Here we are presenting a case with acidosis due to metformin overdose.
Case
A 36-year-old female patient with a history of type 2 diabetes for three years, presented with glyclazide, metformin + vildagliptin treatment. The patient had a history of thyroidectomy and depression. She has been using levothyroxine. Her family history includes diabetes mellitus in her mother and sister and her father died due to a malignancy. Approximately 2–2.5 hours ago, she were found while sleeping at home and brought to emergency service and declared that she had took 50 tablets of metformin + vildagliptin 50/1000 mg for suicide. The patient had no complaints other than fatigue. She was awake and conscious, cooperated and oriented. The patient was hydrated. Stomach lavage was done, activated charcoal was given after that. Then she was hospitalized to the intensive care unit for further follow-up. At the intensive care unit her initial vitals were normal. Arterial blood gas (ABG) revealed pH: 7.333, HCO3:20.3 mmol/l, lactate:5.7 mmol/l. The hemogram and biochemical values of the patient were normal. In the follow-up her creatinine level reached to 1.4 mg/dl. ABG revealed pH: 6.995, HCO3:7.3 mmol/l and lactate:18 mmol/l. Bicarbonate therapy was started and hemodialysis has been started. After dialysis her ABG revealed pH: 7.409, HCO3: 18.7 mmol/l and lactate:7 mmol/l. The patient did not need dialysis again. Her creatinine levels decreased to 0.59 mg/dl. Just before her discharge ABG revealed pH: 7.453, HCO3:29.5 mmol/l and lactate:1 mmol/l and the she was discharged with recommendations.
Conclusion
The most serious side effect of metformin is lactic acidosis due to the inhibition of hepatic gluconeogenesis and/or conversion of alanine pyruvic acid to glucose. The major component of treatment for metformin intoxication is sodium bicarbonate infusion and hemodialysis treatment since it has not an antidote for overdose. Despite the recommendation of sodium bicarbonate in the presence of severe metabolic acidosis (pH < 7.1), there are theoretical disadvantages. Hemodialysis can be used successfully in patients presenting with MALA due to the chronic use of metformin or acute overdose. As in our case, emergency hemodialysis can be life-saving in cases of metformin-induced metabolic + lactic acidosis.

Cognitive status, anxiety and depression in patients with type 2 diabetes mellitus on selective DPP4 inhibitor therapy

Marina Nikolic Djurovic[1], Zvezdana Jemuovic[1], Olga Vasovic[2], Sandra Pekic[1], Dragana Miljic[1], Marko Stojanovic[1], Biljana Salak Djokic[3], Gordana Krljanac[4] & Milan Petakov[1]
[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, University Clinical Center, Belgrade, Serbia; [2]Institute for Gerontology and Palliative Care, Belgrade, Serbia; [3]Clinic for Neurology, University Clinical Center, Belgrade, Serbia; [4]Clinic for Cardiology, University Clinical Center, Belgrade, Serbia.

Introduction
Cognitive functions and mood (anxiety and depression) are often impaired in diabetes mellitus (DM). Dipeptidyl peptidase-4 inhibitor (DPP-4) has been shown to exert beneficial effects on insulin sensitivity and glycoregulation in T2DM patients. Introducing DPP-4 therapy leads to maintaining control of glucose levels which could ameliorate or slow down further cognitive and mood disorders impairment.
Aim
To evaluate influence of selective DPP-4 inhibitor therapy on cognitive functions, anxiety and depression in T2DM patients.
Method
This was controlled, prospective randomized study with 40 patients with T2DM patients on metformin therapy (63.3 ± 7.4 yrs) and 34 healthy subjects (63.6 ± 6 yrs) matched for age, gender and education. In all subjects, glycemia and Hba1c levels were measured before and six months after DPP-4 inhibitor therapy was introduced. Neuropsychological testing included MMSE, verbal and visual attention span, Trail Making tests A and B (TMTA, TMTB), Test for verbal divergent thinking–phonemic and category fluency (FF and CF), Hospital anxiety and depression scale.
Results
Glycemic control was statistically significantly improved after 6 months in 2DM group (Hba1c 8.32 ± 1.4 vs 7.35 ± 1.19, $P < 0.001$). Some aspects of executive functions (TMTA, TMTB, visual span) were better after 6 months like (TMTA 52.45 ± 20.98 vs 48.00 ± 18.84, $P = 0.014$, TMTB 96.06 ± 26.08 vs 87.91 ± 29.14, $P = 0.003$, visual span 4.18 ± 0.80 vs 4.64 ± 0.90, $P = 0.009$) as well as level of depression (HADSD 5.23 ± 3.83 vs 4.27 ± 3.03, $P = 0.009$).
Conclusion
Improvement in cognitive functions and depression in T2DM patients after 6 months on DPP-4 inhibitor therapy were confirmed. Further clinical studies with longer follow up period are necessary to elucidate our findings.

Metabolic effects of liraglutide in type 2 diabetic patients.

Mariola Mendez Muros, Cristobal Morales Portillo, Antonio Manuel Garrido Hermosilla, Vianney Magaly Santiago Septimo, Antonio Perez Perez, Victor Sanchez Margalet & Maria Asuncion Martinez Brocca
Virgen Macarena University Hospital, Seville, Spain.

Objectives
Obesity and type 2 diabetes mellitus (DM2) are risk factors for non-alcoholic fatty liver disease (NAFLD). The main objective was to study the incidence of NAFLD using the Hepatic Steatosis Index (HSI) in obese patients with DM2. Secondary objectives were to analyse the effect of liraglutide over HSI, body mass index (BMI) and glycated hemoglobin (HbA1c).
Methods
Retrospective observational study of obese type 2 diabetic patients treated with liraglutide during the period 2009-2015. Diagnosis of NAFLD was based on the HSI formula = 8 × (ALT/AST ratio) + BMI (+2, if female; +2, if diabetic).
Results
Study sample of 53 patients, 55% males and 45% females, with a mean age of 49.6 years. 100% of patients presented a positive HSI, which improved in 73.5% of them after treatment with liraglutide. Mean HSI after treatment was significantly lower compared to the previous value (p = 0.008). Mean BMI and HbA1c after liraglutide implementation were also significantly lower than before treatment ($P = 6.004^{-06}$ and $P = 1.074^{-08}$, respectively). Triglyceride levels decreased in 60% of patients without statistical significance ($P = 0.054$).
Conclusions
After 3 months of treatment with liraglutide, there was an improvement in HSI, BMI and HbA1c, as well as a reduction in triglyceride levels.

Efficacy of glucose control on a combination of dapagliflozin in people with type 2 diabetes mellitus in Korea

Chong Hwa Kim[1], Ji Oh Mok[2], Ki Young Lee[3] & Sung Rae Kim[4]
[1]Sejong general Hospital, Bucheon, Republic of Korea; [2]Soonchunhyang University Bucheon Hospital, Bucheon, Republic of Korea; [3]Gachon University Gil Hospital, Incheon, Republic of Korea; [4]The Catholic University of Korea Bucheon St Mary's Hospital, Bucheon, Republic of Korea.

Objective
Dapagliflozin, sodium-glucose cotransporter-2 (SGLT-2) inhibitor, reduces hyperglycemia and body weight by inhibiting renal glucose reabsorption.

However, only a few studies have shown the glycemic efficacy on a combination of dapagliflozin in type 2 diabetic patients in Korean. We evaluated the efficacy and safety of glucose control on a combination of dapagliflozin in people with type 2 diabetes in Korea.
Methods
This is a retrospective, observational study, data from 61 patients with 12 months of dapagliflozin(10mg once-daily) therapy were analyzed, visited medical center from January 2015 to July 2016. We had divided into three treatment groups: first group was dual combination of dapagliflozin and metformin (Group 1); second group was triple combination of dapagliflozin and metformin with sulfonylurea or dipeptidyl-peptidase IV(DPP-4) inhibitors (Group 2); third group was quadriple combination of dapagliflozin, metformin and sulfonylurea with DPP-4inhibitors (Group 3).
Results
Of 61 type 2 diabetic sub-jects, 32 (52.5%) were men and 29 (47.5%) were women. Mean age and duration of DM were 58.5 ± 9.6 years and 11.4 ± 5.6 years respectively; mean body weight and BMI were 72.6 ± 12.1 kg and 27.3 ± 3.6 kg/m^2 respectively. Mean HbA1c and 2-hour postprandial glucose levels were 7.6 ± 1.0% and 194.2 ± 69.8 mg/dl respectively. After 12 months, Dapagliflozin leads to improvement in HbA1, 2-hour postprandial glucose(PP2) in each group. In total, the reductions in HbA1c and PP2 levels were −0.61 ± 0.82% (P = 0.000) and −35.4 ± 62 mg/dl (P = 0.000) respectively. In group 1, the reduction rates in HbA1c and PP2 levels were 0.39 ± 0.80% (P = 0.093) and −19.2 ± 41.0 mg/dl (P = 0.152) respectively. In group 2, the reduction in HbA1c and PP2 levels were -0.93 ± 1.0% (P = 0.018) and −63.1 ± 90.6 mg/dl (P = 0.034) respectively. In group 3 the reduction in HbA1c and PP2 levels were −0.65 ± 0.71% (P = 0.002) and −37.9 ± 61.4 mg/dl (P = 0.001) respectively. There were no serious adverse event including hypoglycemia in dapagliflozin group.
Conclusions
In patients with type 2 diabetes, a combination of dapagliflozin improved glycemic control and reduced body weight reduction with safety.

Comparison of occurrence of fasting hyperinsulinemia according to type of insulin analogs

Kyu Jeung Ahn[1,2], Hyoseok Kang[3], In-Jin Cho[2], You-Cheol Hwang[1,2], In-Kyung Jeong[1,2] & Ho-Yeon Chung[1,2]
[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Kyung Hee University School of Medicine, Seoul, Republic of Korea; [2]Department of Endocrinology and Metabolism, Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; [3]Anesthesia and Pain Medicine, Eulji General Hospital, Eulji University, Seoul, Republic of Korea.

Background
A variety of insulin analogs have been developed and used for the treatment of diabetes mellitus. We often experience elevated serum insulin levels when insulin analog is used, and thus have difficulty in assessing insulin resistance and secretion using serum insulin results. This study aimed to investigate the differences in serum fasting insulin level and insulin antibodies according to the type of insulin analogs.
Method
We conducted a retrospective study from 2007 to 2017 in Kyung Hee University Hospital at Gangdong on the Type 2 diabetes mellitus patients who were prescribed insulin analogs (insulin aspart, lipro, glulisine, detemir, glargine, and premixed insulin). We analyzed fasting insulin titers, insulin antibodies, and glycemic parameters after insulin treatment.
Results
A total of 2272 insulin users were analyzed (average age: 56.4 ± 14.6 years, male: 54.7%). Serum fasting insulin level was higher in long-acting insulin analogs group than in other insulins group and was significantly higher in detemir group than glargine group (detemir group: 52.3 ± 82.2, glargine group: 18.2 ± 26.2; other insulins group: 13.3 ± 23.5, P < 0.001). The proportion of patients with fasting insulin levels above 100 μIU/ml was also higher in the detemir group than in the other groups (detemir group: 16.7%, glargine group: 1.3%, other insulins group: 0.6%, P = 0.001). In addition, the positive rate of insulin antibodies was higher in detemir group than in the other groups. However, fasting glucose, C-peptide level, and HbA1c were not significantly different between groups.
Conclusions
Among insulin analogs, insulin detemir is more likely to cause fasting hyperinsulinemia than other insulins. In this case, it is necessary to examine the insulin antibodies and to consider its association.

The impact of different glucose-lowering regimens on cardiovascular disease in type 2 diabetes

Snezana Vujosevic, Selim Agic, Sanja Borozan, Sanja Vucetic, Sreten Kavaric, Olivera Boskovic, Aleksandar Djogo, Djordjije Krnjevic, Emir Muzurovic & Dragomir Madzgalj
Clinical Centre of Montenegro, Podgorica, Montenegro.

Introduction
American Heart Association considers diabetes mellitus (DM) to be one of seven major controllable risk factors for cardiovascular disease. At least 68% of patients age 65 or older with DM die from some form of heart disease while 16% die as a consequence of stroke. Studies conducted in patients with type 2 DM (T2DM) have not confirmed a significant association between a certain types of glucose-lowering drugs and a presence of cardiovascular events.
Aim
To establish a relationship between different treatment regimens in patients with T2DM and a presence of acute or recent cardiovascular event.
Methodology
A cross sectional population based study included patients with both T2DM and myocardial infarction- acute or in the past 1 year, that have been examined in Clinical center of Montenegro during one day. Demographic data were collected, along with a type of treatment for T2DM and current glycoregulation. Statistical analysis was performed using descriptive statistics and Student t-test.
Results
Out of 42 subjects included in study, 23 were female and 19 were male, mean age 66.78 ± 9.67 years. Insulin therapy solely was present in 10 patients (23.8%), combined therapy in 21 (50%) and oral glucose-lowering agents in 11 (26.2%) of patients. The mean value of glycated hemoglobin (HbA1c) in groups respectively was 9.0%, 8.9% and 6.97%. No statistical significance was found between insulin and combined therapy (P = 0.8691), while there were a significant statistical differences between insulin and oral therapy (P = 0.0020) and combined and oral therapy (P = 0.0021).
Conclusion
Glycated hemoglobin, however, could not be a valid surrogate for assessing either the cardiovascular risks or benefits related to diabetes therapy. We concerned that some glucose-lowering agents may impact greater cardiovascular risk but there is no sufficient evidence to support one drug or any combination of other drugs for the reduction of cardiovascular events.

Evaluation of the risk of hypoglycemias using a questionnaire in patients with type 2 diabetes

Mayra Velasquez Arevalo, Olga Simó Servat, Cristina Hernandez, Diana Romero, Carme Creus, Andreea Ciudin, Jordi Mesa & Rafael Simó
Vall d'Hebron University Hospital, Barcelona, Spain.

Introduction
The available questionnaires for the detection of hypoglycemia are designed for patients with type 1 Diabetes (T1DM), and do not take into account some characteristics of patients with type 2 Diabetes (T2DM). For instance most of T2DM patients do not perform capillary blood glucose self-monitoring as part of their daily treatment and hypoglycemia might be underestimated. Nevertheless, hypoglycemia can have a negative impact on T2DM patients, in terms of increasing the risk of dementia and mortality. For this reason, a questionnaire was designed to assess the frequency and severity of hypoglycemia in T2DM.
Methods
A prospective study was performed based on the completion of a questionnaire in patients with T1DM and T2DM between July and December 2016.
Results
310 patients were evaluated (160 with T2DM, 76% of which were under insulin treatment). A total of 53.75% of the patients with T2DM reported at least one episode of hypoglycemia in the last six months (88% treated with insulin), and 20% of the patients had symptoms of nocturnal hypoglycemia. Notably, a 33% of the patients with T2DM reported episodes of asymptomatic hypoglycemia. Regarding the severity, 10.6% of patients with T2DM reported at least one episode of hypoglycemia that required assistance of a third person (vs 17.4% of T1DM) and 3.7% of patients presented an episode that required medical assistance (vs. 3.3% of T1DM). We observed a tendency to underestimation of the hypoglycemic events (both by the patient and the physician) in T2DM patients compared to T1DM: 1/3 of patients with T2DM with nocturnal hypoglycemia did not report it to their endocrinologist and in 1/3 of the cases, the physician did not question about hypoglycemia episodes.
Conclusions
This study shows that a significant percentage of T2DM patients had suffered episodes of hypoglycemia, sometimes severe or nocturnal. A questionnaire aimed at the detection of hypoglycemia in T2DM could be useful, although more studies are necessary for its validation.

The intensity of metabolic processes due to different variants of polymorphism rs1801282 Pro12Ala of the PPARG gene in patients with diabetes mellitus type 2

Farida Valeeva, Ildus Ahmetov, Tatyana Kiseleva, Kamilya Khasanova, Maria Izmailova & Elena Valeeva
Kazan State Medical University, Kazan, Russian Federation.

Aim
To investigate the effect of the standard dietary recommendations in diabetes mellitus type 2 to the intensity of metabolic processes due to different variants of polymorphism rs1801282 Pro12Ala of the PPARG gene.
Materials and methods
37 patients (11 men and 26 women) in the age of 38–76 years old (the mean age 56.8 ± 9.55 y.o.), with the verified diagnosis of diabetes mellitus type 2 (the mean duration of illness 5.7 ± 3.59 years) and the mean BMI 34.49 ± 4.37 were involved in the study. All the patients were on a 3-month balanced diet, where the simple carbs were excluded and the complex carbs were limited. For the estimation of the body compositions the bioelectrical impedance analysis (BMI) was used. The analysis of the rs1801282 Pro12Ala polymorphism of the PPARG gene in buccal cells was performed using Testgen kits (Russia) for RT-PCR. The spreading of the genotypes and the alleles with the literature data (503 people without diabetes mellitus and prediabetes; European population, 1000 genomes) were compared. The statistical analysis was performed by Graph Pad InStat, Microsoft Excel 2007.
Results
The distribution of the frequency of alleles and genotypes did not correspond to the Hardy-Weinberg equilibrium ($\chi^2 = 8.61$; $P = 0.003$), apparently because of a low investigated selection of the polymorphism rs1801282 of a PPARG gene. The distribution of genotypes of the PPARG gene polymorphism (CC – 59.5%, CG – 21.6% GG – 18.9%) and alleles (C – 70% G – 30%) in the group of patients with diabetes mellitus significantly differed from the control group (CC – 76.9%, CG – 22.1%, GG – 1%; C – 88%, G – 12%; OR = 3.09, 95% CI 1.82–5.28; $P = 0.0001$). In the group of patients with the mutant allele G the increase of the comparative quantity of body cell mass was noticed ($-0.92 \pm 5.20\%$) in comparison with the group of patients without the mutant allele ($2.72 \pm 6.87\%$; $P = 0.05$), in time of the absence of the BMI significant changes ($P > 0.05$).
Conclusions
Polymorphism rs1801282 of the PPARG gene has an association with the intensity of the metabolic processes. Thereby, a special meaning has to be due to the personification of not only the medical, but the dietary correction of the carbohydrate metabolism.

A latent autoimmune diabetes in adults (LADA) case renamed after six years of diabetes diagnosis when complicated with diabetic ketoacidosis induced by dapagliflozin

Betül Ekiz-Bilir[1], Bülent Bilir[2] & Gülşah Elbüken[3]
[1]Tekirdag State Hospital, Endocrinology and Metabolic Diseases Division, Tekirdag, Turkey; [2]Namık Kemal University, Medical Faculty, Internal Medicine Department, Tekirdag, Turkey; [3]Namık Kemal University, Medical Faculty, Internal Medicine Department, Endocrinology and Metabolic Diseases Division, Tekirdag, Turkey.

Introduction
LADA (Latent autoimmune diabetes in adults) is an adult-onset and more indolent variety of autoimmune type 1 diabetes mellitus. In autoimmune diabetes, younger individuals typically have a rapid rate of beta-cell destruction and usually present with ketoacidosis, while adults often maintain sufficient insulin secretion to prevent ketoacidosis for many years. LADA is usually misdiagnosed initially as type 2 diabetes due to its late onset but LADA patients are antibody positive and often require insulin therapy within years of diagnosis. We presented a resistant diabetic ketoacidosis case requiring hemodialysis for long-lasting acidosis after starting dapagliflozin in a patient with LADA formerly misdiagnosed as type 2 diabetes.
Case report
A 54-year-old over-weight white woman who had been followed for her euthyroid autoimmune thyroiditis and type 2 diabetes mellitus for 3 years was admitted to our endocrinology out-patient clinics. During another 3-year period she was followed by intensive insulin regimen plus metformin but after initiating a strict diet programme, she had experienced postprandial hypoglycemia episodes on 3×6 units glulisine and 1×10 units glargine insulin. Her glulisine insulin was stopped and dapagliflozin was added to metformin and glargine. At the fourth day of her new treatment, she returned to our emergency department in the state of severe diabetic ketoacidosis (DKA) [glucose 414 mg/dl, arterial pH: 6.82, lactate 4.2 mmol/l, HCO_3: 4.9 mmol/l, pCO_2: 19.8 mmHg, at urinalysis ketonuria (3+), glucosuria (1+)]. İntravenous hydration, insulin infusion, potassium replacement were initiated at our intensive care unit. After 72 hour of her treatment, ketoacidosis was still severe and due to the failure of intravenous bicarbonate treatment also in correcting acidosis, hemodialysis was started. After 3 sessions of hemodialysis, acidosis was relieved and this resistant ketoacidosis treatment could be changed to subcutaneous intensive insulin regimen only at the 8th day of ICU. Metformin and dapagliflozin were not given anymore and she was discharged at the 13th day of admission with intensive insulin regimen. Due to this resistant DKA status, pancreatic islet antibodies were assessed and two of them were measured as positive [Anti-GAD: 3,58 U/ml (reference range: 0-1), ICA was positive]. The diagnosis of the patient were re-evaluated as LADA.
Conclusion
LADA should be kept in mind in adults with diabetes and another autoimmune disease. And gliflozins can cause euglycemic diabetic ketoacidosis especially when the insulin treatment regimen was loosened in intensity in these misdiagnosed patients.

P506

Awareness of patients with diabetes on the disease

Alexandra Kraskovskaya[1], Olga Shyshko[1] & Alens Sazonava[2]
[1]Belarusian State Medical University, Minsk, Belarus; [2]Minsk City Endocrinology Dispensary, Minsk, Belarus.

Relevance
Patients with diabetes are not always sufficiently informed about disease, approaches to its treatment, and the need to prevent complications.

Purpose
To evaluate the awareness of patients about diabetes in inpatient and outpatient settings.
Materials and methods
Participation in the study was accepted by patients with 1 and 2 types of diabetes in inpatient and outpatient settings. The questionnaire consisted of alternations, united in the following sections: taking medications; diet; glucose control; physical activity; adherence to appointments. 74 patients were included in the study.
Results and discussion
1) Education in the school of diabetes. 72% of patients with type 1 diabetes underwent training in the school of diabetes earlier, third (28%) indicated that they attend classes for the first time. Among patients with type 2 diabetes only 33.0% attended classes in the school of diabetes.
2) Self-monitoring of glucose. More than 2 times a day, 75.0% of patients with type 1 diabetes had a glycemia, the remaining 35% – once a day, 1–3 times a week, and 2 – only occasionally. 13.8% control the level of glycemia only in the morning.
3) Nutrition. Differences in the approaches to nutrition in patients with type 1 and 2 diabetes are primarily due to age and lifestyle.
4) Physical activity. Less than half (37.0%), patients with type 1 diabetes regularly exercise, and 63.0% of patients noted that they paid little attention to this. Among patients with type 2 diabetes, 55.8% exercise regularly.
5) Wealth. More than half of patients with type 1 diabetes either feel healthy, 44.4%, or are neutral in the answer to this question (37.0%), and 18.5% do not agree that they are healthy.
6) Compliance with treatment recommendations. Most patients with type 1 and type 2 diabetes (79% and 73% respectively) make efforts to control their condition.
7) Complications. In 24% of patients with diabetes, retinopathy is noted, 10% have polyneuropathy, and 3% have nephropathy. Among patients with diabetes, 9% of patients have retinopathy, 22% have polyneuropathy, and 16% have nephropathy.

Conclusions
- 75% of those surveyed with type 1 diabetes are aware of the importance of the most frequent definition of glycemia. Almost one third of patients with type 1 diabetes rarely have glycemia control.
- In type 2 diabetes, 33.3% of patients erroneously measured the level of glycemia only in the morning, which distorts the results about the variants of glucose values during the day.

Efficacy in metabolic control and weight loss of combined treatment with GLP-1 receptor analogues and SGLT-2 inhibitors

Miguel Damas-Fuentes, Araceli Muñoz-Garach, Silvia Maraver-Selfa, María Molina-Vega, Carmen Hernández-García, Cristina Díaz-Perdigones & Francisco Tinahones-Madueño
Virgen de la Victoria Universitary Hospital, Málaga, Spain.

Introduction
The emergence of a new generation of antidiabetic drugs (GLP-1RA and SGLT-2i) with complementary mechanisms of action offer new alternatives in the treatment of patients with T2D and poor metabolic control.
Objectives
To evaluate the efficacy of the aGLP-1 and iSGLT2 combination on metabolic control, weight, blood pressure and insulin dose in patients with DM2.
Methods
Observational, retrospective study. We studied T2D patients whose habitual treatment had been modified on their last visit, using a combination of GLP-1RA and SGLT2i.
Results
36 patients: 56% women, age 59.1±10.0 years, T2D evolution time 11.3±6.5 years, 64% taking insulin. They presented: 77% hypertension, 71% dyslipidemia, 18% retinopathy, 8% nephropathy and 8% neuropathy. As GLP-1RA, 40% used liraglutide, 34% dulaglutide, 22% exenatide-LAR and 3% lixisenatide. As iSGLT-2, 90% used dapagliflozin, 6% empagliflozin and 3% canagliflozin. After four months of treatment, there was a significant decrease in weight (100.0±26 kg vs 96.9±25.2 kg), BMI (37.2±8 kg/m^2 vs 35.8±7.6 kg/m^2), HbA1c (8.56±1.2% vs 7.6±0.7%), fasting glycemia (168.6±37.9 mg/dl vs 147.7±34.6 mg/dl) and insulin dose (53.7±40.2 IU vs. 47.0±31.4 IU). Also, we found a significative decrease in AST (30±13.8 U/l vs 24.9±1 U/l), consequently decreasing HSI (hepatic steatosis index; 47.3±9.4 vs 45.5±9.3). There were no significant changes in blood pressure, lipid profile or ALT.
Conclusion
1) We observed statistically significant decrease in weight, HbA1c, fasting glycemia and insulin dose. 2) There was significant reduction in AST. 3) Further studies are needed to distinguish which type of patient benefits more from this combination.

Insulin requirements and obstetric outcomes in pregnant woment with type 1 diabetes under continuous subcutaneous insulin infusion (CSII)

Lura Chinchurreta Diez, Marta García, María Jose Goñi, Ana Irigaray, Amaia Sain de los Terreros, Nerea Eguilaz & Lluis Forga
Complejo Hospitalario de Navarra, Pamplona, Spain.

Objectives
The gestations in patients with type 1 diabetes are associated with an increase in maternal-fetal complications. Adequate glycemic control during pregnancy has been shown to reduce adverse events. Given that, the treatment with insulin pump improves glycemic control and that pregnancy implies constant changes in insulin resistance, our objective is to analyze the changes in insulin requirements in pregnant patients under CSII.
Materials and methods
This is a retrospective study of 20 women (39 gestations) with a mean age of 34.3 years (range: 28–41) and a mean time of diabetes duration of 19 years (range: 8, 31). Seven therapies were started with gestational desire (35%) and the mean time under CSII was 4.9 years (range: 0.5–12). Statistical analysis with SPSS 20.0.
Results
The average pre-conception HbA1c was 6.90% (S.D.:0.623) and during pregnancy 6.70% (S.D.:0.61). Thougout pregnancy the total insulin requirements increase by 87.5%: from 33.51 (S.D.:8.85) to 62.84 (S.D.:21.16) (Sig 0.00). These modifications compared with the pregestational values are summarized in the following table (Table 1): nine patients experienced miscarriaged (23%) none preceded by severe hypoglucemia and 1 perinatal death. Macrosomia was found in six gestations (15.38%).
Conclusions
1. During pregnancy, total insulin requirements increase by 87%.
2. This increase occurs at the expense of both basal insulin and carbohydrate-to-insulin-ratio:
   - The increase of the basal insulin is marked after the 2nd trimester, reaching statistical significance.
   - The increase in carbohydrate-to-insulin-ratio is significant in all mealtimes after 2nd trimester, being more marked at breakfast, where it increased by 134% at the end of pregnancy (from 1.08 to 2.22).

Table 1 Modification of insulin requirements during pregnancy.

			Carbohidrate-to-insulin ratio		
Tiempo	Total Insulin	Basal Insulin (24h)	Breakfast	Lunch	Dinner

Addition of sodium-glucose co-transporter type 2 inhibitors to diabetic patients type 2 in treatment with glucagon-like peptide-1 agonists: clinical results

Ma del Carmen Serrano Laguna[1], María Hayón Ponce[1], David Blanquez Martinez[2], María Dolores Avilés Pérez[1] & Elena Torres Vela[1]
[1]UGC Endocrinologia y Nutricion, Hospital Universitario San Cecilio, Granada, Spain; [2]UGC Farmacia Hospitalaria1, Hospital Universitario San Cecilio, Granada, Spain.

Background
The complex involvement of multiple metabolic defects in the pathogenesis of type 2 diabetes mellitus (T2DM) makes difficult the treatment in monotherapy, therefore, the use of different antidiabetic drugs with different and complementary mechanisms of action could result in better glycemic control with favorable metabolic changes.
Objective
To determine the effectiveness and safety of the addition of a sodium-glucose co-transporter type 2 inhibitor (SGLT2 inhibitors) to patients with T2DM in treatment with a glucagon-like peptide analogue type 1 agonist (GLP1 agonist) and poor metabolic control.
Material and methods
Retrospective observational study. We included all T2DM patients in treatment with a GLP1 agonist who were added a SGLT2 inhibitor due to poor metabolic control. Clinical, biochemical and side effects were analyzed at baseline and after a mean treatment period of 6 months. Statistical analysis (SPSS v. 20.0): Wilcoxon test.
Results
We evaluated 62 patients (31M and 31W) with a mean age (mean ± S.D.) of 54.55 ± 9.19 years and an evolution of T2DM of 12.1 ± 6.5 years. 21.5% were on treatment with Dulaglutide + Dapagliflozin, 19.4% Liraglutide + Canagliflozine, 11.3% Liraglutide + Empagliflozine, 16.1% Dulaglutide + Canagliflozine, 8.1% Liraglutide + Dapagliflozin, 6.4% Dulaglutide + Empagliflozine, 6% Exenatide + Dapagliflozin, 4.8% Exenatide + Empagliflozine, 4.8% Exenatide + Canagliflozine and 1.6% Lixisenatide + Dapagliflozin. At baseline, they had a FPG of 188.4 ± 53.6 mg/dl, an HbA1c of 8.85 ± 1.7%, a SBP of 133.7 ± 12.5 mmHg, a DBP of 77.7 ± 7.7 mmHg, a weight of 95.35 ± 24.05 kg, a BMI of 34.47 ± 6.5 kg/m^2 and a dose of basal insulin ($n = 12$) 35.75 ± 18.82 IU/d (0.38 ± 0.21 IU/kg per day). After a mean treatment period of 6.2 ± 3.2 months, there was a significant reduction in FPG (46.04 ± 61.01 mg/dl less ($P = 0.003$)), HbA1c (1.2 ± 1.7% less ($P = 0.002$)), weight (2.49 ± 5.75 kg less ($P = 0.019$)) and BMI (0.67 ± 1.79 less ($P = 0.02$)). There was no significant reduction in basal insulin requirements (4.16 ± 11.76 IU/d (0.04 ± 0.12 IU/Kg/d) ($P = 0.49$)) and blood pressure (SBP (2.95 ± 14.82 mmHg ($P = 0.46$) and DBP (2.27 ± 10.42 mmHg ($P = 0.25$)). There were no cases of treatment withdrawal due to side effects.
Conclusion
The combination of GLP1 agonists and SGLT2 inhibitors may have an additive or synergistic effect with potential favorable results in terms of improved glycemic control and weight reduction.

Psychopathological determinants of enhanced quality of life in continuous subcutaneous insulin infusion therapy

Miguel Pereira[1,2], Ana Gonçalves[3], Celestino Neves[1,4,5], Sofia Oliveira[1,4], César Esteves[1,4], Cristina Arteiro[1], Anabela Costa[1], Carmo Redondo[1] & Davide Carvalho[1,4,5]
[1]Service of Endocrinologia, Diabetes and Metabolism, São João Hospital Center, Porto, Portugal; [2]Psiquiatry and Mental Health Clinic, São João Hospital Center, Porto, Portugal; [3]School of Psychology, Minho University, Braga, Portugal; [4]Faculty of Medicine, University of Porto, Porto, Portugal; [5]Institute for Innovation and Health Research, Porto, Portugal.

Introduction
Scientific progress allowed an evolution on the therapeutic of diabetes mellitus. Continuous subcutaneous insulin infusion therapy (CSII) is one good example, but, beside patients motivation little is known about other psychological factors of success in this therapeutic and how they contribute to quality of life (QoL).
Objectives
Determining some psychopathological predictors of CSII satisfaction and QoL improvement in patients on CSII therapy.
Patients and methods
We gather a sample of 49 diabetic patients in CSII therapy, 59.2% female, with a mean age of 37.9 ± 11.4 years, disease duration of 21.4 ± 8.5 years and a mean CSII usage time of 5.7 ± 2.1 years. We applied the following questionnaires: the insulin delivery system rating questionnaire, the audit of diabetes-dependent quality of life and the brief symptom inventory (BSI). Spearman correlations were used for statistical analysis. A two-tailed value of $P < 0.05$ was considered statistically significant.
Results
First of all we noticed that psychopathological symptomatology was inversely correlated with CSII satisfaction ($r = -0.44$; $P = 0.004$) and overall QoL ($r = -0.43$; $P = 0.003$). The perception that CSII is helpful concerning glicemic variability is the most important contributor to QoL ($r = 0.34$; $P = 0.02$). Results point out that patients who check their blood glucose more often tend to report less worries about diabetes complications, glicemic variability and daily self-security ($r = -0.35$; $P = 0.01$). Nevertheless, 48.9% of patients reported that checking their blood glucose more than four times daily is more than they would like and this fact alone decreases significantly their QoL ($r = -0.47$; $P = 0.001$). Regarding the BSI we noticed that patients with low interpersonal sensitivity tended to report less embarrassment in using CSII therapy ($r = 0.45$; $P = 0.001$). We also found that patients with higher obsessive compulsive symptomatology stated more daily activity interference in CSII therapy, namely, wearing desired clothes ($r = 0.42$; $P = 0.003$), sleep patterns ($r = 0.53$; $P \leq 0.001$), eating habits ($r = 0.30$; $P = 0.04$) and exercising ($r = 0.35$; $P = 0.01$). Lastly, family support, reflected in the form of not arguing attitude, seems to be a psychopathological protector ($r = 0.36$; $P = 0.01$).
Conclusions
In our sample is clear that CSII therapy contributes positively to QoL. However, in order to maximize its impact, it seems relevant to monitor patient's psychopathological register. Addressing these issues previously will probably provide patients and their families with more adaptative strategies in order to enhance better glicemic control.

Effects of *opuntia ficus-indica* plant extract ingestion on glucose and insulin plasma levels during oral glucose tolerance test

Maria Christou[1], Georgios Markozannes[2] & Stelios Tigas[1]
[1]Department of Endocrinology, University of Ioannina, Ioannina, Greece; [2]Department of Hygiene and Epidemiology, Medical School, University of Ioannina, Ioannina, Greece.

Background
Cladodes of the nopal *opuntia streptacantha* (prickly-pear cactus) have been traditionally used for the treatment of diabetes in Mexico. Limited data from studies in experimental animals and humans with prediabetes or type 2 diabetes (DM2), have shown promising antihyperglycemic effects using plant extracts of the *streptacantha* and *ficus-indica opuntia* species. The purpose of this study was to assess the effect of *opuntia ficus-indica* plant extract ingestion on plasma glucose and insulin levels in healthy subjects as well as in subjects with prediabetes or diabetes.
Methods
A total of 35 subjects were studied, subdivided in two groups: subjects with normal glucose tolerance (Group A) and subjects with either prediabetes (IGT and/or IFG) or DM2 treated with diet and/or metformin (Group B). All subjects underwent a 75 g oral glucose tolerance test (OGTT) and plasma glucose and insulin levels were measured at 0, 30, 60, 90 and 120 min. Up to 4 weeks later, subjects underwent a 2nd 75g OGTT, during which they ingested 1000 mg of *Opuntia ficus-indica* dry extract (in a capsule form) 30 min prior to glucose ingestion. Glucose and insulin levels between the two OGTTs were compared by longitudinal analysis.
Results
Group A consisted of 13 healthy subjects (31% male, age 41 ± 15 years (mean ± standard deviation), BMI 28 ± 5 kg/m^2, waist circumference 90 ± 15 cm) and Group B of 22 subjects (16 with prediabetes and six with DM2, 55% male, age 54 ± 14 years, BMI 28 ± 4 kg/m^2). In both Groups A and B, co-administration of the plant extract prior to the 75g OGTT did not result in significant changes in the area under the curve for glucose or in the glucose and insulin levels at any time point (P = ns). At the end of the OGTT (120′) in Group A, were 106 ± 26 versus 102 ± 24 mg/dl, and 29 ± 19 versus 26 ± 22 μIU/ml, respectively ($P > 0.05$). In group B, glucose and insulin values were: 159 ± 70 versus 150 ± 65 mg/dl, and 56 ± 61 versus 43 ± 30 μIU/ml, respectively (P = ns).
Conclusion
Short-term administration of *Opuntia ficus-indica* extract in individuals with normal glucose tolerance, prediabetes or diabetes did not affect glucose and insulin levels during OGTT. To further explore a possible antidiabetic effect, larger studies and long-term administration of this plant extract are required.

Predictive factors of starting insulin in gestational diabetes' Management: About 191 cases

Yasmine Driouich, Siham El Aziz, Salma Bensbaa & Asma Chadli
Endocrinology, Diabetology and Metabolic Diseases - Department Ibn Rochd University Hospital, Casablanca, Morocco.

Introduction
Gestational diabetes' (GDM) intensive management of with adequate insulin therapy prevents maternal, fetal and neonatal complications associated with hyperglycaemia.
Objective
Identify predictive factors for starting insulin in gestational diabetes' management.
Methods
We report a retrospective study conducted from January 2010 to December 2016, involving 191 patients followed in the Endocrinology - Diabetology Department of Ibn Rochd University Hospital of Casablanca for gestational diabetes. The parameters studied were: age, gestational diabetes' recurrence, family history of diabetes, pre-gestational BMI, term of pregnancy at the time of GDM's discovery, initial fasting glucose level and the treatment adopted. Statistical analysis was univariate for all the variables using SPSS version 22.0.0.
Results
Mean age of our patients was 32.5 ± 6.4 years, mean pre-pregnancy BMI 27.7 ± 3.9 kg/m^2. A history of gestational diabetes was found in 14% of pregnant women and macrosomia in 19%. Average term of discovery of the CEO was 23 ± 9.2 SA. Treatment consisted of diet alone in 29% of our patients, insulin therapy in 71%, with a basal regimen in 31% of cases, a basal-plus in 26% and a basal bolus in 43%. Average insulin dose was 0.51 IU/kg/day. Insulin therapy was more frequent when age was greater than 35 years ($P=0.01$), gestational diabetes' discovery term was early (<25 weeks) ($P=0.02$), and initial fasting glucose levels was high (>1.26 g/l) ($P=0.01$). Personal history of macrosomia, gestational diabetes, and overweight were frequently associated with insulin-dependent patients, with no statistically significant relationship.
Discussion
Our results indicates a strong reliance on insulin-therapy in our population, especially since gestational diabetes' term of discovery is early, age is advanced and initial fasting glucose level is high. However, overweight and gestational diabetes history did not have a significant impact.
Conclusion
Insulin initiation predictive factors are important to identify. It is an important step in the management of gestational diabetes to improve maternal and fetal prognosis through close monitoring and rigorous follow-up.

Safety and efficacy of different insulin regimens in treatment of type 2 diabetic patients who insist to fast during Ramadan 1437 (Hijri) In Fayoum Governorate, Egypt

Mohamed A Mashahit, Riham Ahmed Abd El Aal, Eman M Ezzat & Othman Zaki
Fayoum University, Fayoum, Egypt.

Background
Fasting during Ramadan is an obligatory duty for all healthy adult Muslims. However, a lot of type 2 diabetic Muslim patients insist on fasting whatever their condition. There are several potential physiological benefits from fasting, but the prolonged fasting hours during summer provides many questions about safety and efficacy of different insulin regimens for treatment of type 2 diabetic patients during Ramadan. So we aimed in this study is to assess safety and efficacy of different types and different strategies of insulin use in the treatment of type 2 diabetic patients who insist to fast during Ramadan 1437 (Hijri) in Fayoum Governorate.
Patients and methods
This study was conducted on 337 T2DM patients. divided into 3 groups: groups G1 - patients using basal oral regimen, and G2 using premixed insulin regimen and G3 patients on a basal-bolus regimen. For all participants' structured educational sessions, history and clinical examination including blood pressure measurement, waist circumference and BMI, blood glucose, HbA1c, liver, kidney functions and lipid profile before and after Ramadan fast were done. During Ramadan all participants were asked to record readings for the FBS at noon & at 6 pm and a postprandial reading 1–2 hours after breakfast on the following days (2,14,28) and also to record any day that fast was broken with the cause for this.
Results
Hypoglycemic events whether documented or symptomatic were more prevalent (44%&52% respectively) among patients on the basal-bolus regimen with the number of episodes of documented hypoglycemia per patient were higher in this regimen (1.9 ± 0.9) compared to the other two regimens and this difference was statistically significant ($P=0.046$). A statistically highly significant reduction in HbA1c had occurred among patients using premixed insulin $\pm$ oral antidiabetic medications ($P<0.0001$), however, patients on this regimen had the highest prevalence of non-fasting days (44.6%) due to DM.
Conclusion and recommendations
There were comparable results regarding safety and efficacy of the three studied regimens in the treatment of type 2 diabetic during Ramadan. No regimen proved to be superior. Patient education before Ramadan fast is a mandatory step in management.

Pregnancy and diabetes: an overview about 144 patients

Ikram Khalil[1,2], Siham El Aziz[1,2], Salma Bensbaa & Asmaa Chadli
[1]Endocrinology, Diabetology and Metabolic Diseases Department Ibn Rochd University Hospital of Casablanca, Morocco; [2]Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy - University Hassan II - Casablanca, Morocco.

Introduction
Diabetic pregnancy is a high-risk pregnancy requiring a multidisciplinary approach and close monitoring to prevent maternal-fetal complications. Our study objective was to determine the diabetic pregnancies outcome of in order to improve their management.
Patients and methods
A descriptive retrospective study including 144 patients with diabetic pregnancy followed at the Endocrinology-Diabetology service between January 2016 and September 2017. Data collection was done from medical records. The statistical analysis was done by SPSS. The parameters were studied: age, diabetes type, obstetric history, pre-gestational BMI, weight gain during pregnancy, pre-conceptional HbA1c, for gestational diabetes the term of pregnancy at the time of the discovery and the methods of detection, treatment adopted and the degree of glycemic control, degenerative complications and obstetric complications.
Results
The study included 144 patients with an average age of 31,9ans, 32% had gestational diabetes and 68% pre-gestational diabetes. BMI pre-gestational average was 29.27 kg/m^2 with an average weight gain of 8 kg. Physical activity was performed in 34% of patients. Regarding gestational diabetes, gestational age through discovery was 20 weeks of gestation, discovered during a routine screening in 84.7% of patients and clinical signs in 13% of the cases. For screening methods, fasting glucose was requested by 67.3% against 26% for the 75g OGTT. Regarding the pre-gestational diabetes, 25.7% of patients had type 1 diabetes and 42.3% type 2 diabetes with a mean diabetes duration of 6 years and a mean HbA1c of 8.3%. Retinopathy was present in 22.4% of patients and nephropathy in 4%. For treatment, 80.5% of patients were on insulin and 19.5% in lifestyle and diet. Glycemic control was perfect in 56.3% of patients. Regarding obstetric complications we observed: gestational hypertension in 11.8%, preeclampsia at 4.8%, macrosomia in 8.4%, a preterm labor in 3.5%, malformations in 2%, hydramnios in 2%. The arrested pregnancies were observed in 3.5% of the studied cases.
Discussion
As clearly demonstrated our study, diabetic pregnancy remains a challenge for both the patient and for the health care team given the high number of maternal-fetal complications and the management of difficulty that requires collaboration between diabetologist obstetrician and gynecologist.

Moroccan woman pregnant diabetic: what dietary errors? About 60 cases

Ikram Khalil[1,2], Siham El Aziz[1,2], Salma Bensbaa[1,2] & Asmaa Chadli[1,2]
[1]Endocrinology, Diabetology and Metabolic Diseases Department Ibn Rochd University Hospital of Casablanca, Morocco; [2]Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy - University Hassan II-Casablanca-Morocco, Casablanca, Morocco.

Introduction
Diet plays an important role in glycemic control in diabetic pregnant women.

Study objectives
To determine the major dietary errors in pregnant women with diabetes.
Patients and methods
A descriptive retrospective study including 60 patients with diabetic pregnancy hospitalized in Endocrinology and Diabetology service between January to December 2016. Data collection was done from medical records.The statistical analysis was done by SPSS. The parameters were studied: age, body mass index (BMI), gestational age, diabetes type, treatment adopted and the degree of glycemic control, pre-conceptional HbA1c, dietary survey: total level of carbohydrates, distribution according to meals, consumption of fast sugars, simple sugars, vegetables, fruit, meat, fish or egg and dairy products a day.
Results
The study included 60 patients with an average age of 30.4 years. Mean gestational age was 22 weeks of gestation, 26.7% had gestational diabetes and 73.3% pre-gestational diabetes. Correct BMI was found in 21.7%patients, overweight at 33.3% and obesity at 45%. 13.3% of patients were on diet and lifestyle rules and 87.7% were on insulin. Glycemic control was achieved in 42.6% of patients. Total carbohydrate intake was excessive (>220 g/day) in 41.7%, while it was insufficient (<180 g/day) in 16.7%. For meal distribution, 53.4% had an excessive intake at breakfast, 56.7% had an inadequate intake of dinner and 51.7% had adequate intake at lunch. Regarding Snacks, 6.7% of patients observed the 3 snacks and 18.3% took bedtime snack. In qualitative terms, major source of carbohydrates came from starchy foods. Furthermore, 28.3% of patients consumed simple sugars with a high glycemic index. Glycemic control was significantly related to the overall carbohydrate intake ($P<0.05$).
Discussion:
Carbohydrate intake recommended for pregnant women with diabetes is between 180–220 g/day divided into 3 meals and 3 snacks. Our study highlights the different dietary errors either in terms of quantity of carbohydrates or their distribution during the day.

P516

The flexible insulin therapy: satisfaction after the change of treatment? About 73 cases

Zineb Boulbaroud[1,2], Siham El Aziz[1,2] & Asma Chadli[1,2]
[1]Endocrinology, Diabetology and Metabolic Diseases Department Ibn Rochd University Hospital of Casablanca, Morocco; [2]Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy- University Hassan II- Casablanca-Morocco, Casablanca, Morocco.

Introduction
The Flexible Insulin therapy (FIT) is considered as the therapeutic reference of type 1 Diabetes mellitus. FIT Improves diabetic patientâ€™s quality of life with a great benefit, through food flexibility while providing optimal glycemic control with reduced incidence of both acute and chronic complications. The aim of the study was to evaluate satisfaction on changing treatment as a result of education FIT.
Methods
Prospective study including 73 patients with diabetes type 1 (T1D) who participated on FIT program during the period between April 2013- July 2017. To assess satisfaction treatment after FIT, we used validated questionnaires of satisfaction with the treatment by patient during the consultation after the first week for the Diabetes Treatment Satisfaction Questionnaire Version status (DTQ14s) and at consultation after the third month for the Diabetes Treatment Satisfaction Questionnaire change version (DTQ14c). Patients with an overall score $>$ 25 on the scale of DTQ14s were considered very satisfied, or have assigned a score of 3 in items of DTQ14c.
Results
Mean age of patients was 24.7 years (13-49) with a mean diabetes duration of 7 years (5 months-23 years). The A1C average before the FIT was 9.2% (5 to 13.8%). The evolution after 3 months was marked by improving glycemic control found on lowering HbA1c by an average of 1.5% (0.7–3) a significant reduction in the frequency and severity of hypoglycemia. Regarding the initial satisfaction with the treatment, according to the DTQ14s, patients were generally quite satisfied with their treatment with an average overall score to 21/36 Â$\pm$6.8. After 3 months of the FIT, the DTQ14c showed that 65% of patients were very satisfied with the flexibility of the new regimen, 53% of patients reported a better understanding of their diabetes and 72% were convinced from the convenience of their current treatment. Furthermore, 69% of patients were willing to recommend the FIT to other patients.
Conclusion
Despite the binding nature of carbohydrate counting and blood glucose monitoring, FIT allows positively improvement of patientâ€™s quality of life. Most patients find this quite flexible and satisfactory method, enabling them to better assimilate their illness to better daily management of diabetes.

Long-term results of continuous subcutaneous insulin infusion on glycemic control and severe hypoglycemias

Sónia do Vale[1,2], Raquel Carvalho[1], Tânia Matos[1], Cristiana Costa[1], Ana Filipa Martins[1], Catarina Silvestre[1] & Maria João Bugalho[1,2]
[1]Endocrinology Department, Hospital de Santa Maria, Centro Hospitalar Lisboa Norte, EPE, Lisbon, Portugal; [2]Endocrinology Department, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal.

Introduction
The use of Continuous Subcutaneous Insulin Infusion (CSII) is expected to improve glycemic control and to reduce hypoglycemia events. However, long-term beneficial results in glucose control are not always observed. We evaluated long-time glucose control and severe hypoglycemias in type 1 diabetic patients using CSII, without continuous glucose monitoring.
Patients and methods
This was a retrospective study of adult type 1 diabetic patients using CSII, assisted at the endocrinology outpatient department of a tertiary hospital. Mean HbA1c was evaluated before CSII, and each year thereafter. Severe hypoglycemias were registered in the year before CSII and the last two years of follow-up.
Results
Ninety patients were studied (66% female). They used CSII since 34 ± 10 years old and had type 1 diabetes since 18 ± 11 years before. Follow-up with CSII was 6.3 ± 2.6 years. HbA1c at baseline and during follow-up with CSII was as follows: Overall, HbA1c significantly decreased ($P<0.001$) in the first year with CSII and remained lower than baseline during the first six years of follow-up ($P<0.05$). However, higher pre-CSII HbA1c was related to a greater decrease in HbA1c until the last year of follow-up ($r=+0.582$, $P<0.001$, $n=56$). In fact, in patients with baseline HbA1c$\geq$8%, this parameter significantly decreased until the sixth year ($P<0.03$), while for patients with baseline HbA1c$<$8%, it decreased only during the first year of follow-up ($P=0.009$). Severe hypoglycemias (78% in patients with baseline HbA1c$<$8%) significantly reduced after CSII ($P<0.05$).

Table 1

	HbA1c % (mean$\pm$sd)						
Patients	Before	First year	Second year	Third year	Fourth year	Fifth year	Sixth year
All	8.1$\pm$1.2	7.4$\pm$1.0	7.6$\pm$0.9	7.7$\pm$1.0	7.9$\pm$1.1	7.9$\pm$0.9	7.8$\pm$1.0
Baseline HbA1c$<$8%	7.2$\pm$0.6	6.9$\pm$0.7	7.1$\pm$0.8	7.1$\pm$0.9	7.2$\pm$0.7	7.5$\pm$0.8	7.3$\pm$0.8
Baseline HbA1c$\geq$8%	8.8$\pm$1.1	8.0$\pm$0.9	8.1$\pm$0.8	8.1$\pm$0.7	8.3$\pm$0.9	8.2$\pm$0.8	8.2$\pm$1.0

Discussion
The best glycemic control was observed during the first year using CSII, eventually in relation to patients' motivation towards the introduction of a new therapeutic approach. Patients with worse baseline glycemic control were the ones who showed larger improvements with CSII. In fact, CSII was effective in long-term glycemic improvement in patients with baseline HBA1c$\geq$8%. On the other hand, CSII also reduced severe hypoglycemic events, which affected mostly patients with baseline HbA1c$<$8%.

The anxiety and depression disorders in the diabetic type 1 (preliminary results)

Lygie Kibhat[1,2], Siham El Aziz[1,2], Salma Bensbaa[1,2] & Asma Chadli[1,2]
[1]Endocrinology, Diabetology and Metabolic Diseases Department Ibn Rochd University Hospital of Casablanca, Morocco; [2]Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy- University Hassan II, Casablanca, Morocco.

Introduction
The relationship between diabetes and anxiety and depression is bidirectional. Patients with somatic disorders such as diabetes present on average twice more psychiatric disorders than the general population. The aim of our study was to identify the level of anxiety and depression in people with diabetes type 1 and to assess their impact on the clinical features of the disease.

Patients and methods
We conducted a transversal descriptive study including 102 patients with type 1 diabetes, for 8 months (May-December 2017). Assessing anxiety state was made according to the Hamilton and Beck score for depression in Arabic validated. Analysis was performed by SPSS 16.
Results
A mean age was 24 years with, a sex ratio of 1.04 M/F, toxic habits (21.5%), an average diabetes devation of 10.4 years and an uncontrolled diabetes in 83.3% of cases. Degenerative complications were: a retinopathy (20.6%), a nephropathy (20.6%), and neuropathy (16.7%). Incidence of hypoglycemiawas97.05%, irregular follow-up 34.3% of cases. We noted a minor depression (17.6%), a major (11.8%) control glycemia in our patient's depression and a minor anxiety (46%) and major (11%). Anxiety was related to degenerative complications (26.4%). Depression was most noticeable among female patients (20.6%) and contributing factors to this were degenerative complications (14.7%) and lack of financial support (13.72%). Anxiety and depression were not correlated with glycemic control. This highly correlated to the monitoring irregularity.
Conclusion
We emphasize as well the need to integrate research of anxiety and depressive disorders in the care of diabetic type 1 patients, in order and delay the onset of complications.

Intermittent fasting for three months decreases pancreatic islet mass and increases insulin resistance in Wistar rats

Ana Cláudia Munhoz Bonassa & Angelo Rafael Carpinelli
University of São Paulo, São Paulo, Brazil.

Introduction
It is known that fasting causes several physiological changes in the endocrine pancreas, such as insulin secretion, pancreatic islet metabolism and beta cells redox state. However, there is still no consensus about the effects of intermittent fasting (IF), a fad diet widespread by the media and adopted by individuals seeking rapid weight loss. In the present study, we sought to study the effects of the IF diet for three months in an animal model.
Methods
Thirty-day-old female Wistar rats were submitted to IF for three months. During this time body weight and food intake were recorded. After the treatment the animals were killed, and pancreatic islets, perigonadal white adipose tissue, *extensor digitorum longus muscle* tissue and liver were collected for different analyses.
Results
IF decreased body weight and food intake. The stomach was greatly increased in size. There was an increase in adipose tissue and a decrease in muscle tissue. IF caused elevation of plasmatic insulin levels, both baseline and after glucose administration. *In vitro*, IF pancreatic islets had increased insulin secretion, glucose metabolism and net reactive oxygen species production, while decreased their mass. In addition, impairment in AKT phosphorylation was observed in peripheral tissues indicating insulin resistance.
Discussion
Previous studies showed an increase in orexigenic neurotransmitters production in IF, inducing hunger and hyperphagia in the *ad libitum* feeding days. Our experiments demonstrate that, despite the weight loss, IF treatment induces undesirable effects on tissue homeostasis. Therefore, the hyperinsulinemia registered *in vivo* and *in vitro*, associated with the impairment of glucose tolerance and the decrease in AKT phosphorylation, make clear the occurrence of peripheral insulin resistance. The increased metabolism of pancreatic islets dispersed cells, after IF treatment, indorses the higher insulin secretion. Furthermore, the decrease in the pancreatic islet mass indicates that three months of IF treatment cause severe impairment in glucose homeostasis. In conclusion, intermittent fasting diet may not be healthy to be adopted by individuals seeking rapid weight loss.

Cognitive impairment and nutritional status in patients admitted to the Department of Internal Medicine

Francisco J Merida De la Torre & Nieves Bel Peña
Health Management Area Serrania de Malaga, Ronda, Málaga, Spain.

Introduction
Altered nutritional status is a problem in itself that can complicate a patient's disease. In our hospital, the assessment of nutritional status at hospital admission is protocolized and performed by the Clinical Laboratory automatically, through the CONUT system, for three years ago. Our hospital provides assistance to a population of 120,000 patients, from rural areas and with a high average age. Hospital admissions for cognitive impairment are increasing in our hospital as cognitive impairment is increasingly frequent and these patients often present problems of autonomy that complicate their nutrition and their general care.
Hypothesis
Patients with cognitive impairment who has admitted to the hospital have worse nutritional status than the rest of the patients admitted in Departament of Internal Medicine.
Matearial and methods
Nutritional status was analyzed by the CONUT method; age and sex of all patients admitted to Internal Medicine in our hospital during 2017, compared to those who presented cognitive deterioration as the main diagnosis. Descriptive statistics and contingency tables were applied and X^2 test.
Results
During 2017 there were 1637 hospital admissions in Internal Medicine, 52.8% men and 47.2% women. The average age was 67.57 years. 43.7% did not present risk of malnutrition; 37.9% presented a risk of moderate malnutrition and 18.4% presented a risk of severe malnutrition. In the same period of time, there were 208 admissions due to cognitive impairment, 47.8% men and 52.2% women. The average age of this group was 70.45 years. 32.9% did not present risk of malnutrition; 40.8% presented risk of moderate malnutrition and 26.3% presented risk of severe malnutrition. The general group presented some nutritional disorder in 56.3% of the income compared to 67.1% of the group with cognitive deterioration. The results of nutritional risk comparison between both groups did not show significant differences ($P > 0.001$).
Conclusions
Nutritional status is a condition that must be assessed in all hospital admissions. Cognitive impairments, of different etiologies, can also be severely affected by nutritional status. Although in our series it has not been possible to demonstrate significant differences between the patients of both groups, we believe that malnutrition states play an important role in the evolution of cognitive impairments, so their evaluation should be mandatory. A control of the nutritional status of these patients when they return to their home would be very useful to control the nutritional status of these patients.

Deleterious effect of low-dose persistent organic pollutants on insulin secretion in pancreatic β-cell

In-Kyu Lee, Jae-Han Jeon & Chae-Myeong Ha
Kyungpook National University, Daegu, Republic of Korea.

Low-dose persistent organic pollutants (POPs), especially organochlorine pesticides (OCPs) and polychlorinated biphenyls (PCBs), have emerged as a new risk factor for type 2 diabetes. We evaluated whether chronic exposure to low-dose POPs affects insulin secretory function of β-cells in humans and *in vitro* cells. Serum concentrations of OCPs and PCBs were measured in 200 adults without diabetes. Mathematical model-based insulin secretion indices were estimated by using a 2-h seven-sample oral glucose tolerance test. Insulin secretion by INS-1E β-cells was measured after 48 h of treatment with three OCPs or one PCB mixture. Static second-phase insulin secretion significantly decreased with increasing serum concentrations of OCPs. Adjusted means were 63.2, 39.3, 44.1, 39.3, 39.7, and 22.3 across six categories of a summary measure of OCPs ($P_{trend} = 0.02$). Dynamic first-phase insulin secretion remarkably decreased with increasing concentrations of OCPs among only insulin-sensitive individuals ($P_{trend} = 0.02$); the insulin levels among individuals with high OCPs were ~30% of those with low OCPs. Compared with OCPs, PCBs showed weaker associations. The decreased insulin secretion by INS-1E β-cells was observed for even 1 pmol/L OCP. The data from human and *in vitro* cell experiments suggest that chronic exposure to low-dose POPs, especially OCPs, can induce pancreatic β-cell dysfunction.

GLP-1 increases the availability of substrates and prioritizes the use of lipids in muscle metabolism

Laura Toba, Juan Fandiño, Yolanda Diz-Chaves, Lucas Carmelo Gonzalez-Matías & Federico Mallo
CINBIO, Vigo, Spain.

The skeletal muscle expresses the Glucagon-like Peptide 1 (GLP-1) receptor, although its effects in this tissue are not well known. Muscles are a major sink of energy substrates. The aim of our study was to examine the mid-term effect of Liraglutide (LIRA), a GLP-1 receptor agonist, in the expression of molecular indicators of the metabolic activity of the muscle, which includes enzymes, transporters, and intracellular signals. Twenty young Spague-Dawley male rats (350-400 g) were treated for seven days with LIRA (100 µg/Kg/12 hours / i.p) or vehicle. Body weight and food intake were monitored daily. After the sacrifice, samples of muscle and serum was stored at −80° C. We studied the expression by rtPCR of mRNA for GLUT-4, CD-36, GAPT-1, GAPT-4, Fosfofructo-kinase-1 (FFK-1), CPT-1, UCP-2, PPAR-gamma and mTOR. In addition, we studied serum proteomics by the profile adipokine Array Kit (RD systems, bio-Techne) for rat. Treatment with LIRA, reduces total food intake (kCal) and body weight gain just in the first 24 hr but not afterwards. LIRA treatment increases the mRNA expression of the translocase CD36 (+74%) that facilitates the entry to the cell of fatty acids, and the expression of the glucose transporter GLUT4 (+317%). LIRA also increases the expression of PPARγ (+800%) involved in the biogenesis of mitochondria and UCP2 (+298%) that promote the oxidation of fatty acids to the detriment of pyruvate from glycolysis. LIRA does not modify the phosphofructokinase 1 nor of CPT-1 expression. In addition, it reduces the expression of glycerol-3-phosphate acyltransferase-1 (GAPT 1, −80%), limiting the formation of mitochondria ketone bodies, and mTOR (−70%), determinant in the synthesis of new fibres. The administration of LIRA also reduce total fat mass (g/100g bw) and the serum circulating levels of total triglycerides. In conclusion, LIRA promotes the entry of fatty acids and glucose in muscle, facilitates the production of energy from fatty acids and the biogenesis of mitochondria, all together improving the efficiency of the muscular energy machinery.

Plasma levels of perfluoroalkyl substances and risk of type II diabetes mellitus: a prospective nested case-control study

Carolina Donat-Vargas[1], Ingvar A. Bergdahl[2], Andreas Tornevi[2], Maria Wennberg[2], Johan Sommar[2], Hannu Kiviranta[3], Panu Rantakokko[3], Olov Rolandsson[2] & Agneta Åkesson[1]
[1]karolinska Institutet, Stockholm, Sweden. [2]Umeå University, Umeå, Sweden. [3]National Institute for Health and Welfare, Kuopio, Finland.

Background
Perfluoroalkyl Substances (PFAS) have drawn much attention due to environment bioaccumulation potential and their presence worldwide in human blood. Exposure to PFAS is suspected to induce endocrine-disrupting hormonal effects and may be involved in the development of type 2 diabetes (T2D). However, epidemiological evidence is scarce and inconsistent.
Objective
We aimed to investigate the association of PFAS plasma levels on the risk of developing T2D in a Swedish population-based cohort.
Methods
A prospective nested-case control design was applied. Middle-aged subjects participated in a medical examination, completed a lifestyle questionnaire and gave blood samples during 1990-2003. Six different PFAS were measured in plasma. During 10-year average follow-up T2D diagnosis was retrieved from medical records and later validated by specialists according to WHO criteria. A total of 158 T2D cases were matched (1:1) according to gender, age and sample date with participants without T2D (controls). Conditional logistic regressions were used to prospectively estimate the odds ratios (OR) of T2D.
Results
After adjusting for confounders, the risk of diabetes was reduced by 59% in subjects with higher levels of total PFAS in plasma (OR = 0.41; 95% CI 0.18–0.96; *P* trend 0.045; comparing the highest to lowest tertile of the sum of the six standardized PFAS levels). Despite the similar point estimates for the specific individual PFAS (ORs from 0.48 to 0.75), statistical significance was not reached when assessed individually.
Conclusions
We observed that high levels of plasma PFAS in the general population were associated with a lower risk of developing T2D regardless other known risk factors such as age, gender, body mass index and diet. Further work is required to confirm these findings and to clarify potential mechanisms.

Evaluation of the technique of insulin injection Analogue in Tunisia in diabetic type 2 and impact on the glycemic balance: study 56 cases

Boulbaba Boulbaba[1], Rihab Ben Abdallah[2], Mouna Elleuch[1], Mouna Ammar[1], Nadia Charfi[1] & Mohamed Abid[1]
[1]Endocrinology Service CHU Hedi Chaker, Sfax, Tunisia; [2]Faculty of Sciences, Sfax, Tunisia.

Introduction
In Tunisia, only about 10% of people with diabetes practice self-injecting insulin analogues. It is 1 Tunisian adult out of 11 who is affected directly by diabetes. Our goal is to assess diabetes patients' knowledge of insulin injection techniques.
Patients and methods
Prospective study of 56 cases of type 2 diabetic patients in the Endocrinology Department CHU Hedi Chaker Sfax Tunisia. All patients had a questionnaire and clinical examination.
Results
Most hospitalized patients (75%) were between 40-66 years old. With male predominance (sex ratio H / F 2). The majority 65% of our diabetic patients had diabetes evolving for more than 14 years. Only 25% of the patients use the analogues regularly and journaled against 65% find insulin injection difficulties similar 25% forgotten, 35% lack of means to buy the special needles of the pens, and others by the refusal the assumption of responsibility by the National Health Insurance Fund (CNAM). The most commonly used insulin therapy regimen is two injections (60%). Patients self-inject insulin analogue in 65% of cases. Only 10% of the cases respect the standards of storage. On the other hand, 75% do not disinfect either the hands or the injection site. The preferred site was the dominant limb arm in 75% of cases. Only 50% introduce the needle without skin fold at 90 ° and inject the insulin dose by pushing on the plunger without forcing. The maintenance of the system in place for 10 s was respected only in 20% of patients. In this work. Only 25% of diabetic patients had a good glycemic control (HbA1 c = 6.8%) who practice similar injections.
Conclusions
A mastery of insulin injection techniques is of paramount importance to achieve a good balance of diabetes; hence the role of the nurse in diabetic and therapeutic education.

Non-alcoholic fatty liver disease and polycystic ovarian syndrome in lean and obese women of reproductive age

Athina Markou[1], Krystallenia Alexandraki[2], Evita Kafritsa[1], Ioannis Androulakis[1], Vasiliki Syriou[3], Labrini Papanastasiou[1], Eleni Antipa[4], Ageliki Tsikini[4], Christianna Samara[4], George Piaditis[2] & Gregory Kaltsas[2]
[1]Department of Endocrinology and Diabetes Center, General Hospital of Athens 'G.Gennimatas', Athens, Greece; [2]Endocrine Unit, 1st Department of Propaedeutic Medicine, Laiko University Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [3]Pathophysiology Department and First Department of Internal Medicine, Laikon General Hospital and Medical School, National and Kapodistrian University of Athens, Athens, Greece; [4]Department of Radiology, General Hospital of Athens 'G.Gennimatas', Athens, Greece.

Introduction
Non-alcoholic fatty liver disease (NAFLD) is the commonest cause of chronic liver disease in the western world affecting 5-33% of the general population. Polycystic ovarian syndrome (PCOS) is a common endocrinopathy affecting 6-10% of women of reproductive age. In both conditions, insulin resistance (IR) seems to be a common pathogenetic mechanism.

Objective
To investigate the presence of NAFLD in lean and obese women with and without PCOS using biochemistry and imaging modalities such as liver ultrasound (U/S) and computed tomography (CT).
Patients and methods
Eighteen lean and 17 obese control women and 21 lean and 21 obese women with PCOS were studied prospectively. Baseline biochemical profile was followed by a glucose tolerance test and indices of IR were calculated. Ovarian morphology was assessed using transvaginal ultrasonography. Hepatic lipid content was assessed with U/S and CT of the liver.
Results
Mean age was 26 years for all four groups. Mean BMI($\pm$SD) was 21.0$\pm$1.8 kg/m^2 for lean controls and 21.4$\pm$1.9 for lean PCOS and 33.0$\pm$7.4 kg/m^2 for obese controls and 34.6$\pm$6.4 for obese PCOS. Fasting insulin levels and indices of IR showed an incremental continuum trend from the lean controls to lean PCOS to obese controls to obese PCOS. Hepatosteatosis assessed by liver U/S was seen in 15% of lean PCOS, in 37% of obese controls and in 50% of obese PCOS women. Evidence of hepatosteatosis was only found in 1 obese patient with PCOS on liver CT. In the whole population studied there was a negative correlation between waist circumference and mean liver-mean spleen attenuation on liver CT. Age**,** BMI, waist circumference, ALT levels and insulin resistance were independent risk factors associated with NAFLD as assessed on U/S, in lean and obese women of reproductive age with and without PCOS.
Conclusions
NAFLD in more common in obese than lean women with or without PCOS as evaluated by radiologic modalities. Obesity and IR play a determinant role in the development of the disease. Ultrasound is 100% whereas CT is 93% sensitive in detecting NAFLD only when fatty infiltration is at least 33%. Newer methods such as magnetic resonance spectroscopy (MRS) would help to diagnose the disease at earlier stages.

Analysis of the results of fasting test in hypoglycemias study

María Belén Ojeda Schuldt, Isabel Mateo Gavira, Francisco Vilchez López, Julián Tamayo Serrato, Begoña Sánchez Lechuga & Manuel Aguilar Diosdado
Hospital Universitario Puerta del Mar, Cádiz, Spain.

Methods
Retrospective and descriptive study in a sample of 36 patients with suspected hypoglycemia who were admitted to our Service to perform a 72-hour fasting test. Demographic, clinical data and results of fasting test were analyzed. Endogenous hyperinsulinism criteria were considered to be the combination of plasma glucose $<$55 mg dl, insulin $>$3 mcrU / ml and C peptide $>$ 0.6 ng/ml, in the absence of detection of sulfonylureas.
Results
The average age was 37 years old (81.1% women). The average weight was 66.62 kg and BMI 25.93 kg/m^2. They presented an average evolution of clinical syndrome of 4.6 years. 62.2% reported neuroglycopenic symptoms and 86.5% adrenergic symptoms coinciding with an average capillary blood glucose level of 49.52 mg/dl. 17% referred fasting hypoglycemia and 19.4% postprandial hypoglycemia. The average HbA1C was 5.07%. 91.7% improved their symptoms after supplements with sugar (the rest remitted spontaneously). In the initial evaluation, drug, serious illness and hormonal deficit were ruled out. The test was completed in 26.2$\pm$17.58 hours in 5 patients. Only 3 patients (8.3%) were positive for hypoglycemia due to endogenous hyperinsulinism with an average plasma glucose of 37 mg/dl, insulin 10.05 mcrU/ml and peptide C 3.35 ng/ml, subsequently confirming the diagnosis of insulinoma by imaging tests.
Conclusions
Most of patients completed the fasting test for 72 hours without clinical incidents and without hypoglycemia less than 45 mg/dl, ruling out hyperinsulinemic hypoglycaemia.
In view of these data, it could be concluded that it is important to document the Whipple triad before concluding a possible diagnosis of hypoglycemia to avoid unnecessary tests.

Calbindin-d9k interacts with Mucin1, which influences the stability of Hypoxia inducible factor-1a

Bonn Lee, Changhwan Ahn, Ly Duc Viet & Eui-bae Jeung
College of Veterinary Medicine, Chungbuk National University, Cheongju, Republic of Korea.

Introduction
Hypoxia is involved with various physiological activities from glucose metabolism to tumor suppression. Hypoxia-inducible factor (HIF) is known as master regulator of oxygen homeostasis that triggers more than 1,000 related gene expressions. When hypoxia occurs, HIF1a protein is stabilized and starts transcription. Mucin1 mediates the stabilization of HIF1a in a cytoplasm. In addition, cytoplasmic domain of mucin1 and HIf1a form a transcriptional complex at glycolytic gene promoters. Interestingly, in calbindin-d9k knock out mice, both HIF1a and mucin1 were up-regulated in protein level. Calbindin-d9k has been known as a cytosolic calcium-binding protein. However, our results suggest that calbindin-d9k is involved with the interaction between HIF1a and mucin1. In the result of western blots, immunofluorescent and immunoprecipitation, calbindin-d9k was identified to interact with mucin1, which influence the stabilization of HIF1a.
Materials and methods
Eight weeks old C57BL/6 mice and calbindin-d9K Knockout mice were exposed to hypoxia for 3 weeks. Hypoxic condition was created in polycarbonate chamber with nitrogen supply to remove oxygen. Oxygen concentration were measured and maintained thoroughly about 12$\pm$2% partial pressure of O2. Expression of HIF1a and mucin1 protein in kidney were analyzed by Western blotting. Tissue-specific localization of calbindin-d9k and mucin1 were identified by immunofluorescent in kidney. Co-immunoprecipitation was performed to detect calbindin-d9k and mucin1 protein complex.
Results
In the result of western blot, expression of HIF1a and mucin1 were upregulated in calbindin-d9k knockout mice compared to that of wild type mice exposed in normal atmosphere. However, in hypoxia, both knockout and wild type mice showed similar protein expression. Cabindin-d9k and mucin1 were simultaneously detected at the distal convoluted tubules observed by immunofluorescent. In addition, protein complex between calbindin-d9k and mucin1 was identified by co-immunoprecipitation.
Conclusions
Calbindin-d9k was newly identified to interact with mucin1 protein in kidney. Upregulation of HIF1a protein in calbindin-d9k knock out mice might result from the absence of calbindin and mucin interaction.

Genotype- Phenotype correlations of TNF-α, IL-6 and Leptin receptor gene polymorphisms in Poly cystic ovarian syndrome

Rajesh B[1], Ramesh B[1], Gayathri G[1], Venkateshwara Reddy M[1], Vighnesh D[1], Rajkiran Reddy B[2], Chakrapani B[3] & Bhargav PRK[4]
[1]VMC, Kurnool, India; [2]SMART Sunshine Hospital, Hyderabad, India; [3]Neuro Hospital, Nizamabad, India; [4]Endocare Hospital, vijayawada, India.

Introduction
Tumor necrosis factor alpha (TNF-α) and Interleukin-6 (IL-6) are potent immunomodulators and proinflammatory cytokines displaying varied functions. Apart from monocytes/macrophages, they are also produced by the cells in female reproductive tract. Polycystic ovarian syndrome (PCOS) is one of the commonest endocrine disorder amongst women of reproductive age group. Several polymorphisms in the promoter region of the gene TNF-α, IL-6 and Leptin receptors have been described associated with various disease ranging from cancers to PCOS, obesity and infertility. In this context, we evaluated association between PCOS and the promoter single nucleotide polymorphisms of the gene TNF-α –238G/A (rs361525), –308G/A (rs1800629) and –1031T/C (rs1799964); IL-6 –174G/C and *LEPR* 668 A/G.
Material and methods
This is inter-disciplinary study conducted by collaboration between a tertiary care endocrinology hospital, biochemistry department of a teaching medical institute and genetics lab. In this prospective study involving 100 PCOS patients with 100 age matched controls, we employed 3 sets of primers and screened for the known single nucleotide polymorphisms TNF-α, IL-6 and Leptin receptor genes. Apart from qualitative and quantitative evaluation, linkage disequilibrium, multifactor dimensionality reduction analysis and In-silico analysis were performed.

Results
Of identified seventeen haplotypes the haplotype combination "A-A-C-A-C" and "A-G-T-G-C" conferred protection towards PCOS (OR = 0.321, CI = 0.15 – 0.67, $P = 0.002$ and OR = 0.28, CI = 0.11 – 0.73, $P = 0.005$ respectively), while the haplotype combination "A-G-C-A-C" conferred fourfold risk (OR = 3.38, CI = 1.52 – 7.53, $P = 0.0018$) towards PCOS susceptibility. For IL-6 - 174G/C, the percentage of GG, GA and AA genotypes in patients was 24, 44, 32 while it was 25, 45 and 30 in controls respectively. For LEPR gene, the relative risk for the alleles demonstrated a twofold risk of G allele towards disease establishment (OR = 1.62, CI = 1.07 – 2.45, $P = 0.021$).
Conclusions
The present study could not provide a concrete association between the TNF α and IL-6 polymorphisms with PCOS. For Leptin receptor gene, there appears to be role of the AG and GG genotypes, and G allele in contributing towards establishment and progression of PCOS. But further extensive studies are warranted to validate the same phenomenon in the general population and various ethnic groups.

Association of habitual physical activity with leptin gene expression in visceral and subcutaneous adipose tissues among non-diabetic people

Behnaz Mahmoodi[1], Emad Yuzbashian[1], Maryam Zarkesh[2], Golaleh Asghari[1], Mehdi Hedayati[2], Parvin Mirmiran[1] & Alireza Khalaj[3]
[1]Nutrition and Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [3]Tehran Obesity Treatment Center, Department of Surgery, Shahed University, Tehran, Iran, Republic of Islamic.

Introduction
Adipocytokines secreted by adipose tissue are suggested to play a role in the development of obesity-related complications. Leptin is mainly produced and secreted by adipose tissue and appears as an important regulator of energy balance. The relationship between leptin levels and energy expenditure remain unclear. Energy expenditure related to physical activity (PA) is the most variable part of total energy expenditure. There is some evidence that the habitual level of PA may be a significant determinant of leptin concentrations, but the scarce document in leptin gene expression. The aim of this study was to investigate the association between habitual PA and the leptin gene expression among non-diabetic adults.
Materials and methods
Visceral and subcutaneous adipose tissues were gathered from 98 non-diabetic participants aged ≥20, who had undergone elective abdominal surgery. Physical activity was collected using a valid and reliable International Physical Activity Questionnaire (IPAQ)-long form, and the metabolic equivalent of task (MET) was calculated. Respondents were asked to report time spent in PA performed across leisure time, work, domestic activities, and transport at each of 3 intensities: walking, moderate, and vigorous. The mRNA expressions of leptin gene in visceral and subcutaneous adipose tissues were analyzed by Real-Time PCR.
Findings
The mean age of participants (22.7% male) were 41.7 years. No significant difference was observed for leptin gene expression in subcutaneous (−0.135 vs. 0.791, $P = 0.992$) and visceral (−1.582 vs 0.915, $P = 0.891$) fat mass between non-obese (BMI <30 kg/m^2) and obese (BMI ≥ 30 kg/m^2) participants, respectively. After controlling for total energy intake, BMI, and insulin level, total MET ($\beta = -0.428$, $P < 0.001$) was negatively associated with leptin gene expression in visceral adipose tissue among obese participants; however total MET was not significantly related to leptin gene expression in subcutaneous adipose tissue. Besides, MET related home ($\beta = -0.316$, $P = 0.035$) and leisure time ($\beta = -0.651$, $P < 0.001$) were negatively associated with visceral adipose tissue leptin gene expression.
Conclusions
Physical activity is negatively related to leptin gene expression in visceral adipose tissue participants with obesity only and this association is independent of fasting plasma insulin. This finding exaggerated the crucial role of PA to control of the development of obesity.

Anti-insulin resistant effect of ferulic acid in high-fat diet-induced obese mice

Jarinyaporn Naowaboot & Pritsana Piyabhan
Thammasat University, Pathum Thani, Thailand.

This study investigated the action of ferulic acid (FA) on the regulation of insulin sensitivity in high-fat diet (HFD)-induced obese mice. The ICR mice were fed with HFD (45 kcal% lard fat) for 16 weeks. Over the last 8 weeks of HFD feeding, these obese mice were orally administered with FA at doses of 25 and 50 mg/kg/day. At the end of all treatments, the epididymal fat, pancreas and hypothalamus were removed for analysis of biochemical parameters and expression of proteins. FA treatment significantly decreased leptin levels in fat tissue and the insulin levels in pancreas. Interestingly, treatment with FA improved the insulin sensitivity in hypothalamus, and up-regulated the expressions of insulin receptor substrate-1 (IRS-1), phosphatidylinositol-3 kinase (PI3K), and phosphorylated-protein kinase B (Akt) in obese mice. The histological examination showed smaller size of pancreatic islets in obese mice treated with FA compared to untreated obese mice. Overall, this study demonstrated the potential effect of FA for improving insulin function in HFD-induced obese mice. This effect is probably mediated via modulating the PI3K/Akt pathways.

Non-alcoholic fatty liver disease and its association with insulin resistance in an obese population

Frederique Van de Velde[1], Marlies Bekaert[1], Anne Hoorens[2], Marleen Praet[2], Arsène-Hélène Batens[1], Samyah Shadid[1], Yves Van Nieuwenhove[3] & Bruno Lapauw[1]
[1]Ghent University Hospital - Endocrinology, Ghent, Belgium; [2]Ghent University Hospital - Pathology, Ghent, Belgium; [3]Ghent University Hospital - Gastro-Intestinal Surgery, Ghent, Belgium.

Background and aims
Obesity induced inflammation is a key component in the pathogenesis of insulin resistance (IR). In addition, obesity-related non-alcoholic fatty liver disease (NAFLD) also seems to contribute to IR development. Until now, however, it is unclear which, if any component of NAFLD specifically associates with IR. Therefore, the aim is to assess if individual components of NAFLD contribute to IR in obese patients undergoing gastric bypass surgery (GBS).
Subjects and methods
This cross-sectional study included 62 obese patients (mean age 45 ± 10 years; BMI 41.7 ± 4.5 kg/m^2) undergoing GBS and 62 healthy, age-matched control subjects (mean age 45 ± 10 years; BMI 23.5 ± 1.8 kg/m^2). Glucose levels were analysed by hexokinase method and insulin levels with electrochemiluminescence. Homeostasis model assessment-estimated insulin resistance (HOMA-IR) was calculated with following formula HOMA-IR = {fasting glucose (mmol/l) * fasting insulin (μU/ml)}/22.5. Liver biopsies taken during GBS were evaluated using NASH-CRN scoring system (NAS score) and Steatosis, Activity and Fibrosis scoring (SAF score).
Results
GBS patients showed higher glucose, insulin and HOMA-IR levels (all $P < 0.001$) compared to controls. Among GBS patients, according to the SAF score, patients with non-alcoholic steatohepatitis (NASH) had higher glucose levels compared to those without. Besides, with an increasing grade of inflammation patients had higher HOMA-IR and insulin levels ($P < 0.05$), an association that is independent from age, BMI and cholesterol ($F(2,48) = 3309$; $P = 0.045$). Ballooning was not associated with HOMA-IR, insulin or glucose levels, whereas an association between steatosis grade and HOMA-IR levels was lost after controlling for age and BMI. An increasing grade of fibrosis was correlated with insulin and HOMA-IR levels ($r_s = 0.256$, $P = 0.048$ and $r_s = 0.255$, $P = 0.049$; respectively).
Conclusion
This study showed that within an insulin resistant group of obese patients, the level of IR correlates with histopathologic subcomponents of NAFLD. Specifically, whereas steatosis and ballooning are not associated with HOMA-IR, a higher grade of hepatic inflammation was associated with higher IR. For fibrosis, a trend toward higher IR with higher grade of fibrosis was found.

Whether this finding reflects a subgroup of patients with more severe adiposity-related consequences or whether this results from a direct effect of hepatic inflammation (and fibrosis) on IR needs to be further investigated.

Using on-line program of good nutrition and wright diet may reduce the risks of diabetes mellitus in the future

Vadim Krylov
Sechenov University, Moscow, Russian Federation.

Objectives
It is too much easier and cheaper to combat obesity, than in the future to treat diabetes mellitus and its complications.
Methods
We used an online system for patient education (www.rightdiet.ru) based on the video lessons, full of humor, pictures, and cartoons to convey the necessary information on good nutrition, necessary to do exercises and the need for exposure to the sun to our patients.
Results
A patient was in touch with a doctor-endocrinologist in the case of any additional questions. We examined data from a survey of 650 patients registered in the online system and 100 patients control group who received the same recommendations on the appointment. The average weight loss was 7.3 kg in the main group. Regular physical activity was higher in the main group compared with the control one of 245 and 75 min per week respectively. Watching the short movies, the patients formed the habits of good nutrition during the first month already, which includes a diet with restriction of fat, digestible carbohydrates and daily consumption of low-fat dairy products, slow carbohydrates, protein and fiber. Were also presented recommendations for compliance with the physical activity, as well as vitamin D consumption.
Conclusions
Very important how we can make spreading of the material. Often the patient has no opportunity to go to the doctor for an appointment, and during the reception, it is not always possible to discuss all aspects, and even if it was possible, some information is forgotten by patients. So, we need to improve the quality of information material, including using online technologies to improve the quality and duration of life of our patients.

Effectiveness of bariatric surgery in metabolically healthy obese patients

Laura Tuneu[1], Analia Ramos[1], Idoia Genua[1], Nicole Stantonyonge[1], Francisca Caimari[1], Carmen Balague[2], Sonia Fernández-Ananin[2], Antonio Perez[1] & Inka Miñambres[1]
[1]Endocrinology Department, Hospital de Sant Pau, Barcelona, Spain; [2]Surgery Department, Hospital de Sant Pau, Barcelona, Spain.

Objective
To evaluate the effectiveness and security of bariatric surgery in metabolically healthy obese (MHO).
Methods
A retrospective study of a cohort of all obese patients who underwent to bariatric surgery with a minimum two-year follow-up. Databases of all demographic, anthropometric and metabolic characteristics have been collected since 2007. Patients undergoing two surgeries were excluded. We defined as MHO patients those without diagnosis of diabetes or hypoglycemic treatment, basal blood glucose <5.6 mmol/l, HbA1c $<5.7\%$ and lipids (Tg <1.7 mmol/l and HDL $\geq =$ 1 mmol/l men/1.3 mmol/l women) no treated with fibrates. The statistical study was performed using SPSS version 24. Student's T test, Chi squared test, Pearson's correlation and multiple lineal regression were used.
Results
A total of 195 patients were included (mean age 48.8 ± 10.6 years, 68.7% of women) In 126 (64.6%) the surgical technique was the Gastric Sleeve whereas in 69 (35.4%) it was by-pass. Prior to surgery, 35 patients (17.9%) were MHO. Patients with MHO had a higher percentage of women compared with patients without MHO (82.9% vs 65.6% $P=0.046$) and a lower percentage of hypertensive patients (42.9% vs 57.1% $P=0.027$). In the second and third year post-surgery, MHO patients presented a higher % of excess body weight loss (%EBWL) (80.24% vs 69.52%, $P=0.010$ and 77.14% vs 63.66%; $P=0.015$, respectively). Multiple regression analysis showed that age and the presence of MHO inversely correlated with %EBWL. We did not detect any differences of acute complications after bariatric surgery.
Conclusions
Bariatric surgery in patients with MHO is associated with higher weight loss.

The relationship between obesity, insulin resistance and conjunctival impression cytology

Murat Dağdeviren[1], Mustafa Altay[1], Zennure Yıldız[2], Gülçin Şimşek[3], Mehmet Çıtırık[4], İhsan Ateş[5], Tanyel S Dağdeviren[6], Canan Yıldız[7] & Tuğba Şahin[2]
[1]Department of Endocrinology and Metabolism, Sağlık Bilimleri University, Keçiören Health Administration and Research Center, Ankara, Turkey; [2]Department of Ophthalmology, Sağlık Bilimleri University, Keçiören Health Administration and Research Center, Ankara, Turkey; [3]Department of Pathology, Sağlık Bilimleri University, Keçiören Health Administration and Research Center, Ankara, Turkey; [4]Department of Ophthalmology, Sağlık Bilimleri University, Ulucanlar Health Administration and Research Center, Ankara, Turkey; [5]Department of Internal Medicine, Sağlık Bilimleri University, Ankara Numune Health Administration and Research Center, Ankara, Turkey; [6]Department of Family Practice, Sağlık Bilimleri University, Keçiören Health Administration and Research Center, Ankara, Turkey; [7]Department of Internal Medicine, Sağlık Bilimleri University, Keçiören Health Administration and Research Center, Ankara, Turkey.

Introduction
This study was designed to determine whether obesity causes inflammation on both conjunctival epithelium cells as well as on squamous metaplasia.
Materials and methods
Around 61 volunteer participants who had no previous history of illness or drug use were involved in this study. Of them, nearly 20 were obese, and 41 were of normal weight. We measured the glucose and insulin values for all volunteers. We also measured the Body Mass Index (BMI) and Homeostasis Model Assessment for Insulin Resistance (HOMA IR). The impression cytology method was used to analyze the conjunctival epithelium cells and classify them between Grades 0 to 3 according to the Nelson criteria.
Results
While there was a certain level of inflammation on the 90% of, as well as squamous metaplasia (Grade 2-3 inflammation) on the 80% of obese participants, the impression cytology was found to be normal only in two patients. The expected results were observed on the 56.1% of the control group, and the squamous metaplasia rate was nearly 17% ($P<0.001$). 90.9% of the patients with grade 3 inflammation were obese. The variables as independent predictors were found to indicate the existence of inflammation in conjunctivae at various levels; BMI (OR:1,24; $P=0.002$) and HOMA IR (OR $=28.6$; $P=0.001$) in a Model I multivariable regression model, and the existence of obesity (OR:11.91; $P=0.002$) and HOMA IR (OR $=15.08$; $P<0.001$) in a Model II multivariable regression model.
Conclusion
Obesity was found to be a disorder that causes inflammation on the conjunctival epithelium cells for the first time.

Effect of the Andean plant Lampaya on NF-κB and JNK phosphorylation in human macrophages treated with palmitic acid.

Paulina Ormazabal[1,2], Mariana Cifuentes[2], Cecilia Fuentes[2], Adrián Paredes[3] & Glauco Morales[3]
[1]Centro de Estudios de la Salud, Sociedad y enfermedades crónicas no transmisibles (CESSEC), Instituto de Ciencias de la Salud de la Universidad de O'Higgins, Rancagua, Chile; [2]Instituto de Nutrición y Tecnología de los Alimentos (INTA), Universidad de Chile, Santiago, Chile; [3]Departamento de Química, Facultad de Ciencias Básicas y Laboratorio de Química Biológica del Instituto Antofagasta de la Universidad de Antofagasta, Antofagasta, Chile.

Background
Adipose tissue dysfunction occurring in obesity leads to a low grade chronic inflammatory state. Fat tissue from obese individuals has a high infiltration rate of

macrophages contributing to the development of obesity-related inflammation. At the cellular level, inflammation can be triggered by the activation (phosphorylation) of NF-κB as well as JNK. On the other hand, palmitic acid (PA) is a saturated fatty acid found elevated in plasma from obese subjects and shows pro-inflammatory activities in different cell types. Interestingly, people living in the Andean High Plateau in Northern Chile use the plant *Lampaya medicinalis* Phil. (Verbenaceae), known as Lampaya, against inflammatory diseases (rheumatism, arthritis and joint pain). The aim of this study was to evaluate the effect of a hydroalcoholic extract of Lampaya (HEL) against PA- induced inflammation in cultures of human macrophages.
Methods
Macrophages of the cell line THP-1 were incubated for 18 h in the following conditions: i) Control, ii) 0.1 μg/ml HEL, iii) 10 μg/ml HEL, iv) 0.2 mM PA, v) 0.1 μg/ml HEL +0.2 mM PA, vi) 10 μg/ml HEL +0.2 mM PA. Cell viability was determined by Tripan blue exclusion and phosphorylation of JNK and NF-κB was evaluated by Western blot.
Results
0.1 and 10 μg/ml HEL did not affect cell viability compared to the control condition. PA-treated cells showed a 40% reduction in cell viability compared to control. Interestingly, when macrophages were treated with PA plus 0.1 μg/ml or 10 μg/ml HEL viability was restored to the control condition. On the other hand, a 40% increase in NF-κB phosphorylation was found in PA-treated macrophages compared to vehicle-treated cells. JNK phosphorylation was comparable between all experimental conditions assessed. In macrophages co-treated with HEL and PA, NF-κB phosphorylation was comparable to the control condition.
Conclusions
HEL overcomes PA-induced reduction in cell viability as well as the increase in NF-κB activation in THP-1 macrophages. These findings might support the traditional use of the plant for treating pathologies with an inflammatory component, such as the metabolic diseases associated with obesity.

The effect of n-3 PUFA on lipid profile, inflammation and insulin resistance

Mona Nourbakhsh[1,2], Mitra Nourbakhsh[3] & Maryam Razzaghy Azar[1,2]
[1]Hazrat Aliasghar Children's Hospital, Iran University of Medical Sciences, Tehran, Iran, Republic of Islamic; [2]Metabolic Disorders Research Center, Endocrinology and Metabolism Molecular-Cellular Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Republic of Islamic; [3]Department of Biochemistry, Faculty of Medicine, Iran University of Medical Sciences, Tehran, Iran, Republic of Islamic.

Insulin resistance, lipid imbalance and inflammatory process have deleterious effect on cardiovascular system. Omega-3 polyunsaturated fatty acids (n-3 PUFA) (Docosahexaenoic acid [DHA] and Eicosapentaenoic acid [EPA]) are lipids that have beneficial effects. Our objective was to study the effects of n-3PUFA on anthropometric characteristics, inflammation, lipid profile and insulin resistance of the children with obesity.
Materials and methods
Thirty obese children aged 8–18 year with body mass index (BMI) >95% for their age and gender were enrolled into the study. After clinical evaluation and sample collection, patients were treated with 1250 mg of n-3 PUFA containing EPA 425 mg and DHA 325 mg, once a day for three months. Anthropometric characteristics were measured and BMI was calculated. Fasting blood glucose, insulin, CRP and lipids were measured in fasting blood samples before and after intervention. $P<0.05$ was considered significant.
Results
Treatment with n-3 PUFA did not have any significant effect on anthropometric characteristics including BMI, waist and hip circumference and waist to hip circumference ratio. Serum CRP level changed from 2.85 ± 1.65 mg/dl to 1.3 ± 1.03 mg/dl which significantly showed decreased inflammation in response to n-3 PUFA administration ($P<0.001$). In lipid profile, blood triglyceride was changed from 117.5 ± 70.4 mg/dl to 91.8 ± 42.2 ($P=0.01$) and LDL-C from 91.3 ± 20.6 to 81.8 ± 20.6 ($P<0.001$). HDL-C was 42.76 ± 9.2 and reached to 47.14 ± 9.6 ($P=0.05$). Homeostasis model assessment (insulin resistance) (HOMA-IR) changed from 5.14 ± 3.1 to 4.11 ± 2.5 ($P=0.04$).
Conclusion
Short term administration of omega 3 fatty acids decreased insulin resistance and inflammation, changed lipid profile in better conditions but did not change anthropometric characteristics of obese children in short duration of study.

Differences in adipocyte size and adipogenic potential in metabolically healthy and unhealthy obese bariatric surgery patients

Ioana Hristov[1], Crina Tiron[2], Adrian Tiron[2], Daniel Timofte[3], Luminita Labusca[4], Letitia Leustean[5], Teodor Oboroceanu[1] & Veronica Mocanu[1]
[1]Pathophysiology Department UMF Iasi, Iasi, Romania; [2]Transcend Research Center-Regional Institute of Oncology, Iasi, Romania; [3]Surgery Department-UMF Iasi, Iasi, Romania; [4]National Institute of Research and Development for Technical Physics, Iasi, Romania; [5]Endocriology Department UMF Iasi, Iasi, Romania.

Introduction
The adipocyte expansion is a critical process with implications in the pathogenesis of metabolic syndrome and insulin resistance associated to obesity. Impaired adipogenesis leads to dysfunctional, hypertrophic adipocytes, chronic low grade inflammation and insulin resistance.
Methods
Our study included 18 obese patients (13 females and 5 males) mean age 38.76 ± 8.89 years and mean body mass index 46.06 ± 6.48 kg/m2, referred for Laparoscopic Sleeve Gastrectomy procedure. Patients were divided in metabolic healthy obese, MHO (6 patients)and metabolic unhealthy obese, MUHO (12 patients) according to IDF criteria. Antropometric measurements, biochemical and hormonal profile were evaluated. Subcutaneous adipocyte size was assessed using Adiposoft software on microscopic images of formalin fixed adipose tissue. The subcutaneous adipose derived stromal/stem cells (ASCs) were isolated and the mesenchymal origin was demonstrated by cytoskeleton vimentin fluorescent staining. To evaluate the adipogenic capacity of these precursor cells derived from obese patients, the ASCs were grown to confluence and differentiated *in vitro* for 21 ± 3 days using an adipogenic protocol. We evaluated the lipid accumulation in mature adipocytes by specific lipid dye(Oil Red O). Spectrophotometric analysis of the lipid stain was used to quantify the lipid accumulation and fluorescent nuclear dye with DAPI was used for accurate cell count of mature adipocytes.
Results
Mean adipocyte area was significantly lower in MUHO as compared to MHO($P<0.05$) The lipid accumulation in mature adipocytes obtained by isolation, proliferation and differentiation of subcutaneous ASCs was between 12.5% and 108.76%, being significantly higher in the MUHO group($P<0.05$) as compared to MHO. For both groups, significant correlations was found between lipid accumulation and HOMA-IR ($P=0.01$), C peptide ($P<0.05$) and morning cortisol levels ($P<0.05$). No significant correlation was found between lipid accumulation and age or body mass index (BMI).
Conclusion
The evaluation of subcutaneous adipocyte size and adipogenic potential of ASCs derived from subcutaneous adipose tissue could be a good predictor of the metabolic risk for obese patients.

Glucocorticoid positively regulate Agouti-related protein gene

Mitsuru Nishiyama[1], Shuichi Nakayama[1], Yasumasa Iwasaki[2], Shinpei Fujimoto[1] & Yoshio Terada[1]
[1]Department of Endocrinology, Metablism and Nephrology, Kochi Medical School, Kochi University, Nankoku, Japan; [2]Health Care Center, Kochi, Japan.

Purpose
Glucocorticoid is one of the key hormones that regulates energy balance. Glucocorticoid excess induce hyperphagia and obesity (e.g. Cushing syndrome), however, its mechanisms are not fully elucidated. On the other hand, Agouti-related protein (AgRP) is known as an orexigenic neuropeptide, which is expressed in the hypothalamic arcuate nucleus. To clarify the role of Agouti-related protein (AgRP) in glucocorticoid-induced obesity, we investigate here the effect of glucocorticoid on AgRP gene transcription and expression.
Methods
We examined *in vitro* the effect of dexamethasone on the AgRP gene transcription using the reporter assay and the electromobility shift assay (EMSA) in BE(2)C cells. We also examined *in vivo* the effect of corticosterone (CORT) administration on hypothalamic AgRP mRNA in C57BL6 mice using real time PCR.
Results
There are two glucocorticoid responsive elements (GRE1 and GRE2) in AgRP 5'-promoter region. Dexamethasone robust increased AgRP transcriptional

activity. Deletion analysis revealed that GREs were necessary for dexamethasone responsiveness, and binding of glucocorticoid receptor to GREs was confirmed by the EMSA. CORT administration (2 weeks) increased body weight, food consumption and hypothalamic AgRP mRNA expression (AgRP/GAPDH:placebo 100.0±9.9, CORT 133.2±8.4, $P<0.05$).
Conclusion
These results suggest that glucocorticoid positively regulate AgRP gene transcription and expression. Glucocorticoid-induced hypothalamic AgRP could be associated with hyperphagia and obesity in Cushing syndrome.

Relationship between body image perception, diet trial and depression in Korean adults: Korea National Health and Nutrition Examination Survey 2014

Soo Min Hong, Ho Seok Koo & Yang Im Hur
Seoul Paik Hospital, Inje University, Seoul, Republic of Korea.

Introduction
Previously we investigated the relationship between obesity and depression in Korean adults using data from a population-based sample from the 2014 Korea National Health and Nutritional Examination Survey (KNHANES) by cross-sectional study. We further investigated about relationship between body image perception, diet trial and depression in -depth study.
Methods
In total, 4,026 subjects (1,692 men, 2,334 women) aged 19–69 years participated in the 2014 KNHANES. Current depression was defined as a score ≥10 on the nine-item Patient Health Questionnaire (PHQ-9). Height and weight were measured and the body mass index (BMI) was calculated. The participants were asked to complete questionnaires about socio-demographic factors and disease comorbidities, and health-related behaviors. The chi-square test and multivariate logistic regression analyses were performed to examine the relationship between obesity, body image perception, diet trial and depression.
Results
According to body weight status, there was a significant difference in the prevalence of depression (underweight: 16.2%, normal weight: 5.5%, overweight: 4.3%, obese [BMI≥30]: 6.9%). Compared to the normal weight group, the underweight group had a higher adjusted odds ratio (OR) for depression (OR = 3.34, 95% confidence interval [CI]: 2.18, 5.11). For underweight group, when they had body image perception that they are thin or obese, they had higher PHQ-9 scores for depression ($P=0.001$) and only when they had body image perception that they are thin, they had depression (16.2%). For overweight group, only when they had body image perception that they are obese, they had depression (4.3%). For obese group, none of them had depression who had body image perception that they are obese (0%). For groups who tried to loose weight, exercise group had no depression while fasting, skipping meals or taking diet pills group had depression ($P=0.01$).
Conclusions
This study shows differences in the risk of depression depending upon body weight status. Being underweight was correlated with a high risk of developing depression in both men and women in regard to their body image perception as thin or obese. For groups trying to loose weight, exercise may be a better way than fasting, skipping meals or taking diet pills for their mental health.

Obstructive sleep apnea syndrome frequency in obese patients

Gulsah Elbuken[1], Ismail Yildiz[1], Levent Cem Mutlu[2], Nejat Altıntaş[2] & Sayid Shafi Zuhur[1]
[1]Department of Endocrinology and Metabolism, Namik Kemal University Faculty of Medicine, Tekirdag, Turkey; [2]Department of Pulmonary Medicine, Namik Kemal University Faculty of Medicine, Tekirdag, Turkey.

Introduction
Obstructive sleep apnea syndrome (OSAS) is a common disorder whose prevalence is linked to an epidemic of obesity. OSAS is caused by recurrent episodes of upper airway obstruction during sleep, leading to reduction or cessation of the airflow. Studies have shown a strong association among OSAS and cardiovascular morbidity and mortality. Therefore, currently we performe overnight polysomnograpy in all patients with obesity in our outpatient clinic. In order to observe the results, we retrospectively analyzed the polysomnography results of 54 patients with obesity who were followed-up in our outpatient clinic.
Results
Medical records of 54 patients with obesity [22 male and 32 female, mean age 54.5±9.0 and mean Body Mass Index (BMI) of 41±8.0 kg/m^2].The mean age and BMI between male and female patients were not significantly different [55.6±9.0 and 38.3±6.0 kg/m^2; 53.8±8.7 and 41.3±8.8 kg/m^2, respectively ($p>0.05$)]. OSAS was detected in 49 of 54 (90%) patients. Mean BMI was 41.4±8.4 and 35.6±2.9 kg/m^2 in obese patients with and without OSAS, respectively ($P=0.02$). In their medical records, 44 of 49 patient with OSAS were found to be classified according to the severity of OSAS (5 of them were not determined severe or not). These 44 patients with OSAS were divided into 3 subgroups including mild, moderate and severe, according to the severity of OSAS. In this study, 9,11 and 24 patients with mean BMI of 43.7, 38.7 and 43.2 kg/m^2 had mild, moderate and severe OSAS, respectively.No correlation was found between the severity of OSAS and BMI in our study ($P>0.05$).
Conclusion
Although OSAS was more common in patients with BMI of >35 kg/m^2, the severity of OSAS was not related to higher BMI levels. Other confounding factors rather than BMI should be taken in consideration during the assessment of the severity of OSAS.

Impact of bariatric surgery on working productivity in patients with morbid obesity

Diana Romero[1], Guila Fidel[2], María Sonsoles Cepeda[2], Gemma Parramón[2], Mayra Velasquez[2], Enza María Fidilio[2], J M Fort[2], Marta Comas[2], Cristina Hernández[2,1], Rafael Simó[2,1], Jordi Mesa[2] & Andreea Ciudin[2]
[1]VHIR, Barcelona, Spain; [2]Hospital Vall Hebrón, Barcelona, Spain.

Introduction
Morbid obesity (MO) is a major global public health problem, associated with a significant economic burden, both due to its high prevalence and the number and severity of its comorbidities. MO is associated with a high degree of difficulty to lead a normal social and working life. Weight loss is effective in decreasing these risks and to reduce disease severity. Bariatric surgery (BS) is an effective therapy for sustained weight loss and for the improvement of the quality of life of these patients. Nevertheless, data in literature is scarce regarding the impact of BS on the working productivity (WP) of the MO patients. On these bases, the objective of the present study is to evaluate the relationship between BS and WP in MO patients.
Methods
We performed a retrospective revision of the medical records of the consecutive patients that attended the MO Unit of our center between February-October 2017 and had a complete psychological evaluation. The specific psychological exam in the MO Unit was performed using the ZKPQ, STAI, BDI-II, BITE and Rosenberg SS questionnaires as part of the pre-BS evaluation as per protocol. On the day of the visit to our center, the WPAI-GH questionnaire was administered to all the patients.
Results
138 patients were recluted, aging 48.21±10.81 years, 73% women, and 85.4% Caucasian. A total of 56.2% were not employed. 61.03% of the cases underwent BS, with a follow-up of 36.45±27.82 months and a satisfactory evolution (previous BMI 44.12±6.8 kg/m^2 vs post-BS BMI 33.4±5 kg/m^2, $P<0.001$). In the group of BS patients, 83.0% were not previously employed and 3.03% have been reinserted into the labor market after the BS. No significant correlations were found between the WP and the age, gender, ethnicity, any BMI, MO related comorbidities, follow-up time after the BS, surgical technique or socio-economic status. We found significant correlations between the WP and the education level, the presence of depression, anxiety and lack of activity as well as self-esteem evaluated by the psychological tests previous BS.
Conclusion
A significant percentage of patients with MO that underwent BS were not employed, despite the satisfactory evolution in terms of BMI. A significant correlation exists between the WP and the pre-BS psychological profile of the MO patients.

Associations of circulating adipokine levels with metabolic risk factors and renal function in a general population

Stephanie Zylla[1,2], Julian Fischer[1], Henry Völzke[2,3], Jan Kassubek[4], Jens-Peter Kühn[5], Matthias Nauck[1,2] & Nele Friedrich[1,2]
[1]Institute of Clinial Chemistry and Laboratory Medicine, University Medicine Greifswald, Greifswald, Germany; [2]DZHK (German Centre for Cardiovascular Research), Greifswald, Germany; [3]Institute of Community Medicine, University Medicine Greifswald, Greifswald, Germany; [4]Department of Neurology, University of Ulm, Ulm, Germany; [5]Department of Diagnostic Radiology and Neuradiology, University Medicine Greifswald, Greifswald, Germany.

Background, objective
Adipose tissue is known to secrete a multitude of bioactive adipokines and it seems that the majority of these adipokines is implicated in the pathogenesis of obesity and associated metabolic diseases. Existing research studies mostly concentrated on one or two adipokines and therefore, comparisons of the involvement of different adipokines in these disorders are difficult. Furthermore, associations of circulating adipokine levels with different fat compounds or lifestyle factors are mostly missing in existing studies. This study aimed to provide a comprehensive overview of the associations of a panel of circulating adipokines (adiponectin, leptin, resistin, chemerin, vaspin) with metabolic parameters and renal function in a well characterized large population-based study.
Methods
Data from 4129 subjects of the Study of Health in Pomerania were analyzed. Residual method was used to investigate the associations of MRI-quantified liver fat content as well as visceral (VAT) and subcutaneous adipose tissue (SAT) with circulating adipokine levels. Furthermore, multivariable regression models were applied to examine the associations of adipokine concentrations with lifestyle factors (smoking, alcohol consumption, physical inactivity), metabolic phenotypes, and renal function.
Results
Independently of other fat compounds, liver fat content, SAT, and VAT were inversely associated with adiponectin. Furthermore, an independent positive association of liver fat content and SAT with chemerin was observed. The strongest independent association was detected between SAT and leptin. Physically inactive subjects had higher chemerin and leptin levels and smoking led to higher chemerin as well as lower adiponectin and leptin concentrations. Alcohol consumption was associated with adiponectin (positive) and resistin (inverse). Obese subjects showed increased chemerin, leptin, and vaspin levels, but decreased adiponectin concentrations. All adipokines were associated with lipid markers, whereas associations with parameters of glucose metabolism were only seen for adiponectin, chemerin, and leptin. An inverse association of similar strength was observed between chemerin, leptin as well as resistin and estimated glomerular filtration rate (beta -0.2, $P<0.01$).
Conclusion
Our results indicate that the associations between different circulating adipokine levels and metabolic risk factors as well as renal function significantly differ. In general, high adiponectin levels seem to have a protective role whereas increased chemerin, leptin, resistin, or vaspin concentrations seem to be disadvantageous for the investigated alterations. Leptin concentrations play a key role during obesity, whereas for other metabolic disorders adiponectin and chemerin levels seem to be more meaningful. During processes of renal disease circulating chemerin, leptin, and resistin levels might be of similar importance.

Association of sleep duration and obesity according to sex and age in Korean adults: results from the Korea national health and nutrition examination survey 2007–2015

Mi Young Lee[1], Ji Yun Jeong[2], Eun-Hee Cho[3], Jung Min Kim[4] & Mi-Seon Shin[5]
[1]Department of Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea; [2]Department of Internal Medicine, Soonchunhyang University, Gumi, Republic of Korea; [3]School of Medicine, Kangwon National University, Chuncheon, Republic of Korea; [4]Sanggye Paik Hospital, Inje University College of Medicine, Seoul, Republic of Korea; [5]Hanil General Hospital, Seoul, Republic of Korea.

Background/objectives
This study aimed to investigate associations between self-reported sleep duration and general and abdominal obesity in Korean adults stratified according to sex and age.
Subjects/methods
Data from 41,805 adults, 18–110 years of age, collected by the Korean National Health and Nutrition Examination Survey (KNHANES) in 2007 and 2015, were included. Obesity was defined as body mass index (BMI) ≥ 25 kg/m^2, and abdominal obesity as waist circumference ≥ 90 cm in men and ≥ 85 cm in women. To control for sociodemographic and lifestyle factors and comorbidities, multivariable logistic regression was used to calculate adjusted odds ratios (ORs) and 95% confidence intervals (CIs) for obesity and abdominal obesity across sleep duration categories of ≤ 5, 6–8, and ≥ 9 h/day.
Results
The mean ($\pm$ S.E.M.) age was 43.8 ± 0.13 years; BMI was 23.7 ± 0.02 kg/m^2; waist circumference was 81.1 ± 0.08 cm; and sleep duration was 6.9 ± 1.3 h/day. General obesity was present in 13,203 (31.7%) participants and abdominal obesity in 10,712 (23.9%). Among individuals 30–49 years of age, there was an increased adjusted OR for obesity only for sleep duration ≤ 5 h/day compared with sleep duration 6–8 h/day, both in men (OR 1.25 (95% CI 1.02–1.54)) and women (OR 1.56 (95% CI 1.29–1.90)), after controlling for sociodemographic and lifestyle factors. Regarding women, there was increased adjusted OR for abdominal obesity for sleep duration ≤ 5 h/day (OR 1.45 (95% CI 1.18–1.78)) and ≥ 9 h/day (OR 1.38 (95% CI 1.09–1.76)) compared with sleep duration 6–8 h/day. However, for elderly individuals (≥ 65 years), there was a negative association between sleep duration ≤ 5 h/day and obesity, but not with abdominal obesity, in both men and women.
Conclusion
This study demonstrated a significant association between sleep duration and obesity, which varied according to sex and age.

Relation of serum irisin levels, non-alcoholic fatty liver disease, glucose and lipid metabolism parameters in obese children

Gökçen Ulualan[1], Zeynep Küskü-Kiraz[2] & Birgül Kirel[3]
[1]Eskişehir Osmangazi University Faculty of Medicine Department of Pediatrics, Eskişehir, Turkey; [2]Eskişehir Osmangazi University Faculty of Medicine Department of Biochemistry, Eskişehir, Turkey; [3]Eskişehir Osmangazi University Faculty of Medicine Pediatric Endocrinology Unit, Eskişehir, Turkey.

Irisin is a myokine induced by exercise, that converts white fat tissue to brown fat tissue, thereby increasing thermogenesis and providing energy expenditure. The aim of this study is to determine the relationships between serum irisin levels and glucose and lipid parameters in obese children with and without non-alcoholic fatty liver disease (NAFLD). A total of 60 pubertal obese children (31 F, 29 M, age range: 11–18 yrs.) were included in this study. 30 of Whom had NAFLD. The control group consisted of 28 healthy children (14 F, 14 M) who were similar in age and sex to the obese group.
Results
The median serum irisin level was lower in the obese group (5.26 μg/ml (4.2–6) μg/ml) than in the control group (7.5 μg/ml (6.5–9) ($P<0.05$). The median irisin levels in both patients with NAFLD (5.7 μg/ml (4.6–6.5) and without NAFLD (5 μg/ml (3.9–5.7) were lower than the control group's ($P<0.05$). Serum irisin levels were not different between patients with and without NAFLD ($P>0.05$). According to the presence of insulin resistance in the obese group, irisin levels did not change ($P>0.05$). In the obese group, irisin were correlated with BMI, waist and arm circumfrence. In the whole study group, serum irisin levels correlated negatively with BMI, waist, hip and arm circumferences, waist/hip ratio, skinfold thickness (triceps and biceps) and AST, ALT levels. There were no correlations between serum irisin levels and LDL-C, triglyceride and total cholesterol, but a positive correlation was found with HDL-C. Consequently, low serum irisin levels are found in obese children. It is not different between patients with and without NAFLD. Irisin levels are correlated negatively with fat tissue parameters and ALT-AST levels. Low irisin levels may be related to the presence of decreased muscle mass and/or decreased brown adipose tissue and hepatic injury in obesity.

Do dietary acidic and basic amino acids intake play role in FTO gene expression among non-diabetic adults?

Golaleh Asghari[1], Emad Yuzbashian[1], Maryam Zarkesh[2], Parvin Mirmiran[1], Mehdi Hedayati[2] & Alireza Khalaj[3]
[1]Nutrition and Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran; [2]Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran; [3]Tehran Obesity Treatment Center, Department of Surgery, Shahed University, Tehran, Islamic Republic of Iran.

Introduction
The fat mass and obesity-associated gene (FTO) has been shown to be associated with obesity and might be affected by dietary factors. Long-term dietary intake of amino acids are capable to change adipose tissue metabolism through regulation of FTO production. This study aims to examining the association of dietary acidic and basic amino acids (AAs) with FTO gene expression in subcutaneous and visceral adipose tissues among non-diabetic adults.
Methods
A total of 87 adults (23% men), who were free of diabetes and undergone open abdominal surgery were included. Average intakes of acidic AAs including glutamic and aspartic acid, and basic AAs including histidine, arginine, and lysine were collected using a valid and reliable semi-quantitative food frequency questionnaire. During the surgery visceral and subcutaneous adipose tissues were obtained, and FTO gene expression of both fat depots were assessed by Real-Time PCR.
Results
Mean (S.D.) for BMI among obese and non-obese participants were 42.6 (7.3) and 25.3 (3.1) kg/m^2, respectively. The median (25–75 IQR) intake of acidic and basic AAs were 9.7 (6.5–12.0) and 19.8 (25.1–13.7) g/d, which included 9.6 and 18.7 percent of total daily protein intake, respectively. No significant difference was observed for FTO gene expression in subcutaneous (-0.518 vs. 0.395, $P=0.471$) and visceral (-0.999 vs 0.773, $P=0.161$) fat mass between non-obese and obese participants, respectively. After adjusting for BMI and energy intake, 1-gram increment in acidic and basic AAs were accompanied with -0.358 ($P=0.019$) and -0.308 ($P=0.045$) unit increase in subcutaneous and -0.339 ($P=0.017$) and -0.320 ($P=0.020$) unit decrease in visceral FTO gene expression among obese participants, respectively. However, no significant association of acidic and basic AAs intake with neither subcutaneous (($\beta=0.088$, $P=0.632$) and ($\beta=0.119$, $P=0.518$), respectively) nor visceral (($\beta=0.232$, $P=0.257$) and ($\beta=0.230$, $P=0.257$), respectively) adipose tissue were found among non-obese participants.
Conclusion
Our finding showed that higher dietary acidic and basic AAs can decrease FTO gene expression among obese non-diabetic adults.

Long term dietary intake of aromatic amino acids are associated with leptin gene expression in adipose tissues of non-diabetic adults

Golaleh Asghari[1], Emad Yuzbashian[1], Maryam Zarkesh[2], Parvin Mirmiran[1], Mehdi Hedayati[2] & Alireza Khalaj[3]
[1]Nutrition and Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran; [2]Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran; [3]Tehran Obesity Treatment Center, Department of Surgery, Shahed University, Tehran, Islamic Republic of Iran.

Introduction
Among the adipokines, leptin is one of the hormones directly connects to body fat and obesity. Investigating the impacts of dietary amino acids on adipose tissue metabolism have emerged as a fascinating area for researchers which they reported that dietary amino acids can affect and regulate gene activity in adipose tissues both directly and indirectly, with positive or negative effects.
Methods
Visceral and subcutaneous adipose tissues were gathered from 98 non-diabetic participants aged ≥ 20, who had undergone elective abdominal surgery. Average intakes of AAAs including phenylalanine, tyrosine, and tryptophan were collected using a valid and reliable food frequency questionnaire. The leptin gene expression in visceral and subcutaneous adipose tissues was measured by Real-Time PCR.
Results
Mean (S.D.) age and AAA intake of participants (23% male) were 41.7 (14.2) years and 7.38 (3.7) g/day, respectively. Total AAA intakes in ranking order were phenylalanine 3.9 g (the highest), followed by tyrosine 2.3 g, tryptophan 3.3 g, corresponding to 3.7%, 2.1%, and 2.9% of total protein intakes, respectively. No significant difference was observed for leptin gene expression in subcutaneous (-0.135 vs 0.791, $P=0.992$) and visceral (-1.582 vs 0.915, $P=0.891$) fat mass between non-obese (BMI < 30 kg/m^2) and obese (BMI ≥ 30 kg/m^2) participants, respectively. After controlling for BMI and energy, dietary intake of dietary AAA ($\beta=0.404$, $P<0.001$), phenylalanine ($\beta=0.522$, $P<0.001$), tyrosine ($\beta=0.224$, $P=0.081$), and tryptophan ($\beta=0.520$, $P<0.001$) was positively associated with subcutaneous adipose tissues leptin gene expression among obese participants. Besides, a significant positive association of dietary AAA ($\beta=0.513$, $P<0.001$), phenylalanine ($\beta=0.399$, $P<0.001$), tyrosine ($\beta=0.234$, $P=0.078$), and tryptophan ($\beta=0.430$, $P=0.001$) with leptin mRNA from visceral adipose tissue were observed. Among non-obese participants, none of the AAA showed significant association with leptin gene expression in both adipose tissues.
Conclusion
Habitual intake of phenylalanine, tyrosine, and tryptophan were associated with leptin gene expression in visceral and subcutaneous adipose tissues, suggesting an important role of quality proteins intake in adipose tissue to regulate leptin expression.

Assessment of macrophage apoptosis inhibitor (AIM), monocyte chemotactic protein-1 (MCP-1) and C reactive protein (CRP) levels in patients with metabolic syndrome

Emine Merve Savaş[1], Afshin Samadi[2], Hanife Seda Baykal[3], Uğur Ünlütürk[3], İncilay Lay[2], Selen Yılmaz Işıkhan[4] & Ömer Alper Gürlek[2]
[1]Hacettepe University Faculty of Medicine Internal Medicine Department, Ankara, Turkey; [2]Hacettepe University Faculty of Medicine Department of Biochemichistry, Ankara, Turkey; [3]Hacettepe University Faculty of Medicine Endocrinology and Metabolism Department, Ankara, Turkey; [4]Hacettepe University Instutue of Social Science, Ankara, Turkey.

Metabolic syndrome is an important health problem that has been shown to be associated with cardiovascular disease and mortality. Recent studies have shown the importance of inflammation in visceral fat tissue. Macrophage apoptosis inhibitor (AIM) and monocyte chemotactic protein (MCP-1) are molecules that cause migrating to visceral fat tissue of M1 macrophages that initiate adipocyte inflammation. The aim of this study is to understand the role of these molecules in the pathogenesis of the syndrome and to investigate whether they can be used as biomarkers in the diagnosis. For this purpose, 40 metabolic syndrome patients and 40 healthy individuals who were referred to Hacettepe University Hospital were included in the study. The mean age was higher in the metabolic syndrome group (46.68.8 and 40.37.9, $P=0.003$) when there was no gender difference between the groups. Serum AIM, MCP-1 and CRP levels were significantly higher in the metabolic syndrome group ($P<0.01$, $P<0.01$ and $P<0.05$). There was a significant positive correlation between serum AIM, MCP-1 and CRP levels with waist circumference ($r=0.480$, $r=0.663$ and $r=0.418$, $P<0.01$). ROC analysis was performed to determine the best cut points that could be used in the diagnosis of the metabolic syndrome. The area under curve (AUC) of the serum AIM MCP-1 and CRP cut off points (2383.7 pg/ml, 172.8 pg/ml and 0.366 mg/dl) that could be used in the diagnosis of the metabolic syndrome has been found statistically significant (AUC for AIM is 0.767, for MCP-1 is 0.651 and for CRP is 0.907, $P<0.05$). In addition, serum AIM and CRP levels above cut-off point, were independent risk factors for metabolic syndrome, whereas serum MCP-1 level was not independent risk factor. In conclusion AIM and MCP-1 may be effective molecules in the pathogenesis of metabolic syndrome and its subgroups. Serum AIM, MCP-1 and CRP levels can be used as a biomarker for diagnosis of metabolic syndrome.

	MS (+) $n=40$	MS (−) $n=40$	P
AIM (ng/ml)[a]	2506 (1212–4386)	1912 (1168–3564)	0.001

Oxidized low-density lipoprotein (oxLDL) as a possible biomarker of cardiovascular diseases in obese subjects

Elena Parreño[1], Aisa Fornovi[2], Raúl Ballester[3], Luz Martínez[3], Clara Avilés[4], Mariana Martínez[4] & Elena Arjonilla[5]
[1]Hospital de la Vega Lorenzo Guirao, Murcia, Spain; [2]Hospital Vega Baja, Alicante, Spain; [3]Hospital Virgen del Castillo, Murcia, Spain; [4]Hospital Comarcal del Noroeste, Murcia, Spain; [5]Hospital General Universitario Morales Meseguer, Murcia, Spain.

Introduction
oxLDL are produced from the oxidation of low density lipoprotein (LDL) by macrophages and endothelial cells, becoming cytotoxic and immunogenic. They are also a potent inhibitor of the macrophages mobility, contributing to the vascular wall progressive inflammatory infiltration and atherosclerosis formation. Weight loss can prevent atherosclerotic plaque progression of and acute coronary events in obese subjects, so that oxLDL could be used a biomarker of cardiovascular diseases.
Objective
- To study oxLDL levels in patients with morbid obesity and lean subjects, as well as analyzing changes in oxLDL levels in patients with morbid obesity after significant weight loss due to bariatric surgery.

Methods
- No randomized clinical trial.
- 68 patients with morbid obesity and 31 healthy subjects with normal weight.
- Variables studied: BMI (kg/m^2), waist-hip ratio (WHR), systolic and diastolic blood pressure (SBP and DBP, mmHg), total cholesterol (TC, mg/dl), LDL (mg/dl), high density lipoprotein (HDL, mg/dl), triglycerides (TG, mg/dl), high-sensitivity C-reactive protein (hs-CRP, mg/l) and oxLDL (mg/dl).
- Obese patients underwent gastric bypass surgery and, after 12 months and major weight loss, the same variables were reassessed.

Results
We found a statistically significant difference in plasma levels of oxLDL in the group of morbidly obese 1.28 ± 0.39 mg/dl compared with subjects with normal weight 1.13 ± 0.26 mg/dl ($P = 0.038$). In obese patients 1 year after surgery and after a significant weight loss, SBP, DBP, TC, LDL, TG and hs-CRP levels significantly decreased, and HDL levels increased significantly. Despite this, the oxLDL values did not vary significantly with respect to the baseline, with levels of 1.26 ± 0.37 mg/dl. When dividing the obese patients into two groups based on the median of oxLDL (1.19 mg/dl), it was found that in the group with oxLDL levels above the median there was a significant decrease one year after surgery (1.55 ± 0.34 vs. 1.36 ± 0.33 mg/dl, $P = 0.01$).
Conclusion
Significant differences between oxLDL levels among morbid obesity patients and healthy subjects were found, although the levels did not decrease after weight loss despite the improvement in the lipid profile experienced, SBP, DBP and the decrease in hs-CRP. However, oxLDL levels decreased in obese patients with higher levels of oxLDL before surgery, so that oxLDL could be a biomarker in cardiovascular diseases, but not in early stages of it.

Effects on comorbidities and safety of bariatric surgery in morbid obesity patients

Maria Belén Ojeda Schuldt, Isabel Mateo Gavira, Daniel Medina Rivero, Laura Larrán Escandón, María Ángeles Mayo Ossorio, Jose Manuel Pacheco García & Manuel Aguilar Diosdado
Hospital Universitario Puerta del Mar, Cádiz, Spain.

Objectives
1) To determine the prevalence on the main comorbidities in morbid obese patients; 2) To analize the bariatric surgery effects on the comorbidities; and 3) To evaluate the complications of bariatric surgery
Methods
Cohort study with intrasubject measures (before-after) in a sample of 333 patients with morbid obesity who underwent bariatric surgery (bypass gastric or sleeve gastrectomy) in Puerta del Mar Hospital (Cádiz, Spain) between 2005 and 2015. Demographic characteristics, anthropometric parameters, cardiovascular risk factors and surgical complications were analyzed baseline and two years after surgery.
Results
A total of 333 patients were included (71.5% female), with mean age 40.05 ± 9.98 years. The mean preoperative BMI was 50.21 ± 6.98 kg/m^2. Before surgery 26.45% were smokers, 42.3% had hypertension, 45% dyslipidemia and 26.3% diabetes. 5.1% of patients underwent bypass gastric and 44.9% sleeve gastrectomy. After 2 years of follow up, the percentage of weight lost was 69.16%. Remission of hypertension, dyslipidemia and diabetes mellitus type 2 had occurred in 68.4%, 75.5% and 77.6% respectively ($P < 0.001$). Levels of HbA1c, cholesterol and trygliceridemia were reduced significantly after surgery. 12% of patients had early complications and 17.5% developed later complications (The most frequent complication was eventration).
Conclusions
Bariatric surgery in our area is an effective tool in weight loss. It is related with early beneficial effects on metabolic disorders and have similar rate of surgical complications compared with other series.

P550

Association of total antioxidant capacity and p53 mRNA levels in subcutaneous adipose tissue of obese subjects

Maryam Zarkesh[1], Emad Yuzbashian[1], Atoosa Saeedpour[2], Golaleh Asghari[1], Mehdi Hedayati[1], Maasomeh Hajizadeh[2], Parvin Mirmiran[2] & Alireza Khalaj[3]
[1]Research Institute for Endocrine Sciences, Tehran, Islamic Republic of Iran; [2]National Nutrition and Food Technology Research Institute, Tehran, Islamic Republic of Iran; [3]Department of Surgery, Shahed University, Tehran, Islamic Republic of Iran.

Objective
Dietary total antioxidant capacity (TAC) has been assumed as a useful tool to consider the relationship between the cumulative antioxidant food capacity and several chronic disorders. The contribution of p53 to many aspects of age-associated diseases, such as cardiovascular and metabolic disorders has been recognized. The role of dietary TAC in adipose tissues metabolism especially its association with P53 gene expression is not established yet in fat mass. The aim of the study was to investigate the association of dietary TAC intake with p53 gene expression in omental and subcutaneous adipose tissues of obese and non-obese adults.
Methods
In this cross-sectional study, omental and subcutaneous adipose tissues of 98 non-diabetic participants including 44 subjects with BMI < 30 and 54 subjects with BMI ≥ 30 kg/m^2 were collected from who had undergone elective abdominal surgery. Usual intake of participants was assessed by a relative and validated semi-quantitative food-frequency questionnaire (FFQ) before the surgery. Dietary TAC intake was assessed based on the oxygen radical absorbance capacity method. The p53 gene expression was measured by using SYBR Green Real-Time PCR.
Results
The mean age of non-obese and obese participants was 46.3 ± 15.3 and 37.9 ± 11.6 years, respectively, which was significantly different ($P = 0.003$). The dietary TAC intake was 317.6 and 288.7 μmolTE/100g in obese and non-obese participants, respectively ($P = 0.434$). The mRNA levels of p53 in subcutaneous adipose tissues was 0.77 ± 4.84 and -0.06 ± 4.61 in obese and non-obese participants, respectively ($P = 0.397$) and in omental adipose tissue was -0.23 ± 4.50 and 1.35 ± 4.00 in obese and non-obese ones, respectively ($P = 0.078$). After controlling for age and total energy intake, TAC positively associated with subcutaneous adipose tissue p53 mRNA levels in obese participants ($B = 0.274$, $P = 0.043$). There was no significant association in omental adipose tissues ($B = 0.005$, $P = 0.974$).
Conclusion
Higher intake of TAC in the regular diet was associated with p53 gene expression in the subcutaneous adipose tissue; supporting this idea, that overall antioxidant capacity of diet is by affecting the intracellular concentration of p53 protects one from the development of carcinoma.

P551

Influence of lifestyle modification on leptin and insulin resistance to prevent type 2 diabetes mellitus development

Elena Shishko, Tatyana Mokhort & Elena Mokhort
Belarusian State Medical University, Minsk, Belarus.

The aim of the present study was to determine the change of fasting serum leptin and insulin levels and insulin resistance in patients with risk factors of diabetes mellitus of type 2 (DM 2) including impaired glucose tolerance/impaired fasting glucose (IGT/IFG).

Material and methods
The study included 100 patients (32 men, 68 female) 25–65 years old at risk factors of DM 2. All patients received recommendations on a balanced diet and physical activity. The average fasting plasma glucose (FPG), HbA1c, fasting serum leptin was detected by sensitive ELISA.
Results
During 18 months our study 56 patients carried out this recommendations (research group) and 44 patients did not (control group). Patients of the research group demonstrated mean reduction of body mass index (-2.6 ± 0.4 kg/m^2) and persons of the control group had significant increase of these parameters ($P<0.05$). Among subjects with IGT/IFG at baseline, glucose levels normalized in 56.0% of patients from the research group and 4.5% in control group ($P<0.001$). FPG and HbA1c in research group decreased from 11.9 ± 4.3 to 9.6 ± 4.5 μU/ml and from 6.4 ± 0.3 to 6.1 ± 0.3% accordingly ($P<0.05$). In control group the specified parameters had increased significantly ($P<0.01$). The serum leptin median in research group was decreased from 34.7 to 26.4 ng/ml (-23.9%, $P<0.001$) and increased in control group ($+17.9$%, $P<0.01$). The risk reduction of DM 2 development among patients of the research group was 48.0% compared to the control group.
Conclusion
Thereby, lifestyle modification can prevent the development of DM 2 in subjects with risk factors by reduction leptin.

Postprandial glucose, insulin, and incretin responses to different type of breads in healthy overweight and obese individuals

Merve Kayali[1], Yildiz Tutuncu[2], Sebiha Ozge Duman[3] & Nevin Dinccag[2]
[1]IETT Health Department, Istanbul, Turkey; [2]Istanbul University, Istanbul Faculty of Medicine, Endocrinology and Metabolism Division, Istanbul, Turkey; [3]Istanbul University, Istanbul Faculty of Medicine, Oncology Institute, Istanbul, Turkey.

Background
Worldwide, bread is one of the most consumed foodstuff. White bread is made of white flour and process involves the exclusion of bran and embryo. On contrary, these are preserved in whole wheath. Compared the whole grain bread, most commercial white wheat breads contain little dietary fiber and it is assumed to cause more drastic rise and fall on glucose and insulin levels.
Objective
Aiming to investigate 3-hour effect of two different type of breads 21 volunteers (mean age: $37,6 \pm 6,4$ y); 10 overweight [(mean body mass index (in kg/m^2): $27,5 \pm 1,2$)] and 11 obese [(mean body mass index (in kg/m^2): $32,7 \pm 1,6$)] individuals with normal glucose tolerance were recruited into this study. The test products as indicated on Table 1 were whole-grain bread and white wheat bread. Each product provided 50 g available carbohydrate and was served in random order with breakfast with one-week intervals. Fasting and 3 postprandial blood samples were collected at intervals of 60 min for 3 h to determine plasma glucose, glucagon-like peptide 1 (GLP-1), serum insulin concentrations. Rates of increase in glucose and insulin levels of test breads were determined by calculating the area under the curve (AUC)
Results
While high GLP-1 levels was found on postprandial 120th minute, both glucose and insulin levels did not increase in the test with white bread at overweight individuals. On contrary at obese individuals glucose levels was found high level during 3 h and insulin levels was increased on 60th minute significantly ($P<0.05$) after consumption white wheat bread.
As a conclusion
White bread consumption is not healthy in society. Whole grain bread consumption should be recommended to obese people especially, in order to prevent their metabolic changes in their future lives.

Table 1 The nutrient contents of test samples containing 50 g of CHO

	White wheat bread	Whole grain bread
Carbohydrate (g/100 g)	50	50
Protein (g/100 g)	8.07	8.51
Fat (g/100 g)	1.53	1.61
Fiber (g)	5.61	8.68
Energy(kcal)	258	267

The effects of bariatic surgery on clinical, renal parameters and urine ngal levels in diabetic and non-diabetic obese patients

Onur Elbasan[1], Hande Peynirci[2], Soner Cander[3], Özen Öz Gül[3], Melahat Dirican[4] & Canan Ersoy[3]
[1]Marmara Üniversitesi Pendik Eğitim ve Araştırma Hastanesi Endokrinoloji Bilim Dalı, İstanbul, Turkey; [2]Kanuni Sultan Süleyman Eğitim ve Araştırma Hastanesi Endokrinoloji Bilim Dalı, İstanbul, Turkey; [3]Uludağ Ünivesitesi Tıp Fakültesi Hastanesi Endokrinoloji Bilim Dalı, Bursa, Turkey; [4]Uludağ Ünivesitesi Tıp Fakültesi Hastanesi Biyokimya Anabilim Dalı, Bursa, Turkey.

Background
It is known that obesity-related renal damage,regardless of type 2 diabetes and hypertension, may improve by weight-loss modalities. In this study, we aimed to evaluate the effect of bariatric surgery on glycemic and lipid parameters, anthropometric measurements, renal parameters and urine NGAL (Neutrophil Gelatinase-Associated Lipocalin) levels in obese diabetic or nondiabetic patients who has not respond to medical treatment
Materials and methods
In our study, laparoscopic sleeve gastrectomy was performed in 10 diabetic and 9 non-diabetic patients between the ages of 18–65, BMI ≥ 40 kg/m^2, who were approved by the bariatric surgery committee. Anthropometric measurements, biochemical values, and spot urine examination in preoperative and postoperative 6th week were obtained from the routine polyclinic examination. Urinary NGAL levels were measured with spectrophotometry using enzymatic immunoassay method.
Results
In general, a significant decrease in weight, BMI, fasting plasma glucose, fasting plasma glucose (FPG) and HbA1c values were found in the patients at 6th month after surgery compared to preoperative status ($P<0.001$, $P<0.001$, $P=0.003$, $P=0.001$, $P<0.001$). There was also a significant decrease in systolic and diastolic blood pressures and HOMA-IR values ($P=0.004$, $P=0.014$, $P=0.001$). There was also a significant decrease in triglyceride values ($P=0.005$), but there were no significant changes in LDL, HDL and total cholesterol. Serum creatinine was significantly decreased ($P=0.014$), but microalbumin (mAlb), mAlb/creatinine, NGAL and NGAL/creatinin values were not significantly changed. In the comparison of diabetic and non-diabetic cases, the decrease in FPG was significantly higher in the diabetic group ($P=0.005$), but there was no significant difference between the groups in terms of percentage changes of other parameters.
Discussion
Bariatric surgery is an effective method for the treatment of obesity and many related parameters. However, the pathogenesis of obesity-related renal damage has not yet been clarified and stronger data are needed to say that NGAL is a predictor of renal damage in the chronic period.

Are there differences in cardiovascular risk between metabolically healthy and sick obese?

María Rosa Alhambra Expósito, Concepción Muñoz Jiménez, Alfonso Calañas Continente & María José Molina Puerta
Hu Reina Sofía, Córdoba, Spain.

Introduction
Obesity is a major health problem and a risk factor for the development of other diseases. However, there are morbid obese subjects of long evolution that can be considered metabolically healthy obese, whose existence is in doubt for many clinicians.
Objetive
To analyze if there are differences in cardiovascular risk between metabolically healthy (MHO) and sick obese (MSO), matched by age, sex and body mass index (BMI).
Material and methods
We include patients who underwent bariatric surgery in our hospital. We divided them into two groups (MHO and MSO), matched by age (+/- 3 years), BMI (according to the obesity degrees) and by sex. The MHO were defined because they did not meet any criteria of the ATP III and because they did not have previous cardiovascular disease.
Results
164 patients were included. Basal characteristics were show in table 1. MHO had higher HDL level, lower triglycerides, glucose, HbA1c and lower values of systolic and diastolic blood pressure than MSO. The cardiovascular risk measured by Score was significantly lower in the MHO (0.04±0.19), than MSO (0.26±0.81), *P* 0.019). The same happened with the Framingham scale (MHO 0.04±0.190 vs MSO 4.04±3.66, *P* 0.001)

	MHO	MSO	P-value
Age (years)	38.46±10.40	38.57±10.21	0.946
Sex (♀ - ♂ %)	80.5 – 19.5	80.5 – 19.5	1
BMI (Kg/m^2)	50.51±8.45	50.38±7.64	0.916
Maximum weight (Kg)	136.89±22.35	140.22±28.85	0.348
Lost exccess wetht. (%)	59.81±22.59	56.47±23.12	0.378
Dyslipidemia (%)	0	19.6	0.001
Total colesterol (mg/dl)	175.42±34.61	176.49±39.43	0.855
HDL –c (mg/dl)	57.71±9.33	43.59±10.59	0.000
LDL –c (mg/dl)	109.26±28.08	118.46±35.06	0.066
Triglycerides (mg/dl)	90.07±30.70	115.44±6.76	0.002
DM (%)	0	34,3	0.001
Glucose (mg/dl)	89.62±7.70	105.35±38.74	0.000
HbA1c (%)	5.70±0.58	6.29±1.64	0.020
HTA (%)	0	36,6	0.001
TA S (mmHg)	119.19±8.14	128.79±19.06	0.000
TA D (mmHg)	71.68±6.62	78.33±13.57	0.000
Smoke (%)	22	23.2	0.454

Conclusions
In our series, MHO have a lower cardiovascular risk both for the scale and for Framinghan, adjusting for age, sex and degree of obesity.

Menopausal hormone therapy is associated with reduced fat mass and in particular a significant decrease of the intravisceral abdominal fat, the OsteoLaus cohort

Georgios Papadakis[1], Didier Hans[2], Peter Vollenweider[3], Elena Gonzalez Rodriguez[1,2], Gerard Waeber[3], Pedro Marques-Vidal[3] & Olivier Lamy[2,3]
[1]Service of Endocrinology, Diabetes and Metabolism,Lausanne University Hospital, Lausanne, Switzerland; [2]Center of Bone diseases, Lausanne Univesity Hospital, Lausanne, Switzerland; [3]Service of Internal Medicine, Lausanne University Hospital, Lausanne, Switzerland.

Background
We previously showed that menopausal hormone therapy (MHT) favorably affects both bone density and microarchitecture with persistent benefit after its withdrawal (1). Looking for indirect factors contributing to bone effects, we investigated the relation between MHT and changes on fat and lean (muscular) tissue. Existing results on MHT and body composition are conflicting and large cohort studies are lacking.
Material and methods
The OsteoLaus cross-sectional population-based study includes 1'500 women aged 50 to 80 years (Lausanne, Switzerland). Current or past MHT use was assessed by questionnaire. Body composition evaluation by DXA was performed in a subgroup ($n=1094$). After exclusion of participants with hormone modifying treatments, the remaining women were divided in 3 groups based on MHT status: Never (NU, $n=549$), Current (CU, $n=216$) and Past (PU, $n=288$) Users.
Results
The 3 groups differed in age: 66.8±6.3, 62.6±6.7 and 61.3±7.9 years for PU, CU and NU respectively. Average time since MHT withdrawal in PU was 8.5 years. All the results were age-adjusted. CU exhibited lower BMI (−0.9 kg/m^2), compared to NU ($P=.02$). In particular, reduced intravisceral and android fat was noted (CU vs PU, $P=.02$ and .03 respectively). Total fat mass tended to be lower for CU ($P=.06$) with absolute values of 22.0±0.5 and 23.3±0.5 kg in CU and NU respectively. PU did not present any benefit regarding fat tissue in comparison with NU. That was the case even when only early MHT discontinuers (<2 years) were analyzed. There was no difference between groups regarding gynoid fat mass. Both CU and PU showed did not statistically exceed NU regarding total or regional lean mass nor muscle strength assessed by handgrip measurement. Assessment of caloric intake and physical activity did not reveal differences that could explain MHT-related fat mass reduction.
Conclusion
MHT is associated with less adiposity, due to reduction in android fat mass. The significant decrease of intravisceral fat mass in CU is of particular interest, given the strong link of the latter with cardiovascular risk. In contrast to our previous data for bone parameters, the benefit of MHT for fat mass reduction is not preserved in PU.

P557

Effect of surgical weight loss on the inflammatory hematological parameters in short term

Hilal Nemli[1], Gürcan Kısakol[2], Sinem Devrim Küçüksaraç Kıyıcı[2], Metin Güçlü[2] & Nizameddin Koca[2]
[1]Yenişehir Devlet hastanesi, Bursa, Turkey; [2]Sağlık Bilimleri Ün. Bursa Yüksek İhtisas EAH, Bursa, Turkey.

Introduction
In obesity, MPV is found higher compared to healthy controls. It was found that the level of NLR was predictive of the development of type 2 diabetes with high sensitivity and specificity in morbid obese patients. PLR is a new biological indicator that can assess the presence and severity of inflammation. However, in obese patients PLR was not found to associate with degree of of obesity or ratio of weight loss. Regarding the platelet count (PC) in obesity, conflicting results were reported. In some, although increased, the platelet counts were still in the normal range in obese patients.
Aim
In this study we aimed to observe the effect of surgical weight loss on Inflammatory hematological parameters and to observe the correlation between weight loss rate and hematological parameters.
Materials and methods
Eighty patients were included into the study and blood samples were taken at preop and at 3rd and 6th months.
Results
Decreases in NLR and MPV both 3rd and 6th months were statistically significant. PLR did not change at both 3rd and 6th months compared to baseline but PC was significantly lower at both 3rd and 6th months. Correlation analysis did not demonstrate any correlation between weight loss rate and MPV, NLR and PC but did with PLR at 3rd month however at 6th month there was no correlation between all the hematologic parameters and weight loss.

MPV	P
3. mo→0. mo	<0.001
6. mo→0. mo	0.008
NLR	P
3. mo→0. mo	<0.001
6. mo→0. mo	0.001
PLR	P
3. mo→0. mo	0.666
6. mo→0. mo	0.870
PC(10^3/ml)	P
3. mo→0. mo	<0.001
6. mo→0. mo	<0.001

Discussion
We studied preoperatively and postoperatively MPV, NLR, PLR, PLT changes in patients who underwent bariatric surgery. Post op values demostrated improvement in MPV, decrease in NLR, PLT at 3rd and 6th months, but we observed that these changes did not correlate with weight loss rates. These data are consistent with the literature and show that the inflammation formed by obesity regresses after surgery. The fact that the changes in these parameters are independent of the weight loss rates suggests that our data primarily represent early results and secondly it may be the effect of individual metabolic differences.

Carotidintima-mediacomplexthickness and sex steroid levels in severly obese women of reproductive age

Milina Tančić-Gajić, Miomira Ivović, Ljiljana Marina, Zorana Arizanović, Marija Ilievski, Aleksandra Kendereški, Dragan Micić & Svetlana Vujović
Faculty of Medicine, University of Belgrade, Serbia Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia.

Introduction
Obesity is often accompanied by comorbidites predisposing atherosclerosis. Carotid intima-media complex thickness (CIMT) is consisdered as a marker of initial asymptomatic atherosclerosis. The relationship of sex hormones to obesity and atherosclerosis has been extensively studied.
Objective
The objective of the study was to analyze the correlation CIMT and sex steroid levels in severly obese pre-menopausal women.
Methods and patients
This was a cross-sectional clinical study. The study included 65 severely obese pre-menopausal women aged 35.0±8.7 years with Body Mass Index (BMI) ≥35 kg/m^2. Anthropometric parameters and reproductive hormones were measured. Carotid intima-media thickness (CIMT) was assessed using a high-resolution B-mode ultrasound system. The average of maximal values of the right and left CIMT were used as a mean CIMT value.
Results
Anthropometric, hormonal and CIMT data was as follows: TT 124.1±24.0 kg, BMI 47.8±9.2 kg/m^2, waist circumference 127.6±17.9 cm, hip circumference 138.5±17.6 cm, FSH 8.1±3.4 IU/l, LH 4.8±2.9 IU/l, estradiol 196.4±109.0 pmol/l, testosterone 2.48±2.9 nmol/l, SHBG 23.1±12.0 nmol/l, androstendione 2.25±1.2 ng/ml, DHEAS 5.2±3.6 μmol/l, CIMT 0.44±0.1 mm. There was significant correlation between CIMT and waist circumference ($P<0.05$), without significant corelation between CMIT and sex steroid levels ($P>0.05$).
Conclusion
Obesity, especially central obesity has the crucial influence on carotid intima-media complex thickness and cardiovascular events in the future.

Effect of pre-gestational weight and gestational weight gain in women with gestational diabetes controlled with medication on pregnancy outcome-is recommended weight gain too liberal?

Ronit Koren[1,2,3], Yuval Hochman[1,3], Shlomit Koren[3,4], Tomer Ziv-Baran[3,5] & Yifat Wiener[2,3]
[1]Department of Internal Medicine A, Assaf Harofeh Medical Center, Zerifin, Israel; [2]Division of Maternal Fetal Medicine, Department of Obstetrics and Gynecology, Zerifin, Israel; [3]Sackler Faculty of Medicine, Tel-Aviv University, Tel Aviv, Israel; [4]Diabetes unit, Assaf Harofeh Medical Center, Zerifin, Israel; [5]Department of Epidemiology and Preventive Medicine, School of Public Health, Tel Aviv, Israel.

Aim
The aim of this study was to evaluate the effect of pre-gestational body mass index (BMI) and gestational weight gain (GWG) on adverse pregnancy outcomes in women with gestational diabetes mellitus (GDM) controlled with medication.
Methods
We conducted a retrospective cohort study of women with singleton pregnancies, diagnosed with GDM and treated with glucose lowering agents that were followed and gave birth between 2005–2015 in the Assaf Harofeh medical center, Israel.
Results
There were 280 women who met inclusion criteria. Mean maternal age was 33.92±5.2; 64.8% had a family history of DM and 39.7% had a history of GDM in previous pregnancies. Classification and regression tree method identified four groups according to adverse outcomes, consisted of 74 women with pre-gestational BMI below 25, 98 women with BMI 25–31, 90 women 31–39 and 18 women above 39. Respectively, the mean GWG was 12 kg (8–16), 11 kg (8–15), 7.5 kg (3.75–11) and 5 kg (-1.5–11.5). Mean GWG was significantly ($P<0.001$) different between groups. The risk for composite maternal and neonatal adverse outcomes was higher in the groups of BMI 25–31 (73.5%) and 31–39 (83.3%) in comparison to BMI <25 (51.4%) and 39< (55.6%), $P<0.001$. In the subgroup of women with pre-gestational BMI of <25, weight gain of more than the median resulted in odds ratio of 2.75 (1.07–7.08, p=0.036) for adverse pregnancy outcomes compared with women who gained less than the Mean GWG. When adjusted for potential confounders, the odds ratio for adverse outcome in women with BMI <25 who gained above the median weight increased to 4.8 (1.6–14.5, $P=<0.001$). Maternal age was independently associated with adverse outcomes in women with BMI 25–39 but not above 39, though this subgroup was relatively small.
Conclusion
Maternal obesity is related to adverse pregnancy outcomes. Moreover, GDM women with normal pre-gestational BMI who gained weight according to latest institute of medicine recommendations still experienced adverse outcomes. It is possible that weight gain recommendations for this group are too liberal.

The effects of endurance exercise training on chemerin, apelin, and visfatin in metabolically healthy obese young males

Sang Bae Lee, Jung Hye Kim, Kahui Park, Ji Sun Nam, Shinae Kang, Jong Suk Park, Chul Woo Ahn & Yu-Sik Kim
Yonsei University College of Medicine, Gangnam Severance Hospital, Seoul, Republic of Korea.

Purpose
This study investigated the exercise-induced changes in novel adipokines (visfatin, chemerin, and apelin) related to obesity and metabolism, and their correlations with the changes in the measures of obesity and glucose homeostasis after the 8-wk exercise intervention.
Methods
Forty metabolically heathy obese young males were randomly assigned either to control (*C*, $n=12$) or exercise group (*Ex*, $n=28$). The subjects in exercise group participated in an 8-wk supervised endurance exercise training program and they

completed four sessions of treadmill running at 65-75% of their maximal oxygen consumption to burn approximately 600 Kcal per session. Anthropometric measures, various metabolic serum markers and the serum concentrations of total adiponectin, high molecular weighted adiponectin, leptin, visfatin, chemerin, and apelin were assessed at pre- and post-intervention.
Results
Serum levels of visfatin, chemerin, and apelin were significantly more decreased in *Ex* compare to *C* group during 8-wk intervention (-5.96 ± 6.07 vs. 0.75 ± 2.29 ng/mL, −26.64 ± 40.15 vs. 19.0 ± 43.61 ng/mL and −129.47 ± 138.01 vs. 83.08 ± 153.39 pg/mL, *respectively*, all $P < .05$). The change in serum apelin level was significantly correlated with the changes in fasting plasma insulin (FPI, $\beta = 0.672$), homeostasis model for insulin resistance (HOMA-IR, $\beta = 0.603$) and β-cell function (HOMA-β, $\beta = 0.696$), and quantitative insulin sensitivity check index (QUICKI, $\beta = -0.613$, *all* $P < 0.05$). These correlations remained after the adjustment for the confounders. The changes in visfatin and chemerin showed significant correlations with the changes in obesity measures.
Conclusions
Endurance exercise induced significant changes in serum concentrations of visfatin, chemerin and apelin in metabolically healthy obese young males. These changes seem to be involved in the etiology of obesity and glucose homeostasis

Absence of leptin signaling during development causes metabolic and neuronal disturbances in adult life

Jose Donato Jr., Angela Ramos-Lobo, Isadora Furigo & Pryscila Teixeira
Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil.

The hormone leptin is required for the energy balance regulation. However, leptin also controls many other biological functions. Among these actions, some authors suggest that leptin exhibits neurotrophic effects in early life and plays a key role in the development of neurocircuitries that regulate energy metabolism. However, the precise role of leptin during development is still unclear. Thus, our study had the objective to investigate the consequences of the absence of leptin signaling during development. For this purpose, a LoxP-flanked transcription-blocking cassette was inserted in the *Lepr* gene to generate mice *Null* for the leptin receptor (LepR). This mouse was bred with animals expressing Cre-ERT2 fusion protein under the human ubiquitin C promoter sequence. Consequently, tamoxifen injections can induce Cre Recombinase activity and restore LepR gene expression in LepRNull-Ubi mice. Adult LepRNull and LepRNull-Ubi mice were morbidly obese and hyperphagic, as expected. LepR reactivation in 10 week old animals caused a robust decrease in food intake and body weight only in LepRNull-Ubi mice. While LepRNull mice remained unresponsive to leptin, an acute leptin injection was able to induce STAT3 phosphorylation in the hypothalamus of LepRNull-Ubi mice after tamoxifen treatment and reduce their food intake to a similar extent than control lean (Ubi) mice. Six weeks after LepR reactivation, food intake of LepRNull-Ubi mice was completely normalized. However, LepRNull-Ubi mice remained heavier and had higher body adiposity and leptinemia than Ubi mice, possibly due to a partial recovery in their energy expenditure. This defect is not explained by weight loss since LepR reactivation before the onset of obesity (4 weeks of life) could not prevent the suppressed energy expenditure of LepRNull-Ubi mice. In contrast, the insulin resistance exhibited by the reactivation of LepR in adult mice was no longer apparent when the reactivation occurred in younger LepRNull-Ubi mice, suggesting a weight loss-induced effect. Hypothalamic mRNA levels of AgRP and NPY were restored in LepRNull-Ubi mice, but POMC and CART expression remained suppressed. Notably, LepR reactivation in adult animals increased brain mass, but was not enough to normalize it. Conversely, the neural projections from the arcuate nucleus (ARH) to the paraventricular nucleus were completely restored in adult LepRNull-Ubi mice to levels found in lean control mice. In summary, we provided novel and substantial evidence that leptin signaling during early life is required for the energy homeostasis in adulthood, but not via the development of ARH neural projections.

The relationship between arterial stiffness and obesity in kidney transplant recipients

Alparslan Ersoy[1], Nizameddin Koca[2], Barış Şensoy[3], Sümeyye Güllülü[3] & Canan Ersoy[4]
[1]Uludağ University Medical Faculty, Department of Nephrology, Bursa, Turkey; [2]University of Health Sciences, Bursa Yuksek Ihtisas Training and Research Hospital, Bursa, Turkey; [3]Uludağ University Medical Faculty, Department of Cardiology, Bursa, Turkey; [4]Uludağ University Medical Faculty, Department of Endocrinology and Metabolism, Bursa, Turkey.

Obesity and cardiovascular disease (CVD) risk in recipients increase after kidney transplantation due to immunosuppressive drugs, non-traditional risk factors related to immunosuppressive drugs or chronic kidney disease (CKD). Inflammation, endothelial dysfunction, arterial stiffness (AS) and vascular calcification are common complications contributed to the development of CVD in patients with CKD. We aimed to evaluate the relationship between AS and obesity in transplant recipients.
Methods
This cross-sectional study conducted in consecutive 62 patients who underwent kidney transplantation. Our cohort excluded patients with coronary artery disease and heart failure. The patients were divided into three groups according to body mass index (BMI, kg/m^2): normal weight (<25, $n=28$, 8 males), overweight (25-29.9, $n=23$, 16 males) and obese (≥ 30, $n=11$, 5 males). Laboratory tests, high sensitive C-reactive protein (hsCRP), left ventricle mass index (LVMI), left ventricular hypertrophy (LVH) and AS (large vessel elasticity index-C1, small vessel elasticity index-C2) were measured.
Results
Median dialysis duration and follow-up time after transplant were 33 and 20 months, respectively. The mean age of overweight group was higher than that of normal weight group ($P < 0.026$). Donor age, blood pressures, dialysis and transplant durations, hypertensive and diabetic patient ratios, serum creatinine, uric acid, glucose, total cholesterol, LDL cholesterol, HDL cholesterol, triglyceride and urinary albumin excretion levels in the groups were comparable. Being smoker (27.3%, $P=0.020$) and family obesity history (63.6%, $P=0.002$) in obese group was higher than other groups. The CKD-EPI glomerular filtration rate in normal weight group (66.7 ± 17.7 ml/min) was higher than those of overweight (54.3 ± 19.7 ml/min, $P=0.017$) and obese (61.2 ± 19.5 ml/min, $P=0.047$) groups. The LVMI and hsCRP level in obese group was higher than that of normal weight (140 ± 28 vs. 117 ± 31 g/m^2, $P=0.003$ and 3.46 ± 6.2 vs. 11.9 ± 14.2 mg/l, $P=0.037$, respectively). There was no significant difference in proteinuria, anemia, LVH and valvular calcification ratios, C1 and C2 measurements between three groups.
Conclusion
We found that LVMI and hsCRP were higher in obese recipients, but not non-traditional risk factors such as anemia, proteinuria and AS.

Anti-obesity effect of green alga sulphated polysaccharide on high fat diet

Rihab Ben Abdallah[1], Boulbaba Kolsi[2], Mouna Elleuch[2], Mouna Mnif[2] & Mohamed Abid[2]
[1]Faculty of Sciences of Sfax, 3038 Sfax, Tunisia., Sfax, Tunisia; [2]Department of endocrinology, CHU Hedi Chaker, Sfax, Tunisia.

Obesity is considered as an exceeding life style disorder notably in developing countries and it is prevailing at a frightful speed in new world countries as a result of fast food intake, causing raised blood cholesterol levels, which in turn can damage many systems in the body. The present study investigates the hypolipidemic effects of sulphated polysaccharide obtained from Codium fragile (CFSP) in induced obese rats (HFD). The results showed an increase in body weight of HFD rats by 21.56% as compared to control normal rats. Moreover, serum lipase activity underwent an increase which led to an increase in the levels of total cholesterol (T-Ch), triglycerides (TG) and low density lipoprotein cholesterol (LDL-Ch) in serum associeted with a decrease in the level of high density lipoprotein cholesterol (HDL-Ch) in untreated HFD rats. This diet has disrupted the antioxidant status by decreasing the activities of antioxidant enzymes (superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPX)) and subsequently an increase in thiobarbituric acid reactive substances (TBARS) level in liver and kidney of obese rats. All these disturbances are significantly corrected by CFSP administration with no fatty deposits in the liver and a protective effect against renal histological alteration. This confirms the important role of this polysaccharide in the fight against oxidative stress and the prevention of hyperlipidemia.

Serum oxytocin in elderly patients with metabolic syndrome

Salwa Hosny, Meram Bekhet, Ahmed Bahaaeldin & Mary Mahrous
Ain Shams University, Cairo, Egypt.

Background
The term metabolic syndrome refers to a cluster of associated symptoms composed of impaired fasting glucose, abdominal obesity, hypertension, and dyslipidaemia. Metabolic syndrome is associated with an increased risk of cardiovascular and diabetes-associated morbidity and mortality. Further, there is evidence that metabolic syndrome is an effective and simple clinical tool for identifying high-risk subjects predisposed to cardiovascular diseases and diabetes mellitus type2. Oxytocin regulates food intake, carbohydrate and lipid metabolism. They respond to an increase in glucose and insulin (which occurs in metabolic syndrome as a powerful example for hyperinsulinemia due to insulin resistance and consequently hyperglycaemia) with an increase in intracellular [Ca2+] and increased oxytocin release.
Aim of the work
To assess the relationship between serum oxytocin levels and presence of metabolic syndrome in patients over 55 years old.
Patient and Methods
Our study was conducted on 90 elderly subjects (aged 55 years old or more). They were divided into Group I, 60 patients fulfilling the criteria of metabolic syndrome, according to guidelines from the National Heart, Lung, and Blood Institute (NHLBI), group II, 30 healthy subjects as a control group. All participants were subjected to history taking, full clinical examination, anthropometric measurement and laboratory investigations including Fasting plasma glucose, 2 hours plasma glucose, HbA1c, serum cholesterol, triglycerides, LDL-c, HDL-c, insulin resistance by HOMA, serum oxytocin.
Results
Serum oxytocin levels in patients with metabolic syndrome were significantly higher (Median = 25 (21–56.5)) than in control group (Median = 19.5 (16–23) with ($Z = -2.700$ and $P = 0.007$). Its level was significantly positively correlated with Waist circumference ($r = 0.336$, $P = 0.009$), DM duration ($r = 0.604$, $P = 0.000$), and FPG ($r = 0.411$, $P = 0.000$). It was found that the level of oxytocin in men was higher (IQR = 50(22–80) than in women (IQR = 22(20–25) with ($Z = -3.398$ $P = 0.001$).
Conclusion
Serum oxytocin is higher in elderly patients with metabolic syndrome with significant rise more observed in males than in females.

Study on some biochemical parameters in peripheral blood of animals upon diet-induced obesity and insulin resistance modeling

Anvar Abduvaliev, Shakhlo Musaeva, Sanobar Irgasheva, Mukhammadjon Mustafakulov, Elvira Ibragimova & Talat Saatov
Institute of Bioorganic Chemistry, Uzbekistan Academy of Sciences, Tashkent, Uzbekistan.

The work was initiated to study some biochemical parameters in peripheral blood of animals upon diet-induced obesity and insulin resistance modeling. Obesity was induced in BALB/c mice by keeping them on the high- carbon diet for 13 weeks. The commercially available kits were used to assay glucose, alkaline phosphatase, creatine kinase and cholesterol; concentrations of testosterone were measured by the enzyme immunoassay. The high carbon diet in BALB/c mice served as a basis for the animal model with experimental obesity and insulin resistance. In the animals the diet-induced obesity was accompanied with body mass gain (by 48%), increase in the levels of glucose (6.68 ± 0.94 versus 2.43 ± 0.52 mmol/l in the control animals) and total cholesterol (2.02 ± 0.52 versus 0.54 ± 0.20 mmol/l in the control animals), and reduction in their insulin sensitivity. The high carbon diet used in the study was established to cause changes in blood serum biochemical parameters. The activities of alkaline phosphatase and creatine kinase were found to decline to be 64.9 ± 7.88 IU versus 347.6 ± 13.8 IU and 56.6 ± 2.11 U/l versus 364.0 ± 10.37 U/l in the controls, respectively. The changes could associate with injuries of hepatocytes due to type 2 diabetes mellitus onset. Concentrations of testosterone in the animals under study were found increased (66.05 nmol/l versus 34.33 ± 3.38 nmol/l in the controls), and obesity, lipid metabolism disorders and insulin resistance are thought to induce the increase of the hormone in the experimental animals' blood serum. All the changes above could be attributed to the compensatory mechanisms triggering restoration of functional and proliferative activity of hepatocytes. The 13-week high-carbon diet in BALB/c mice was shown to cause diet-induced obesity with insulin resistance accompanied by changes in some biochemical parameters of experimental animals' blood.

Does follicle stimulating hormone effect adiposity in patients with hypergonadotrophic hypogonadism: a retrospective study

Ibrahim Demirci, Cem Haymana, Nese Ersoz Gulcelik, Yusuf Alper Sonmez, Coskun Meric, Aydogan Aydogdu, Orhan Demir & Omer Azal
Gulhane Training and Research Hospital, department of Endocrinology and Metabolism, Ankara, Turkey.

Introduction
Recent studies showed that post-menopausal osteoporosis and weight gain starts at the perimenopause stage, a period characterized by relatively stable estrogen and rising FSH levels. FSH is found to be associated with adiposity in women, which is also a great risk factor for type 2 DM. There is also a sharp increase in visceral adiposity during this life stage, which coincides with the emergence of disrupted energy balance and reduced physical activity. There is consistent evidence from basic and preclinical research that the disruption of estradiol signaling, accelerates fat accumulation. The excess fat seems to accumulate disproportionately in the abdominal region and leads to insulin resistance and dyslipidemia. We therefore decided to investigate the FSH – BMI and waist circumference relation in a small group of male patient with hyper gonadotrophic hypogonadism, who have similar laboratuary values of perimenopausal women.
Methods
A total of 230 young male patients with newly diagnosed hyper gonadotrophic hypogonadism (mean age: 21.16 ± 1.79 years) were analyzed retrospectively. 77 of the patients had a diagnose of Klinefelter's syndrome, the rest didn't have any genetic testing. Only the measurements at the time of diagnosis (untreated) were taken. FSH, LH, total and free testosterone, estradiol were analyzed for possible correlation with BMI and waist circumference.
Results
The mean values of FSH, LH and total testosterone were all compatible with the diagnosis of hypergonadothrophic hypogonadism (Table 1). Only a slight negative correlation was found between LH and BMI. When we limited the analysis to the patients with documented diagnosis of Klinefelter's syndrome the results were similar.
Conclusion
We didn't find any significant correlation between FSH and abdominal circumference, waist circumference or BMI. The younger age and low BMI values of our study population may play role on these results. The lack of body fat

distribution analysis, either by bio-impedance or radiologic imaging techniques was also a limitation of our study.

Table 1 The demographic and metabolic parameters of the patients with hypergonadotrophic hypogonadism

	Patients (n = 230)
Age (yr)	21.16 (±1.79)
Diag. of KS (n,%)	77 (33.5%)
BMI (kg/m$^{2)}$	22.35 (±4.03)
AC (cm)	60.06 (±35.61)
WC (cm)	71.02 (±39.51)
Total-C (mg/dl)	163.46 (±30.42)
FSH (mIU/ml)	347.64 (±33.66)
LH (mIU/ml)	27.21 (±14.85)
T.Testosterone (ng/dl)	0.93 (±0.93)

Psychosocial aspects and hygiene-dietetic habits in a group of patients in follow-up before bariatric surgery

Daniel Medina Rivero[1], Isabel María Mateo Gavira[1], Amelia Rodríguez Martín[2], Laura Larrán Escandón[1] & Manuel Aguilar Diosdado[1]
[1]Hospital Universitario Puerta del Mar, Cádiz, Spain; [2]Universidad de Cádiz, Cádiz, Spain.

Objectives
To evaluate the psychosocial aspects and the common dietary habits in a group of patients in follow-up in specific consultation of bariatric surgery prior to the intervention.
Methods
Cross-sectional study of patients in follow-up in the specific morbid obesity consultation of the University Hospital Puerta del Mar (Cádiz) not intervened.
Results
110 patients were analyzed, of which 68.2% are women, with an average age of 44.63 years. Regarding the level of studies, 30.2% had only primary studies and 47.7% had primary and secondary studies. 32.7% were unemployed and 8.4% were disabled. 55.5% acknowledge regular physical exercise and 56.1% recognize a fast food intake, although 83.6% refer to a healthy and balanced diet. The majority (83.7%) have good family support.
Conclusions
The profile of patients undergoing follow-up in our consultation prior to bariatric surgery usually presents a basic level of studies -primary and secondary-, relatively frequent in the case of unemployment or early retirement. Only half of patients exercise regularly and bad dietary habits persist in terms of fast food intake.

Psychosocial aspects and hygiene-dietetic habits in a group of patients intervened for bariatric surgery

Daniel Medina Rivero[1], Isabel María Mateo Gavira[1], Amelia Rodríguez Martín[2], Laura Larrán Escandón[1] & Manuel Aguiliar Diosdado[1]
[1]Hospital Universitario Puerta del Mar, Cádiz, Spain; [2]Universidad de Cádiz, Cádiz, Spain.

Objectives
To evaluate the psychosocial aspects and the common dietary habits in a group of patients undergoing bariatric surgery.
Methods
Cross-sectional study of patients in follow-up in the specific consultation of morbid obesity of the University Hospital Puerta del Mar (Cádiz) intervened, at 6–12 months of follow-up.
Results
88 patients were analyzed, of which 70.5% ($N = 62$) are women, with an average age of 45.01 ± 8.55 years. The BMI before the intervention was 47.29 ± 5.54 kg/m^2 being 34.52 ± 6.48 kg/m^2 at present. Regarding the level of studies, 30.2% had only primary studies. 26.7% were unemployed and 15% disabled. 81.6% admit regular physical exercise and 12.9% admit fast food intake after surgery, and 20.7% continue with snacking throughout the day. The majority (90.7%) has good family support.
Conclusions
The profile of the patients in our area usually presents a basic level of studies -primary and secondary-, in situations of unemployment or early retirement, and after surgery they show changes in their dietary habits and physical exercise, although they frequently persist with inadequate habits.

Body mass index versus visceral adiposity index as predictors for dyslipidemia and liver stiffness in HIV/HCV co-infected patients with liver fibrosis

Carolina García-Figueras-Mateos & Manuel Cayón-Blanco
Hospital SAS Jerez de la Frontera, Jerez de la Frontera, Spain.

Introduction
Association between liver fibrosis and body mass index (BMI) is well known in HIV/HCV patients, is linked to worse lipid profile and is widely used to predict liver fibrosis in this population. Nevertheless, recent studies show a stronger link between dyslipidemia and liver stiffness with visceral adiposity index (VAI) in general population. The main aim of this study was to investigate the accuracy of VAI and BMI as predictors for liver fibrosis and dyslipidemia in a cohort of HIV/HCV co-infected patients.
Methods/design
We conducted a cross-sectional study in a cohort of HIV/HCV co-infected outpatients attended in our hospital. Demographic, clinical and anthropometric variables were collected. Liver stiffness was measured by transient elastography (Fibroscan™). Liver fibrosis was defined as the presence of a liver stiffness ≥ 7.2 kPa. Patients were classified as obese, if BMI ≥ 30 kg/m^2, and as normal weight if BMI between 18.5 – 24.9 kg/m^2. Further, patients were divided into three groups according to VAI score tertiles.
Results
Thirty-nine HIV/HCV co-infected individuals (97.4% male, mean age: 47.4 ± 5.2 years) were included. Patients with normal weight compared to obese individuals had significantly lower HDLc levels (41.4 ± 8.8 mg/dl vs 51.4 ± 16.7 mg/dl; $P = 0.03$) but no differences were found in other lipid profile, in a univariate analysis. When the cohort was classified according to VAI tertiles, patients with the highest VAI score (third tertile) had higher triglycerides serum levels (233.1 ± 81.2 vs 85.9 ± 31.1 mg/dl; $P < 0.001$), higher LDLc levels (115.1 ± 40.1 vs 78 ± 22.2 mg/dl; $P = 0.006$) and lower HDLc (34.4 ± 8.2 vs 60.9 ± 16.7 mg/dl; $P < 0.001$). Though both BMI and VAI showed a positive correlation with liver stiffness, this association was stronger for VAI than the observed for BMI ($r = 0.392$; $P = 0.004$ vs $r = 0.291$; $P = 0.035$).
Conclusions
According to our results, VAI score is more accurate than BMI to predict liver fibrosis and dyslipidemia in this population. We propose routine use of VAI to identify HIV/HCV co-infected patients at risk for liver fibrosis and/or dyslipidemia.

Effect of 8 weeks of hypocaloric diet and physical activity on thyroid hormones, irisin and insulin sensitivity in obese otherwise healthy subjects.

Adela Penesova, Boris Bajer, Zofia Radikova, Andrea Havranova, Richard Imrich & Miroslav Vlcek
Institute of Clinical and Translational Research, Biomedical Research Center of Slovak Academy of Sciences, Bratislava, Slovakia.

Hypothyroidism is associated with modest weight gain, but there is a lack of clarity regarding subclinical hypothyroidism and obesity. Studies with bariatric surgery showed that 15–25% of extremely obese subjects had subclinical hypothyroidism. Therefore the goal of this *study* was to evaluate the effect of intensified life style intervention on insulin sensitivity, irisin concentration and thyroid function parameters.

Methods

A randomized interventional clinical study (NCT02325804) included life style intervention: hypocaloric diet (30% restriction of calories) and physical activity 150 minutes/week. Before and after 8 weeks of intervention all patients underwent complete medical examination (measurement of physical fitness, resting metabolic rate (RMR), body composition analysis, oral glucose tolerance test, parameters of lipid metabolism, irisin concentration and thyroid function parameters. Insulin sensitivity was evaluated according to the homeostasis model assessment of insulin resistance (HOMA-IR) and insulin sensitivity indices according Matsuda and Cederholm were calculated (ISIMat and ISICed).

Results

So far 43 patients (14 M/29 F, mean age 43 ± 12 yrs., body fat % 36 ± 6) finished the intervention. At baseline 9 patients had thyroid stimulating hormone (TSH) in the range 2.5–5.0 ng/ml, indicating subclinical hypothyroidism. The average reduction of body weight was 6.8 ± 4.9 kg (0–15 kg; $P \leq 0.0001$), Insulin sensitivity improved (IR HOMA 2.71 ± 3.90 vs. 1.24 ± 0.83; $P = 0.01$; ISIMat 6.64 ± 4.38 vs. 8.93 ± 5.36 $P \leq 0.001$; ISICed 59.1 ± 21.4 vs. 64.7 ± 22.2 $P = 0.03$). TSH significantly decreased after intervention (2.04 ± 1.24 vs. 1.69 ± 0.81 $P = 0.03$) and free thyroxine remained unchanged (13.7 ± 2.7 vs. 13.4 ± 2.9, $P = 0.7$). Plasma irisin significantly decreased after intervention (233 ± 66 vs. 167 ± 88 ng/ml; $P \leq 0.001$) and positively correlated with ISImat, however only after intervention (P 0.05).

Conclusion

Results of our study are in line of previous results about beneficial effect of intensive life style changes on insulin sensitivity and thyroid function. Novel view indicates that changes in thyroid-stimulating hormone (TSH) could well be secondary to obesity. Supported by grants APVV 15-0228; VEGA 2/0161/16

The comparison of different obesity criterias in kidney transplant recipients

Alparslan Ersoy[1], İlknur Arslan[1], Özen Öz Gül[2], Soner Cander[2] & Canan Ersoy[2]
[1]Department of Nephrology, Uludağ University Medical Faculty, Bursa, Turkey; [2]Department of Endocrinology and Metabolism, Uludağ University Medical Faculty, Bursa, Turkey.

Weight gain and obesity are frequent problems after kidney transplantation. Potential causes of weight gain are use of immunosuppressive drugs and changes in life style such as dietary intake and insufficient physical activity. This study aimed to evaluate the different general and abdominal obesity criterias and post-transplant weight changes in kidney transplant recipients.

Methods

This prospective study included consecutive 112 (62 females, 50 males) patients, with a mean age of 41.5 ± 11.1 years who underwent kidney transplantation. Obesity was assessed by calculating body mass index (BMI) for general obesity, and waist (WaC) and hip (HC) circumferences and waist to hip ratio (WHR) for abdominal obesity. Optimal WaC is evaluated and categorized differently by different organizations like International Diabetes Federation (IDF) and World Health Organization (WHO). Obesity classification according to WaC defined by IDF and WHO was ≥ 94 and ≥ 102 cm for males and ≥ 80 and ≥ 88 cm for females, respectively. WHR was considered as obese if > 0.9 for males and > 0.8 for females.

Results

The measurements of the patients were obtained during 4 years after transplantation. The median weight gain was 3.6 kg at 1st year ($n = 112$), 5.6 kg at 2nd year ($n = 112$), 7.8 kg at 3rd year ($n = 112$) and 8.5 kg at 4th year ($n = 95$, 43 males, 52 females). The median values at pre-transplant and post-transplant 1st, 2nd, 3rd and 4th years were 23.4, 25.0, 25.8, 25.8 and 26.5 kg/m^2 for BMI; 84, 89, 89, 90 and 90 cm for WaC; 94, 98, 98.5, 100 and 100 cm for HC; 0.9, 0.89, 0.89, 0.92 and 0.91 for WHR, respectively. The increases in these parameters were significant when compared to pretransplant values except WHR ($P < 0.001$). When the obesity criterias were evaluated separately, obese ratios for BMI, WaC-IDF, WaC-WHO and WHR were 7.1%, 42.9%, 20.5% and 75.9% at pre-transplant, 14.3%, 56.3%, 38.4% and 75.9% at 1st year, 20.5%, 55.4%, 41.1% and 69.6% at 2nd year, 24.1%, 58%, 40.2% and 68.8% at 3rd year, and 27.4%, 56.8%, 45.3% and 70.5% at 4th year, respectively.

Conclusion

We observed a continous weight gain in our kidney transplant patients. When different obesity criterias were taken into account, the ratios of obese patients also varied. The ratios were higher by WHR and lower by BMI. After the second year there was a relative slowdown at the rate of obesity increase. Abdominal obesity seemed to be a more prominent problem compared to general obesity.

Effect of the rs12324955 polymorphism of the FTO gene in the intervention for the weight reduction in obese patients with the use of technological resources

Antonio Ballesteros Martín-Portugués[1], Susana Rodrigo Cano[1,2], Susana Tenes Rodrigo[1], Carolina Ortega Azorín[3,4], Eva María Asensio Márquez[3,4], José Vicente Sorlí Guerola[3,4], Dolores Corella Piquer[3,4] & Juan Francisco Merino Torres[1,2]
[1]Endocrinology and Nutrition Department, Hospital Universitari i Politècnic La Fe, Valencia, Spain; [2]Unidad Mixta de Investigación en Endocrinología, Nutrición y Dietética, Instituto Investigación Sanitaria La Fe, Valencia, Spain; [3]Preventive Medicine Department, School of Medicine, University of Valencia, Valencia, Spain; [4]CIBER Fisiopatología de la Obesidad y Nutrición, Valencia, Spain.

Introduction

Obesity is a multifactorial disease in whose genetic factors are involved. The integration of this factors will allow to state personalized prevention strategies, where the constant contact with the patient will have a greater success for them to follow up recommendations. Continuous technological changes allow bigger accessibility to communication, having platforms with remote control.

Objective

Assessing the effectiveness of an Intelligent Platform of Biomedical to Monitor, Treat and Personalized Prevention in obesity and cardiometabolic risk versus a non technological intervention for the obesity treatment, considering the participants' genetic characteristics.

Materials and methods

71 obese subjects, between 18 and 65 years, of the PREDIRCAM study (prospective cohortes intervention study) were included. Recruitment, the participants were randomized in intensified intervention group (control group) or technological intensified intervention group (intervention group). The follow up was made for 6 months. Anthropometric data, biochemical data and environmental data with questionnaires were obtained. The rs12324955 of the FTO gene was determined through TaqMan probes.

Results

88.7% were women. After 6 months, data of 46.5% to the sample were obtained, because the rest had not completed the full term yet. After 6 months of intervention the subjects showed less weight, hip and BMI (weight: -4.39 ± 5.61 kg; hip: -3.93 ± 5.11 cm; BMI: -1.63 ± 1.96 kg/m^2, $P < 0{,}001$ in all cases) . When dividing according to the intervention group, technological group subjects showed also a significant reduction in the total and c-LDL according to the baseline (total cholesterol: -15.47 ± 21.01 mg/dl, $P = 0.008$; c-LDL: -10.19 ± 14.77 mg/dl $P = 0.015$). According to the genotype rs12324955 no differences were found in at baseline, but after intervention the carriers of the A allele showed a light greater decrease in weight that GG homozygotes (A carriers: -5.88 ± 5.00 kg, $P < 0.001$; GG homozygotes: -3.96 ± 2.95 kg, $P = 0.002$). After segmenting by the intervention group, everybody lost weight significantly after intervention, these differences were more significant in carriers of the A allele of the technological group (non technological: carriers A: -6.07 ± 6.41 kg $P = 0.022$, GG homozygotes: -4.50 ± 4.78 kg $P = 0.047$; technological: carriers A: -5.66 ± 3.16 kg $P = 0.001$, GG homozygotes:- 3.49 ± 3.33 kg $P = 0.021$).

Conclusion

The intensive intervention to modify the obese people's lifestyle shows a decrease in weight loss, being this intervention more effective in rs12324955 carriers A subjects and with intervention done using technological applications.

Novel indicator of abdominal obesity strongly associated with cardiovascular disease

Dong Sun Kim[1], Jung Hwan Park[1], Ohk-Hyun Ryu[2], Wankyo Chung[3] & Shinje Moon[2]
[1]Department of Internal Medicine, Hanyang University College of Medicine, Seoul, Republic of Korea; [2]Division of Endocrinology and Metabolism, Hallym University College of Medicine, Chuncheon-si, Republic of Korea; [3]Department of Public Health Science, Graduate School of Public Health, Seoul National University, Seoul, Republic of Korea.

Obesity is one of the leading causes of elevated cardiovascular disease (CVD) mortality and morbidity. Several indicators of abdominal obesity such as body mass index (BMI) and waist circumference (WC) are available. BMI and WC have limitations in stratifying cardio-metabolic risks. Another obesity measure, A Body Shape Index (ABSI), has been introduced but its applicability remains limited. To address this, the z-score of the log-transformed ABSI (LBSIZ) was recently developed. This study aimed to examine the ability of LBSIZ, compared to that of WC and BMI, to predict CVD risk. The study included participants who were recruited from the Korean Genome and Epidemiology Study, a population-based cohort study and followed for 10 years. A total of 8485 participants were analysed. The area under the curve was 0.633 (95% confidence interval [CI]: 0.611-0.655) for LBSIZ, 0.604 (95% CI: 0.580-0.627) for WC, and 0.538 (95% CI: 0.514-0.562) for BMI. In multivariate Cox regression analysis, BMI and WC showed the lowest risk for CVD events in 2nd decile and an overall J-shaped relationship with their deciles (p-trend: <0.001 WC vs 0.03 BMI). However, LBSIZ showed the lowest risk for CVD events in the 1st decile and a linear relationship across its deciles (p-trend of <0.001). The results of this study indicate that participants with high level of LBSIZ have significantly higher rate of CVD events than those with low level and LBSIZ is more strongly associated with CVD risk than BMI and WC in general population.

The effect of laparoscopic sleeve gastrectomy on kidney function

Bianca Leca[1], Elisabeta Sava[1,2], Iulia Soare[2], Sorina Martin[1,2], Bogdan Smeu[3], Catalin Copaescu[3], Anca Sirbu[1,2] & Simona Fica[1,2]
[1]Endocrinology Department, Elias University Clinical Hospital, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Ponderas Academic Hospital, Bucharest, Romania.

Introduction
Higher body mass index (BMI) has been associated with adverse renal outcomes, including chronic kidney disease (CKD), progression to end-stage renal disease (ESRD), nephrolithiasis and renal cell cancer. Several studies have shown that weight loss following bariatric surgery has a positive effect on kidney function, mediated by a reduction in proteinuria, glomerular hyperfiltration and improvements in blood pressure and insulin resistance. The aim of this study was to examine the changes in estimated glomerular filtration rate (eGFR) in a group of morbidly obese patients 6 months after laparoscopic sleeve gastrectomy (LSG).
Materials and methods
221 severely obese patients (65.2% women, mean age $=41.97\pm11.24$ years, mean BMI $=44.7\pm8.57$ kg/m^2) underwent a complete clinical and biochemical assessment before and 6 months after LSG. The variation of parameter values(Δ) was expressed in percentages out of the preoperative values. Kidney function was calculated using the MDRD-4 formula.
Results
Of the 221 patients, 53.4% were hypertensive, 25.4% had diabetes and 53.8% presented with metabolic syndrome (MetS). Six months after surgery BMI declined to 31.84 ± 6.7kg/m^2 ($P<0.001$) and an excess weight loss (EWL) of 73.86 ± 30.33% was observed. In addition, the prevalence of CKD risk factors decreased significantly to 34.3%, 8.5% and 14% for hypertension, diabetes and MetS respectively ($P<0.001$). Regarding the kindney function, 71.5% of patients had an eGFR lower than 90 ml/min/1.73 m^2, with mean eGFR $=82.15\pm18.50$ ml/min/1.73 m^2. Postoperatively, eGFR increased to 86.33 ± 20.4 ml/min/1.73 m^2 ($P<0.001$) and 60.2% had an eGFR <90 ml/min/1.73 m^2 ($P<0.001$). Negative correlations were established between ΔeGFR and ΔBMI ($r=-0.195$, $P=0.004$), Δcalcium levels ($r=-0.273$, $P=0.038$). Patients were further examined after being separated by baseline eGFR (<90 and >90 ml/min/1.73 m^2). Comparing the two groups, the patients from the eGFR <90 group were older (44.03 ± 10.09 vs 36.81 ± 10.2 years, $P<0.001$) and had a lower BMI (43.69 ± 7.97 vs 46.8 ± 9.6 kg/m^2, $P=0.014$). While a slight increase in eGFR was noticed in the <90 group (73.29 ± 10.38 preoperatively vs 79.28 ± 15.87 ml/min/1.73 m^2 postoperatively, $P<0.001$), there was no change in the >90 group (104.38 ± 15.48 preoperatively vs 104.02 ± 20.13 ml/min/1.73 m^2 postoperatively, $P=0.068$).
Conclusion
Bariatric surgery is an effective method of improving CKD risk factors such as hypertension and diabetes and weight loss is associated with an increase in eGFR in patients with renal impairment.

Prevalence and pathophysiology of early dumping in patients after primary Roux-en-Y gastric bypass during a mixed meal tolerance test

Ragnild Wijma[1], Marloes Emous[1], Erik Totté[1], Merel van den Broek[2], Albert Wolthuis[3], Anke Laskewitz[3], Anneke Muller-Kobold[4], Bruce Wolffenbuttel[5] & André van Beek[5]
[1]Department of Bariatric and Metabolic Surgery, Heelkunde Friesland Groep, Medical Center Leeuwarden, Leeuwarden, Netherlands; [2]Department of Endocrinology, Medical Center Leeuwarden, Leeuwarden, Netherlands; [3]Certe Laboratories, Medical Center Leeuwarden, Leeuwarden, Netherlands; [4]Department of Laboratory Medicine, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [5]Department of Endocrinology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands.

Introduction
The endocrinologist is confronted with an increasingly large population of postbariatric patients who present with endocrine problems. One of these is early dumping, a complication that may be the result of increased entero-endocrine activity. To address the prevalence of early dumping and to gain further insight into its pathophysiology, we performed a Mixed Meal Tolerance Test (MMTT) in a random sample of patients after Roux-en-Y gastric bypass (RYGB).
Methods
A random sample of 140 patients who underwent primary RYGB surgery between 2008 and 2011 were invited to participate. In total, 46 patients completed the MMTT with a standardized liquid supplement. The Dumping Severity Score (DSS) for early dumping was assessed every 30 minutes. Blood samples were collected at baseline, every 10 min during the first half hour and at 60 min after the start. The samples were assessed for hematocrit and glucagon-like-peptide-1 (GLP-1), Peptide YY (PYY), and vasoactive intestinal peptide (VIP).
Results
The prevalence of a high suspicion of early dumping based on the DSS was 26%. There was no difference in blood pressure and heart rate between patients with high or low suspicion of early dumping. The percentual change in hematocrit was slightly higher in patients with high suspicion of early dumping. No differences were seen for inactive GLP-1 and VIP between patients with high or low suspicion of early dumping. Patients with high suspicion of early dumping had higher levels of active GLP-1 and PYY.
Conclusion
The prevalence of complaints suggestive of early dumping in a random population of patients at mid-term post-RYGB is 26 percent in response to a mixed meal. Postprandial increases in both GLP-1 and PYY are associated with complaints of early dumping, suggesting gut L-cell overactivity in this syndrome.

Weight loss and metabolic parameters after laparoscopic sleeve gastrectomy

Elisabeta Sava[1,2], Bianca Leca[1], Anca Sirbu[1,2], Iulia Soare[1,2], Sorina Martin[1,2], Bogdan Smeu[3], Catalin Copaescu[3] & Simona Fica[1,2]
[1]Endocrinology Department, Elias Emergency University Hospital, Bucharest, Romania; [2]Endocrinology Department, 'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania; [3]Ponderas Academic Hospital, Bucharest, Romania.

Introduction
Obesity, defined as a BMI ≥30 kg/m^2, is the most common chronic metabolic disease in the world and its prevalence has strongly increased. *Obesity* is associated with multiple comorbidities, including cardiovascular disease, hypertension, insulin resistance, dyslipidemia, type 2 diabetes, sleep apnea and

certain cancers. Bariatric surgery is the most effective treatment for severe obesity and produces dramatic and durable weight loss. The aim of the study was to evaluate weight loss and changes in the metabolic profile in a period between 6 months and 5 years after laparoscopic sleeve gastrectomy (LSG).
Methods
An observational study was conducted. It included 40 patients having morbid obesity and undergoing bariatric surgery, respectively LSG. Preoperative and postoperative data (6 months and 5 years) was collected and analyzed. The following parameters were measured: weight, height, waist, hip; BMI and EWL (excess weight loss) were calculated. Fasting glucose, insulin level, uric acid and lipid profile were measured and HOMA IR (homeostasis model assessment of insulin resistance) was calculated.
Results
Preoperatively, the mean age was 44.55 ± 8.95 years, mean BMI was 46.61 ± 10.06 kg/m^2, mean waist was 131.25 ± 20.30 cm, and mean cholesterol level was 210 ± 41.47 mg/dl. After 6 months, mean BMI decreased to 33.95 ± 7.28 kg/m^2 and to 35.11 ± 7.28 kg/m^2 after 5 years. On average, patients had EWL of 66.71% at 6-month follow-up and 57.29% at 5-years follow-up. There were remarkable improvements in lipid profile. The mean levels of high-density lipoprotein (HDL) cholesterol after surgery were significantly higher (41.95 ± 9.53 mg/dl vs 47.42 ± 12.09 mg/dl six months after surgery vs 54.25 ± 12.52 mg/dl after 5 years, $P < 0.05$). Triglycerides, uric acid and glucose levels were significantly reduced from 159.69 ± 66.644 mg/dl, 7.39 ± 4.81 mg/dl and 118.64 mg/dl at baseline to 108.23 ± 79 mg/dl, 5.07 ± 1.55 mg/dl, and 86.08 ± 9.72 mg/dl after 6 months and 105.24 ± 51.86 mg/dl, 5.49 ± 1.25 mg/dl, and 93.96 ± 13.73 mg/dl after 5 years. After 6 months, HOMA index improved from 7.62 ± 7.25 to 1.44 ± 1.59 ($P < 0.05$). Compared to baseline, improvement was maintained in the data collected after 5 years (2.97 ± 3.58, $P < 0.05$).
Conclusion
LGS determines both short and long term improvements in weight loss and metabolic parameters.

Anthropometric and body composition evolution in individuals in weight loss

Bruno Sousa
[1]Universidade Lusófona de Humanidades e Tecnologias, Lisbon, Portugal; [2]CBIOS – Center for Research in Biosciences and Health Technologies, Lisbon, Portugal.

Introduction
A large proportion of the Portuguese population has overweight and the process of weight loss is often focused solely on weight. However, it is essential that there is a good evolution of the body composition, namely in the decrease of fat.
Objective
Evaluate the anthropometric and body composition evolution in a group of individuals followed for a weight loss.
Methodology
This sample consisted of 30 adult and who were being followed up at a weight loss clinic. An initial anthropometric evaluation (M0) was performed by weight (kg) and height (cm) and body mass index (kg/m^2) was calculated. Body composition was assessed using a tetrapolar bioimpedance (Bodystat 1500) and it was prescribed a structured individual food plan. The body composition evaluation included fat (%), fat mass (kg), fat free mass (%) and total body water (%). The same evaluations were performed after 1 month (M1) and 2 months (M2).
Results
This sample consisted of 70% ($n = 21$) of female subjects and had a mean age of 40 (± 12.9) years. The percentage of the mean weight lost to M1 was 3.44 (± 3.38)% and up to the M2 of 5.53 (± 3.13)%. The mean body fat percentage lost to M1 was 3.69 (± 5.86)% and up to M2 of 6.93 (± 5.50)%. Women lost a higher percentage of weight, but men lost a higher percentage of fat. Weight and fat loss were always higher in the first month in both sexes.
Conclusions
Despite the evolution of weight loss, it is in the decrease of body fat that there is a greater evolution, and it is in the first month that the positive evolution in these parameters was more pronounced.

Free and dipeptide forms of L-glutamine supplementation attenuate parameters of oxidative stress and nonalcoholic fatty liver disease (NAFLD), and improve glucose metabolism in insulin resistant Ob/Ob mice

Jaqueline Santos Moreira Leite, Hilton Takahashi, Layanne Cabral da C de Araujo, José Donato Junior, Vinicius Fernandes Cruzat & Ângelo Rafael Carpinelli
Department of Physiology and Biophysics, Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil.

Introduction
The availability of the body's most abundant amino acid, glutamine is compromised in obesity-associated diabetes. This may impair glucose metabolism by increasing hepatic insulin resistance, oxidative stress and the development of nonalcoholic fatty liver disease (NAFLD).
Objective
Evaluate the effects of free and dipeptide (DIP, L-alanyl-L-glutamine) forms of L-glutamine on glucose metabolism, biomarkers of oxidative stress and NAFLD in insulin resistant Ob/Ob mice.
Methods
C57/BL6 adult male mice were distributed into five groups: WT and Ob/Ob (CTRL) mice receiving water, and Ob/Ob mice supplemented with either DIP or free L-glutamine (GLN). The supplements were offered in a 4% drinking water solution for 40 days prior to euthanasia. Glucose metabolism was evaluated by glucose and insulin tolerance tests (GTT and ITT, respectively) performed at the end of the 40 days of supplementation. After euthanasia plasma glutamine, glucose, insulin and triglycerides (TG) concentrations were analysed. TG, reduced and oxidized glutathione (GSH and GSSG, respectively), TBARS, translocation of NRF-2, and histology were measured in the liver. Statistical differences between groups were determined using One-way ANOVA with post-hoc Tukey HSD.
Results
In plasma, GLN and DIP supplements increased glutamine concentration, while fasting TG, glucose and insulin levels reduced compared to the CTRL group ($P < 0.05$). GLN and DIP supplements also improved GTT and ITT responses. This result could be linked to an observed increase in glutamine and GSH concentration, NRF-2 translocation, as well as reduced TG and fat droplets deposition in the liver ($P < 0.05$).
Conclusion
Free and DIP forms of L-glutamine supplementation attenuate parameters of oxidative stress and NAFLD, and improve glucose metabolism in insulin resistant Ob/Ob mice.

Role of IGF1 in regulation of SOD 1 expression and mTOR/S6K signaling in heart of obese male rats

Milan Obradovic, Julijana Stanimirovic, Anastasija Panic, Sonja Zafirovic & Esma Isenovic
Department for Molecular Genetics and Radiobiology, Vinca Institute of Nuclear Science, University of Belgrade, Belgrade, Serbia.

Aim
Obesity is associated with activation of mammalian target of rapamycin (mTOR)/ribosomal S6 kinase (S6K) signaling pathway that promotes cardiac hypertrophy, insulin resistance, endothelial dysfunction and oxidative stress. Although activation of mTOR/S6K has a harmful effect, simultaneously it represents adaptive metabolic response that protects cells from excessive nutrient intake. Insulin like growth factor-1 (IGF1) exerts pleiotropic action on heart promoting vasorelaxation, antiinflammatory, antiatherogenic and antioxidant activity. Aim of this study was to evaluate how IGF1 treatment influences mTOR/S6K signaling pathway and SOD 1 expression in heart of obese rats.
Methods
Male Wistar rats were fed with standard laboratory diet or high fat (HF) diet (42% of fat) for 12 weeks and then half of all animals were treated intraperitoneally with one dose of IGF1 (50 μg/kg). After 24 h of treatment the animals were sacrificed and hearts excised. The expression of SOD 1 protein and phosphorylation and expression of mTOR and p70 S6K proteins were measured in rat heart lysates by Western blot method.

Results
Decreased level of SOD1 protein was observed in hearts of normally fed rats treated with IGF1 ($P<0.01$) and obese rats ($P<0.001$), while it was increased in IGF1 treated obese rats. The activation of cardiac mTOR was increased in normally fed IGF1 treated rats ($P<0.001$) and obese rats ($P<0.05$), while it was decreased in IGF1 treated obese rats ($P<0.01$). The results also show that activation of p70 S6K was increased in heart of normally fed rats treated with IGF1 ($P<0.01$) and obese rats ($P<0.05$), while it was decreased in IGF1 treated obese rats ($P<0.05$).
Conclusion
Results suggest that in heart of obese rats, IGF1 mitigates detrimental effects of obesity by increasing expression of SOD 1 protein, probably through mechanism that involves downregulation of mTOR/p70 S6K signaling pathway.

Introduction
Insulin resistance (IR), a pathological state of low sensitivity to insulin in humans and animlas, is closely associated with type 2 diabetes mellitus, obesity and cardiovasculare dieseas. IR can be quantified using detailed protocols, such as the euglycemic-hyperinsulinemic clamp (EC) technique and the intravenous glucose tolerance test, or based on indices derived from the oral glucose tolerance test. Although these indices showed greater association with the incidence of diabetes, they allow no personalized estimation of the individual risk and cannot be used for monitoring of the individual changes in the insulin resistance. The modification of nutritional pattern is one of the first steps of prevention the IR and associated diseases. Diets with increased intake of branched chain amino acid lead to increase in IR in animals and human, possibly via disruption of insulin signaling in skeletal muscle. Here we aimed to investigate the changes in the plasma metabolome during constant insulin infusion. Additionally, the correlations between baseline concentrations of metabolites and changes of IR, which was measured in the EC-experiments, after high-protein and control diet were studied.
Methods
In the first study (NCT00774488), middle-aged healthy obese subjects ($n=14$) underwent saline infusion and/or EC at a steady-state capillary plasma glucose concentration of 4.4 mmol/l. Plasma metabolites were measured using time-of-flight gas chromatography-mass spectrometry (GC-TOF/MS) technique. In the second study (NCT00579657), a randomized, controlled nutritional intervention (18-weeks) was conducted in 72 non-diabetic participants (overweight/obese: 29/43) with at least one further risk factor of metabolic syndrome. Participants were group-matched and allocated to 4 isoenergetic supplemented diets: control; high cereal-fiber; high-protein; or moderately increased cereal-fiber and protein (MIX). Whole-body IR was measured using EC. Plasma metabolome and IR were studied at 0, 6 and 18-weeks.
Results
Eight metabolites: altrose, asparagine, glycerol-2-phosphate, gulose, heptadecanoic acid, phenylalanine, pyroglutamate and talose correlated with high-protein diet-induced changes in IR and significantly changed during EC.
Conclusions
Multimarker strategy with use of plasma metabolic profiling appears to be a useful tool for both the assessment of IR and the 'metabolic signature of insulin effects' (i.e. doping control of elite athletes) in humans.

"A new life in a new body": the evolution of pregnancy following bariatric surgery in obese females

Mayra Velasquez Arevalo, Enzamaria Fidilio, Mireia Guerrero, Neus Castillejo, Marta Comas, Maria Goya, Oscar Gonzalez, Jordi Mesa, Cristina Hernandez, Rafael Simó & Andreea Ciudin
Vall d'Hebron University Hospital, Barcelona, Spain.

Introduction
Maternal obesity (MO) increases the risk of gestational and neonatal complications. Bariatric surgery (BS) is currently the most effective long-term treatment of MO. The sustained weight loss after BS reduces the risk of maternal comorbidities during pregnancy. Nevertheless, BS is associated with an important risk of nutrients deficiency, and some data indicate that might increase the risk of prematurity and low birth weight. The objective of the present study is to evaluate the evolution of the pregnancy ending with a living child following bariatric surgery in obese females following BS in our center.
Methods
We performed a retrospective observational study by reviewing the medical records of MO females that underwent BS between January 2004 and October 2016 in our center and that had a pregnancy that finalized with a living child.
Results
A total of 20 pregnancies that finalized with a living child were registered. All the pregnancies were spontaneous, after 3.4 ± 2.9 years following BS. The BMI pre-BS was 43.9 ± 4.7 kg/m^2. At the moment of conception the maternal mean age was 33 ± 4.6 years and the BMI was 30.6 ± 4.9 kg/m^2. The course of gestation was normal and full term in all cases. Of all the patients, 8 (40%) underwent Sleeve gastrectomy (SG) and 12 (60%) underwent Roux-en-Y gastric bypass (RYGB). Gestacional diabetes was registered in 3 (15%) cases, similar to the general population. The birth weight of the children was 3032 ± 3.81 g. The incidence rate of small-for-gestational age birth was 25%, higher than 10% in the general population. There were no significant differences between the two surgical techniques regarding the evolution of pregnancy and the need of vitamin supplements. No neonatal complications were observed.
Conclusion
In our study BS did not increased the risk of prematurity or complications during pregnancy. We found an increased risk of small-for-gestational-age compared with general population.

Temporal analysis of the HFD consumption in the mice small intestine physiology: possible correlation between metabolic disorders and HFD-induced obesity

Camille Perella Coutinho, Tatiana Carolina Alba-Loureiro, Andressa Harumi Torelli Hijo & Francemilson Goulart-Silva
Department of Physiology and Biophysics – ICB/USP, São Paulo, Brazil.

Introduction and aim
Obesity is a public health problem characterized by metabolic and endocrine disorders. Currently, it has been observed an increase of the obesity induced by high fat diet (HFD) and, considering that small intestine is the most important absorptive site of the nutrients, it is very interesting to evaluate the impact of HFD intake on that first place of nutrients entry, that is, the small intestine. Taken into account that dyslipidemia and hypertension are obesity common findings, we attempted to evaluate whether HFD consumption affects the microsomal triglyceride transfer protein (MTTP) and NHE3, since they promote triglyceride and sodium absorption, respectively. Considering that nutrients absorption could contribute to body weight gain and obesity, we also evaluated the nutrients

transporters: SGLT1, GLUT2 and GLUT5 for carbohydrates, PEPT1 for peptides, FATP4, CD36/SR-B2 and NPC1L1 for long-chain fatty acids and cholesterol, respectively.
Methods
C57bl/6 male mice were fed standard diet (LFD) or HFD for three, six, nine or twelve weeks. At the end of each time, mice were killed and small intestine was removed and opened to detach the absorptive epithelium from mucosa. The epithelium was homogenate in appropriate lysis buffer and submitted to Western blotting (WB) technique for MTTP, NHE3, SGLT1, GLUT2, GLUT5, PEPT1, FATP4, CD36/SR-B2 and NPC1L1. PKA and PKC activities were analyzed by ELISA.
Results
HFD consumption from third up to 12th week increased MTTP and NHE3 content, but decreased the GLUT2, PEPT1 and NPC1L1. HFD also decreased the CD36/SR-B2 content, but only from 9th up to 12th week. HFD did not affect the SGLT1, GLUT5 and FATP4 content at any time-course studied. HFD also decreased PKA and PKC activities at 12th week.
Conclusion
Considering that mice began to gain weight from the third week after HFD consumption, the reduction of GLUT2, PEPT1 and NPC1L1 might interpose to the nutrients uptake, which could constitute a counter-regulation mechanism to limit the gain weight and adiposity. That condition could be reinforced by the decreased CD36/SR-B2 content observed from ninth week of HFD. Regarding the increase of MTTP and NHE3, we could infer that MTTP contributes to dyslipidemia and NHE3 contributes to hypertension both observed in the obesity and that constitutes the risk factors for cardiovascular diseases. Besides, all of these alterations might be linked to the reduction of PKA and PCK activities, at least for the NHE3, whose activity is known to be decreased by PKA.

Effect of gastrointestinal hormones on bone metabolism after bariatric surgery

Nuria Vilarrasa[1,2], Andreu Simó-Servat[1], Anna Casajoana[3], Fernando Guerrero-Pérez[1], Carmen Gómez-Vaquero[4], Eva Martinez[1], Nuria Virgili[1], Rafael López-Urdiales[1], Sonia Fernández-Veledo[2,5] & Joan Vendrell[2,5]
[1]Endocrinology and Nutrition Department, Barcelona, Spain; [2]CIBERDEM, Barcelona, Spain; [3]Bariatric Surgery Unitb, Spain; [4]Rheumatology Department, Hospital Universitari de Bellvitge-IDIBELL, Barcelona, Spain; [5]Hospital Universitari de Tarragona Joan XXIII, Institut d'Investigacions Sanitàries Pere Virgili, Tarragona, Spain.

Introduction
In vitro and animal studies have suggested that changes in the secretion of ghrelin, PYY, GLP-1, GLP-2 can influence bone metabolism. An increase in osteoblastic differentiation has been observed after the administration of ghrelin and GLP-1. GLP-2 has been associated with a decrease in bone resorption and PYY inversely with markers of bone formation.
Objective
To analyze the association of gastrointestinal hormones with changes in bone mineral density (BMD) and markers of bone resorption after metabolic gastric bypass (mRYGB), Sleeve Gastrectomy (SG) and Greater Curvature Plication (GCP).
Material and methods
Prospective, controlled and randomized study in patients with type 2 diabetes and morbid obesity. Forty-five patients aged 49.4 years, BMI 39.4 $\pm$ 1.9 kg/m^2, were randomized to mRYGB, SG and GCP. Body composition, BMD and phospho-calcium metabolism, initially and at 12 months were studied. Standard meal test with determination of glucose, insulinemia, GLP-1, GLP-2 and fasting analysis of PYY, ghrelin and glucagon were performed before and at 12 months after surgery.
Results
At 12 months after surgery, the percentage of BMD loss in the lumbar spine (LS) was higher after mRYGB compared to SG and GCP (7.29 $\pm$ 4.6 vs. 0.48 $\pm$ 3.9 vs. 1, 2 $\pm$ 2.7%, $P < 0.05$) with similar findings at the femoral neck. The concentrations of osteocalcin were higher after mRYGB. The secretion of GLP-1 and GLP-2 increased after surgery, but only significantly in mRYGB. Before surgery, PYY and glucagon correlated with CMO (bone mineral content) in LS ($r = 0.325$, $P = 0.044$ and $r = 0.374$, $P = 0.018$). One year after surgery, the AUC for GLP-1 was associated with BMD in LS ($r = -0.335$, $P = 0.049$) and ghrelin with CMO at that level ($r = -0.41$, $P = 0.010$). In the regression analysis, the type of surgery was the main determinant of the decrease in BMD but not the hormonal changes.
Conclusions
Changes in gastrointestinal hormones seem to play a role although not relevant in bone metabolism after bariatric surgery.

Instituto de Investigación Biomédica de Málaga (IBIMA), Complejo Hospitalario de Málaga (Hospital Regional Universitario)/Universidad de Málaga., Malaga, Spain.

Introduction and aims
Autophagy is an essential process for cell homeostasis that implies recycling and degradation of damaged organelles and long-lived proteins. It is induced during caloric restriction (in order to obtain energy) or other stress-inducing conditions. Autophagy is initiated by autophagosome formation, a double-membrane vesicle which engulfs cellular components and delivers them for degradation by fusing with lysosomes. Thus, proper autophagy regulation favours cell survival thanks to the turn-over of damaged organelles and energy supply. Although obesity is frequently associated with other metabolic diseases, there are also non-diabetic obese subjects as well as diabetic or insulin-resistant non-obese individuals. For this reason, it has been suggested that functional state of adipose tissue (AT) rather than AT size is which determines the development of metabolic disorders. Despite the fact that previous associations have been described between AT autophagy activation and obesity and diabetes, these paradoxical phenotypes have not been studied, and it has only been analyzed a few of the molecules implied in AT autophagy regarding obesity and carbohydrate disorders in human studies.Thus, the aim of this study was to analyze AT gene expression of molecules implied in the different steps of autophagy according to the degree of obesity and the glycemic status.
Methods
The expression of genes implied in the different steps of autophagy in visceral and subcutaneous AT (VAT and SAT, respectively) was analyzed in the study subjects classified according to their BMI in lean, oeverweight, obese and morbidly obese subjects and to their glycemic status (defined by glucose levels and the insulin resistance index HOMA-IR) in diabetic/high-insulin-resistant subjects (D/HIR) and low-insulin-resistant subjects (LIR).
Results
Comparisons between D/HIR and LIR subjects paired by BMI showed a diminished VAT and SAT expression of genes related to autophagosome formation in patients with alterations in glucose metabolism which was more noticeable in morbidly obese subjects. Significant differences regarding BMI were only found in LIR subjects, having LIR lean subjects higher VAT and SAT expression of these genes than LIR subjects with higher BMI. Gene expression of molecules implied in autophagosome induction and elongation correlated significantly and negatively with HOMA-IR and BMI.
Conclusion
Low autophagy induction in AT is related to a higher susceptibility to insulin resistance and diabetes development which is more noticeable in extreme obesity.

A newly inflammatory marker in overweight patients: triggering receptor expressed on myeloid cellls-1

Aydin Cifci[1], Senay Arikan Durmaz[2], Kubra Oklu[1], Didem Katar[3], Hakan Boyunaga[4] & Nermin Dindar Badem[4]
[1]Department of Internal Medicine, Kirikkale, Turkey; [2]Department of Endocrinology and Metabolism, Kirikkale, Turkey; [3]Department of Chest Disease, Ankara, Turkey; [4], Kirikkale, Turkey.

Introduction and aims
Triggering receptor expressed on myeloid cells 1 (TREM-1) is secreted by macrophage and neutrophils in adipose tissue to released pro-inflammatory chemokines and cytokines. TREM-1 activate Janus kinase 2 (JAK2), protein kinase B (PKB/AKT) and extracellular signal related kinase (ERK1/2) pathways and upregulate the expression of genes involved in the inflammatory response. We aimed to indicate associations with serum TREM-1 levels, total sulfhydryl (SH) and malondialdhyde (MDA) levels in overweight patients.
Materials and methods
Twenty overweight patients (OG) and 20 age-matched healthy subjects (CG) (BMI 27.4 ± 1.2 vs 21.9 ± 2.3 kg/m^2, $P = 0.0001$, respectively) were included in our study. Anthropometric measurements were performed by bioelectrical impedance (TANITA BC-420 MA). All complete blood count, biochemical and hormonal analysis associated with obesity were performed by automatic analyzer. Serum TREM-1 levels, MDA and SH levels were measured by Elisa. Homeostasis model assessment (HOMA-IR) was used as a formula: Fasting insulin (mU/l)xfasting glucose (mmol/l)/22.5
Results
Serum TREM-1(225.1 ± 313.1 vs 45.2 ± 17.0 pg/ml, $P = 0.046$, respectively) and SH levels (75 ± 148.9 and 31.7 ± 18.7 µmol/l ($P = 0.033$), respectively) in OG significantly higher than CG. There was no significant difference in serum MDA levels. HOMA-IR in OG was significantly higher than CG (3.2 ± 3.4 vs1.9 ± 1.6). A positive correlation was found between TREM-1 and fat mass ($r = 0.412$, $P = 0.008$).
Conclusions
We first demonstrated to high serum TREM-1 level might early inflammatory marker in overweight patients.

Pre-operative evaluation of obese patients admitted for bariatric surgery: observations suggesting the introduction of a detailed screening for thyroid diseases

Daniela Gallo[1], Silvia Ippolito[1], Jessica Sabatino[1], Giovanni Veronesi[2], Francesco Frattini[3], Eugenia Dozio[1], Eugenia Trotti[1], Valeria Cortinovis[4], Federico Giussani[4], Adriana Lai[1], Lorenza Sassi[1], Maria Laura Tanda[1], Marco Ferrario[2], Luigi Bartalena[1] & Eliana Piantanida[1]
[1]Department of Medicine and Surgery, University of Insubria, Varese, Italy; [2]Department of Medicine and Surgery, EPIMED Center, University of Insubria, Varese, Italy; [3]Research Center for Endocrine Surgery, Department of Medicine and Surgery, University of Insubria, Varese, Italy; [4]School of Medicine, University of Insubria, Varese, Italy.

Background
So far, guidelines for bariatric surgery do no recommend the universal screening for thyroid diseases, except the TSH measurement in selected patients. However, a possible interplay between obesity (possibly complicated by obesity-related comorbidities) and thyroid diseases has been postulated.
Objective
Aim of the study was to investigate the prevalence of thyroid diseases in a cohort of obese patients, evaluated for bariatric surgery. Methods in the study period 2014–2017, 88 patients (72 women and 16 men, mean age 43 ± 11 years), with second or third class obesity, were consecutively screened at the Outpatients Clinic for the study of Obesity, University of Insubria. All patients had preliminary psychosocial tests, nutritional, surgical and endocrinological evaluations. Beyond the pre-operative analysis recommended by the international and national guidelines, serum TSH, TPOAb and TgAb levels and neck ultrasound were assessed. When clinically appropriate, further tests, such as calcitonin determination and thyroid fine needle aspiration were performed. Thyroid diseases were classified as thyroid autoimmune disease, nodular disease, goiter, primitive hypothyroidism or hyperthyroidism.
Results
45/88 patients were eligible for bariatric surgery. Data were collected on the whole study-population (88 patients). Interestingly, patients that fulfilled the diagnosis of metabolic syndrome (34%) had higher incidence of thyroid diseases ($P = 0.002$). Forty patients out of eighty-eight patients (45.5%) had thyroid diseases (17 new cases, 42.5%). Among patients with known thyroid diseases, 23% were treated with levothyroxine (mean dose 0.86 mcg/Kg body weight/day). Mean thyroid volume was 16.7 ± 6.5 ml in women and 17.5 ± 2.9 ml in men; mean TSH level was 2.1 ± 1.2 µU/ml. According to the results of thyroid ultrasound, 78% of patients had hypoecogenic pattern, 24% (21/88) had goiter (52% previously undiagnosed), while 35% had nodular disease (31/88, new diagnosis in 55% of cases). Fifteen patients had autoimmune thyroiditis (17%), of which 40% was newly discovered. Two patients had differentiated thyroid carcinoma (one new case).
Conclusion
Prevalence of thyroid diseases, especially goiter (24% vs 10% in the general population), was higher in the study-population than that observed in normal-weight patients. Interestingly a high proportion of thyroid diseases were undiagnosed. Moreover the incidence of thyroid diseases was higher in patients with metabolic syndrome. Consistent evidences from large trials are warranted. According to these preliminary data, we suggest the introduction of detailed thyroid screening in pre-operative evaluation of obese patients admitted for bariatric surgery.

Strength training results in reduced fat accumulation and improved blood lipid profile even in the absence of skeletal muscle hypertrophy in obese rats induced by high-fat diet

Catarina Contreiro, Andressa Damiani, Leonardo Caldas, Breno Nogueira, André Leopoldo, Ana Paula Lima-Leopoldo & Lucas Guimarães-Ferreira
Federal University of Espirito Santo, Vitoria, Brazil.

Obesity is a chronic multifactorial disease characterized by accumulation of body fat and is associated with a number of comorbidities, such as diabetes and cardiovascular disease. The treatment of obesity depends to the severity of the disease, however, healthy eating with caloric restriction and physical activity are important strategies. In the present study, we aimed to evaluate the effect of obesity associated with strength training on skeletal muscle morphology, body adiposity and metabolic parameters in a rodent model. 58 male Wistar rats were randomized into two groups: control, fed standard diet (C), and obese, fed a high fat diet (49.2% fat) (Ob). The experimental protocol consisted of 28 weeks, being divided into three moments: M1) induction to obesity; M2) maintenance of obesity and; M3) strength training protocol. After the maintenance of obesity period, animals were randomized into two new groups. Thus, the study was finally composed of four groups: sedentary control (CS), control submitted to the strength training protocol (CT), obese sedentary (ObS) and obese submitted to strength training protocol (ObT). Strength training was performed on a ladder 3 times a week for 10 weeks. High-fat diet was efficient to induce animals to obesity in the second week of the experimental protocol, initiating the period of exposure to obesity. Training protocol did not result in hypertrophy of soleus, tibialis, plantar and FHL skeletal muscles, as neither wet and dry muscle weight nor fiber cross-sectional areas were different among groups. The training protocol used was efficient to increase absolute strength, but the capacity to produce strength seems to be impaired in obesity when relative strength was evaluated. Body weight gain was lower in the groups submitted to strength training compared to sedentary groups (ObT vs ObS, CTF vs CS). High-fat diet-induced obesity resulted at higher body adiposity and blood leptin levels but this was attenuated by training. ObT group presented lower total body fat, adiposity index and blood leptin levels compared to ObS group. ObS blood triglycerides were higher compared to CS and CT, but training reversed this effect in ObT group. Blood total cholesterol and HDL were not different among groups. Therefore, the strength training in obese rats promoted metabolic adaptations and reduction in adiposity even in the absence of muscle hypertrophy.

Association between Leptin gene polymorphisms and plasma leptin level in three consanguineous families with obesity

Mouna Fourati[1], Faten Hadjkacem[1], Dorra Ghorbel[1], Houcem Elomma Mrabet[1], Salwa Sessi[2], Faiza Fakhfakh[3] & Mohamed Abid[1]
[1]Unit of Obesity and Metabolic Syndrome, Department of Endocrinology, Hedi Chaker Hospital, Sfax, Tunisia; [2]Regional Hospital Kerkenah, Sfax, Tunisia; [3]Department of Life Sciences, Faculty of Science of Sfax, Sfax, Tunisia.

Leptin (*LEP*) gene is one of the most promising candidate genes for obesity. The aim of this study was to investigate the impact of *LEP* polymorphisms on obesity, anthropometric and biochemical parameters in a sample of three Tunisian consanguineous families with obesity. Seven single nucleotide polymorphisms (SNPs) in 5′ region of *LEP* gene were genotyped in three consanguineous families including 33 individuals. The previously reported *LEP* SNPs (H1328084, H1328082, rs10487506, H1328081, H1328080, G-2548A and A19G) were evaluated by PCR-RFLP and direct sequencing methods. Single SNP association and haplotype association analyses were performed using the family-based association test (FBAT). To determine allele frequencies of these SNPs in general population, 52 unrelated individuals from the general Tunisian population were also analyzed. Our results showed that H1328084 and A19G SNPs were associated with plasma leptin level (H1328084: A > G, $Z=2.058$, $P=0.039$; A19G: G > A, $Z=2.058$, $P=0.039$). When haplotypes were constructed with these two markers, the risk AA haplotype (frequency 57.1%) was positively associated with plasma leptin level ($Z=2.058$, $P=0.039$). Moreover, SNPs H1328084 and A19G are predicted to modify transcription-factor binding sites. In conclusion, our study provided that two functional variants in 5′ regulatory region of *LEP* gene are associated with plasma leptin level as a quantitative trait. It suggested that H1328084 and A19G have an important role in regulating plasma leptin level.

Quality of life after sleeve gastrectomy

Marwa Omri, Faten Mahjoub, Nadia Ben Amor, Awatef Kacem, Sabeh Bhouri & Henda Jamoussi
National institute of nutrition of Tunis, Tunis, Tunisia.

Aim
Morbid obesity associated with obesity-related diseases has a negative impact on the quality of life. The aim of the study was to assess the impact of bariatric treatment on the quality of life among patients with morbid obesity who underwent sleeve gastrectomy.
Methodology
Thirty obese patients undergoing sleeve gastrectomy were included in our study. Their weight, height, body mass index were measured at baseline and 6 months after surgery. The quality of live was assessed, 6 months after sleeve gastrectomy by the baros quality of life questionnaire.
Results
Mean patient age was 36.77 ± 7.82. Eighty percent of the study patients were women. Average excess weight lost at 6 months was 43.53%. The score obtained by patients in the questionnaire about the improvement in the quality of life showed excellent (7%), very good (37%), good (36%), fair (13%) and failure (7%) results. There was clinical improvement after surgery in all comorbidities investigated. An association ($r=0.564$, $P=0{,}001$) was found between the Baros score and the excess weight lost.
Conclusion
The weight loss was critical to improve the quality of life of patients submitted to sleeve gastrectomy and led to the improvement of the associated comorbidities.

Folic acid status in morbidly obese patients seeking sleeve gastrectomy

Marwa Omri, Faten Mahjoub, Amina Bibi, Sabeh Bhouri, Awatef Kacem & Henda Jamoussi
National Institute of Nutrition of Tunis, Tunis, Tunisia.

Background
A high prevalence of vitamin deficiencies in obese subjects has been reported. Bariatric surgery is the most effective long-term treatment of morbid obesity, but this treatment can result in secondary vitamin deficiency.
Aim
The aim of our study was to evaluate the folic acid status in obese patients before sleeve gastrectomy.
Methods
This was a descriptive study including a population of obese patients reffered to our unit for evaluation for bariatric surgery. Their weight, height, BMI and waist circumference were measured. The basal folic acid blood level were determined. It was considered as normal for levels between 3.89 and 26.8 ng/ml.
Results
Among 30 patients evaluated, females accounted for 80% of the overall sample. Mean patient age was 36.8 ± 7.8 years. Average weight was 137.38 ± 24.32 kg. Average BMI was 50.38 ± 8.58 kg/m^2. Average waist circumference was 138.23 ± 14.97 cm. Mean folic acid blood level preoperatively was 5.03 ± 3.28 ng/ml. About half of the patients (43%) had a folic acid deficiency. Average caloric intake was 3944.53 ± 1683.41 kcal/day. Mean folate intake was 187.87 ± 102.01 µg per day. It was insufficient in 93% of patients. A statistically significant association was found between the folic acid blood level and the daily folate intake. The correlation analysis between anthropometric parameters and folic acid blood level did not show a signifivant statistical association.
Conclusion
Our data suggest that Obesity is a risk factor for folic acid deficiency. This deficiency is likely to worsen after bariatric surgey. Thereby, a preoperative nutritional assessment is important to detect and correct Folic acid deficiency.

Activation of p53 with low doses doxorubicin reduce the acumulation of lipids in two *in vitro* models of liver steatosis

Marcos Fernandez Fondevila[1], Begoña Porteiro Coto[1], Xabier Buque[2], María Jesús González Rellán[1], Uxía Fernández Paz[1], Alfonso Mora[3], Daniel Beiroa[1], Ana Senra[1], Rosalía Gallego[4], Miguel López[1], Guadalupe Sabio[3], Carlos Diéguez[1], Patricia Aspichueta[2] & Rubén Nogueiras Pozo[1]
[1]Department of Physiology, CIMUS, University of Santiago de Compostela, Santiago de Compostela, Spain; [2]Biocruces Research Institute, Bizcaia, Spain; [3]Centro Nacional de Investigaciones Cardiovasculares Carlos III (CNIC), Madrid, Spain; [4]Department of Morphological Sciences of Santiago de Compostela, Santiago de Compostela, Spain.

Introduction
p53 is transcription factor widely known because of its antitumoral actions. New evidences suggest that p53 also play a key role in the regulation of metabolic homeostasis and specifically in the lipid metabolism.
Objective
We hypothesize that the chemical activation of p53 with low doses of doxorubicin could ameliorate the lipid metabolism in *in vitro* models of liver steatosis.
Methods
We treated with low concentrations of doxorubicin two human hepatic cell lines, HepG2 and THLE-2, exposed to oleic acid to induce lipid accumulation. Furthermore, we administered doxorubicin to HepG2 cells downregulating p53 with siRNAs.
Results
The doxorubicin treatment reduced the lipid accumulation in two human hepatic cell lines in a p53-dependent manner. The drug stimulated the lipid oxidation and inhibited the *de novo* lipogenesis at concentrations that did not affect the cell viability or apoptosis.
Conclusion
The activation of p53 with low doses of doxorubicin could provide a new strategy to reduce the lipid accumulation in the liver of patients with hepatic steatosis.

Association of dietary factors and dynamic thiol/disulphide homeostasis in subjects with coronary artery disease

Reyhan Bilici Salman[1], Neşe Ersöz Gülçelik[2] & Tülay Omma[3]
[1]Division of Rheumatology, Department of Internal Medicine – Gazi Unıversity Faculty of Medicine, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Gülhane Training and Resarch Hospital, Ankara, Turkey; [3]Department of Endocrinology and Metabolism, Ankara Training and Resarch Hospital, Ankara, Turkey.

Background
Enviromental factors such as life style changes and dieatary factors become more important on the background of coronary artery disease (CAD). The thiols were the main part of the non-enzymatic antioxidant system in the body and they are the first defensive molecules in elimination of oxidant agents. As a result, thiol levels may be an earlier indicator for CAD. There is limited data on the relation of dietary factors with thiol/disulfide homeostasis in patients with CAD. Therofore the aim of the study was to evaluate relationship between dietary factors and thiol/disulfide homeostasis in patients with CAD.
Methods
Fifty-four patients diagnosed with CAD and 74 healthy volunteers were included in the study. Blood samples were collected for biochemical markers. Nutrition assessment was done once at the time of recruitment; based on previous two days 24 h dietary recall. Serum thiol/disulfide homeostasis was studied with a new and fully automatic analysis method.
Results
There was no age difference between CAD and control groups ($P=0.08$). Also, presences of hypertension, dyslipidemia were similar in all groups. There were significant differences between CAD and healthy volunteers in native thiol ($P=0.000$), total thiol ($P=0.000$), disulfide/native thiol ($P=0.042$), disulfide/total thiol ($P=0.004$), and native thiol/total thiol ($P=0.005$). There were no significant differences in disulfide levels between two groups ($P=0,61$). Patients with known CAD had similar protein ($P=0.09$) and fat intake ($P=0.08$) but had significantly lower energy ($P=0.002$) carbonhydrate intake ($P<0.001$) and dietary fiber intake ($P=0.001$) as compared to control group. Among vitamins; folic acid, niacin, riboflavin, total B6, vitamin A, vitamin C and beta-caroten were similar in CAD and control group except thiamine. ($P=0.047$). There was significantly lower intake of minerals in CAD. Carbonhydrate intake was correlated with native thiol and total thiol levels in CAD patients. ($P<0.001$ and $P<0.001$ respectively). Protein was correlated with native thiol ($P=0.005$) and total thiol levels ($P=0.001$). Also dietary fiber showed relation with native thiol ($P<0.001$)and total thiol levels ($P<0.001$) but did not show any relation with disulphide levels ($P=0.101$). But fat showed relation with only total thiol ($P=0.029$).
Conclusions
In this study oxidation parameters were decreased in CAD patients. Diet is one of the factor affecting CAD and can be related to the oxidation parameters such as thiol/disulfide homeostasis. Increased dietary fiber consumption is associated with increased antioxidant capacity. Carbonhydrate and total dietary fiber intake are associated with thiol/disulfide homeostasis in patients with CAD.

Effects of a combined lifestyle intervention on anthropometric parameters and long-term cortisol after 10 and 75 weeks: a longitudinal study

Simone Janmaat, Mesut Savas, Vincent Wester, Eline van der Valk, Erica van den Akker, Yolanda de Rijke & Elisabeth van Rossum
Erasmus Medical Centre, Rotterdam, Netherlands.

Introduction
The prevalence of obesity is still increasing and is accompanied by significant health problems. High exposure to glucocorticoids, including the stress hormone cortisol, has been suggested to play a role in the development of obesity and associated cardiometabolic derangements. We previously showed that obese persons are exposed to high long-term cortisol levels as measured in scalp hair. It is not known whether these elevated cortisol levels decrease with weight loss. In order to further investigate this relationship, we assessed the longitudinal effects of a combined lifestyle intervention (CLI), on anthropometric parameters and long-term cortisol in obese patients.
Methods
We enrolled 106 adult obese patients (mean age 42.2 years, 73.6% female, mean BMI 40.3 kg/m^2) who were treated at the Obesity Center CGG (Centrum Gezond Gewicht) between October 2011 and March 2016, and had at least one obesity-related comorbidity. All patients underwent CLI, consisting of guided exercising, dietetics, and cognitive behavioural therapy. Anthropometric parameters (weight, BMI, waist circumference) and hair samples (long-term cortisol) were assessed at intake, after 10 intensive weeks, and at the end of the intervention at 75 weeks. Repeated measures ANOVAs were performed to calculate the change over time in weight, BMI, waist circumference and long-term cortisol.
Results
After 10 weeks of intensive CLI, a significant decrease in weight (-6.01 kg (5.1%), $P<0.001$), BMI (-2.05 kg/m^2, $P<0.001$), and waist circumference (-6.76 cm, $P<0.001$) was found. The decline persisted over time and patients were in general able to sustain the loss at the end of the intervention (weight -6.52 kg (5.5%), BMI -2.21 kg/m^2, and waist circumference -7.28 cm, all $P<0.001$). Long-term cortisol levels decreased from 5.31 pg/mg (95% CI 3.88, 6.74) at baseline to 4.59 pg/mg (95% 3.54, 5.63) at 10 weeks, and to 2.87 (95% CI 2.02, 3.72) at 75 weeks. The decrease in long-term cortisol levels after 75 weeks was significant ($P<0.001$).
Conclusions
After a CLI, which yielded sustained weight loss and a decrease in abdominal fat in patients with obesity, long-term cortisol levels significantly decreased. Further research is needed to investigate whether this decrease in long-term cortisol levels is caused by CLI per se, or due to the reduction in weight and whether this decrease is related to cardiometabolic improvements.

The preoperative diagnosis of type 2 diabetes in the absence of antidiabetic treatment is associated with a worse performance after gastric-bypass compared to patients without diabetes

Javier Gargallo[1], Sara Laguna[2], María Llavero[1], Carolina M Perdomo[1], Victor Valentí[1], Javier Escalada[1], Javier Gómez-Ambrosi[1], Camilo Silva[1], Gema Frühbeck[1] & Javier Salvador[1]
[1]University Clinic of Navarra, Pamplona, Spain; [2]Hospital Calahorra, Calahorra, Spain.

Objectives and methods
The mechanism that explains the different weight response to various treatments in obese type 2 diabetes (DM2) patients, compared to those without diabetes, is still unknown. In order to establish the weight response to Roux-en-Y Gastric Bypass (RYGB), 268 patients with morbid obesity (IMC 45.4$\pm$0.4 kg/m^2) were classified by OGTT as having normal glucose tolerance (Grupo A. $n=107$), prediabetes (Grupo B. $n=96$) and recently diagnosed DM2 (Grupo C. $n=65$). No antidiabetic drugs were given in any patient. Anthropometry, body composition (Bod-Pod) and HOMA-R index were assessed at baseline and 1, 6, 12, 18, 24, 36, 48, 60 and 72 months after surgery in all patients.
Results
The mean nadir BMI (kg/m^2) occurred 24 m after RYGB in group A (28.8$\pm$0.6 kg/m^2) and 18 m after surgery in groups B (28.3$\pm$0.7 kg/m^2) and C (30.8$\pm$0.7 kg/m^2). The mean nadir of percent body fat was greater than 30% in all three groups (A: 33.8$\pm$1.2%; B:35.9$\pm$1.4; C:36.5$\pm$1.3%). The percentage reduction of BMI respect to baseline was lower in group C compared to group A at 24 m (30.3$\pm$3.5 vs. 34.4$\pm$1.3%; $P<0.01$), 36 m (28.1$\pm$4.8 vs. 33.2$\pm$1.6%; $P<0.01$) and 48 m post RYGB (25.7$\pm$3.9 vs. 31.7$\pm$1.3%; $P<0.05$). The percentage reduction in fat mass (%) was lower in group C compared to group A at 12 m (28.1$\pm$1.7 vs. 35$\pm$1.7%; $P<0.05$), 18 m (27.4$\pm$1.9 vs. 36.2$\pm$2.2%; $P<0.01$), 24 m (21.9$\pm$1.6 vs. 33.9$\pm$2.5%; $P<0.01$) and 48 m (13.8$\pm$2.3 vs. 30.3$\pm$3.5%; $P<0.001$). Group A and B did not differ in any parameter. HOMA-R index, which was elevated before surgery in all groups, was normalized after 6 months from RYGB without any differences between the different groups.
Conclusions
After RYGB, and when compared with normal glucose tolerant and prediabetic subjects, patients with DM2 have lower weight loss and fat mass reduction, despite they did not receive any antidiabetic treatment, excluding the participation of this factor. These results suggest that DM2 is associated with poorer results following RYGB. There were no differences between groups in HOMA-R index, suggesting that variations in insulin resistance do not play a role in this phenomenon.

Investigation of the effect of dietary fat content on obesity and metabolic syndrome in smokers

Reyhan Bilici Salman[1], Neşe Ersöz Gülçelik[2] & Tülay Omma[3]
[1]Division of Rheumatology, Department of Internal Medicine – Gazi Unıversity Faculty of Medicine, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Gülhane Training and Resarch Hospital, Ankara, Turkey; [3]Department of Endocrinology and Metabolism, Ankara Training and Resarch Hospital, Ankara, Turkey.

Background
Despite the efforts to reduce smoking, unfortunately there is a common belief in society to avoid smoking cessation or quitting smoking for weight control. As well as many negative effects of smoking, people continue to smoke instead of diet and life change. Nicotine plus high fat diet (HFD) induces intramyocellular lipid accumulation and mitochondrial abnormalities in obese mice. There is limited data in the relation of dietary fat content and metabolic syndrome in Turkish smoker population.
Objectives
Therefore the aim of the study is to investigate the relationship between dietary fat content and anthropometric measurements for smokers and non-smokers; as well as the effects of smoking and dietary fat content on obesity, metabolic syndrome.
Methods
In total 211 participants 104 smoker,107 non smoker were included in this prospective cross-sectional study. Venous blood samples were collected after a 12h fasting to determine glucose, high-density lipoprotein (HDL-c), and triglyceride levels. Anthropometric measurements and resting blood pressure were also evaluated. Food consumption was assessed through the 24-hour dietary recall method, and the amount of fat consumed by a single dietician is calculated as low or high. Metabolic syndrome was defined according to the International Diabetes Federation definition guidelines.
Results
There was no relationship between smokers and non-smokers anthropometric parameters except hip circumference. Hip circumference of the non-smokers were statistically higher than smokers ($P=0.02$). HFD and metabolic syndrome were not statistically important both of smokers and non-smokers ($P=0.21$ and $P=0.48$). In non-smokers high fat diet induces poor glycemic control ($P=0.20$). There was no relationship between dietery fat content and non alcoholic fatty liver disease in smokers and non-smokers ($P=0.07$ and $P=0.18$).
Conclusion
We observed that smoking reduced only the hip circumference in smokers. But there is widespread belief that smoking has a positive effect on weight in the community. Smokers did not show improvement in weight control and obesity-related metabolic values. We observed that dietary fat content was not associated with smoking and the metabolic syndrome.

Food addiction: its prevalence among obese patients

Bouizammarne Ilham, El Mghari Ghizlane & El Ansari Nawal
Department of Endocrinology, Diabetes and Metabolic Diseases, Marrakesh, Morocco.

Introduction
The concept of food addiction, which refers to people who exhibit signs of dependence to some high-fat and high-sugar foods, was recently proposed by applying DSM criteria of substance dependence to eating behavior. The Aim of This *study is* to assess the *prevalence of food addiction* among obese patients.
Material and methods
This is a retrospective hospital record-based study of obese patients followed up in the day hospital and education unit of the department of endocrinology of the CHU Mohamed VI of Marrakech. This study was carried out using a Yale Food Addiction Scale questionnaire (YFAS).
Results
A total of 68 obese patients were analyzed, of which the majority were female, the mean age of presentation in years is 47.16 years. The average BMI was 41.4 kg/m^2. The morbid obesity was noted in 52.9% of the cases. All cases presented either abdominal or visceral obesity. The majority of obese patients were sedentary (65%) and food addiction was found among 35.2% of patients. Nibbling behavior hyperphagia was noted in 44% of cases.
Conclusion
The prevalence of food addiction is higher among overweight and obese patients, patients with certain psychopathological characteristics (depression, Attention Deficit Hyperactivity disorder, and high impulsivity), single patient and in patients with neurobiological *dysregulation of brain reward systems*; It is not currently demonstrated that this disorder is systematically responsible for weight gain and/or obesity. Food addiction is a clinical and multidimensional concept which requires integrated care with psychotherapy, pharmacological and social lines of approach. This concept has also practical implications in terms of prevention and public health.

Deciphering the functional role of host-microbiota interactions on metabolic health induced by Roux-en-Y gastric bypass (RYGB) surgery

Julia Münzker[1], Nadine Haase[1], Lucas Scheffler[1], Robert Sucher[2], Jiesi Chen[1], Julia Reichert[3], Rima Chakaroun[1], Alyce Crane[1], Sven Haange[4], Ulrike Rolle-Kampczyk[4], Sjaak Riede[1], Martin von Bergen[4], Peter Kovacs[1], Ute Krügel[3] & Wiebke Fenske[1]
[1]Department of Medicine, Integrated Research and Treatment Centre for Adiposity Diseases, Leipzig, Germany; [2]Department of Visceral, Transplant, Thoracic and Vascular Surgery, University Hospital Leipzig, Leipzig, Germany; [3]Rudolf Boehm Institute of Pharmacology and Toxicology, Clinical Pharmacology, University of Leipzig, Leipzig, Germany; [4]Department of Molecular Systems Biology, Helmholtz Centre for Environmental Research, Leipzig, Germany.

Roux-en-Y gastric bypass (RYGB) surgery results in rapid weight loss, reduced adiposity and improved overall metabolism. These health benefits cannot solely be attributed to the reduced caloric intake, but the exact mechanisms are still incompletely understood. Several studies in rodents and humans demonstrated alterations of the gut microbiota following RYGB, suggesting a crucial role of the host-microbial interactions for the beneficial effects of surgery. This study aimed to assess whether the altered gut milieu composition after RYGB is necessary or even sufficient to promote beneficial effects on energy balance and metabolism in a rat model of diet-induced obesity (DIO). Pilot studies prove that the beneficial effects of RYGB on body composition, food intake and glucose homeostasis are dependent on the gut microbial composition and can be abolished via broad range antibiotic administration via drinking water. Allogenic fecal microbial transfer (FMT) from RYGB-operated to DIO animals mimics the beneficial effects on feeding, adiposity and glucose control without surgical gut reconfiguration. In contrast, FMT from metabolically healthy lean donors to DIO animals shows no beneficial effects on metabolism. These preliminary findings affirm the hypothesis that the altered gut microbiome plays an important functional role in the metabolic improvements after RYGB, and that transferring the altered RYGB-gut milieu into a DIO organism is potent enough to accomplish the beneficial metabolic effects without surgical gut reconfiguration.

Obesity and dementia: the misleading "obesity paradox"

Adriana Pané[1], Jordi Pegueroles[2,3], Sabina Ruiz[1], Laura Videla[2,4], Maria Carmona-Iragui[2,3], Eduard Vilaplana[2,3], Victor Montal[2,3], Anna Casajoana[5], Josep Vidal[1,6,7], Juan Fortea[2,3] & Amanda Jiménez[1,6]
[1]Endocrinology Department, Obesity Unit of Hospital Clínic, Barcelona, Spain; [2]Department of Neurology, Memory Unit. Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [3]Centro de Investigación Biomédica en Red de Enfermedades Neurodegenerativas (CIBERNED), San Sebastián, Spain; [4]Barcelona Down Medical Center, Barcelona, Spain; [5]General Surgery Service, Hospital de Barcelona-SCIAS, Barcelona, Spain; [6]Institut d'Investigacions Biomèdiques August Pi Sunyer, Barcelona, Spain; [7]Centro de Investigación Biomédica en Red de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Barcelona, Spain.

Background
Mid-life obesity is a risk factor for Alzheimer's disease (AD). On the contrary, late-life obesity has been identified as a protective factor for dementia. Recent published studies have shown that weight loss predicts and precedes dementia diagnosis by decades. Thus, paradoxical effect of body weight across lifespan, the so called "obesity paradox", might be explained by reverse causality. Structural magnetic resonance imaging (MRI) has been extensively used to characterize healthy and pathological aging. Establishing the relationship between BMI and brain structural changes would help to better understand the effects of adiposity on the brain.
Objectives
We aimed to assess the association between late-life obesity and brain structure considering the potential confounding effect of weight loss.
Methods
We included 131 cognitively normal elderly subjects (mean age: 73.4 ± 6.2 years) with available 3T MRI scan from the *Alzheimer's Disease Neuroimaging Initiative* (ADNI) cohort. Significant weight loss was defined as relative weight loss ≥ 5% of baseline weight. We compared the cross-sectional cortical thickness (CTh) related to the BMI in (1) all the cohort and (2) after the exclusion of individuals with significant weight loss. CTh was extracted using *Free Surfer Software*. All analysis were adjusted by potential confounders (age, sex and APOE genotype).
Results
After a mean follow-up of 50.5 ± 30.5 months, 31 (23.6%) subjects experienced significant weight loss (FWE < 0.05). At baseline, these individuals presented decreased CTh in temporal regions of the right hemisphere (FWE < 0.05). When the whole cohort was included in the analysis, there was a weak, although significant, lineal correlation between BMI and cortical thinning. This association was restricted to the occipital region (FWE < 0.05). Results significantly changed after having excluded the subjects with weight loss. In this context, several clusters of linear association emerged in widespread areas of both hemispheres including occipital, temporal and frontal regions (FWE < 0.05).
Conclusions
Late-life unintentional weight loss is related to cortical thinning. Similarly, late-life obesity is associated with cortical thinning. However, weight loss negatively confounds this association.

Influence of body weight loss on gait and stability function in patients with obesity

Valeriia Vasileva, Larisa Marchenkova & Michail Eryomushkin
Federal State Budget Institution "National Medical Research Center for Rehabilitation and Balneology" of the Ministry of Health of the Russian Federation, Moscow, Russian Federation.

Objective
In our research we studied changes of gait and balance parameters and falls frequency in obese patients during weight loss.
Materials and methods
We examined 37 patients aged 23–69 years (average age 53.6 ± 11.1 years) with BMI ≥ 35 kg/m^2 (average BMI 40.9 ± 9.3 kg/m^2). All patients received recommendations to adhere hypocaloric diet and perform physical exercises in order to reduce body weight. We evaluated baseline body weight, BMI, the number of falls for 3 months, 10 meters walk test along a flat surface, Romberg test and stabilometry (Stabilan - 01) were conducted.
Results
After 3 months, the average body weight in the group decreased from 124.1 ± 26.6 kg to 118.1 ± 23.4 kg, $P = 0.022$ (95% CI: 2.78, 9.22), the number of falls for 3 months reduced from 0.14 ± 0.34 to 0, $P = 0.023$ (95% CI: 0.02; 0.25), the results of 10 m walk test decreased from 113.0 ± 8.82 m/sec to 105.5 ± 3.03 m/ses, $P = 0.005$ (95% CI: 2.86, 12.14). According to the stabilometry data the coefficient of stability improved from 113.5 ± 9.11% to 104.0 ± 2.16%, $P = 0.012$ (95% CI: 3.035, 16.10), deviation of the pressure center in the sagittal and frontal plane decreased from 113.6 ± 9.1 mm to 104.0 ± 2.2 mm, $P = 0.01$ (95% CI: 3.03, 16.1), the movement speed of the pressure center increased from 113.4 ± 8.9 mm/sec to 104.0 ± 2.2 mm/sec, $P = 0.01$ (95% CI: 3.04; 15.81), speed index changed from 113.0 ± 9.1 to 104.0 ± 2.2, $P = 0.01$ (95% CI: 3.0, 16.1) and overall rating movement reduced from 109.9 ± 6.8 to 104.0 ± 2.0, $P = 0.0037$ (95% CI: 0.5; 11.2).
Conclusion
Weight loss in obese patients is associated with the decline of falls frequency, improvement of gait speed, statics and balance functions.

Keywords: obesity, gait speed, gait stability.

Magnetic resonance imaging of human supraclavicular brown adipose tissue

Gani Gashi[1], Philipp Madoerin[2], Claudia Irene Maushart[3], Regina Michel[3], Jael Rut Senn[3], Oliver Bieri[2] & Matthias Johannes Betz[3]
[1]Department of Endocrinology, Diabetes and Metabolism, University Hospital Basel, Basel, and University of Basel, Basel, Switzerland; [2]Department of Radiology, Division of MRI Physics, University Hospital Basel, Basel, Switzerland; [3]Department of Endocrinology, Diabetes and Metabolism, University Hospital Basel and University of Basel, Basel, Switzerland.

Background
Imaging of brown adipose tissue (BAT) is currently performed with combined positron emission tomography and x-ray computed tomography (PET-CT). Recent studies showed promising imaging features of BAT with magnetic resonance imaging (MRI) through modified 2-point-dixon (mDixon) water-fat separation method. The aim of this study was to establish a reliable MRI-procedure for quantification of BAT volumes and weighted fat-fraction (WFF) and to correlate them to cold-induced thermogenesis (CIT).
Methods
23 healthy volunteers (13 males, 10 females, age 18–47 years) were recruited for this prospective, observational study. Energy expenditure (EE) was measured in supine position by indirect calorimetry during warm conditions and after a mild cold stimulus of 120 minutes. CIT was defined as the difference between EE during cold (EE_{cold}) and warm (EE_{warm}) conditions. MRI was performed on a Siemens MAGNETOM Prisma 3T using mDixon water-fat separation method and T2* relaxation time. MRI was performed twice, once during warm conditions and once during mild cold exposure with a cooling vest. Volumes of supraclavicular BAT-depots ($_{sc}$BAT) and WFF were calculated by manual segmentation using ITK-Snap. Primary Endpoint was correlation of $_{sc}$BAT volume with CIT. Data were analysed in R/R-Studio and are given as mean ± standard deviation.
Results
Mean Volume of both $_{sc}$BAT was 71.4 ml ± 39.4 ml. Mean WFF was 74.2% ± 6%. Mean EE_{warm} was 1638 kcal/day ± 362 kcal/day and EE_{cold} 1794 kcal/day ± 408 kcal/day. Mean CIT was 156 kcal/day ± 133 kcal/day respectively 8.5% ± 9.6% of $EE_{warm.}$ Contrary to our assumption, we found no correlation between the volume of $_{sc}$BAT and CIT ($r = 0.05$, $P = 0.87$) or between WFF and CIT ($r = 0.13$, $P = 0.66$). $_{sc}$BAT volume correlated however significantly with increasing age ($r = 0.59$, $P = 0.003$), body mass index ($r = 0.53$, $P < 0.0001$) and WFF ($r = 0.39$, $P = 0.0016$).
Conclusion
Despite the correlation between MRI and glucose uptake of human brown adipose tissue in recent studies, our study found no correlation between the volume and WFF of BAT to cold induced, non-shivering thermogenesis. Thus, MRI without tracer-based molecular imaging is currently not a promising tool for determining the metabolic activity of human brown adipose tissue.

Benign symmetric lipomatosis (Madelung's disease)

Antonio F Oliveira-Filho[1], Renata N Velloso[2], Sofia NP Oliveira[3], Paula FV Medeiros[3] & Adriana B Nunes[2]
[1]Paraiba Health Department FAP Hospital, Campina Grande, Brazil; [2]Federal University Rio Grande Norte, Natal, Brazil; [3]Federal University Campina Grande, Campina Grande, Brazil.

Multiple benign symmetric lipomatosis (Madelung's disease, Launois–Bensaude syndrome) is significantly rare disease characterised by symmetrical focal deposition of adipose tissue in the neck, upper part of the arms, back, pelvis, and thigh. Although its etiology is uncertain, it has been associated with genetic factors, mitochondrial inheritance and alcoholism. Its pathogenesis seems to include a dysfunction of cAMP and levels of catecholamines in adipocytes. This condition is an important differential diagnosis from obesity. Long-term large lipomatous deposits are cosmetically deforming, and the upper aerodigestive tract and great veins may be compressed. Patients do not effectively lose subcutaneous adipose tissue from lifestyle changes and recurrence after lipectomy is highly frequent. This report presents six cases of non-related patients diagnosed with benign multiple symmetric lipomatosis. Case 1: A 28-years-old, Afro-American woman presented with a mass deposition in the back and neck (horse collar) since her 8 years of age and later associated with polyneuropathy. Her father has similar condition. The patient was treated with lipectomy twice with recurrence. Case 2: A 36-years-old woman without family history presented with mass deposition in the neck and back, observed since 30 years old. Also clinical and karyotype findings confirmed Down's syndrome. The patient has refused surgical treatment. Case 3: A 55-years-old woman, with no comorbidities nor family history, presented with fat deposition in both upper arms, evident for 15 years. Case 4: A 31-years-old woman, with no family history and no other comorbidities, presented deposition in both arms and the back of the neck (humpback) evident since 20 years old. Case 5: A 32-years-old woman, alcoholic, with family history of Madelung's disease presented mass in the neck and armpit from 8 years ago. Case 6: A 53-years-old man, alcoholic for seven years, with no family history, presented deforming fat deposition in the neck and upper chest evident seven years ago. He has refused surgical treatment and ceased alcoholism. In all patients, CT findings confirmed the presence of fat deposits. These cases illustrate the variability of clinical presentation of benign multiple symmetric lipomatosis. Fat deposition site could vary. Association with polyneuropathy, alcoholism, dyslipidaemia, Down's syndrome and different inheritance patterns were present. Nevertheless, none of the cases presented diabetes, hypertension, epilepsy or neuromuscular disorders. In summary, the reported cases support the idea that such syndrome may have intervening factors inducing a variety of distinct phenotypic patterns.

DXA Body Composition with Visceral Fat analysis improves categorization of the metabolic diseases risk

Silvana Di Gregorio[1,2], Lara Horsch[2,3], Cecilia Costamagna[3,4] & Roberto Villavicencio[3]
[2]Fundacion Villavicencio, Rosario, Spain; [2]Grupo Medico Oroño, Rosario, Argentina; [3]Fundacion Villavicencio, Rosario, Argentina; [4]ELAS. Departamento Densitometria, Rosario, Argentina.

Introduction
Many people suffered diverse diseases associated to central obesity. Actually the most frequent tool to estimate the abdominal fat is waist perimeter. In the past and the DXA software was adapted to measure fat content in abdominal region but the visceral and subcutaneous fat couldn't be differentiated.
Objective
Evaluate all tools available and establish the most sensible to discriminate the patients whose had risk to suffer metabolic diseases associated to central obesity.
Methods
Eighty eight patients (26 men, 62 women), were derivatives for endocrinological assessment. Clinical parameters were evaluated as systolic blood pressure and waist perimeter (WP) and biochemical parameters such as glycemia; insulinemia; Homa index; total cholesterol; HDL; LDL; Triglycerides. Total body composition scans using GE-iDXA model device was used. Analysis of the whole-body DXA scans was performed using specific CoreScan software (Version 14.1). We analyzed DXA variables (Total fat mass –TFM-; abdominal fat mass –AFM-visceral fat –Core-Vat- VFM-; and anthropometrics variables (BMI; WP)divided by gender. The continues were analyzed by T-Test (mean) and a regression tests were applied to evaluate the correlations, with a value of $P<0.05$ as significant.
Results
Forty eight were non metabolic affected (all biochemical parameters were normal, they were "Control"), 40 were classified as metabolic affected (Insulin Resistance; Metabolic Syndrome; dyslipemia). There was not statistical difference in age between normal and patients. We stratified by gender and analyzed the results comparing affected to non-affected. Women group showed all parameters significantly higher in patients group (WP: 92.8 vs 81 cm; TFM 36.238 vs 27.105 kg; AFM: 3.108 vs: 2.170 kg; VFM: 1.037 vs 0.534 kg) Men group had not significant differences at TFM (29.695 vs 24.399 kg – $P=0.08$) and were significantly higher the follow parameters: AFM: 2,940.3 vs: 2.137 kg; VFM: 1.385 vs 0.922 kg). Insulin and HOMA Index showed stronger correlations to abdominal fat measured by DXA (Insulin to: to AFM: R2; 0.598; VFM: R2 0.642; VFD: R2 0.682; HOMA to AFM: R2; 0.598; VFM: R2: 0.642) than the correlations with anthropometrics parameters (Insulin To WP R2: 0.200; HOMA index: R2: 0.218).
Conclusion
The anthropometrics parameters are useful but under estimate the prevalence of metabolic diseases related to central obesity, we propose combine with DXA measurements to improve the patients categorization.

Influence of sleeve gastrectomy on leptin to adiponectin ratio in severely obese adults: A prospective cohort study

Mohammed Faraz Rafey[1], Clarissa Ern Hui Fang[1], Iulia Ioana[1], Helena Griffin[1], Mary Hynes[1], Timothy O'brien[1,2], Oliver Mcanena[3], Paula O'shea[1], Chris Collins[3] & Francis Martin Finucane[1,2]
[1]Bariatric Medicine Service, Centre of Diabetes, Endocrinology and Metabolism, Galway University Hospitals and HRB Clinical Research Facility, Galway, Ireland; [2]Department of Medicine, National University of Ireland Galway, Galway, Ireland; [3]Department of Surgery, National University of Ireland Galway, Galway, Ireland.

Background
Bariatric surgery is known to dramatically increase insulin sensitivity in severely obese adults. However quantifying insulin sensitivity in these patients with methods such as the hyperinsulinaemic euglycaemic clamp is technically challenging. The leptin to adiponectin ratio (LAR) has previously been validated as a measure of whole body insulin sensitivity. Leptin is a known mediator of metabolic and cardiovascular complications of obesity. Adiponectin has anti-atherogenic, antidiabetic, and anti-inflammatory properties. The influence of bariatric surgery on LAR has not previously been described.
Aim and objectives
We sought to determine changes in LAR over 12 months in severely obese adults undergoing sleeve gastrectomy.
Methods
We conducted a single-centre, prospective cohort study of all patients undergoing sleeve gastrectomy between September and December 2016. Anthropometric data, metabolic profiles, leptin and adiponectin levels were collected before and one year after surgery. Leptin and adiponectin were both measured using the two-site micro titre plate-based DELFIA assay. Data are presented as means $\pm$ standard deviation. Comparisons between baseline and follow up measures were performed using a paired *T*-test.
Results
Twenty-five patients underwent surgery, and 17 of these (12 female, 9 with diabetes mellitus (DM) (defined as baseline HbA1c $\geq$ 48 mmol/mol)) attended for follow up at 12 months and were included in analyses. Mean age was 52.2 ± 8.3 (range 39–71) years. Mean follow up interval was 12 ± 1 (range 10–13) months. Weight reduced from 130.5 ± 30.8 kg to 97.5 ± 21.6 kg ($P<0.001$), BMI from 46.8 ± 7.8 to 35.3 ± 7.2 kgm^{-2} ($P<0.001$), excess body weight percentage from 87.5 ± 31.2 to 41.3 ± 28.8% ($P<0.001$) and alanine aminotransferase reduced from 33.8 ± 16.6 to 15.7 ± 5.5 mmol/l ($P<0.001$). Overall, HbA1c did not change, with baseline and follow up values of 50.5 ± 16.2 and 44.5 ± 13.2 mmol/mol, respectively ($P=0.12$), with a non-significant trend to reduction in DM patients from 62 ± 13.2 to 53.3 ± 11.8 mmol/mol ($P=0.081$). Overall, leptin came down from 40.6 ± 24.8 to 30.8 ± 30.4 ng/ml ($P=0.16$) and adiponectin increased from 4.48 ± 1.58 to 8.92 ± 6.36 µg/ml ($P=0.004$) while LAR came down from 8.88 ± 4.76 to 5.26 ± 6.52 ng/µg ($P=0.036$) and in DM patients from 8.2 ± 3.5 to 5.1 ± 3.2 ng/µg ($P=0.038$).
Conclusion
These preliminary data from a single centre study suggest that relatively high levels of insulin resistance, as evidenced by high LAR, are reduced 12 months after sleeve gastrectomy, both in patients with and without DM. Further studies are warranted to determine whether LAR can serve as a useful prognostic test or an indicator of metabolic response to bariatric surgery.

Differences in percentage of weight loss and secondary effects after one and two months of treatment with liraglutide versus naltrexone/bupropion

Beatriz Voltas Arribas, Carlos Sánchez Juan, Juan Carlos Ferrer García, Ana Artero Fullana, Pablo Sanz Revert, Cristian Marco Alacid & Mario López Merseguer
Hospital General de Valencia, Valencia, Spain.

Introduction
Obesity is one of the most prevalent health problems in our society. The marketing of Liraglutide and the Naltrexone/Bupropion combination has been given the green light.
Objectives
To analyze the differences in a series of 19 patients assigned to treatment with Liraglutide or Naltrexone/Bupropion.
Material and methods
A descriptive analysis was carried out using Stata. 19 patients were included, 9 were treated with Liraglutide and 10 with Naltrexone/Bupropion. We analyzed the percentage of weight loss and side effects at one month and two months after treatment initiation.
Results
Of the 9 patients included in the Liraglutide arm, 2 were male and 7 were female, with a mean age of 56.22 and a mean BMI of 41.35. From the Naltrexone/Bupropion group, 5 male and 5 female participants, with a mean age of 52.90 and an initial BMI of 34.40. After one month of treatment, a % weight loss of 3.81 was observed for the Liraglutide group versus 1.06 for Naltrexone/Bupropion (difference of means 2.75). After two months, a 7.51% weight loss was observed for Liraglutide versus 0.12% for Naltrexone/Bupropion (mean difference 7.40), the latter being statistically significant. 77.8% of patients treated with Liraglutide developed secondary side effects at the first month (28.57% at the second visit), only one patient withdrew from taking the drug. In the Naltrexone/Bupropion group, side effects were observed in 20% with two dropouts for this reason (another 4 abandoned the treatment for other reasons). Regarding the dosage of Liraglutide per month, 11% of Liraglutide 1.2 mg, 33% 1.8 mg, 33% 2.4 mg, 22% 3 mg. At two months, 43.86% 1.8 mg and 57.14% 3 mg.
Conclusions
In our clinical practice we observed a greater weight loss % in the Liraglutide group, especially at two months of treatment. The number of negative side effects was greater for Liraglutide, primarily in the first month, with a higher abandonment rate for Naltrexone/Bupropion.

Prevalence of obesity in a population of patients with HIV: relationship with clinical lipodistrophy, effect of sex, age, viral replication, duration of disease and cart

Vanessa Guerreiro[1,2], Joao Neves[1,2,3], Rosario Serrão[3,4], Antonio Sarmento[2,4], David Carvalho[1,2,3] & Paula Freitas[1,2,3]
[1]Departamento Endocrinologia CHSJ, Porto, Portugal; [2]Faculdade de medicina Porto, Porto, Portugal; [3]Instituto de investigação e inovação em saude, Universidade do Porto, Porto, Portugal; [4]Departamento infecciologia CHSJ, Porto, Portugal.

Introduction
Adipose tissue disturbances (lipodystrophy and obesity) are prevalent in patients infected with HIV. Our aims were to evaluate the prevalence of obesity and the association with lipodystrophy, the effect of gender, age, viral replication, duration of disease and cART in a population of HIV patients under cART.
Methods
In this retrospective study, 580 patients were included. The characteristics of the population are presented through percentage, mean and standard deviation. For comparison, *t*-test and chi-square test were used. Logistic regression model was used to adjust the confounding factors. Patients were classified according to the prevalence or absence of clinical lipodystrophy and in 4 categories of body composition: 1) without lipodystrophy (without lipoatrophy and without abdominal prominence-AP); 2) isolated AP; 3) isolated lipoatrophy; 4) mixed forms of lipodystrophy (with lipoatrophy and with AP). AP was defined according to the waist circumference criteria of the IDF.
Results
Of the 580 HIV patients (414 men), 5.17% were underweight, 40.69% normal weight, 34.66% overweight and 19.48% obese; 15.4% had no lipodystrophy; 30.62% isolated AP; 27.17% isolated lipoatrophy and 28.1% mixed form of lipodystrophy. In obese patients, clinical lipodystrophy was present in 28.6%, being significantly lower in patients with excess weight [odss ratio (OR) = 0.12; 95% CI] and in those with obesity [OR = 0.32; 95% CI], when compared with those of low weight, regardless of sex, age, duration of cART, HIV or viral load. There was an association ($P < 0.001$) between BMI and body fat categories. The presence of lipoatrophy decreases with increasing BMI: in patients with low BMI, 24.1% had no lipodystrophy and 72.41% had lipoatrophy alone; in those who were overweight, most had mixed forms of lipodystrophy (41.24%), and AP was also common (39.69%); in those with obesity, most of them (70.3%) had isolated AP. The prevalence of obesity was not influenced by viral suppression, sex, age, duration of HIV infection or cART.
Conclusion
In this population of patients infected with HIV, excess weight, obesity or some degree of alteration in the distribution of body fat were very prevalent. The presence of clinical lipodystrophy was lower in overweight and obese patients than in those with low weight regardless of gender, age, duration of cART or infection with HIV and viral load. Patients with obesity had lower viral suppression, and the prevalence of obesity was not influenced by sex, age, duration of HIV infection or cART.

rs1800497 polymorphism of the DRD2 Gene assosiation with plasma leptin and dofamine Levels in obese and lean children

Liudmila Viazava[1], Anzhalika Solntsava[2], Elena Aksionava[3] & Elena Dashkevich[4]
[1]Republican Centerof Medical Rehabilitation and Balneotherapy, Minsk, Belarus; [2]Belorussian State Medical University, Minsk, Belarus; [3]Institute of Genetics and Cytology of the National Academy of Sciences of Belarus, Minsk, Belarus; [4]Health institution Municipal Hospital, Minsk, Belarus.

Background and aim
The TaqI (rs1800497) polymorphism of the Dopamine Receptor type 2 (DRD2) gene allele has been commonly related to increased ad lib food intake, weight gain, and risk for obesity overeating and risk for obesity. We supposed to find associations between body mass index (BMI), the TaqI (rs1800497) polymorphism of the Dopamine Receptor type 2 (DRD2) gene and plasma leptin and dopamine in children with alimentary and extreme obesity and normal weight.
Materials and methods
Retrospective analysis in 288 children aged from 0,4 to 17,9 years were performed in children who appealed to endocrinologist for medical aid from 2009 to 2015 y. 179 children were randomly genotyped in the rs1800497 of DRD2 gene. Children were split up in terms of BMI into 3 groups: the 1st – normal weight (NW) (± 1 S.D.S., $n = 30$), the 2nd – alimentary obesity (AO) ($\geq +2$ S.D.S. $< +4$ S.D.S., $n = 98$), the 3rd – extreme obesity (EO) ($\geq +4$ S.D.S., $n = 160$). Plasma dopamine (D) and leptin (L) concentrations were detected by enzyme-linked immunosorbent assay (ELISA). According to percentiles of D levels children were divided to 4 groups: the 1st – patients with low D levels (< 4.99 pg/ml); th 2nd – decreased D (4.99 – 11.64 pg/ml); 3rd – increased D (11.65 – 60.0 pg/ml); 4th – high D levels (> 60.0 pg/ml). Analogically patients were split up depending on L concentrations: the 1st – low L (< 13.15 ng/ml); the 2nd – decreased L (13.15 – 23.78 ng/ml); the 3rd – increased (23.79 – 40.18 ng/ml); the 4th – high L (> 40.18 ng/ml). Statistical analysis were performed by means of SPSS 21.0 (χ^2-criterion, likehood ratio) ($P < 0.05$).
Result
Children with NW had 6.7% of high D levels, 40% - decreased D, in comparison with EO group who had 32% patients with high D concentrations and 28% - increased D ($P = 0.038$). There were found out L levels differences: 86.7% children with NW had low L; 34.7% patients with AO L levels were increased; 31.5% children with EO had high L concentrations and only 17.7% had low L ($P = 0.0001$). Children with AO and EO had raised A1 TaqI DRD2 allele frequencies: in 45.5% equally in contrast with NW patients (9.1%) ($P = 0.012$). There were not any links between A1A1 genotype, plasma D and L concentrations.
Conclusions
A1A1 allelic variant of TaqI (rs1800497) DRD2 polymorphism were significantly associated to plasma leptin and dopamine concentrations and BMI ($P = 0.012$, $P = 0.038$, $P = 0.0001$ respectively).

The correlation between urinary ketosis and metabolic indices in healthy young adolescents of Korea

Hannah Seok, Tae Seo Sohn & Hyun Shik Son
Uijeongbu St. Mary's Hospital, The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.

Background and aims
The prevalence of metabolic syndrome in Korean youth population has been increased by introduction of Western diet in the past decades. The aim of this study was to investigate the incidence of urinary ketosis and correlation with metabolic indices in healthy adolescents in Korea.
Materials and methods
This was a large-scale, community-based study conducted from January 2007 to December 2010. A total of 1,349 subjects (749 males and 600 females) aged 15 through 19 years without history of diabetes were enrolled. Urine ketone was analyzed by semi-quantitative dipstick method.
Results
The prevalence of urinary ketosis was 24.2% (21.6% in male and 27.5% in female). The presence of urinary ketosis was negatively correlated with fasting glucose, fasting insulin, HOMA-IR, and triglyceride level, and positively correlated with HDL-cholesterol in males ($r=-0.086$, -0.095, -0.090, -0.084 and 0.100 respectively, all $P<0.05$), and females ($r=-0.124$, -0.189, -0.185, -0.141 and 0.134 respectively, all $P<0.05$).
Conclusion
Urinary ketosis was common in Korean healthy adolescents. Urinary ketosis was correlated with more metabolically healthy profiles in this population.

Peculiarities of functional activity of thrombocytes in adolescents with diabetes mellitus tipe 1

Nataliia Nikolaeva, Nina Bolotova, Vadim Polyakov, Elena Dronova & Nadezhda Nikolaeva
Saratov State Medical University, Saratov, Russian Federation.

Thrombocytes play important role in pathogenesis of diabetic vascular complications.
Aim
To study peculiarities of functional activity of thrombocytes in adolescents with diabetes mellitus type 1 (T1DM).
Patients and methods
98 adolescents (42 boys, 56 girls) 12–16 y.o. with T1DM were examined. The duration of the disease was: less than 1 year in 25 patients (HbAc1 $7.4\pm0.3\%$) – group 1, from 1 to 5 years in 40 patients (HbAc1 $8.9\pm1.2\%$) – group 2, more then 5 years in 33 patients (HbAc1 $10.3\pm1.7\%$) – group 3. Control group: 40 healthy adolescents 12-16 y.o. The indexes of trombocyte aggregation (degree, speed and time of aggregation) measured by laser method with different inductors (ADP, kollagen, adrenalin) and intravascular aggregation were evaluated.
Results
Levels of ADP- and adrenalin-stimulating aggregation, speed of kollagen-stimulating aggregation and intravascular aggregation of thrombocytes were increased in group 1 in comparance of control group ($P<0.05$). Levels of ADP- and kollagen-stimulating aggregation ($P<0.05$) and intravascular aggregation ($P<0.001$) were also increased in group 2. Decrease of aggregation time was revealed in this group ($P<0.05$). Increase of all indexes of functional activity of thrombocytes ($P<0.05$) and increase of intravascular aggregation ($P<0.001$) were found in patients of group 3 in comparance of control group.
Conclusions
Functional activity of thrombocytes in adolescents with T1DM appeared to increase in correlation with duration of the disease and it may demand treatment with heparinoids.

Sex differences in glucocorticoid-induced metabolic disturbances in mice

Kasiphak Kaikaew[1,2], Jacobie Steenbergen[1], Jan Kroon[3], Onno C Meijer[3], Aldo Grefhorst[1] & Jenny A Visser[1]
[1]Department of Internal Medicine, Erasmus MC, Rotterdam, Netherlands; [2]Department of Physiology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [3]Division of Endocrinology, Department of Medicine, Leiden University Medical Center, Leiden, Netherlands.

Introduction
Glucocorticoids (GCs) are widely used anti-inflammatory medications that cause many metabolic side effects. Long-term treatment with GCs causes obesity and induces insulin resistance in many metabolic tissues, including adipose tissue and muscle. Factors secreted by adipose tissue, so-called adipokines, including leptin and adiponectin, also regulate the glucose-insulin axis. Obesity increases circulating leptin but decreases adiponectin levels. Despite several studies on GC regulation of adipose tissue function, mass, and distribution, the sex-specific effects of GCs have not been well elucidated. Here, we studied the effects of high-dose corticosterone (rodent GC) on glucose metabolism and circulating adipokines.
Methods
Nine-week-old male and female C57BL/6J mice were implanted with 50 mg corticosterone (Cort) or vehicle (Veh) pellets (6 animals per condition). Ad-lib blood glucose levels were measured every 2 days. Two weeks after implantation, we measured fasting glucose levels, collected blood samples for adipokine measurement, and performed an intraperitoneal glucose tolerance test (IPGTT). Data are shown as mean $\pm$ SD.
Results
Corticosterone treatment increased food intake in both sexes, but increased ad-lib blood glucose levels only in male mice (Veh-male 8.2 ± 0.3 mM, Cort-male 14.8 ± 1.6 mM, Veh-female 7.6 ± 0.4 mM, Cort-female 6.6 ± 0.5 mM; $P<0.001$). Corticosterone strongly increased fasting plasma insulin levels in both sexes (Veh-male 50 ± 17 pM, Cort-male 1071 ± 438 pM, Veh-female 28 ± 5 pM, Cort-female 1104 ± 631 mmol/l; $p_{Cort}<0.001$), but fasting blood glucose levels of both sexes remained within normal range. Corticosterone increased fat mass and serum leptin levels in both sexes. Surprisingly, adiponectin levels were also increased. Female mice had a higher basal adiponectin/leptin ratio than male mice and corticosterone markedly reduced the ratios in both sexes (Veh-male 34 ± 24, Cort-male 1.9 ± 0.3, Veh-female 375 ± 351, Cort-female 3.9 ± 1.4; $p_{Sex}=.035$, $p_{Cort}=.015$). IPGTT showed that corticosterone treatment resulted in blunted peak glucose levels in both sexes but more pronounced in female mice.
Conclusions
Sub-chronic high-dose GC causes insulin resistance without fasting hyperglycemia in both sexes of mice, but causes remarkably high glucose levels in the ad-lib fed condition in male mice only. GCs increase fat mass and alter circulating adipokine levels in both sexes. Adipose tissue adaptation such as an increased adiponectin secretion may be a crucial initial protective mechanism against the GC-induced metabolic disturbances.

A case of diabetic patient with recurrent ketosis after U-300 glargine treatment

Tuğçe Ulaşli[1], Aşkin Güngüneş[2] & Şenay Arikan Durmaz[2]
[1]Department of Internal Medicine School of Medicine, Kirikkale, Turkey; [2]Department of Endocrinology of School of Medcine, Kirikkale, Turkey.

Introduction
U-300 glargine is a new generation long acting insulin. Nocturnal hypoglicemia and weight gain with U-300 glargine is lower than U-100 glargine. However, it may take 3–4 days for U-300 glargine to reach stable state in plasma. We report a diabetic case with recurrent ketosis after U-300 glargine.
Case presentation
A 20 years old woman with type 1 diabetes mellitus who uses basal and bolus insulin (U-300 glargine and insülin aspart). She applied to emergency clinic with stomachache, diarrhea and nausea. The patient did not use insulin for a few days because of these complaints. As a laboratory results, plasma glucose concentration: 380 mg/dl, 3 positive ketones in urine analysis, PH: 7,07 in venous blood gas analysis, HCO3: 6 mmol/L. She was hospitalized in intensive care unit with diabetic ketoacidosis. Diabetic ketoasidosis improved after fluid, electrolyte replacement and insulin treatment. Urine examination showed ketones to be negative We started her routine basal- bolus insulin treatment with U-300 insulin glargine and insülin aspart. We observed again ketones (+2 positive) in urine analysis 10 hours later under her routine basal bolus treatment.
Conclusion
U300 glargine use may be associated with ketosis relapse in early period after diabetic ketoacidosis has improved, in this respect the physician must be careful.

Safety and efficacy of the available oral anti diabetic drugs in treating type-2 diabetics during Ramadan1437(Hijri)fasting in Fayoum Governate

Mohamed A Mashahit[1], Sally N Abo El-seoud[1], Norhan M Sayed[1] & Noha K Abd El-Ghafar[2]
[1]Department of Internal Medicine, Faculty of Medicine, Fayoum University, Egypt; [2]Department of Clinical Pathology, Faculty of Medicine, Fayoum University, Egypt.

Introduction
Fasting in Ramadan is one of the five pillars of Islam. Without relevant medical advice and intervention, fasting can put patients with T2DM at an increased risk of serious complications. The aim of this study was to compare the effectiveness and safety of available oral anti diabetic drugs in treating type-2 diabetics during Ramadan fasting.
Methods
More than 400 T2DM patients were included in this 16-week prospective study, data were collected up to 6 weeks before and 16 weeks after Ramadan fasting. Patients who had received metformin alone or with sulfonylurea (SU), DPP4-I or TZDs or any combination of the afromentioned were enrolled into the study.
Results
This study concluded that mean total HbA1c improved during Ramadan ($P<0.001$). This study also found that patients treated with SUs experienced major hypoglycemic events Similarly, a fewer patients experienced weight gain when treated with TZDs. On the contrary we found that there was no evidence of hyperglycemia or hypoglycemia in patients using DPP4-I.
Conclusions
There are several potential benefits of fasting during Ramadan. Active glucose monitoring throughout the holy month of Ramadan enabled us to pick up more hypoglycaemic episodes. The study revealed that the preferred antidiabetic drugs during Ramadan are DPP4-I.

Endocrine Disruptors

P614

Assessment of endocrine disrupting chemical screening using differentiated cardiomyocyte from mES cell

Jae-Hwan Lee, Dinh Nam Tran, Thi Hoai Thu Nguyen, Thi Bich Thuy Vo, Yeong-Min Yoo, Eui-Man Jung & Eui-Bae Jeung
Chungbuk National University, Cheongju, Republic of Korea.

Endocrine-disrupting chemicals (EDCs) are structures similar to steroids hormones which can interfere with hormone synthesis and normal physiological functions of male and female reproductive organs. EDCs tend to bind to steroid hormone receptors. Sex steroid hormones influence calcium signaling of the cardiac muscle in early embryo-development. Progesterone (P4) has been reported to affect both blood pressure and other aspects of the cardiovascular system. To confirm the affect of progesterone (P4), octyl-phenol (OP) and bisphenol A (BPA) on early differentiation of mouse embryonic stem (ES) cells into cardiomyocytes, the hanging-drop method was performed to form embryoid bodies. The mouse embryoid bodies (mEB) were suspended, attached onto 6 well plates and cultured in differentiation medium containing steroid-free FBS without LIF. P4, OP and BPA were treated at two days after attachment and media were replaced every two days. To investigate the calcium signaling, the mRNA level of calcium channel genes such as Trpv2 and contraction-related genes such as Ryr2, Cam2 and Mlck3 was analysed. In addition, mifepristone (RU486), which is a synthetic steroid that has an affinity for PR, was used to confirm the impact of P4 through PR. To determine if RU486 is capable of attenuating the inhibition effect, RU486 was applied for one day starting on day 11. Trpv2, Ryr2, Calm2 and Mlck3 decreased in the P4-treated group. RU486 treatment led to recovery of the decreased of cytosolic calcium-related genes in parallel with a reduction in the of PR. Treatment of OP and BPA were alter the of calcium channel and muscle-contraction related genes. These findings maybe be useful for screening EDCs during cardiac developmental process.

Disruption of amelogenesis by Adult Exposure to Di(2-ethylhexyl) Phthalate in Mice

Sylvie Babajko[1,2], Ai Thu Bui[1,2], Sophia Houari[1,2], Sophia Houari[1,2] & Ariane Berdal[1,2]
[1]Centre de Recherche des Cordeliers, Paris, France; [2]Université Paris-Diderot, Paris, France.

MIH (Molar Incisor Hypomineralyzation) is a recently described enamel pathology that affects now 15 to 18% of children worldwide. Its prevalence increased similarly to other pathologies associated to exposure to Endocrine Disrupting Chemicals (EDCs). In addition, MIH affects selectively permanent first molars and incisors, the first developing teeth during the perinatal period also the time window with the highest susceptibility to EDCs. Our previous published data showed the bisphenol A (BPA) as a causal factor of MIH. In the present study, we compare the effects of BPA and Di(2-ethylhexyl) phthalate (DEHP) in male mice as both EDCs were widely used by plastic industry and found in many good consumers. Eight weeks-old C57bl6 mice were exposed to increasing dose of DEHP from 0.5 to 50 µg/kg/day during 4 weeks. Clinical observation of continually growing incisors showed 11% of teeth with enamel breakdown and 11% of completely broken teeth. MicroCT analysis revealed increased enamel volume contrary to BPA that decreased enamel volume and mineralization. Ameloblasts forming the dental epithelium are cells in charge of enamel synthesis. Their precise function changes during amelogenesis according to their stage of differentiation. They first secrete enamel matrix proteins (mainly amelogenin and enamelin) determinant for enamel thickness and volume, and second they expression many ion transporters (SLC26A family) and proteases (MMP20 and KLK4) necessary for the terminal and complete mineralization of enamel. RT-PCR analysis of microdissected dental epithelium showed that SLC26A4/pendrin is a common target gene of DEHP and BPA but MMP20 is modulated by DEHP only whereas enamelin by BPA only. In vitro analysis are currently carried out to identify underlying molecular mechanisms. In conclusion our data showed that several EDCs can disrupt amelogenesis but their target genes and mechanisms of action appeared different generating different enamel defects. Characterization of enamel defects may help to reconstitute the history of exposure to pollutants during the perinatal period and use them as early marker of exposure to these molecules.

Use of a new classification algorithm based on administrative health databases to estimate incidence and prevalence of acromegaly in Piedmont Region, Italy

Marina Caputo[1], Andrealuna Ucciero[2], Chiara Mele[1], Lucrezia De Marchi[1], Corrado Magnani[2], Paolo Marzullo[1], Francesco Barone-Adesi[3] & Gianluca Aimaretti[1]
[1]Endocrinology, Department of Translational Medicine, Università degli Studi del Piemonte Orientale, Novara, Italy; [2]Statistics and Epidemiology, Department of Translational Medicine, Università degli Studi del Piemonte Orientale, Novara, Italy; [3]Epidemiology, Department of Pharmacological Sciences, Università degli Studi del Piemonte Orientale, Novara, Italy.

Background and aim
Information on incidence and prevalence of acromegaly usually originates from studies performed in referral endocrine care centers, whose catchment areas do not generally cover the entire population. Administrative databases can provide key information to assess the impact of acromegaly on patients and health systems. Our study aimed at estimating the prevalence and incidence data of acromegaly stratified by age and sex using data obtained in the Piedmont region, Italy.
Methods
A retrospective study was conducted in the Piedmont region from January 1st 2012 to December 31th 2016 using administrative health databases of hospital discharge forms, certification of chronic diseases, drug prescriptions, specialist outpatients, and radiological data. Cases of acromegaly were defined if at least two claims from the four following databases were accomplished: i) hospital records with acromegaly diagnosis code (ICD-9-CM: 253.0); ii) exemptions from co-payment for acromegaly (code: 001); iii) prescriptions for Octreotide LAR, Lanreotide Autogel, Pegvisomant, Pasireotide LAR; iv) prescriptions for pituitary MRI or CT scans. Cases were excluded if subjects received less than three separate drug prescriptions or if carrying a diagnosis different from acromegaly.
Results
In the period 2012–2016, 369 individuals (M = 146, F = 223) were documented in the Piedmont population meeting our criteria for acromegaly. Overall incidence was 5.3 per million population per year (95% CI: 4.2–6.7), and overall prevalence was 83 cases per million inhabitants (95% CI: 75–92). Mean age was 50.9 years. Both incidence and prevalence rates were slightly higher among women (Rate Ratio: 1.08, Prevalence Ratio: 1.43). Age-specific incidence rates were similar in the two sexes up to the age of 39 years but seemed to diverge thereafter, with an increasing trend among men. Prevalence was substantially higher in women between 40 and 80 years of age and increased continuously up to 79 years in both sexes.
Conclusions
This is the first population-based study conducted in Italy to estimate incidence and prevalence of acromegaly. Current results are consistent with the available literature on this topic and show a higher prevalence than previously reported. Even if our algorithm requires proper validation, it could represent a comprehensive tool to describe the pattern of acromegaly, to assess its burden on patients and health care systems, and to provide guidance on resources allocation, especially in countries were national registries on acromegaly are not available.

Living with acromegaly: patient journey in europe vs USA
Judith Hey-Hadavi[1], Joli vanderLans[2], Maria Cannito[1] & Nicky Kelepouris[3]
[1]Pfizer Inc, New York, USA; [2]Pfizer Inc, Capelle a/d IJssel, USA; [3]Pfizer Inc, Collegevill, USA.

Introduction
Patients with acromegaly have often a challenging path from diagnosis to treatment start and to long-term care. Two separate acromegaly patient advisory panels (one in Europe and one in USA) were conducted with the aim to better learn about their experience and how this could be improved. This format was chosen to allow direct patient to patient interactions and to understand possible unmet needs and opportunities within the acromegaly community. An independent moderator facilitated the meetings and discussions.
Findings
In Europe, 7 patients (2 UK, 2 France, 2 Belgium, 1 Spain; 2M: 5F time since diagnosis 2–17yrs) attended, while in US 8 patients (3M, 5F, time since diagnosis 2–10 yrs.) attended. All patients had prior pituitary surgery and were receiving medical treatment. In both groups, most patients reported that their journey was challenging regardless of symptoms or age at time of diagnosis. For the majority of patients, symptoms went unrecognized for years (range 5–15 years) prior to diagnosis and included: headaches, arthralgia, fatigue, cessation of menses, weight gain and changes in physical appearance (US only). The European patients reported that their Health Care Providers (HCPs) were supportive and were generally satisfied with their care once the diagnosis was made. They recognized and accepted that living with symptoms of acromegaly and ongoing treatment will be 'part of life'. However, they would like more connections with other acromegaly patients for support. All US patients were concerned about their QoL and life expectancy; 6/8 reported a disconnect from their HCPs as to perceived control and care. The patient advisors proposed several ideas to improve their experience, i.e. HCP education, patient support, ambassador programs, patient panels and personalized approach.
Conclusions
Hearing directly from patients with acromegaly in an advisory panel setting is an innovative way of learning and understanding outside the traditional clinical setting. We identified differences in patient's experience in Europe vs US especially in acceptance of their disease and perceived care from their endocrinologist. There remains a major need for ongoing education, awareness and resources for patients as well as physicians to benefit their long-term care.

Online health information seeking behavior by patients prior to their outpatient appointments in endocrinology
Angelos Kyriacou[1,2,3] & Cathy Sherratt[1]
[1]Edge Hill University, Ormskirk, UK; [2]CEDM Centre of Endocrinology, DIabetes & Metabolism, Lemesos, Cyprus; [3]Evangelismos Hospital, Paphos, Cyprus.

Background
The internet is becoming an increasingly important medium for health-related information and is considered a means for aiding patient empowerment. Online health information (OHI) seeking behavior has never been studied in the field of endocrinology.
Objective
We set out to examine the frequency, how and why the internet is utilized for health-related information and the impact of such activity. Future information needs were also investigated.
Methods
A cross-sectional mixed-methods study was performed with more quantitative data. Qualitative data underwent thematic analysis. Patients attending a general endocrinology clinic were recruited from two clinical sites. A questionnaire survey was designed to answer our specific research questions.
Results
312 patients were included of which 251 (80.4%) were females; the response rate was 78.4%. OHI seeking was reported by 175 patients (56.1% of the whole study population and 78.1% among those that sought any health-related information); it was commoner among new patients ($P = 0.038$). OHI seekers perceived OHI to be of high quality (135, 77.1%) and demonstrated a good understanding of what constitutes trustworthy information. Notwithstanding, 71 (40.6%) relied on the top search engine options as their main criterion for choosing a website and 104 (59.4%) were not aware of website certification tools like HONcode. OHI seekers sought general information (90, 51.4%); this was confirmed by thematic analysis which also revealed that ease of access and the wealth of information offered by this medium are important reasons why they go online. Among OHI seekers, 63 (36.6%) reported that their behavior changed after seeking OHI

e.g. by improved self-care or compliance. Only 45 (25.7%) of OHI seekers discussed the information they gathered with their endocrinologist. If an interactive e-learning module was available, 194 (62.2%) of the 312 patients expressed a will to use it, especially existing OHI seekers ($P < 0.0001$) and those reporting a need for more health-related information ($P = 0.024$).
Conclusions
OHI seeking is practiced by the majority of endocrine patients before their appointments. Patients have a good awareness of what makes a website trustworthy, but more education and guidance is needed. The reason they seek OHI is because they want to gather more general health information, but are also attracted by the inherent characteristics of the internet. Patients should be encouraged by their doctors to discuss their online gathered information. Many endocrine patients are keen to utilize e-learning modules, even those patients that are not current OHI seekers.

Overuseoflaboratory and ultrasonographic examinations in thyreidology: Study from the Slovak Republic

Ján Bielik[1] & Matej Bielik[2]
[1]Faculty of HealthCare, Trenčín University, Trencin, Slovakia; [2]KAMEAT, Endocrinology Outpatients Department, Nové Mesto nad Váhom, Slovakia.

Objectives
Slovakia is gradually implementing health technology assessment (HTA). This method evaluated the issue of possible overuse of laboratory and imaging investigations in thyroidology for the last 10 years. The analysis being divided between 2008–2011 and 2012–2017. In this study we publish the outputs from the first stage phase.
Methods
The study was conducted using data from patient records of the General Health Insurance Company, a.s., 2011 registered approximately 3 400 000 policyholders (64.7%). Laboratory (fT3, fT4, TSH, ATPO, aTG, thyroglobulin, TRAK) and USG thyroid examinations were assigned a diagnosis E.00-E.07.
Results
The number of examined patients with these diagnoses had a permanent growth tendency: 2008 – 168.200, 2009 – 176.349, 2010 – 229.524, 2011 – 240.662. The same tendency was observed in laboratory examinations: 2008 – 414.904, 2009 – 449.500, 2010 – 605.268, 2011 – 620.378, as well as USG examinations: 2008 – 102.212, 2009 – 109.700, 2010 – 148.528, 2011 – 156.775. Year 2011 brought these results in laboratory examinations: fT4 – 196.785, TbG – 1.247, fT3 – 50.701, aTG – 58.139, aTPO – 64.910, TSH – 237.460, TRAK – 11.136. 2008 was similar in all laboratory examinations. The average number of laboratory and USG examinations per patient was – 3.074 examinations, 2009 – 3.171, 2010 – 3.284, 2011 – 3.229 examinations. The cost of these tests was calculated per 1 patient per year. 2008 – € 23.35, 2009 – € 25.59, 2010 – € 25.82, and € 26.76 in 2011. The total cost of these laboratory/USG examinations was in 2008 – 3 070 828/856 093 €, 2009 – 3 263 430/913 730 €, 2010 – 4 388 179/1 238 203 €, and 2011 – 4 223 686/€ 1,308,098.
Conclusions
Proposals for measures to reduce the costs of overuse of these examinations may be different according to the methodology used (based on the costs of 2011 – 4 223 686 or 1 308 098 €): A. When reducing the reimbursement to the level of the Slovak average, the saving would be approximately 442 535 € (8% of total costs). B. The savings would be around 525 130 € for the selected examinations – 9.49%. C. By reducing the average number of laboratory examinations from 3.4 to 3.0, the savings would reach about € 496 705, i.e. 11.76% and in case of USG testing from 1.15 to 1.0, the savings would reach 170 576 €, ie. 13.04%.

Restless legs syndrome in population of patients with thyroid disease in comparison to general populaton – questionnaire study

Szymon Suwała[1], Jakub Rzeszuto[2] & Roman Junik[1]
[1]Department of Endocrinology and Diabetology, Collegium Medicum in Bydgoszcz, University of Nicolaus Copernicus in Torun, Bydgoszcz, Poland; [2]Students Scientific Club of Deparment of Endocrinology and Diabetology Collegium Medicum in Bydgoszcz, University of Nicolaus Copernicus in Torun, Bydgoszcz, Poland.

Introduction
Restless legs syndrome (RLS), also known as Willis-Ekbom disease, is a common condition of the nervous system. It causes an overwhelming, irresistible urge to move the legs, mainly in the evening and night hours. It occurs in 7.2–10.0% of the population of western countries. Etiopathogenesis of RLS is not fully understood, but there is a hypothesis than an important role may play the imbalance between thyroid function and the dopaminergic system. The main aim of the study is to assess the incidence of RLS in population of patients with thyroid diseases and compare its epidemiology to the general population.
Material and methods
In the study we used online survey (based on the Google Spreadsheet mechanism), which was distributed via social media in groups associating patients with thyroid diseases (test group) and outside them (control group). The questionnaire included questions about all of criteria for the diagnosis of RLS, according to the International Restless Legs Syndrome Study Group consensus (2014).
Results
In pilot study based on responses from 94 respondents, a slightly more frequent occurrence of RLS symptoms was found in patients with thyroid disease than in the control group ($\Delta = 1.18\%$, but $P = 0.09$). Research in progress – full results (based on a group exceeding the minimum sample size, i.e. >384 respondents) will be presented during the conference.
Conclusion
Based on the current results of the study, patients with thyroid disease more often report RLS than in the general population. Full conclusions will be presented during the conference.

Corticosteroid secretion after the soy extract application to orchidectomized adult male rats

Vladimir Ajdzanovic[1], Dragana Miljic[2], Natasa Ristic[1], Lazo Pendovski[3], Florina Percinic-Popovska[3], Zoran Rovcanin[4] & Verica Milosevic[1]
[1]Department of Cytology, Institute for Biological Research 'Sinisa Stankovic', University of Belgrade, Belgrade, Serbia; [2]Department of Neuroendocrinology, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia; [3]Faculty of Veterinary Medicine, 'Ss. Cyril and Methodius' University in Skopje, Skopje, Macedonia, Republic of the former Yugoslav; [4]Health Center 'Stari Grad', Belgrade, Serbia.

Herein, we have tested the effects of application of commercial soy extract, rich in estrogen-like isoflavones, to orchidectomized adult rats (the model of mild andropause), on the corticosteroid secretion. Exploited animal model provides the opportunity to examine the potential effects of steroid-like compounds in the hormonal milieu deprived of endogenous sex steroids along with preserved hippocampal and hypothalamic regulation of the adrenal gland function. The experimental groups included sham-operated (**SO**), orchidectomized (**Orx**) and soy extract-treated orchidectomized (**Orx**+**Soy**; 30 mg/kg b.m. *s.c.*, for 3 weeks) rats. Plasma level of ACTH and serum levels of aldosterone, corticosterone and DHEA were determined by the immunoassays. **Orchidectomy** caused the increase ($P<0.05$) of circulating ACTH, aldosterone and DHEA by 57.0%, 2.6 and 2.0 folds respectively, compared to **SO** group. In **Orx**+**Soy** group, blood levels of ACTH and corticosterone were higher ($P<0.05$) by 99.5% and 79.6% respectively, in comparison with **SO** group. Also, the treatment of **orchidectomized** rats with **soy extract** elevated ($P<0.05$) the systemic levels of ACTH, aldosterone and corticosterone by 26.9%, 2.7 folds and 56.4% respectively, while the circulating DHEA level was decreased (65.6%; $P<0.05$), all compared to the corresponding parameters in **Orx** rats. Summarily, soy extract raised the ACTH level which has stimulatory influence on the mineralocorticoid and glucocorticoid output, while the adrenal androgens consequently fallen, in the rat model of mild andropause. The data support impression of a beneficial effect of soy isoflavone mixture on the homeostatic response to stress, but also call for precautions in the case of cardiovascular issues presence.

High prevalence of suppressed adrenal cortical function in kidney transplanted patients during low-dose prednisolone therapy

Amalie Valentin[1], Stina Willemoes Borresen[1], Marianne Rix[2], Thomas Elung-Jensen[2], Søren Schwartz Sørensen[2] & Ulla Feldt-Rasmussen[1]
[1]Department of Endocrinology, Rigshospitalet, Copenhagen, Denmark; [2]Department of Nephrology, Rigshospitalet, Copenhagen, Denmark.

Introduction
Maintenance immunosuppressive regimens after renal transplantation (RTx) most often include prednisolone which may induce secondary adrenal insufficiency. Adrenal insufficiency is a potentially life-threatening side effect to glucocorticoid treatment due to the risk of acute adrenal crisis. We aimed to investigate the prevalence of prednisolone-induced adrenal insufficiency in RTx patients receiving long-term low-dose prednisolone treatment.
Material and methods
In a case-control study, 30 RTx patients (17 males, mean age 50.4 s.d. 13.1) treated with prednisolone and 30 dialysis patients (19 males, mean age 59 s.d. 13.1) not treated with prednisolone underwent testing for adrenal insufficiency by a 250 µg Synacthen test. RTx patients were transplanted at least one year before enrollment and receiving continuous treatment with either 5 or 7.5 mg prednisolone/day for at least 6 months before the study. Fifteen peritoneal dialysis (CAPD) patients and 15 haemodialysis patients comprised the control group. The Synacthen test was performed fasting in the morning. Transplanted patients paused prednisolone for 48 hours before the test and all patients ($n=7$) paused locally applied glucocorticoids for as long as possible. Normal adrenal function was defined as P-cortisol $\geq$420 nmol/l 30 min after Synacthen injection, as validated for the local Roche Elecsys® Cortisol II assay.
Results
Of the RTx patients, 13 (43%; CI: 27–61%) had an insufficient response to the Synacthen test compared to one patient in the control group (3%; CI: 0.6–17%) ($P=0.0004$). Insufficient response in RTx patients was seen in 9/25 and 4/5 patients treated with 5 and 7.5 mg prednisolone/day respectively. For the RTx group both baseline P-cortisol and 30 min P-cortisol was generally lower compared to dialysis patients with a mean of 265 nmol/l (s.d. 100) vs 350 nmol/l (s.d. 69) for baseline P-cortisol and mean of 411 nmol/l (s.d. 153) vs 623 nmol/l (s.d. 99) nmol/l for 30 min P-cortisol ($P<0.0001$). No correlation was found between duration of treatment and 30 min P-cortisol ($P=0.68$, $r=0.08$). Of the seven patients treated with local glucocorticoids, 3/4 were insufficient in the transplant group and 1/3 in the control group.
Conclusion
We found a high prevalence of adrenal insufficiency among RTx patients receiving low-dose prednisolone treatment. We therefore advocate for an increased clinical alertness and a discussion of how to manage the risk of adrenal insufficiency in patients with a kidney graft.

Frequency of multiple endocrine neoplasia-1 in patients with primary hyperparathyroidism

Muhammet Cuneyt Bilginer[1], Cevdet Aydin[1], Sevgul Faki[1], Oya Topaloglu[1], Hanife Saat[2], Busranur Cavdarli[2], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Ankara Yildirim Beyazit University School of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Diskapi Yildirim Beyazit Education and Research Hospital, Department of Medical Genetics, Ankara, Turkey; [3]Ankara Numune Education and Research Hospital, Department of Medical Genetics, Ankara, Turkey.

Aim
Multiple endocrine neoplasia-1 (MEN-1) is described in patients as presence of clinical two or more primary MEN-1 associated tumors or patients who have MEN-1 clinics and also have family members with MEN-1 associated tumors. It is associated with loss of activation genetic mutation in a tumor suppressor gene called Menin. MEN-1 is associated with tumors involving the parathyroid glands, anterior hypophysis, and pancreatic islet cells. Primary hyperparathyroidism (PHPT) is the most common feature of MEN-1. In this study, we aimed to evaluate the frequency of MEN-1 associated mutation in patients with PHPT.
Materials and methods
We scanned the medical records of 361 patients with PHPT who were followed-up in our department between January 2010-December 2017. We presented the data of 14 patients who had genetic analysis due to suspicious clinical findings.
Results
Totally 14 patients (two men, 12 women; median age 31.2$\pm$5.7 years) with PHPT were evaluated in genetic analysis. Menin gene mutation was found in 3 (21.4%) patients. In overall patients with PHPT ($n=361$),frequency of MEN-1 ($n=3$) was evaluated as 0.83%. Genetic analysis of three patients with menin mutation were as follows:
Case 1
A 37-year-old man presented with a history of recurrent nephrolithiasis during 14 years. He was diagnosed as PHPT after biochemical analysis. Genetic analysis was reported as MEN-1:c.643_646delACAG (p.Thr215Serfs*13) heterozygous. Other tumoral components of MEN-1 were not found in physical and laboratory examinations.
Case 2
A 35-year-old man was diagnosed as PHPT and prolactinoma. Genetic analysis was reported as MEN-1: c.654+1G>A heterozygous. He did not have other MEN-1 associated tumors.
Case 3
A 26-year-old woman who had hypoglycemia, hyperammonemia, hyperinsulism, partial empty sella and hyperprolactinemia in her medical history was evaluated. Genetic analysis was associated with heterozygous genomic changes as c984c>a in MEN-1 gene on 7th exon.

Conclusion
MEN-1 frequency in PHPT patients is estimated as 1–18%. The diagnosis of PHPT is usually made in second decade in MEN-1 patients. So, the guidelines mostly recommend scanning for PHPT before 30 years of age. In our study population, two patients are between ages of 30 and 40 years. It must be kept in mind that the estimated penetrance of 100% is present up to 40–50 years of age in an individual harboring the MEN-1 gene.

Impact of the metabolic syndrome on the renal function after partial nephrectomy for nonmetastatic localized renal cell carcinoma

Kays Chaker, Ahmed Sellami, Yassine Ouanes, Mohamed Ali Ben Chehida, Mohamed Ali Essid, Mokhtar Bibi, Karem Abid, Sami Ben Rhouma & Yassine Nouira
Urology Department, La Rabta Hospital, Tunis, Tunisia.

Introduction and objectives
The most important risk factors of chronic kidney disease (CKD) are diabetes and hypertension. In addition, obesity and metabolic syndrome (MetS) are independent predictive factors of CKD. The objective of our study was to investigate if MetS affects renal function of patients who underwent partial nephrectomy for localized renal cell carcinoma (RCC).
Patients and methods
50 cases of T1N0M0 RCC patients who underwent partial nephrectomy between 2002 and 2016 at our institution were reviewed retrospectively. Patient's history and clinicopathological characteristics of RCC were compared with and without MetS status. Estimated glomerular filtration (eGFR) was calculated using the Modification of Diet in Renal Disease (MDRD) formula. We evaluated preoperative and postoperative eGFR, as well as overall survival (OS) with MetS status. Data was analyzed using two-sample Student's *t*-tests and the Pearson's χ^2-test (categorical variables). Survival analysis was estimated using kaplan-Meier method comparing with MetS status.
Results
Gender and age had not a statistically-significant impact in patients with and without MetS. ($P>0.05$). Clinicopathological characteristics of RCC were not different in both groups ($P>0.05$). In MetS(+), preoperative and postoperative eGFR were lower than MetS(−) (70.2 ± 25.44 vs 78.6 ± 26.17; 57.3 ± 24.6 vs 71.6 ± 28.1). The difference between preoperative and postoperative eGFR was statistically different between the two groups ($P=0.04$).Overall survival stratified with MetS status wasn't statistically different ($P>0.05$).
Conclusion
Although preoperative and postoperative eGFR are lower in MetS(+) and the changes of eGFR are different between the two groups after partial nephrectomy, MetSdid does not affect overall survival.

Is SFRP-4 an early potential biomarker related to diabetes and hypertension, in patients with androgenic alopecia?

Suleyman Ipekci[1], Mehmet Sozen[2], Sedat Abusoglu[3], Suleyman Baldane[1], Fatma Akyurek[4], Cem Onur Kirac[1], Ayse Gul Kebapcilar[5], Ali Unlu[3] & Levent Kebapcilar[1]
[1]Selcuk University Faculty of Medicine, Division of Endocrinology, Konya, Turkey; [2]Selcuk University Faculty of Medicine, Department of Internal Medicine, Konya, Turkey; [3]Selcuk University Faculty of Medicine, Department of Biochemistry, Konya, Turkey; [4]Selcuk University Faculty of Medicine, Department of Dermatology, Konya, Turkey; [5]Selcuk University Faculty of Medicine, Department of Gynecology and Obstetrics, Konya, Turkey.

Androgenic alopecia (AGA) is an important clinical issue that can cause significant cosmetic problems. Many factors such as genetic, androgen hormones, environmental factors, and inflammation are involved in the pathogenesis of androgenic alopecia. Insulin and insulin resistance have been found increased in individuals with AGA. There are many proinflammatory substances which are playing role in the pathogenesis of androgenic alopecia. Secreted frizzled related protein-4 (SFRP-4) serves as the regulator of insulin exocytosis in pancreatic islet cells. Recently reports have been shown that SFRP-4 serum levels were correlated with insulin resistance and type 2 diabetes mellitus. In two small but notable cohort studies, presuming that SFRP-4 might be an early diabetic indicator, SFRP-4 was observed to increase in serum a few years before the diagnosis of diabetes. In this study, it is aimed to determine the levels of SFRP-4 in androgenic alopecia. Forty-one male patients aged 25–45 years with the complaint of male pattern hair loss which is started before 30 years old and 40 male patients without alopecia were involved to the study. The androgenic alopecia types of patients were determined according to the Hamilton-Norward classification. Specific enzyme-linked immunosorbent assay kits were used for serum SFRP-4 measurement. Ambulatory blood pressure measurements were performed to all participants with an oscillometric type Mobil O Graph NG instrument. The age, BMI and smoking rates were not significantly different between two groups ($P>0.05$). In the group with androgenic alopecia, the SFRP-4 median was 1.50 ng/ml (normal: 0.01–21.20) while in the control group it was 0.57 ng/ml (0.04–5.20) ($P=0.025$). Ambulatory blood pressure measurements were not different between the two groups ($P>0.05$). Spearman's correlation test showed a significantly positive correlation between SFRP-4 and HOMA-IR, sensitive CRP, BMI, and night pulse rate (respectively: rho$=0.265$, $P=0.017$; $\rho=0.274$, $P=0.013$; $\rho=0.220$, $P=0.049$; $\rho=0.226$, $P=0.042$), and a mild negative correlation with HDL-cholesterol values in the AGA group ($\rho=-0.242$, $P=0.030$). In many studies serum SFRP-4 levels were higher in patients with diabetes. We also found that SFRP-4 levels were significantly correlated with BMI, HOMA-IR levels at early ages in men with androgenic alopecia in our study. SFRP-4 may play an important role in the pathogenesis of androgenic alopecia, which could be an early indicator of insulin resistance, diabetes and hypertension that may develop in later ages of these subjects.

Multi-hormonal deficits in heart failure with preserved ejection Fraction: prevalence and impact on diastolic dysfunction

Carmine Bruno[1], Angela Maria Rita Favuzzi[2], Edoardo Vergani[1], Angela Venuti[2], Maria Anna Nicolazzi[2], Mariella Fuorlo[2], Raffaele Landolfi[2] & Antonio Mancini[1]
[1]Internal Medicine Department, Division of Endocrinology, Catholic University of the Sacred Heart, Rome, Italy; [2]Internal Medicine Department, Division of Internal Medicine and Cardiovascular Diseases, Catholic University of the Sacred Heart, Rome, Italy.

Background
In heart failure with reduced ejection fraction (HFrEF), catabolic mechanisms have a strong negative impact on morbidity and mortality. The relationship between anabolic hormonal deficit, thyroid function and heart failure with preserved ejection fraction (HFpEF) has still been poorly investigated. For this reason, we tried to define the prevalence of multi-hormonal deficiencies in HFpEF patients and the relationships between hormonal deficits and echocardiographic indexes.
Materials and methods
40 patients, 27 men and 13 women, aged 59–92 years, were enrolled. Mean BMI was 28.22 ± 4.96 kg/mq. Thirty-six patients showed a moderate degree of diastolic dysfunction (90%) and four patients a mild grade one (10%). Twenty-nine patients (72.5%) were in NYHA III functional class, eleven in NYHA II functional class (27.5%). After an overnight fast, a basal sample was collected for evaluation of N-terminal pro-brain natriuretic peptide, fasting glucose, thyroid-stimulating hormone, free triiodothyronine, free thyroxine, insulin-like growth

factor-1, dehydroepiandrosterone-sulfate, total testosterone (only in male subjects). An echocardiography evaluation was performed.
Results
Only one patient (2.5%) did not exhibit hormonal deficit, eight patients (20%) had deficit of one hormone, 18 patients (45%) of two axes, 12 patients (30%) of three axes, one patient (2.5%) of all four axes. Among them: 97.5% had DHEAS deficiency, 67.5% IGF-1 deficiency, 37% testosterone deficiency, 22.5% a 'Low-T3 syndrome', 20% subclinical hypothyroidism. Patients with IGF-1 deficit showed higher values of left atrial volume, of systolic pulmonary artery pressure (SPAP), of tricuspidal peak velocity (TPV), and lower values of tricuspid annular plane systolic excursion (TAPSE) and TAPSE/SPAP ratio. Patients with testosterone deficiency had higher SPAP and TPV; patients with low T3 syndrome had higher value of right ventricular mid cavity diameter. Hormonal dysfunction was independent from the presence of comorbidities, and there was no difference between male and female subjects.
Conclusions
Multi-hormonal deficits are associated with right ventricular dysfunction and diastolic dysfunction in patients with HFpEF. Therefore they can be considered as an independent factor negatively influencing natural history of the syndrome.

Cross-hormone treatment: review of cardiovascular risk factors and bone mineral density in 25 transsexual subjects followed in a tertiary hospital

Ane Azkutia, Lorea Herráiz, Inés Jiménez, Elvira Barrio, Elvira Ramos, Martín Cuesta & Ángel Díaz
Hospital Clínico San Carlos, Madrid, Spain.

Introduction and objectives
Transsexuality refers to discrepancy between the assigned sex/gender at birth and the one that the subject identifies with. The use of the cross hormone treatment as sex/gender change method implies the necessity of monitorize the hormone levels and potential treatment risks. Our study tries to evaluate the relationship between the hormone changes and the changes in the cardiovascular risk factors and the bone mineral density.
Methods
We conducted a retrospective analysis of 25 transsexual subjects (nine transsexual women (36%) and 16 transsexual men (64%)) receiving cross hormone treatment for 24 months and monitoring in Hospital Clínico San Carlos. Demographic information, cardiovascular risk factors and bone mineral data were collected.
Results
25 patients were evaluated with a mean of age of 37.8 ± 10.3 for transsexual women and 34.13 ± 10.6 for transsexual men ($P = 0.39$). 33% of transsexual women and 13% of men were smokers ($P < 0.01$). Mean of spine T-score for transsexual women was 1.06 ± 0.18 and 0.83 ± 0.33 for men ($P < 0.05$). No other cardiovascular risk factors were found nor differences between both groups. During the 24 month follow-up, no worsening of cardiovascular risk factors was found in both groups. According to the transsexual women it was found a significant reduction in systolic blood pressure (SBP) (117 mmHg $\pm$ 9.12 mmHg vs 112.2 mmHg $\pm$ 12.1 mmHg ($P = 0.04$)). On the other hand, it was identified a positive correlation between testosterone levels and first, total cholesterol ($r = 0.69$, $P < 0.04$) and second, LDL-c ($r = 0.73$, $P < 0.02$), showing that the higher testosterone levels, the higher cholesterol ones. No differences in terms of bone mineral density were found in any of the groups.
Conclusions
According to our results, the cross hormone treatment is safe in terms of no worsening cardiovascular risk factors and bone mineral density. In order to avoid long term worsening in both aspects it is very important to maintain de estradiol and testosterone levels in the correct range and try to look carefully the cardiovascular risk factors.

How the diagnose of the dilatation of ascending aorta in Turner syndrome can be verified?

Ruta Kriksciuniene[1,2], Mindaugas Zaikauskas[1], Saulius Lukosevicius[1,2], Birute Zilaitiene[1,2] & Rasa Verkauskiene[1,2]
[1]Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Hospital of Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction
Two major strategies can be used to verify the diagnosis of ascending aortic dilatation in Turner syndrome (TS): the diameter of the aorta adjusted for body surface area (BSA) can be estimated or the ratio of the ascending/descending aorta may be assessed.
Aim
To identify the difference of the prevalence of ascending aortic dilatation in patients with Turner syndrome by measuring the diameter of the ascending aorta adjusted for BSA and by estimating the ratio of ascending/descending diameter of aorta (AD/DD).
Methods
63 women with TS (45, X 68%) treated in the Hospital of Lithuanian University of Health Sciences were the subjects of the study. Seven of the patients were excluded from the study as MRI angiography was contraindicative. 56 females with TS $\geq$18 yrs (mean age 30.98 ± 9.1 yrs) underwent MRI angiography using Gadolinium based contrast media. Diameters of the ascending aorta were evaluated in three positions: in the level of the aortic sinuses (D1), in sinotubular junction (D2) and in the inferior margin of the right pulmonary artery (D3). The largest diameter of the aorta was included in the analysis. The diameter of descending aorta was measured between the left pulmonary artery and the superior part of the left atrium (D4). Aortic dilatation was considered to be present if the larger diameter of ascending aorta (AA) was ≥ 2 cm/m^2 (BSA-normalized) and/or the ascending and the descending ratio (AD/DD ratio) was ≥ 1.5.
Results
Out of 56 studied women, 48% ($n = 27$) had the diameter of the ascending aorta ≥ 2 cm/m^2, 32.14% ($n = 18$) had aortic dilatation confirmed after calculating the AD/DD ratio ($\geq$ 1.5). No significant difference was found ($P = 0.057$). If the dilatation of the ascending aorta was present the measurements of the ascending aorta were larger in all positions (D1 17.07 mm/m^2 vs. 22.8 mm/m^2, $P < 0.001$; D2 14 mm/m^2 vs 17.6, $P < 0.001$; D3 15.26 mm/m^2 vs 19.49 mm/m^2). The size of the aorta correlated with age in all positions (D1 $r = 0.362$, $P = 0.006$; D2 $r = 0.336$, $P = 0.011$; D3 $r = 0.381$, $P = 0.004$; D4 $r = 0.484$, $P < 0.001$).
Conclusion
Measuring the diameter of ascending aorta adjusted for BSA or calculating the ratio of the ascending/descending aorta can verify the existence of aortic dilatation equivalently in Turner syndrome.

Fibroblast growth factor-21 predicts adverse outcome in community-acquired pneumonia

Fahim Ebrahimi[1], Carole Wolffenbuttel[1,2], Claudine A Blum[1,3], Beat Müller[3], Philipp Schuetz[3], Mirjam Christ-Crain[1] & Matthias Johannes Betz[1]
[1]Department of Endocrinology, Diabetes and Metabolism, University Hospital Basel and University of Basel, Basel, Switzerland; [2]Department of Internal Medicine, UMC Utrecht, Utrecht, Netherlands; [3]University Department of Medicine, Kantonsspital Aarau, Aarau, Switzerland.

Introduction
Fibroblast growth factor-21 (FGF-21) is a recently discovered hormone acting as a central regulator of metabolism via adaptation of glucose homeostasis, insulin sensitivity, and ketogenesis. While acute systemic inflammatory conditions come along with profound alterations of metabolism, the role of FGF-21 in these acute phase responses is still unknown.
Methods
This is a secondary analysis of two randomized, controlled trials in patients presenting to the emergency department with community-acquired pneumonia. Multivariate regression models were performed to analyze associations of FGF-21 with disease severity, mortality, length of hospital stay and duration of antibiotic treatment.
Results
A total of 509 patients were included in the analysis, 150 patients from the ProCAP trial and 359 from the STEP trial. Serum FGF-21 on admission was significantly correlated to disease severity as measured by pneumonia severity index ($R^2=0.159$, $P<0.0001$). FGF-21 levels at admission were associated with reduced likelihood of clinical stability, adjusted hazard ratio (HR) 0.88 (95% CI, 0.81–0.96; $P=0.006$) and consecutively prolonged duration of intravenous antibiotic therapy (adjusted HR 0.56; 95% CI, 0.15–0.97; $P=0.008$). FGF-21 levels were higher at admission in nonsurvivors than in survivors (median 1307.6 vs 416.7 pg/ml; $P<0.001$), yielding a 1.41-fold increased adjusted odds ratio of 30-day mortality (95% CI, 1.05–1.90; $P=0.02$). FGF-21 was found to identify patients for 30-day mortality with superior discriminative power (AUC 0.74) compared to procalcitonin (AUC 0.62) or c-reactive protein (AUC 0.48).
Discussion
FGF-21 was markedly increased in patients with community-acquired pneumonia and was found to identify patients at risk for adverse outcome more effectively than routine diagnostic markers.

Low dose duloxetine and the risk of hyponatraemia

Tahir Omer & Ian Seetho
Cambridge University Hospital, Cambridge, UK.

Duloxetine is a serotonin/norepinephrine reuptake inhibitor, prescribed frequently as a first line treatment for Diabetic neuropathy. It is also prescribed for treatment of depression, anxiety disorder and chronic musculoskeletal pain. Hyponatremia is a known adverse effect of most SSRIs including duloxetine and can potentially be life-threatening.Duloxetine induced hyponatremia, however, is relatively rare specially on low doses and is typically seen in the elderly frail patients. We report a case of duloxetine-induced hyponatremia in a 76 year old lady with a background of type 2 diabetes mellitus, hypertrophic obstructive cardiomyopathy, orthostatic hypotension and gradual functional decline and increased frailty. Initially on Fludricortisone and Midodrine for orthostatic hypotension, she was started on Duloxetine by her family doctor for neuropathic pain a week prior to presentation. She was not on diuretics. She then presented to the A&E with frontal headache, confusion, disoreintation and recurrent vomiting. Laboratory findings revealed hyponatremia, low serum and raised urine osmolalities, and increased urine sodium. Her TSH and Cortisol levels were normal. Syndrome of inappropriate antidiuretic hormone was considered and, duloxetine was discontinued. She was treated with fluid restriction, and required intravenous sodium chloride administeration due to hypotension. She responded well to treatment and her confusion and vomiting were improved after correction of sodium. Health care practitioners in general and diabetologist in specific should be aware of the possibility of duloxetine-induced hyponatremia, particularly in elderly frail patients.Elderly people are vulnerable because fluid levels become more difficult for the body to regulate.Close laboratory monitoring is essential after initiation of treatment.

Endocrine disorders in a patient affected by MELAS syndrome: a case study

Ewa Obel[1], Marcin Lewicki[2], Agnieszka Zwolak[3], Agata Smoleń[2] & Jerzy Tarach[1]
[1]Chair and Department of Endocrinology, Medical Universisty of Lublin, Lublin, Poland; [2]Chair and Department of Epidemiology and Clinical Research Methodology, Medical University of Lublin, Lublin, Poland; [3]Chair of Internal Medicine and Department of Internal Medicine in Nursing, Medical University of Lublin, Lublin, Poland.

Introduction
Mitochondrial myopathy, encephalopathy, lactic acidosis, and stroke-like episodes, combined together, under the name of MELAS syndrome, constitute one of the mitochondrial genetic diseases with dominant progressive neurodegenerative symptoms. Although nervous system involvement is often the first manifestation of the disease, during the course of the disorder, patient can develop a wide spectrum of endocrine disorders ranging from GH deficiency and hypoparathyroidism to diabetes.
Case study
19-year old patient with MELAS syndrome was admitted to the Department of Endocrinology for routine check-up and evaluation of carbohydrate metabolism. He presented with standard features of the symptom like: encephalopathy, myopathy, hearing impairment, mental retardation, vision disturbances and history of seizures and stroke-like episodes. During the course of the disease he developed numerous endocrine manifestations of this mitochondrial pathology. He was diagnosed with short stature due to GH deficiency, after that, based on decreased calcium and PTH levels, hypoparathyroidism was recognized and suplementation was introduced. Later he was diagnosed with secondary adrenal insufficiency requiring hydrocortisone replacement therapy. During evaluation of delayed puberty hypogonadotropic hypogonadism was identified. Additionally the review of medical history revealed recurring episodes of hyponatremia probably due to unrecognized SIADH syndrome. During current hospital stay we evaluated the carbohydrate metabolism ruling out mitochondrial diabetes. Fasting glucose was within normal limits and HbA1c level was at 5.4%. Further diagnostic unmasked concomitant insulin resistance with HOMA-IR at 3.3. The dose of hydrocortisone was adjusted and the patient was referred to endocrine outpatient clinic for regular follow-up.
Conclusions
Endocrine dysfunctions, with many of them occurring concomitantly, complicating the course of the disease, are an important aspect of mitochondrial diseases, especially in patients with MELAS. Mitochondrial diabetes is hypothesized to occur as a result of insulin deficiency rather than insulin resistance, however, in some patients, the second mechanism may also play a crucial role

Patient with neurofibromatosis type 1 and follicular thyroid cancer

Fotini Kanouta[1], Styliani Kalaitzidou[1], Eleni Triantafillou[1], Aspasia Drousou[1], Taxiarchis Kyrimis[1], Dimitra Tampouratzi[1], Michalis Kotis[1], Georgios Papadakis[2], Victoria Kaltzidou[1], Eirini Veniou[1], Anna Drakopoulou[1], Chrysa Karavasili[1], Georgios Mastorakos[3] & Athanasia Tertipi[1]
[1]Endocrinology Department, Metaxa Anticancer Hospital, Piraeus, Greece; [2]STEPS Stoffwechselzentrum, Biel/Bienne, Switzerland; [3]Endocrinology Clinic, Aretaieion Hospital, Athens University Medical School, Athens, Greece.

Objectives
Neurofibromatosis type 1 (NF1) is an autosomal, dominant, genetic disorder. The genetic lesion in neurofibromatosis type 1 is located at locus 17q11.2 that harbors the neurofibromin gene. Patients have 3-4 times higher possibility to develop malignancies relative to the general population. The endocrine manifestations of neurofibromatosis include precocious puberty, short stature, osteoporosis and pheochromocytoma. We present a patient with neurofibromatosis type 1 and thyroid carcinoma.
Methods
A 46-years-old female patient unterwent total thyreoidectomy for multinodular goiter. Pathology report revealed a macrofollicular variant of follicular thyroid

carcinoma, 4 cm in maximum diameter ($T_2N_0M_0$). The patient reveived radioactive iodine (^{131}I) therapy 70 mCi and L-thyroxine suppression therapy. From the medical history the patient reported a brain tumor surgery, at the left brain lobe, at the age of 4 years, which resulted in left facial nerve palsy. She also had delayed puberty.
Results
From the clinical examination the patient had typical signs of NF1 such as café au lait spots, subcutaneous neurofibromas, axillary freckles, as well as hamartomas of the iris (Lisch nodules) and low stature. In the family history there were no family members with NF-1 reported. The patient fulfilled the 4 out of 7 diagnostic criteria of NF-1. Brain MRI reported gliotic lesions in the hypoplastic left lobe and the cerebellum. The biopsy of a skin nodule revealed neurofibroma, whereas further diagnostic examinations for pheochromocytoma and osteoporosis were negative.
Conclusion
Clinical diagnosis requires the presence of at least 2 of the 7 criteria to confirm the presence of NF1. Many of these signs do not appear until later childhood or adolescence and the diagnosis often is delayed, despite suspicious features for NF1. Although rare, the coexistence of thyroid cancer is possible and should be evaluated

A rare mediastinal signet-ring cell carcinoma revealed after postpartum thyroiditis – a coincidence or a link?

Cristina Ene[1], Ramona Bica[2], Magdalena Zidu[2], Aida Mihailovici[1], Adrian Istrate[1,3] & Ana-Maria Tanase[1,4]
[1]"Dr. Victor Babes" Foundation, Bucharest, Romania; [2]"Dr. Victor Babes" Foundetion, Bucharest, Romania; [3]Central Military Hospital, Bucharest, Romania; [4]Colentina Hospital, Bucharest, Romania.

Introduction
Postpartum thyroiditis is an autoimmune process that occurs in 5% of the women, precipitated by immunological rebound. The majority off signet-ring cell carcinoma (SRCC) tumors arise from the stomach, colon and breast, malignant transformation of a bronchogenic cysts being exceptionally.
Aim
We present a case of a rare mediastinal SRCC of the mediastinum, diagnosed initially with a postpartum thyroiditis.
Case presentation
A 34 years old woman presented with complains of neck and anterior thoracic discomfort, agitation, palpitation, 3 months after getting birth. The initial workup found thyrotoxicosis, with high level of thyroid antibodies and autoimmune pattern at ultrasonography, with reduced uptake of Tc-99m pertechnetate at thyroid scintigraphy. Thyrotoxicosis remission, after 2 months of evolution, revealed a superior cava vein syndrome. Chest radiography showed a large mediastinum and cystic-tumor in CT. She associated pericardial effusion, without hemodynamic significance. In spite of sophisticated diagnostic workup, detailed investigations fail to reveal other site implicated at the moment. The tumor resection was complicated with metastatic involvement of the pleura with massive pleural effusion, rising level of the pericardial fluid with carcinomatous signet-ring cells, poor response to treatment and breast metastasis later on. The histopathology and immunohistochemistry of mediastinal mass and breast nodule concluded that it is the case of a very rare mediastinal bronchogenic cyst with malignant transformation in a SRCC. The overall progression was poor with the patient's death 1 year after diagnosis.
Conclusion
There are limited data about evolution of bronchogenic cysts or SRCC in pregnancy or postpartum and how endogenous estrogens influences tumor's grow. The malignant transformation of a bronchogenic cyst happens exceptionally. We know that postpartum thyroiditis is precipitated by immunological rebound that follows the partial immunosuppression of pregnancy and malignancy is also an immunosuppressive state, so the association of postpartum thyroiditis in this conditions is uncommon.

When it is the time of prophylactic thyroidectomy to children with medullary thyroid cancer with RET proto-oncogene Cys634Trp mutation in a family with multiple endocrine neoplasia type 2A

Corina Galesanu[1,2], Dan Niculescu[1], Luminita Apostu[2] & Mihail Romeo Galesanu[3]
[1]University of Medicine and Pharmacy "Grigore T. Popa "Iasi, Iasi, Romania; [2]"Sf. Spiridon" Emergency Clinical Hospital Iasi, Iasi, Romania; [3]Romanian Academy of Medical Sciences, Radiology,, Iasi, Romania.

Background
Almost all patients with Multiple Endocrine Neoplasia, type 2A (MEN 2A) have MTC. C-cell hyperplasia develops early in life and can be viewed as the precursor lesion for MTC. Children with MEN2A who have a total early thyroidectomy have an excellent chance of remaining disease-free.
Objectives
To follow-up the children with RET mutation in a family with MEN2A.
Methods
We report a family with MEN2A in which the first patient had bilateral pheochromocytoma associated with MTC. Molecular genetic testing of the RET exon confirmed the mutation at codon 634(Cys634Trp) in RET exon 11.We screened all her family members; six had the same RET proto-oncogene mutation; four females and two children. A boy had normal level of calcitonin (identiphied with RET mutation at two months), his mother developed MTC during pregnancy. The second boy-ten years old had high level of calcitonin; his mother had MTC and bilateral pheochromocytoma. Monitoring the children to every 6 months: physical neck examination and neck ultrasound, blood tests of calcitonin and CEA.
Results
In our group, the boy who was diagnosed at 2 months with RET mutation has been prophylactic thyroidectomies at 7 years. He presented two areas of C-cell hyperplasia. The second boy who now has 17 years has high values of calcitonin and CEA, and parents refuse the surgical excision.
Conclusion
At the child presented by us, parents delaying the agreement for thyroidectomy, and this could result in the development of the MTC.

Subacute thyroiditis in association with psoriasis and behcet's disease

Paulo Carvalho Ferreira[1], Bruno Maia[2], António Marinho[3], Ana Veloso[4], Ivo Cunha[4], Inês Leite[5] & Filipe Mota[1]
[1]Endocrinology Service, Hospital Pedro Hispano, ULS Matosinhos, Matosinhos, Portugal; [2]USF Eça de Queirós, ACeS Póvoa de Varzim/ Vila do Conde, Póvoa de Varzim, Portugal; [3]Internal Medicine Service, Centro Hospitalar do Porto, Porto, Portugal; [4]Internal Medicine Service, Hospital Pedro Hispano, ULS Matosinhos, Matosinhos, Portugal; [5]Dermatology Service, Hospital Pedro Hispano, ULS Matosinhos, Matosinhos, Portugal-.

Introduction
Subacute thyroiditis is usually a self-limited pathology, possibly of viral aetiology, defined by cervical pain and sometimes systemic symptoms. Its association with autoimmune diseases doesn't seem to be more frequent than in the general population.
Clinical case
Clinical findings of thyrotoxicosis with 3 weeks of evolution associated with anterior cervical pain and fever up to 38 °C. The patient presented with recurrent mouth sores since childhood and vaginal sores in the prior year. She also presented with hand nail *pitting* and onycholysis in the former 4 years. The maternal aunt had thyroid cancer and two maternal cousins had multinodular goitre. No family history of autoimmune diseases. The thyroid ultrasound revealed an enlarged lobulated gland with hypoechoic areas. Periodic analytical study was conducted (in 2^{nd}/ 4^{th}/ 9^{th}/ 15^{th} weeks): TSH – 0,024/ <0,01/ 32,139/ 4,69 µUI/ mL (0,35–4,94); free T3 – 5,33/ 3,27/ 2,81/ 3,19 pg/ mL (1,71–3,71); free T4 – 2,39/ 1,28/ 0,62/ 0,88 ng/ dL (0,70–1,48); C reactive protein – 66,80/ 27/ 0,4/ 0,2 mg/ L (<0,5); anti-thyroid antibodies were negative. Eight months after the beginning of the symptoms, TSH was of 0,894 µUI/ mL. The patient was initially treated with propanolol 20 mg every 8 hours and ibuprofen 400 mg every 8 hours. In this period she referred worsening of the mouth sores. In subsequent consultations the dose of beta-blocker was progressively diminished until its suspension after 2 months. A progressive improvement of the pain symptoms took place with complete disappearance after 6 months. The patient was at the same time observed by the Dermatology speciality which diagnosed nail psoriasis. Despite a period of clear, short, analytical hypothyroidism, it was decided not to initiate levothyroxine given the absence of symptoms related to it. In the beginning of 2017 the patient was observed in the autoimmune diseases

consultation were she was diagnosed with Behçet's Disease. From the undertaken study, it stands out the positivity for HLA-B*35 and HLA-A*02 antigens.
Conclusions
Subacute thyroiditis usually presents a self-limited, typical evolution, and remits without leaving sequelae. In the presented case it was possible to document that particular evolutional pattern, even in the context of significative analytical hypothyroidism. Within our knowledge, the association between Subacute Thyroiditis, Behçet's Disease and Psoriasis has never been reported. In the first, it is documented an increase in prevalence of antigen HLA-B*35, and in the last two of the antigen HLA-A*02.

DOI: 10.1530/endoabs.56.P635

P636

Primary haemoglobinopathies as a cause of secondary endocrinopathies

Yuvanaa Subramaniam, Gideon Mlawa & Nemanja Stojanovic
Queen's Hospital, Romford, London, UK.

Background
Haemoglobinopathies are inherited disorders of haemoglobin that predispose to endocrinopathies. The common ones include growth delay, hypogonadism and subsequent osteopaenia. Less commonly seen are diabetes mellitus, thyroid and adrenal disorders. Aetiology is multifactorial and includes tissue hypoxia, chronic anaemia, iron overload, high energy demand, genetic influence and malnourishment. We present three case reports which illustrate the endocrinopathies amongst patients with thalassaemia and sickle cell disease.
Cases
A 27 year old, transfusion dependent, lady with sickle cell disease presented with amenorrhoea for 5 years. She had a normal menarche. She was previously on a combined contraceptive pill and was having menstrual periods. Since stopping, she has noticed complete amenorrhoea. She denied galactorrhoea, headache or visual disturbance. Her hormonal profile showed low levels of luteinising hormone (LH), 0.9iU/L and oestradiol (E2) <70 pmol/L.Prolactin was normal. MR pituitary was unremarkable. Bone density scan (DEXA) showed osteopaenia. She was referred to another hospital with haemoglobinopathy service for joint fertility management. A 50 year old lady with transfusion dependant beta thalassaemia major had diabetes mellitus, osteoporosis and premature ovarian failure. She is currently on novorapid, lantus, deferasirox and penicillin v. Hormonal profile showed low levels of LH, follicular stimulating hormone (FSH) and E2. DEXA scan was in keeping with osteoporosis (lumbar spine T score of -3). Her diabetes and premature ovarian failure are secondary to transfusion related haemosiderosis. She was referred to joint fertility clinic and successfully delivered her first baby at the age of 33 after in-vitro fertilisation and is now on continuous femoston and osteoporosis treatment. She has regular follow ups with an endocrinologist. A 27 year old beta thalassaemia major sufferer presented with growth delay, amenorrhoea and osteoporosis as a consequence of transfusion related iron overload. She was referred to paediatrics endocrinology earlier on due to her growth delay. She was on growth hormone until the age of 20. Menarche was normal. She was started on HRT for premature ovarian failure. Recognition of endocrine disturbance is of utmost importance in the follow up of haemoglobinopathies. Hormone replacement therapy plays an important role in treatment and ensuring adequate quality of life in these patients. They should be routinely screened for osteoporosis. In females, establishment of desire for pregnancy should be done earlier on as they may require assistance with fertility which are best cared for in a multidisciplinary team setting.

Effect of desacyl ghrelin on protein expression of GHS-R1 receptor in human placental cells

María de la Luz Jaramillo-Narváez[1], Ma. Guadalupe León-Verdín[2], Federico Martínez Montes[3], María Luisa Lazo de la Vega Monroy[1] & Gloria Barbosa Sabanero[1]
[1]Departamento de Ciencias Médicas, División de Ciencias de la Salud, Universidad de Guanajuato, Campus León, León Guanajuato, Mexico; [2]Delegación Estatal IMSS, León Guanajuato, Mexico; [3]Departamento de Bioquímica, Facultad de Medicina, UNAM, Ciudad de México, Mexico.

Introduction
Ghrelin is an orexigenic hormone with two isoforms: Acyl Ghrelin (AG) and Desacyl Ghrelin (DAG). AG binds to its specific receptor GHS-R1 and stimulates growth hormone secretion. DAG also binds to GHS-R1 receptor, but with 1000 times less affinity than AG. Effect of DAG on cell proliferation and inhibition of apoptosis has been reported. However, there are no studies of DAG function in human placenta. For first time, this work analyzed the effect of DAG on viability, proliferation and protein expression of GHS-R1 of human placenta cells.
Objective
To evaluate the effect of DAG on viability, proliferation and protein expression of GHS-R1 receptor in human placental cells line BeWo.
Materials and methods
BeWo cells were cultured in F-12K medium and incubated for 72 h at 37 °C and 5% CO2. First, BeWo cells were incubated for 24 h. Then, cells were treated with 3nM DAG for 12, 24, 48 and 72 h for viability assay and 24 h in the case of cell proliferation assay. To evaluate protein expression of GHS-R1 receptor, cellular homogenates were analyzed by Western Blot using anti-GHS-R1 (1:1000) as first antibody by 20 h and anti-mouse (1:22500) as secondary antibody by 2 h. Results were analyzed by ANOVA; $p \leq 0.05$ was considered as significant.
Results
Cells treated with DAG did not show differences in cellular viability ($P>0.05$) compared against control cells at all times examined. Similarly, proliferation of cells treated with DAG was not different ($P>0.05$) from control cells at 24 h. GHS-R1 protein expression of cells treated with DAG increased 42% at 12 h ($P=0.029$) and 36% at 24 h ($P=0.025$). However, GHS-R1 protein expression decreased 35% at 48 h ($P=0.005$) compared with control cells.
Conclusions
DAG has no effect on viability and proliferation of human placental cytotrophoblast cells. However, DAG induces changes in protein expression of GHS-R1 receptor, suggesting that could induce signals downstream of this receptor, on sensors or nutrient transporters.

Short-term impact of the 2017 diabetes awareness day in Greece

Ioannis Ilias, Ioannis Kakoulidis, Georgia Skitzi & Eftychia Koukkou
Endocrine Unit, Elena Venizelou Hospital, Athens, Greece.

Introduction/Aim
Disease awareness days are numerous and varied [1]. In the present study we tried to assess the short-term impact of the 2017 diabetes awareness day in Greece by examining localized relevant internet-based searches.
Materials/Methods
We collected data from Google Trends™ regarding relative [internet] search volumes (RSVs) with key words "diabetes" (in Greek and English; study group) and "breast cancer" (also in Greek and English; control group). We collected only data from Greece from the seventh day preceding Diabetes Awareness Day (DAD; November 14, 2017) and Breast Cancer Awareness Day (BCAD; October 25, 2017) till the seventh day following these days. Comparisons of RSVs of the days preceding and following DAD and BCAD were done with the Wilcoxon paired test and the Sign test (statistical significance was set at $P<0.05$).
Results
There were significantly more RSVs for diabetes than breast cancer ($P=0.001$, Wilcoxon test) and significantly more RSVs in the days preceding than the days following DAD or BCAD ($P=0.016$, Sign test).
Discussion/Conclusion
Diabetes was interestingly more popular in internet searches than breast cancer. Apparently diabetes is more diversified as a search term than breast cancer (a lot of its internet searches concern diet, recipes and lifestyle modifications) and this may - partially - explain its predominance. However, more RSVs were noted before than after DDF or BCAD; this finding may indicate a lower than anticipated effectiveness of these disease awareness days and lends credence to their critics [2].

Optimization of the use of outpatient diabetes center through a coordinated task force between primary care and endocrinology unit

María Belén Ojeda Schuldt[1], Isabel Mateo Gavira[1], Begoña Sánchez Lechuga[1], Laura Larrán Escandón[1], Mar Roca Rodríguez[1], Antonio Zarallo Pérez[2] & Manuel Aguilar Diosdado[1]
[1]Hospital Universitario Puerta del Mar, Cádiz, Spain; [2]Centro de Salud Cayetano Roldán, San Fernando, Spain.

Objetives
To analyze the profile of patients referred from Primary Care (PC) to Outpatient Diabetes Center (ODC), as well as the evolution of self-assessment measured by Chronic Care Model IEMAC (Instrument for the Evaluation of Attention Chronicity Models) tool after implementation of a coordinated Task Force between Primary Care and Endocrinology Unit.
Methods
The working group of the Advanced Diabetes Center in Cádiz-San Fernando Sanitary Area was constituted in 2014, with health professionals of different profiles and care's level (one primary care physician from each of the 10 Health Centers of the area, 4 primary care nurses, 5 endocrinologists and 2 endocrinology nurses) The initial self-assessment was made by using IEMAC-Diabetes tool. A value proposal was developed with priority areas of intervention, aimed primarily to propagate Outpatient Diabetes Center's service portfolio and thus optimizing its use. The data of patients referred to ODC were analyzed from April 2015 to December 2016.
Results
A total of 295 patients were derived to ODC (aged 63.03 ± 16.3 years) with HbA1c of 8.54%. The association with other cardiovascular risk factors was 66% hypertension, 56.6% dyslipidemia and 57.8% excess weight. The rate of micro and macrovascular complications was 46.6% and 44.4% respectively. After one year follow up, a significant HbA1c reduction was observed. In 2015, only 40% fulfilled criteria included in the agreed Outpatient Diabetes Center's portfolio and in 2016 amounted to 76%. The most common reason for referral was diabetic foot (37%). Of these, 24% required minor amputation and 9% greater. The self-assessment over attention of patients with diabetes, evaluated through IEMAC among the professionals of the task force, improved from an overall score of 32/100 initially to 55/100 after two years.
Conclusions
After implementation of a coordinated task force group between Primary Care and Endocrinology Unit in Puerta del Mar Hospital, the adequacy in the referral to Outpatient Diabetes Center has improved significantly, with an increase in the score of the self-assessment on attention to patients with diabetes in the area.

The 4-hydroxynonenal mediated oxidative damage of blood proteins and lipids involves secondary lipid peroxidation reactions

Mahmoud A. Alfaqih[1], Ayman G. Mustafa[1,2] & Othman Al-shboul[1]
[1]Jordan University of Science and Technology, Irbid, Jordan; [2]Qatar University, Doha, Qatar.

Lipid peroxidation is linked with several metabolic diseases. Lipid peroxidation causes cellular damage through reactive aldehyde species such as 4-hydroxyonenal (4-HNE). The exact mechanism(s) by which 4-HNE causes damage in the intravascular compartment is not exactly known. Using an *in vitro* system, we investigated the damage induced by 4-HNE on the blood by measuring protein carbonyl groups and thiobarbituric acid reactive substances (TBARS) following 4-HNE treatment. We showed that treatment with 4-HNE increased the carbonylation of proteins and the formation of TBARS in the blood plasma. We also tested whether phenelzine, a scavenger of aldehyde species, or U-83836E, a scavenger of lipid peroxy radicals, attenuates the damage caused by 4-HNE. We showed that phenelzine or U-83836E can both mitigate the effects of 4-HNE on the proteins and the lipids of the blood plasma. We explained the above results through a model that involves secondary lipid peroxidation reactions initiated by 4-HNE.

Effect of duration of exposure to glucose-based peritoneal dialysis fluid on peritoneal membrane thickness

Ayşegül Oruç[1], Zemine Doğrusöz[1], Naile Bolca[2], Rahime Korkmaz Mertsöz[2], Suat Akgür[1], Abdülmecit Yıldız[1], Canan Ersoy[3], Mahmut Yavuz[1] & Alparslan Ersoy[1]
[1]Uludağ University Medical Faculty, Department of Nephrology, Bursa, Turkey; [2]Uludağ University Medical Faculty, Department of Radiology, Bursa, Turkey; [3]Uludağ University Medical Faculty, Department of Endocrinology and Metabolism, Bursa, Turkey.

The efficacy of peritoneal dialysis (PD) is closely related to the status of the peritoneum. Long-term PD leads to structural and functional changes in the peritoneum and affects dialysis adequacy. Also high-glucose content of dialysate accelerates peritoneal fibrosis. It is reported that ultrasonography (USG) reflects parietal peritoneal membrane thickness and PD duration is related with peritoneal thickness. This study aimed to evaluate peritoneal thickness with USG in PD patients.
Method
A total 20 adult PD patients (mean age 48.8 ± 3.8 years, 65% female) were included in the study. The patients used continuous ambulatory ($n = 14$) or automated ($n = 6$) PD regimen with 1.36%, 2.27% and 3.86% glucose based solutions. Patients were divided into two groups according to PD treatment durations: shorter than 60 months (Group 1, 34.6 ± 4.8 months, n = 10) and longer than 60 months (Group 2, 110.9 ± 8.6 months, $n = 10$). Dialysis adequacy (D/P creatinine, pKT/V, creatinine clearance) and parietal peritoneum thickness of two groups were measured.
Results
The mean ages, gender distributions, body mass indexes and PD types of both groups were comparable. There was no statistically significant difference between D/P creatinine, pKT/V and creatinine clearance values of the two groups at the initial and last visits. The final ultrafiltration amount was significantly higher (1269 ± 496 vs. 847 ± 344 mL, $P = 0.034$) and the residual urine volume was significantly lower (275 ± 544 vs. 799 ± 525 mL, $P = 0.016$) in group 2. In all patients, the creatinine clearance and the amount of residual urine significantly decreased, and the amount of ultrafiltration increased over time ($P < 0.001$). There was no significant difference in creatinine clearance, ultrafiltration amount and residual urine volume percent changes between the two groups. Parietal peritoneum thickness values of group 1 and 2 were similar in the right upper (0.38 ± 0.11 vs. 0.40 ± 0.06 mm), left upper (0.40 ± 0.07 vs. 0.41 ± 0.11 mm), right lower (0.42 ± 0.11 vs. 0.41 ± 0.11 mm) and left lower (0.42 ± 0.11 vs. 0.41 ± 0.09 mm) zones, respectively ($P > 0.05$).
Conclusion
As the duration of PD treatment increases, the peritoneal structure changes. We did not find out any difference in peritoneal thickness between the groups according to PD duration. We found a decrease in PD efficacy over time with glucose based solutions in different concentrations, but this decrease was not related to the duration of the treatment.

Coexistence of mitochondrial diabetes and primary amyloidosis

Wajdi Safi[1], Mouna Tabbebi[2], Faten Hadj Kacem[1], Dorra Ghorbel[1], Nabila Rekik[1], Mouna Mnif Feki[1], Fatma Mnif[1], Faiza Fakhfakh[2] & Mohamed Abid[1]
[1]Endocrinology Department, Hedi Chaker Hospital, Sfax, Tunisia; [2]Laboratory of Molecular and Functional Genetics, Faculty of Sciences, Sfax, Tunisia.

Introduction
Primary amyloidosis is a multi-systemic disease difficult to identify given the diversity of the disorders that it can cause especially at an early stage of the disease. This makes its diagnosis difficult in case of association with a pathology that can be intricate with its clinical expression. In this context we report the first case in the literature associating mitochondrial diabetes (DM) with a primary amyloidosis
Case
A 32 years old girl, with family history of diabetes and maternal transmission, refer to our service for diabetes of primo discovery revealed by a frank hyperglycaemia without ketosis. The negativity of anti-beta cell antibodies and the presence of extra-pancreatic manifestations at type of bilateral perception deafness, sensitivomotor neuropathy, glomerular nephropathy and the presence of jagged red fibers characteristic of mitochondrial cytopathy on muscle biopsy, led

us to retain the diagnosis of a DM. The biomolecular study then confirmed the mutation most frequently described in the literature: m.3243A > G (tRNA Leu) in the mitochondrial genome. Moreover, in front of the echocardiography appearance of concentric hypertrophic cardiomyopathy, with hyperechoic and brilliant granite appearance, unusual in DM and suggestive of overload cardiomyopathy, a biopsy of the salivary glands was performed and confirming the presence of a primary amyloidosis.

Discussion and conclusion

The association of DM with amyloidosis has never been described in the literature. Such an association may be a prototype of interrelation between the nuclear genome involving genes having a key role in the metabolism of amyloid deposits and the mitochondrial genome thus inducing a vicious circle that can sustain a process of cellular apoptosis induced by an alteration of the dynamism of the intra-mitochondrial respiratory chain already reported *in vitro*. Certainly the progress of molecular biology and a better understanding of signaling signals of intracellular proteins allowing clarifying the etiopathogenic link of such an association.

Role of Pro-inflammatory biomarkers in Graves' disease: A case-control Study

Rajesh B[1], Ramesh B[1], Venkateshwara Reddy M[1], Vighnesh D[1], Gayathri G[1], Rajkiran Reddy B[2], Chakrapani B[3] & Bhargav PRK[4]
[1]VMC, Kurnool, India; [2]SMART Sunshine Hospital, Hyderabad, India; [3]Neuro Hospital, Nizamabad, India; [4]Endocare Hospital, Vijayawada, India.

Introduction

Graves' disease (GD) is one of the commonest organ specific autoimmune thyroid disease. Surgical thyroidectomy is one of the definitive treatment modalities. Autoimmunity has been implicated as one of the main cause of GD. In this context, we set out study the role of Pro- inflammatory cytokines in GD.

Material and methods

This prospective case-control study was conducted on surgically managed GD patients. Institutional ethical committee approval was obtained. Diagnosis of GD was based on clinical picture, thyroid function tests, radionuclide scanning and histopathology. Exclusion criteria were subjects any systemic or chronic inflammatory disease or any medication which interferes with the normal function of the hypothalamic-pituitary-gonadal axis. Serum samples were collected from 32 GD subjects and 30 age matched healthy controls. Interleukin-6 (IL-6), Tumour necrosis factor-alpha (TNF-α) and high sensitive C reactive protein (hsCRP), Leptin levels were measured in all serum samples. Statistical analysis was performed by one way ANOVA with Dunnet's test and Pearson correlation tests.

Results

The mean hSCRP level in GD and controls were 16.6 ± 2.1 mg/mL and 5.8 ± 1.1 mg/mL respectively. The mean TNF-α level, IL-6 level and Leptin levels were 256 ± 21 pg/mL, 11.4 ± 3.2 pg/mL and 27.5 ± 4.4 ng/mL respectively. There was statistically significant difference of all the pro-inflammatory cytokines compared to controls (P value < 0.05).

Conclusions

This study shows raised titers of pro-inflammatory markers – IL-6, TNF-α and hsCRP, leptin correlated with GD suggesting a contributory role. But, the exact immuno-modulatory role and pathogenetic mechanism needs active research.

Endoplasmic reticulum stress-mediated apoptosis and cell cycle arrest were caused by resveratrol, a phytoestrogen, in malignant melanoma cells

Gun-Hwi Lee, Jae-Rim Heo, Kyung-A Hwang & Kyung-Chul Choi
Laboratory of Biochemistry and Immunology and, Laboratory of Internal Medicine, Veterinary Medical Center and College of Veterinary Medicine, Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Resveratrol, a dietary product present in grapes, vegetables, and berries, is phytoestrogen that regulates signaling pathways that control cell division, and growth, apoptosis, and metastasis. Melanoma, also known as malignant melanoma, is a type of cancer that develops from the pigment-containing cells known as melanocytes. Especially, malignant melanoma is pernicious and proliferates more readily than any other skin cancer. In the present study, we evaluated the anti-cancer effect of resveratrol on melanoma cell proliferation. Treating A375SM cells with resveratrol resulted in a decrease in cell growth. We also examined the alteration of cell cycle-related genes by western blot. Treatment with resveratrol was found to increase the gene expression of p21 and p27 and decrease the gene expression of cyclin B. We confirmed the generation of ROS and ER stress at both the cellular and protein level using a DCF-DA assay, TUNEL assay, and western blot. Resveratrol induced the ROS-p38-p53 pathway by increasing the gene expression of phosphorylated p38 MAPK (p-p38 MAPK) and the p53 and ER stress pathway by increasing the gene expression of phosphorylated eIF2α (p-eIF2α) and CHOP. The enhanced ROS-p38-p53 pathway and ER stress pathway promoted apoptosis by downregulating Bcl-2 expression and upregulating BAX expression. Overall, resveratrol appears to be an inducer of ROS generation and ER stress and can be responsible for growth inhibition and cell cycle arrest of A375SM melanoma cells.

Endocrine related adverse events associated with immune checkpoint blockade therapy: a retrospective analysis

Valentina Lo Preiato[1], Stefania Salvagni[2], Caterina Gianni[2], Danilo Ribichini[1], Nicola Bianchi[1], Uberto Pagotto[1], Andrea Ardizzoni[2] & Carla Pelusi[1]
[1]Division of Endocrinology, Dept. of Medical and Surgical Sciences, S. Orsola-Malpighi Hospital, University Alma Mater Studiorum, Bologna, Italy; [2]Division of Oncology, S. Orsola-Malpighi Hospital, University Alma Mater Studiorum, Bologna, Italy.

Background

Immune checkpoint inhibitors (ICI) have become a clinically validated treatment for numerous types of tumor including melanoma, lung, and kidney carcinoma. These treatments can cause immune-related adverse events affecting several organs including the endocrine system.

Aims

The aim of this study was to characterize the type and the onset of the ICI associated-endocrinopathies.

Materials and methods

This retrospective cohort evaluation included patients with advanced cancer candidate for ICI treatment attending the Oncology Unit at S.Orsola-Malpighi Hospital of Bologna from January2016 to September2017. All patients were treated with a different schedule according to the Authority-approved ICI doses and administration.

Results

Sixty-nine patients were included in this study and they were followed for 32 weeks in average (range 2 to 88 weeks). Fifty-one patients were treated with nivolumab ($n=23$ lung-carcinoma, $n=22$ melanoma, $n=6$ kidney-carcinoma), 12 with pembrolizumab ($n=10$ melanoma, $n=2$ lung-carcinoma), 4 with ipilimumab ($n=2$ kidney carcinoma, $n=2$ melanoma), and 2 with ipilimumab + nivolumab ($n=1$ melanoma, $n=1$ liver-cancer). Among these 69 cases, 10 (14.5%) showed drug-induced endocrinopathies: 1 had a central hypoadrenalism with ipilimumab, 1 had a sudden-onset of diabetes mellitus with nivolumab, and 8 developed thyrotoxicosis with nivolumab ($n=5$), with ipilimumab + nivolumab ($n=2$) and with pembrolizumab ($n=1$). Central hypoadrenalism and diabetes developed at 4th (12 weeks) and at the 26th drug administration (52 weeks), respectively. These subjects required gluco-corticoid and insulin lifelong replacement therapy, respectively. Instead, thyrotoxicosis induced by nivolumab and pembrolizumab occurred at the 3rd drug administration (6-9 weeks), whereas those caused by ipilimumab + nivolumab appeared in one subject at the 3rd (6 weeks) and the other at the 7th drug administration (14 weeks). The average time of thyrotoxicosis was 3 weeks (1-8 weeks). Of these 8 thyrotoxicosis, 4 subjects progressed to overt hypothyroidism ($n=2$ nivolumab, $n=2$ ipilimumab + nivolumab) and 4 to euthyroidism ($n=3$ nivolumab, $n=1$ pembrolizumab). All these subjects had no previous history of thyroid disease. The etiology of the endocrinopathies are presumably immune, however the specific known autoimmunity in selected patients was negative (anti-GAD antibodies for diabetes, and anti-thyroid peroxidase, anti-tireoglobulin, anti-TSH receptors in 2 thyrotoxicosis).

Conclusion
In our clinical records, endocrine related adverse events were relatively common with thyrotoxicosis being the most frequent. All adverse events were successfully managed without needing to stop ICI treatment. These findings suggest that a close interaction between the endocrinologist and oncologist should be advocated for a rapid identification and treatment of ICI-induced endocrinopathies.

Evolution of endocrine surgery during three consecutive years in a tertiary-care university hospital of Madrid (Spain)

Beatriz Lecumberri, Blanca Vicandi, Rita Regojo, Carlos Pérez López, Pamela Chávez, Luis Martínez-Piñeiro, Joaquín Díaz, Fernando Carceller, David Hardisson & Lucrecia Herranz
La Paz University Hospital, Madrid, Spain.

Introduction
The availability of an increasing therapeutic arsenal for endocrine diseases seems to explain the current trend towards a decrease in the indications of endocrine surgery. However, this trend requires a detailed study before being confirmed in our setting.
Objectives:
We aimed to assess the trends in the performance of endocrine surgery, in children and adults, during three consecutive years (2014, 2015 and 2016) in our University Tertiary-Care Referral Hospital, settled in Madrid (Spain).
Methods
We contacted the Pathology Service and the main surgical Services involved, collected the number of thyroidectomies, parathyroidectomies, adrenalectomies and surgeries in the hypothalamic-pituitary area per year in the period of study, and calculated the corresponding interannual and overall variation rates.
Results
The number of thyroidectomies, parathyroidectomies, adrenalectomies and surgeries of lesions in the hypothalamic-pituitary area performed per year were 264, 57, 30 and 43, respectively, for 2014; 259, 63, 22 and 39 for 2015; and 260, 52, 15 and 17 for 2016. The number of surgeries of the hypothalamic-pituitary area in children were 8, 9 and 7, in 2014, 2015 and 2016, respectively, whereas in adults were 35, 30 and 10. This means an overall decrease in the number of surgeries in the hypothalamic-pituitary area of 60.5% between 2014 and 2016, due, almost entirely, to the reduction of surgeries in adults (71.4%), and a global decrement of 50% in the number of adrenalectomies, while the number of thyroidectomies and parathyroidectomies remained stable during the study period, showing small interannual variation rates and annual averages of 261 and 57, respectively.
Conclusions
There is a strong and consisting trend towards a decrease in the number of surgeries in the hypothalamic-pituitary area (particularly in adults) and adrenalectomies during the last 3 years, while the number of thyroidectomies and parathyroidectomies has remained stable in the same period of time in our Tertiary-Care Referral Hospital. Further studies are required to evaluate the presence of similar trends in other medical centers of the rest of Spain and Europe, and, in case they are confirmed, analyze their causes as well as the potential associated economic impact in the medium and long-term.

New germline mutation of the *CDC73* gene in a Romanian family with hyperparathyroidism-jaw tumour syndrome

Daniel Grigorie[1,2], Simone Ciuffi[3], Francesco Franceschelli[3], Alina Sucaliuc[1,2] & Maria Luisa Brandi[3]
[1]National Institute of Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine, Bucharest, Romania; [3]Department of Surgery and Translational Medicine, University of Florence, Florence, Italy.

Introduction
Hyperparathyroidism-jaw tumour (HPT-JT) syndrome is a rare autosomal dominant cause of familial hyperparathyroidism associated with ossifying fibromas (OF) of the maxillofacial bones and increased risk of parathyroid carcinoma, caused by inactivating germline mutation of the cell division cycle 73 (*CDC73*) gene.
Case report
We report the first Romanian family with HPT-JT and genetic screening of *CDC73* gene. Three of the six screened family members included in this study had biochemical evidence of HPT and surgically proven parathyroid tumours. The index case (female, 35 yrs; Ca = 13.9 mg/dl; PTH = 327 pg/ml) had a parathyroid carcinoma and had been previously operated for OF of the jaw and uterine fibroid. At the time of screening she was asymptomatic 5 yr after parathyroid surgery.There were no renal lesions and jaw tumors in other family members. Two of the three afected members had parathyroid carcinomas (the index case and one of her brothers, 44 yrs, persistent HPT after many surgeries Ca = 11.3 mg/dl; PTH = 193.7 pg/ml) and one had two parathyroid adenomas (the brother's son, 24 yrs, Ca = 12.2 mg/dl; PTH = 176 pg/ml). The genetic screening of *CDC73* gene (PCR amplification and direct Sanger sequencing on genomic DNA extracted from peripheral blood leukocytes) revealed that 4 of 6 patients showed a new heterozygous germline deletion of one nucleotide: c.128-IVS1 + 1 delG. The parents were alive and asymptomatic, the father been the carrier of the mutation; the index case' s daughter was negative for the mutation.
Conclusion
We identified a new germline mutation in a Romanian family of HPT-JT and confirmed the incomplete penetrance and the variable expression of the mutation.

Quality of life after medical versus surgical castration for locally advanced or metastatic prostate cancer

Kays Chaker, Ahmed Sellami, Yassine Ouanes, Mohamed Ali Essid, Karem Abid, Sami Ben Rhouma & Yassine Nouira
Urology Department, La Rabta Hospital, Tunis, Tunisia.

Introduction
Metastatic or locally advanced prostate cancer is treated with surgical or medical hormone therapy. Preservation of the patient's quality of life is a major parameter that influences the management at this stage. Comparative studies between both types of hormone therapy that consider the patient's quality of life are almost nonexistent. The objective of our study is to evaluate the impact of medical and surgical castration on the quality of life in patients with locally advanced or metastatic prostate cancer.
Methods
A retrospective and comparative study including 200 patients with locally advanced or metastatic prostate cancer. 90 patients had medical castration and 110 patients underwent surgical castration. They were questioned about their quality of life using the â€oeexpanded prostate cancer index composits which includes urinary, digestive, sexual and hormonal evaluation.
Results
The two groups were comparable about age, clinical examination, tumor staging, histological results and initial rate of PSA. The difference between the two groups was statistically significant concerning digestive and hormonal evaluation. Indeed, strangury was more frequently found in patients having medical castration ($P = 0.03$). Intestinal transit disorders were also more frequently found in patients who had medical castration ($P = 0.03$). Hot flashes were more frequent and embarrassing in patients having medical castration than patients having surgical castration ($P = 0.1$ and 0.008 respectively). Nipple pain was more frequently found in patients with medical castration ($P = 0.02$). The two groups were similar about sexual and urinary evaluation.
Conclusions
Surgical castration is as effective as medical castration and has the advantage of better preservation of the patient's quality of life.

Endocrinological side effects of immunotherapy

Idoia Genua[1], Nicole Stantonyonge[1], Laura Tuneu[1], Mariona Riudavets[2], Margarita Majem[2] & Cintia González[1,3]
[1]Endocrinology Service. Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [2]Oncology Service. Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [3]Universidad Autónoma de Barcelona. CIBER-BBN (grupo EDUAB-HSP), Barcelona, Spain.

Introduction
The use of immunotherapy in oncology patients is increasing and is likely to continue to increase in the future. It is widely known that therapies have endocrinological side effects which can be serious, but maybe are also useful indicators to judge a response to the treatment. Presently, we do have not enough information regarding these side effects and their evolution.
Materials and methods
Observational and retrospective study of 162 oncology patients treated with immunotherapy in a third level hospital since 2014. Patients taking part in a double blind trial were excluded. The results were analysed with SPSS 24 package.
Results
Results from 162 patients were analysed (78% men, mean age of cancer diagnosis: 64 ± 11 years). 43% were treated with Nivolumab, 27% Pembrolizumab, 18% Atezolizumab, 3% Ipilimumab. 20 patients (12%) developed endocrine toxicity, with the thyroid being the most affected gland (11% of total patients). There was just 1 case of Hypophysitis, which occurred in a patient treated with Ipilimumab. 13% of patients treated with anti-PD1 had a thyroid disorder (60% hypothyroidism and 40% hyperthyroidism). Most side effects where reported with Nivolumab (55%), however, this was also the most frequently used drug and so it was deemed to be not statistically significant. The mean time between the first dose of the drug and the detection of the toxicity was 104 ± 129 days, separated by toxicities; hypothyroidism was developed in 80 ± 65 days (median 60 days) and hyperthyroidism in 142 ± 212 days (median 52 days). The evolution of these side effects in the thyroid gland, 88% of hypothyroidism and 29% of hyperthyroidism respectively, are persist. The case of hypophysitis persists.
Conclusions
Endocrine toxicity is a frequently observed side effect of immunotherapy with thyroid disorders being the most commonly reported, predominantly hypothyroidism. The incidence of our series is similar to other published series. The time to onset is variable, with a median of 2 months in the case of hypothyroidism. If hypothyroidism appears, it seems to be persistent but further long term studies are required.

Non-genomic effects of thyroid hormones on mesenchymal stem cells in tumour angiogenesis

Kathrin A Schmohl, Maike Dohmann, Nathalie Schwenk, Peter Bartenstein, Peter J Nelson & Christine Spitzweg
University Hospital of Munich, LMU Munich, Munich, Germany.

Tumour stroma formation is associated with angiogenesis and requires interactions of various different cell types, including endothelial cells and mesenchymal stem cells (MSCs), which are actively recruited into growing tumour stroma. Thyroid hormones T3 and T4 act as non-classical proangiogenic modulators mediated by non-genomic mechanisms via cell surface receptor integrin $\alpha v\beta 3$. The deaminated T4 derivative tetrac is a specific inhibitor of thyroid hormone action at the integrin site. The aim of this study was to evaluate the effects of T3 and T4 versus tetrac on MSCs in the context of angiogenesis. Treatment of primary human MSCs with T3 or T4 in the presence of hepatocellular carcinoma (HCC) cell-conditioned medium resulted in stimulation of expression of genes associated with angiogenesis as determined by qPCR. Additional treatment with tetrac reversed these effects. Primary human umbilical vein endothelial cells (HUVECs) were seeded on Matrigel and tube formation was analysed microscopically. Compared to untreated HUVECs, treatment with thyroid hormones and MSC-conditioned medium stimulated tube formation, while tetrac reduced tube formation. As the vascular endothelial growth factor (VEGF) is a critical angiogenesis mediator, we established a reporter gene system by placing the sodium iodide symporter (NIS) gene under control of the VEGF promoter. MSCs transfected with this construct (VEGF-NIS-MSCs) showed enhanced perchlorate-sensitive NIS-mediated iodide uptake activity *in vitro* after stimulation with HCC cell-conditioned medium and either T3 or T4 that was blocked by tetrac. T3 effects were additionally blocked both by the PI3K pathway inhibitor LY294002 and the ERK1/2 pathway inhibitor RAF265, while T4 effects were only blocked upon RAF265 treatment, supporting integrin $\alpha v\beta 3$-dependency. Effects of thyroid hormone on VEGF-driven NIS expression in MSCs *in vivo* were evaluated by iodide-124 PET in an orthotopic HCC xenograft mouse model. Tumoural radioiodide uptake demonstrated successful tumoural recruitment of VEGF-NIS-MSCs after systemic application followed by VEGF promoter-driven NIS expression. In hyperthyroid animals, a strongly enhanced radioiodide signal was detected in tumours compared to euthyroid and hypothyroid mice, while treatment with tetrac resulted in a markedly reduced signal. These data confirm the *in vitro* data suggesting significant thyroid hormone-mediated stimulation of VEGF in HCC tumours that was inhibited by tetrac. Our data suggest that thyroid hormones T3 and T4 influence angiogenic signalling in MSCs in an integrin-dependent fashion, providing further evidence of the critical role of thyroid hormones in the regulation of angiogenesis and the anti-angiogenic activity of tetrac in the context of tumour stroma formation.

Targeting Treatment Resistance in Breast Cancer Subtypes via LMTK3 Inhibition

Angeliki Ditsiou, Teresa Gagliano, Chrisostomos Prodromou, Jose Gascon, Sophie Mumford, Darren Le Grand & Georgios Giamas
University of Sussex, Brighton, UK.

Introduction
LMTK3 is an oncogenic Receptor Tyrosine Kinase (RTK) implicated in resistance to endocrine therapy in breast cancer. Initially, LMTK3 was described as a regulator of Estrogen Receptor alpha ($ER\alpha$) since it was found able to protect it from ubiquitin-mediated proteasomal degradation. In a cohort of breast cancer (BC) patients ($n > 600$), LMTK3 protein levels and intronic polymorphisms were significantly associated with disease-free and overall survival and predicted response to endocrine therapy. These data were validated in an Asian cohort in which it was shown that LMTK3 was associated with more aggressive tumours. In addition, LMTK3 was demonstrated to contribute in BC invasion and migration. Recently, a new scaffolding function of LMTK3 was described that results in cancer progression through chromatin remodelling.
Aim
This study aims to identify selective LMTK3 inhibitors that can be used to enable pathway investigation and establish onward tractability of these compounds for future translational activities.
Materials and methods
The Bellbrook Laboratories Transcreener® assay kit was employed and 30,000 compounds were screened to detect novel LMTK3 inhibitors. Nearly 100 of them significantly inhibited LMTK3 activity and were therefore chosen for 10-point concentration-response profiling in duplicate and LC-MS analysis. The top 50 test compounds were clustered into unique chemotypes and were further tested using radiolabelled *in vitro* kinase assays. The top 5 compounds from two chemotypes were selected to be evaluated with hit-to-lead medicinal chemistry. Subsequently, an active site-directed competition binding assay (DiscoveRx KINOMEscan) was used to quantitatively measure the interactions between the top 5 hit compounds and more than 450 purified human kinases and disease relevant mutant variants.
Results and discussion
Two (C28 and C36) out of the 30,000 compounds that were screened inhibited by $>95\%$ the activity of only 10 and 8 kinases respectively. Moreover, the S(35) selectivity index of C28 was 0.186 while the selectivity index of C36 was 0.114. Interestingly, quantitative analysis of 38 kinase inhibitors currently used in clinical oncology showed a comparably low S(35) score as C28 and C36. It is expected that the crystallization of the LMTK3 kinase domain that is currently being conducted as well as co-crystallization experiments with these inhibitors and other analogues will guide a rational optimisation strategy of each chemotype.
Conclusion
More work is required; however, these data represent a step towards the development of the first LMTK3 inhibitors that may have potential for broad clinical utility in breast cancer.

Metformin and Simvastatin: a therapeutic combination to reduce the aggressiveness of glioblastoma multiforme

Antonio C Fuentes-Fayos[1,2,3,4], Mari C Vázquez-Borrego[1,2,3,4], Beth Mansfield[1,2,3,4,5], Cristóbal Blanco-Acevedo[1,2,3,4,6], Juan Solivera[1,2,3,4,6], Justo P Castaño[1,2,3,4] & Raul M Luque[1,2,3,4]
[1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain; [2]Department of Cell Biology, Physiology and Immunology, University of Cordoba, Cordoba, Spain; [3]Reina Sofia University Hospital (HURS), Cordoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Cordoba, Spain; [5]Cardiff University, Wales, UK; [6]Neurology Service, HURS, Cordoba, Spain.

Gliomas constitute the most frequent type of brain tumors and are characterized by a rapid growth and high diffusion through the brain. In particular, astrocytomas are a subtype of malignant gliomas that are graded from low to high aggressiveness (i.e. grade I, II, III and IV), being grade IV (glioblastoma multiforme, GBM) the most malignant type, and one of the most common cancers in the brain and CNS. To date, surgery is the first-line therapy combined with chemotherapy or radiotherapy; however, about two-thirds of patients do not have a survival rate greater than two years after diagnosis. Thus, it is necessary to develop new strategies to identify novel therapeutic targets for these devastating tumor pathologies. Metformin and Simvastatin are drugs commonly used to treat T2D patients and hypercholesterolemia, respectively. Interestingly, both compounds seem to exert anti-tumoral actions individually in different tumor types through AMPK-dependent and -independent pathways. Therefore, the aim of this study was to evaluate the anti-tumoral actions of metformin (10 mM) and simvastatin (10nM), individually and in combination, on key functional parameters (cell proliferation and migration rate) in human primary GBM cell cultures and GBM cell lines (U87 and U118), and to determine the signaling mechanisms behind these actions in GMB cells. We found that metformin and simvastatin alone inhibited cell proliferation in primary GBM cell cultures and GBM cell lines at 48 h and 72 h of incubation. Moreover, co-administration of metformin and simvastatin exerted an additive inhibitory effect on GBM cell proliferation compared to each compound alone. In addition, metformin, but not simvastatin, reduced cell migration in the U118 GBM cell line at 6 h, but not at 24 h, of incubation, whereas, co-administration of metformin and simvastatin significantly reduced the migration capacity of U118 GBM cell line at both incubation times (6 h and 24 h). Further analysis indicated that the anti-tumoral actions of metformin and simvastatin on GBM cells involve both common and distinct signaling pathways and are likely mediated through dissimilar molecular mechanisms. Altogether, our results demonstrate that metformin and simvastatin alone, and especially in combination, exert clear anti-tumoral effects in human primary GBM cell cultures and GBM cell lines, thus suggesting that these compounds deserve to be further explored as novel potential therapeutic tools for the treatment of patients with high-grade astrocytomas.

Inhibition of alternative splicing using the spliceosome inhibitor Pladienolide B reduces aggressiveness of prostate cancer cells *in vitro*

Juan M Jiménez-Vacas[1,2,3,4], Vicente Herrero-Aguayo[1,2,3,4], Antonio J León-González[1,2,3,4], Gómez-Gómez Enrique[1,3,5], Prudencio Sáez-Martínez[1,2,3,4], María J Requena-Tapia[1,3,5], Justo P Castaño[1,2,3,4], Manuel D Gahete[1,2,3,4] & Raul M Luque[1,2,3,4]
[1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain; [2]Department of Cell Biology, Physiology and Immunology, University of Cordoba, Cordoba, Spain; [3]Reina Sofia University Hospital (HURS), Cordoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Cordoba, Spain; [5]Urology Service, HURS/IMIBIC, Cordoba, Spain.

Prostate cancer (PCa) is a complex and heterogeneous cancer that progresses from slow-growing, tissue-confined lesions, to highly aggressive and metastatic forms. Among the different processes involved in this progression, dysregulation of the alternative splicing mechanism, and, particularly, the generation of the spliced androgen receptor variant-7 (ARv7), plays a critical role in the pharmacological resistance of PCa patients (i.e. Abiraterone or Enzalutamide). In this context, recent studies have shown that Pladienolide-B, an inhibitor of the spliceosome (the molecular machinery that conducts alternative splicing), exhibits important anti-tumor effects in different cancer types; although, its role in PCa remains unknown. Hence, we aimed to determine the direct effects of Pladienolide-B in PCa cell-lines (LNCaP, 22Rv1, DU145, PC-3) and in normal prostate cells (RWPE-1 cell-line and primary cell-cultures obtained from cystoprostatectomies) by analysing different functional parameters such as cell proliferation, cell migration, tumorosphere formation and/or colony formation. Moreover, the expression of 45 splicing machinery components (major and minor spliceosome and splicing factors) was determined in the normal (RWPE-1) and tumoral (LNCaP/22Rv1/PC-3) prostate cell-lines in response to Pladienolide-B treatment by using a microfluidic-based qPCR array. Our results revealed that Pladienolide-B was able to reduce the proliferation of PCa cell lines, at 24-, 48- and 72-h in a dose-dependent manner (100 nM–0.01 nM), being this inhibitory effect significantly greater in PCa cell-lines compared to normal prostate cells (RWPE-1 and primary cell-cultures) at a dose of 100 nM. Interestingly, the antitumoral capacity of Pladienolide-B was corroborated by the inhibition of cell migration and tumorospheres/colonies formation in all PCa cell lines tested. Moreover, treatment with Pladienolide-B dramatically reduced the expression of proliferation markers (Ki67 and PTTG), EMT markers (Vimentin) and markers of PCa agressiveness (PCA3, androgen-receptor and ARv7 splicing variant) in PCa cell lines. Finally, Pladienolide-B was able to markedly alter the expression of numerous spliceosome components and splicing factors, some of them associated to higher PCa aggressiveness, such as SFPQ, KHDRSB1, SRRM4, NOVA1, ESRP1 and ESRP2. Taken together, our results demonstrate that Pladienolide-B clearly reduces PCa aggressiveness features *in vitro*, by the dysregulation of the expression of several splicing factors and tumor markers, suggesting a potential novel therapeutic role of this compound in PCa.

Fibroblast-kinome silencing to identifies putative mediator of Triple-negative breast cancer (TNBC) invasion

Teresa Gagliano, Viviana Vella, Kamila Bienkowska, Angeliki Ditsiou & Georgios Giamas
University of Sussex, Brighton, UK.

Kinases represent a main therapeutic targets in cancer treatment as their impairing is related to tumor growth and progression. Despite the increasing evidence that tumor microenvironment (TME) signaling influences the behavior of surrounding cancer epithelial cells, still little is known about what changes in stromal cells influence tumor cells' behavior. TNBC patients are still lacking an effective therapy, as not much is known about the biology of this BC tumor subtype. TNBC trials focus mainly on targeting epithelial cancer cells by using a combination of kinase inhibitors and standard chemotherapy however these therapeutic regimens are not considering the action of stromal cells. **Our aim is to I**dentify fibroblasts-expressed kinases that modulate tumor cells' invasion and Characterize the mechanism by which these kinases promote/reduce tumor invasion.A library of SiRNA targeting 710 Kinases was used to transfect Human Mammary Fibroblast (HMF) and normal lung fibroblast (MRC5). 24h after transfection, fibroblasts were co-cultured with MDA-MB-231 for 3Dspheroids formation. Matrigel and chemoattractants were added to promote invasion that was evaluated by spheroids pictures analysis. kinases silenced spheroids were compared to controls. We identified PIK3Cδ, whose silencing decreased TNBC invasion rate, suggesting a pro-invasive role of this kinase. PIK3Cδ is essential for regulating chemokine production in leukocytes and promotes migration during inflammation. It has been shown that PIK3Cδ inhibitors (CAL -101) interfere in tumour-stroma interactions without directly killing cancer cells. Despite PIK3Cδ being expressed mainly in leucocytes, we detected high PIK3Cδ protein expression in various fibroblast cell lines and in primary fibroblasts derived from TNBC patients; however, PIK3Cδ was hardly detectable in a panel of breast cancer cell lines. Treatment with CAL -101, affected cell viability of fibroblasts cell lines, while it had limited/no effects on breast cancer cells. Fibroblasts treated with CAL -101 showed a decreased AKT phosphorylation, a downstream target of PIK3Cδ. Pretreatment of fibroblasts with CAL -101 significantly decreased TNBC cells' invasion in both 2D and 3D co-culture experiments. Interestingly, using transwell systems we found that co-culture with TNBC cells increased PIK3Cδ expression in fibroblasts, suggesting a feedback loop that 'fueled' tumor progression. Ongoing experiments are suggesting a paracrine signaling mechanism that may lead to the promotion of TNBC via PIK3Cδ fibroblasts expression. Using a novel 3D co-culture invasion assay, we identified stromal PIK3Cδ as a key mediator of TNBC invasion. Our results suggest that targeting PIK3Cδ in the tumor microenvironment may represent a novel strategy for TNBC therapy.

Expression of Toll/interleukin-1 receptor (TIR)-associated protein in primary hyperparathyroidism.

Oliwia Segiet[1], Adam Piecuch[1], Marlena Brzozowa-Zasada[1], Mariusz Deska[2], Grzegorz Buła[2], Jacek Gawrychowski[2] & Romuald Wojnicz[1]
[1]Department of Histology and Embryology, School of Medicine with the Division of Dentistry in Zabrze, Medical University of Silesia, Katowice, Poland; [2]Department of General and Endocrine Surgery, School of Medicine with the Division of Dentistry in Zabrze, Medical University of Silesia, Katowice, Poland.

Background
Primary hyperparathyroidism is one of the most common endocrine disorders caused by adenoma (80%), hyperplasia (15%) and carcinoma (5%). It is often difficult to differentiate between hyperplasia from an adenoma of a parathyroid gland. Toll/interleukin-1 receptor (TIR)-associated protein (TIRAP) is an adaptor protein for Toll-like receptors-2 and -4 (TLR2/4) which are engaged in transducing the signal to downstream molecules. Several studies have shown the increased role of this protein in pathogenesis of hyperplastic lesions and neoplasm development.
Aim
The aim of the study was to assess the immunohistochemical expression of TIRAP as a potentially useful in diagnosis of hyperplastic lesions of the parathyroid glands.
Methods
For immunohistochemistry, parathyroid specimens of patients undertaken surgery due to primary hyperparathyroidism caused by adenoma and primary hyperplasia were investigated. Frozen sections were incubated with purified mouse monoclonal antihuman antibody anti-TIRAP. The immunohistological investigations were performed by the BrightVision method from ImmunoLogic. The number of proliferating cells were counted and expressed as a mean value of at least 6 counted high power fields (HPF, x 400). The sections were counterstained with Mayer's haematoxylin.
Results
The expression of TIRAP was significantly increased in parathyroid adenomas and hyperplasias compared to healthy parathyroid glands.
Conclusions
TIRAP might be useful in differential diagnosis between hyperplastic lesions of parathyroid gland.

DOI: 10.1530/endoabs.56.P655

Expression of TICAM-2 in hyperplastic lesions of the parathyroid glands.

Oliwia Segiet[1], Adam Piecuch[1], Marlena Brzozowa-Zasada[1], Mariusz Deska[2], Grzegorz Buła[2], Jacek Gawrychowski[2] & Romuald Wojnicz[1]
[1]Department of Histology and Embryology, School of Medicine with the Division of Dentistry in Zabrze, Medical University of Silesia, Katowice, Poland; [2]Department of General and Endocrine Surgery, School of Medicine with the Division of Dentistry in Zabrze, Medical University of Silesia, Katowice, Poland.

Background
Even if a great number of studies have been developed recently, the molecular mechanisms of pathogenesis of hyperplastic lesions of the parathyroid glands are not well understood. The link between systemic inflammation and promotion of neoplasm is well established. Chronic infection and inflammation are considered two of the most prominent epigenetic and environmental factors contributing to tumor formation. Toll like receptors (TLRs) are essential components of innate immune system that protect the host against bacterial and viral infection. Toll/interleukin-1 receptor/resistance (TIR) adaptor protein (TICAM-2) can physically bind TIR domains and influence cell signaling. TICAM-2 interacts with TLR3 and mediates dsRNA activation of interferon-beta through NFkappaB.
Aim
The aim of the study was to assess the immunohistochemical expression of TICAM-2 as a potentially useful in diagnosis of hyperplastic lesions of the parathyroid glands.
Methods
For immunohistochemistry, parathyroid specimens of patients undertaken surgery due to primary hyperparathyroidism caused by adenoma and primary hyperplasia were investigated. Frozen sections were incubated with purified mouse monoclonal antihuman antibody anti-TICAM-2. The immunohistological investigations were performed by the BrightVision method from ImmunoLogic. The number of proliferating cells were counted and expressed as a mean value of at least 6 counted high power fields (HPF, $\times$400). The sections were counterstained with Mayer's haematoxylin.
Results
Positive TICAM-2 immunoreaction was significantly increased in parathyroid adenomas, compared to hyperplasias and healthy parathyroid glands, whereas the expression of TICAM-2 was higher in hyperplasias than in controls. Positively stained cells were localized in the well vascularized region of the parathyroid nodule.
Conclusions
Our study indicated the important role of TICAM-2 in primary hyperparathyroidism and could be a potential therapetical targets. TICAM-2 might be useful in diagnosis of primary hyperparathyroidism. A better understanding of molecular profiling in primary hyperparathyroidism could result in more precise assessment of diagnosis and more effective treatment, especially in those cases in which the commonly used parameters are insufficient.

Dream recall and content vs the menstrual cycle: a cross-sectional study

Ioannis Ilias[1], Nikolas Tiberius Ekonomou[2,3], Anastasia Lekkou[1] & Eftychia Koukkou[1]
[1]Department of Endocrinology, E Venizelou Hospital, Athens, Greece; [2]Sleep Study Unit, Eginition Hospital, University of Athens, Athens, Greece; [3]Enypnion Sleep Disorders – Epilepsy Center, Athens, Greece.

Introduction-Aim
Manifest dream content is rarely studied in dream research. Conflicting results have been presented regarding dream recall and affect vis-à-vis the menstrual cycle. Progestagens may improve dream recall. Thus, we aimed to assess dream recall/affect vis-à-vis the menstrual cycle in a large sample of women.
Subjects-methods
We studied 779 women (mean age $+$s.d.: $31+9$ years). The subjects were given once a simple questionnaire with items regarding age, menstrual cycle duration, day of their menstrual cycle, dream recall regarding previous night's dreams and dream affect/emotional content (positive or negative). We studied only women with self-reported regular menstrual cycles of 21–35 days in a cross-sectional fashion. We considered that the luteal phase of the menstrual cycle was relatively stable for all women, with a duration of 14 days. Statistical analysis was done with analysis of covariance, with dream recall and content as dependent variables, age as a covariate and menstrual phase as a factor.
Results
According to the subjects' responses 400 women were in the follicular phase and 379 in the luteal phase. Three hundred and two women recalled the previous nights' dreams, 159 reporting positive/pleasant dream affect/content and 143 reporting negative/unpleasant dream affect/content. Age was not associated with dream recall or content; the latter was not associated with menstrual phase ($P>0.5$). However, in women who recalled their dreams, there was a weak association of dream content with menstrual phase (and more in detail, of those with positive affect with the luteal phase, $P=0.06$).
Discussion
In women that recalled the previous nights' dreams a tendency towards pleasant dream content was noted in the luteal phase.

Autoimmune thyroiditis and repeated pregnancy loss: a role for associated autoimmune disorders?

Camilla Virili[1], Miriam Cellini[1], Maria Giulia Santaguida[1], Nunzia Brusca[1], Ilaria Stramazzo[1], Lucilla Gargano[2] & Marco Centanni[1]
[1]Department of Medico-surgical Sciences and Biotechnologies, Sapienza University of Rome, Latina, Italy; [2]AUSL Latina, Latina, Italy.

Repeated pregnancy loss (RPL), defined as two or more spontaneous abortions, may be associated with autoimmune thyroiditis (AT), either isolated or associated with polyautoimmune disorders (PD), which include antiphospholipid syndrome. An increased occurrence of RPL has been reported in patients with isolated AT but very few data are available on the influence of concurrent auto-aggressive

disorders on RPL and this represented the aim of our study. A cohort of 1765 consecutively examined women with AT was retrospectively analyzed. Of these, 1501 had isolated AT and 264 had a simultaneous autoimmune disorder. Some 29% of women (516 out of 1765) had an abortion but only 87 (4.93%; median age = 28 years) had at least 2 abortions within the first 20 weeks of gestation. RPL rate was highly different when analyzed in women with isolated AT ($n=65$; 4.33%) and in those with PD ($n=22$, 8.33%; $P=0.0085$; OR = 2.01). Neither age nor thyroid function were significantly different in these subgroups at the time of first abortion. Similarly, no correlation between the levels of anti-thyroperoxidase antibodies and the number of abortion has been observed in both groups. Analyzing the role of thyroid function as source of bias, RPL rate appeared to be similar in hypothyroid women with isolated AT and with PD (1.8 vs 2.3%; $P=$ ns). On the contrary, among euthyroid women, RPL rate was higher in those with PD than in those with isolated AT (5.3 vs 1.9%; $P=0.0035$ OR = 2.842). In the subgroup of women, in whom successful pregnancy has never been observed ($n=15$; 17.2%), the occurrence of RPL was again lower in women with isolated AT than in those with PD ($P=0.0263$). In these latter, the presence of anti-phospholipid antibodies syndrome accounted for just 1/3 of RPL. These data indicated that the risk of repeated pregnancy loss in patients with thyroid autoimmunity is higher in the presence of further autoimmune disorders in an age- and function- independent way.

Audit of the management of adult patients with turner syndrome at the Nottingham University Hospitals (NUH), England

Boon Fei Tan, Seifeldin Yahia & Simon Page
Nottingham University Hospitals, Nottingham, UK.

Introduction
Turner Syndrome is a chromosomal disorder that is characterized by short stature and gonadal dysgenesis, affecting 1 in 2500 female live births. It is associated with a wide variety of conditions that could lead to significant morbidity and mortality if not followed up and managed appropriately. A multidisciplinary approach is important in the management of these patients. This audit aims to review the current practice of a specialist Turners Syndrome clinic in a secondary care hospital (Nottingham University Hospital, England) and to assess if standards of care are met.
Methods
A retrospective study of 37 patients who attended the clinic from Jan 2015 to Jan 2016 was done. Criteria based on two international guidelines were used. Information was gathered from local computer system which held tests reports and clinic letters.
Results
Median age of patients was 27 years old (range: 18–48). Areas well monitored (>85%) were bone health (with DEXA scan), U&E, LFT, VitD, calcium levels and the type of hormone therapy used. Areas less well monitored (50–85%) were thyroid function, coeliac screening, diabetes screening, ECHO and renal ultrasound. Areas that needed significant improvement (<50%) were audiology, lipid, FSH and LH level monitoring. 4 patients had an abnormal ECHO but only 1 went on to have an MRI. Only 24.3% of patients had a cardiac MRI. A majority of patients were on HRT (94.6%) but only 11.4% was on a transdermal form.
Conclusions
The audit showed varying performance in different areas. A standardized checklist and patient booklet for each patient review will be introduced to help identify tests due and to allow easy access to results that may have been done at another location. We would also consider doing more cardiac MRIs to pick up cardiac abnormalities that may have been missed on ECHO and to offer patients a switch from oral to transdermal HRT which is known to be more physiological.

Cognitive functions in adult women with turner syndrome

Egle Vaiciuliene[1], Ruta Kriksciuniene[1], Lina Lasaite[2], Birute Zilaitiene[1,2] & Rasa Verkauskiene[1,2]
[1]Department of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction
Turner syndrome (TS) is associated with specific physical features, as well as a particular neuropsychological profile and social and behavioral features. It is common practice in the case of TS to treat short stature with growth hormone preparations and to induce puberty with estrogens at an age as close to normal puberty as possible. Nevertheless results of some studies show that despite the treatment, some women with TS still experience psychosocial problems, impaired cognitive functions and lower quality of life. The aim of the study was to analyze cognitive functions in adult women with Turner syndrome.
Methods
A total of 65 women with genetically confirmed TS ≥ 18 yrs (age 30.2 ± 9.0 years) and 65 age-matched healthy women (age 29.2 ± 7.1 years, $P=0.807$) were recruited for the study. Cognitive functions were evaluated by Trail Making Test. Trail Making Test is a timed test in which the subject connects an altering sequence of numbers (Trail making A) or numbers and letters (Trail making B) in ascending order. The score on the Trail making A test, which is based on the time required to complete the sequence, is a measure of attention and visual scanning abilities. Trail making B is a test of executive function and psychomotor speed. A higher score denotes worse cognitive functioning. Sex hormones – Sex hormone-binding globulin (SHBG), Estradiol (E2), Luteinizing hormone (LH), Follicle-stimulating hormone (FSH), Dehydroepiandrosterone (DHEAS) and Testosterone (T) concentrations were measured in TS patients in the relationship with cognitive functions.
Results
Patients with TS were of a significantly shorter stature than age-matched control women (151.9 ± 6.8 cm vs 167.4 ± 5.9 cm, $P<0.001$). Trail Making A (42.7 ± 17.4 vs 26.2 ± 7.1, $P=<0.001$) and Trail Making B (86.0 ± 30.6 vs 53.8 ± 12.4, $P=<0.001$) showed worse cognitive functions in women with TS than in healthy age-matched women. Significant correlations between DHEAS ($r=-0.442$, $P=0.006$), T ($r=-0.465$, $P=0.003$) and Trail Making A test were found. The relation between T ($r=-0.426$, $P=0.006$), height ($r=-0,355$, $P=0,019$) and Trail Making B test in females with TS were identified, after adjusted for height the relation between T and Trail Making B remained insignificant ($r=-0.1503$, $P=0.136$). In conclusion, adult women with Turner syndrome have shorter stature and worse cognitive functions than age-matched healthy controls. The state of sex hormones and height in patients with Turner syndrome may be related with cognitive functions.

Screening for liver abnormalities in turner syndrome: audit from a single centre

Matilde Calanchini & Helen E Turner
Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford University Hospital NHS Trust, Oxford, UK.

Introduction
Liver involvement is frequent in Turner syndrome (TS) with a reported prevalence of abnormal liver function tests (LFTs) ranging 20–80%. Marked architectural changes and cirrhosis may be found in TS-women, associated with an increased incidence and risk of mortality.
Recent studies and guidelines recommended:
– monitoring annually all LFTs (International TS-Guidelines)
– to improve detection of liver disease, use Fibrosis-4 (FIB-4) score in patients with raised LTFs (EASL-EASD-EASO-Guidelines)
– perform abdominal ultrasound examination and liver stiffness measurement using Fibroscan in patients with unexplained elevated aminotransferases (EASL-EASD-EASO-Guidelines; Liver involvement in TS. *Roulot D.* Liver Int)
Aim
Audit to evaluate the current clinical practice in a large TS adult clinic in relation to the screening/management of liver abnormality against the aforementioned standards.
Methods
Data on 102 women with TS attending the adult TS-clinic over a one-year period (1/2015-1/2016) were retrospectively collected.
Results
Annually LFTs were performed in 98% of women for ALT, 37.2% for AST, 69.6% for GGT and ALP. There was a higher prevalence of LFT measurements among women who were previously diagnosed with LFT abnormalities, in particular for AST 33.9% (21/62) vs 42.5% in women with a history of LFT elevation and for GGT 66.1% (41/62) vs 75% (30/40).
Among patients with persistently elevated aminotransferases (20/102),
– FIB-4 was calculable in 55% (11/20) because of AST missing measurement, but only 54.5% (6/11) had a FIB-4 calculated

– 80% (16/20) were referred for liver ultrasound examination
– 50% (10/20) were referred for Fibroscan
Discussion
It is encouraging that LFTs were checked in the majority of TS-women, but AST being not part of the standard routine was only checked in 37%. There was a higher compliance for monitoring all LFTs among women who were previously known to have LFT abnormalities. The FIB-4 index was calculated in half of patients with persistently raised LFTs. The liver ultrasound was performed in the majority of women, while the Fibroscan was requested only in half of those. The newer investigations highlighted areas where the clinical approach with regard to the assessment/management of liver involvement in TS could be improved. We suggest the following strategies and a reaudit in one-year time: a) use pre-printed blood forms to include all LFT panel; b) add into the TS-clinic record form the previous LFTs results and related FIB-4 index; c) upload onto the clinic computers the online Fib-4 calculators; d) programme multidisciplinary meeting with the hepatologists.

Cardiac evaluation in turner syndrome: echocardiography versus cardiac magnetic resonance

Matilde Calanchini[1,2], Elizabeth Orchard[3], Saul Myerson[4], Fiona McMillan[4], Jason Bradley-Watson[3], Andrea Fabbri[2] & Helen E Turner[1]
[1]Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford University Hospital NHS Trust, Oxford, UK; [2]Department of Systems Medicine, Endocrinology and Metabolism Unit, University of Rome Tor Vergata, Rome, Italy; [3]ACHD Cardiology, Oxford University Hospital NHS Trust, Oxford, UK; [4]Centre for Clinical Magnetic Resonance Research, Oxford University Hospital NHS Trust, Oxford, UK.

Introduction
Women with turner syndrome (TS) have an increased risk of aortic dissection at young age. Bicuspid aortic valve (BAV) and aortic dilatation, both associated with TS, are risk factors. Preliminary studies suggested that cardiac MR (CMR) perfoms better than transthoracic echocardiography (TTE) for evaluating BAV and aortic dilatation, probably related to the frequent chest abnormalities in TS.
Aim
To evaluate the ability and comparability of TTE and CMR for detection of BAV and assessment of ascending aorta (AA) diameter in women with TS.
Methods
365 scans in 99 adult TS women: 287 TTE/94 women and 98 CMR/78 women (5 with no TTE). For TTE *versus* CMR AA diameter comparison, only scans performed within a 2-year period (78 scans) were considered. TTE and CMR exams were reviewed by TTE and CMR expert cardiologists.
Results
Assessment of BAV was difficult due to poor visualization with TTE in 31.9% (30/94) of patients and in 17.4% (50/287) of scans. In women with multiple TTE (74) 10.8% had discordant diagnosis. Valve assessement using CMR was not possible in 20.5% (16/78) of patients and in 17.3% (17/98) of scans. Among 73 patients with both TTE and CMR scans, CMR was concordant with TTE for the diagnosis of BAV in 56.2% (41/73), discordant in 9.6% (7/73), able to assess the valve in 13.7% (10/73) of women where were poorly visualized by TTE, and not able to assess the valve in 20.6% (15/73). The AA diameter was difficult to assess with TTE in 36.2% (34/94) of women and 16% (46/287) of scans. AA measurements were feasible in all CMR. Pearson's correlation between TTE and CMR AA measurements was $+0.723$ ($P<0.001$). Among scans performed with both techniques within a 2-year period, 72% showed a discrepancy between AA diameters:
- TTE underestimated CMR measurements in 32% (25/78) with a difference ≥ 3 mm in 16.7% (13/78).
- TTE overestimated CMR measurements in 40% (31/78) with a difference ≥ 3 mm in 18% (14/78).

In 10.3% of scans the results were the same and in 18% diameter was only measurable with CMR.
Conclusions
TTE assessment of BAV and aortic dilatation in women with TS is technically limited and frequently unreliable. CMR is the preferred imaging technique for overcoming the difficulties in assessment of aortic valve and aortopathy, and thus of aortic dissection risk, supporting the recent International TS Guidelines that recommend expert and multidiscliplinary approach.

IGF-1 corellates with cognitive status in esrd patients undergoing haemodialysis

Vladimir Prelevic, Danilo Radunovic, Tanja Antunovic, Marina Ratkovic, Najdana Gligorovic-Barhanovic & Snezana Vujosevic
Clinical Center of Montenegro, Podgorica, Montenegro.

Backrounds
Prevalence of cognitive function decline in End Stage Renal Disease (ESRD) patients undergoing hemodialysis is higher than in general population. We analyzed risk factors for cognitive function decline in those patients.
Study design
This study included 93 ESRD patients undergoing hemodialysis two or three times a week in Center for hemodialysis, Clinical center of Montenegro and two regional centers for hemodialysis in Montenegro. The cognitive status of patients was assessed using the Mini Mental Score Examination (MMSE) test. Laboratory data about risk factors for cognitive function decline was obtained in Center for clinical-laboratory diagnostic in Clinical center of Montenegro.
Results
All 93 patients have been divided into three groups according the results of MMSE. Patients in first group had severe cognitive impairment and MMSE score below 17 (26.88%), patients in second group with MMSE score 18–23 had moderate cognitive impairment (40.86%) and third group of patients have MMSE >24 and no cognitive impairment (32.26% of patients enrolled in study). There were no significant differences between groups for gender, smoking habits and level of parathyroid hormone. Level of schooling was significantly different between groups of patients ($P<0.001$). Laboratory markers observed in this study with significant differences between groups were: IGF 1, IGFBP 3, erythrocytes and hemoglobin ($P<0.001$, $P=0.004$, $P<0.001$, $P=0.002$ respectively). IGF 1 proved to be of great importance for evaluating cognitive status in our study. This marker was statistically different between groups ($P<0.001$) and Tukey post hoc analysis showed significant differences between all three groups (first and second group $P=0.045$, second and third group $P=0.015$, first and third group $P<0.001$).
Conclusion
Our data suggest that IGF 1 can be considered as novel biomarker for assessment of cognitive functioning in CKD patients what can be of huge clinical importance. This can be important and the particular new significance of this survey in relation to other studies.

IGF-I is not suppressed in adolescents submitted to resistance training and can be a marker of training status

Marcos Correa Jr[1], Hugo Tourinho Filho[2] & Carlos Martinelli Jr[1]
[1]Ribeirão Preto Medical School, Ribeirão Preto, Brazil; [2]School of Physical Education and Sports of Ribeirão Preto, Ribeirão Preto, Brazil.

Background
Regular physical exercise during childhood and adolescence can promote growth and development of muscle and bone mass. Although physical exercise is closely linked to the anabolic function of the GH /IGF-I axis the real impact of resistance training on GH/IGF axis is still unclear. The kinetics of IGF-I and IGFBP-3 during chronic training is not fully understood yet and an initial catabolic phase followed by an later anabolic phase has been reported in swimmers.
Aim
The aim of the present study was to analyse the kinetics of IGF-I and IGFBP-3 in adolescents undergoing ten weeks of hypertrophy training.
Methods
Twenty-two male volunteers aged 18–25 years with at least 6 month experience in resistance training were enrolled and submitted to a standard hypertrophy training program during 10 weeks. Serum IGF-I and IGFBP-3 concentrations were determined before, 30 min-after and 24h-after the training session at the 1st, 5th and 10th week of resistance training. Body composition, lean mass, muscle mass, fat percentage and body mass index were also evaluated at the 1st, 5th and 10th week and compared to the changes in serum IGF-I and IGFBP-3. Data were paired compared.

Results
IGF-I levels increased during the training session at the 1st evaluation ($P=0.03$) and also increased during the 10 weeks of training ($P<0.003$). No changes in IGFBP-3 levels were observed during a training session or during the 10 weeks of training. Body mass, lean mass, fat percentage and body mass index of the volunteers remained unchanged throughout the 10 weeks of training. A negative correlation was observed between the changes in serum IGF-I concentrations and the variation in muscle mass or lean mass when data from the 1st and the 10th weeks were compared ($r=-0.62$; $P=0.002$).
Conclusion
In summary, no catabolic phase was detected in adolescents during hypertrophy training; IGF-I was sensitive to the acute and chronic effects of resistance training and can be considered as a biomarker of training status in non-athlete volunteers. The negative correlation between the variations in lean mass and IGF-I could suggest a training-induced increase in IGF-I sensitivity.

Effects of zinc, magnesium and vitamin B6 (ZMA) supplementation on serum IGF-I, IGFBP-3 and Testosterone concentrations in young athletes

Henrique Cerqueira[1], Hugo Tourinho Filho[2] & Carlos Martinelli Jr[1]
[1]Ribeirão Preto Medical School, Ribeirão Preto, Brazil; [2]School of Physical Education and Sports of Ribeirão Preto, Ribeirão Preto, Brazil.

Background
The GH-IGF system plays an important role in strength gain. Some studies suggest that Zinc, Magnesium and Pyridoxine (ZMA) supplementation could increase GH/IGF and testosterone levels in young subjects. This hypothetical increase could lead to significant changes in body composition. ZMA is a very popular supplement, easily found in specialty stores, and it is presumed to increase GH, IGF-I and testosterone levels. However, studies are divergent regarding its efficacy.
Aim
The present study aimed to verify the effects of physical training associated with 8-week ZMA supplementation on the IGF-I, IGFBP-3 and testosterone levels in young males.
Methods
Eighteen healthy male amateur American football players aged 18–25 years with at least 1 year experience in this sport modality were included in the study and followed during 8 weeks of training. The training consisted of a 90 min-conditioning session based on strength and aerobic exercises twice a week and specific tactic training also twice a week in different days. Energy intake and diet composition were determined by nutritionist. It was a double-blind study and the subjects were divided into two groups: ZMA and placebo groups according to the supplementation received. Anthropometric evaluation and blood sampling, for serum IGF-I, IGFBP-3 and testosterone determination, were performed at two different moments: at the beginning (M1) and after 8 weeks of supplementation (M2).
Results
Serum IGF-I and IGFBP-3 concentrations were higher at M2 in both groups. The increase was similar in the ZMA and in the placebo group. Testosterone concentrations were also higher at M2 than at M1 in a similar degree in both groups. The changes in anthropometric parameters that indicate lean mass gain or body fat mass reduction were similar in both groups.
Conclusion
The findings suggest that extra doses of the micronutrients present in the ZMA do not bring any additional benefits, either in the body composition or in the hormonal levels in subjects under adequate diet. Testosterone increase could partially explain the change in IGF-I and IGFBP-3.

Single center three years' experience with non-diabetic hypoglycemia in a tertiary hospital, Nepal

Suman Baral & Vivek Pant
Tribhuvan University Teaching Hospital, Kathmandu, Nepal.

Introduction
Diagnosis of hypoglycemia in non-diabetics is challenging in most of the cases. Appropriate diagnosis is possible only after taking proper history and performing appropriate laboratory investigation in appropriate time. The purpose of this study is to find the spectrum of etiology of hypoglycemia in non-diabetics in a tertiary hospital in a developing world with limited resources. This may help physicians working in similar situations.
Materials and methods
All patients admitted since June 2014 to June 2017 in the Tribhuvan University teaching hospital, Kathmandu for the evaluation of hypoglycemia were included in the study. Patients with diabetes and related hypoglycemia, gastric and intestinal/bowel surgeries, sepsis, starvation, cardiac, renal and hepatic failure in whom the cause of hypoglycemia was obvious were excluded from the study. In remaining twenty-one cases proper history was taken, and appropriate laboratory investigation was done. Two days of strict observation along with 72 h fasting and critical blood sampling for serum insulin and c- peptide was done.
Results
In twenty-one nondiabetic hypoglycemic patients, twelve were female and nine were male. The cause of hypoglycemia was presence of insulin autoantibody in five cases, adrenal insufficiency in five cases, reactive hypoglycemia in four cases, insulinoma in four cases, drug induced (excluding OHAs) in two cases and non-islet cell tumor hypoglycemia (Doege-Potter Syndrome) in one case. Six patients had autoimmune disease (Grave's disease in four cases, SLE in one case and RA in one case). Five cases were insulin auto antibody positive (except one patient with RA). Four out of five cases of adrenal insufficiency were due to secondary adrenal insufficiency. Among these four cases, three were female with Sheehan's syndrome. All four patients with reactive hypoglycemia were male and all of them presented to hospital for their concern about possibility of road traffic accident. Three out of four cases of insulinoma were male while one was female who also had associated primary hyperparathyroidism and later diagnosed as MEN 1 syndrome. In patients with drug induced hypoglycemia one was female diagnosed with RA who was taking hydroxychloroquine while another was a male taking ciprofloxacin for chronic pyelonephritis.
Conclusion
Insulin autoantibody related followed by adrenal insufficiency secondary to Sheehan's syndrome remains the commonest cause of hypoglycemia in non-diabetics in female while reactive hypoglycemia is the commonest cause in male.

Does gender affirming hormone therapy affect anger proneness in transgender persons?

Justine Defreyne[1], Els Elaut[2], Baudewijntje Kreukels[3], Gunter Heylens[2], Thomas Schreiner[4], Alessandra Daphne Fisher[5], Martin Den Heijer[6] & Guy T'Sjoen[7,8]
[1]Ghent University Hospital, Department of Endocrinology, Ghent, Belgium; [2]Ghent University Hospital, Center for Sexology and Gender, Ghent, Belgium; [3]VU University Medical Center, Center of Expertise on Gender Dysphoria, Amsterdam, Netherlands; [4]Department of Endocrinology, Oslo University Hospital, Oslo, Norway; [5]Sexual Medicine and Andrology Unit, Department of Experimental, Clinical and Biomedical Sciences, University of Florence, Florence, Italy; [6]Department of Endocrinology, Department of Internal Medicine, VU, University Medical Center, Amsterdam, Netherlands; [7]Department of Endocrinology, Ghent University Hospital, Ghent, Belgium; [8]Center for Sexology and Gender, Ghent University Hospital, Ghent, Belgium.

Introduction
Anger is an emotional state of feelings varying from mild irritation to intense rage, whereas aggression implies externalizing angry emotions through destructive/punitive behavior towards other persons/objects. Although research on the relationship between testosterone and aggression is inconclusive, the WPATH SOC 7 guidelines have warned for an increase in aggression in transgender men (TM) taking testosterone treatment.

Aims
1. As aggression is initiated by angry feelings, we aim to assess whether anger proneness increases in TM and decreases in transgender women (TW) after initiation of gender affirming treatment.
2. To identify predictors for an increase (TM) or decrease (TW) of anger proneness.
Methods
This prospective cohort study is part of the European Network for the Investigation of Gender Incongruence (ENIGI). Anger was prospectively assessed in 440 TM and 468 TW by STAXI-2 (State-Trait Anger Expression Inventory 2) questionnaire during three year follow-up, starting at initiation of hormone treatment. Upon first clinical contact, participants filled in psychological questionnaires (Kreukels, 2012). Data were analyzed cross-sectionally and prospectively.
Results
Baseline STAXI-2 scores were comparable in TW and TM (15.0 (15.0–16.8) and 15.0 (15.0–16.0), $P=0.777$). TM showed a small increase in total STAXI-2 scores after three months, compared to baseline (+0.90, 95%CI 0.037–1.75, $P=0.041$), decreasing after one year (−1.296, 95% CI −2.15 to −0.44) to scores comparable to baseline ($P=0.235$), after which scores remained stable. At three months, there was no correlation between STAXI-2 scores and serum total testosterone or oestradiol levels, nor an association with co-existent psychiatric morbidities assessed by MINI plus and SCL-90R. At three months of testosterone treatment (cross-sectionally), TM reporting stronger negative affect (PANAS) experienced more anger proneness ($\rho=0.113$, $P=0.003$). Over 36 months in TM (prospectively), anger proneness was positively correlated to negative affect ($\rho=0.415$, $P<0.001$) and SCL-factors somatization ($\rho=0.075$, $P=0.033$), paranoid ideation/psychoticism ($\rho=0.101$, $P=0.004$), depression ($\rho=0.082$, $P=0.019$) and interpersonal sensitivity ($\rho=0.119$, $P=0.001$). In TW, STAXI-2 scores did not change over time ($P=0.952$). At three months, there was no correlation between STAXI-2 scores and serum testosterone.
Conclusions
Evidence from a prospective study shows no association between anger proneness and exogenous testosterone administration in TM. TM with psychological/psychiatric difficulties before gender affirming therapy are more likely to show a (temporarily) increase in anger proneness.

Cigarette smoking and neuroreceptors genetic variations: a handshake between genetic and environmental factors leading to nicotine addiction

Muhammad Mobeen Zafar, Imtiaz Ahmad, Muhammad Saqlain Raja, Shagufta Kiani, Muhammad Sheeraz Ahmed, Shakeel Raza, Muhammad Gulfraz & Ghazala Kaukab
University Institute of Biochemistry and Biotechnology Pir Mehr Ali Shah Arid Agriculture University, Rawalpindi, Pakistan.

Cigarette smoking is the major cause of disease related deaths in the world. Cigarette smoke contains many harmful chemicals, among them nicotine is the most potent one. The root cause of smoking hazards is nicotine addiction or dependence (ND). Environmental as well as genetic factors are reported to influence smoking which leads to nicotine addiction in all age groups especially. Neurexin1 is a cell adhesion protein important for synapse formation and *CHRNB4* is cholinergic receptor beta polypeptide. Studies have revealed a strong association between nicotine addiction and genetic variants in NRXN 1 and CHRNB4 genes in different world populations. Genetic associations of rs6721498 and rs17487223 SNPs of NRXN1 and CHRNB4 genes with ND were explored in Pakistani tobacco smokers. The questionnaire based data and blood and were collected from three hundred (300) individuals belonging to different ethnicities of Pakistan and categorized into non-smokers and smokers and habitual smokers. Based on Fagerstrom test, smokers and habitual smokers were categorized as Nicotine dependent and non-dependent. DNA was extracted and PCR-RFLP based genotyping of rs6721498 and rs17487223 SNPs performed for. Allele and genotyping frequencies were calculated and their associations with nicotine dependence was estimated. Association of nicotine dependence with anthropometric variables was also calculated. Allele Frequency of minor allele (A) of rs6721498 was 0.74 in nicotine dependent subjects and homozygous A/A genotype minor allele (A) increased risk of ND by 10.5 folds while allele frequency of minor allele (T) of rs17487223 was 0.56 and homozygous T/T genotype of minor allele (T) increased risk of ND by 8.44 folds. The socio-economic factors like education and tea/coffee intake increased risk of developing N.D by 5.76 and 3.32 times respectively while age, income status, ethnicity, Family history, stimulus, and obesity lacked significance of associations. Based on the highly strong associations of the minor alleles of both SNPs with nicotine addiction, it could be concluded that rs6721498 of NRXN1 and rs17487223 of CHRNB4 gene SNPs are risk markers of exploring nicotine dependence in Pakistani smokers. The environmental/socioeconomic parameters like caffeine intake and education also expressed significant association with ND. Subjects with Punjabi and Pothohari were more at risk of ND as compared to Pathan and other ethnic groups of Pakistan. Present study signifies role of genetic as well as environmental/socioeconomic risk factors that could lead to ND.

Association of OPRD1 rs569356 SNP with Stress Response in opioid addicts

Faiqa Rashid, Muhammad Mobeen Zafar, Imtiaz Ahmed, Shagusta Jabeen, Muhammad Sheeraz Ahmad, Nasir Mehmood Minhas & Ghazala Kaukab
University Institute of Biochemistry and Biotechnology Pir Mehr Ali Shah Arid Agriculture University, Rawalpindi, Pakistan.

As a lingering, often deteriorating brain disease, addiction causes neurotic drug seeking and utilization along with injurious significances to the addicts and to those living around them. Biological, genetic and a number of intrinsic and extrinsic environmental constituents are most vital in entire risk factors of drug addiction. Among addictive drugs opioid dependence is considered as the most deliberated drug abuse disorder and a major social dilemma worldwide. Opioids induce their action through opioid receptors. Among opioid receptors, the δ receptor encoded by OPRDI gene is involved in opioid addiction susceptibility. Genetic associations of polymorphisms in *OPRD1 gene e.g. rs569356 with heroin addiction are being reported in different world populations.* Opioid addiction has been strongly linked to stress conditions which increases craving for drug, development of addictive behaviors, as well as relapse to opioid use which in turn accelerates the major component of stress response system, Hypothalamus Pituitary Adrenal axis (HPA axis). Cortisol, as a final product of HPA axis of stress response in humans, is evaluated in blood serum of opioid addicts and thus could be used as a marker of stress response. The relationship between cortisol levels and *rs569356 SNP* in opioid addicts has not been explored yet. Keeping with the crucial roles of OPRDI receptor in drug addiction and cortisol as a stress response, present study was designed to investigate association of the risk allele of *rs569356 OPRDI variant with stress response in Pakistani opioid addicts. Whole blood samples from opioid addicts were collected for the extraction of g*enomic DNA and cortisol from serum. Genotyping of *rs569356 was carried out* by using allele specific PCR while cortisol levels were estimated by approaching ELISA. Allele frequencies were estimated through χ^2-test while association analyses were performed through regression models. Our results have shown high frequency of minor G allele of rs569356 (0.42) in drug addicts while the ancestral 'A' allele frequency was 0.58. Social and addictive behaviors including family history, guilt of addictive habits, family issues, and disturbance in daily routine significantly associated with drug addiction ($P=0.000$). The minor allele G of rs569356 SNP lacked association with opioid addiction but showed strong correlation with serum cortisol levels Our results confirm the role of minor G allele as risk marker of opioid addiction in Pakistani population through its role in elevating the stress responses (cortisol).

Pro-inflammatory Socs3 inactivation in *Kiss1*-expressing cells does not affect reproduction and metabolism in mice

Tabata M Bohlen, Daniella G de Paula, Thaís T Zampieri, José Donato Jr & Renata Frazão
University of São Paulo, São Paulo, Brazil.

It is well established that the kisspeptins are the main activators of GnRH neurons and therefore essential for the onset of puberty and reproduction. Previous studies have suggested that kisspeptin neurons are possibly major targets of pro-inflammatory cytokines to regulate reproduction. SOCS (suppressor of cytokine signaling) are proteins that regulate, as it says, cytokines. They inhibit the transduction of intracellular effects caused by those molecules, once that cytokines recruit multiple intracellular signaling pathways that can induce either acute or long lasting/genomic responses in several tissues. Among the different SOCS proteins, SOCS3 plays a major role regulating the sensitivity of pro-inflammatory cytokines. Considering that *Kiss1* mRNA coding is also found in other tissues besides the brain-related reproductive areas, the goal of the present study was to evaluate whether *Socs3* inactivation in kisspeptin cells may modulate the development and metabolism of mice. We bred the Kiss1-Cre strain with mice carrying loxP-flanked *Socs3* alleles. Mice carrying the kisspeptin-specific deletion were homozygous for the loxP-flanked *Socs3* allele and hemizygous for the Kiss1-Cre transgene (Kiss1 SOCS3 KO), whereas their control group was composed of animals containing a homozygous loxP-flanked *Socs3* allele. Sexual maturation was evaluated daily by determining the age of balano-preputial separation and by the age at vaginal opening, the first occurrence of vaginal cornification in the vaginal lavage (first estrus) and the first occurrence of an estrus cycle of normal duration. Body weight was recorded weekly and at every event of sexual maturation observed. Adult mice were submitted to glucose and insulin tolerance test or to a lipopolysaccharide S (LPS) acute injection. The adult animals were euthanized and adipose fat pad was collected. We observed that the sexual maturation of mice was not affected by specific *Socs3* inactivation. No significant differences in body weight during development or adipose fat pads weight at adult age were observed between groups. Glucose and insulin sensitivity were similar between Kiss1 SOCS3 KO and control mice. Additionally, by using a model of acute inflammation we observed that specific *Socs3* inactivation did not modulate the anorectic effects of inflammation induced by LPS. Our results demonstrated that *Socs3* inactivation in *Kiss1*-expressing cells, does not affect the development of mice. Suggesting that the previous observed role of the kisspeptin neurons as targets of pro-inflammatory cytokines may be indirect or depend on other signaling pathway not assed in the present work.

Vitamin D abolishes the dexamethasone-induced apoptosis in acute myeloid leukemia cells via regulation of Notch signaling

Angeliki G Karapanagioti[1], Narjes Nasiri-Ansari[1], Anna Angelousi[2], Vasiliki Kalotychou[2], Athanasios G Papavasilliou[1] & Eva Kassi[1,2]
[1]Department of Biological Chemistry, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece; [2]1st Department of Internal Medicine, Laikon General Hospital, National and Kapodistrian University of Athens, Athens, Greece.

Introduction
Glucocorticoids are used for treatment of various hematological malignancies such as Acute Myeloid Leukemia (AML). Glucocorticoids are known to induce apoptosis by regulating the expression of key anti- or pro-apoptotic genes. Vitamin D induces apoptosis and cell cycle arrest in various types of cancer cells. Despite recent advances in treatment of AML, the poor response rate to therapy remains a big challenge.Therefore, discovering new factors that can affect therapeutic response to Glucocorticoid therapy is mandatory.
Aim
I) to investigate the effect of $1,25(OH)_2$vitamin D_3 (VitD) on glucocorticoid-induced AML cells apoptosis and/or cell cycle arrest, II)to determine whether this effect is mediated through activation of Notch-1 signaling.
Methods
Kasumi-1 cells were either incubated for 72 hours with dexamethasone (Dex-10^{-6}M and 10^{-7}M) alone or pre-incubated with VitD (10^{-7}-10^{-9}M) for 24 h. MTS assay was performed to quantify viable cells whereas apoptosis was measured by flow cytometry (Annexin V/PI staining). The mRNA expression of *Mcl-1, Noxa, Bcl-2, Bax, p21, Notch-1 and Notch-2* genes implicated in apoptosis and cell cycle arrest, was evaluated by qPCR. Notch-1 and cleaved Notch-1 (NICD-active-form) protein levels were measured by Western blot.
Results
The results of MTS and FACS indicate that Dex induced apoptosis in Kasumi cells dose-dependently, however this effect was attenuated significantly in cells pre-incubated with VitD. Pre-incubation of cells with VitD for 24h followed by co-incubation with Dex for further 72h increased the Bcl-2/Bax ratio significantly via reducing the Bax mRNA expression while did not change the mRNA MCL-1/NOXA ratio compared to those cells incubated with Dex alone. P21 mRNA expression was reduced significantly in cells pre-incubated with VitD compared to cells incubated with Dex alone. The Notch-1 and its intracellular domain protein levels was not detectable in the presence of dexamethasone at lower concentration. The protein level of Notch-1 as well as NICD were significantly increased in cells pre-incubated with VitD (10^{-8}M) and then co-incubated with Dex (10^{-7}M) as compared to cells incubated with Dex (10^{-7}M) alone.
Conclusions
VitD exerts inhibitory effect against Dex induced-apoptosis in Kasumi-1 cells via increasing Bcl2/Bax ratio, while MCL-1/NOXA ratio did not seem to play important role. VitD can induce cell survival by inhibition of GC-mediated cell cycle arrest through activation of Notch-1 signaling, which could in turn result in reduction of p21 expression.

1,25 dihydroxyvitamin D reverses everolimus resistance in hepatocellular carcinoma activating mesenchymal-epithelial transition and miR-375

Claudia Pivonello[1], Donatella Paola Provvisiero[1], Mariarosaria Negri[1], Gilda Di Gennaro[1], Cristina de Angelis[1,2], Roberta Patalano[1], Giacomo Galdiero[1], Chiara Simeoli[1], Renata Simona Auriemma[1], Maria Cristina De Martino[1], Annamaria Colao[1] & Rosario Pivonello[1]
[1]Department of Clinical Medicine and Surgery, University of Naples, Naples, Italy; [2]I.O.S. & COLEMAN Srl, Naples, Italy.

HCC is a difficult-to-treat-cancer with poor prognosis. EVOLVE-1 trial demonstrated that EVE did not improve overall survival in molecularly and clinically unselected patients with advanced HCC resistant to sorafenib. In selected patients, the well-established antitumor effect of EVE could make this a potential adjuvant therapy. Unfortunately, EVE acquired resistance due to the

tumor adaptation to chronic drug use is a current challenge. VitD was deemed as potential regimen to treat several cancers alone or in combination with other drugs. The aim of this study was to explore the role of VitD pre-treatment in the re-sensitization to EVE in two models of HCC cell lines, PLC/PRF/5 and JHH-6 cell lines resistant to EVE (PLC/PRF/5 EveR and JHH-6 EveR). EveR cells were obtained after 4 months of treatment with EVE 10^{-8}M. VitD receptor (VDR) expression was confirmed by RT-qPCR and WB. DNA assay was established to evaluate the proliferation rate in parental and EveR cells after EVE treatment (from 10^{-14}M to 10^{-8}M) alone or in combination with VitD (10^{-7}M). Epithelial–mesenchymal transition (EMT) markers were evaluated by IF in parental and EveR cells, even after VitD treatment. miRNA PCR Arrays were employed to investigate the difference in parental and EveR cells after 12hrs of treatment with VitD. EVE long-term exposure increased mRNA and protein VDR expression in PLC/PRF/5 EveR but not in JHH-6 EveR cells. Contrary to EveR, in parental cells, EVE significantly reduced cell proliferation in a dose-dependent manner after 6 days of treatment where VitD did not improve EVE effect. In both EveR cells 12 and 24hrs of VitD pre-treatment was sufficient to significantly restore EVE efficacy at concentration ranging from 10^{-14}M to 10^{-8}M. In EveR cells, EVE 10^{-8}M chronic treatment increased the protein expression of mesenchymal markers, but VitD prolonged treatment restored epithelial markers protein expression. miRNA expression analysis in EveR cells revealed miR-375 downregulation compared to parental ones, conversely, EveR cells treated with VitD for 12hrs showed miR-375 upregulation compared to EveR cells. Treatment with VitD was able to downregulate metadherin and Yes Associated Protein 1, genes involved in drug resistance and bioinformatically predicted miR-375 target genes, expression in both EveR cells. These data suggested the use of VitD to overcome EVE acquired resistance in HCC reverting EMT and downregulating the expression of genes involved in drug resistance acting trough the regulation of miR-375.

Inactive AT1 angiotensin receptor acts as a signaling hub: a novel mechanism of receptor cross-talk

András D Tóth[1,2], Susanne Prokop[1], Pál Gyombolai[1], Péter Várnai[1,2], Vsevolod V Gurevich[3], Gábor Turu[1,2], András Balla[1,2] & László Hunyady[1,2]
[1]Department of Physiology, Semmelweis University, Budapaest, Hungary; [2]MTA-SE Laboratory of Molecular Physiology, Hungarian Academy of Sciences and Semmelweis University, Budapest, Hungary; [3]Department of Pharmacology, Vanderbilt University, Nashville, USA.

It is generally believed that the signal transduction of AT1 angiotensin receptor (AT1R), the major receptor of angiotensin II, requires ligand binding and subsequent adoption of its active conformation. Activated AT1R induces a plethora of signaling pathways, in contrast to inactive AT1R, which was thought to be silent in terms of signaling. We hypothesized that unliganded, but phosphorylated AT1R may recruit β-arrestins, the key proteins of receptor desensitization, internalization, and signaling. Since phosphorylation of AT1R is induced by a variety of other receptors, the β-arrestin activation by heterologously-phosphorylated AT1R may represent a novel mechanism of signal transduction and receptor cross-talk.In this study, we demonstrated that activation of protein kinase C (PKC) by phorbol myristate acetate, Gq/11-coupled GPCR or epidermal growth factor receptor stimulation promotes β-arrestin2 recruitment to AT1R even in the absence of AngII. We also provided evidence that endogenous purinergic receptors can exert the same effect, proving that the interaction can be triggered at physiological levels of PKC activation. We found that heterologous mechanisms of β-arrestin recruitment to AT1R does not demand the active state of the receptor and was dependent on the stability lock. This interaction required the association of phosphorylated serine-threonine clusters in the receptor's C-terminus and two conserved phosphate-binding lysines in the β-arrestin2 N-domain, resulting in sustained binding between these proteins. Using improved FlAsH-based β-arrestin2 conformational biosensors in BRET (bioluminescence energy transfer) measurements, we showed that β-arrestin2 binds to PKC-phosphorylated AT1R in a distinct active conformation, which triggers MAPK recruitment and receptor internalization. Our results reveal that AT1R may also function as a scaffold protein, demonstrating its novel role in signaling and receptor cross-talk.This work was supported by the Hungarian National Research, Development and Innovation Fund (NKFI K116954 and NVKP_16-1-2016-0039).

Gender specific differences in patients with metabolic syndrome and major depression

Alina Mihaela Pascu[1], Petru Iulian Ifteni[1,2], Andreea Teodorescu[1,2], Vladimir Poroch[3,4], Silvia Nicoleta Moga[5] & Victoria Burtea[1]
[1]Faculty of Medicine, Transilvania University of Brasov, Brasov, Romania; [2]Clinical Hospital of Neurology and Psychiatry, Brasov, Romania; [3]Faculty of Medicine, "Grigore T. Popa" University of Medicine anf Pharmacy Iasi, Iasi, Romania; [4]Regional Institute of Oncology Iasi, Iasi, Romania; [5]Clinical Emergency County Hospital Brasov, Brasov, Romania.

Background
Metabolic syndrome (MetSy) comprises a cluster of risk factors (central obesity, high blood pressure, low high density lipoprotein [HDL]-cholesterol, elevated triglycerides and hyperglycaemia) associated to the risk of cardiovascular diseases development. Depression has also been reported to be associated with an increased risk for diabetes and cardiovascular diseases, the underlying mechanisms being still poorly described. MetSy may mediate this association, but only limited data have been reported to support whether MetSy and depression are connected, and, moreover, whether this connection is gender-specific.
Objectives
The study aimed to evaluate the gender differences in patients with MetSy and depression.
Methods
Seventy patients with major depressive disorder (MDD) and MetSy were studied. The MDD was diagnosed according to DSM-IV-TR. MetSy was screened for considering the International Diabetes Federation consensus worldwide de-finition of the Metabolic Syndrome.
Results
The study group comprised 45 women and 25 men hospitalized for MDD (gender ratio F:M = 1.8), with an average age of 45.34 ± 5.43 years. The mean age of onset of the MDD was 41.12 years. The group of patients associating MDD and MetSy consisted of 15 women and 11 men (gender ratio 1.36, with no significant statistical difference). The female subjects associating MetSy met 4 or even 5 diagnosis criteria, compared to the male subjects, who generally met only 3 diagnosis criteria. The most frequent MetSy diagnosis criteria were high blood pressure, increased levels of triglycerides and increased levels of glucose, with no statistical significant differences between the male and the female groups. The maximum range of systolic blood pressure was higher in the female group compared to the male group (195 mmHg *vs.* 165 mmHg, P = 0.03). There was a significant difference in the mean triglyceride level: the female group had higher values compared to the male group (mean value 229.7 mg/dL *vs.* 212.31 mg/dL, $P < 0.05$). The female group had also higher HDL-cholesterol levels (mean value 44 mg/dL *vs.* 35 mmol/L, $P = 0.04$).
Conclusions
The metabolic syndrome is associated with depression irrespective of gender. Patients with depression may be prone to metabolic syndrome both because of poor health-related behaviours and lifestyle, and antidepressant medication, causing prolongation of the depression episodes, increasing the percentage of relapses, and lowering the adherence to treatment. These findings highlight the importance of screening for depression in patients with metabolic syndrome, as lifestyle changes could reduce the visceral adiposity and inflammation that might ameliorate depression.

Background
Registries are of key importance for a centre of expertise. Endo-ERN consists of 71 reference centres (RCs) that cover several groups of rare endocrine conditions within 8 themes (www.endo-ern.eu). It is unclear if awareness, participation and availability of registries is uniform for all conditions within Endo-ERN.
Objective
To determine the extent of engagement in registries of Endo-ERN members.
Methods
Endo-ERN RC leads were invited to participate in a survey of their awareness and participation in local, national and international registries and their views on future priorities using a Likert scale of 1–5 where 5 was the greatest priority.
Results
A RC response rate of 82% was obtained. Of the 29 centres surveyed within the glucose theme, 62% reported an awareness of an international registry for rare diabetes with a 48% participation rate. A priority score of 5 was only attributed to rare diabetes. Of the 33 centres within the adrenal theme, awareness of an international registry was 61% for adrenocortical tumours (ACT) and participation was 39%. Pheochromocytoma, ACT and CAH were rated as 5. Of the 37 centres within the sex development theme, 50% reported awareness and participation was 37% for DSD; all conditions were rated as 5. Of the 43 centres within the pituitary theme, international registry awareness was 33% for pituitary adenoma whilst participation was 23%. Pituitary adenoma was the only condition rated as 5. Of the 31 centres within the rare genetic tumour theme, 19% reported an international registry awareness for MEN1 and 6% reported participation; all conditions were rated as 5. Of the 30 centres within the growth theme, international registry awareness was 17% for Prader Willi Syndrome and participation was 10%. All conditions were rated as 5. Of the 29 centres within the Calcium/Phosphate theme, international registry awareness was 14% for phosphate disorders and participation was 7%. Hypocalcaemia and hypophosphataemia were rated as 5. Of the 35 centres within the thyroid theme, international registry awareness for thyroid carcinoma was 14% and participation was 0%, with 4 of 6 conditions being rated as 5.
Conclusion
Whilst there is a clear need to develop new detailed disease registries, there is also a need to improve the awareness and signposting of existing registries. A common platform that is used by the whole endocrine community and which directs the user to high quality detailed disease registries has the potential to achieve this objective.

Long-term endocrine sequelae of patients with beta-thalassemia following bone marrow transplantation in childhood/adolescence

Georgia Ntali[1], Stella Roidi[2], Stavroula Michala[2], Anna Paisiou[3], Ioulia Peristeri[3], Stephanos Michalakos[4], Elpida Vlachopapadopoulou[4] & Vassiliki Kitra[3]
[1]Department of Endocrinology and Diabetes, Evangelismos Hospital, Athens, Greece; [2]1st Department of Obstetrics and Gynecology, National and Kapodistrian University of Athens, Alexandra Hospital, Athens, Greece; [3]Stem Cell Transplantation Unit, "Agia Sophia" Children's Hospital – "Elpida", Athens, Greece; [4]Department of Endocrinology-Growth and Development, "Panagiotis & Aglaia", Children's Hospital, Athens, Greece.

Introduction
Allogeneic bone marrow transplantation (BMT) represents the only effective approach to the cure of thalassemia major, offering high rates of success especially in a pediatric setting. Endocrine complications are expected in these patients due to both primary disease and BMT process. Iron overload, desferrioxamine treatment, cytotoxic agents used in the preparative regimen, and posttransplant immunosuppression period contribute to various endocrine disorders.
Aim
To evaluate the long-term endocrine sequelae of patients with thalassemia major (TM) who underwent bone marrow transplantation (BMT) during their childhood/adolescence.
Patients and Methods
The records of patients with beta thalassemia who received bone marrow transplant during their childhood/adolescence and were followed in an Adult Endocrinology Unit were reviewed.
Results
A total of 11 patients (5 males and 6 females) who were transplanted from an HLA matched donor were identified. Their median age at bone marrow transplantation was 13(3–17) yrs. At last assessment, their median age was 28 (19–33) years old, their median height 165 (158–170) cm, their weight 65 (50–85) kg and their BMI 24.1 (17.5–29.4) kg/cm^2. Median follow-up duration was 15 (6–21) years.At last assessment 5/11 (45.5%) had hypothyroidism, and were on thyroxine replacement, 8/11 (72%) had osteopenia/osteoporosis, 2/11 (18.18%) had hypogonadotrophic hypogonadism and 9/11 (81.81%) had hypergonadotropic hypogonadism. All females and 3 males were on gonadal steroids. Two women had conceived spontaneously while on hormone replacement therapy and their pregnancies were both uneventful. None of the patients had adrenal insufficiency and diabetes mellitus. Two females had developed genitalia graft versus host disease (GvHD).
Conclusions
Although allogeneic BMT is known as the only definitive treatment of thalassemia major, it cannot eliminate all potential risks of endocrine dysfunction. Our results indicate that clinical findings of organ dysfunction may present or remain in the late period. Therefore, patients should be monitored for endocrine and other late complications as chronic graft-versus-host disease (GVHD) after BMT regularly.

Non-classical congenital adrenal hyperplasia: the most frequent mutations

Maria Hayon, Maria del Carmen Serrano, David Blanquez, Jose Maria Gomez & Elena Torres
Hospital Universitario San Cecilio, Granada, Spain.

Background and Objective
Congenital adrenal hyperplasia (CAH) is one of the most common diseases in pediatric endocrinology. Non-classical (NC-CAH) forms are characterized by milder enzyme dysfunction and manifests commonly in adolescence or adulthood. The most frequent form of NC-CAH occurs due to 21-hydroxylase deficiency which is caused by defects in the CYP21A2 gene. Our aim was to describe the most common 21-hydroxylase gene (CYP21A2) mutations in our geographical area in pediatric patients with clinical and biochemical diagnosis of NC-CAH and to determine bone age advance respect to Chronological age at diagnosis moment.
Setting and Method
A genetic study of the most frequent 21-hydroxylase mutations was requested in prepubertal patients with clinical and biochemical diagnosis of NC-CAH. Bone age at diagnosis was also determined using the Grewlich and Pyle reading methods. Main outcome measures 21-hydroxylase gene (CYP21A2) mutations.
Results
We evaluated 18 patients (12 women and 6 men) with a mean age at diagnosis (mean $\pm$ SD) of 7.61 $\pm$ 2.23 years. The most frequent clinical presentation was precocious puberty (66.7%) followed by virilization (22.2%) and precocious puberty + apocrine sweating (5.6%); in 1 patient the genetic study was requested for a family history of NC-CAH without symptoms. In the genetic study, the most frequent genotypes were: V281L in heterozygosis (61.1%) and homozygosis (11.1%), I2splice in heterozygosis (5.6%), V281L/I2splice (5.6%), V281L/P453S (5.6%), P453S in heterozygosis (5.6%) and Cluster E6/V281L/L307 frameshift/Q318X (5.6%). Of the 36 alleles studied, the V281L mutation was found in 75%. Mean bone age advance was 1.83 $\pm$ 0.71 years.

Conclusion
The NC-CAH is more frequent in the female sex, precocious puberty is the most common symptom and the V281L mutation is the most frequent in our environment. The patients affected usually present bone age advance respect to the chronological age at diagnosis.

Characterization of sex hormone binding globulin ligands with potential to enhance sex steroid action

Phillip Round[1], Samir Das[1], Kristiina Wähälä[2], Filip Van Petegem[1] & Geoffrey Hammond[1]
[1]University of British Columbia, Vancouver, Canada; [2]University of Helsinki, Helsinki, Finland.

Sex Hormone binding globulin (SHBG) is a plasma steroid binding protein that is the major determinant androgen and estrogen access to target tissues. Several ligands of SHBG have been predicted by computational methods or discovered through basic research, they include pharmaceutical, natural plant extracts and anthropogenic endocrine disrupting compounds. In this study we characterized 3,4-Divanillyltetrahydrofuran (DVT), a non-steroidal ligand of SHBG, and Danazol, a synthetic steroid-like molecule, using X-ray crystallography, steroid binding capacity assays, and cell reporter assays. DVT is present in organic extracts of Urtica dioica root that are used in natural health supplements to enhance the anabolic activities of testosterone by virtue of its ability to displace testosterone from SHBG. Danazol treatment has been used pharmaceutically to treat endometriosis, but more recently has been reported to lead to telomere elongation; an effect that is known to estrogen-dependent and may be related to the ability of Danazol to displace estradiol from the SHBG binding site. The binding affinities of DVT and Danazol for SHBG, are 1.47% and 2.81%, respectively, relative to that for testosterone. The crystal structure of E176K SHBG LG4 Domain with DVT or Danazol in the binding site was solved to 1.7 Å and 1.75 Å resolution, respectively. Danazol resides in the SHBG steroid-binding site in essentially the same orientation as Dihydrotestosterone (DHT) and like DHT its binding affinity was unaffected by Zn^{2+}. By contrast, the binding pose of DVT in the SHBG steroid-binding site was similar to those of estrogens, resulting in a similar positioning of key residues in and around the binding pocket, and as observed from estrogens the SHBG binding affinity for DVT is substantially reduced in the presence of Zn^{2+}. These results indicate that the SHBG binding site can accommodate ligands with structures that diverge significantly from the natural steroid structure. To examine the physiological relevance of DVT binding to SHBG, we used an *in vitro* luciferase reporter assays of androgen receptor activity in kidney cell lines. This showed that DVT is capable of displacing DHT from SHBG in media, resulting in dose dependant increase in androgen receptor mediated luciferase reporter activity, thus confirming that non-steroidal ligands of SHBG can displace natural steroid from their SHBG binding site and may be of utility in promoting the biological activities of endogenous sex steroids.

Relationship between salivary cortisol circadian rhythm and body composition in the postmenopausal women of the population cohort OsteoLaus

Elena Gonzalez Rodriguez[1,2], Georgios Papadakis[2], Peter Vollenweider[3], Martin Preisig[4], Gerard Waeber[3], Didier Hans[1], Pedro Marques-Vidal[3] & Olivier Lamy[1,3]
[1]Center of Bone Diseases, CHUV, Lausanne, Switzerland; [2]Service of Endocrinology, Diabetes and Metabolism, CHUV, Lausanne, Switzerland; [3]Internal Medicine Unit, Internal Medicine Department, CHUV, Lausanne, Switzerland; [4]Epidemiology and Psychopathology Research Unit, Psychiatric Department, CHUV, Lausanne, Switzerland.

Introduction
Aging is associated with a decrease in muscle and bone mass, and a gain in fat mass. Similar changes are more pronounced in hypercortisolism. We previously demonstrated that high 8 PM salivary cortisol is independently associated with increased prevalence of radiologic vertebral fractures. We wanted to determine whether salivary cortisol circadian rhythm played also a role on body composition.
Material and Methods
Cross-sectional study including 538 women >50 years old (mean age 63.6 ± 7.5) from the OsteoLaus cohort. Included participants had: body composition assessment by DXA, salivary cortisol circadian rhythm measures (awakening, 30 minutes thereafter, 11 AM and 8 PM) and assessment of handgrip. On top of body composition parameters, sarcopenia prevalence, as defined by the EWGSOP group (appendicular lean mass by height squared (ALMI) $<$ 5.5 kg/m^2 and muscle strength $<$ 20 kg), was analyzed.
Results
Salivary cortisol at 11 AM and 8 PM increased with age. We found no association between salivary cortisol circadian rhythm values and fat distribution (total fat, fat mass index, or visceral fat). Neither total lean mass, nor ALMI were separately associated with salivary cortisol measures. There were 15 sarcopenic participants that were older (67.5 ± 7.5 vs. 63.4 ± 7.5 yo) and had lower BMI (20.4 ± 2.8 vs. 26.2 ± 4.6 kg/m^2). Sarcopenia presence was positively associated to 11 AM and 8 PM values in monovariate analysis and after adjustment to age and BMI (adjusted p-values 0.021 and 0.044, respectively). Sarcopenic participants had significantly higher values of salivary cortisol than not sarcopenic participants at 11 AM (13.1 ± 6.5 vs. 9.2 ± 4.5 mmol/l) and 8 PM (5.1 ± 5.1 vs. 3.3 ± 2.1 mmol).
Conclusions
Salivary cortisol values are not associated to fat neither lean mass distribution as assessed by DXA. However, highest values at nadir time points 11 AM and 8 PM are associated to sarcopenia prevalence as defined by the EWGSOP group, independently of age and BMI. If these results are confirmed in other studies, the measurement of salivary cortisol at 8 PM may play a role in the assessment of sarcopenia.

Proteolytically cleaved forms of corticosteroid-binding globulin with low steroid-binding affinity are not present in human plasma

Lesley Hill[1], Dimitra Vassiliadi[2] & Geoffrey Hammond[1]
[1]University of British Columbia, Vancouver, Canada; [2]Evangelismos Hospital, Athens, Greece.

Corticosteroid-binding globulin (CBG) transports glucocorticoids in blood and is a serine protease inhibitor family member. Plasma CBG has a reactive center loop (RCL) structure that when cleaved by specific proteases, including neutrophil elastase, results in a loss of high affinity steroid-binding activity. Measurements of CBG levels are typically based on functional assays of its steroid-binding capacity or immunoassays, including enzyme-linked immunosorbant assays (ELISAs). Recently, CBG levels have been measured using different ELISAs that rely on monoclonal antibodies that discriminate between CBG molecules with an intact versus a cleaved RCL. In blood samples from healthy and diseased individuals, discrepancies in CBG levels measured using these ELISAs have been interpreted as evidence for CBG with a cleaved RCL and a low affinity for cortisol. We have questioned these assumptions by studying the steroid-binding activity and biochemical properties of CBG in blood samples in which there is a clear discrepancy in ELISA measurements. In addition, we sought to identify RCL-cleaved forms of human CBG in blood samples from patients suffering from acute inflammation in an intensive care unit (ICU) setting, in whom plasma CBG levels are very low. Our results found no evidence for cleavage of the RCL in CBG in blood samples from ICU patients, irrespective of whether their CBG ELISA measurements were concordant or discrepant. The absence of CBG with a cleaved RCL was also demonstrated using a heat-ramp polymerization assay in a serum sample that exhibits a discordancy in ELISA values. Moreover, when a monoclonal antibody designed to specifically recognize an intact RCL was used to immuno-absorb CBG from a discrepant sample, the residual CBG molecules had the same high affinity (Kd $\sim$1.75 nM) for corticosterone as CBG in the sample prior to immuno-absorption (Kd $\sim$1.72 nM) or in samples in which there is no discrepancy in ELISA values. It is therefore suggested that in some

samples, CBG molecules react abnormally to ELISAs because of structural differences that influence the epitopes recognized by specific monoclonal antibodies.

Role of Pro-inflammatory biomarkers in Hashimoto's thyroiditis: A prospective study

B Ramesh[1], B Rajesh[1], B Rajkiran Reddy[2], G Gayathri[1], M Venkateshwara Reddy[1], D Vighnesh[1], B Chakrapani[3] & PRK Bhargav[4]
[1]VMC, Kurnool, India; [2]SMART Sunshine Hospital, Hyderabad, India; [3]Neuro Hospital, Nizamabad, India; [4]Endocare Hospital, Vijayawada, India.

Introduction
Hashimoto's thyroiditis (HT) is one of the commonest organ specific autoimmune thyroid disease. Though it is mostly treated medically, certain goitrous forms require surgical thyroidectomy for various indications. Autoimmunity has been implicated as one of the main cause of HT. In this context, we set out study the role of Pro- inflammatory cytokines in HT.
Material and methods
This prospective case-control study was conducted on surgically managed HT patients. Institutional ethical committee approval was obtained. Diagnosis of HT was based on thyroid function tests, anti-TPO antibody titer, radionuclide scanning and histopathology. Exclusion criteria were subjects any systemic or chronic inflammatory disease or any medication which interferes with the normal function of the hypothalamic-pituitary-gonadal axis. Serum samples were collected from 25 HT subjects and 25 age matched healthy controls. Interleukin-6 (IL-6), Tumour necrosis factor-alpha (TNF-α) and high sensitive C reactive protein (hsCRP), Leptin levels were measured in all serum samples. Statistical analysis was performed by one way ANOVA with Dunnet's test and Pearson correlation tests.
Results
The mean hSCRP level in GD and controls were 14.7 ± 2.9 mg/mL and 6.5 ± 1.7 mg/mL respectively. The mean TNF-α level, IL-6 level and Leptin levels were 234 ± 26 pg/mL, 12.6 ± 4.5 pg/mL and 32 ± 4.9 ng/mL respectively. There was statistically significant difference of all the pro-inflammatory cytokines compared to controls (P value < 0.05).
Conclusions
This study shows raised titers of pro-inflammatory markers – IL-6, TNF-α and hsCRP, leptin correlated with HT suggesting a contributory role. But, the exact immuno-modulatory role and pathogenetic mechanism needs active research.
Keywords: Hashimoto's thyroiditis, Tumour necrosis factor, Interleukin-6, Goiter, Auto-immunity, Leptin

Autoimmune thyroiditis and chronic spontaneous urticaria – case series

Cristina Ene & Elena Madalan
"Dr. Victor Babes" Foundation, Bucharest, Romania.

Introduction
Chronic spontaneous urticaria (CSU) has many links to autoimmune disorders, one of a described association being with autoimmune thyroiditis. The prevalence of thyroid antibodies is as high as 50% in patients with CSU. However, the pathogenic mechanism whereby thyroid autoimmunity is link to CSU is still poorly understood.
Methods
We have analysed a case series of 20 patients with chronic urticaria and elevated TPO-antibodies, that have been presented in our departments of endocrinology and allergology within one year. After excluded all other causes of hives, patients had blood sample for thyroid antibodies and hormone levels, the eosinophil blood count, inflammatory markers, serum protein electrophoresis and immunoglobulin levels.
Results
We had 20 female patients. 11 of them (55%) were euthyroid; 4 had hypothyroidism (20%) – 3 subclinical and one overt hypothyroidism; 5 patients had hyperthyroidism (25%) – 3 subclinical and 2 patients with clinical hyperthyroidism (one with Basedow 's Disease and one with Hashitoxicosis). We observed a biological particularity: 2 patients had associated histamine intolerance, with low level of diamine oxidase (DAO) activity, in both cases normal thyroid function.
Conclusion/Comments
The association of chronic spontaneous urticaria and autoimmune thyroiditis can hide a genetic predisposition to autoimmune diseases. It is possible that they have a common pathogenic pathway. In large studies hypothyroidism is more common than hyperthyroidism; we had more hyperthyroid patients, but just one developed Basedow's Disease, all of the rest having a mild hyperthyroidism as an early phase of chronic autoimmune thyroiditis. There have been only a few reports on the pathophysiology of reduced DAO activity in CSU. It is known that a low activity is linked with bowel inflammation and there is an individual variability in DAO expression in epithelial cells. There has been so far no causal link between autoimmune thyroiditis and reduced DAO activity. Our 2 patients had normal thyroid function and, maybe, the links could be genetic. More studies are needed to elucidate the role of thyroid function and TPO-Abs in chronic urticaria.

Thyroid cancer

P685

Late diagnosis of type 2B multiple endocrine neoplasia (MEN 2B) in a 24-year-old patient

Raquel Vaz de Castor[1], José Maria Aragüés[2], Florbela Ferreira[1] & Maria João Bugalho[1]
[1]Endocrinology Department, Hospital de Santa Maria, Centro Hospitalar Lisboa Norte, EPE, Lisboa, Portugal; [2]Endocrinology Department, Hospital Beatriz Ângelo, Lisboa, Portugal.

We present the case of a 24-year-old melanodermic male patient from Angola referred to the Endocrinology department of a central hospital, in Lisbon, Portugal. He presented skeletal deformities and joint laxity, and numerous mucosal neuromas of the oral cavity since early childhood. Recurrent diarrhea was also reported but elevated blood pressure was not observed at that time. Multinodular goiter (nodules $>$ 40 mm) was identified in physical examination and microcalcifications were evident in thyroid ultrasound. Calcitonin and Carcinogenic embryonic antigen levels were 9891 pg/ml and 471 ng/ml, respectively, at the time. Histologic diagnosis of medullary thyroid carcinoma was established after total thyroidectomy, and cervical lymph node resection ensued. Solid adrenal nodules were identified bilaterally in a CT scan, but washout above 60% suggested benignity. Serum methanephrines were three times higher than reference value but MIBG scan and Octreoscan were both not suggestive of pheocromocytoma. The patient remained normotensive until the age of 29. Only then, after repeated MIBG, laparoscopic bilateral adrenalectomy was performed and two solid heterogeneous lesions measuring 16 and 30 mm, on the right and left adrenal glands, respectively, were removed. Histological analysis confirmed 4 benign pheocromocytoma. DNA analysis of the RET gene identified a heterozygous germline mutation: c. 2753T $>$ C (p. Met918Thr). Follow-up CT scan identified *de novo* multiple secondary liver lesions. Current calcitonin and CEA levels are 11217 pg/ml and 179 ng/ml, respectively, and diarrhea is still the main complaint, requiring symptomatic therapy. Herein, we present a case of late MEN 2B diagnosis in order to reinforce the need for a higher awareness of the specific phenotype in order to accomplish the goal of a timely and adequate treatment.

Cyclical cushing presented as PCOS in 37 years old lady

Bayar Qasim
Department of Medicine, College of Medicine, University of Duhok, Duhok, Iraq.

Introduction
PCOS is the most frequent endocrine disorder in women of reproductive age but its diagnosis remains one of the most challenging issues in endocrinology, gynecology, and reproductive medicine. Cyclic Cushing's syndrome (CS) is a rare disorder, characterized by repeated episodes of cortisol excess interspersed by periods of normal cortisol secretion.
History
37 years old lady presented with weight gain for 2 years duration. She has noticed that her weight and hirsutism fluctuated significantly in cycles despite strict dieting and regular exercises, for which she visited many clinics for almost 2 years. She finally diagnosed as a case PCOS. Upon more history taking her weight increased by 20 kilograms mainly trunkal. There was no associated proximal myopathy. She was also complaining from amenorrhoea. There was no easy bruising, or striae.
Diagnosis and Treatment
On presentation BMI was 50 kg/m2 witht marked truncal obesity. Blood pressure was 160/80 mmHg and there were no other clinical stigmata of hypercortisolism. The diagnosis of PCOS was revised and possibility of Cushing's syndrome kept in mind especially in setting high blood pressure and progressive weight-gain. 17-OHP and serum testosterone was normal. 24-hour urinary free cortisol excretion was high at 280 (normal $<$200 nmol/24 h) and overnight dexamethasone suppression test was normal too. These tests repeated after 4 weeks and were normal again. After another 6 weeks, patient continues to complain of more weight gain and appearance of few striae, here the tests repeated and both 24-hour urinary free cortisol and overnight dexamethasone suppression tests were positive (repeated twice) also midnight salivary cortisol level increased. 48 hr low dose Dexamethasone suppression test showed failure of cortisol suppression (Baseline 400 nmol/l; 48 hr 125 nmol/l) confirming endogenous hypercortisolism. High dose DST suppressed cortisol to 49 nmol/l confirming ACTH dependent Cushing Syndrome (ACTH 32 ng/L; normal range 0.1 to 47). Pituitary MRI demonstrated a 12$\times$10 mm adenoma. Transphenoidal pituitary surgery was performed, however patient continue to have hypercortisolism after surgery, then she underwent radiotherapy and she received ketoconazole for controlling her cortisol level which continue to show fluctuations.
Conclusion
Cyclical Cushing Syndrome is a rare entity and often misdiagnosed. Cyclical manifestation of hypercortisolism symptoms and signs are suggestive of the diagnosis and endocrine testing during symptoms will help to reach the diagnosis. A high index of suspicion is crucial for diagnosis.

Combined cavernous and inferior petrosal sinus sampling in the differential diagnostic of ACTH-dependent Cushing's syndrome

Natalia Gussaova, Uliana Tsoy, Alexander Savello, Natalia Plotnikova, Vladislav Cherebillo, Artem Paltsev, Alexander Tsiberkin, Anna Dalmatova, Lidia Belousova, Ivan Rudakov, Pavel Ryazanov & Elena Grineva
Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation.

Purpose
Inferior petrosal sinus sampling (IPSS) is considered the gold standard test for the differential diagnosis of ACTH-dependent Cushing's syndrome, but false-negative results have been reported in 1–10% cases. Cavernous sinus sampling (CSS) was suggested as a diagnostic tool in a complex ACTH-dependent Cushing's syndrome cases.
Aim
To study the role of bilateral combined cavernous and inferior petrosal sinus sampling (BCIPSS) in differential diagnosis of ACTH-dependent Cushing's syndrome.
Materials and methods
34 patients (6 men) mean age 42,2$\pm$12,9(25–67) with ACTH-dependent Cushing's syndrome were included. ACTH-dependent hypercorticism was diagnosed according to generally accepted recommendations. Indications for BCIPSS were: MRI pituitary adenoma size $<$8 mm in 26 cases or absence of pituitary tumor in 8 cases. ACTH CS(IPS)/P ratio$\geq$2 or normalized ACTH/prolactin CS(IPS)/P basal ratio$\geq$0,8 indicated the Cushing disease (CD). Ectopic ACTH-dependent syndrome (EAS) was diagnosed if ACTH CS(IPS)/P ratio was$<$2 or normalized ACTH/prolactin CS/P and IPS/P basal ratio was$<$0,6. All patients underwent surgery (transsphenoidal endoscopic adenomectomy in patients with CD, resection of ectopic ACTH-producing tumor in patients with EAS). Diagnosis CD or EAS was approved by immunohistochemistry and/or clinical improvement (adrenal insufficiency after operation).
Results
In 28 patients ACTH CS(IPS)/P ratio was$\geq$2, that confirmed pituitary origin. Noteworthy, in two patients the data for CD were obtained only by the results of CS sampling, and in four only by the data of the IPS sampling. All patients underwent TSS, CD diagnosis after surgery was confirmed in everyone. In 6 patients ACTH CS(IPS)/P ratio indicated EAS: it was$<$2. But in three of them normalized ACTH/prolactin CS(IPS)/P basal ratio was$\geq$0,8; also, they harbored an adenoma according to pituitary MRI. CD considered confirmed and TSS was performed in these three patients and subsequent IHC study confirmed the ACTH-secreting adenoma. In two patients the normalized ACTH/prolactin CS/P and IPS/P basal ratio was$<$0.6, in one 0.7. A survey to identify the source of ectopic ACTH-production was done. In one case it was pheochromocytoma with ectopic ACTH-secretion and in two cases bronchial carcinoid. All patients were successfully operated on.
Conclusion
According to our data, in the differential diagnostic of ACTH-dependent Cushing's syndrome combined CS and IPS sampling may improve the results and increase the accuracy of the method. In ambiguous cases normalized ACTH/prolactin CS(IPS)/P basal ratio can be effectively used.

Hair cortisol in adults with Prader-Willi syndrome

Hasanain Shukur[1], Yolanda de Rijke[2], Elisabeth van Rossum[2], Olle Kämpe[1] & Charlotte Hoybye[1]
[1]Karolinska Institute, Stockholm, Sweden; [2]Erasmus MC, Rotterdam, Netherlands.

Background
Prader-Willi syndrome (PWS) is a rare genetic, neurodevelopmental disorder. In adults the syndrome is characterized by muscular hypotonia, hyperphagia, increased risk of morbid obesity and behavioral problems. Endocrine insufficiencies are common, although insufficient function of the hypothalamus-pituitary-adrenal (HPA) axis seems to be rare. The effect of long term exposure to cortisol, which is associated with stress and obesity, is unknown in PWS. Measurement of hair cortisol is a convenient, non-invasive method to assess chronic stress.
Aims
To evaluate long-term exposure to cortisol by measurement of hair cortisol and relate levels to BMI and stress
Methods and materials
29 adults PWS patients, 15 men and 14 women, median age 29 years, BMI 27 kg/m^2, participated. A scalp hair sample was collected and analyzed for cortisol concentration. In addition, the patients or their relatives answered questions related to anthropometry and factors potentially influencing hair analysis.
Results
Median hair cortisol was 3.0 pg/mg (range $<$1.3 to 105.6) and mean 95%CI was 12.9 pg/mg (3.7, 22.1). Hair cortisol levels were positively correlated to age and BMI ($P<0.001$ for both). Six patients had elevated cortisol levels, in 5 of them related to significant stressful events.
Conclusion
Hair cortisol concentrations were comparable to upper limit for healthy individuals and long-term stress lead to an increase in hair cortisol. All together our results indicate a normal function of the HPA-axis in this cohort of adults with PWS.

Absent adrenarche in adults with congenital hypopituitarism

Fotini Adamidou[1], Athanasios Christoforidis[2], Georgios Tsoutsas[1], Frangiski Tsatsou[3], Lazaros Lazarou[1] & Marina Kita[1]
[1]Endocrinology Department, Ippokration General Hospital, Thessaloniki, Greece; [2]First Pediatric Department, Ippokration General Hospital, Thessaloniki, Greece; [3]Second Dermatology Department, Papageorgiou General Hospital, Thessaloniki, Greece.

Background
The mechanisms regulating adrenarche have not been elucidated, although evidence supports a critical role for ACTH and possibly other unidentified pituitary or adrenal contributing factors. Absent adrenarche has been described in children with a variety of sellar tumors. We describe a case series of five adults with congenital hypopituitarism and absent adrenarche.
Cases
Three females and two males with "idiopathic" congenital hypopituitarism, median age 24 years, of which one male and one female were siblings. All patients had GH, gonadotropin and thyrotropin deficiencies and were diagnosed with hypopituitarism in childhood (median age 7). The two male patients opted to restart GH replacement several years after having been treated as children. None had a history of adrenal crisis. All but one female patient were treated with hydrocortisone. The patient not receiving hydrocortisone had subclinical ACTH deficiency, with normal morning ACTH and cortisol levels, but subnormal cortisol peak at 13.9 mcg/dl during an insulin tolerance test. One male patient had developed full body hair following consistent testosterone replacement since puberty, while the other male started developing axillary and pubic hair following re-institution of, and adherence to testosterone replacement. Associated abnormalities noted: the patients had skin dryness of various degrees and puffy hands and feet. One male was diagnosed with lichen planopilaris by skin biopsy taken from the scalp and had significant lymphedema at the lower extremities, one female has isolated dextrocardia, psoriasis and vitiligo. The two affected siblings have sinus bradycardia with a resting rate of 45 bpm; their unaffected brother also has sinus bradycardia. All patients had frankly low age and sex-adjusted serum levels of dehydroepiandrosterone sulphate (DHEAS).
Conclusions
This likely heterogenous group of adults with congenital hypopituitarism failed to demonstrate adrenarche. Androgen-dependent hair appeared only after testosterone replacement in the males. Genetic and metabolomic profiling is needed to enhance understanding of the interplay between pituitary hormonal stimuli, the intra-adrenal environment and even the specific follicle characteristics underlying the process of adrenarche.

Prolonged QT intervals in a patient with empty sella and isolated ACTH deficiency.

Julia Silva-Fernández[1], Francisco Javier Gómez-Alfonso[1], Virgilio Martínez-Mateo[2], Florentino Del Val-Zaballos[1], Belvis Torres-Arroyo[1], Paloma González-Lázaro[1], Cristina Contreras-Pascual[1], Rafael García-Ruiz[3], Álvaro García-Manzanares Vázquez de Agredos[1] & Inés Gómez-García[1]
[1]Sección de Endocrinología y Nutrición.Hospital Mancha Centro, Alcázar de San Juan, Spain; [2]Sección de Cardiología. Hospital Mancha Centro., Alcázar de San Juan, Spain; [3]Sección Neurología. Hospital Mancha Centro., Alcázar de San Juan, Spain.

Introduction
Adrenal crisis is a life-threatening emergency, however, the relation between adrenal crisis and life-threatening arrhythmia is not known. We describe the case of a patient with adrenal crisis and arrhythmia with prolongation of QT interval.
Case report
A 56-year-old woman was admitted to our hospital because of syncope. She reported having had similar episodes in the last year. She had no previous diagnoses and was not receiving any treatment. She presented at the emergency department with new episodes of syncope and depressed level of consciousness. The ECG strip showed prolongation of QT interval and the ECG monitoring registered polymorphic VT (Torsade de Pointes), so the patient was referred to the intensive care unit. On physical examination, her palpebral conjunctiva was pale, and her skin and her tongue were not pigmented. Routine blood examination revealed hyponatremia (126 mEq/L) and hyperkalemia (5.7 mEq/L) with low glucose levels. Fluid therapy with a dextrose solution was necessary to maintain normal glycemia. She was suspected to have adrenal insufficiency and the cortisol blood level confirmed this diagnosis (0.19 mg/dl). Endocrinological examination revealed normal pituitary function except for very low serum concentrations of ACTH and cortisol. Ultrasound echocardiography showed normal cardiac size and function of the left ventricle. On the basis of this diagnosis, hydrocortisone replacement was started. After hydrocortisone replacement was started, the sodium level returned to normal and the QT intervals of ECG were normalized. Pituitary magnetic resonance imaging showed empty sella.

Laboratory data		Normal range
Na+	126 mEq/L	(136-146)
K+	5.7 mEq/L	(3.5-5.1)
Cortisol	0.19 mg/dl	>18
ACTH	4 pg/ml	(4.7-40)

Conclusion
Long QT syndrome is one of the symptoms of isolated ACTH deficiency and is known to be a risk factor for cardiovascular events. In these patients, prolonged QTs can be reversed by glucocorticoid replacement.

Delayed puberty vs hipogonadotropic hypogonadism; how long to wait to treat?

Araceli Muñoz-Garach, Cristina Diaz-Perdigones, Isabel Cornejo-Pareja, Isabel Mancha-Doblas & Francisco J Tinahones
Universitary Hospital Virgen de la Victoria, Malaga, Spain.

We presented the case of a 21 years old patient, derived from Primary Care to evaluate low testosterone levels (total testosterone (TT) 0.44 ng/ml). His father had delayed pubety and his mother menarche was at 11 years. No other personal history of interest. He had adequate child development and vaccination. No parotiditis. He referred some morning erections. Weight 59 kg, size 171 cm and BMI 20.17 kg/m^2. Testes volume (TV) of 4-5 cc, scanty pubic hair. Tanner stage 1-2. No dysmorphic features. We repeated blood test: TT 0.20 ng/ml, sex hormone binding protein (SHBG) 89.8 nmol/l, follicule stimulation hormone (FSH) and lutein hormone (LH) inappropriately low. He had normal basal pituitary hormones. His bone age was according. Testicular and abdomen ultrasound were normal and karyotype was 46XY.Pituitary MRI showed normal hyphofysis. Smell test showed no alteration. We proposed a differential diagnosis between delayed puberty or hypogonadotropic hypogonadism. We started treatment with low doses of human chorionic gonadotropin (HCG), 1000 ui 3 days a week. After 3 months of treatment, he had TV 8-10 cc, greater development of secondary sexual characteristics. TT 8.57 ng/ml, SHBG 52.7 nmol/l. Treatment was maintained six months. At that time he had TV of 10-12 cc, greater development of total muscle mass. TT 4.19 ng/ml, SHBG 39.1 nmol/l. Spermiogram persisted in cryptospornozoospermia hypospermia. According to TT levels we suspended HCG treatment and schedule a blood test control to assess testosterone levels without stimulation. After 3 months without any medication TT levels had decreased again below normal range (1.25 ng/ml).

This fact guided us towards the need for definitive treatment with testosterone. We started replacement with low dose of cypionate testosterone and progressive increase. Currently he had good testosterone levels with the substitution treatment. Genetic study for possible mutations had showed a variant in heterozygosis described as of uncertain clinical significance c.566G>A (p.Arg189His) in the FGFR1 gene. The study made to his parents showed that his mother is a carrier of the same variant. To date and due to the lack of evidence linking this variant with pathology to be inherited from an apparently healthy parent, it is probably an inherited polymorphism. It should be noted that the existing bibliography recommends reanalyzing the existence of a less defined phenotype of the parent carrier to rule out causality. This study does not rule out the genetic origin of the process or the consequent risk of repetition.

P693

Isolated secondary adrenal insufficiency associated with primary hypothyroidism presenting with hypoglycemic coma

Samat Zhantleyev[1,2] & Nataliya Likhodey[3]
[1]First MSMU I.M. Sechenov (2010-2012), Moscow, Russian Federation; [2]LLP 'Em Alu Plus', Ust-Kamenogorsk, Kazakhstan; [3]First MSMU I.M. Sechenov, Moscow, Russian Federation.

A 27-years old man admitted unconscious due to severe hypoglycemia of 18 mg/dl with right-sided hemiparesis and hypotension. There was a several months history of tiredness and weight loss. Past medical history was remarkable for traumatic brain injury after unexplained syncope, primary hypothyroidism and an episode of hypoglycemia of 2 mmol/l with total improvement after iv infusion of glucose(five months previously). There was no history of drug or alcohol intake. He was on levothyroxine replacement therapy at the dosage of 75 mcg. He appeared lean (weight 58 kg, height 185 cm). There was no abnormal skin or mucosal pigmentation and secondary sexual characteristics were normal. His laboratory findings of TSH 20.35 μIU/l (0.2–4.2), free T4 3.7 ng/L (8.0–17.0), cortisol 2 ug/l (45–260) and plasma ACTH 1.7 ng/l (7.2–63.3) were consistent with adrenal insufficiency and uncompensated hypothyroidism. Abdominal CT-scan showed normal adrenal glands and cholelithiasis. During MRI of the brain pathology of the hypothalamus-pituitary region was excluded. He showed quick improvement after iv infusion of glucose and hydrocortisone with complete resolution of right-sided hemiparesis in two weeks. One month after he re-admitted for evaluation the hypothalamic-pituitary-adrenal axis. Basal morning hormone levels suggested secondary adrenal deficiency without other significant changes in pituitary and islet-cells function: cortisol <28 nmol/l (119–618), ACTH <1.1 pmol/l (0–10.2), TSH 15.5 μIU/l (0.4–4.0), free T4 18.6 pmol/l (11.5–23.2), insulin 11.6 mIU/l (5.0–25.0), C-peptid 0.73 nmol/l (0.5–2.5), LH 3.6 IU/l (0.6–12.0), FSH 7.28 IU/l (1.0–12.0), total testosterone 10.4 nmol/l (3–12), GH 0.4 μIU/l (0.16–13.0), IGF1 238 ng/ml (117–329), prolactin 548.6 mcIU/ml (40–390). After insulin-induced hypoglycemia there was an absence of cortisol and ACTH increase – cortisol remained <27.6 nmol/l (119–618) and ACTH <1.1 pmol/l (0–10.2) at the glucose level of 20 mg/dl on the 50th minute. There were no growth hormone changes of clinical significance in the test. These results confirmed isolated ACTH deficiency whereas hyperinsulinism and other causes of hypoglycemia and syncope were excluded. Patient discharged on hydrocortisone 25 mg and levothyroxine 100 mcg per day. During a year follow-up there were no episodes of hypoglycemia and fatigue.

Conclusion

This case shows the importance of timely investigation of episodes of hypoglycemia of unclear origin in patients with existent autoimmune disorders to exclude secondary adrenal insufficiency.

Clinical case of exogenous Cushing Syndrome during injections and on topical glucocorticoids

Natalia Budul & Irina Komerdus
Moscow Regional Research and Clinical Institute, Moscow, Russian Federation.

Background

Topical glucocorticoids (GCS) are seems to have low percent of adverse effects (AE). However, inappropriate use led to AE.

Material and methods

One patient with psoriasis received topical GCS (clobetasol), one patient with coxarthrosis - steroid injections (diprospan).

Cases

Woman A., 32 y.o., applied topical GCS (clobetasol) for 9 weeks for psoriasis. Area of application – abdomen and elbows. Frequency of application – daily, one tube. Three weeks after the beginning of the above therapy, she noted a proximal muscle weakness, facial plethora, striae (purple, 1.5 cm wide), weight gain (3 kg). Oral glucose tolerance test (OGTT) revealed impaired glucose tolerance (IGT). ACTH and UFC were low. It took 1.5 months for restore of pituitary-adrenal axis. Man O., 57 y.o, made by themselves injections of diprospan (1 ml/5 mg) once a week for 12 months to treat coxarthrosis. After 3 months of such therapy a proximal muscle weakness, facial plethora, striae (purple, 2.0 cm wide) occurred. Ten months after the beginning of above therapy, he noted an acute pain in his back. On MRI – compressive vertebral fractures of Th6, 11, 12, L3. On DEXA – osteoporosis. Laboratory evaluation 7 days after last injection: deficiency of vitamin D, ACTH – 5.3 pg/ml (7.2–63.6 pg/ml), serum cortisol – 1.0 mkg/dl (6.2–19.4 mkg/dl), normal level of calcium. Now he has secondary adrenal insufficiency.

Conclusion

Topical GCS in large doses can cause secondary adrenal insufficiency. Uncontrolled GCS injections lead to severe adverse effects.

An acromegaly case; presented from pituitary apoplexia to overt acromegaly before diagnosis

Burcin Gonul[1], Alev Selek[2], Berrin Cetinarslan[2], Zeynep Canturk[2] & Ilhan Tarkun[2]
[1]Department of Internal Medicine, Faculty of Medicine, Kocaeli University, Kocaeli, Turkey; [2]Department of Endocrinology and Metabolism, Faculty of Medicine, Kocaeli University, Kocaeli, Turkey.

Pituitary adenomas are the most common lesions of sellar cavity. The usual symptoms are associated with endocrine dysfunctions and mass effects. In this case, a 39 year old female presented with headache for one year and progressive blurred vision, nausea, vomiting for two days. Brain magnetic resonance imaging showed a 16×9 mm hemorrhagic macroadenoma in sellar cavity concordant with apoplexia and anterior pituitary hormone deficiency. The patient underwent transshphenoidal surgery and necrotic, heterogeneous hemorrhagic adenoma was excised. Pathology showed extensive coagulation necrosis and hemosiderin pigments therefore immunohistochemical staining could not be performed. After her admission to our clinic there were no typical features suggesting acromegaly or Cushing's disease and postoperative anterior pituitary hormone deficiency has not been recovered as well as insulin like growth factor 1 (IGF1) levels. Hence, she was put on hormone replacement therapy for desmopressin, levothyroxine, hydrocortisone, estrogen and progesterone. After 5-years of follow up period, some clinical features such as; enlargement of hands and feet, macroglossia and maloclusion in teeth were noticed. Subsequent investigations showed moderately elevated serum growth hormone (GH) (7.39 ng/ml) and IGF1 levels (553.4 ng/ml). An oral glucose tolerance test was perfomed and nadir GH level was 2 ng/ml. Pituitary MRI revealed a recurrent pituitary adenoma 25×16×19 mm in size without invasion to adjacent structures. The patient was diagnosed as recurrent GH secreting pituitary adenoma which had been cured by apoplexia before. Transshphenoidal surgery was performed for adenomectomy and the pathology confirmed the diagnosis. Ki-67 proliferation index was very high as 20% and p53 was immunoreactive, which predicted an agressive tumor. As GH and IGF1 levels were still elevated at the third month of surgery she was put on lanreotide LAR 90 mg/28 day. The dose was titrated to 120 mg/28 day as we could not achieve controlled disease. Although there were no visible residual tumor on postoperative MRI, the disease was uncontrolled even though cabergoline addition. Disease control was achieved on the 6. months of gamma-knife therapy. The clinical signs of hormonal hypersecretion might regress in case of apoplexia, therefore the clinicians should always be alert for reappearance of the disease on follow-up. This case also underscores the higher Ki-67 index and extensive p53 immunoreactivity which might be seen in recurrent cases after apoplexia.

Acute hyponatraemia complicating therapy of acute hepatic porphyria need immediate correction before become symptomatic: a case report

Dragan Tesic[1], Predrag Petrovic[2], Tatjana Pesic[3], Edita Stokic[1], Milioca Medic[1], Milena Mitrovic[1], Dragana Tomic/Naglic[1], Tijana Icin[1], Ivana Bajkin[1] & Mirjana Tomic[2]
[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases Clinical Centre of Vojvodina, Novi Sad, Serbia; [2]Emergency Center Clinical Centre of Vojvodina, Novi Sad, Serbia; [3]Clinic of gastroenetrology and hepatology Clinical Centre of Vojvodina, Novi Sad, Serbia.

Introduction
Acute hepatic porphyria is a relatively rare metabolic disorder. Its typical clinical manifeastations are abdominal symptoms and/or troubles belonging to the cerebral oedema. Clinical picture of acute abdomen is frequent and unsuccessful surgical treatment leads to the diagnosis of porphyria.
Case description
Female, born in 1987, presented in emergency surgical unit as appendictis. She was operated but the problems did not disappear. After 3 days, the patient was readmitted with abdominal pain, vomiting and lack of wind and stools, weaknesses. The urine was reddish and at the end porfobilinogen in urine was confirmed.The day before the admittance to the hospital sodium level was 134 mmol/l and on the day of admittance 128 mmol/l. Therapy with 1000 ml 5% glucosae and 1000 ml Ringer solution was administered. Tommorow morning, the patient was with similar troubles but her Na was 116 mmol/l. She was considered to be acute asymptomatic hyponatraemia. 10% glucose solution plus 20 ml 50% glucose was continued plus 0.9% NaCl.The next morning she started to feel bowel movements and since one week ago she started to feel better. However, suddenly patient developed seizures, with foam on mouth, circulatory collaps and respiratory arrhest. Na at that moment was 113 mmol/l. Patient was successfully reanimated. That day received 10 g/24 h od sodium chloide and only 3g as 'bolus'. On that therapy tomorrow morning Na was almost unchanged, as it was the case during the whole previous day (110–116 mmol/l). So we decided to give 3g NaCl (125 ml of 3% SolNaCl) on 2–3 h, a total of 12 g. during the day and Na raised to 120 mmol/l, with desired +7 mmol/l rise per day. Next day Na was 130 mmol/l with the need of only one dose of 3 g NaCl. We confirmed acute hepatic porphyria by porphobilinogen of 67, uroporphyrin 455 and coproporhyrin 1333 mmol/l in urine. During the treatment pottassiium level was between 3.1–3.5 mmol/l.
Discussion
The aim of this case report is to emphasize the importance of rapid correction of acute hyponatriaemia, whatever its cause is. Sodium incerase have to be not more than 10 mmol/l/24 h. We do not have to wait hyponatraemia symptomaticity as it was in our case report. As we are affraid of cardiac arrhythmias in case od low potassium, we shoud escape raised intracranial pressure symptomts of low sodium. Patients syster, also with porphyria, died suddenly when she was 20 y. old.

Pasireotide a new option for acromegaly

Filiz Eksi Haydardedeoglu, Okan Bakiner, Emre Bozkirli, Gülay Simsek Bagir & Melek Eda Ertorer
Baskent University Adana Teaching and Research Center Deparment of Endocrinology and Metabolism, Adana, Turkey.

Background
Acromegaly is a rare neuroendocrine disorder caused by secretion of excessive levels of growth hormone. Somatostatin receptor ligands (SRLs) are first-line medical therapies for patients in whom surgery has failed or is contraindicated. We report a case who had inadequate response to multiple therapies including surgery,radiotherapy,octreotide,lanreotide,cabergoline and pegvisomant.
Case
An 44-year-old woman was admitted to our hospital with a past medical history of acromegaly diagnosed 6 months ago. Initially she was treated with transcranial surgery for a 3 cm hypophyseal macroadenoma. She was given steroid and L-thyroxin replacement therapy after surgery. Physical examination revealed an overweight female patient with enlarged nose,lips,coarse facial features, macroglossia and enlargement of both hands. She had been receiving lanreotide for 6 months. Serum growth hormone (GH) and IGF1 levels were 6.66 ng/ml and 1291 ng/ml respectively**.** MRI(Magnetic Resonance Imaging) showed a 1.5 cm and a 1.2 cm residual tumors with suprasellar extension and optic nerve traction. Bitemporal hemianopsia was present on visual field examination. Serum GH and IGF1 levels were 40 ng/ml and 3985 ng/ml preoperatively. In the course of the disease,persistent elevated GH and IGF1 levels were observed. Tumour debulking is not recommended because of the cavernous sinus involvement. Two years after surgery, 180 gy conventional radiotherapy was performed because of inadequate response to medical therapy. In the course of the disease medication was modified as follows: Lanreotide switched to octreotide, combined with cabergoline. 2 years later, pegvisomant was started at initial dosage of 10 mg/day then titrated. During this medication, eventhough a slight decrease was observed, IGF1 levels were stil high. Despite these regimens, the biochemical markers were stil elevated,visual field defects were stil present and MRI revealed no significant change in residues. 1.5 years later, all medications were stopped and pasireotide was started with dosage of 0.6 mg/s.c./daily. Within 3 months after pasireotide treatment, a significant decrease was observed on GH an IGF1 levels. At the end of 6 years,biochemical remission was achieved. For diabetes management she used insulin but after biochemical control, insulin was stopped and GLP-1 receptor agonists were given. Her blood glucose levels were normal with this medication.
Conclusion
Pasireotide is a multireceptor-targeted SRLs. It seems to be a proper medical option for treatment of severe acromegaly cases who are resistant to other SRLs.

Diabetes insipidus as first clinical manifestation of pineal tumor

Cristina Lorenzo González, Elena Márquez Mesa, Yolanda Zambrano Huerta, María Pilar Olvera Márquez, María Teresa Herrera Arranz & Enrique Palacio Abizanda
Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Spain.

Introduction
Central diabetes insipidus is a disorder characterized by polyuria and polydipsia due to vasopressin deficiency caused by a lesion at the hypothalamo-hypophyseal axis. Frequently, central diabetes insipidus is wrongly considered idiopathic if not associated with other neurological signs and symptoms. Herein we present the report of a case that illustrates the difficulties in the diagnosis of this condition.
Case report
A 17 year-old male was admitted to our hospital with history of polydipsia, polyuria, and nocturia for 2 months with no neurological symptoms. These clinical manifestations characterized the presence of diabetes insipidus, so performance of a water deprivation test was indicated: after a 4-hour fasting period, there was increase in the plasma concentration with no increase in urinary concentration; 1 hour after the stimulus with desmopressin, there was an evident increase in urinary osmolality. Thus, we confirmed the presence of central diabetes insipidus, and therapy with desmopressin was initiated. We completed the study with a magnetic resonance that showed 'Pituitary stalk with nodularity in its most cranial portion and iso-intense with respect to the adjacent parenchyma'. Considering the radiological and clinical findings and the absence of abnormality in the pituitary hormonal study, initial diagnosis was idiopathic central diabetes insipidus, nevertheless a close follow up of pituitary nodularity described would be done. Two months later, our patient referred frontal headache associated with nausea and vomiting, so a new magnetic resonance was performed. Imaging showed 'a mass in the pineal region (18×18×19 mm) causing obstruction of the aqueduct of Silvio, with acute obstructive hydrocephalus data'. The most probable diagnostic hypothesis was pineal tumor; among these tumors, germinoma is the most common histological type and it was confirmed with a biopsy. Serum levels of alpha-fetoprotein and HCG were measured, with high level results for HCG. Radiotherapy was indicated, and it was performed with an initial satisfactory clinical and imaging response. However, our patient currently is receiving chemotherapy because of leptomeningeal tumor dissemination.
Conclusions
Our case report shows the difficulties in the diagnosis of tumors at the pineal region. Germinomas may have central diabetes insipidus as their first

manifestation. The symptoms of diabetes insipidus may precede the alterations in the magnetic resonance. Whenever diabetes insipidus is present, we should perform a complete study, considering that the presence of these tumors cannot be discarded, even in cases of an initially normal neurological examination.

Acromegaly and subclinical Cushing's disease: a rare case of a pituitary macroadenoma secreting both GH and ACTH

Teodora Teusan[1], Mihaela Ciobotar[1], Maria-Christina Ungureanu[1,2], Cristina Preda[1,2], Alexandru Florescu[2], Voichita Mogoş[1,2], Daniel Rotariu[3] & Letitia Leuştean[1,2]
[1]Department of Endocrinolgy, 'St Spiridon' Clinical Emergency Hospital, Iasi, Romania; [2]'Gr. T. Popa' University of Medicine and Pharmacy, Iasi, Romania; [3]Departament of Neurosurgery, 'Prof. Dr. Nicolae Oblu' Emergency Hospital, Iasi, Romania.

Introduction
Plurihormonal pituitary adenomas are unusual tumors which typically belong to one cell lineage and have an incidence of approximately 1.3%, the most common combination being GH, PRL and glycoprotein hormone subunits. There are a few cases in the literature describing cosecretion of GH and ACTH from a pituitary adenoma, the incriminated pathogenesis being the origin from different cell lineages and the aberrant patterns of transcription factors.
Case report
We report the case of a 49 years-old male patient who accused headaches and elevated arterial blood pressure. Physical examination showed a fully developed acromegaly, multiple papillomas and a lipoma, with no cushingoid features. Pituitary investigations revealed hypersecretion of both somatotrophic and corticotrophic axes and the MRI described a pituitary macroadenoma with compressive effects on the pituitary stalk and the optic chiasm. He underwent transsphenoidal surgery. The immunohistochemical staining confirmed the GH secretion with minimal expression of ACTH, PRL, TSH and relatively reduced proliferative activity (Ki67-7%). Postoperative follow-up revealed a tumoral rest with persistent hypersecretion of GH and ACTH, with no inhibition at low dose of dexamethasone. We obtained control of the acromegaly under somatostatine analogs and cabergoline, while for the corticotrophic component of the tumor, we considered appropriate in this case stereotactic radiotherapy. The patient currently is in observation regarding the effect of this therapy.
Conclusions
We describe an uncommon case of a mixt secretion of GH and ACTH from a pituitary macroadenoma; while we controlled the somatotrophic component, concerning the ACTH hypersecretion, we will take into consideration treatment with pasireotide in case of inefficiency of the Gamma-knife surgery.

Hypogonadism following high-voltage electrical brain injury

Vitoria Pires
Armed Forces Hospital, Lisboa, Portugal.

Introduction
Male hypogonadotropic hypogonadism (HH) is a consequence of congenital or acquired diseases that affect the hypothalamus or the pituitary gland. In HH, secretion of gonadotropin releasing hormone (GnRH) is absent or inadequate. Diagnosis during adulthood (after normal puberty) suggests an acquired etiology. Acquired hypogonadotropic hypogonadism can be caused by drugs, infectious or infiltrative lesions, systemic diseases, radiation and TBI. Post-TBI neuroendocrine disorders have been increasingly acknowledged in recent years, especially related to road accidents, sports or falls. The frequency of hypopituitarism after TBI varies between 15-50% among different studies. Hypopituitarism can be complete (panhypopituitarism) or parcial (isolated deficiency). GH is the most common hormone lost after TBI, followed by ACTH, gonadotropins (FSH and LH), and TSH.
Case study
Man, 38, a member of the Air Force Rescue Squadrons, single, with a 7-year-old son, presents with asthenia, insomnia, decreased libido and difficulty in erection in early 2015. Blood tests revealed a low testosterone level, with gonadotropins in the normal range, suggestive of central hypogonadism. An evaluation of the pituitary axis was performed and cleared and an imaging study with MRI-CE did not report space occupying lesions (SOL). In the etiological evaluation for hypogonadism there is a history of orchidopexy, with a decrease in testis at the age of 8. Also, a work accident in late 2014 with electrocussion without apparent sequels. He is currently being medicated with testosterone IM 3/3 months with strong clinical and analytical improvement.
Discussion
The causes of acquired hypogonadotropic hypogonadism are multiple. In our patient we could not find any obvious etiology. There was no history of trauma, infection, systemic illnesses and he denied drug abuse. The MRI excluded the presence of any SOL. The only apparent insult to our patient's pituitary was therefore electrical brain injury. Several authors have found similarities between victims of electrical injuries and of head trauma, although the mechanism of lesion is still uncertain. Given the temporal relationship between the work accident and the beginning of the symptoms (about 6 months), it was hypothesized that HH could be a deficit resulting from high-voltage electrical brain injury. We found no similar cases reported in the literature, therefore only time will tell if the condition may be reversible. Hormonal replacement therapy may reduce morbidity, optimize rehabilitation and improve the quality of life of the patients.

A case of hypothalamic-pituitary disease: who's the deceiving suspect?

Tess Van Meerhaeghe, Jean De Schepper & Brigitte Velkeniers
Universitair ziekenhuis Brussels, Brussels, Belgium.

Introduction
Diagnosis and treatment of neurosarcoidosis (NS) can be challenging. We describe an unsual presentation of an isolated NS in a 21 year old adult, initially presenting with central diabetes insipidus (DI) associated with a stalk thickening at the age of 14.
Case description
A 21 year old patient was first seen at the department of endocrinology after a 9 years follow-up for panhypopituitarism. He presented at the age of 14 years at the pediatric endocrinology clinic with a central DI, related to a lymphocytic infundulonеurohypophysitis. In the following years, he developed a panhypopituitarism, which was correctly substitued. Yearly MRI of the brain showed no changes of the anterior pituitary and a stable aspect of the infiltration of the stalk for almost 3 years after the initial diagnosis. At transition to adult endocrinology clinic, MRI re-evaluation for headache showed however an extension of the lesion to suprasellar with an involvement of the optic chiasm. A lumbar puncture showed lymphocytic pleiocytosis and elevated protein level, whereas beta-HCG and alpho-fetoprotein were negative. A chest CT only showed few mediastinal adenopathies. An elevated serum angiotension converting enzyme level was documented, whereas antinuclear antibodies and antineutrophil cytoplasmatic antibodies were negative. He was treated empirically with corticosteroids 0.5 mg/kg based on the clinical diagnosis of NS. Three months later, an aggravation of the visual defect in the left eye with a significant increase in the volume of the suprasellar mass on MRI was documented. Furthermore, he developed a Cushing syndrome related to the corticotherapy. Since the corticotherapy did not ameliorate neither the clinical nor the radiological features, a stereotactic brain biopsy was planned. The biopsy showed a granulomatous inflammation, compatible with NS. He was subsequently treated with 3 pulse doses 1gr solumedrol and was started on mycophenolate mofetil 1 g 2x/day. He received in parallel a treatment with low dose radiotherapy. A control MRI of the brain 2 months later, showed a nearly complete involution of the contrast enhancing lesion, but an unchanged thickening of the optic chiasm. MMF was given for 12 months.

Conclusion
Isolated NS is rare in children. This case report is exceptional because of the lag time of almost 9 years between initial symptoms and the finding of an evolutive infiltrative lesion to suprasellar. NS can be the only manifestation of an underlying systemic sarcoidosis, and although good response to corticosteroids in general, addition of other immunomodulators may be necessary.

Cyclic Cushing's syndrome: a difficult diagnosis

Rosa Márquez-Pardo, Lourdes García-García-Doncel & María-Gloria Baena-Nieto
Jerez Hospital, Jerez de la Frontera, Spain.

Introduction
Cyclic Cushing's syndrome (CS) is a rare disorder characterized by repeated episodes of cortisol excess interspersed by periods of normal cortisol secretion. These phases may range from days to years. The diagnosis is a difficult challenge.
Case report
We present a case of 56-year-old women with hyperglycemia, hypertension, central obesity, edema, bruising, fatigue and emotional lability for several years. Laboratory tests: glucose 141, HbA1c 11%, LDL-cholesterol 121, HDL-cholesterol 84, triglycerides 95, Na 143 and K 3.3, 24-hour urinary free cortisol 662 µg (4.3–176), cortisol rhythm with basal serum cortisol 9 h 8.5 and 21 h 24 µg/dl, 1-mg overnight dexametasone suppression test revealed a morning serum cortisol concentration of 18.6 µg/dl (<1.8), ACTH 75 pg/ml (5–50) and 8-mg overnight suppression test pointed a pretreatment morning serum cortisol 30.1 which was suppressed to 6.8 µg/dl (71%). Pituitary magnetic resonance was normal. Inferior petrosal sinus sampling (IPSS) was ordered but it was cancelled because clinical and biochemical hypercortisolism disappeared. Three months later, hypercortisolism appeared and immediately IPSS was made. IPSS was diagnosis of a central source for ACTH secretion. The patient was treated successfully with transsphenoidal hypophysectomy. Histopathology revealed a 4.5 mm pituitary corticotroph microadenoma. After that, there were normalization of the hypercortisolism and the phenotype but hypopituitarism was established.
Conclusions
The diagnosis of cyclic CS is difficult to make given the variations in clinical presentation, the unpredictability of cyclic secretion and the lack of uniformity in etiology. Causes of cyclic CS are multiple dominated by pituitary adenoma. Patients can have periods of clinical improvement during these quiescent phases or remain symptomatic. IPSS should be made only when biochemical hypercortisolism is present at the same time.

A rare cause of central hypothyroidism: oral isotretinoin treatment

Özen Öz Gül[1], Soner Cander[1], Murat Çalapkulu[2], Canan Ersoy[1] & Erdinç Ertürk[1]
[1]Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey; [2]Uludag University Medical School, Department of Internal Medicine, Bursa, Turkey.

Background
Isotretinoin has been used for many years to treat moderate or severe nodulocystic acne, disorders of sebaceous gland and keratinization and in the prevention of skin cancer. Certain types of retinoids may cause abnormalities in serum thyroid function tests by suppressing thyroid stimulating hormone (TSH). However, it is uncertain whether systemic isotretinoin has any effect on thyroid functions.
Case
18 years old woman has admitted to our hospital complaints of fatigue and drowsiness. She has no known systemic disease. At the dermatology clinic, she was prescribed isotretinoin (30 mg/day) for the treatment of severe acne. At the 3rd month of the treatment, laboratory tests revealed decreased sT4: 0.74 ng/dl (normal range: 0.89–1.37), sT3: 1.92 pg/ml (normal range: 2.25–3.85), and TSH: 0.023 µIU/ml (normal range: 0.47–3.41) levels. All other pituitary hormone levels were analyzed and found to be at normal blood values. Since the magnetic resonance imaging of the pituitary gland was reported as normal by the radiology department, the central hypothyroidism of the patient was thought to be related to the medication she was receiving for acne treatment. The isotretinoin was planned to discontinue and levothyroxine was also started for thyroid hormone replacement therapy. By the end of the 2-week levothyroxine treatment, blood hormone levels were determined as st3: 2.95 ng/dl, st4: 0.95 ng/dl and TSH: 1.133 µIU/ml. The patient's symptoms improved after the levothyroxine treatment.
Conclusion
Although central hypothyroidism has not been shown to be clearly associated with isotretinoin therapy, it has been suggested that central hypothyroidism in our patient related with isotretinoin treatment. Therefore, we recommend that patients receiving isotretinoin therapy should be evaluated symptoms of hypothyroidism and performed thyroid function tests.

The complexity of management of persistent acromegaly from repeated surgical interventions and multiple medical therapies

Nilamanjari Nagarajan[1], Seifeldin Yahia[2] & Saiful Kassim[1]
[1]North Devon District Hospital, Northern Devon Healthcare NHS Trust, Barnstaple, UK; [2]King's Mill Hospital, Sherwood Forest Hospitals NHS Foundation Trust, Sutton-in-Ashfield, UK.

Acromegaly prevalence is 2.8–13.7 cases per 100,000. Diagnosis at the early stages can be quite challenging and management is complex involving various specialties to achieve remission of the condition. September 2013, 49 year old lady presented to optometry with few months of bumping into things. She was later found to have superior bitemporal hemianopia. She later described having to change her wedding rings multiple times over the past year with increase in size of shoes. 3 months after presentation, January 2014, diagnosis of acromegaly was made with IGF-1 level of 90.7 nmol/l (4–29 nmol/l) and nadir growth hormone level of 19.3 pg/l. Urgent MRI visualised 2.5*2.4 cm pituitary adenoma with suprasellar extension. A month later she underwent transphenoidal debulking. Histology stained very strongly for growth hormone. Post operative scan showed good tumour bulk reduction and two areas of residual tissue, one posteriorly and the other close to the cavernous sinus. Post-surgically bilateral hemianopia showed marked improvement. Patient was started on 60 mg Lanreotide. After a month due to lack of response this was increased to 90 mg. Medication was eventually stopped after 3 months due to nausea, abdominal discomfort, diarrhoea and later on muscle twitches. Methionine-PET scan showed clear focus within the pituitary that was likely to be the source of ongoing excess growth hormone production. Second debulking operation was done April 2016. IGF-1 stayed constant between July and Septemper of 2016 at 105.4 nmol/l. Patient underwent 5 week radiotherapy early 2017. Lanreotide was re-trialled and stopped due to itching and twitching. Cabergoline was used next and echocardiography follow up showed no evidence of valvular dysfunction. Cabergoline dose was increased and she had side effects which led to it being stopped (nausea drowsiness 24 hours after each dose). Patient was commenced on Pegvisomant and IGF-1 levels fell from 94 to 35 nmol/l; currently on an increased dose of Pegvisomant from 10 to 15 mg SC due to slight increase of IGF-1 levels from 35 to 43 nmol/l.
Conclusion
Management of acromegaly is complex and requires extensive input from both surgical and medical specialties. Debulking is successful in 74% of patients with macroadenoma. Medical therapies can include Somatostatin analogues, cabergoline, octreotide and at last resort pegvisomant. Multidisciplinary approach is essential for remission of the condition with long term monitoring for co-morbidities, notably cardiovascular outcomes.

A case of hypopituitarism due to acute invasive fungal rhinosinusitis

Mizuho Okazaki[1], Mitsuru Nishiyama[2], Shogo Funakoshi[2], Yoshihisa Matsumura[1], Shinpei Fujimoto[2] & Yoshio Terada[2]
[1]Department of Clinical Laboratory, Kochi Medical School, Kochi, Japan; [2]Department of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi, Japan.

Background
Acute invasive fungal rhinosinusitis (AIFR) is a rare but fatal infection that occurs primarily in immunocompromized individuals. It is characterized by fungal invasion into the mucosa and submucosal structures of the paranasal sinuses with extension into adjacent structures, including the paranasal soft tissues, orbit and cranial vault. We present here a case of hypopituitarism due to AIFR with intracranial lesion.
Case
A 59-year-old man, whose past medical history were total gastrectomy due to gastric carcinoma and cerebral hemorrhage, appeared general fatigue. He was diagnosed as hyponatremia due to unknown origin and transferred to our hospital for further examinations. He presented body weight los, right eyelid ptosis and ocular movement disorder. Laboratory data showed severe hyponatremia (Na 119 mEq/ml) and hypopituitarism (ACTH 8.8 pg/ml, Cortisol 4.3 μg/dl, TSH 1.1 μIU/ml, fT_4 0.38 ng/dl) confirmed by endocrinological examinations, on the other hand, b-D-glucan was normal range (9.3 pg/ml). Brain MRI showed an intracranial mass lesion of irregular form at right cavernous sinus and sphenoidal sinus, which considered as culprit lesion of right eye symptoms. A stenosis of right internal carotid artery was also observed, and it progressed to complete obstruction later. Nasal endoscopy revealed a fungal ball at sphenoidal sinus and Aspergillus Fumigatus was detected by culture. Overall, he was diagnosed as hypopituitarism, oculomotor nerve palsy and obstruction of right internal carotid artery due to AIFR. Antifungal agents (VRCZ, MCFG) and hormone replacement therapy (hydrocortisone, LT_4) were started, and then general fatigue, hyponatremia, and eyelid ptosis were gradually improved.
Conclusion
AIFR is usually diagnosed and treated by otolaryngologist, and there are seldom reports on hypopituitarism due to AIFR as the present case. It should be considered AIFR is one of the differential diagnoses in a patient who appears hypopituitarism and/or cranial nerve disturbances, although AIFR with cranial invasion is extremely rare.

An unexpected cause of severe hypokalemia

Rim Belaid, Maroua Bennour, Olfa Hentati, Hajer Kandara, Ines Kamoun & Leïla Ben Salem
Endocrinology and Nutrition Departement, National Nutrition Institute, Tunis, Tunisia.

Background
Although the most common causes of hypokalemia are diuretic use and gastrointestinal losses, elevated cortisol levels can also cause hypokalemia through its effects on the renin-angiotensin-aldosterone system.
Case report
A 56-year-old woman with a history of diabetes mellitus and hypertension, presented to our emergency department with fast progressing generalized weakness, abdominal discomfort and diarrhea. Digestive tract diseases were ruled out. Physical examination revealed a female with hyperpigmented face, buffalo neck, and thin upper and lower extremities. She had neither abdominal striae nor moon face. Electrocardiogram (ECG) showed a regular sinus rhythm with diffuse flat T-waves. Laboratory tests indicated hyperglycemia, metabolic alkalosis, thrombocytopenia (15,000 elt/mm^3) and persistent severe hypokalemia (up to 1.9 mmol/l) despite the intravenous infusion of potassium. Markedly elevated plasma ACTH (1782 ng/ml (VN: 10–48)) and cortisol (1340 nmol/l (VN: 200–600)) levels were observed. No suppression of serum cortisol level with high-dose dexamethasone test was found, confirming ectopic ACTH dependent cushing's syndrome (ECS). Chest X ray was normal. Computed tomographic (CT) scan detected a large mass of 53*27*25 mm at the corporo-caudal portion of the pancreas with multiple hepatic and peritoneal metastases. The severe metabolic alkalosis secondary to glucocorticoid-induced excessive mineralocorticoid activity was treated with potassium supplements and spironolactone. A CT-guided biopsy of the mass to determine her pathological type could not be done because of the severe thrombocytopenia. The bone marrow aspiration had not shown metastases. Further investigations havenot been done because of the rapidly fatal evolution.
Conclusion
This case illustrated a rare cause of Cushing's syndrome, ectopic ACTH secretion. A quarter of these cases remain occult without determining the source of the ectopic secretion. They generally present with electrolyte disturbances rather than typical cushingoid feature because the hypercortisolism is an acute phenomenon and the patients generally do not survive long enough until morphologic changes occur.

Atypical pituitary adenoma: a case of histological mimicry

Katharina Schilbach[1], Wolfgang Saeger[2], Sylvère Störmann[1] & Jochen Schopohl[1]
[1]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, Munich, Germany; [2]Institut für Neuropathologie der Universität Hamburg, Hamburg, Germany.

We present the case of a 67-year-old man who presented to the outpatient clinic for endocrinological evaluation after partial resection of an atypical pituitary adenoma (APA). Pathohistological assessment of two independent and experienced neuropathologists resulted in a diagnosis of APA with unusually high proliferation indices (Ki67 10–20%/p53 30%) and immunoreactivity for LH, FSH and the alpha-subunit. Clinical examination as well as laboratory testing revealed no significant pathologies, particularly with regard to the pituitary function. This was also true at the follow-up examination 6 month later, after the patient received adjuvant radiotherapy. Another 8 month later the patient presented in a markedly deteriorated state with fatigue and chronic pain syndrome due to multiple vertebral body fractures. Medical workup revealed the diagnosis of a stage III (International Staging System) IgG-kappa type multiple myeloma. With knowledge of the underlying disease the neuropathological examinations were repeated and immunohistochemical staining with antibodies to CD138, CD38 and kappa light chains confirmed pituitary manifestation of the multiple myeloma, although positive staining for LH, FSH and the alpha-subunit was present. On the basis of these findings 138 classical histological specimens of multiple myelomas were examined regarding to gonadotropin and alpha-subunit expression: 2 and 3 tumors expressed LH and FSH, respectively, and nuclear and cytoplasmatic staining of the alpha-subunit was present in a multitude of cases. Most likely, unspecific binding of the used antibodies caused the positive staining. However, in the presented case, this phenomenon supported the initial diagnosis auf APA. This case illustrates that extraosseous manifestation of a multiple myeloma should be considered in cases of APA with high proliferation indices.

Bromocriptine for management of a patient with cranipharyngioma and central hyperthermia after neurosurgery: a case report

Anca-Georgiana Tudurean-Olteanu[1], Anamaria Hrişcă[1,2], Mirela Claudia Nechita[1], Daniel Rotariu[2,3], Cristina Preda[1,2], Letiția Leuștean[1,2] & Maria Christina Ungureanu[1,2]
[1]Endocrinology Department, 'Saint Spiridon' Clinical Emergency Hospital, Iasi, Romania; [2]'Grigore T. Popa' University of Medicine and Pharmacy, Iasi, Romania; [3]Neurosurgery Department, 'Nicolae Oblu' Clinical Emergency Hospital, Iasi, Romania.

Introduction
Central hyperthermia is frequent in patients with brain injury and is characterized by a rapid onset with high temperatures, marked temperature fluctuations and poor response to antipyretics. It is associated with worse outcomes in the injured brain, thus it is important to aggressively manage it.
Case-report
We report a case of a 9-year-old boy diagnosed with sellar and suprasellar adamantimomatous craniopharyngioma at the age of 5 when he underwent quasitotal resection. After neurosurgery he developed panhypopituitarism and he received replacement hormonal therapy. Notably, the growth rate was one over expectations of about 7 cm/year despite the somatotropic pituitary insufficiency. The evolution was favorable for 4 years when the MRI scan detects tumor recurrence in the third ventricle that required neurosurgery. He was admitted to

the Iaşi Endocrinology Department following the quasitotal resection of the recurrent craniopharyngioma. During his admission he developed intractable fever which persisted despite antipyretics. A complete fever workup was performed, but no definite infection source was found. Central fever was a result of damage or dysfunction to central fever control centers, such as at the level of the diencephalon. Bromocriptine was started resulting in control of central hyperthermia. A week later the fever did not exceed 38°C and the month following the treatment the body temperature baseline was reduced to 37°C.
Conclusions
We reported a case of prolonged central fever after neurosurgery of a recurrent craniopharyngioma in a child who was successfully treated with bromocriptine. Althought he developed panhypopituitarism after neurosurgery, he associated normal growth rates and growth hormone therapy was not need.
Keywords: bromocriptine, central hyperthermia, craniopharyngioma.

Successful management of Cushing's disease in pregnancy: a case report

Adnan Batman, Feyza Yener Ozturk, Esra Cil Sen, Rumeysa Selvinaz Erol, Muhammed Masum Canat, Emre Sedar Saygili, Sezin Dogan Cakir, Seda Eren Basmaz, Duygu Yildiz & Yuksel Altuntas
University of Health Sciences, Sisli Hamidiye Etfal Training and Research Hospital, Endocrinology and Metabolism Department, Istanbul, Turkey.

Introduction
Cushing's disease (CD) frequently leads to hypogonadotropic hypogonadism by hypercortisolism and hyperandrogenemia. In the literature, there are totally 96 cases of CD and pregnancy. Only four of 11 cases, operated transsphenoidally, were cured. We aimed to present a case of CD developing pregnancy in which hypercortisolism was successfully controlled by transsphenoidal surgery (TSS) in 2nd trimester.
Case report
28 years old female was admitted with complaints of not able to lose weight after delivery and hirsutism. She had diagnosis of ALL 9 years ago and two operations because of avascular femoral necrosis. Physical examination revealed supraclavicular fat deposition, purple stria on abdomen, ecchymotic lesions on skin,diffuse hyerpigmentation on back and hirsutism. BMI was 33 kg/m^2. Laboratory investigations were compatible with ACTH dependent hypercortisolism. Sella MRI showed pituitary adenoma 12 mm in diameter in left side. She was diagnosed as CD, referred to neurosurgery. While waiting for operation, pregnancy (11 weeks) was determined. Her pregnancy had been developed after diagnosis of CD. Urinary free cortisol(UFC) excretion was 992 μg/24 hr (N:36–192 μg/24 hr). In the 2nd trimester, TSS was performed at 18th week of gestation and ACTH secreting pituitary adenoma with Ki67 2% was confirmed. As her postoperative 3rd day serum cortisol was 23 μg/dl, no need for steroid replacement was found. Postoperative UFC on first month was 152 μg/24 hr. At 6th week postoperatively, she was admitted with hypotension and nausea. Basal serum cortisol was 6.34 μg/dl. But enough increment was determined at 250 μg ACTH stimulation test (peak 33 μg/dl). Due to her low basal serum cortisol inspite of pregnancy, symptoms compatible with adrenal failure and only 6 weeks past from TSS, steroid replacement therapy was started for secondary adrenal failure with hydrocortisone 15 mg/day. Her complaints regressed after therapy. At 31st week of gestation, she gave birth to a baby by C/S. There were no complications for mother in peripartum period. The infant was treated for congenital pneumonia and jaundice in neonatal intensive care unit. Steroid replacement was stopped as hypothalamo-pituitary-adrenal axis was found to be normal with 250 μg ACTH stimulation test (peak cortisol: 23.31 μg/dl). On postpartum 2nd month, she was totally fine with BMI 26,17 kg/m^2, basal serum cortisol: 6.63 μg/dl, 1 mg DST: 0.56 μg/dl, UFC: 60.8 μg/24 hr.
Discussion
Pregnancy is rarely encountered during CD. Hypercortisolism is associated with increased maternal and fetal morbidity and mortality. UFC is the preferred test for diagnosis and follow-up during pregnancy. Management of patients should be performed at experienced centers and TSS should be considered as priority.
DOI: 10.1530/endoabs.56.P709

A case of diabetes insiputus due to ectopically located neurohypophysis presented during pregnancy

Muhammet Cuneyt Bilginer[1], Burcak Polat[1], Berna Ogmen[2], Oya Topaloglu[1], Husniye Baser[2], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Ankara Yildirim Beyazit University, School of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Atatürk Education and Research Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey.

Background
Gestational diabetes insipidus (DI) is a rare complication of pregnancy, usually developing in the last trimester and resolves spontaneously 4–6 weeks *post-partum.* It is mainly caused by excessive vasopressinase activity, an enzyme expressed by placental trophoblasts which metabolises arginine vasopressin (AVP). However in some cases, it can develop in a patient who had limited reserve of ADH and marginal central DI prior to pregnancy and may not resolve after delivery. Herein we represent a case of DI developed in pregnancy and consisted after delivery due to ectopically located neurohypophysis.
Case
24 year old female patient admitted to our clinics with the complaints of polyuria and polydipsia. The amount of daily consumed water was 18 l. The complaints were started in the last 2 months of pregnancy and did not resolve in 2 years after delivery. She did not have any previously diagnosed psychiatric illness such as obsessive compulsive disorder, somatization or depression. She did not have history of head trauma or symptom or sign of any pituitary hormone deficiency. She was not using any drugs which could be related with DI. In the basal biochemistry, the serum Na level was 143 mmol/l, serum osmolarity was 293 mosm/l. The urine osmolarity was 93 mosm/l. Anterior pituitary hormone levels were normal except mildly elevated prolactin (29 ng/ml). She was hospitalized for water deprivation test. During the test, urine osmolarity did not change with water deprivation but became %200 concentrated after vasopressin which was compatible with cental DI. In the pituitary MRI neurohypophyseal T1-bright spot situated ectopically in the infundibulum. Desmopressin nasal sprey was started and the symptoms resolved immediately.
Conclusion
Gestational DI is a rare complication of pregnancy occurring in two to four out of 100,000 pregnancies. It usually develops at second half of pregnancy and remits spontaneously 4–6 weeks after delivery. Serum and urine osmolality are required for the diagnosis, but other tests such as serum sodium, glucose, urea, creatinine, liver function may be informative. The water deprivation test is normally not recommended during pregnancy because it may lead to significant dehydration, and should be dane in the post partum priod. After delivery pituitary MRI should be performed at some point to exclude lesions in the hypothalamo-pituitary region.

A case with panhypopituitarism due to aneursymal hemorrhage of internal carotid artery and coil embolisation

Muzaffer Serdar Deniz[1], Basak Bolayir[1], Aydin Tuncer Sel[1], Halit Nahit Sendur[2], Alev Altinova[1], Fusun Toruner[1], Ali Yusuf Oner[1], Mehmet Ayhan Karakoc[1] & Mujde Akturk[1]
[1]Department of Endocrinology and Metabolism, Gazi University Faculty of Medicine, Ankara, Turkey; [2]Department of Radiology, Gazi University Faculty of Medicine, Ankara, Turkey.

Aneurysmal subarachnoid hemorrhage has been reported to be associated with hypopituitarism. Also, internal carotid artery coil embolisation for aneurysmal hemorrhage is a rare cause of hypopituitarism. 58-year-old female patient who admitted to Emergency Department of Gazi University Medical Faculty due to visual loss and severe headache that did not respond to analgesics accompanied by nausea-vomiting starting 4–5 days ago. Sixth cranial nerve paralysis and bilateral temporal hemianopsia were detected in the neurological examination. In the Cranial computerised tomography (CT), there were widespread subarachnoid hemorrhages. In the Cranial CT Angiography, an aneurysm (29×18×18 mm) involving the cavernous segment of the right internal carotid artery (ICA) was observed. For this reason, selective cerebral angiography was performed. Coiling embolisation was performed for the aneurysm. Later, the complaints of mouth dryness, polyuria, polydipsia, and fatigue were developed in 2–3 days after subrachnoid hemorrhage and coil embolisation. The laboratory analysis showed that Na: 149 (136–145) meq/l, urinary density: 1008 (1010–1020), IGF-1: 78.5 (81–225) ng/ml, GH: 0.36 (0.01–8) ng/ml, ACTH: 19.6 (0–46) pg/ml, Cortisol 1.52 (4.6–22.8) μg/dl, FSH: 5.53 (23.9–119.1) mIU/l, LH: 0.36 (16.3–54.8)

mIU/l, E_2: 11 pg/ml (10–28), prolactin: 0 (2.4–20.9) ng/ml, TSH 0.47 (0.57–5.6) μgIU/ml, free T_3: 1.3 (2.3–4.2) pg/ml and free T_4: 0.9 (0.74–1.52) ng/dl. In the cranial MRI after the procedure, aneurysm lumen was filled with coils and its mass effect caused substantial displacement of the hypophysis gland to the left side. Clinical features, laboratory findings and imaging suggested panhypopituitarism associated with aneurysmal hemorrhage of internal carotid artery as well as procedure of coil embolisation. Corticosteroid, vasopressin and levothyroxine replacement treatment were started. After the hormonal replacement therapy, general condition of the patient and vision improved, nausea and vomiting stopped and urine output decreased. In conlusion, we presented a rare case who had panhypopituitarism including diabetes insipidus developed in 2–3 days after aneurysmal hemorrhage of internal carotid artery and coil embolisation of carotid artery aneursym. This rare cause of pituitary dysfunction should be kept in mind in the clinical setting.

Progressive optic glioma and concomitant precocious puberty: case report

Jihed Ben Lagha, Manel Jemel, Sabrine Mekni, Taghrid Naceri, Ines Kamoun & Leila Ben Salem
Endocrinology and Nutrition Departement, National Nutrition Institute, Tunis, Tunisia.

Low-grade gliomas are the most common brain tumor in children, accounting for 30–50% of central nervous system tumors in the pediatric age group. They can occur anywhere within the central nervous system (CNS) including the optic pathway (5%). When optic gliomas involve the hypothalamus, patients will often present endocrinopathy. Signs of such involvement can include growth failure and precocious puberty. In this report, we present the case of 8 years three months girls with the history of Low-grade glioma of the Optic pathway diagnosed at the age of 1 year 8/12 in the context of visual acuity loss, nystagmus, and optic nerve pallor on examination. She underwent chemotherapy with periodic control by the carcinologiste. In the follow up since the age of 7 years she developed a progression of her glioma with concomitant linear growth acceleration. At the age of 8 years, she was referred to our department for breast development. On physical examination, his weight was 54 Kg (60–75p) and height was 141 cm (+3DS). Breast development were compatible with tanner stage 3 and no pubic hair was present. Ultrasound imaging showed ovaries were prominent (right ovary: 2× 1 cm and left ovary: 1,8×1 cm) with absence of follicles, uterus was measuring about 4×2,5 cm Biochemical measurements revealed a basal (FSH) level of 6.28 mUI/ml, LH level of 2.63 mU/ml, and Estradiol level of 58.39 ng/l. The bone age was 15 years. The patient was diagnosed with central precocious puberty and started on gonadotropin-releasing hormone (GnRH) agonist treatment (triptorelin acetate 11.5 mg every 3 months). During follow up, 6 months of starting treatment, his progression of puberty has been arrested. With this case report, we would like to emphasize that the growth acceleration in a young child presenting a glioma of the optic pathway should alert the physician to consider a diagnosis of precocious puberty at the early stage.

A singular case of hypohidrotic ectodermal dysplasia associated with acromegaly

Hana Bel Hadj Hassen, Manel Jemel, Sabrine Mekni, Jihed Ben Lagha, Ines Kamoun & Ben Salem Leila
Endocrinology and Nutrition Departement, National Nutrition Institute, Tunis, Tunisia.

Hypohidrotic ectodermal dysplasia (HED) is a rare genetic disorder characterized by the faulty development of the ectodermal structure, resulting in most notably anhydrosis/hypohydrosis, hypotrichosis and hypodontia. Affected individuals tend to have sparse scalp and body hair (Hypohidrotic), absent teeth (hypodontia) or small and pointed teeth. HED is associated with distinctive facial features including a proeminent forehead, thick lips, and flattened bridge of the nose. These facial features can also be noted in acromegalic patients who developed gradually changes including enlargement of the forehead, and nose; and thickened lips. Here we describe a singular association of these two pathologies. A 27 year men with no prior medical history, presented with diabetic ketoacidosis. On further complaints, he reported increasing shoe size, intermittent headache. Acromegaly was suspected and was confirmed by elevated GH under hyperglycemia (0.8 ng/ml), and elevated IGF-1. Pituitary MRI was indicated. The intraoral examination revealed partial edentulism with a single tooth erupted in the lower jaw since childhood. Lips were everted. He had sparse, thin, lightly pigmented scalp hair. There was periorbital hyperpigmentation. When asked about a similar history in the family patient gave a positive history of his nieces (brother's daughters) suffering from a similar complaint of edentulism. These findings matched typical features of anhidrotic ectodermal dysplasia. To our knowledge this is the first case of the literature reporting the association of Hypohidrotic ectodermal dysplasia with Acromegaly. These too pathologies can share some facial features. A minitious examination of acromegalic patient can reveal such underlying disease.

Sever hyponatraemia and SIADH secondary Bartezomib: case report

Tahir Omer, Amardass Dhami & Rajeev Kumar
Bedford, UK.

Introduction
The Syndrome of Inappropriate Antidiuretic Hormone (SIADH) is considered to be the most common cause of euvolemic hyponatremia. The most common malignancy associated with SIADH is small cell lung cancer with multiple myeloma only observed in few cases worldwide of SIADH. The first line of treatment used in multiple myeloma chemotherapy currently is a proteasome inhibitor, Bortezomib, which is considered significantly more tolerable compared with traditional chemotherapeutic drugs. Bortezomib has been reported to have a wide-ranging side effect profile affecting different systems. However, the endocrine system is rarely affected in patients receiving bortezomib. Eelctrolyte disturbance has been reported in 1–10% of patients treated with Bortezomib with sever hyponatraemia reported in 2.6%. We present a case of Bortezomib induced SIADH with sever hyponatraemia in a newly diagnosed multiple myeloma, with other potential causes of SIADH excluded. A tumour-related cause was deemed very unlikely as hyponatremia was only observed after treatment with Bortezomib and was not present at the time of diagnosis of multiple myeloma.
Case
A 71-year-old lady who was recently diagnosed with IgG kappa multiple myeloma with multiple lytic lesions (skull, cervical spine, thoracic spine) presented to the haematology clinic with progressively worsening fatigue, shortness of breath and dizziness following day 22 of her chemotherapy cycle. She was clinically euovolaemic with no neurological compromise. A blood test showed severe hyponatremia (107 mmol/l) and she was referred to the acute medical unit for admission. A diagnosis of SIADH was made according to Bartter-Schwartz criteria. Her serum osmolality was 226 mOsm/kg [275–295 mosm/kg], urine osmolality was 119 mOsm/Kg [300–900 mOsm/kg] and, her urine Na was 49 mEq/L/day. her Cortisol level and TSH were normal. A chest X ray and CT head were normal. Her sodium level gradually improved in a progressive manner following fluid restriction to 750 ml/day with close monitoring.Her Sodium level on discharge was 135 mmol/L. Bortezomib injection were stopped and her symptoms have improved dramatically.
Conclusion
Health care practitioners should be aware of the possibility of Bortezomib-induced hyponatremia. Close clinical and laboratory monitoring for electrolyte disturbance, neurological disturbances or confusion is essential after initiation of treatment.

Hypopituitarism due to cerebral abscess

Dimitra Pappa, Pinelopi Thoda, Anastasia-Konstantina Sakali, Eleni Georgiou, Ioannis Gountios & Alexandra Bargiota
Department of Endocrinology and Metabolic Diseases, University Hospital of Larissa, Larissa, Greece.

Introduction
Infectious diseases of the central nervous system (CNS) have been associated with hypopituitarism which relates to the severity, the localization and the cause of the infection. We present here a case of a CNS abscess and hormone deficiencies. A 53 years old man referred to the emergency department of our hospital with high fever and confusion and a 3 day history of weakness and

anorexia. On clinical examination he was febrile (38.4°C), disoriented in time and place, and slightly lethargic. He had ophthalmoplegia, eyelid ptosis, mydriasis and non reactive pupil of the right eye and no other significant findings. Investigations revealed increased white blood cells count, C- Reactive Protein and Erythrocyte Sedimentation Rate. A brain MRI showed a lesion in the sphenoid and cavernous sinus, expanding to the sellar and hypersellar region and retrobulbar oedema in the right eye and he was commenced on intravenous antibiotics. A laboratory evaluation of his pituitary function was performed, which reveal hypopituitarism (Cortisol = 1,8 μ g/dl, ACTH = 4 pg/ml, FSH = 2.41 mIU/ml, LH = 0.29 mIU/ml, Testo = 0.389 ng/ml, TSH = 0.08 μIU/ml, FT4 = 0.83 ng/dl, IGF-1 = 56 ng/ml (71–284 for his age)) and the patient was put on hormonal replacement therapy with hydrocortisone, thyroxin and testosterone. A transphenoidal approach to the lesion at the sphenoid sinus was performed a few days later and the diagnosis of the cerebral abscess was made, but no pathogens were found, probably because he was already receiving antibiotics. On the 9th day on antibiotics he was apyrexial, alert with no confusion. Six months later he was still on oral antibiotics, clinically well, with great improvement of his MRI brain findings, but he was still requiring hormone replacement.

Conclusions

Hypopituitarism due to cerebral abscess is rare, can occur at an early or a late stage and can be either transient or permanent. Its diagnosis may be difficult, demands great suspicion and these patients need a long term follow up.

Low-symptomatic PRL-secreting pituitary adenoma in patient with morbid obesity

Oksana Logvinova, Ekaterina Troshina & Natal'ya Mazurina
Endocrinology Research Centre, Moscow, Russian Federation.

Introduction

Obesity is one of the most common endocrine disorders. Obesity can either be a symptom of numerous diseases or be associated with them, including cases, when patient does not have other complaints besides excess weight. This should be considered before initiating obesity treatment.

Case

A 42-year-old male visited endocrinologist, complaining of overweight. Minimum weight from his adulthood was 70 kg, maximum was for that moment–124.5 kg, BMI – 43.3 kg/m^2, waist circumference – 134 cm. Weight increase was gradual, for several years. Patient used to have 3 main meals, physical activity was low. He did not complain of sexual dysfunction, as he was divorced and did not live a sexual life. He did not take any medications. Headaches were infrequent: one time in six months; there was no vision impairment, no clinical features of acromegaly, no galactorrhea, however, patient's habitus was slightly effeminate. Fasting plasma glucose level was 5.3 mmol/l, after 120 minutes OGTT – 8.53 mmol/l, HbA1c – 6.1%, insulin – 24.02, LDL-cholesterol – 3.27 mmol/l. Other parameters of biochemical blood test were within reference range. Endogenous hypercortisolism and hypothyroidism were excluded. Patient's testosterone level was 1.88 nmol/l, LH – 0.24, FSH – 1.77, PRL – 7509 mIU/l. We performed pituitary MRI, which revealed a macroadenoma 18 × 16 × 16 mm in size, with MR-signs of subacute hemorrhage. Patient reported that he had no injuries for the whole year and the last episode of headaches was in several months ago. Perimetry revealed no vision field impairment. We started treating patient with cabergoline and advised him to adhere to a hypocaloric diet with low content of animal fats and quickly digestible carbohydrates, and everyday walking. After 3 months of treatment level of PRL was 502 mIU/l, weight decreased on 19.5 kg (from 124.5 to 105 kg), BMI estimated 35.5kg/m^2. There were some improvements in lab parameters: glucose after 120 minutes OGTT – 7.8 mmol/l, HbA1c – 5.8%, insulin – 16.2, LDL-cholesterol – 3.0 mmol/l. These results were achieved without any pharmacotherapy of obesity. Patient continued therapy with cabergoline and follow diet and physical activity guidelines. Repeated MRI is planned after 3 months of treatment.

Conclusion

Our case shows that despite prevalence of primary obesity, associate endocrinopathies should also be taken into consideration. In our patient, a treatment of hyperprolactinemia with cabergoline was accompanied by a decrease in body weight and metabolic parameters improvement, even without pharmacotherapy of obesity.

Cushing's disease, bilateral adrenal hyperplasia and ARMC5 mutation – case report

Valentina Elezovic Kovacevic, Djuro Macut, Jadranka Antic, Sanja Ognjanovic, Tatjana Isailovic, Bojana Popovic, Ivana Bozic-Antic, Tamara Bogavac, Dusan Ilic & Svetozar Damjanovic
Clinic for Endocrinology, Diabetes and Metabolic Disease, Clinical Center of Serbia, Belgrade, Serbia.

Germline ARMC5 mutations have been described as the most frequent genetic abnormality found in patients diagnosed with primary bilateral macronodular adrenal hyperplasia (PBMAH). PBMAH is a rare etiology of Cushing's syndrome. This gene has been proposed to acts as a tumor-suppressor gene. A 36-years old female presented to us with clinical signs of hypercortisolism. ACTH dependent Cushing's syndrome was confirmed soon after. Pituitary magnetic resonance imaging (MRI) revealed hypointensed lesion, 12mm in size, in right part of the pituitary gland. At the same time abdominal MRI described bilateral adrenal hyperplasia. Transsphenoidal pituitary surgery was performed and ACTH secreting pituitary adenoma with Crooke's hyaline was found on patohystology. Genetic screening for MEN1 and AIP were negative, but germline mutation was identified in exon 2 (I170V) of ARMC5 gene. LOH in tumor tissue is in course. We continuated 3 months follow up and patient was disease free. Six moths after surgery patient had positive hormonal and MRI findings for pituitary adenoma remnant. Abdominal MRI was still unchainged. In further course patient was treated with stereotactic radiosurgery. On her regular follow up pituitary MRI still shows tumor remnant (6 mm) and adrenal hyperplasia is same in diameter. Functional testing demonstrate lack of cortisol supresion in overnight dexamethasone suppression test and high normal levels of ACTH. We presented a patient with Cushing's disease, bilateral adrenal hyperplasia and ARMC5 mutation. After the treatment, our patient still has endogenous hypercortisolism and inadequate ACTH secretion which is probably due to Cushing's disease. It is also possible that adrenal hyperplasia contribute to hypercortisolemia due to ARMC5 mutation. So far we know that ARMC5 mutation lead to PBMAH. Recent studies have shown that the various ARMC5 isoforms were present in most endocrine tissues including the pituitary, adrenal glands and the pancreas. Future studies are necessary and could possibly indicate if ARMC5 mutation is responsible for multi-glandular tumor syndrome.

Post-traumatic hypopituitarism – a case report

Elena Lazar[1], Alexandra Marin[1], Ruxandra Dobrescu[1] & Corin Badiu[1,2]
[1]National Institute of Endocrinology, Bucharest, Romania; [2]University of Medicine and Pharmacy, Bucharest, Romania.

Background

Head trauma of sufficient severity, particularly causing fracture to the skull base, can cause deficient secretion of anterior pituitary hormones and vasopressin. Severe hypopituitarism and diabetes insipidus (DI) are common post-traumatic events but they can recover 3 and 12 months afterwards.

Objective

To report a case of a woman with post-traumatic hypopituitarism and DI after car accident.

Case report

A 31 year old woman, was victim of a car accident three months ago, with fracture of the base of the skull following which she was admitted in ICU. A cerebrospinal fluid rhinorrhea remitted spontaneously, and the patients presented with a transient episode of polyuria. After recovery she was discharged without any pituitary substitution therapy. At admission in our Endocrine Dpt. after 3 months, she had progressive fatigue, faintness, diarrhoea, secondary amenorrhea. Pituitary MRI showed a focal anterior pituitary lesion compatible with a subacute hematoma. Clinic and laboratory examination revealed hypopituitarism: central hypothyroidism (TSH = 0.0197 uUI/ml, FT4 = 10.05 pmol/l), low IGF-1 = 21.22 ng/ml, hypocortisolism (ACTH = 1pg/ml, cortisol in the morning (8AM) = 3.84ug/dl); hypogonadotropic hypogonadism, (FSH = 0.86mUI/ml, LH = 0.23mUI/ml, Estradiol = 10pg/ml), normal prolactin, (6.14 ng/ml), hyponatremia, hypokalemia, anemia (Hb = 10,7g/dl) and inflammatory syndrome (VSH = 39.4mm/h). After starting the correction of cortisol deficiency the subclinical central diabetes insipidus was gradually exposed, leading to polyuria (6.5 l urine/day, spontaneous urine osmolality = 81 mOsm/kg, plasma osmolality = 293 mOsm/kg). In addition to hydrocortisone we started DDAVP and LT4 with net improvement of the clinical condition.

Conclusion
Posttraumatic diabetes insipidus is devoid of clinical signs in the absence of adequate adrenocortical function. Progressive substitution leads to clinical expression of DI. We recommend that patients with major head injury, especially those with fractures of the base of the skull, should be closely monitored for symptoms and signs of endocrine dysfunction. Regular follow-up is then recommended to monitor for possible remission of the pituitary deficits.

From adrenal incidentalomas to Cushing's disease

Teresa Alves Pereira[1], Lia Ferreira[1], Inês Furtado[2], Ana Lopes[1], Liliana Fonseca[1], Cláudia Amaral[1], Isabel Palma[1] & Helena Cardoso[1]
[1]Endocrinology Department – Centro Hospitalar do Porto, Porto, Portugal; [2]Medicine Department – Centro Hospitalar do Porto, Porto, Portugal.

Introduction
Adrenal incidentalomas are asymptomatic adrenal masses found accidentally during routine examination, not intended for adrenal pathology evaluation. The functionality of these lesions must be further investigated. Rarely, bilateral adrenal nodular hyperplasia can be detected in a patient with Cushing's disease. The authors present the case of a patient with possible autonomous cortisol secretion of adrenal origin that eventually emerged as Cushing's disease.
Clinical case
A 69 years old male, with known history of arterial hypertension, dyslipidaemia and ischemic heart disease, was observed in an Endocrinology outpatient clinic due to adrenal incidentalomas in 2015. Upon investigating axillary adenopathies, thoracoabdominal CT scan revealed adrenal nodules measuring 23 and 15 mm on the right adrenal gland and two 16mm nodules on the left gland. All the nodules had typical adenoma features, except one on the left, which was hyperdense but had a homogeneous contrast distribution. The patient had no clinical features of Cushing's syndrome. The patient was evaluated for hormone excess: 1mg overnight dexamethasone test not suppressed (3.8 µg/dl) with an overlapping Liddle test; normal urinary 24-hour cortisoluria: 15.0 µg/24h (4.3–176.0) and ACTH <5.0 pg/ml. Urinary normetanephrine and plasmatic catecholamine levels were elevated, but less than twice the normal value. IMIBG scintigraphy was negative. Aldosterone/active renin ratio was normal; thyroid function and fosfocalcic metabolism were also normal. The authors concluded that the patient had a possible autonomous cortisol secretion and opted for a strategy of surveillance – clinical, analytical and imagiological. Two years later, in 2017, the patient presented with syncope and altered mental status and underwent a cerebral CT scan, showing a large expansive lesion on the sphenoidal body, with enlargement of the sella turcica; a second tumoral lesion on the anterior skull base was described, with cystic and solid areas (possibly a pituitary adenoma). There was no hormonal deficit. Cerebral MRI further characterized the lesion on the sphenoidal body extending to the anterior skull base, possibly a meningioma, craniopharyngioma or a pituitary macroadenoma. The patient was admitted for transcranial surgery. Anatomopathological analysis confirmed the diagnosis of a pituitary adenoma, with positive ACTH immunohistochemistry.
Conclusions
In face of a patient with an ACTH producing pituitary adenoma with bilateral adrenal nodules and an investigation directing towards a possible ACTH-independent hypercortisolism, the possibility of a previous bilateral adrenal hyperplasia, which was posteriorly autonomized, is considered. However, it is not possible to exclude concomitant functional adrenal and pituitary nodules.

Somatostatin analogue use to treat visual field loss in acromegaly newly diagnosed in pregnancy

Anne Marie Hannon, Isolda Frizelle & Domhnall J O'Halloran
Department of Diabetes and Endocrinology, Cork University Hospital, Cork, Ireland.

Acromegaly is a rare disease characterised by excessive Growth Hormone production. Subfertility is common in acromegaly and has various aetiologies, therefore pregnancy in acromegaly is rare. The limited data that is available would suggest that pregnancy in acromegaly is generally safe. However, there have been reports of tumour expansion during pregnancy. Here we present a case of first presentation of acromegaly in pregnancy and subsequent rescue of visual field loss with somatostatin analogue therapy. A 32 year old woman presented at 11 week's gestation of a planned pregnancy to her local hospital with headaches. She had a past medical history of asthma and depression. A CT brain demonstrated a pituitary lesion. She was referred to her regional endocrine centre and was noted to have features of acromegaly. She had an oral glucose tolerance test at 12/40 to confirm the diagnosis; her plasma glucose concentrations were in the normal range, however she failed to suppress her plasma GH. Her IGf-1 was also significantly elevated at 82 nmol/L (normal range 9–33 nmol/L). MRI confirmed a $3.2\times2.7\times2.8$ cm mass with significant compression of the infundibulum and optic chiasm. She had a left upper quadrantanopia visual field loss on formal testing. On discussion of both surgical and medical options our patient opted for medical therapy and was initiated on 100 micrograms tds Octreotide subcutaneously at 16/40. Visual fields completely recovered on repeat visual field testing after 2 weeks. At 24/40 there was further deterioration in visual fields, at which point we increased the Octreotide dose to 150 micrograms tds. This once again allowed return of visual fields to normal within 2 weeks. She was diagnosed with gestational diabetes when screened at 14/40. She was initially treated with diet modifications but was commenced on insulin at 22/40 due to elevated fasting capillary glucose readings. There was no significant increase in insulin requirements following the increase in octreotide dose. She remained normotensive throughout pregnancy. Foetal growth continued along the 50th centile throughout pregnancy. An elective caesarean section was planned at 34/40. The foetal weight was 3.2 kg at birth with an APGAR score of 9. She is menstruating regularly post-partum. She is currently stable on 40 mg octreotide LAR and has been referred for surgical intervention. This is the first case we are aware of where octreotide was used to treat visual field deficit in the setting of Acromegaly newly diagnosed in pregnancy.

P721

Late onset adrenocorticotrope deficiency in combined pituitary hormone deficiency caused by a mutation of the PROP1 gene

Sílvia Paredes, Olinda Marques & Marta Alves
Hospital de Braga, Braga, Portugal.

Introduction
PROP1-related combined pituitary hormone deficiency (CPHD) is associated with deficiencies of growth hormone (GH); thyroid-stimulating hormone (TSH); gonadotropins, luteinizing hormone (LH) and follicle-stimulating hormone (FSH); prolactin (PRL); and occasionally adrenocorticotropic hormone (ACTH).
Clinical case
We report a clinical case of a progressive CPHD in a man presenting with first symptoms of hypocortisolism at the age of 75 years. This patient's initial symptoms were growth retardation, with final height 134 cm. There was a family history of growth retardation, namely his sister. Hypogonadism was present, with incomplete secondary sexual development and associated infertility. Hypothyroidism was diagnosed at the age of 68 years and replacement with levothyroxine was started. At the age of 75, he was admitted in the emergency room with psychiatric symptoms such as confusion and disorientation and hyponatremia. Hypocortisolism was diagnosed, treatment with hydrocortisone was started and it was referred to an endocrinology consultation. At this point cortisol, ACTH, TSH, fT3, fT4, GH, LH, FSH and PRL were measured in basal conditions, confirming central hypothyroidism, hypogonadism and hypocortisolism, a low PRL and GH deficiency. Magnetic resonance imaging evidenced a markedly atrophic anterior pituitary. Molecular analysis of PROP1 gene was performed by PCR amplification and 2 variants were detected ($c.296G>A$ and $c.358C>T$) in heterozygosity in PROP1 gene.
Conclusion
With this clinical case we want to point out the late diagnosis of this patient, despite a complete clinical picture being present. This case also suggests that, in these patients, corticotrophs may be involved at a rather late age.

DOI: 10.1530/endoabs.56.P721

P722

Sever protracted hypernatraemia following Hyperosmolar hyperglycaemic state: Case report

Tahir Omer, Thomas Western & John Kalk
Bedford Hospital, Bedford, UK.

Introduction
Nephrogenic diabetes insipidus is caused by a deficiency in the action of anti-diuretic hormone, and can be life threatening if not treated appropriately. Lithium

is a commonly used mood stabiliser in psychiatry and is known to cause NDI in around 12% of patients. It has been reported in the literature that severe hyperglycemic state may trigger symptomatic lithium-induced NDI in patients who had been on prolonged lithium therapy.

Case

We report the case of a 57-year-old male with a background of bipolar disorder (on lithium for almost 30 years) and type 2 diabetes on OHAs, who presented to A&E following collapse at home. blood test: sodium 148 mmol/L (133–146), blood glucose level of 44 mmol/L (3–6), K 5.1 mmol/L (3.5–5.3), Urea 41.2 mmol/L (2.5–7.8), Creatinine 444 micromol/L (60–110). He was treated for HHS with adequate fluid resuscitation with 0.9% normal saline and intravenous insulin. His sodium level, however, continued to rise reaching 177 mmol/L in 3 days. His urine output ranged from 4 to 9.0 L/day, serum osmolality 366 mosmol/Kg, urine osmolality 206 mmol/L, urine sodium 87 mmol/L, suggesting DI. He received a trial of desmopressin. This failed to reduce his urine output (day 5: 4522 ml, day 6: 4685 ml). Pituitary function test showed hypogonadtrophic hypogonadism, LH 2.3 iu/L (2–9), FSH 0.9 iu/L (2–12), Testosterone 1.2 nmol/L (9–29), normal Thyroid and HPA axis.An MRI pituitary showed no abnormalities. The lack of response to Desmopressin with the normal pituitary morphology and function apart from secondary hypogonadism (which is likely to be functional due to systemic illness) lead us to believe that this is the case of NDI. His lithium level at presentation was 1.04 mmol/L (0.5–1.2). However, lithium serum levels and clinical findings do not always overlap. The clinical situation was complicated by the initial presentation of HHS and AKI, which are normally managed with large volumes of fluids. Through accurate titration of fluids to sodium levels and careful monitoring of hydration status, the sodium level normalised in a gradual progressive manner from 174 to 144 mmol/L over two weeks. Proper glycemic control was achieved with the addition of regular insulin and his acute kidney injury resolved.

Conclusion

Hyperglycemic state with large losses of body water may aggravate and unmask lithium-induced nephrogenic diabetes insipidus (NDI) which had been asymptomatic previously. This case highlights the importance of strict fluid and electrolyte balance in the management of NDI.

Unusual complication of a pituitary adenoma: Pituitary abscess

Mehdi Kalthoum, Mouna Elleuch, Faten Hadjkacem, Nadia Charfi, Fatma Mnif & Mohamed Abid
CHU Hedi Chaker, Sfax, Tunisia.

Introduction

Pituitary abscesses are rare entities that can occur either as primary infections or secondarily to different causes. Primary pituitary abscess arises within a previously healthy gland, while secondary abscess occurs in pituitary gland that harbors a pre-existing lesion (adenoma, craniopharyngioma, or Rathke's cleft cyst). Only 23 cases of secondarily infected adenomas were reported in the literature.

Case report

A 38-years-old man presented with an acute worsening of headaches, double vision and mild left ptosis. His medical history was notable for a known and untreated pituitary adenoma. He denied any fevers, chills, night sweats, neck pain, nuchal rigidity, or photophobia. On examination, he was alert and fully oriented. Vital signs were normal without evidence of fever. His neurologic examination was notable for left ptosis and a dysconjugate gaze with mild impairment of the left medial, superior, and inferior rectus muscles. Visual field assessment was normal. The remaining cranial nerve and neurologic examination were normal. After 3 days of hospitalization, the patient developed fever with no meningitis symptoms. C-reactive protein was increased from 20 mg/l to 305 mg/l with hyperleucocytosis at 21000/ml. Magnetic resonance imaging showed a 4.5 cm partially cystic, partially solid contrast-enhancing sellar mass with extension into the suprasellar cistern, the cavernous sinus and to the left internal carotid. Laboratory analysis revealed no hematologic or electrolyte abnormalities. Endocrine studies were notable for central hypothyroidism with low levels of prolactin, adrenocorticotropic hormone, luteinizing hormone, follicle-stimulating hormone and testosterone. Growth hormone and insulinlike growth factor 1 were not measured. An endoscopic endonasal transphenoidal approach to the sella was used to treat this lesion. Clear fluid and thicker purulent discharge were released on opening the cyst wall. The patient was started on broadspectrum intravenous antibiotics, including vancomycin, ceftriaxone, and metronidazole at meningitic doses. Histopathologic Analysis showed pituitary adenoma and robust inflammatory infiltrate composed of predominantly neutrophils admixed within the neoplastic cells. Tumor cells were positive for human growth hormone, prolactin, adrenocorticotropic hormone.

Conclusion

Pituitary abscesses are rare disorders responsible for high mortality risk. Mortality and morbidity can be reduced by early surgical drainage and appropriate antibiotic treatments. The typical MRI findings are of high importance for the diagnosis of the disorder. The transsphenoidal approach should be preferred in surgery and appropriate antimicrobial therapy should be administered according to the surgical specimen's culture. Additionally, these cases should closely be followed up in terms of pituitary insufficiency, surgical complications and infection.

Two year old follow up of Hypophysitis secondary to the checkpoint inhibitor Pembrolizumab - a case report

Cian Anderson[1], James Griffin[1], Susan McKenna[2], Ana Santos[3], Jenny Westrup[1,3,4], Fergal Kelleher[5] & Margaret Griffin[1,2,4]
[1]University College Dublin, School of Medicine and Medical Sciences, Dublin, Ireland; [2]Dept of Diabetes, Beacon Hospital, Dublin, Ireland; [3]Dept of Medical Oncology, Beacon Hospital, Dublin, Ireland; [4]UCD Beacon Hospital Academy, Dublin, Ireland; [5]Department of Medical Oncology, SJUH, Dublin, Ireland.

Ipilimumab (an anti-CTLA-4 antibody) treatment has been associated with Immune Related Adverse Events (iRAEs) of the endocrine system. However the frequency of iRAEs in programmed cell death (PD-1) receptor agent use is incompletely characterised, though initial studies report an incidence of 0.5%. We present a case of Pembrolizumab-induced hypophysitis in a 47 yo. male with melanoma. Presenting in 2007 with an initial diagnosis of melanoma, with lymph node recurrence in 2013. He entered adjuvant clinical trial of Vemurafenib versus placebo (patient unblined to placebo arm). In 2015 he presented with oligometastatic M1a disease and received 4 courses of Ipilimumab. During this Ipilimumab treatment he had a sarcoidosis-type reaction and erythema nodosum. Pembrolizumab therapy was introduced due to progression of melanoma. While asymptomatic his TSH fell from 0.988 pre-treatment to 0.1 mIU/ml after third course of therapy with fT4 13.43 pmol/l pre vs 15.33 pmol/l post. MRI pituitary was normal. Synacthen test (post stimulation cortisol 570 nmol/l) was normal with a normal GCT for cortisol + Growth hormone. Thyroid USS and uptake scan were normal, TPO and TRAb negative. TSH recovered over 5 days reaching 2.92 mIU/ml. A diagnosis of Grade 2 hypophysitis was made and patient was discharged well. He re-presented 10 days later with severe headache and TSH was 0.045. He received pulse iv steroids then oral steroids as per protocol for Grade 3 hypophysitis. While he demonstrated deficiencies in thyroid and sex hormones requiring temporary supplementation he ultimately had a full recovery in regard to his pituitary function and steroids were tapered to discontinue in full. At 28 months Cortisol was 247 nmol/l (1 pm), TSH 0.557 mIU/l, FT4 13.8 pmol/l, Testosterone 18.8 nmol/l, FSH 2.41, LH 2.03, Prolactin 127 mIU/l. He subsequently commenced immunotherapy with Vemurafenib and Cobimetanib developing transient inflammatory like arthritis which responded to anti-inflammatory therapy and dose reduction in Venurafenib. While hypothyroidism is noted commonly in patients receiving Pembrolizumab, hypophysitis is rare. The recognition and management of hypopituitarism and particularly potential associated adrenal insufficiency is increasingly important in the endocrine management of oncology patients. Our case exemplifies that hormone replacement may not be required longterm in such patients. This case demonstrates the potential to be hormone replacement free post pembrolizumab indused hypophysititis at long term follow up. As these agents are used increasingly in the future this case report may help to direct endocrine management of iRAEs.

Meningoencefalitis as a complication of transsphenoidal surgery of a pituitary adenoma: case report

Mariana Tomé Fernández-Ladreda[1], Marta Iturregui[2] & Esperanza Miranda Sancho[3]
[1]Endocrinología Hospital Punta De Europa, Algeciras, Spain; [2]Hospital Quirón Campo De Gibraltar, Algeciras, Spain; [3]Hospital Punta De Europa, Algeciras, Spain.

Introduction
Transsphenoidal surgery is the preferred approach in patients with pituitary tumours. Transsphenoidal resection of pituitary tumors may account for as much as 20% of all intracranial operations performed for primary brain tumors. Meningitis is a rare complication accounting for less than 2% of procedures.
Methods
We report the case of an elderly patient with a sellar mass who was admitted to the hospital with a central nerve system infection 15 days after brain surgery (transsphenoidal resection).
Results
We present the case of a 77 years old woman with no personal history of interest except for primary hypothyroidism in treatment with 50 mcg of L-thyroxine, who was diagnosed of a sellar mass of 4.5 cm as she was being studied for headache and severe visual loss. This lesion was compatible with a macroadenoma with suprasellar extension with mass effect on optic chiasm. No campimetry could be performed due to severe visual impairment. Hormonal evaluation showed mild-moderate elevation of prolactin (86.9 ng/ml; Normal range 10-30), probably related to pituitary stalk compression, moderate elevation of gonadotropins considering her postmenopausal state (LH 9 μU/ml; FSH 24 9 μU/ml), undetectable levels of IGF-1 and normal levels of cortisol and thyroid hormones. With the diagnosis of pituitary macroadenoma of 4.5 cm with optic chiasm compression and 2 pituitary axis affected (somatotropic and gonadotropic axis) she underwent transsphenoidal resection of the tumour. Inmediately after surgery cortisol and free thyroid hormones levels decreased and she was discharge of hospital with hydrocortisone 30 mg per day and L-Thyroxine 88 mcg per day. 15 days after surgery our patient was admitted to the hospital with headache, confusion and disorientation. No other neurological focal signs were found. A lumbar puncture showed 5440 leukocytes/μL (98% polymorponuclear); glucose 1 mg/dl and proteins 180 mg/dl indicating a bacterial infection, however, no microbiological findings were seen on CSF cultures. After 15 days of treatment with Meropenem, Vancomicyn and Ampicilin our patient recovered completely and was discharged with her usual substitution treatment. She had not presented any other complications so far.
Conclusion
Transsphenoidal surgery is the most common approach for removing pituitary adenomas. Meningitis is a rare complication of this technique but we must consider it in those patients who present with neurological signs, fever or headache after pituitary surgery.

A family with Kallmann syndrome due to a novel *FGFR1* mutation

Ana Sousa Martins[1], Louise Gregory[2] & Mehul Dattani[1]
[1]Great Ormond Street Hospital, London, UK; [2]UCL Great Ormond Street Institute of Child Health, London, UK.

Introduction
Kallmann syndrome (KS) is a developmental disorder characterised by hypogonadotropic hypogonadism and anosmia. Known genetic causes account for up to 30% of patients with KS, with *FGFR1* mutations being identified in 10%. FGFR1-related KS has an autosomal dominant inheritance with incomplete penetrance. We present a family with KS due to a novel variably penetrant *FGFR1* mutation, where the presenting features included cleft lip/palate and anosmia.
Case presentation
A 9-year-old girl (proband) was referred to the Endocrinology Department with short stature, cleft lip and later anosmia. Her height was 122.9 cm (SDS −1.29; MPH 68th centile) with weight 23.1 kg (SDS −1.3); she was prepubertal. Laboratory tests showed undetectable LH and FSH, with normal concentrations of other pituitary hormones. MRI showed structurally normal pituitary gland and olfactory bulbs. Her 6-year-old brother presented with previously repaired cleft lip and palate, short stature and later anosmia. His height was 110.5 cm (SDS −1.18) with weight 18.2 kg (SDS −1.36). He had normal prepubertal genitalia, with testicular volumes of 2 ml. Basal pituitary function was normal. MRI revealed a small anterior pituitary. Molecular analysis revealed a heterozygous deletion, c.915delG, in exon 8 of *FGFR1* in both siblings, resulting in a truncated protein, p.[Glu305AspfsTer17], that is not present on the ExAC Browser. It was inherited from their father who had normal height (SDS 1.23) and fertility, although his puberty was late. The proband was still prepubertal at age 11.5 years, with poor growth. Additional investigations included a glucagon stimulation test with normal response (peak GH 29.3 mcg/l) and GnRH stimulation test with LH and FSH peaks of 1.4 U/l and 1.3 U/l, respectively. Oestradiol was undetectable. She started treatment with ethinyloestradiol, with subsequent pubertal development and improved growth. She also had an audiogram that revealed mild conductive hearing loss. Her brother is currently 11 years old and is growing normally (height velocity 4.9 cm/yr). A GnRH test will be performed at the appropriate age.
Discussion
This case reflects the clinical heterogeneity of KS due to *FGFR1* mutations. In KS, other developmental anomalies can occur, including renal agenesis, skeletal anomalies, hearing impairment, and cleft lip/palate, the latter occurring in 25–30% of patients with FGFR1-related KS. Here, both siblings presented with cleft lip or palate, and the proband had conductive hearing loss. Interestingly, they also both developed *café au lait* spots; whether this is an unreported feature of *FGFR1* mutations is uncertain.

Cushing disease and pregnancy: Report of 2 cases

Sara Atraki[1], Siham El Aziz[2], Selma Bensbaa[1] & Asmaa Chadli[1]
[1]Endocrinology, Diabetology and Metabolic Diseases Department Ibn Rochd University Hospital of Casablanca, Morocco; Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy- University Hassan II, Casablanca, Morocco; [2]Endocrinology, Diabetology and Metabolic Diseases Department Ibn Rochd University Hospital of Casablanca, Morocco; Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy- University Hassan II- Casablanca-Morocco, Casablanca, Morocco.

Introduction
Cushing's syndrome usually causes hypogonadism. Occurrence of pregnancy in this context is rare, and is associated with significant morbidity and perinatal mortality. We report two cases of pregnancies in two patients with Cushing's disease.
Case 1
Our first Patient was 37-year-old who presented during the second trimester of pregnancy a Cushing syndrome. The positive diagnosis was made regadless clinical signs and a hight free urinary cortisol at 4839 nmol / L, ACTH was normal at 4.4 pmol. The retaining etiology was a macroadenoma mesured 17×11× 10 mm lowering the sellar floor and opto-chiasmatic tanks with visual field impairment: presence of central scotomas and devices. Treatment consisted of a transsphenoidal resection at 13 weeks of prangnancy. Evolution was marked by the occurrence of spontaneous abortion 16 days postoperatively.
Case 2
Our second patient was 35-year-old and operated for Cushing's disease with recurrence of her illness. The indication of revision surgery for a microadenoma was made after medical preparation by ketoconazole which was interrompted at the discovery of a 6 weeks pregnancy. In the absence of clinical and biological signs of disease activity revision surgery was scheduled after childbirth. Pregnancy was achived without maternal or fetal complications.
Discussion
Cushing's disease and pregnancy is a rare combination and it can causes a therapeutic management problem with a high risk of maternal and fetal complications.

CNNHC: Preliminary results of treatment with recombinant somatropin

Margarida Bastos[1], Alice Mirante[1], Bernardo Marques[2], Joana Serra Caetano[1], Caldas Afonso[3], Carlos Vasconcelos[4], Conceicão Bacelar[3], Conceicão Pereira[5], Lurdes Lopes[6], Marcelo Fonseca[7], Miguel Patrício[7], César Esteves[8], Florbela Ferreira[9], Graciete Bragança[10], Luísa Raimundo[11], Lurdes Matos[6], Manuel Foutoura[8] & Teresa Borges[3]
[1]Centro Hospitalar e Universitário de Coimbra, EPE, Coimbra, Portugal; [2]Instituto Português de Oncologia de Coimbra FG, EPE, Coimbra, Portugal; [3]Centro Hospitalar do Porto, EPE, Porto, Portugal; [4]Centro Hospitalar de Lisboa Ocidental, EPE, Lisbon, Portugal; [5]Instituto Português de Oncologia de Lisboa FG, EPE, Lisbon, Portugal; [6]Centro Hospitalar de Lisboa Central, EPE, Lisbon, Portugal; [7]Unidade Unidade Local de Saúde de Matosinhos, Matosinhos, Portugal; [8]Centro Hospitalar de São João, Porto, Portugal; [9]Centro Hospitalar de Lisboa Norte, Lisbon, Portugal; [10]Hospital Fernando da Fonseca, Amadora, Portugal; [11]Hospital Garcia de Orta, Almada, Portugal.

Introduction
Treatment with recombinant Somatropin (rSMT) is safe and has greatly improved the approach of children and adolescents with somatropin deficiency (SMTD) and other growth disorders. In our country, rSMT therapy is approved for isolated/multiple somatropin deficiency, small for gestational age (SGA), chronic kidney disease (CKD), Turner syndrome (TS) and Prader Willi syndrome (PWS). A National Commitee (CNNHC) is responsible for the analysis of each case and treatment approval.
Methods/design
We performed a restrospective and comparative study of 111 patients who completed rSMT treatment, monitored by the CNNHC. The parameters evaluated included midparental target height (MTH), sex, diagnosis, duration of treatment and age, height, growth velocity (VC) at the beginning and end of treatment. Children with isolated SMTD and multiple pituitary deficiency (group 1) were compared to children in need of supraphysiological doses of rSMT (group 2). The association between variables was evaluated using paired samples *t*-test and the independent samples t-test.
Results
Most patients were female (58%) and mean age at the beginning of treatment was 9.8 ± 3.5 years; mean duration of treatment was 6.3 ± 3.4 years. Isolated SMTD was the most common cause (51%), followed by TS (30%), multiple deficiency (7%), CKD (6%), SGA (5%) and PWS (1%). The highest increase of stature was observed in the group of children with isolated SMTD (mean SDS variation of $+1.4$), followed by multiple pituitay deficiency ($+1.38$), CKD ($+1.2$), ST ($+0$, 5), SGA ($+0.47$) and SPW ($+0.29$). When comparing both groups, we found that, prior to treatment, GV is higher in group 2 children (3.6 cm/year vs 4.4 cm/year; $P=0.014$). In group 1, mean baseline height was higher (122.4 ± 19 cm *versus* 113.6 ± 18 cm; $P=0.019$), as was the final height (155.7 ± 12 cm vs 145.8 ± 11.8 cm, $P < 0.001$) and the mean SDS variation (1.43 vs 0.63, $P < 0.001$). The difference between final height and MTH was higher in group 2 (-5.3 cm vs -13.2 cm; $P=0.001$).
Discussion
The primary goal of rSMT in children is acceleration of growth velocity to promote normalization of growth and stature appropriate for the child's genetic potential. This preliminary study suggests that children with isolated/multiple rSMT deficiency show better results with rSMT treatment. However, most patients start treatment quite late and this fact may hinder its efficacy.

The value of a holistic needs assessment tool in the care of patients with acromegaly

Sherwin Criseno, Andrea Mason, John Ayuk & Niki Karavitaki
University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK.

Background
It is well established that patients with acromegaly have compromised quality of life both during active disease, as well as whilst on remission. (1). In the recent years, there has been increasing emphasis on the importance of considering health-related quality of life (QoL) outcomes in the care of patients with acromegaly. The University Hospitals Birmingham NHS Foundation Trust introduced and implemented the use of a holistic needs assessment (HNA) tool in the Pituitary Service in 2014.
Aims
To gain a better insight of the needs of patients with acromegaly, as reported by them in the HNA questionnaire.
Patients and methods
A structured HNA, incorporating 11 indicators of psychosocial distress (issues concerning: original diagnosis and treatment; complications; hormone; heart problems; fertility; sexual; psychological; social/family; education/employment; healthy lifestyle, and spirituality/faith/belief) was offered to all patients with acromegaly on arrival at the Pituitary clinic prior to consultation with the health care professional. An audit of the responses was carried out over a 15-month period (May 2014 – August 2015).
Results
A total of 92 patients (with active disease or in remission following various treatments) completed a HNA form. Of the 11 areas assessed, patients were most concerned about their hormone issues (50% of patients indicated that they are either worried/very worried/extremely worried), complications of their condition and treatment (42.39%), original diagnosis and treatment (40.21%), healthy lifestyle (40.21%), and heart problems (36.96%). Additionally, more than quarter (28.26%) of patients expressed concerns about their psychological well-being.
Conclusions
The use of the HNA tool has enabled us to structure and adapt our consultation to focus on what matters most to each individual patient. It is proving to be a very reliable tool in identifying patients' needs as well as identifying the support that patients consider to be a priority.

The down-regulated Tumour suppressor Wnt Inhibitory Factor 1 (WIF1) regulates non-Canonical Wnt signalling in Pituitary Adenomas (PA)

Robert Formosa, Joseph Borg & Josanne Vassallo
University of Malta, Msida, Malta.

The Wnt developmental pathway has been implicated in tumour growth and development in a number of tissues. Most frequently, the canonical Wnt pathway acting through the nuclear translocation of B-catenin has been the key player in driving tumour growth. However, non-canonical Wnt pathways, namely the Wnt-Calcium signalling and the Wnt-planar polarity pathways have also been found de-regulated in a number of cancers. In this study, microarray analysis on locally resected PA revealed strong down-regulation Wnt pathway antagonists, namely the Wnt inhibitory factor 1 (WIF1) and the secreted frizzled-related proteins 2 and 4 (SFRP2 and 4). These results have been confirmed by qPCR and shown that WIF1 is under – expressed in all tumour types while SFRP's tend to be repressed in functional PAs. The aim of this study was to functionally assess the role of WIF1 in PA in relation to the different Wnt signalling pathways using two established cell lines, the rat sommatotroph/lactrotroph GH3 and prolactinoma MMQ cell lines in the presence of known canonical and non-canonical Wnt ligands, Wnt3, Wnt4 and Wnt5a. WIF1 over-expression reduced significantly GH3 and MMQ cell proliferation using a fluorescent-based Alamar Blue assay, both in the absence and presence of Wnt ligands. However, both Wnt ligands and lithium chloride, an established canonical Wnt pathway activator, failed to activate β-catenin driven transcription using the TOP/FOP flash luciferase system. In fact, canonical Wnt signalling appears to be completely absent in GH3 and MMQ cells. In order to study the influence of Wnt ligands and their inhibitor, WIF1, on other non-canonical Wnt pathways, the Wnt-Calcium signalling pathway was chosen, owing to the important role that calcium signalling plays in regulating hormone release from these cells. Using the FluoForte Calcium assay (Enzo Biologicals, US) to assess free calcium in real-time in the chosen cell lines, we studied the effect of the Wnt ligands in the absence and presence of the WIF1 inhibitor. Wnt ligands activated calcium release with variable potentials with WIF1 displaying an inhibitory but selective role on this effect. Real-time PCR of targets of the canonical and non-canonical Wnt pathways is also being undertaken together with analysis of growth hormone and prolactin secretion from both cell lines. Preliminary data reveals that the Wnt agonists may activate the Wnt-Calcium signalling pathway and WIF1 could play a role in PA by inhibiting specific aspects of this pathway.

Cabergoline treatment results in the case of pituitary microadenoma with co-secretion of growth hormone and prolactin

Soner Cander[1], Ozen Oz Gul[1], Pinar Sisman[2], Elif Gunes[1] & Canan Ersoy[1]
[1]Uludag University, Bursa, Turkey; [2]Medicana Hospital, Bursa, Turkey.

Introduction
The most frequently secreted hormone in pituitary adenomas is prolactin, but prolactin and growth hormone co-secretion are also seen at not an uncommon frequency. Co-secretion of growth hormone has also been reported after long-term follow up in the prolactinoma patients which well controlled with cabergoline therapy. In this case report, we aimed to discuss the results of cabergoline therapy in a case of co-secreting GH and prolactine with a normal IGF1 level and no acromegalic features at the beginning.
Case
A 58-year-old woman is diagnosed with a pituitary adenoma five years ago. She was being examined for hypoglycemic symptoms but the prolactin level was 82.6 ng/mL(1.2–29.9), pituitary MRI revealed a lesion of 6×5 mm in size and cabergoline treatment was started. After two years, the treatment was discontinued because the patient was asymptomatic, the lesion was shrinking and she was in the postmenopausal period. In the follow-up of third years, patient's showed acromegalic features such as growth in hands and feet, thickening in fingers, in the laboratory examination IGF1 was normal, but growth hormone(GH) was not suppressed with OGTT. Since the size of the mass increased to 9×6 mm in pituitary MRI cabergoline treatment was started again. The pre-treatment IGF1 level was 323 ng/mL(81–225,the patient's age group) at the highest, while the control visits were between 157 and 237 ng/mL. Post-treatment yearly MRIs revealed the mass size decreased to 7×7 mm and stabilized. Cabergoline therapy is planned to be continued due to the absence of significant symptom.
Conclussion
Co-secretion is usually seen in tumors with somatotrophs and mammotrophs together, mammosomatotrophic cell-derived tumors and acidophilic stem cell-derived tumors and usually acromegalic findings were at the beginning in the first two conditions. In the later, acromegaly is added shortly after the presence of the prolactinoma and these tumors are aggressive. Classically, the first treatment option for mixed tumors is surgical. However, cabergoline is effective in both prolactinoma and GH-secreting adenomas. In the present case, it seems that there is a progression in a milder level that can be controlled with cabergoline. Accordingly, it can be argued that some mixed pituitary tumors may be mildly progressive in nature, and in such cases, medical treatment may be an appropriate treatment option for these pituitary tumors with co-secretion of prolactin and GH.

Pituitary apoplexy after pregnancy in a patient with microprolactinoma

Soner Cander[1], Ozen Oz Gul[1], Filiz Mercan[1], Pinar Sisman[2] & Canan Ersoy[1]
[1]Uludag University, Bursa, Turkey; [2]Medicana Hospital, Bursa, Turkey.

Case
An 18-years-old female patient suffering from headache, pituitary magnetic resonance imaging (MRI) revealed a lesion compatible with pituitary microadenoma; 8.5×5 mm in size, in the right lateral and extending to the midline of the pituitary gland. Cabergoline treatment was initiated in the external center with a prolactin level of 77 ng/ml and no other pituitary hormone abnormality. Unplanned pregnancy occurred in the patient who continued this treatment for about two months and the treatment was stopped by considering the size of the adenoma. One month later, when the patient is re-evaluated due to increased headache, in the cranial MRI; the size of the pituitary gland was increased and the hypo intense appearance was determined in the posterior part of the gland, which may be significant in terms of bleeding. Then one week after, the patient complained of blurred vision, nausea and dizziness, and applied to the emergency clinic. Repeated cranial MRI in the hospitalized patient was showed bilocular cystic appearance, 12×13×19 mm in size and found to have a fluid-fluid level in the pituitary gland localization, and was compatible with haemorrhage. Patient was had normal visual field and cortisol response and cabergoline treatment started again at the 17th+2 gestational week of the pregnancy and then, headache and other complaints were decreased.
Discussion
Pituitary apoplexy is a rare clinical syndrome characterized by sudden increase in pituitary gland volume due to ischemia and/or necrosis, usually associated with a pituitary adenoma. The coexistence of sudden onset clinical symptoms (headache, visual impairment, ophthalmoplegia) is a defining feature of classical pituitary apoplexy. Most cases are between 50 and 60 years of age and are more common in males and in the non-functioning macroadenomas. Pregnancy is a predisposition due to the formation of a relative ischemic environment by causing hyperplasia in the pituitary. Apoplexy has been reported after cabergoline treatment and it is mostly seen after macroadenomas and follow-up is recommended especially in macroadenomas after treatment. There are only a few reports of microadenoma related apoplexy in the literature. It can be argued that this may be related to the fading of the table and the skipping of the recognition. From this point of view, clinicians should be more careful not to skip the situations where positive results can be obtained with conservative methods like our case.

Sexually dimorphic gene expression in lactotroph pituitary tumours of different behaviours

Anne Wierinckx[1,2,3], Etienne Delgrange[4], Alexandre Vasiljevic[1,2,5], Emmanuel Jouanneau[1,2,6], Joël Lachuer[1,2,3], Jacqueline Trouillas[1,5] & Gérald Raverot[1,2,7]
[1]Université Lyon 1, Université de Lyon, Lyon, France; [2]Cancer Research Center of Lyon, Lyon, France; [3]ProfileXpert, SFR-Est, CNRS UMR-S3453, INSERM US7, Lyon, France; [4]Service d'Endocrinologie, CHU UCL Namur, Université catholique de Louvain, Mont-sur-Meuse, Belgium; [5]Centre de Pathologie Est, Groupement Hospitalier Est, Hospices Civils de Lyon, Bron, France; [6]Service de Neurochirurgie, Groupement Hospitalier Est, Hospices Civils de Lyon, Bron, France; [7]Fédération d'Endocrinologie, Groupement Hospitalier Est, Hospices Civils de Lyon, Bron, France.

Introduction
Various tumours have a worse prognosis in male than in female. This is also true for lactotroph tumours. Indeed it is known that aggressive and malignant tumours, resistant to dopamine agonists, are more frequent in male than female and are associated to lower ESR1 expression.
Objectives
Our aims are to study the genes differentially expressed and the chromosomic alterations in lactotroph tumours between male and female and their relationships with estrogen pathway.
Material and methods
We compared 30 lactotroph tumours in male ($n=20$) and female ($n=10$). They were classified into 5 grades: benign (grades 1a-1b), invasive (grade 2a), suspected of malignancy (grade 2b) and malignant with metastasis (grade 3). The differential gene expression of all tumours were analyzed with CodeLink Uniset Human Whole Genome bioarrays. The chromosomic alterations using Affymetrix Genome-wide human SNP array 6.0 chip were compared in twelve of them (6 males and 6 females). The differences according to the sex, and the pathological classification was functionaly analysed with Ingenuity pathway analysis (Qiagen).
Results
In these lactotroph tumours, functional analysis of significantly deregulated genes (P value <0.05) showed that cell morphology, cell growth and proliferation, development and cell movement are significantly different between male and female. Among the genes significantly differentially expressed, 120 genes are increased and 20 genes are decreased (fold changes at least 2). Some genes as CTAG2, FGF13 and VEGF-D located on the X chromosome are particularly dysregulated in these tumours. Some of them are involved in the estrogen receptors pathway. CGH analysis highlighted the deletion of the 11 chromosome in 5/6 aggressive and malignant tumours in both sexes, and one chromosomic insertion into aggressive lactotroph tumours only in male. If we compare transcriptomic and CGH analysis, two genes are up regulated in man lactotroph tumours and located on inserted chromosomic region. Both genes are implicated in cell growth and proliferation and may be related to estrogen receptors pathway.
Conclusion
This integrative study demonstrates a sexually dimorphic gene expression and chromosomic alterations in lactotroph pituitary tumours. The differentially expressed genes are implicated in tumour growth, invasion and malignancy and some of them are in relation with the estrogen receptors pathway.

Comparison of clinical and subclinical apoplexy in pituitary adenomas

Monica Livia Gheorghiu[1,2], Alexandra Bouariu[2], Raluca Alexandra Trifanescu[1,2], Catalina Poiana[1,2] & Corin Badiu[1,2]
[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania.

Pituitary apoplexy is a rare syndrome due to a clinically overt hemorrhagic infarction, described in 2–7% of pituitary adenomas. A subclinical usually asymptomatic pituitary hemorrhage and/or infarction may be detected on routine imaging or during histopathological examination in 25–28% of patients with pituitary adenomas.
Aim
We compared the clinical features and evolution of 166 patients with subclinical pituitary apoplexy (SPA) and 46 patients with clinical apoplexy (CA) admitted between 1995 and 2018, diagnosed by suggestive imaging for pituitary haemorrhage and/or pathological exam.
Results
Mean age at diagnostic was 40 years (14–79) for SCA patients and 46 years (16–85) in CA patients, $P<0.05$. Female to male ratio was 2:1 for SCA and 1:1.7 for CA. Macroadenomas were 86% in SCA and 98% in CA patients. In SCA 100 patients (60%) were diagnosed after previous treatments for the pituitary adenoma and 66 patients *per primam* (at the diagnosis of the pituitary tumor), while in CA 91% were diagnosed *per primam*. In SCA about 63% had prolactinomas, while in CA 72% had non-functioning adenomas. Clinically, in SCA 35% had mild-to-moderate headaches (compared to 98% severe headaches in CA), 6% visual field defects (in patients with per primam subclinical apoplexy) versus 80% in CA, none had diabetes insipidus in SCA, compared to 28% in CA patients ($P<0.05$). Hypopituitarism was recorded in 65% of patients with *per primam* SPA and in 42% of those previously treated, as compared to 96% in CA patients, $P<0.01$. Pituitary surgery was done in 17% of SCA patients and 91% of CA patients, radiotherapy in 6% SCA and 13% of CA patients, pharmacological treatment (mainly dopamine agonists) in 76% SCA and 17% CA, no treatment in 19% SCA and 9% CA patients. In patients with SPA, after median follow-up of 71 months, the cure rate was 4.5% in *per primam* SPA and 9% in the second group (none spontaneous). In CA, after median follow-up of 78 months, cure occurred in 25% of patients (spontaneous in 4% of patients). Tumor growth after SPA was recorded in 12–13% of patients and after CA in 2% ($P<0.05$). Conclusion. Subclinical apoplexy in pituitary adenomas is more frequent in males and in prolactinomas, while clinical apoplexy is more frequent in women and in non-functioning adenomas. Subclinical apoplexy does not seem to increase the cure rate in pituitary adenomas.

Utility of a 3D spheroid cell culture system in neuroendocrine tumors

AD Herrera-Martínez[1,2], ESR van Dungen[1], F Dogan[1], PM van Koetsveld1[1], JP Castaño[2], RA Feelders[1] & LJ Hofland[1]
[1]Department of Internal Medicine, division of Endocrinology, Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands; [2]Maimonides Institute for Biomedical Research of Cordoba (IMIBIC), Córdoba, Spain.

In vitro 3D cell culture systems seem to appropriately reproduce the tumor cell microenvironment, including nutrients-oxygen conditions and cell-cell interactions. These models may better mimic *in vivo* tumor conditions and more accurately reproduce drug treatments effects. Since most *in vitro* studies in neuroendocrine tumors (NETs) are performed in 2D culture systems (monolayer), we aimed to compare the monolayer system with a 3D spheroid cell culture system using a human pancreatic neuroendocrine tumor (PNET) model.
Methods
Human BON-1 and QGP-1 PNET cells were used. Total cell number, viability, cell growth, spheroid size, serotonin/chromogranin A (CgA) secretion and somatostatin receptor (sst) and dopamine receptor type 2 (D2R) mRNA expression were assessed in different medium conditions.
Results
Spheroid cultures of BON-1/QGP-1 allowed better cell survival in serum-deprived conditions, compared with monolayer cultures. Total cell number and spheroid size increased in a parallel and time-dependent manner in BON-1 spheroids. In contrast, the increase in total cell number and spheroid size in QGP-1 spheroids were dissociated, probably due to increased cell compactness. In BON-1, Serotonin and CgA release increased in parallel with the increase in spheroid size and total cell number. Hormone release was evaluated in monolayer cultures only after three days because of decreased cell viability after seven days. PNET spheroid growth exhibited time-dependent changes in the mRNA expression of sst subtype and D2R receptors, which was most evident in QGP-1.
Conclusions
These results suggest that spheroids 3D cultures may be a novel method for evaluating cell proliferation and secretion in NET cell models and could help to explain the heterogeneity in NETs. Spheroid cultures grow relatively serum-independent and spheroid size is not an appropriate measure of cell growth in 3D QGP-1 cultures.

Exposure of GH in acromegalic patients associated with sleep apnea, but not other clinical results: Experience of a center from 2006 to 2017

Cátia Ferrinho, Sequeira Duarte, Ricardo Capitão, Francisco Sousa Santos, Catarina Roque, Rute Ferreira, Clotilde Gouveia, Catarina Saraiva, Manuela Oliveira, Conceição Marques, Joana Graça, Jorge Azinheira & Carlos Vasconcelos
Hospital Egas Moniz, Lisboa, Portugal.

Aim
Acromegaly is associated with premature dead and a number of risk factors for cardiovascular disease (CVD). We aimed to examine the concept of cumulative GH exposure with regard to the presence these risk factors and cancer in acromegalic patients.
Methods
Retrospective observational study in all acromegalic patients from 2006 to 2017 with a minimum of 3 years of follow-up. We exclude patients not treated. GH exposure was calculated as median GH or IGF1 multiplied by the years of follow-up. We also calculate IGF1, % IGF1 above ULN for sex and age. We also used Sagit scale to access comorbidities. We review clinical registries of those patients, and categorized them in disease remission, controlled by therapy or active disease. We used descriptive statistics, t-test for continuous variables and chi-squared distribution for categorical variables. The threshold for statistical significance was $P<0.05$ for each test.
Results
We found 77.9% macroadenomas, 18.2% microadenomas and 3.9% invasive in 78 acromegalic patients. The mean age at diagnose was 51 ± 18.9 years and 68% were female. Most patients were submitted to surgery and transphenoidal resection was the first treatment in 76.2% of patients. Radiotherapy was used in 2.6%, in the early years for those who refuse the surgery. As first therapy, somatostatin analogues were prescribed in 6.6% of patients and dopamine agonists in 10.3% reflecting the high frequency of somatomammotrophic pituitary adenomas. They were followed-up for 12.0 ± 0.2 years. The same drugs, Pegvisomant, subsequent surgery or radiotherapy were also used for those that do not achieved the safety levels of the guidelines. At the last evaluation 42.3% of the patients were on remission, 38.5% had the disease controlled by therapy and 19.2% had active disease in spite of the current treatment. The prevalence of hypertension was 65.4%, diabetes 39.4%, coronary artery disease 32.1% and 14.1% had also cancer. Only sleep apnea (present in 10.3% of patients) was significantly associated with the IGF1 exposure ($P=0.043$). Death occurred in 15.4% of patients during the follow-up. They were older with longer duration of follow-up. GH exposure was significantly associated with larger tumors with supra selar extension.
Conclusions
We found significant associations between GH or IGF1 exposures with larger tumors, but not with the prevalence of CVD, CVD risk factors or cancer. Only OSA was significantly associated with IGF1 exposure. These findings are new and deserve further evaluation in larger populations, with a prospective design.

Prolactinomas and Pregnancy: pregnancies medically induced...

Maryam Soussou, Ghizlane El mghari & Nawal El Ansari
Department of Endocrinology Diabetes and Metabolic Diseases, Laboratory PCIM FMPM, Cadi Ayad University, CHU Mohamed VI, Marrakech, Morocco.

Introduction
Prolactinomas are the most common hormone secreting pituitary adenomas. Also hyperprolactinemia is the cause of a third of all cases of female infertility, yet with

adequate management, most patients are able to achieve pregnancy. The purpose of this paper is to reporte the effectiveness of medical treatment in restoring fertility, while managing prolactinoma.And also to illustrate the follow-up of prolactinoma during pragnancy.
Cases
The first patient was 32 years old, had galactorrhea associated with amenorrhea about 3 years ago. Subsequent investigations revealed hyperprolactinemia. Pituitary MRI confirmed a sellar lesion (<1 cm). the therapeutic decision was to treat with Cabergoline.The second patient was 42 years old, had a macro-prolactinoma revealed by cycle disorders installed 17 years ago, complicated 4 years later of spontaneous galactorrhea. The investigations revealed an hyperprolactinemia with a sellar lesion measuring 11×11 mm, because of financial problems, the patient could not receive medication and got complications such us, visual disturbances and headache, with increasing of the size of the tumor (12 mm×16 mm). She was treated immediately with Cabergoline.The third one was a 41 years old patient, she had a macro-prolactinoma revealed by secondary amenorrhea and galactorrhea with bilateral visual acuity decrease. She was treated with bromocriptine. The three women did not follow the instructions of making contraceptifs précautions and became pregnant after few months of treatment. The management of each case was depending on the tumor volume.
Conclusion
Treatment with dopamine agonists usually restores ovulation and fertility. The treatment with Cabergoline is generally being preferred to bromocriptine because of its higher therapeutic efficacy/adverse effects ratio.

Sheehan's syndrome: Pregnancy is still possible...

Maryam Soussou, Ghizlane El Mghari & Nawal El Ansari
Department of Endocrinology Diabetes and Metabolic Diseases, Laboratory PCIM FMPM, Cadi Ayad University, CHU Mohamed VI, Marrakech, Morocco.

Introduction
Sheehan's syndrome (SS) is the development of partial or complete hypopituitarism following parturition, preceded in most of the cases by severe postpartum hemorrhage. The disease continues to be common in some developing countries.Some of the anterior pituitary functions like gonadotrophic and corticotrophic secretions may be preserved in these women. The purpose of this observation is to reporte a rare case of spontaneous pregnancy occurs in a patient followed for Sheehan's syndrome, as well as to indicate the principles of management.
Case
H.T. a 38-year-old woman, delivered her first child in 2007 with a delivery bleeding. She didn't had lactation failure and did resume menstrual cycles. She had a cesarean delivery in her second pregnancy in 2010, it was complicated by bleeding as well and was transfused, and was hospitalised 10 days in intensive care. The Investigations revealed central hypothyroidism and cortisol deficiency. She was put on hydrocortisone and Levothyroxin. She had also developped spaniomenorrhea. Five years laters, the patient was prangnant and was reffered to us for the follow-up, whitch was based on clinical and biological monitoring of substitutions associated with obstetrical monitoring. The birth took place without incident. The MRI had objectified an empty sellar.
Discussion
Spontaneous pregnancy rarely occurs while Sheehan's syndrom. Hypopituitarism during pregnancy should be followed strictly, and normal hormone levels should be achieved before any pregnancy. In our case, after the confirmation of Sheehan's syndrome, menstrual cycles remained irregular, the patient was not taking contraception, although she did not want a child. The patient received informations about the safety of her pregnancy if followed- up regularly. Indeed, it has been reported that inadequate hormone replacement in pregnant women with Sheehan's syndrome cause miscarriage in 50% cases and 27% of maternal mortality.
Conclusion
Because of hypopituitarism signs are non specific, the diagnosis of Sheehan syndrome should be considered, in any patient with postpartum hemorrhage history. In patients with preserved gonadal function, contraceptive use should be recommended.

Craniofacial fibrous dysplasia and long-term untreated GH excess in McCune–Albright syndrome

Beatriz Lecumberri[1], Mariana Gomes[1], José Juan Pozo Kreilinger[1], Isabel Esteban[1], Arantxa Royo[1], Guiomar Pérez de Nanclares[2] & Alvaro Gómez de la Riva[1]
[1]La Paz University Hospital, Madrid, Spain; [2]Araba University Hospital, Vitoria, Spain.

Introduction
Craniofacial fibrous dysplasia, characteristic of McCune-Albright syndrome (MAS), is usually present in patients with MAS related GH excess, and complicates their neurosurgical approach. We describe a 21-year-old male with severe craniofacial fibrous dysplasia and acute obstructive hydrocephalus due to a 39×35 mm cystic lesion in the third ventricle that occluded Monro's foramina, in whom MAS and long-term untreated acromegaly were discovered.
Methods
This report describes the presentation, diagnostic process, treatments and outcome of a young male patient with abnormal dysplastic growth of craniofacial bone structures, that reduced the optic canal and orbits, and occupied completely the sphenoid sinus, who presented with rapidly progressive headache. It also includes the results of a detailed GNAS genetic study in blood, pituitary, and bone tissues.
Results
Surgical resection of the tumor using a transcranial transcortical-transventricular approach and opening of the suprasellar cistern resolved the hydrocephalus and associated symptoms. Histologic and genetic studies of the extracted tissues, together with a hormonal evaluation, confirmed the presence of a colloid cyst combined with a GH-secreting pituitary adenoma with a Ki 67 proliferative index of 9%, and MAS. The GNAS gene p.Arg201His mutation in mosaicism was present in the pituitary tissue, but was not found in blood and decalcified paraffin-embedded bone tissue. Adequate control of his GH hypersecretion with somatostatin analogs and cabergoline was achieved.
Conclusion
This is the first reported case of a colloid cyst of the third ventricle in a patient with MAS. Our results suggest that MAS related long-standing GH excess may promote abnormal progressive dysplastic growth of craniofacial bones that might force any entrapped intrasellar lesion to grow upwards to the third ventricle, and should be ruled out and treated promptly in young patients with fibrous dysplasia. Hormonal evaluation and multidisciplinary approach before any surgery in these patients may help to optimize surgical results and guide further treatments to avoid long-term deleterious impact of hyperfunctioning endocrinopathies.

GH replacement therapy (GHRT) in adult patients with GH deficiency (GHD): a long term follow up

Begoña Pla Peris, Ana María Ramos-Leví, Clara Marijuan, Elena Fernandez, Nerea Aguirre, Alexia Mossé, Sara Jiménez, Iñigo Hernando, Marcos Lahera Vargas & Mónica Marazuela Azpiroz
Hospital Universitario La Princesa, Madrid, Spain.

Introduction
GH deficiency (GHD) leads to altered body composition, lipid metabolism and quality of life, and is also associated to an increased cardiovascular morbidity and mortality. The aim of this study was to evaluate long-term changes after treatment with GH replacement therapy (GHRT).
Methods
We retrospectively reviewed adult patients with GHD in our clinic who were treated with GHRT. We evaluated demographic (etiology, age, dose), anthropometric (body composition, bone mineral density), and analytical data (glucose, lipid, hepatic and renal profile, and IGF1 levels), as well as quality of life (QoLAGHDA), at the time of initiating GHRT and after the last dose.
Results
We evaluated 37 patients (31 males, aged 39.4±14 years at the onset of GHRT). There were nine cases of childhood-onset GHRT, seven due to congenital hypoplasia, and 28 cases with adult-onset, mainly due to surgical intervention

after pituitary macroadenoma (14) and craneopharyngioma (4). Patients were treated during 9.2 (2–15) years. Mean duration of follow-up was 10.8 (1–23) years. GHRT dose increased from 0.20 (0.1–1.0) mg at onset, to 0.30 (0.1–1.2) mg at the last follow-up visit ($P=0.05$), and IGF1 levels increased (88 ± 57.2 to 177.4 ± 50.6 µg/l, $P<0.001$). We observed a decrease in body fat mass (36.6 ± 9.3 to 33.1 ± 8.1%, $P=0.011$) and an increase in BMI (26.9 ± 5.0 to 28.4 ± 5.6, $P=0.014$). No significant changes in body lean mass were found. An increase in Hba1c and HDL-C levels was noted (5.1 ± 0.8 to 5.7 ± 0.8%, $P=0.007$, and 51.45 ± 15.0 to 59.88 ± 21.7 mg/dl, $P=0.003$, respectively), but the decrease in LDL-C or triglyceride levels was not significant. No hepatic or renal side-effects were reported. A non-significant increase in vertebral and femoral neck T-score was noted. Quality of life improved (13.7–6.5 points, $P<0.001$). 4 patients developed diabetes (only 2 already presented it at the time of starting GHRT). GHRT was withdrawn due to lack of efficiency, increase in tumor volume or for re-evaluation in 3, 1 and 3 cases, respectively.

Conclusion

GHRT improved body fat mass, HDL-c and quality of life. The effect on glucose metabolism or bone mineral density may be controversial, and other changes were less relevant. The role of these modifications in the overall improvement of the cardiovascular risk in patients with GHD deserves further investigation.

P741

IGF1 level and GH dose adjustmentin adults with GH deficiency (AGHD): experience from a Registry in France

Françoise Borson-Chazot[1], Véronique Pascal-Vigneron[2], Sylvie Salenave[3], Evguenia Hacques[4] & Béatrice Villette[4]
[1]Hôpital Louis Pradel, Bron, Lyon, France; [2]CHRU, Nancy, France; [3]Hôpital Bicêtre, Kremlin Bicêtre, France; [4]Novo Nordisk, La Défense, France.

Objective

IGF1 is the most useful serum marker for GH dose titration in adults. The authors focused on the GH dose adjustment with extreme IGF1 values (< −2S.D.; > +2S.D.).

Methods

French observational study of AGHD patients treated with Norditropin®. Prospective follow up until 5 years.

Results (median [Q1; Q3]):

328 AGHD, 39.2 ± 14.3 years old were included. GH median dose was 0.30 mg/d [0.20; 0.40]; IGF1 level was available in 97% of patients and was −0.9 S.D. [−7.2; 3.9]. Each year the GH dose modified in around 28% of patients (1st year in 32.6%, 5th year in 25.4%). At the end of the follow up the median GH dose was 0.40 mg/d [0.30; 0.60]. IGF1 measured annually in 80% of patients. Each year around 80% of patients had IGF1 between −2S.D. and +2S.D. During follow up 242 extreme IGF1 values were observed in 145 (44%) patients. And at N + 1 visit no dose adjustment occurred in 72.2% ($N=52$) of patients with IGF1 > +2SD ($n=61$) for a median dose 0.30 mg/d [0.20; 0.40] vs 49.3% (N = 36) with IGF1 < −2 S.D. (n = 49) for a median dose 0.45 mg/d [0.40; 0.60] (Tables 1 and 2).

Table 1 IGF1 < −2s.d. with GH dose adaptation (73 patients) (dose, median, (mg/d) [Q1; Q3]).

N = patients, n = IGF1 values	V N	V N + 1
Dose increase (N = 29, n = 36)		
Dose	0.40 [0.30; 0.55]	0.60 [0.48; 0.80]
Dose reduction, (N = 3, n = 3)		
Dose	0.60 [0.45; 0.80]	0.40 [0.00; 0.40]

Table 2 IGF1 > +2s.d. with GH dose adaptation (72 patients) (dose, median, (mg/d) [Q1; Q3]).

N = patients, n = IGF1 values	V N	V N + 1
Dose increase (N = 7, n = 7)		
Dose	0.30 [0.20; 0.80]	0.40 [0.30; 1.00]
Dose reduction, (N = 25, n = 27)		
Dose	0.60 [0.20; 0.60]	0.30 [0.10; 0.40]

Conclusion

IGF1 was regularly measured in AGHD patients treated with GH in accordance with the guidelines and was in normal range for the majority. In this observational study, extreme IGF1 values were not systematically accompanied by dose adjustment. It could be explained by low GH dose prescribed and the fact that IGF1 is not the single factor of GH dose adaptation. Not taking in consideration at the visit with extreme IGF1 level the efficacy and tolerability of GH treatment is the limitation of this observation.

Hirsutism as presenting clinical sign of acromegaly

Maria Pissia, Spyridon Sapounas, George Simeakis, Ioanna Patinioti, Katerina Saltiki, Vassiliki Vasileiou, Maria Alevizaki, Eleni Anastasiou & Evangelia Zapanti
Endocrinology Dept Alexandra Hospital, Athens, Greece.

Case report

Hirsutism although common in acromegaly (24%) is not considered as the prevalent symptom of the disease. Here we describe a seventy-one year old woman with a 2-year history of hyperandronism and subtle acromegalic features (macroglossia, sleep apnea). Clinical examination showed hirsutism (Ferrimann-Gallwey score 20/34), acanthosis nigricans and mild clitoridomegaly. Blood examination revealed elevated IGF-1: 502 ng/ml (69–200 ng/ml) and standard oral glucose tolerance test (OGTT) showed a diabetic curve and failed to show suppression of GH levels (post glucose GH: 1.8 ng/ml). The diagnosis of acromegaly was made accordingly. Laboratory results also revealed elevated levels of testosterone: 4.0 nmol/l (0.35–2.6) and androstenedione: 3.7 ng/ml (0.3–3.5) and normal levels of DHEAS: 2.69 µmol/l (1.77–10.5). Sella MRI was negative for pituitary adenoma. Further imaging failed to identify any cause for GH excess. Ultrasound of the ovaries did not reveal any morphologic abnormalities. The patient was treated with SST analogs with prompt response. Hormonal follow-up and imaging were normal. This case intends to emphasize that hirsutism may rarely be a prominent feature of acromegaly. The recognition of hyperandrogenism in a subset of acromegalic patients with hirsutism as a cardinal feature would facilitate early detection and diagnosis.

Desensitization of the human motilin receptor by motilin and motilides

Bunzo Matsuura, Akiko Takano, Tomoe Kawamura, Shin Yamamoto, Hidenori Senba, Teruki Miyake, Shinya Furukawa, Masanori Abe & Yoichi Hiasa
Ehime University, Toon, Japan.

The motilin receptor (MLNR) belongs to a family of Class I G protein-coupled receptors, and is an important endogenous regulator of gastrointestinal motor function. Motilin and erythromycin (EM), two chemically distinct full agonists of the motilin receptor, bind to distinct regions of this receptor, while the action of these different chemical classes of agonists likely yields a common activation state of the cytosolic face of this receptor that is responsible for interaction with its G protein. In the current work, we studied the desensitization of the MLNR by motilin and motilides in CHO cell line stably expressing the cloned Halo-tagged MLNR. We also studied receptor internalization following application of motilin and motilides visualized by using Halo-tagged MLNR. Desensitization of the MLNR was induced by prestimulation of CHO cells expressing Halo-tagged MLNR with concentration of over 10^{-8} M of motilin, while was not induced by prestimulation with any concentration of EM or other macrolides. Halo-tagged MLNR was trafficking into the cytosol after motilin and EM stimulation and was recycling to cell surface more slowly with motilin stimulation than with EM stimulation. These data supported that it should be possible to develop motilides with high potency and less desensitizing ability.

Clinical and radiological characteristics of patients with primary empty sella

Rym Belaid[1], Nadia Mchirgui[1], Imen Rojbi[1], Amel Jaidane[2], Ibtissem Ben Nacef[1], Karima Khiari[1], Haroun Ouertani[2] & Néjib Ben Abdallah[1]
[1]Departement of Endocrinology, Internal Medicine A, Charles Nicolle's Hospital, Tunis, Tunisia; [2]Department of Endocrinology, Military Hospital, Tunis, Tunisia.

Background
The primary empty sella (PES) is radiologically defined as partial when less than 50% of the sella is filled with cerebrospinal fluid (CSF) and pituitary gland thickness is $\geq$3 mm or total when more than 50% of the sella is filled with CSF and the gland thickness is $\leq$2 mm in diameter.The aim of our study was to evaluate clinical and radiological aspects of PES.
Methods
We retrospectively evaluated clinical features and radiological findings of 36 patients with PES followed in the internal medicine department of the Charles Nicolle's hospital and the endocrinology department of the Military Hospital of Tunis between 1992 and 2016.
Results
Our study included 26 women and 10 men with an average age of 47.64 $\pm$ 15.47 years [9–83]. Of the risk factors of PES, multiparity was detected in 76% of the female patients. Obesity, hypertension, diabetes mellitus and autoimmune hypothyroidism were found in 41.6%, 38.9%, 27.8% and 8.3% of the whole study group,respectively. Only one patient had idiopathic intracranial hypertension. Endocrine signs were the most common presenting symtoms (52.7%). More than half of our patients complained of headache. The diagnosis was confirmed by pituitary magnetic resonance imaging (MRI) in the majority of cases. Sixty one of the patients had partial empty sella and the remaining 39% had total empty sella. Other radiological abnormalities on MRI were associated with PES: an absence of the normal posterior pituitary bright signal in 2 patients consulting for polyuria and an optic chiasm ptosis in a patient with campimetric defect. No significant differences were found among the partial and total empty sella subgroups in terms of risk factors of PES.
Conclusion
PES is a radiological entity that is often asymptomatic and discovered fortuitously but can induce variable neurological, hormonal and ophthalmological disorders. This diagnosis must be evoked in a middle-aged, obese, multiparous and hypertensive woman presenting with a symptomatology suggestive of pituitary deficiency or chronic headache.

Serum sodium is inversely related to frailty and bone mineral density (BMD) in human immunodeficiency virus (HIV)-infected patients

Sara De Vincentis[1,2], Maria Chiara Decaroli[1,2], Chiara Diazzi[1,3], Daniele Santi[1,3], Federica Carli[4], Stefano Zona[4], Giovanni Guaraldi[4] & Vincenzo Rochira[1,3]
[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Unit of Endocrinology, Department of Internal Medicine, Endocrinology, Metabolism, and Geriatrics, Azienda Ospedaliero-Universitaria di Modena, Modena, Italy; [3]Unit of Endocrinology, Department of Internal Medicine, Endocrinology, Metabolism, and Geriatrics, Azienda Ospedaliero-Universitaria di Modena, Ospedale Civile di Baggiovara, Modena, Italy; [4]Multidisciplinary Metabolic Clinic, Unit of Infectious Diseases, University of Modena and Reggio Emilia, Modena, Italy.

Background
HIV-infected patients are predisposed to an increased risk of hyponatremia. In healthy population, low sodium is associated with impaired health status and reduced BMD, but less is known about this association in HIV-infection.
Aim
To investigate the relationship between serum sodium, frailty and BMD in a large cohort of HIV-infected patients.
Methodology
A retrospective, observational, cohort study on adult HIV-infected patients (age $\geq$18 years), attending the Multidisciplinary Metabolic Clinic of Modena, was carried out including all sodium examinations performed at the Modena lab from 2007 to 2017 available in a large database. Laboratory ranges of normality for sodium (136–146 mEq/l) were used to subdivide records in hyponatremic (HypoNa), hypernatremic (HyperNa) and normonatremic (NormoNa) groups. BMD was measured at total body, lumbar spine (L1–L4) and total hip using a Hologic QDR-2000 densitometer (DXA). Frailty was calculated through 38-item multimorbidity frailty index.
Statistical analysis
Parameters were not normally distributed and Kruskal-Wallis test, followed by Dunn's test, was used to compare continuous variables. Correlations were performed using linear regression models.
Results
8101 records (5454 from males and 2647 from females) of serum sodium (mean 139.4 $\pm$ 3.1 mEq/l) evaluated in HIV-infected patients (mean age 49.0 $\pm$ 7.9 years) were considered. 617 (7.6%), HypoNa, 44 (0.5%) HyperNa and 7440 (91.8%) NormoNa were found. Frailty score was inversely related to serum sodium ($r = -0.174$, $R^2 = 0.03$, $P < 0.0001$), even after the exclusion of HyperNa group ($R = -0.191$, $R^2 = 0.036$, $P < 0.0001$). Frailty was significantly higher in HypoNa than NormoNa ($P < 0.001$). Considering results at DXA examination, BMD was normal in 30.3% and reduced in 69.7% (54.8% osteopenia, 14.9% osteoporosis). Total body BMD, but not femoral nor lumbar, directly correlated with serum sodium ($R = 0.049$, $P < 0.001$) and it was significantly lower in HypoNa compared to NormoNa ($P = 0.029$).
Conclusions
This study shows that serum sodium is inversely related to frailty, suggesting its potential role as reliable and cheap marker in the HIV-infection follow-up. Furthermore, we demonstrate a direct correlation between sodium and body BMD in HIV-infected patients, similarly to general population.

Sox 2 expression in human pituitary adenomas-correlations with pituitary function

Cristina Capatina[1,2], Anca Cimpeanu[3], Marius Raica[3], Mihail Coculescu[1] & Catalina Poiana[1,2]
[1]Carol Davila UMPh, Department of Endocrinology, Bucharest, Romania; [2]C.I. Parhon National institute of Endocrinology, Bucharest, Romania; [3]Victor Babes UMPh, Timisoara, Romania.

Introduction
Sox2 is a widely expressed marker of progenitor and stem cells in various organs, strongly expressed within Rathke's pouch and the neural ectoderm. It exerts a critical role in the early stages of pituitary development but it is still expressed in the adult gland. Sox2 expression in pituitary adenomas and its possible correlation with clinicopathologic characteristics have not been investigated so far.
Aim
To evaluate the immunohistochemical expression of Sox2 protein in pituitary adenomas.
Subjects and methods
We included in the study 34 pituitary adenoma samples (13 GH-secreting, ten prolactinomas with proven resistance to dopamine agonists and 10 non-functioning adenomas) prelevated at the time of the neurosurgical intervention. Tissue samples were analyzed by immunohistochemistry for pituitary hormones and Sox2 expression by the avidin-biotin-HRPA method.
Results
Sox2 positive expression was detected in 16 patients (47.05% of cases) and did not show an association with tumor volume or extension at diagnosis. GH-secreting tumors were immunopositive for Sox2 in 57.14% of cases, prolactinomas in 60% and non-functioning pituitary adenomas in only 20% of cases (significantly higher percentage of Sox2 positivity among secreting tumors, $P = 0.041$). 58.82% of all patients (20 cases) had pituitary insufficiency at diagnosis. At diagnosis, the percentage of corticotrophin and gonadotrophin deficiency was significantly higher in patients with Sox2 negative tumors compared to those with Sox2 positive tumors ($P = 0.047$ and 0.041, respectively). In cases associated with hypopituitarism, the number of endocrine pituitary axes affected was not significantly different compared to Sox2 positive tumors.
Conclusion
Sox2 positive expression is frequent in pituitary adenomas (especially in secreting tumors) but is not correlated to tumor size or invasiveness. However, intratumoral Sox2 expression is associated with a lower percentage of pituitary insufficiency.

P747

The probability of recurrence of the Cushing's disease within three years after surgical treatment depends on the ACTH and cortisol levels in early post-surgery period

Elena Nadezhdina, Olga Rebrova, Oksana Ivaschenko, Vilen Azizyan & Andrey Grigoriev
Endocrinology Research centre, Moscow, Russian Federation.

Objective
The search for the predictors of the Cushing's disease (CD) recurrence after surgical treatment among the following parameters - gender, age, adenoma size, preoperative levels of ACTH (morning) and cortisol (evening) in the blood, postoperative levels of ACTH (morning) and cortisol (morning) in the blood.
Material and methods
A retro- and prospective monocenter study of treatment outcomes in 181 patients with confirmed diagnosis of Cushing's disease who underwent endoscopic transsphenoidal adenomectomy between 2007 and 2014 was performed. The inclusion criteria were: the absence of previous pathogenetic treatment (neurosurgical, medical and radiation therapy) for this disease and the development of remission of the disease in the early postoperative period in the form of adrenal insufficiency or normalization of the morning ACTH and cortisol secretion. The group consisted of 29 men and 152 women. The duration of follow-up period was three years and more. Within 3 years the remission was preserved in 135 patients (24 men, 111 women), the recurrence of Cushing's disease developed in 46 patients (five men and 41 women). Recurrence probability, relative risks (RR) and 95% confidence intervals were calculated.
Results
No relationship between preoperative data (age, gender, adenoma size, preoperative levels of ACTH and plasma cortisol and serum, free cortisol level in daily urine) and the probability of recurrence of CD was found. However, the probability of CD recurrence was associated with levels of ACTH and cortisol in the early postoperative period. In patients with ACTH level less than 7 pg/ml, three year recurrence appeared to be 8%, 95% CI (3%, 17%), while at the level of $\geq$7 pg/ml recurrence was observed in 37% (28%, 46%) cases, RR 0.23 (0.09; 0.51). In patients with cortisol level below 123 nmol/l the recurrence developed in 17% (11%, 24%) of cases, while in patients with cortisol level $\geq$123 nmol/l, recurrence was equal to 50% (35%, 65%), RR 0.34 (0.21, 0.57).
Conclusion
The development of adrenal insufficiency with the decrease in ACTH level less than 7 pg/ml and cortisol level less than 123 nmol/l in early post-surgery period significantly reduces the probability of the recurrence of CD within three years after surgery.
Key words: Cushing's disease, adrenocorticotropic hormone (ACTH), transsphenoidal adenomectomy, cortisol, recurrence.

[1]Clinic for Endocrinology, Diabetes Mellitus and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia; [2]School of Medicine, University Belgrade, Belgrade, Serbia; [3]Mother and Child Health Care Institute of Serbia 'Dr Vukan Cupic', Belgrade, Serbia; [4]University Children's Clinic, Tirsova, Belgrade, Serbia; [5]Institute of Medical Statistics and Informatics, Belgrade, Serbia.

Transition from childhood to adulthood is particularly important in patients with COGHD mainly because of the associated metabolic abnormalities, inadequate body composition and decreased bone mineral density (BMD). There is a lack of large monocentric studies related to this issue.
Design
Monocentric, observational, retrospective cross-sectional study.
Patients
We collected 85 COGHD patients (58 males, aged 17–26 years) transferred from pediatric to adult endocrinology department from 2005 to 2017. Median age at transfer was 19.9 $\pm$ 1.5 years.
Methods
We investigated the metabolic status (glycaemia and insulin in OGTT, HOMA-IR, lipids, HbA1c), body composition (% fat, fat mass - FM and lean body mass – LBM) and BMD (BMD g/cm^2, Z score-DXA method) of patients at first evaluation after transfer. Related to the etiology of COGHD, two subgroups of enrolled patients were compared. First subgroup consisted subjects with congenital cause of GHD (CH-COGHD) while second subgroup presented patients with history of hypothalamic/pituitary tumor (TU-COGHD). These subgroups were matched by age, sex and BMI.
Results
CH-COGHD was detected in 64.7% cases, while TU-COGHD, idiopathic and other etiologies were reported in 23.5%, 7.0% and 4.7% of patients respectively. All patients had GH replacement during childhood (duration therapy 5.7 $\pm$ 2.0 yrs). The pause in GH replacement was 2.3 $\pm$ 1.7 before the transfer. Isolated GHD showed 18.8% cases, multiple pituitary hormone deficiency 65.8% while 9.4% of patients recovered GH axis. Combined pituitary hormonal loss was frequently reported in TU-COGHD ($P<0.05$). Radiotherapy was performed in 25% of patients with hypothalamic/pituitary tumors. Peak and AUC of insulin in OGTT, HOMA-IR and triglycerids were significantly higher in TU-COGHD ($P<0.05$). Peak and AUC of glycaemia in OGTT, HbA1c, cholesterol, % fat and FM showed also higher levels in TU-COGHD subgroup, but not significantly ($P>0.05$). In addition, LBM, BMD (g/cm^2) and Z score demonstrated lower values in TU-COGHD subgroup, statistically not significant ($P>0.05$).
Conclusion
Patients with COGHD caused by hypothalamic/pituitary tumors are at an increased risk for the metabolic syndrome in transition period. Also, they have a tendency to decreased lean body mass and BMD compared to patients with congenital COGHD. Young adults with COGHD after achievement a final height should be carefully monitored by adult endocrinologist in terms of their metabolic balance, adequate body composition and bone status.

Latest safety outcomes from the PATRO adults study of omnitrope® for the treatment of adult patients with growth hormone deficiency

Paolo Beck-Peccoz[1], Charlotte Höybye[2], Robert Murray[3], Suat Simsek[4], Markus Zabransky[5], Hichem Zouater[5] & Günter Stalla[6]
[1]Fondazione Istituto di Ricovero e Cura a Carattere Scientifico Cà Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Karolinska University Hospital, Stockholm, Sweden; [3]St James's University Hospital, Leeds, UK; [4]Medisch Centrum Alkmaar, Alkmaar, Netherlands; [5]Sandoz International GmbH, Holzkirchen, Germany. [6]Max Planck Institute of Psychiatry, Munich, Germany.

Introduction
Omnitrope® (Sandoz) is a recombinant human growth hormone (rhGH) and was the first biosimilar medicine approved by the European Medicines Agency. PATRO Adults is an international, longitudinal, non-interventional study of the long-term safety and efficacy of Omnitrope® in adults treated in routine clinical practice. The study provides data on the long-term safety of rhGH in adult patients with severe GH deficiency (GHD). Here we present safety data from an interim analysis.
Methods
The study includes adult patients who are receiving treatment with Omnitrope® and have provided informed consent. Patients treated with another rhGH before starting Omnitrope® therapy are also eligible for inclusion. The current interim analysis aims to provide data on the risk of glucose intolerance and diabetes.
Results
As of December 2017, 1236 patients had been enrolled on the study; 1038 (84.0%) had adulthood-onset GHD and 188 (15.2%) had childhood-onset GHD. Overall, 629 (50.9%) patients had been pre-treated with another rhGH. Mean (standard deviation (S.D.)) age was 49.4 (15.3) years, and mean (S.D.) BMI was 29.5 (6.3) kg/m^2. In total 3420 adverse events (AEs) in 801 patients have been reported, with 622 (321 (26.0%) patients) of these regarded as serious. One hundred and fifty AEs in 88 (7.1%) patients were suspected to be related to Omnitrope®; these included general disorders/administration site conditions in 20 patients, nervous system disorders in 25 patients and musculoskeletal/connective tissue disorders in 33 patients. A total of 26 serious AEs (SAEs) in 18 (1.5%) patients were suspected to be related to Omnitrope®, leading to treatment discontinuation in six patients. Treatment-related SAEs included two incidences of diabetes. The first case was diabetes mellitus aggravation in a 45 year old male with adulthood-onset GHD, following 4–6 months of GH therapy; Omnitrope® was permanently discontinued. The second case was worsening of diabetes mellitus in a male aged 72 years with adulthood-onset GHD, following 19 years of GH therapy; Omnitrope® treatment was interrupted. Since the start of the study, 263 patients discontinued treatment, of which 25 (9.5%) were due to AEs related to rhGH treatment.

Conclusions
Based on this interim analysis, Omnitrope® treatment in adults with GHD is well tolerated in a real-life clinical practice setting, irrespective of pre-treatment status. The ongoing PATRO Adults study will provide further data on the diabetogenic potential and overall safety of long-term GH treatment in this population.

The different response of somatotropic system to genistein and daidzein in the rat hypothalamus
Svetlana Trifunović[1], Branka Šošić-Jurjević[2], Milica Manojlović-Stojanoski[2], Nataša Ristić[2], Nataša Nestorović[2], Branko Filipović[2] & Verica Milošević[2]
[1]University of Belgrade Institute for Biological Research 'Siniša Stanković', Belgrade, Serbia; [2]University of Belgrade, Institute for Biological Research 'Siniša Stanković', Belgrade, Serbia.

The different response of somatotropic system to genistein and daidzein in the rat hypothalamus: Svetlana Trifunović, Branka Šošić-Jurjević, Milica Manojlović-Stojanoski, Nataša Ristić, Nataša Nestorović, Branko Filipović, Verica Milošević University of Belgrade, Institute for Biological Research 'Siniša Stanković', Department of Cytology, Belgrade, Serbia The different response of somatotropic system to genistein and daidzein in the rat hypothalamus Emerging evidence suggests that consumption of nutrients rich in isoflavones may has a beneficial effect on numerous diseases in animals and humans. On the other hand, given the structural similarity with estrogens, isoflavones: genistein (G) and daidzein (D), may cause adverse health effects via endocrine-mediated mechanisms in an organism. Our prior results has demonstrated that G exposure, could significantly increase activity of somatotropic system in the hypothalamus. Exactly, genistein's treatment increased: the arcuate (Arc) nucleus volume, the volume density of growth hormone releasing hormone (GHRH) neurons- 26% and somatostatin (SS) neurons-1.5 fold, accompanied by higher GHRH and SS staining intensity in the median eminence (ME). However, there is no evidence as to whether D exposure, has the same effect. Using histological and stereological approach we investigated the effects of D on GHRH and SS neurons in the hypothalamus, as well as their content in the ME. The Arc nucleus volume was decreased by 17% following D, in the comparison to G treatment. The same parameter wasn't change after D exposure in comparison to the control value. Also, the periventricular (Pe) nucleus volume was decreased by 15% in the D treated group in comparison to the G group. The Pe nucleus volume wasn't change after D exposure in comparison to the control. The volume density of GHRH and SS neurons within Arc and Pe nucleus respectively, significantly decreased following D in comparison to G treatment. There is no changes in the GHRH and SS staining intensity in ME after D treatment in comparison to the control, while differences was noticed in comparison to the G treatment. The stronger affinity of G for the estrogen receptors is a probable cause of greater changes in the level of the hypothalamus following genistein's treatment vs. daidzein's treatment. Also, the application's method (subcutaneously injected genistein and daidzein) i.e. reduced conversion of D into a more potent equol by enterobacteria, might be the basis for obtained results. Therefore, the eventual changes at the level of hypothalamus should be investigated after feeding experimental animals with isoflavones rich diet.

Efficacy and safety of a combinated pasireotide lar, pegvisomant and cabergoline treatment in four cases of aggressive somatotrophinomas
Chiara Bima, Sabrina Chiloiro, Antonella Giampietro, Antonio Bianchi, Serena Piacentini, Domenico Milardi, Tommaso Tartaglione, Liverana Lauretti, Carmelo Anile, Alfredo Pontecorvi & Laura De Marinis
Catholic University of the Sacred Heart, Rome, Italy.

Introduction
A significant number of GH-secreting pituitary adenomas show an aggressive behavior, therefore, when uncontrolled acromegaly persists, a pharmaceutical combination may improve biochemical control, with reduction of disease morbidity and mortality. We aimed to describe the clinical features of four patients successfully treated with a pharmacological combination of pasireotide LAR, pegvisomant and cabergoline.

Case reports
Acromegaly was diagnosed in young age, except for one patient that received diagnosis at the age of 65. Hormonal assays documented impaired secretion of IGF-1 (>1100 ng/ml) and GH (>8 ng/ml), without any suppression at OGTT. Contrasted pituitary and brain MR showed in all cases the presence of a pituitary macroadenoma extending in the cavernous sinuses, optical chiasm, sphenoid sinus and third ventricle. Patients underwent one or two neurosurgical procedures through the transfenoidal approach and, in one case, through the transcranial route. In one patient, neurosurgery was not carried out because of multiple comorbidities. Histological examination demonstrated pituitary adenomas with diffuse immunostaining for GH and, in one case, also for PRL, with Ki67 labelling index >1.5%. Immunohistochemistry for SSTRs subtypes showed in one case high expression of SSTR5 (score 3) and absence of SSTR2 (score 0) and in another case decreased expression of both SSTR 2 and SSTR5 (score 2). According to persistence of high levels of IGF-1 after neurosurgery and after SSAs and DA combined treatment (>1000 ng/ml), pegvisomant was added in increasing dosage up to 30 mg/day, without any important biochemical improvement (IGF-1 >500 ng/ml). Thus, patients suspended conventional SSAs therapy and began pasireotide Lar up to 60 mg/month, with improved disease control (IGF-1 age- and sexed-normalized) and stability of residual tumor mass at radiological evaluation. None of patients had significant adverse effects, particularly worsening of glycemic status.
Conclusions
Treating patients with acromegaly can be extremely challenging, and inadequate disease control may lead to serious consequences. Pegvisomant and combination therapies have been used to manage patients uncontrolled on first-generation SSAs. Several factors can predict poor response to SSAs, such as young age, high tumor size, elevated Ki67 index, reduced SSTR2/SSTR5 and sparsely granulated pattern of tumor. Pasireotide LAR seems to be a promising medical therapy for patients that cannot be controlled with conventional SSAs, accordingly to the pattern of SSTRs expression. Therefore, a multimodal therapeutic approach with pasireotide LAR, cabergoline and pegvisomant can be effective and safe in the management of resistant disease.

Pediatric hyperprolactinemia: a review of 25 cases
Aydilek Dagdeviren Cakir, Hande Turan, Oya Ercan & Olcay Evliyaoglu
Istanbul University Cerrahpasa School of Medicine, Istanbul, Turkey.

Objective
Hyperprolactinemia is a rare endocrine disorder in childhood, which may be due to various etiological factors and may present with different signs and symptoms. We aimed to evaluate the etiologic reasons, clinical features and outcome in hyperprolactinemia patients retrospectively.
Method
Data from 25 patients who were followed up with hyperprolactinemia between years 2009 and 2017 were evaluated.
Results
A total of 25 patients [23 female (92%) and 2 male (8%)], with a mean referral age of 15.6±1.2 years were enrolled in the study. The mean duration of follow up was 21.1±11.5 (6-46) months. In 2 patients who presented with pubertal gynecomastia and acne vulgaris, macroprolactinemia (prolactine levels; 47.4 and 47.3 ng/ml) was detected. The most frequent symptoms were menstrual disorders (15 of 23), galactorrhea (7 of 23). Visual field defect was only seen in patients with macroadenoma. All patients were at pubertal stage. The mean prolactin level of the patients ($n=23$), female group ($n=22$) and male group ($n=1$) were 138.6±106.2 (31.5-479), 123.2±79.4 (31.5-315), 479 ng/ml, respectively. Eleven patients had microadenoma, six had macroadenoma, five were diagnosed with idiopathic hyperprolactinemia and Rathke's cleft cyst was found in one. Cabergoline (0.25-0.5 mg/week in one /two doses) were given to all as initial therapy. Treatment was switched to bromocriptine in one because of treatment intolerance. All but one of the patients were responsive to medical treatment, gonadal and neurological functions were normalized. The patient who was unresponsive to medical treatment was male and had macroadenoma (35× 20 mm) secreting PRL and growth hormone. Tumor was invasive to cavernous sinus and causing visual field defect. Surgery was performed as twice and gama knife was also performed for residual tumor and medical treatment(cabergoline and sandostatine) was continued after surgery. Hypothyroidism and hypocortisolemia were developed after treatment. No pituitary hormone abnormality was observed in others. Two patients with macroadenoma, one with microadenoma left follow up. Tumor sizes were not changed significantly in the majority of patients, only in two, tumor regressed totally. Treatment was completed in five, mean treatment duration was 23 (12-36) months.

Conclusion
Hyperprolactinemia should be considered in the differential diagnosis of cases with amenorrhea (primary/secondary), oligomenorrhea, galactorrhea. Medical treatment should be the first-line treatment option in both microadenoma and macroadenoma cases. Surgery should be employed in cases that have cavernous sinüs invasion or signs of nerve compression.

Could predict the postoperative rosnance the acromegaly cure?

María Rosa Alhambra Expósito, María Sagrario Lombardo Galera, Angel Rebollo Román & M. Ángeles Gálvez Moreno
Hu Reina Sofía, Córdoba, Spain.

Acromegaly is caused by excessive growth hormone (GH) secretion from pituitary adenomas. Transphenoidal surgery is the first-choice treatment, but new drug therapies (e.g. somatostatin analogs, SSA) offer promising avenues for medical treatment. Complementary diagnostic tools may assist this strategy, helping to refine drug choice. Here, we investigate the associations between postsurgical radiological features and molecular phenotype of pituitary tumors from acromegalic patients and cure acromegaly. This observational study included 17 acromegaly patients (38.4 ± 15.6 yrs; 64.7% women), diagnosed from 2007 to 2012 at the Endocrinology and Nutrition Unit of the Reina Sofia Hospital, in whom surgery, radiology and molecular phenotyping of the adenoma was carried out. Magnetic resonance was performed to localize the tumors, which were all macroadenomas (94.6%) at diagnosis except for 1 microadenoma. Of the 3 patients who met criteria for cure, the postoperative magnetic resonance was normal (p 0.071). There are no differences in postoperative resonance among patients who had been on treatment with SSA. Of the 13 patients treated preoperatively with PFS, 2 had normal and 11 abnormal postoperative MRI (p 0.730). There are no differences in GH, IGF-1 or nadir GH among patients who had normal or abnormal postoperative MRI. GH preoperative in patients with normal MR were 10.50 ± 4.29 ng/dl, IGF-1 754.19 ± 98.97 and Nadir GH 1.69 ± 0.23 ng/dl, in anormal MR were 7.29 ± 8.11, 576.19 ± 295.76 and 7.02 ± 8.36 respectively.
Conclusion
When the postoperative resonance is normal, the healing is significantly greater.

Initiation of tolvaptan therapy for mild/moderate chronic SIADH-induced hyponatremia in a day-ward

Elvira Ramos, Elvira Barrio, Paz de Miguel, Martin Cuesta, Luzdivina Fernandez, Maria Victoria Saez de Parayuelo, Anba María Cruz, Marta Ortiz, Alfonso Calle & Isabelle Runkle
Hospital Clínico San Carlos, Madrid, Spain.

Introduction
Tolvaptan is the only V2-receptor antagonist authorized for use in Europe in patients with SIADH. Its initiation requires hospitalization. Our goal was to analyze the safety and efficacy of tolvaptan started in a Hospital Day-Ward.
Material and methods
Retrospective descriptive study of 33 ambulatory patients with mild/moderate SIADH-induced chronic sustained hyponatremia initiating tolvaptan therapy in the Day-Ward of a tertiary center over a 4-year period (2014-2017). Following obtention of Blood/urine samples, 7.5mg of tolvaptan were administered at 08:15AM, with patients instructed to drink freely. Blood/urine tests repeated 6, 24 and 48 hours post-initial tolvaptan dose (ITD). Electrolytes in mmol/L, osmolality(Osm) in mOsm/kg. If serum 6-hour sodium(SNa) rose < 5, patients returned the following morning. "Braking protocol": If 6-hour SNa rose 5 mmol, 3 mcg DDAVP were administered sc; 6 mmol rise: DDVP + 5% dextrose iv 2cc/kg/hour for 2 hours; ≥ 7: DDAVP + dextrose 3cc/kg/hour 3 hours, with patients returning the following morning. "Braked" patients received 7.5mg on day 2, non-braked 15mg, with overcorrection ruled out. A 24h-hour SNa increment > 10 or 48-hour rise > 18 was considered overcorrection. Results as Mean (Standard Deviation) or median [Interquartile range].
Results
Age: 71.7 (9.09). 25/33 women. Principal SIADH etiologies: 11/33 oncological, 6/33 pharmacological, 5/33 neurological. Baseline: SNa 129.6 (2.6), SOsm 270 (7.2), Urine(U) Na 76 [54-118], UOsm 378 [279-519]. 6-hours post-ITD: SNa rose 3.1(2.4). 8/33 presented SNa ascent ≥ 5 and Braking protocol applied. 24-hours post-ITD: SNa rose 3.7 (2.3) from baseline. In 15/33 SNa rose ≤ 2 mmol/L, in 18/33 SNa rose 3-10 mmol/L, with no significant difference between "braked" and "non-braked" patients. No patient presented overcorrection. Men presented a significantly higher 24h-SNa rise than women: 4.9 (2.8) versus 3.2 (1.9) respectively ($P = 0.043$). 48-hours post-ITD: SNa rose 5.55 (2.74) from baseline. 22/33 (66.7%) of patients attained SNa ≥ 135. The maximum 48-hour rise: 12. SNa levels at 6, 24 and 48 hours post-tolvaptan initiation were all significantly higher than at baseline ($P < 0.0001$ in all). Neither initial SNa nor UOsm predicted the 6, 24 or 48-hour SNa increment. No side effects were observed.
Conclusions
Two-thirds of the patients attained eunatremia after 48 hours, with no cases of overcorrection. The protocol is safe and effective for initiation of tolvaptan therapy in a day-ward, avoiding the need for conventional hospitalization in these ambulatory SIADH patients.

Ki67 as a marker of recurrence in craniopharyngioma

Antonio Jesús Martínez Ortega[1], Eva María Venegas Moreno[1], María Elena Dios Fuentes[1], Pablo Jesús Remón Ruíz[1], Francisco Javier Márquez Rivas[2], Ariel Kaen[2], Eugenio Cárdenas Ruíz-Valdepeñas[2], Antonio David Cano González[1,3] & Alfonso Manuel Soto Moreno[1]
[1]Endocrinology Department Virgen del Rocío University Hospital, Seville, Spain; [2]Neurosurgery Department Virgen del Rocío University Hospital, Seville, Spain; [3]Instituto de Biomedicina de Sevilla (IBIS) – Biomedicine Institute of Seville, Seville, Spain.

Craniopharyngiomas (CP) are low-prevalent tumors characterized for their local invasiveness and poor clinical outcomes, often requiring aggressive therapeutic measures. Ki67 is a marker of proliferation with good correlation with tumor recurrence in many solid tumors but this relationship is unclear in CP. Our aim is to determine whether Ki67 could be a marker for recurrence in CP.
Material and methods
Descriptive retrospective observational study. All patients with confirmed histology of CP and tissue sample available for immunohistochemical analysis admitted to the Endocrinology Department from Virgen Del Rocio University Hospital (Seville, Spain) from January 2000 to December 2013 were included. Immunohistochemical analysis for Ki67 was performed on tumor samples following standard procedures. Tumors were in 2 groups according to the Ki67 proliferation index (number of positive cells per high power field score: Group A (Ki67 < 10%) and group B (Ki67 > 10%). Quantitative variables are expressed as Median [Interquartile Range], while qualitative ones are expressed as number of patients/patients with available data (percentage). As all variables followed a non-parametric distribution (Demonstrated by Shapiro-Wilks and Kolmogorov-Smirnov tests when appropriate), Chi-Square, Fisher's exact test and Z-test with Benjamini-Hochberg correction were used when needed. A p-value < 0.05 was considered as significant.
Results
Our study population included 29 patients (12 male and 17 female), with a median age at diagnosis of 28.5 years [IQR7.25-46.00]. 12 were children (under 18 years old), and 17 adults (older than 18). A higher tumor recurrence rate was found in tumors with Ki67 proliferative index > 10%, 8/9 (88.9%) in comparison with Ki67 < 10% (6/15, 40.0%, $P = 0.019$). In children, six tumors display Ki67 < 10% and 6 Ki67 > 10%; recurrences were observed in 2/6 (33.3%) in the first group and in 6/6 (100%) in the second, respectively ($P = 0.061$). In adults, 9 tumors displayed Ki67 < 10% and 3 patients Ki67 > 10% (in 5 patients, no reliable data could be obtained); recurrences were observed in 4/9 (44.4%) in the first group and in 2/3 (66.7%) in the second, respectively ($P = 1{,}000$). There were no differences between age groups.
Conclusions
In our series, CP with Ki67 proliferative index > 10% are more likely to recur; sub-analysis per age group shows the same pattern. These findings support the use of Ki67 as a marker for recurrence in CP.

Pituitary abscesses diagnosis and therapeutic approach in a reference unit

Miriam Cozar, Eva Venegas, Elena Dios, David Cano, Ainara Madrazo, Pablo Remón, Enrique Jiménez, Florinda Roldán, Eugenio Cárdenas, Ariel Kaen & Alfonso Soto
Hospital Universitario Virgen del Rocío, Sevilla, Spain.

Introduction
Pituitary abscess (PA) is a rare condition, representing less than 1% of pituitary lessions. Only around 200 cases have been reported in the scientific literature. Preoperative diagnosis is often challenging due to nonspecific clinical and radiological manifestations.
Materials and methods
Retrospective descriptive cohort study. We analyze demographic and clinical variables, hormonal involvement, recurrence, type of surgery and antibiotic therapy. Data were obtained from electronic health records with patient's informed consent.
Results
Seven cases were found mean age 54 ± 31 years, 71.4% were women and a mean follow-up 4 ± 10 years. At presentation, 100% reported headache, 57.1% (4) exhibited diabetes insipidus and 42.9% (3) had visual impairment. No cases presented with fever and leukocytosis was observed in 57.1%. Three of them (42.9%) were primary abscesses; three developed after pituitary adenoma surgery and 1 after Rathke's cleft cyst surgery, with a mean time between surgery and abscess development of 4 ± 15 years. All of them were submitted to transesfenoidal surgery. Panhypopituitarism was observed in 42.9% (3), ACTH, TSH and FSH/LH in 28.6% (2) and 2 presented isolated GH or TSH impairment. Four patients were diagnosed intraoperatively. Gram cultures were positive in 85.7% (6). The organisms isolated from the cultured material were Staphylococcus Aureus (42.9%, 3), P. Acnes (14.3%, 1) and Corynebacterium (14.3%, 1). Sequential antibiotic therapy with linezolid was used in 42.9% (3). After the initial operative and antibiotic treatment, cure was obtained in 85.7% of the patients and only one recidive of a primary abscess was observed 3 years after the first surgery.
Conclutions
We describe a large cohort of patients compared to the reported cases in the scientific literature. We observed a high cure rate in our serie, with just one case of recurrence, probably due to consecutive surgical and medical treatment.

Efficacy and effectiveness of pegvisomant monotherapy in treatment patients with acromegaly – systematic review with meta-analysis

Ewa Borowiack[1], Monika Borowiack[1], Joanna Jarosz[1], Anna Nowotarska[1], Patrycja Przęda-Machno[2] & Małgorzata Konopka-Pliszka[2]
[1]Nuevo Hta, Cracow, Poland; [2]Pfizer LCC, Warsaw, Poland.

Objectives
The aim of this systematic review was assessment of clinical efficacy of pegvisomant (PEG) in the treatment of adult patients (age ≥ 18 years) with acromegaly.
Methods
The review was conducted according to the Cochrane Collaboration guidelines and polish recommendations of The Agency for Health Technology Assessment and Tariff System. Since acromegaly is a rare disease, not only randomized clinical trials (RCTs), but also real world data (registry, observational studies) were the scope of interest. Calculations (statistical aggregation) were performed using the StatsDirect® 3 statistical package.
Results
One multicenter RCT was identified, which examined the health effects of three doses (10, 15 and 20 mg) of PEG on adults with acromegaly. Further observation (extension phase) was also presented in a period of 18 months. The probability of achieved IGF-1 normalization for PEG 10 mg, 15 mg, 20 mg was respectively 3.97, 7.15, 8.49 higher than in placebo group. After 18 months, 97% of patients achieved normalization. The results from real world data (8 non-RCTs studies) confirm the high effectiveness of the therapy. Calculated weighted average percentages of normalization of IGF-1 after 6 and 12 months and at least 5 years were as follows: 55% (95% CI: 51%, 59%); 60% (95% CI: 56%; 64%) and 69% (95% CI: 64%; 74%).
Conclusions
All the identified scientific evidence confirmed effectiveness of PEG administered as monotherapy in nearly 1,500 acromegalic patients, who did not respond to previous treatment in the long-term follow-up to 11 years of therapy. PEG is currently the only drug, recommended by clinical guidelines for the treatment of acromegaly, that can be offered to treat acromegalic patients, who did not respond well to surgery and/or radiation therapy, and to treatment with somatostatin analogues.

The occurrence of hyperprolactinemia in a hormonally inactive pituitary adenoma

Mijgona Safarova[1], Said Ismailov[2], Zamira Khalimova[3], Saida Khodjaeva[1], Aliya Gumarova[3], Ozoda Azimova[1], Aleksandra Vodovskaya[1] & Saodat Issaeva[3]
[1]Center for the Scientific and Clinical Study of Endocrinology, Uzbekistan Public Health Ministry, Tashkent Medical Pediatric Institute, Tashkent, Uzbekistan; [2]Tashkent Medical Pediatric Institute, Tashkent, Uzbekistan; [3]Center for the Scientific and Clinical Study of Endocrinology, Uzbekistan Public Health Ministry, Tashkent, Tashkent, Uzbekistan.

Aim
The work was initiated to study prolactin levels in hormonally inactive pituitary adenoma by the size of the tumor.
Material and methods
We examined 85 patients with hormonally inactive pituitary adenomas, 45 women and 40 men among them aged from 18 to 50 years (mean age 44.5 ± 3.85 years). The disease duration from the onset to diagnosis based on the medical history and MRI ranged from 1 to 15 years.
Results and discussion
Guided by the aim of study we divided the patients into three groups. 26 patients with the tumor size up to 10 mm were included into the first group. 33 patients with the tumor size up to 20 mm comprised the second group. 26 patients with the tumor size 30 and more mm were included into the third group. Analysis of hormonal parameters demonstrated correlation between prolactin level and the tumor size. Hyperprolactinemia was registered in 2%, 45% and 100% of patients in the first group, second and third groups, respectively. In patients with macroadenomas hyperprolactinemia was clinically presented in combination with hypopituitarism. Among patients of the third group, chiasmal and cephalgic syndromes, the latter with the oculomotor nerve damage, were the main symptoms; lactorrhea-amenorrhea syndrome came the third.
Conclusions
Quite frequent sign of hormonally inactive adenoma, hyperprolactinemia upon formations in chiasmal-sellar area not always can be an outcome of prolactin-secreting adenomas; the fact is to be taken into account in choosing the treatment tactics.

Body composition and bone health in patients treated for craniopharyngioma: a retrospective 10 year follow-up study

Selvetta S. van Santen[1,2], Casper Hammarstrand[3,4], Daniel Olsson[3,4], Mark Wijnen[1,2], Gudmundur Johannsson[3,4], Aart J. van der Lely[1] & Sebastian Neggers[1,2,5]
[1]Department of Internal Medicine, Endocrinology, Erasmus Medical Center, Rotterdam, Netherlands; [2]Department of Paediatric Oncology/Haematology, Erasmus MC, Rotterdam, Netherlands; [3]Department of Endocrinology, Sahlgrenska University Hospital, Gothenburg, Sweden; [4]Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden; [5]Princess Maxima Centre for Paediatric Oncology, Utrec, Netherlands.

Introduction
Craniopharyngiomas are benign tumors in the suprasellar region that have encouraging survival rates between 77-93%. Unfortunately, long-term sequelae are frequent, resulting in excessive endocrine and metabolic morbidity, including premature cardiovascular disease and reduced bone health.
Objective
To determine the prevalence of unfavorable body composition and low bone mineral density (BMD) in patients with craniopharyngioma.
Methods
We studied a retrospective cohort of 93 Dutch and Swedish patients with craniopharyngioma, with at least two DXA-scans available. Outcomes of the first and last available DXA-scans (i.e. BMD, fat free mass index (FFMI), fat mass

index (FMI), and body mass index (BMI)), were expressed as standard deviation scores (SDS) based on age, sex, and country of origin, and compared. The prevalence of osteopenia and osteoporosis (BMD SDS <-1) was also studied.
Results
The cohort included 47 females (51%) and 45 patients with childhood-onset (48%). Mean age at follow-up was 48 years (range 16-78), and mean time between DXA-scans was 10 years (range 0.08 - 23). At presentation, 55 patients had growth hormone deficiency (60%), 40 hypogonadotropic hypogonadism (44%), 58 ACTH insufficiency (63%), 64 TSH insufficiency (70%), and 49 diabetes insipidus (53%). At the first DXA-scan, mean SDS for BMD of the total body was -0.64 (range −4.21–2.40, $n=72$), mean SDS for femur neck was −0.60 (range −4.55–3.80, $n=63$), mean SDS for L2-L4 was −0.64 (range −3.50–3.90, $n=66$), mean SDS for FFMI 0.22 (range −2.98–3.97, $n=59$), mean SDS for FMI 1.50 (range −0.93–5.02, $n=59$), and mean SDS for BMI 1.53 (range −1.71–7.55, $n=80$). Over time, a significant increase was observed for SDS of BMD of the total body (mean difference 0.68 [95%CI 0.38-0.93; $P<0.01$]) and femur neck (mean difference 0.57 [95%CI 0.06-1.09; $P=0.03$]), SDS of the BMD of L2-L4 (mean difference 0.80 [95%CI 0.28-1.18; $P<0.01$]), and SDS of FFMI (mean difference 0.99 [95%CI 0.54-1.44; $P<0.01$]). Correspondingly, the prevalence of osteopenia and osteoporosis of L2-L4 declined from 47% to 34% ($P<0.05$).
Conclusions
Our cohort of craniopharyngioma patients is at risk of unfavorable body composition, reflected by high FMI and BMI, and of decreased bone health, reflected by negative mean values for SDS for BMD. SDS for BMD of L2-L4, femur neck, and total body, as well as FFMI increased over time, while SDS for BMI and FMI did not change. Also, the proportion of subjects with either osteoporosis or osteopenia in their lumbar spine decreased over time.

Postoperative basal serum cortisol as a predictor of long-term hypothalamic-pituitary-adrenal axis integrity after endonasal transsphenoidal surgery for sellar and suprasellar masses

David Males Maldonado, Alba Martín, Soledad Librizzi, Cristina Martín-Arriscado, Igor Paredes, José Fernández Alen, Alfonso Lagares, Mercedes Aramendi & María Calatayud
Hospital Universitario 12 de Octubre, Madrid, Spain.

Introduction
Endonasal endoscopic transsphenoidal surgery (EETS) for a sellar or suprasellar mass poses potential complications, including transient or permanent hypopituitarism. Adrenocortical insufficiency is especially worrisome given its potentially life-threatening course, if untreated. Usual clinical practice includes administration of perioperative "stress doses" of steroids followed by long term steroid replacement until the hypothalamic-pituitary-adrenal axis (HPA) is reevaluated. High-dose steroid treatment carries potential side effects.
Objective
To determine if post-surgical morning serum cortisol levels can reliably predict development of long-term hypocortisolism (LT-hC), and the risk factors associated with post-surgery LT-hC.
Materials and methods
Retrospective review of patients who underwent EETS from January 2016-December 2017 in our hospital. Data on tumor size, histology, presurgical hormone deficits and baseline hormonal levels were recollected, and logistic regression analysis was performed to calculate the odds ratio (OR) for development of LT-hC. Patients with Cushing's disease were excluded. Morning serum cortisol level was measured on postoperative day-3 (POD3), and replacement steroid therapy was initiated if deemed necessary. Diagnosis of LT-hC was established based on HPA-axis tests at follow-up. An area under the ROC (AUROC) curve was calculated to determine the cortisol level that best predicts the development of LT-hC.
Results
Forty patients underwent EETS for a sellar or suprasellar mass: 67.5% non-functioning adenomas, 20% functioning adenomas, 5% cysts, 5% craneopharyngiomas, 2.5% meningiomas,. A diagnosis of permanent post-surgical hypocortisolism was made in 11 patients (27.5%). Patients who develop LT-hC have masses >30 mm (mean 35±10 mm). The presence of a presurgical hormone deficit was associated with the development of LT-hC ($P<0.05$]; OR 31.99, 18.33 and 18.00 for central hypothyroidism, central hypogonadism and GH deficit, respectively). Conversely, patients who developed LT-hC were more likely to develop a new-onset post-surgical hormone deficit (OR 57.49 and 14.67% for central hypothyroidism and central hypogonadism, respectively). There were no patients with LT-hC who developed permanent diabetes insipidus. The AUROC curve analysis found that a POD3 morning serum cortisol level >11.2 ug/dl yields a 95.65% sensibility, a 58.82 specificity and a 90.91% negative predictive value for ruling out long-term hypocortisolism.
Conclusions
POD3 morning serum cortisol level can predict development of LT-hC. Levels >11.2 ug/dl reliably rule out LT-hC and may help to avoid over-treatment with steroid replacement in most patients who conserve HPA-axis integrity. Patients with large tumor size and other presurgical hormonal deficits have a higher risk of developing LT-hC after EETS.

P761

Recurrence of hyperprolactinemia after dopamine agonists withdrawal

Cristina Contreras Pascual, Paloma González Lázaro, Julia Silva Fernández, Inés Gómez García, Belvis María Torres Arroyo, Florentino del Val Zaballos, Francisco Javier Gómez Alfonso & Álvaro García Manzanares Vázquez
Hospital la Mancha Centro, Alcázar de San Juan (Ciudad Real), Spain.

Introduction
Prolactinomas are the most common tumors among functional pituitary adenomas and they constitute 40% of all pituitary tumors. Dopamine agonists (DA) are considered the primary treatment of prolactinoma. DA can lead to complete remission (including eradicacion of the tumor), allowing discotinuation of treatment. So far, there aren't clinical criteria with sufficient predictive value for long-term remission.
Objective
To assess the effect of DA withdrawal, the current recurrence of hyperprolactinemia, and posible factors that predict recurrence.
Patients and methods
We evaluated DA withdrawal in 16 patients with prolactinoma who received DA for at least 2 years with normalization of prolactin levels. Factors that predict recurrence were evaluated.
Results
Sixteen patients (fifteen female and one male) aged between 47 and 27 years at diagnosis were analyzed. Seven patients showed recurrence after dopamine agonists withdrawal while nine remained without dissease signs or symptoms. The most frequent indicator of recurrence was asymptomathic hyperprolactinemia (85%).

Table 1 Data of the remission and recurrence groups about sex, sellar adenoma, microprolactinoma and tumoral mass reduction.

	REMISSION (9/16)	RECURRENCE (7/16)	p
SEX (FEMALE)	9/9 (100%)	6/7 (85.7%)	ns
SELLAR ADENOMA	7/9 (77.7%)	5/7 (71.4%)	
MICROPROLACTINOMA	7/9 (77.7%)	5/7 (71.4%)	
TUMORAL MASS REDUCTION >20%	3/8 (37.5%)	4/7 (57.1%)	

Table 2 Data of the remission group about age at diagnosis, baseline PRL levels, PRL levels after treatment, treatment dose and adenoma diameter.

	Remission group		Recurrence group		p
	AVERAGE	±	AVERAGE	±	ns
Age at diagnosis (years)	35.47	8.33	41	6.19	
Baseline PRL levels (ng/dl)	214.94	209.94	333.64	515.84	
PRL levels after treatment (ng/dl)	14.92	12.74	21.70	28.91	
Initial treatment dose (mg/week)	6.28	7.71	2.41	3.33	
Adenoma diameter (mm)	7.74	2.81	10.42	9.18	
Time to treatment withdrawal (months)	36.12	25.62	18.71	14.10	

Conclusions
The sample is too small to achieve significance but baseline tumor size, baseline PRL level, initial treatment dose and time receiving DA seem to predict recurrence. Significant reduction in tumor size, sex and age don't seem to predict the risk of recurrence.

A case of impaired vision after cabergoline therapy of macroprolactinoma: case report

M Delgado[1], N Jauregui[1], S Saenz[1], J Paz[1], L Alvarez[2], O Quintana[1], Marialejandra Delgado Rojas[3] & Jose Luis Paz Ibarra[3]
[1]Division of Endocrinology and Metabolism – HNERM, Lima, Peru; [2]Division of Neurosurgery – HNERM, Lima, Peru; [3]Hospital Edgardo Rebagliatti, Lima, Peru.

Case report
A male 30 years old, presented with a 12-month history of retro-orbital and frontal headache, oppressive type of moderate intensity, which subsides with analgesics. Subsequently, deterioration of bilateral visual fields, predominantly left side, after that was investigated by a neurologist in INCN in January 2013. A magnetic resonance imaginig scan of the brain showed a 45×50 mm pituitary macroadenoma, with suprasellar extension bowing the optic chiasm and cavernous sinus invasion. Initial laboratory: PRL: 6470 ng/mL, patient was treated with prednisone 5 mg qd and LT4 100 ug qd and cabergoline (CBG) 1.5 mg/week for 12 months; with effect on his symptoms, improved vision and headache episodes; after that he was taken CBG irregularly, even suspended for about three months. Six months before admission to ER, presents moderate intensity headache and progressive deterioration of bilateral visual fields predominantly left, therefore CBG were restarted (1.5 mg/week). On admission, severe headache and persistence of visual impairment were reported. MRI showed parietal lobe herniation into sella. Admission lab: PRL: 112 ng/ml, GH 0.05 ng/ml, TSH 1.84 uUl/ml, T4L 0.78 ng/dl, ACTH 17 pg/ml, cortisol 16.8 ug/dl, IGF-1 164 ng/ml. He subsequently underwent a left pterional craniotomy, optic nerve decompression, plasty of bone sellar region. Findings: gyrus rectus-frontal lobe herniation into sella, made marked compression of the optic chiasm and left optic nerve; intrasellar solid tumor with cystic degeneration. In the postoperative, visual fields improve and headaches disappears; PRL: 87 ng/ml, T4L 0.80 ng/dl, IGF-1: 78.8 ng/ml, cortisol 12 ug/dl, thyroid medication continues, and CBG doses diminishes to 1 mg/week.
Conclusions
Prolactinomas on CBG experienced, at least 50% of tumor regression during the first 6 months, but rarely has reported this severe adverse effect of the tumor shrinkage, as in this case, brain or brainstem herniation into sella may occur, depending on the pretreatment tumoral extension. The prompt identification of visual defects should lead to optimization of medical treatment aiming at visual improvement and prevention of further deterioration.

The levels of serum osmolality, sodium, and copeptin as predictors of the development of postoperative diabetes insipidus

Daria Mikhaylova, Larisa Dzeranova, Ekaterina Pigarova, Ludmila Rozhinskaya, Andrey Grigoriev, Vilen Azizyan & Oksana Ivashenko
Endocrinology Research Centre, Moscow, Russian Federation.

Objective
To assess the levels of osmolality, sodium in blood and urine, and copeptin level in patients after transnasal adenomectomy for pituitary adenomas.
Materials and methods
A total of 154 patients, aged 18 to 65 years, were included in this study and underwent transnasal adenomectomy. Surgical treatment was performed in 73 patients with Cushing's disease, 66 – acromegaly, 4 – prolactinoma, 9 – hormonally inactive adenoma, 1 – Nelson syndrome, 1 – TSH-oma. Before and after surgery, patients were assessed the sodium levels, blood and urine osmolality, and 30 patients were tested for copeptin.
Results
The development of a permanent form of central diabetes insipidus (central DI) in the postoperative period was noted in 22 patients (14.3%), transient form was detected in 39 patients (25.3%). In 2 patients (1.3%) development of hyponatremia was noted. In 91 patients (59%) there was no development of water-electrolyte disturbances. When assessing the level of blood osmolality in the dynamics of patients of different groups, no statistically significant differences were found ($P > 0.05$), however, when assessing the blood sodium level, significant differences were revealed in the postoperative period in patients with transient DI compared to the group of patients without water-electrolyte disorders ($P = 0.024$ and $P = 0.015$ for 1–3 and 5–7 days of follow-up, respectively), and significant differences in pre- and postoperative sodium levels were found in patients with transient ($P < 0.008$) and permanent form of DI ($P < 0.05$). When assessing the level of copeptin, there were no statistically significant differences between pre- and postoperative levels, but patients with a permanent central DI form had a sharp decrease in its level (median 10.13 (6.181; 10.98) pmol/L before the procedure, 5.265 [4.7, 8.262] pmol/L after the intervention). When assessing the level of osmolality and sodium in urine, significant differences in the indices of osmolality and sodium in patients with a constant and transient form of central DI were found in comparison with patients without disturbances ($P < 0.05$), and significant differences in the level of osmolality of urine in the dynamics in patients with transient form of the central DI ($P < 0.006$).
Conclusions
Blood sodium, osmolality and sodium in urine indicators are sensitive markers for diagnosis and prediction of further development of water-electrolyte disturbances in the early postoperative period. The level of copeptin as a predictor of the development of the permanent form of central DI, is a promising marker for further study.

Pregnancy outcomes in women with active acromegaly.

Svetlana Vorotnikova, Arina Tarasova, Ekaterina Pigarova, Alexander Lutsenko, Irina Stanoevich & Larisa Dzeranova
Endocrinology Research Centre, Moscow, Russian Federation.

Growth hormone (GH) producing tumors are commonly associated with menstrual disorders and anovulation because of the direct effects of tumor mass on gonadotropins and possible association with hyperprolactinemia. However, some women with acromegaly get pregnant, which rises up a lot of questions about medication, complications and follow-up. We report outcomes of 7 cases of pregnancy in patients with active acromegaly. A median age of patients was 30 years, four of them were with macroadenoma and 3 - microsomatotropinoma. All women had elevated levels of GH and IGF-1 at the period of conception – 7.6 ng/ml [6.1;16.4] and 550 ng/ml [453.7;674.5], respectively. Three patients also had a mild hyperprolactinemia, two women previously underwent transnasal adenomectomy and one – radiation therapy without complete affect. Only three women had regular menstrual function, two had amenorrhea and two – oligomenorrhea. In 57% of cases patients got pregnant during complex therapy with octreotide (mean dose 20 mg per 28 days) and cabergoline (mean dose 1 mg per week), period of treatment before conception varied from 1 to 35 months. Of 7 pregnancies only 5 resulted in births, in one patient, with diabetes mellitus and poor glucose control, a spontaneous miscarriage was registered at 9 weeks of gestation and one woman required medical abortion at 10 weeks due to the episodes of severe hypotension. The average gestational duration was 39 weeks. Preterm delivery occurred in one woman at 24 weeks that led to newborn death, other children were healthy (average height – 52.3 cm, weight – 3332.5 g). These clinical cases demonstrate that women with acromegaly do have a reproductive potential in spite of menstrual disorders and a lot of comorbidities. Pregnancy in active stage of the disease can be complicated by miscarriage and preterm delivery. So preconception counselling and intensive monitoring during gestation is necessary for successful pregnancy and neonatal outcome.

Rathke's cleft cyst mimiking pituitary apoplexy: a case report

Ines Barka, Faiza Bensmaine, Moctar Bah, Clara Bouche & Jean Francois Gautier
Endocrinology Department, Lariboisiere Hospital, Paris, France.

Introduction
The most common sellar lesions are mainly due to pituitary adenomas, craniopharyngiomas and benign cysts. Rathke's cleft cyst (RCC) is a developmental sellar or suprasellar cystic lesion, which rarely becomes symptomatic. Here, we present an interesting case of intra sellar RCC, with a presenting feature of acute pituitary apoplexy.
Case report
A 39 year old healthy women was referred to the emergency room for sudden headache and fatigue without visual disturbance. Neurological examination was within normal limits and brain CT scan revealed a high density 9 mm area in the sella suggesting a pituitary apoplexy. The patient was hospitalized and treated with hydrocortison infusion. Hormonal profile was within normal limits indicating normal pituitary function. On MRI study, oval slightly hyperintense areas measuring 10-mm were noted on T1 weighted that turned hypointense on T2 weighted sequence. The same lesions were seen in pituitary MRI realized 5 years ago showing stability of the mass which highly suggested the diagnosis of RCC.
Conclusion
RCCs are rarely symptomatic. CT and MRI brain studies are essential in establishing the diagnosis In the presence of apoplectic symptoms. However, it is important to include RCC in addition to pituitary apoplexy in the differential diagnosis.

Quality of life acromegalic patients based on the AcroQoL questionnaire

Yulia Pokramovich[1], Alexander Dreval[1], Irena Ilovayskaya[1] & Aliya Gilyazova[2]
[1]Moscow Regional Research Clinical Institute of M.F. Vladimirsky, Moscow, Russian Federation; [2]Polyclinic No. 3 Federal Public Health Institution "Medical-sanitary Station of the Ministry of Internal Affairs of Russia for the city of Moscow", Moscow, Russian Federation.

Introduction
Acromegaly is a rare chronic disease caused by growth hormone (GH) and insulin-like growth factor 1 type (IRF-1) excess. However, reaching biochemical control of the disease does not always guarantee the improvement of symptoms that play a significant role in the quality of life associated with human health (HRQoL), in particular, patients with acromegaly.
Goal
To investigate the quality of life in patients with acromegaly in the Moscow region.
Material and methods
The study included 114 patients aged 18 to 83 years (average age 56 years (13.6; 25.2)). All patients were divided into two groups by age - over 50 ($n=77$) and/or under 50 ($n=38$). Also, the patients were divided into groups, depending on the previous treatment. All patients were divided into two groups: uncontrolled current (active acromegaly) and controlled for (acromegaly in remission based on the previously proposed remission criteria. The data are presented as a median (range). Changes in the levels of GH and IGF-1, as well as the AcroQoL score, were analyzed using the Mann-Whitney U test, $P<0.05$ was considered statistically significant.
Results
The quality of life of patients with controlled and uncontrolled disease is no different (or maybe better this way: There is no difference between the QOL in patients with controlled and uncontrolled acromegaly). The IGF-1 level and the percentage of excess IGF-1 significantly correlated with the parameter "personal relationship" ($P=0.026/0.05$). For other hormonal parameters and quality of life significant correlations were not received ($P>0.05$). Surgical treatment and radiation therapy do not affect the QOL of patients, and therapy ASS effect on QOL only in the parameter "physical score" ($P=0.034$). In the group of patients who did not receive treatment earlier, QOL parameters "total score" and "physical score" is higher than in the group of patients receiving therapy.
The conclusion
Treatment either does not affect the quality of life (surgical, radiation, for example) or worsens it. This can be explained by the fact that there are no fast, instantly noticeable results of using modern methods of acromegalic therapy, and complications from them are manifested rather distinctly. As a result, the patient may get the impression that his quality of life has worsened, despite the fact that in the long term the appropriateness of the specific treatment is absolutely proven.

Female patients with acromegaly in Russian hypothalamic and pituitary tumors registry (OGGO)

Alexander Lutsenko, Svetlana Vorotnikova, Irina Stanoevich, Elena Przhiyalkovskaya, Ekaterina Pigarova, Liudmila Rozhinskaya & Zhanna Belaya
Endocrinology Research Centre, Moscow, Russian Federation.

Aim
To assess the data of the registry concerning women with acromegaly.
Materials and methods
Russian hypothalamic and pituitary tumors registry database, containing the information on 3968 acromegalic patients.
Results
From all patients with acromegaly registered in the database, 2878 patients (72.5%) are women. We assessed the following data on gonadal status and reproductive function in this group: 512 patients have irregular menses, 117 patients have complaints on low libido, 90 complain of galactorrhea, 71 reported inability to conceive. 26 patients had hypogonadism prior to diagnosis, 60 after pituitary surgery, 15 after pituitary radiation therapy. 44 patient were pregnant during the disease. In the group of patients with active disease ($n=907$), 11% have pituitary microadenomas, 43% macroadenomas, in 46% of patients there is no data regarding current pituitary tumor size. Transnasal transsphenoidal pituitary surgery was performed in 291 patients, 75 patients underwent radiotherapy, 527 and 242 patients are treated with somatostatin analogues and dopamine agonists respectively. Data on disease state is available in 1927 patients (67%): 29.7% have remission, 23.2% have partial remisson, 47.1% have active disease.
Conclusions
Russian hypothalamic-pituitary tumors registry contains useful clinical data on acromegalic patients. However, the data concerning gonadal status and reproductive function is lacking. It could be explained by either low rate of complaints itself or by lack of active assessment by physicians. Thus, it is essential to drive health care practitioners towards more active gonadal status and reproductive function assessment in women with acromegaly, because the rate of reproductive disorders in this group of patients may be higher than in population.

ACTH-secreting pituitary adenomas surgical outcomes and complications in Endoscopic transsphenoidal pituitary surgery (ETPS)

Pablo Remon-Ruiz[1], Elena Dios-Fuentes[1], Eva Venegas[1], Ariel Kaen[1], Eugenio Cardenas[1], Natividad Garcia[2], Florinda Roldan[1], Elena Fajardo[1], David Cano[1] & Alfonso Soto[1]
[1]University Hospital Virgen del Rocio, Sevilla, Spain; [2]University Hospital Virgen Macarena, SEVILLA, Spain.

Methods
Descriptive retrospective study among patients who underwent ETPS for ACTH-secreting pituitary adenomas performed by the same surgical team from January/2013 to January/2017.
Results
27 ACTH-secreting pituitary adenomas operated via ETPS. 20 (74.1%) were women, median age at surgery was 43.25 [29.65–61.59] years and median follow-up was 3.13 [1.6–6.69] years. Presurgically, 25 (92.59%) patients recieved drugs for control cortisol hypersecretion; all 25 recieved Ketoconazol, in the other 2 (7.41%) the treatment (ketoconazol) was discontinued due to hypertransaminasemia. Median presurgical dosage was 600 [400–600] mg/día. 8 (29.62%) patients were macroadeomas with a median size of 6.55 [5–12] mm. 1 (3.7%) showed a Ki expression >3% and 3 (11.1%) patients showed cavernous sinus invasion. 19 (70.37%) patients were operated by first time, 7 (25.93%) had been previously operated one time and 1 (3.7) had been operated two times before the ETPS aproach. 16 (84.21%) of the first operated patients showed at the end of observation period healing criteria, 2 of them were precociously reoperated due to tumor remains were observed in postsurgical MRI. Among first operated patients

4 were macroadenomas, and all of them were disease-free at the end of observation period; 15 were microadenomas and 12 (80%) were disease-free at the end of the study. After the surgery, 13 (68.42%) developed transient diabetes insipidous, 2 (10.53%) patients thyroid dysfunction, 11 (57.89%) steroid dysfunction and 1 (5.26%) gonadal one. 1 patient showed presurgical campymetric defects which showed an improvement after de surgery. 8 patients operated in this period had been operated previously via transsphenoidal microscopical. At the end of the observation period 6 (75%) patients were disease free. Al complications after surgery in reoperated patients, 1 patient showed a suspected meningitis and hydrocefalus. 3 (37.5%) developed postsurgical DI, 1 (12.5%) steroid dysfunction and 1 (12.5%) thyroid dysfunction.
Conclusions
In our series, ETPS showed better results than microscopic approach if we compare our series with the literature and no further complications were found. ETPS is shown as a very useful thecnique in patients previously operated by a microcopic approach.

Clinical outcomes and complications in Endoscopic transsphenoidal pituitary surgery (ETPS) for Non-functioning pituitary adenomas

Pablo Remon-Ruiz[1], Elena Dios[1], Eva Venegas[1], Eugenio Cardenas[1], Ariel Kaen[1], Natividad Garcia[2], Florinda Roldan[1], Elena Fajardo[1], David Cano[1] & Alfonso Soto[1]
[1]University Hospital Virgen del Rocio, Sevilla, Spain; [2]University Hospital Virgen Macarena, Sevilla, Spain.

Methods
We conducted a retrospective descriptive study including 67 patients with non-functioning pituitary adenomas surgicaly removed via ETPS beetwen January/2013 to January/2017.
Results
Among 67 patients with non-functioning pituitary adenomas surgicaly removed via ETPS 44 (65.67%) were men. 52 (77.61%) patients recieved their first surgery, 14 (20.9%) had been operated one time before and 1 (1.49%) had been operated two times. Every patient reoperated had been previously operated by transsphenoidal microscopic approach before ETPS. Presurgical median age was 55.53 [44.09–69.38] years and median follow-up was 3.67 [2.25–5.69] years. Presurgically, 37 (56.06%) patients showed thyroid dysfunction, 18 (27.27%), steriod dysfunction, 41 (62.12%) gonadal dysfunction and 25 (37.88%) somatotropic deficiency. 16 (23.88%) adenomas were null cell, 11 (16.42%) silent corticotroph, 3 (4.48%) silent somatotroph (1 showed PRL cosecretion), 2 PRL (2.99%), 1 (1.49%) TSH, and the other were gonadotroph adenomas. 6 (8.96%) showed Ki$>$3%. Median utmor size was 27 [21.7–33.7] mm, 45 (67.16%) showed a size $>$25 mm and 29 (43.28%) Knosp 3–4. 52 (77.61%) were operated by first time. 36 (69.23%) patients showed healing criteria at the end of observation, 4 (7.69%) tumor remaining $<$1 cm and 11 (21.15%) had tumor remaining $>$1 cm. Among 23 patients with Knos 3–4, 13 (56.52%) showed healing criteria. Every patients with tumor remains $>$1 cm were adenomas $>$25 mm, 10 (90.9%) showed cavernous sinus invasion. 33 (63.46%) showed presurgical campymetric defects; 21 (63.63%) resolved completely their campimetric defects, 10 (30.3%) showed a partial resolution and no changes were found in 2 (6.06%) patients. After surgery, transient diabetes insipidous was diagnosed in 15 (28.84%) patients, DI permanent in 2 (3.85%), transient SiADH was found in 3 (5.77%). Among patient without hormone involvement, 8 (34.78%) developed a steroid deficiency and 9 (42.86%) gonadal defect. 1 suspected meningitis was observed. Among reoperated patients. 6 (40%) had healing criteria, 3 (20%) tumor remaining $<$1 cm and 6 (40%) tumor remaining $>$1 cm. 1 patient showed a meningitis. As complications 1 patient presented a suspected meningitis. 7 (46.67%) patients had campimetric defects, after surgery 1 (14.29%) resolved completely their campimetric defects, 6 (85.71%) showed an improvement. After surgery, among patients without endocrine involvement, 3 (42.86%) presented thyroid deficiency, 3 (33.33%) steroid, 1 (25%) gonadal deficiency.
Conclusions
In our series, ETPS have shown better outcomes than transsphenoidal microscopic approach if we compare our series with the literature. This approach leads to complete curation in patients with sinus involvement.

Somatostatin analogues therapy of clinically non-functioning pituitary adenomas- impact on tumour volume and visual field

Natalia Bozena Zawada
Department of Clinical Endocrinology, Medical University of Lodz, Lodz, Poland.

Introduction
Surgery remains the first-line treatment of clinically non-functioning pituitary adenomas (NFPA). However, the presence of somatostatin receptors (SSTR) in these tumours forms the basis of clinical use of somatostatin analogues (SSA). Visualisation of SSTR in scintigraphy is compulsory to introduce SSA therapy in NFPA.
Aim
To assess the effectiveness of long-term somatostatin analogues treatment on tumour volume and visual field in patients with NFPA.
Material and methods
Twenty five patients with diagnosed NFPA and strong expression of SSTR in scintigraphy were enrolled in the study. Patients were divided into 2 subgroups: subgroup A, which comprises 8 patients treated with SSA in primary therapy and subgroup B including 17 patients treated with SSA after incomplete surgery. All patients received octreotide LAR 20 mg or lanreotide 120 mg every four weeks and the duration of therapy varied from 7 months to 14 years. Patient's condition, tumour size, visual field and undesirable effects were evaluated in the study.
Results
Almost 70% of patients felt clinical improvement in headaches, which occurred less frequently and were less intense. Stabilisation of tumour size was achieved in 60% of patients. Reduction of tumour volume was only observed in patients treated with SSA as adjuvant therapy after incomplete surgery (23.5% of subgroup B). Adenoma shrinkage was not always associated with improvement in the visual field. Tumour progression was noted with similar frequency in both subgroups (25% subgroup A vs. 23.5% subgroup B). Tumour enlargement correlated with deterioration of visual field. Moreover, an increase of adenoma size was observed within first 2 years of the therapy, while tumour shrinkage occurred 3–5 years after introduction of SSA treatment. SSA were well-tolerated and only four patients developed asymptomatic cholelithiasis during the pharmacotherapy.
Conclusion
SSA are effective in both primary and secondary therapy of NFPA. Long-term treatment with SSA results in stabilisation of tumour size in the majority of cases. SSA therapy should be considered in postoperative treatment of NFPA as tumour shrinkage may be observed in some cases.

Therapeutic results of growth hormone substitution in children monitored for a growth hormone deficiency: about a Tunisian population

Najoua Lassoued, Selmane Ouannes, Bahri Mahjoub, Habib Soua, Hechmi Ben Hammouda, Raoudha Boussoffara & Mohamed Taher Sfar
Pediatric Department, Taher Sfar University Hospital, Mahdia, Tunisia.

Introduction
Many problems hinder the diagnostic and therapeutic approach of growth hormone deficiency (GHD) in developing countries. The lack of early diagnosis and adequate treatment have adverse consequences, especially the small final height with the resulting psychological impact. Our study examined 40 cases of GHD who received treatment by recombinant human Growth Hormone (rhGH).
Patients and methods
This is a retrospective longitudinal study of 40 cases of GHD collected in the pediatric department of Mahdia between 1994 and 2014.
Results
The mean chronologiacal age (CA) at the start of treatment was 9.91 ± 0.55 years with an average processing times of 10.37 ± 1.99 months. The mean duration of treatment for all patients was 3.3 ± 0.3 years. At the time of this study, 60% of patients (group A) still received rhGH, 17.5% of patients (group B) defaulted from follow-up and 22.5% of patients (group C) completed their course of rhGH after an average treatment duration of 3.95 ± 0.91 years. Among these patients (group C), four had a 15 year bone age, two had reached their mid-parental height (MPH), one patient had a growth height less than 2 cm/year, and one patient received treatment for only 12 months because of medical insurance problems. The final height (after treatment completion for group C and at the last check up for group B and A) was between -2 s.d. and the mean height in 54.2% of patients

in group A, in 57.2% of patients in group B and in 66.7% of patients in group C. This corresponds to a height outcome of 0.95 s.d. ±0.14 in group A, 0.71 s.d. ± 0.42 in group B and 1.33 s.d. ±0.23 in group C. Thirty-three point three percent of patients in group C were able to reach their MPH. There were a strong correlation between the height outcome and the mean duration of treatment, the CA at the start of treatment and the height at the start of treatment. This implies earli diagnosis, early treatment and a regular follow-up.
Conclusion
The initial approach to rhGH substitution focused on growth only and ended once adult height was reached. But monitoring children with GHD has revealed the need to define the factors that predict the persistence of this deficit in adulthood and the need to continue the treatment.

GH deficiency in children

Najoua Lassoued, Selmen Ouannes, Bahri Mahjoub, Hechmi Ben Hammouda, Habib Soua, Raoudha Boussoffara & Mohamed Taher Sfar
Pediatric Department, Taher Sfar University Hospital, Mahdia, Tunisia.

Introduction
GH deficiency (GHD) is a rare etiology of late growth. Its exact prevalence is unknown in emerging countries such as Tunisia. Despite a very suggestive clinical presentation, the diagnosis of GHD remains difficult and relatively late in some patients. Our study examined 40 cases of GHD in the Sahel region of Tunisia.
Patients and methods
This is a retrospective longitudinal study of 40 cases of GHD collected in the pediatric department of Mahdia between 1994 and 2014.
Results
The mean age at diagnosis was 8.31±0.56 years with a sex ratio of 2.07. The mean height at the first visit was 111.38±2.99 cm. The mean bone age (BA) at the time of diagnosis was 5.12±0.5 years. The delay of BA over the chronological age was of 3.41±0.38 yearson average. the diagnosis of total GHD was found in 65% of patients and partial GHD in 35% of patients. Magnetic resonance imaging of the hypothalamic-pituitary region was normal in 60% of patients. Pituitary stalk interruption was observed in 10% of patients, an empty sella was observed in 7.5% of patients, a pituitary hypoplasia was observed in 5% of patients and a posterior pituitary ectopia was found in 5% of patients. The karyotype was only done in 6 patients. Five patients had a normal karyotype 46,XX and only one patient had a karyotype 46,Xi(Xq). The association of Turner syndrome and GHD has already been reported in the literature. Three patients had pubertal delay at the time of diagnosis. The diagnosis of simple pubertal delay was retained in two of them, while it was very likely a pubertal delay secondary to hypogonadotropic hypogonadism in the third.
Conclusion
Despite a very evocative clinical picture, the diagnosis of GHd remains difficult and relatively late in some patients. This delay is explained by the lack of knowledge of the pathology and by the absence of anthropometric monitoring.

Re-evaluation of GH secretion during the transition age in patients with childhood-onset isolated GH deficiency (IGHD) after GH therapy (GHRx)

Sofia Leka-Emiri[1], Stefanos Stergiotis[1], Vasilios Petrou[1], Maria Kafetzi[2], Petychaki Fotini[1], Vlachopapadopoulou Elpis-Athina[1] & Stefanos Michalacos[1]
[1]Endocrine Division, P&A Kyriakou Children'S Hospital, Athens, Greece; [2]Biochemistry – Hormonology, P&A Kyriakou Children'S Hospital, Athens, Greece.

Objectives
GH in addition to promote linear growth during childhood influences several key metabolic processes as well. In the transition period, from late adolescence to early adulthood, GH plays an important role in skeletal mineralization and muscle mass maturation as well as in developing a favorable cardiometabolic profile. Therefore, several lines of evidence propose GH replacement to be continued if GH evaluation at the transition age fulfills established criteria. The aim of this study was to evaluate GH secretion of patients with childhood-onset isolated GH deficiency (IGHD) at transition age.
Methods
Twenty two patients with childhood-onset IGHD [15 males; age 16.1 years (±1.4)] were re-evaluated for GH secretion (using clonidine or glucagon stimulation test) and a GH peak <5 ng/ml was used for the diagnosis of GHD at the transition phase at least four weeks after discontinuation of therapy.
Results
Seven patients out of twenty two with childhood-onset IGHD [5 males; age 16.5 years (±1.6)] (31.8%) were GHD at retesting. Main characteristics of IGHD patients at diagnosis and IGHD or GH-sufficient (GHS) patients at the end of GHRx are shown in Table 1.

Table 1

Characteristics of the patients*	IGHD at diagnosis (n=22)	IGHD in transition (n=7)	GHS in transition (15)
Age at diagnosis (years)	9.6 (2.8)	8.6 (3.1)	10.1 (2.6)
Sex (M: F)	15:7	5:2	10:5
Height (cm)	127.9 (13.1)	120.5 (12.3)	131.5 (13.1)
Target height (cm)	166.6 (6.8)	167.9 (6.7)	166.1 (7.1)
GH peaks at diagnosis 1st test	5.79 (2.7)	6.3 (2.6)	5.5 (2.8)
2nd test	5.12 (2.5)	5.1 (2.3)	5.1 (2,6)
< 5 ng/ml	1st test: 10 2nd test: 9	7	0
5–10 ng/ml	1st test: 12 2nd test: 13	0	11
>10 ng/ml		0	4
Age at the GH re-evaluation (years)	16.1 (1.4)	16.5 (1.6)	15.9 (1.3)
GH peak at the end of GHRx (ng/ml)	7.3 (3.8)	2.8 (1.4)	9.3 (2.6)
Height at the end of GHRx (cm)	162.8 (9)	163.4 (11.7)	162.5 (8.1)

*Values are means ±s.d.

Conclusions
This study demonstrates that one third of childhood - onset IGHD persists during the transition period. Discontinuation of GH therapy may have unfavorable outcome regarding bone density, body composition and lipid profile. Substitution therapy with appropriate adult dosing should be considered.

Maternal uniparental disomy of the chromosome 14: a case report of mosaicism

Anna Tortora, Mario Vitale & Domenico La Sala
University of Salerno, Salerno, Italy.

UPD is a congenital disease characterized by the presence of two homologous chromosomes inherited from one parent in a diploid offspring. Its effects can be dramatic when the expression of essential genes is lacking. This is due to a phenomenon known as *genomic imprinting* where only one of the two chromosomal copies is active, depending on the parent of origin. Maternal uniparental disomy of the chromosome 14 (UPD 14 mat) is a rare disorder characterized by prenatal and postnatal growth retardation, neonatal hypotonia, feeding difficulty, motor development delay, mild to moderate intellectual disability, mild facial dysmorphism, truncal obesity, small hands and feet, short stature and precocious puberty. Here we report a case of mosaic UPD(14)mat. G.N. is a girl born to a healthy mother with negative family history for genetic diseases. She was delivered at 37 weeks. Birth weight was at 20th centile, height at 18th centile. She displayed feeding difficulty and week sucking, hypotonia, micrognathia, low-set ears, hypertelorism, open foramen ovale, agenesis of the left hand. At the age of one year she practiced genetic examination with evidence of mosaicism 47XX+mar/46XX; so, she was diagnosed with UPD 14 mat. At the age of 6 years, she came to our Clinic for precocious puberty and growth rate reduction (−2 SD). Height was at 25th centile, weight at 3th centile, Tanner stage B2PH3. She presented with normal motor development and intellectual ability. Her physical features were normal; her craniofacial features included minimal ocular hypertelorism and slightly depressed nasal bridge. ECG, ultrasound thyroid and abdominal examinations were normal. The uterus had normal length and ovaries multiple sub-centimetric follicles. Bone age was 7 years. MRI displayed a normal pituitary gland. All the following hormones were in the normal range for gender and age: LH, FSH, 17BEstradiol, Testosterone, TSH, IGF-1. Tests by Arginine and Clonidine showed a pathological GH peak value while GnRH test demonstrated a puberal peak values of gonadotropins; so the patient was diagnosed with growth hormone deficiency (GHD) and precocious puberty.Therapy with Triptorelin and rhGH was prescribed. After six months,

therapeutic efficacy was confirmed because the patient's height increased by 5.5 cm and there was no progress of her secondary sexual characteristics. This is the first case described in UPD (14) mat in the form of a mosaic. Mosaicism limited the clinical features while some somatic defects and endocrinological disorders persisted. Therapy applied was effective at control after one year.

Final height in cancer survivors undergoing treatment with somatotropin

Catarina de Oliveira Pereira, Joana Serra Caetano, Alice Carvalho, Manuel Brito, Rita Cardoso, Isabel Dinis & Alice Mirante
Hospital Pediátrico – Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal.

Somatotropin is essential not only for linear growth but also for important metabolic functions. Its deficiency is usually the first and most common endocrinopathy induced by cancer disease and its treatments, mainly cranial irradiation. Although somatotropin replacement therapy is safe and effective in promoting a better linear growth, studies of final height in childhood cancer survivors treated with somatotropin are limited. This study was performed to examine growth outcomes in these patients. A retrospective analysis was performed, through consultation of the clinical processes. We included all childhood cancer survivors treated with somatotropin in a pediatric endocrinology department, between 1988 and 2016. Statistical analysis was performed using SPSS v24. Were included 28 cancer survivors, 64.3% male. The median age at cancer diagnosis was 5.6 years and 60.7% had central nervous system tumors; 60.7% undertook surgery, 71.4% radiotherapy and 67.9% chemotherapy. Only 42.9% had IGF1 more than 2 SDS below the mean, being the most frequent criteria to investigate somatotropin deficiency the height velocity more than 3 SDS below the mean. There were concomitant endocrinopathies in 50% of patients. Somatotropin treatment was started at a median of 11.3 years. The initial height was -2.14 SDS and increased to -1.81 SDS by 1 year, -1.68 SDS by 2 years, and -1.56 SDS by 3 years with somatotropin treatment. There were differences between the initial height and by 1 year ($P<0.001$), by 1 and 2 years ($P=0.006$) and between initial and final height ($P=0.025$). Despite that, this patients' adult height was significantly lower than the midparental height ($P=0.006$). The body mass index decreased, significantly in the first year of treatment ($P=0.002$). The initial IGF1 concentration was -2.02 SDS and increased significantly to 0.93 SDS by 1 year ($P<0.001$). The differences between chronological and bone age decreased throughout the treatment with a significant difference between the beginning and the third year of treatment ($P=0.047$). Median treatment duration was 4.0 years (min 6 months, max 11 years). Difference between adult height and midparental height was not associated with gender, group of tumor, concomitant endocrinopathies, age or puberty stage at beginning. We concluded that the improvement of linear growth was significant, mainly in the first year of treatment, but these patients did not achieve their genetic potential for height. The physicians must be aware and search for this endocrinopathy in this group of patients and treatment should be started as soon as possible.

*Equal contribution.

Introduction
Pregnancy in hypopituitary women is a rare and poorly studied clinical condition. Management difficulties and obstetrical complications have been associated with this condition.

Objectives
To define the characteristics, follow-up and perinatal outcomes in hypopituitary pregnant women attended at our centre.
Methods
The clinical data of the hypopituitary pregnant women (deficiency of two or more pituitary hormones), and details on delivery and the newborn are collected prospectively. Here we present eight pregnancies in seven women who had been diagnosed with hypopituitarism before pregnancy.
Results
The median age of the patients was 35 years; hypopituitarism had been diagnosed a mean of 19.5 years prior to pregnancy. The cause of hypopituitarism was pituitary agenesis in two patients, macroprolactinoma in another 2, 1 corticotroph adenoma, 1 hypophysitis, 1 empty sella and 1 granular cell tumour. All pituitary tumours had undergone surgery, but none had received radiotherapy. At the beginning of pregnancy, no patient presented hormonal hypersecretion. There were 7 GH and GnRH deficits, 6 of TSH, 3 of ACTH and 2 of ADH. Five women with GH deficiency had received GH substitution therapy. Six women required assisted reproduction techniques (4 controlled ovarian stimulation, 1 intrauterine insemination, 1 *in vitro* fertilization). During pregnancy, GH replacement was stopped, hydrocortisone dose was maintained, whereas levothyroxine and desmopressin doses were increased. One patient developed *de novo* diabetes insipidus. No acute complications were identified. Gestational age at birth ranged from 36^+ to 42^+ weeks; five patients required labour induction. Delivery was by caesarean section in five cases and vaginal in 3. No foetal distress occurred. Average weight of the newborns (five girls, three boys) was 3200 g and the 5 min Apgar score was 9. No relevant perinatal complications were observed. Four patients experienced a milk surge.
Conclusion
The perinatal outcome of this group of patients with hypopituitarism was satisfactory. It is important to keep in mind the possibility of *de novo* hormonal deficiencies during pregnancy.

Functional analysis of aryl hydrocarbon receptor (AHR) polymorphisms in pituitary adenomas (PAs) in the presence of 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD)

Jessica Debattista, Robert Formosa & Josanne Vassallo
University of Malta, Imsida, Malta.

Background
PAs are the most frequent pituitary neoplasms, however molecular pathogenesis is largely unknown. The AHR is a ligand-activated transcription factor that regulates expression of various genes that mediate cellular response to xenobiotics. The exact functional role of two AHR single nucleotide polymorphisms (SNPs); Arginine554Lysine (Arg554Lys) and Valine570Isoleucine (Val570Ile) has not yet been established, however studies suggest that these mutations might increase risk of developing PAs. To date, functional analysis of regarding the significance of these AHR SNPs in pituitary pathophysiology has never been analysed.
Aims
- Elucidate the effect of wildtype and polymorphic AHR on GH3 cell proliferation and on AHR-transcriptional response in the presence and absence of TCDD.
- Determine the allele frequency of the most common AHR SNP; the Arg554Lys in PA patients and in a small cohort of the Maltese population.

Method
The two missense mutations were introduced within the AHR-expressing vector and transfected in GH3 cells by magnetofaction, followed by the exposure to TCDD. Cell viability of GH3 transfected cells was measured using the MTT assay. Functional analysis of GH3 transfected cells treated with TCDD was carried out using luciferase assay and real-time PCR to detect and quantify the AHR-transcriptional activity. Genotyping of the Arg554Lys was performed on PA patients and neonatal controls using allele specific PCR. The Mann-Whitney test was used to compare two groups and Kruskall-Wallis test was used to compare three groups or more.
Results
In the absence and presence of low TCDD concentrations (1 and 10 nM), overexpression of wildtype AHR (wtAHR) did not affect GH3 cell proliferation. GH3 cells transfected with the AHR mutants did not exhibit any significant differences in their proliferative ability when compared with the wtAHR, both in the presence and absence of TCDD. Luciferase reporter analysis showed that there was a significant difference between the treated and untreated wtAHR ($P=0.016$), however this difference was not observed between the treated and untreated AHR mutants. Statistically significant difference in *Cyp1a1* gene expression analysis

was detected between the treated and untreated wtAHR ($P=0.021$), Arg554Lys ($P=0.005$) and Val570Ile ($P=0.054$). Genotyping of the Arg554Lys in patients with PA gave a minor allele frequency (MAF) of 3% vs 0% in neonatal controls.
Conclusion
Gene expression and quantification analyses of AHR-target genes suggests that these AHR mutants might interfere with AHR target gene expression. Genotyping results suggested that this mutation is quite rare and may be similar to the frequencies of other European populations.

Comparative differential effects of secretagogues upon regulation of pituitary GH in several vertebrates

Valeria Alejandra Urban Sosa[1], José Ávila Mendoza[2], Martha Carranza Salas[1], Carlos Guillermo Martínez Moreno[1], Maricela Luna Muñoz[1] & Carlos Arámburo[1]
[1]Universidad Nacional Autónoma de México, Instituto de Neurobiología, Querétaro, Mexico; [2]University of Michigan, Ann Arbor, USA.

It is known that the synthesis and release of pituitary GH is controlled by complex neuroendocrine mechanisms that involve several neuropeptides, such as GHRH, SST, PACAP, TRH, GnRH, Ghrelin, among other regulators. Previous reports indicate that, during vertebrate evolution, the potency and efficacy of these secretagogues may vary and play differential effects upon GH regulation. In this work we aimed to study, *in vitro*, the capacity of these peptides to control the expression and secretion of pituitary GH in three vertebrate models: rat (mammals), chicken (birds) and iguana (reptiles), employing pituitary cultures at different incubation periods (0–6 h) and two doses of the secretagogues (1 and 10 nM). Results showed that GHRH significantly stimulated GH mRNA expression as well as GH secretion in the three species within the first hour of incubation, in comparison to the controls. However, its effect upon GH mRNA was 60 times greater in iguana than in the other species. TRH had no effect on GH secretion in any incubation period, but it stimulated GH mRNA expression in all species and, in the case of iguana, its effect was 150 times higher than in the others. PACAP stimulated GH mRNA expression at 4 h in chicken pituitary cultures, whereas no significant differences were observed in rats and iguanas. Ghrelin increased GH secretion in chickens, but had no effect in its mRNA synthesis, contrary to what was found in iguana cultures where GH mRNA significantly diminished. GnRH stimulated both GH mRNA expression and GH release in chicken pituitary cultures, while in iguana only GH secretion was significantly increased. On the other hand, SST strongly inhibited GH mRNA expression and GH release in the iguana, while no significant effect was directly observed in rats and chickens, at the doses and time-frame conditions employed. Results indicate that there is a differential effect of these secretagogues upon GH synthesis and secretion during vertebrate evolution, and further studies are needed to understand how these mechanisms have evolved.

Next generation sequencing for characterization of mitochondrial genome in pituitary adenomas

Kinga Németh[1], Ottó Darvasi[2], István Likó[2], Nikolette Szücs[1], Sándor Czirják[3], Lilla Reiniger[4], Borbála Szabó[5], Péter Igaz[1], Attila Patócs[2,5] & Henriett Butz[2,5]
[1]2nd Department of Medicine, Faculty of Medicine, Semmelweis University, Budapest, Hungary; [2]MTA-SE 'Lendulet' Hereditary Endocrine Tumors Research Group, Hungarian Academy of Sciences and Semmelweis University, Budapest, Hungary; [3]National Institute of Clinical Neurosciences, Budapest, Hungary; [4]1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary; [5]Department of Laboratory Medicine, Semmelweis University, Budapest, Hungary.

Introduction
Disrupted mitochondrial functions and genetic variations of mitochondrial DNA (mtDNA) have been observed in different tumors. Regarding pituitary adenomas mtDNA was evaluated only in oncocytic type using PCR based methods and it showed high prevalence of Complex I variants. Next generation sequencing (NGS) allows high throughput sequencing and it is useful for accurate identification of heteroplasmy of mitochondrial genome as well.
Aim
We aimed to investigate the entire mitochondrial genome in different adenoma types.
Material and methods
We collected 22 gonadotroph (GO), 11 GH producing (GH) and 11 null-cell (NC) adenoma specimens from samples removed by transsphenoidal surgery. From fresh frozen tissues DNA extraction was performed using QIAamp Fast DNA Tissue Kit. For library preparation VariantPro Amplicon Mitochondrion Panel kit was used. The total mtDNA (16569 bp) was sequenced on Illumina MiSeq Instrument. Following complex bioinformatic analysis Revised Cambridge Reference Sequence (rCRS) of the human mitochondrial DNA was used as reference. Heteroplasmy was determined using 3% cutoff.
Results
The whole mitochondrial genome were covered by 630 ± 370 (avg $\pm$ S.E.) reads per base. 496 variants were identified in adenomas compared to reference sequence. Overall a low (7.22%) heteroplasmy prevalence was found. Based on mitochondrial sequence variants by hierarchical cluster analysis we could not discriminate different adenoma types. No association between Ki-67 index or recurrent-nonrecurrent status of adenomas and mitochondrial variants were detected. Four variants appeared more often in null-cell adenomas compared to gonadotroph adenomas (chrM_188: 18% vs 0%, chrM_16093: 18% vs 0%, chrM_185: 27% vs 0% and chrM_14798: 36% vs 5%; Padj = 0.0246, 0.0246, 0.01542 and 0.01829, respectively). Of these variants chrM_14798, chrM_4216 and chrM_15452 are non-synonymous polymorphisms leading to amino acid change in MT-CYB (mitochondrially encoded cytochrome b) and in MT-ND1 (mitochondrially encoded NADH dehydrogenase 1) genes. We identified chrM_16189 variant (non-protein coding variant) in 40% (6/15) of nonrecurrent adenomas compared to recurrent ones where this variant was not present (0/11) ($P=0.0209$).
Conclusions
Next-generation sequencing is a reliable method for investigating mitochondrial genome and heteroplasmy in pituitary adenomas. In pituitary adenomas the prevalence of heteroplasmy of mitochondrial genome is low suggesting that these alterations may not influence mitochondrial function considerably. Of pituitary tumours only null cell adenomas possess alterations of mitochondrial genome with potential functional consequences suggesting that during the development of this subtype of pituitary tumours mitochondrial function-associated mechanisms may have role.

Pituitary cell activation and recruitment in hipothyroidism

Fernando Oroz, Montserrat García-Lavandeira, Sihara Pérez-Romero, Ángela García-Rendueles & Clara V Álvarez
Center for Research in Molecular Medicine and Chronic Diseases (CiMUS), Santiago de Compostela, Spain.

Pituitary stem cells have been characterized in the postnatal pituitary. We now know they are organized in a niche and co-express specific markers such as Sox2, Sox9 or Gfra2. Although many studies by our group and others have been dedicated to its characterization *in situ* it is under discussion their role in the maintenance and turnover of the pituitary in physiological conditions or physiological pituitary challenges. It's not known if the stem cells are required and which molecular mechanisms are implicated in recruitment/differentiation. We established a model of hypothyroidism in rodents similar to human conditions in which levels of thyroxine are maintained just below the lower normal cut-off. We studied pituitary extracts in a precise time-course for stem cell and differentiation markers of thyrotropes. We have found that Shh is increased immediately after the establishing of the hypothyroidism. Following this, we purified the Gfra2+ stem cell population from vehicle and short-term hypothyroid animals and grown them as spheres in absence of serum. Spheres grow during the days of culture duplicating from day 1 to day 5 when they reach a plateau. Gfra2+ cells obtained from hypothyroid animals produce a significantly higher level of spheres per well both at day 1 and at day 5. When cultured in presence of cyclopamine, a Shh inhibitor, the number of spheres is significantly reduced in the hypothyroid Gfra2+ but not in the control wells. We used immunofluorescence techniques to see what happen in the intact pituitary niche in vivo. A genetic mouse model of tracing where Gfra2/Sox2 positive cells are induced to express GFP long-term after the tamoxifen injection was followed in a time-course under the same conditions of above vehicle/hypothyroidism. There was a significant increase of the Sox2 positive cell in long-term hypothyroid mice compared with vehicle treated. Tracing the GFP+ population through a time-course, we detected a significant increase in the double GFP/TSH+ cells in the adenopituitary of hypothyroid mice compared to vehicle treated. This data confirm that Sox2 positive cells recruited from the pituitary niche are able to

differentiate into TSH producing cells. In summary, our results indicate that the Gfra2/Sox2 population, the pituitary stem cells, are activated when a mild hypothyroidism is induced. Results *in vitro* and *in vivo* confirm that initially (short-term hypothyroidism) the stem cells are driven to proliferate and expand while later (long-term hypothyroidism) differentiate into thyrotropes.

SOM230 exerts anti-proliferative actions by reducing phospho-ERK1/2 levels in ACTH-secreting pituitary tumour cells

Donatella Treppiedi, Erika Peverelli, Elena Giardino, Rosa Catalano, Federica Mangili, Maura Arosio & Giovanna Mantovani
Endocrine Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico; Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy.

Currently, the multi-ligand somatostatin (SS) analogue pasireotide (SOM230) is the only pituitary-targeted drug used to treat patients with Cushing's disease. SOM230 displays the highest affinity to somatostatin receptor type 5 (SSTR5) and compared to octreotide resulted more effective in reducing ACTH release. Despite its anti-secretory role, SOM230 has been associated with tumor shrinkage in patients subjected to long term treatment, although to date the key factors involved are poor elucidated. The present work aimed to investigate the molecular mechanisms implicated in SOM230-induced cytostatic and cytotoxic effects in ACTH-secreting primary tumour cultures and murine corticotroph tumour cells line, AtT-20. First, by western blot we found SSTR5 expressed at comparable levels in 17 different ACTH-secreting pituitary samples, whereas SSTR2 was detectable in 15 out of 17 tissues. SSTR5 and SSTR2 were expressed in AtT-20 cells. Then, we tested the effect of 96h stimulation with 1 μM SOM230 on cell proliferation in 6 different ACTH-secreting tumors by measuring 5-bromo-20-deoxyuridine incorporation during DNA synthesis. We found a significant *in vitro* suppression of cell growth in half of the analyzed samples ($-12.1 \pm 4.3\%$, $P<0.01$). Accordingly, SOM230 significantly inhibited cell growth in a dose-dependent manner in AtT-20 cells ($-10.5 \pm 7.7\%$ at 10 nM, $P<0.05$; $-3.9 \pm 10.9\%$ at 100nM, $P<0.05$; $-26.8 \pm 8.9\%$ at 1 μM, $P<0.01$), whilst octreotide was effective only at 1 μM ($-13.3 \pm 9.1\%$, $P<0.05$). To investigate whether direct antiproliferative actions SOM230-mediated might involve MAPK and cyclins pathways, we evaluated the expression level of phospho-ERK1/2 and CD1 in ACTH-secreting primary cultures exposed to 1 μM of SOM230. SOM230 reduced phospho-ERK1/2 levels in 5 of 8 tumours tested ($-36.4 \pm 20.5\%$, $P<0.01$), whereas no significant difference was found in CD1 expression levels in 3 tumours. These data were further confirmed in AtT-20 cells, where octreotide did not have any effect. Furthermore, we found that 48h incubation with 1 μM SOM230 was able to induce a significant increase of caspase 3/7 activity in 2 of 4 ACTH-secreting primary cultures ($17 \pm 3.6\%$, $P<0.05$). Altogether these data suggest a downstream implication of phospho-ERK1/2 inhibition in ACTH-secreting pituitary tumour cells by SOM230 resulting in cell proliferation suppression and indicating that broader-spectrum SS analogues may play a crucial role in the treatment of tumours where the MAPK pathway is overactivated. Moreover, we describe a pro-apoptotic effect of SOM230. Ongoing experiments are aimed to discriminate the specificity effects played by SSTR5 and SSTR2.

Factors associated with SF1 gene expression in clinically non-functioning pituitary adenomas

Michela Anna Polidoro[1], Roberta Morace[2], Antonietta Arcella[2], Vincenzo Esposito[2,3], Felice Giangaspero[2,4] & Marie-Lise Jaffrain-Rea[1,2]
[1]Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, L'Aquila, Italy; [2]Neuromed, IRCCS, Pozzilli, Italy; [3]Neurosurgery, University La Sapienza, Rome, Italy; [4]Pathology, University La Sapienza, Rome, Italy.

Clinically non-functioning pituitary adenomas (NFPAs) are a heterogenous group of tumours including silent secreting (somatotroph, corticotroph, rarely lactotroph), as well as gonadotroph (Gn-PA) and null cell (nc-PA) adenomas. These are usually identified by immunostaining for pituitary hormones, though an increasing role for pituitary transcription factors is being recognized for the identification of pituitary cell lineage. The *Steroidogenic Factor 1* (SF1) is involved in gonadotroph differentiation. In addition to Gn-PA, most nc-PA are currently believed to be of gonadotroph origin. SF1 also plays a role in adrenal development and overexperession of SF1 has been reported in adrenocortical tumours.

Aim of the study

To identify factors associated with SF1 gene expression in NFPA.

Material and methods

Twenty-nine NFPA (23 Gn-PA, 6 nc-PA) were selected for SF1 semi-quantitative gene expression by Real-Time RT-PCR analysis after preliminary RT-PCR for Tpit and Pit-1 gene expression, in order to exclude normal pituitary contamination and tumours arising from other pituitary cell lineages. RNA was extracted from surgical samples placed in a RNA later solution before freezing at $-80°C$ until processing. Genes encoding βFSH, βLH, Cyclin D1, Cyclin B1, Caspase 3, Aryl hydrocarbon Interacting protein (AIP) and the dopamine 2 receptor (D2R) were also measured semi-quantitatively. Beta-actin was used as a house-keeping gene. Non-parametric statistical analysis was performed using Wilcoxon and Spearman tests.

Results

SF1 gene expression was significantly higher in Gn-PA than in nc-PA ($P=0.0166$), with no difference between male ($n=20$) and female ($n=9$) tumours. No significant variations in SF1 was found according to tumour invasiveness, maximal tumor diameter, Ki67 index, Cyclin B1, Cyclin D1 or caspase 3 expression. SF1 was strongly correlated with βLH expression ($n=0.77$, $P<0.0001$ in the whole series, $n=0.71$, $P=0.0001$ in Gn-PA) whereas correlations with βFSH only approached significance ($n=0.37$, $P=0.0502$ in the whole series, $P=$ns in Gn-PA). A positive correlation was also observed between SF1 and AIP ($r=0.52$, $P=0.0038$ in the whole series, $n=0.47$, $P=0.023$ in Gn-PA) and in particular with D2R expression ($n=0.67$, $P<0.0001$ in the whole series, $n=0.56$, $P=0.007$ in Gn-PA).

Conclusion

SF1 is a marker of gonadotroph differentiation in NFPA and its expression is significantly correlated with βLH, AIP and D2R. In contrast, it does not appear to be influenced by patients gender or by tumour volume or aggressiveness. The potential implications of SF1 expression in NPFA should be further evaluated.

Corticotroph pituitary adenomas: the functioning vs the silent: a gene expression study comparing differentially expressed genes in the regulation of POMC

Kjersti Ringvoll Normann[1,2,3], Arvind Sundaram[4], Kristin Astrid Berland Øystese[1,2], Tove Lekva[3], Alexander Eieland[1], Jens Bollerslev[1,2] & Nicoleta Cristina Olarescu[1,3]
[1]Section of Specialized Endocrinology, Department of Endocrinology, Oslo University Hospital, Oslo, Norway; [2]Faculty of Medicine, University of Oslo, Oslo, Norway; [3]Research Institute for Internal Medicine, Oslo University Hospital, Oslo, Norway; [4]Department of Medical Genetics, Oslo University Hospital, Oslo, Norway.

Background

The exact mechanism behind the hypersecretion of ACTH and lack of negative cortisol feedback on POMC regulation in functional corticotroph adenomas (FCA) is unknown. Silent corticotroph adenomas (SCA) express, but do not secrete functional ACTH and have lower POMC expression. Using RT-qPCR and immunohistochemistry, previous studies have identified some POMC-transcription factors, regulators and processing enzymes to be differentially expressed between FCA and SCA. For example, several G protein-coupled receptor (GPCR) molecules synergistically affect POMC downstream signalling and increase its expression. Also, some GTPases regulating intracellular vesicle trafficking, separately and cooperatively stimulate ACTH secretion in AtT20 cells.

Aim

To investigate differentially expressed genes (DEGs) between FCA and SCA with focus on POMC-expression regulators such as GPCR signalling and intracellular vesicle trafficking and to elucidate the mechanisms behind the SCA silence.

Material and methods

RNA sequencing was performed using Illumina high-throughput sequencing in six FCA (three women, five microadenomas) and six SCA (two women, all macroadenomas). All adenomas stained positive for ACTH. Data were analysed using the tophat 2- cufflinks-CummeRbund pipeline.

Results
We found 631 significant DEGs (fold change (FC) > 1.9, q < 0.05) of which 345 were up-regulated and 286 were down-regulated in SCA compared to FCA. As expected, POMC (FC = 33.3) and POMC transcription factors NUR77 (FC = 6.8) and TBX19 (FC = 3.8) had lower expression in SCA. PCSK2 (FC = 18.3), a POMC processing enzyme, was up-regulated in SCA. Reactome pathway analysis categorized 79 DEGs involved in 'signal transduction' including 12 up-regulated and 16 down-regulated in GPCR signalling. Among these, EDN3 (FC = 190.6), RGS16 (FC = 19.1), GNAS (FC = 2.3), were up-regulated, GNG2 (FC = 3.9), ADCY5 (FC = 5.0), GRK3 (FC = 2.8), MAPK1 (FC = 2.3), and RASGRF2 (FC = 5.9) were down-regulated in FCA compared to SCA. There were 24 DEGs found to be involved in 'vesicle transport'. Among these, RAB8B (FC = 2.7), RAB3C (FC = 2.6) and RAB3GAP1 (FC = 2.4) had lower expression, whereas ALS2CL (FC = 4.1) and TRIP8B (FC = 2.8) had higher expression in FCA compared to SCA.
Conclusion
RNA-seq. analysis showed that the FCA and SCA separate in two groups with a high number of DEGs. Lower POMC- and higher PCSK2 expression in SCA could explain the diminished ACTH production. Interestingly, the opposite regulation of RAB8B and TRIP8B suggests that they have different stimulatory effect on ACTH secretion. Several regulators of GPCR signalling and vesicle transport molecules were found to be differentially expressed and investigating their mechanism of action in further *in vitro* studies will increase our understanding on POMC regulation and may yield valuable knowledge for drug development.

CGH array analysis of pituitary tumors revealed a highly-disrupted genome

Hélène Lasolle[1,2], Mad-Hélénie Elsensohn[3], Eudeline Alix[1], Clément Bonnefille[1], Jessica Michel[1], Claire Bardel[1,2], Pascal Roy[2,3], Damien Sanlaville[1,2] & Gérald Raverot[1,2]
[1]Hospices Civils de Lyon, Bron, France; [2]Université Lyon 1, Lyon, France; [3]Hospices Civils de Lyon, Lyon, France.

Introduction
Genetic of pituitary tumors (PT) is incompletely understood. The aim of this study was to search for somatic copy number variations (CNV) in pituitary tumors and evaluate their prognostic impact on tumor recurrence.
Methods
CGH array analysis (Agilent SurePrint G3 Human CGH + SNP Microarray 4× 180 K) was performed on 196 fresh-frozen PT (67 gonadotroph, 31 corticotroph, 38 prolactinomas, 60 somatotroph). PT were classified according to the five-tiered classification grading based on invasion on magnetic resonance imaging, immunocytochemical profile, Ki-67, mitotic index, and p53 positivity. ACGH data were analyzed after centralization, normalization and circular binary segmentation steps. Gains and losses were considered when Log2 ratio > 0.14 and < −0.15 respectively. Hierarchical clustering using Jaccard index was first performed considering altered vs unaltered probes. Effect of quantity of alterations on recurrence was then studied using logistic regression models.
Results
124 patients (63%) presented recurrence during the 5 years of follow-up. Most of PT were macro-adenomas (182) and 84 were invasive PT. Sex ratio males/females was 1.3:1. 84 PT (43%) presented a highly-disrupted genome (>5% of altered probes). Clustering could classify PT according to the tumor type: the cluster of PT with rare alterations gathered gonadotroph tumors together, while the cluster of PT with numerous alterations was heterogeneous and did not separate the prolactinomas from corticotroph and somatotroph PT. Indeed, the quantity of altered probes was higher in prolactinomas (median = 38% of probes, min = 0%, max = 96%) compared to other groups: corticotroph (median = 12%, min = 0%, max = 76%), somatotroph (median = 4%, min = 0%, max = 99%), and gonadotroph which presented rare alterations (median = 0%, min = 0%, max = 22%). Alterations in prolactinomas were preferentially gains (median = 35%, min = 0%, max = 96%) than deletions (median = 0%, min = 0%, max = 24%). When the whole cohort was considered, we were not able to identify a common alteration shared by the different types. We found that the quantity of alterations could not predict recurrence (P value = 0.52) whereas age at diagnosis and clinico-pathological grades could (P value = 0.0006, 0.0003 and 0.00007 for age, grade 2a and 2b respectively).
Conclusions
aCGH analysis of PT showed many CNV which could concern the entire genome in some prolactinomas or somatotroph tumors. The CNV occurrence was highly dependent on tumor type but did not predict recurrence within 5 years of follow-up. PT, except gonadotroph, are characterized by high genomic instability.

Treatment with antidiabetic biguanide drugs directly impacts the function of multiple pituitary cell types from two non-human primate models

Antonio J León-González[1,2,3,4], Mari C Vázquez-Borrego[1,2,3,4], Antonio C Fuentes-Fayos[1,2,3,4], Manuel D Gahete[1,2,3,4], Justo P Castaño[1,2,3,4], Rhonda D Kineman[5] & Raúl M Luque[1,2,3,4]
[1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), 14004, Córdoba, Spain; [2]Department of Cell Biology, Physiology and Immunology, University of Cordoba, 14004, Córdoba, Spain; [3]Reina Sofia University Hospital (HURS), 14004, Córdoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), 14004, Córdoba, Spain; [5]Research and Development Division, Jesse Brown Veterans Affairs Medical Center and, Department of Medicine, Section of Endocrinology, Diabetes, and Metabolism, University of Illinois at Chicago, Chicago, USA.

Antidiabetic biguanides, such as metformin (the most commonly prescribed drug to treat type 2 diabetes) and phenformin, are synthetic insulin-sensitizing agents. In addition to their well-known anti-hyperglycemic actions, biguanides are being also studied in other medical disorders due to the beneficial effects that they exert in important pathologies, including cardiovascular disease or different types of cancer. Although some scattered studies have suggested that metformin could modulate the production of pituitary hormones in certain pathological conditions, there are no previous reports describing the direct role that biguanides may play in the regulation of anterior pituitary cell types in the normal gland, especially in humans or primates. It is widely known that the pituitary gland is a master player in the control of body homeostasis and metabolism, owing to its ability to integrate multiple signals to modulate hormonal secretions that are involved in the control of key peripheral organs/tissues. Accordingly, this study was aimed to elucidate the direct effects of two biguanides (metformin and phenformin) on the expression and secretion of all pituitary hormones in two primate species (*Papio anubis* and *Macaca fascicularis)*, which closely model human physiology. Moreover, to better understand the mechanisms behind the putative actions of these biguanides, we used pharmacological inhibitors of various intracellular signalling-pathways. Metformin and phenformin inhibited basal GH, ACTH and FSH secretion in a dose-and time-dependent fashion, but did not alter PRL, LH or TSH secretion or ghrelin/GHRH-stimulated hormonal release. Moreover, metformin and phenformin also reduced GH and ACTH expression without altering that of other pituitary hormones (PRL/LH/FSH/TSH). Treatment with these biguanides did not affect normal pituitary cell viability. Interestingly, metformin and phenformin increased the expression of sst2, sst5, IGF1R, Ins-R and leptin-R in baboon primary pituitary cell cultures. Finally, we demonstrated that metformin requires PI3K, mTOR and intracellular Ca^{2+} pathways to exert its actions on the modulation of GH/ACTH/FSH secretion, but also MAPK-signalling in the case of GH modulation. Altogether, our results provide strong, primary evidence for the direct actions of biguanides in the control of normal pituitary cell function in two primate models. This information could be relevant for the current understanding of normal human pituitary function in patients treated with metformin, given the likely translation of the findings in primate models into human pathophysiology. Furthermore our results invite to explore potential therapeutic effects of these compounds in pituitary dysfunctions (i.e. somatotropinomas, corticotropinomas and gonadotropinomas).

Enhanced expression of the transcriptional activators YAP and TAZ in non-secreting pituitary tumours

Paraskevi Xekouki[1,2], Emily Lodge[2,3], Ran Li[4], Jörg Flitsch[5], Stefan Bornstein[3,6], Marily Theodoropoulou[7] & Cynthia Andoniadou[2,6]
[1]Department of Endocrinology, King's College London, London, UK; [2]Centre for Craniofacial and Regenerative Biology, King's College London, London, UK; [3]Department of Endocrinology and Diabetes, King's College London, London, UK; [4]Department of Neurosurgery, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Tongji, China; [5]Department of Neurosurgery, Hamburg University Medical Center, Hamburg, Germany; [6]Department of Internal Medicine III, Carl Gustav Carus Medical School, Technical University of Dresden, Dresden, Germany; [7]Medizinische Klinik und Poliklinik IV, Ludwig-Maximilians-Universität München, Munich, Germany.

The Hippo kinase cascade is a crucial signalling pathway regulating organ growth during development in numerous organs. There is mounting evidence implicating this signalling pathway in tumour formation, where it is emerging as an anti-cancer target due to effective pharmacological inhibition of its transcriptional activators YAP/TAZ. We previously demonstrated activity of the Hippo kinase cascade in the mouse pituitary and nuclear association of YAP/TAZ with SOX2 expressing pituitary stem cells. Here we sought to investigate whether these components are expressed in the human pituitary and if their expression may be deranged in human pituitary tumours. We analysed pathway component expression by immunofluorescence during human pituitary gland development, in the adult pituitary, null cell non-functioning pituitary adenomas (NFPAs), adamantinomatous craniopharyngiomas (ACPs), papillary craniopharyngiomas (PCPs) and prolactinomas. We find that the Hippo pathway is active during human pituitary development and adulthood and that YAP/TAZ are expressed in a similar pattern to SOX2 positive cells. Our data reveal an enrichment of YAP/TAZ in the majority of non-sereting tumours, in contrast to differentiated tumours, which display low or absent levels. To determine the effect of this pathway on endocrine cell type differentiation, we knocked down Lats1, encoding the kinase responsible for phosphorylating and inactivating YAP/TAZ, in the GH3 rat mammosomatotropinoma cells. Loss of LATS1 led to accumulation of both proteins and suppressed *Prl* and *Gh* promoter activity. In conclusion, we have demonstrated activity of the Hippo kinase cascade in the human pituitary and association of YAP/TAZ with the undifferentiated state both *in vitro* in GH3 cells and *in vivo* in the normal pituitary and pituitary tumours. Characterisation of this pathway in pituitary tumours is of potential prognostic value, opening up putative avenues for treatments combating tissue growth.

P787

Activation of pituitary stem cells through modulation of the LATS/YAP/TAZ cascade

Emily Lodge[1], John Russell[1], Alice Santambrogio[1,2], Paraskevi Xekouki[1], Stefan Bornstein[1,2] & Cynthia Andoniadou[1,2]
[1]King's College London, London, UK; [2]TU Dresden, Dresden, Germany.

Pituitary stem cells (PSCs) expressing SOX2 persist throughout life, giving rise to all pituitary endocrine lineages. These cells are highly active at early postnatal stages but this potential declines with age, rendering them mostly inactive in adulthood. The LATS/YAP/TAZ signaling cascade can influence stem cell fate and activity in multiple tissues and we previously identified activity of this axis in the developing and postnatal pituitary. Using a series of genetic manipulations, we aimed to establish the functional role of this axis in PSC regulation in mouse. Conditional deletion of LATS1 kinase in the pituitary is sufficient to lead to accumulation of YAP/TAZ and subsequent anterior pituitary tumour formation. These non-functioning tumours are mostly composed of SOX2 positive cells and display histological features of carcinomas. Genetic experiments targeting only the SOX2 population, identify pituitary stem cells as the cell of origin of the tumours. Conditional expression of a constitutive-active form of YAP in the pituitary does not lead to tumour formation, revealing that YAP alone is not sufficient to mediate this phenotype. However, it is sufficient to drive expansion of the SOX2 pituitary stem cell pool at postnatal stages and to reinstate their activation. Together, out data show a crucial role of the LATS/YAP/TAZ axis in regulation of the pituitary stem cell pool, an important step toward future regenerative approaches.

Sheehan's syndrome: clinical and laboratory evaluation of 80 cases

Emna Elfaleh, Ibtissem Oueslati, Melika Chihaoui, Meriem Yazidi, Fatma Chaker, Ons Rejeb & Hedia Slimane
Department of Endocrinology, La Rabta Hospital, Tunis, Tunisia.

Introduction
Sheehan's syndrome (SS) is defined as partial or complete hypopituitarism occurring due to massive postpartum uterine hemorrhage that leads to pituitary infarction. Patients with SS have varying degrees of anterior pituitary hormone deficiency. The aim of our study was to evaluate the clinical and hormonal characteristics of patients with SS.
Methods
Eighteen patients with SS were enrolled in a retrospective and descriptive study. Medical history, physical examination findings and hormonal profiles were documented and analyzed.
Results
The mean age of participants at diagnosis was 41.76 ± 11.31 years, with a mean diagnostic delay of 8.8 ± 8.01 years. Their past obstetric history showed that the mean number of pregnancies was 5.43 ± 2.57, that of deliveries was 4.56 ± 2.41 and miscarriages was 1.24 ± 1.5. Eleven of our patients (13.57%) had a home birth. Seventy-six patients (95%) reported amenorrhea starting immediately after delivery, while four (5%) patients had regular menses after the last delivery. In addition, 67 (83.8%) patients had postpartum agalactia. Overall hormonal assessment at the date of diagnosis revealed that all of the patients had hypogonadotropic hypogonadism and adrenal insufficiency, while 79 (98.8%) patients had secondary hypothyroidism and 72 (90%) patients had prolactin deficiency. Diabetes insipidus has not been found in any patient. Somatropic function was investigated in only 7 patients and was deficient in all of them. Twenty-five patients had pituitary MRI and ten patients had pituitary CT reports. According to CT and MRI findings, 30 patients with SS had a completely empty sella, while five patients had a partially empty sella.
Conclusion
Sheehan's syndrome is a frequent cause of hypopituitarism in underdeveloped countries. Physicians need to be aware of the most important clues for diagnosis to avoid delays in diagnosis and treatment. Appropriate replacement therapy is necessary to reduce the morbidity and mortality of patients.

Metabolic and cardiovascular outcome in patients with Sheehan's syndrome

Emna Elfaleh, Ibtissem Oueslati, Melika Chihaoui, Meriem Yazidi, Ons Rejeb, Fatma Chaker & Hedia Slimane
Department of Endocrinology, La Rabta Hospital, Tunis, Tunisia.

Introduction
Sheehan's syndrome (SS) is postpartum hypopituitarism caused by necrosis of the pituitary gland. Patients with SS have varying degrees of anteriorpituitary hormone deficiency and have an increased mortality from cardiovascular disease. Inadequate hormone replacement is one of the possible causes of this increased mortality. The aim of our study was to assess metabolic and cardiovascular outcome in patients with SS.
Methods
In a retrospective study, we included 80 patients with hypopituitarism due to SS. Metabolic disorders were determined and cardiovascular risk was assessed using Framingham score. 10-year CVD risk was categorized into low risk: $<10\%$, moderate risk: (10–20) and high risk: $>20\%$.
Results
The study population had a mean age of 41.6 ± 11.31 years and a mean follow up period of 23.4 ± 11.2 years. All of the participants had hypogonadotropic hypogonadism and adrenal insufficiency, while 79 (98.8%) patients had secondary hypothyroidism. Somatotropic function was investigated in only seven patients and was deficient in all of them. The mean BMI was $26.55 \pm 5.04\ kg/m^2$. Obesity was found in 15% and overweight in 35% of patients. Prevalences of hypertension, hyperlipidaemia, diabetes mellitus and smoking were 22%, 25%, 21% and 14%, respectively. In all patients, the mean Framingham score was 5.85 ± 5.69. The cardiovascular risk was low, moderate and high in 85%, 11% and 3.7% of patients, respectively. The Framingham score was correlated with age ($r=0.55$, $P<0.001$), fasting plasma glucose ($r=0.42$, $P=0.02$) and systolic blood pressure ($r=0.32$, $P=0.04$).

Conclusion
Patients with SS exhibit a higher cardiovascular risk. The increased cardiovascular morbidity could be attributed to inadequate estrogen or thyroid hormone treatment, also unsubstituted GHdeficiency is probably an important contributing factor.

Final results of NordiNet® international outcome study: key outcomes

Lars Savendahl[1], Gediminas Puras[2], Birgitte Tønnes Pedersen[3] & Matthias Weber[4]
[1]Department of Women's and Children's Health, Karolinska Institutet and Pediatric Endocrinology Unit, Karolinska University Hospital, Stockholm, Sweden; [2]Novo Nordisk Health Care AG, Zurich, Switzerland; [3]Novo Nordisk A/S, Søborg, Denmark; [4]Department of Endocrinology and Metabolism, Medical Clinic, University of Mainz, Mainz, Germany.

Background
The NordiNet® International Outcome Study (IOS) (NCT00960128), a non-interventional study (2006–2016), assessed the effectiveness and safety of real-life treatment with Norditropin®. Out of 20,548 enrolled patients, 20,195 (paediatric/adult; 17,711/2484) were included in the full analysis set (FAS) and 12,938 (11,967/971) in the effectiveness analysis set (EAS). Outcomes were assessed in children with growth hormone deficiency (GHD), born small for gestational age (SGA), Turner syndrome (TS), and Noonan syndrome (NS), and in adults with GHD (AGHD).
Methods
Patient information was entered by participating physicians using a web-based system. Among other endpoints, change from baseline in height standard deviation scores (ΔHSDS) and insulin-like growth factor-I (ΔIGF-I) SDS were assessed. Non-serious (NS) adverse reactions (NSARs), SARs, and serious adverse events (SAEs) were recorded. Data are mean (SD).
Results
Patient numbers by indication were (FAS/EAS): GHD, 9967/7141; SGA, 4274/3200; TS, 1374/936; NS, 154/106; AGHD, 2321/971; 'other', 2105/584. At treatment start, patients born SGA (7.9 (3.4) years) were the youngest (GHD, 9.1 (4.1)), TS, 8.7 (3.8), NS, 8.9 (3.8). Average GH dose (mg/kg per day) was lower for GHD (0.032 (0.008)) versus SGA (0.038 (0.009)), TS (0.044 (0.009)) or NS (0.040 (0.009)). Treatment follow-up (years) was longer for patients with TS (4.3 (2.8)) versus GHD (3.8 (2.9)), born SGA (3.6 (2.8)) or NS (3.4 (2.9)). Patients born SGA were shortest (height s.d.s.) at baseline (−2.97 (0.91)) (GHD, −2.55 (1.10), TS, −2.66 (0.93); NS, −2.83 (1.13)). ΔHSDS was greatest in year 1 (baseline to year 1 visit): GHD, 0.69 (0.56); SGA, 0.65 (0.44); TS, 0.54 (0.36); NS 0.51 (0.38). ΔHSDS (baseline to near adult height): GHD, 1.42 (1.19); SGA, 1.11 (0.81); TS, 0.83 (0.87); NS, 1.43 (0.59).
AGHD: age at treatment start (years), females, 46.6 (14.0), males, 49.3 (14.6); mean GH dose (mg/day), females, 0.338 (0.177), males, 0.289 (0.157); treatment follow-up (years), females, 4.9 (4.2), males, 5.0 (4.2) years; baseline IGF-I SDS, females, −1.09 (1.44), males, −1.12 (1.60). IGF-I SDS increased year-on-year from baseline (ΔIGF-I s.d.s. from baseline at year 1: female, 1.20 (1.51), male, 1.52 (1.47)). Safety: no new safety signals were observed. Number of events/number of patients were: paediatric, NSARs, 288/249; SARs, 133/90; SAEs, 352/224; adults, NSARs, 69/54; SARs, 38/29; SAEs, 200/119.
Conclusions
NordiNet IOS data showed that Norditropin was associated with increased HSDS in paediatric patients and increased IGF-I SDS in patients with AGHD supporting the effectiveness of GH therapy. No new safety signals were revealed.

Relationship between cortisol increment and basal cortisol: implications for the insulin tolerance test in assessing corticotrop insufficiency

Mohamed Taieb Ach[1], Monia Zaouali[2], Yosra Hasni[1], Asma Ben Abdelkarim[1], Amel Maaroufi[1], Kacem Maha[1], Molka Chaieb[1] & Koussay Ach[1]
[1]Endocrinology Department University Hospital Farhat Hached, Sousse, Tunisia; [2]Physiology and Functional Explorations Department, University Hospital Farhat Hached, Sousse, Tunisia.

Introduction
The insulin tolerance test (ITT) is accepted as the gold-standard test in the evaluation of adrenal and GH axis in patients with pituitary disorders. Diagnostic criteria that requires a minimum increment in serum cortisol is considered invalid although individuals who have a lower basal serum cortisol concentration because of recent ACTH deficiency may be maximally stimulated by ITT and thus able to further increase cortisol secretion without reaching the cut-off. Analyzing the relationship between cortisol Increment and basal cortisol could lead to precious information, and perform a prediction of adrenal insufficiency (AI). We therefore decided to investigate the relationship between the peak and basal cortisol values after the ITT.
Patients and methods
This was a prospective study in which ITT was performed in 81 patients with pituitary disorders. Serum cortisol was measured. We divided our population in Group 1 (G1): Adrenal Insufficiency (Peak cortisol < 200ng/mL) and Group 2 (G2): normal response (Peak cortisol > 200 ng/ml). Sampling took place at 0, 10, 20, 30, 45, and 60 min. The cortisol increment was plotted against basal cortisol. Receiver-operating characteristic (ROC) analysis was performed to identify a cortisol increment peak with the best sensitivity and specificity for AI prediction.
Results
The mean baseline cortisol levels was 95.40 ± 47.08 ng/ml with a peak level of 179.75 ± 79.005 ng/ml (60^{th} min, $P < 10^{-3}$). In ITT, 44/81 (54.3%) subjects had a peak of cortisol response < 200 ng/ml and were classified as Group 1 (G1). Basal cortisol was significantly lower in the group 1 with 72.68 ± 33.13 ng/ml than in the group 2 with 122.43 ± 47.26 ng/ml ($P < 10^{-3}$). The mean cortisol increment peak in group 1 subjects was 50.61 ± 30.34 ng/ml significantly lower compared to a mean increment peak of 122.02 ± 51.40ng/ml in Group 2 patients ($P < 10^{-3}$). The highest proportion of correctly classified patients (84.04%) evaluated by ROC curve analysis was obtained for ITT-induced cortisol increment peak cut-off of 87 ng/ml (sensitivity 85%; specificity 84%; AUC = 0.885; 95% confidence interval 0.80–0.96).
Conclusion
Our study showed a marked interdependence of the basal cortisol concentration, peak cortisol concentration, and increases in serum cortisol concentration. Our finding indicates that, considering the induced cortisol increment peak cut-off of 87 ng/ml, we can identify, with a statistical concordance, 84.04% of adrenal insufficient under ITT.

A case of pituitary metastasis in female patient with an invasive breast carcinoma

Emna Elfaleh, Ibtissem Oueslati, Melika Chihaoui, Meriem Yazidi, Fatma Chaker, Ons Rejeb & Hedia Slimane
Department of Endocrinology, La Rabta Hospital, Tunis, Tunisia.

Introduction
Pituitary metastases are rare complications of malignancy, representing only 1% of surgical tumours of the pituitary gland. They are usually encountered in elderly patients with disseminated malignant disease. The most frequent are metastases of breast and lung cancer. In this report, we describe a rare case of a metastatic breast cancer to the pituitary gland.
Observation
A 32-year-old female presented with blurred vision and diminished visual acuity in the last two weeks. Her past personal history included invasive ductal breast carcinoma diagnosed 2 years ago, treated with left mastectomy, axillary dissection and adjuvant chemotherapy. In the previous year, multiple bone metastases were diagnosed and she was treated with palliative radiotherapy. The ophthalmic exam displayed a papill edema in both eyes and a bi-temporal hemianopsia. Magnetic resonance imaging of the pituitary region showed a large heterogeneous mass measuring 27 x 22 x 19 mm. Moreover, the mass had a supra-sellar extension and was infiltrating the optic chiasm. Laboratory investigation showed panhypopituitarism. The patient was put on hormone replacement therapy. Then, a transsphenoidal surgery was performed with a subtotal resection of the tumour. The histological findings identified the mass as a malignant neoplasm compatible with metastatic breast cancer and specifically a poorly differentiated adenocarcinoma.
Conclusion
Pituitary metastases are uncommon and difficult to diagnose. Clinical neurological symptoms and signs of panhypopituitarism should suggest the presence of a pituitary metastasis in a cancer patient, particularly in a context of metastatic disease. Diagnosis needs to be confirmed by radiological imaging and histology. Treatment is essentially palliative and depends on the extent of disease and symptoms.

Non-classical factors of cardiovascular risk in acromegaly

Betina Biagetti[1], Anna Aulinas[2], Roser Ferrer[1], Gabriel Obiols[1], Andrea Ciudin[1], Belen Dalama[1], Natividad López[1], Esther García-Fernandez[1], María Jose Arnau-Vives[1] & Jordi Mesa[1]
[1]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [2]Hospital Universitari de Vic, Barcelona, Spain.

Background
Acromegaly (ACRO) is associated with greater cardiovascular morbidity and mortality, however, this is not entirely explained by the increase in classic cardiovascular risk factors (CVRF). C-reactive protein, galectin 3, adiponectin, B-type natriuretic peptide (BNP), apolipoprotein E, interleukin-6 and echocardiographic variables such as epicardial fat (EF) and interventricular septum thickness (IST) have been suggested as non-classical CVRF in the general population. Our hypothesis is that these non-classical CVRF could be increased in ACRO and contribute to this higher cardiovascular morbidity and mortality.
Objective
To assess if there are differences in non-classic CVRF in patients with ACRO compared with controls matched by age sex and BMI. Material and methods: We analyzed, 30 patients with ACRO (16 males, 5 with active disease) and 30 matched controls (by age, sex and body mass index (BMI)) with mean age of 53.9 ± 11.0 years. Classic CVRFs, echocardiographic parameters and blood sample with non-classical CVRF determination. were evaluated.
Results
Both cohorts were identical regarding the presence of classical CVRF (hypertension, dyslipidemia, diabetes, and smoking). The ACRO cohort presented higher EF and IST compared to the control group (0.65 ± 0.16 vs. 0.43 ± 0.14 cm, $P = 0.001$ and 11.31 ± 1.17 vs. 10.64 ± 1.47 mm, $P = 0.035$, respectively). Likewise BNP was found higher in the ACRO group compared to controls (32.93 ± 5.50 vs 11.96 ± 2.16 pg / mL $P < 0.0026$. No statistically significant differences were observed in other markers. In the multiple linear regression model that included (ACRO, BNP, gender, adiponectin and IST), only the presence of ACRO and BNP, were independents predictors of EF (ß: 0.34 $P < 0.001$, and ß: 0.05 P: 0.05 and R2Adj. 0.42) influenced by adiponectin that acts as an interaction variable.
Conclusions
Patients with ACRO compared to their paired controls that were homogeneous in classic CVRF, have higher EF and BNP (influenced by adiponectin) EF and BNP have been related to increased cardiovascular complications in the general population and could explain the excess cardiovascular risk in acromegaly.

A comparison of pituitary function in primary and secondary empty sella: preliminary data

Elisa Magnani[1,2], Maria Chiara Decaroli[1,2], Laura Leoni[1], Chiara Diazzi[1,2,3] & Vincenzo Rochira[1,2]
[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Department of Internal Medicine, Endocrinology, Metabolism, and Geriatrics, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy; [3]Azienda Sanitaria Locale of Modena, Modena, Italy.

Background
Empty sella (ES), the herniation of the subarachnoid space within sella associated with a variable flattening of the pituitary gland, is classified as primary (PES) or secondary (SES) on the basis of etiological factors.
Aim
To assess the differences between PES and SES in terms of pituitary function.
Methods
Clinical, radiological and hormonal data were retrospectively extrapolated from the records of 85 patients with a diagnosis of ES made between 1990 and 2016, attending to the Pituitary Unity of Azienda Ospedaliero-Universitaria of Modena, Italy. The pituitary function was assessed by basal hormonal measurements and dynamic tests in an appropriate clinical context. Chi square was used for comparison of categorical variables.
Results
Fifty-nine patients with PES (male/female ratio:1/2) and 26 with SES (male/female ratio:1.4/1) were considered. The mean age at diagnosis was 54 ± 17 years in PES and 45 ± 15 years in SES. Among PES 54% of patients had a normal pituitary function and 64% didn't take replacement treatment, while in SES the percentages decreased to 28% and 35% respectively (Chi-square = 16.8, $P < 0.0001$). Accordingly, the overall number of pituitary deficits was higher in SES than in PES and even each single pituitary deficit occurred more frequently in SES ($P < 0.05$). Mild hyperprolactinemia was present in 24% of PES and 22% of SES. A variable degree of hypopituitarism was found in 36% of PES and 58% of SES. Hypogonadism and growth hormone deficiency were the prevalent deficits among PES (61%) and SES (80%) respectively. The radiological degree of ES (partial vs total) didn't influence the pituitary function.
Discussion
Our preliminary results confirm a higher prevalence of endocrine alterations in SES compared to PES but, in contrast with previous reports in literature, hypogonadism is the most frequent alteration in our PES patients. These data suggest that SES requires a more accurate endocrine screening and follow-up and, if confirmed by prospective studies, may open new insights on the management of ES.

Thyroid autoimmunity in patients with empty sella syndrome

Abdulmuttalip Arslan[1], Mahmut Şenyurt[2], Ayse Carlioglu[3] & Senay Durmaz[4]
[1]Erzurum Regional Training and Research Hospital, Department of Internal Medicine, Erzurum, Turkey; [2]Erzurum Regional Training and Research Hospital, Department of Clinical Biochemistry, Erzurum, Turkey; [3]Erzurum Regional Training and Research Hospital, Department of Endocrinology, Erzurum, Turkey; [4]Kırıkkale University, Faculty of Medicine, Erzurum, Turkey.

Purpose
The aim of this study was to evaluate the association and frequency of thyroid autoimmunity in patients with empty sella syndrome and to evaluate the possible effects of thyroid auto-antibodies on clinical and laboratory findings in patients with empty sella syndrome.
Materials and methods
We recruited 93 patients (female) and 22 male patients (mean age 55.51 ± 14.82) who were admitted to the Endocrinology Clinic of Erzurum Regional Training and Research Hospital between January 2010 and December 2016. 105 healthy individuals (84.8% female) were included in the healthy, body mass index (BMI) normal values and defined as the control group. Empty sella diagnosis was based on pituitary magnetic resonance (MR) results. As a criterion of euthyroid Hashimoto Thyroiditis (HT); Patients with normal thyroid function tests, positive thyroid auto-antibodies and radiologic appearance compatible with HT were accepted as patients.
Results
There was no statistically significant difference between the two groups in terms of BMI, TSH, prolactin, ACTH, GH ($P > 0.05$). Cortisol levels were significantly lower in the patients with empty sella syndrome than in the control group ($P = 0.037$). Empty sella and control groups were evaluated for the association of euthyroid Hashimoto's disease. Euthyroid HT was diagnosed in 41 (35.6%) of the empty sella group and 1 (0.95%) of the control group ($P \leq 0.001$). There was a significant positive correlation between Anti-TPO and Anti-TG and empty sella syndrome ($r = 0.65$, $P \leq 0.001$, $r = 0.63$, $P \leq 0.001$, respectively). There was a statistically significant positive correlation between Anti-TPO and Anti-TG, euthyroid HT, age, BMI, right thyroid volume, left thyroid volume, FT3 and FT4 ($P < 0.05$). In ROC analysis, sensitivity for Anti-TPO ≥ 9.5 was 94.5% and specificity 72% for empty sella. For Anti-TG $\geq$ 10.5, the sensitivity was 80% and the specificity was 79%. The AUC value of Anti-TPO was 87.9% ($P \leq 0.001$) and the AUC value of Anti-TG was 86.4% ($P \leq 0.001$).
Discussion
There is a positive relationship between thyroid auto-antibodies and the clinical and laboratory findings of the empty sella. As a result, it is possible that some of the idiopathic empty sella syndrome cases occur via HT. It is advisable to investigate the presence of HT in patients with empty sella syndrome. Therefore, when supported by controlled clinical trials, it will be clear that future euthyroid HT may be a risk factor for empty sella. Further work is needed.

Assessment of prevalence and severity of depressive symptoms in patients with acromegaly using the beck depression inventory II (BDI-II) – own observations

Joanna Malicka[1], Dariusz Malicki[2], Maria Kurowska[1], Emilia Potembska[3] & Jerzy S. Tarach[1]
[1]Department of Endocrinology, Medical University, Lublin, Poland; [2]Alcohol Dependence Treatment Ward, Neuropsychiatric Hospital, Lublin, Poland; [3]Department of Psychiatric Nursing, Medical University, Lublin, Poland.

Background
Prolonged exposure to excessive concentrations of GH and IGF-1 in acromegaly continues to affect patients' appearance and negatively influences their self-evaluation, personal relations and morbidity. Besides chronic GH/IGF-1 excess could be deleterious to the brain through many mechanisms.
Objectives
The aim of the study was to evaluate the influence of acromegaly on the prevalence and the severity of depressive symptoms in patients with cured or controlled and uncontrolled disease in own material.
Material and methods
The study group comprised 56 patients with acromegaly. On the basis of GH and IGF-1 levels the whole group was divided into two subgroups: with controlled/cured and with uncontrolled acromegaly. The presence and severity of depression were assessed on the basis of Beck Depression Inventory II.
Results
The mean score of BDI-II was 13.43 ± 10.41. There was no significant difference in the severity of depressive symptoms between patients with cured/controlled and uncontrolled acromegaly ($P = 0.620$), with micro and macroadenomas or with and without hypopituitarism. There were no significant correlations between BDI-II scores and GH or IGF-1 levels, patients' age or duration of the illness.
Conclusions
In acromegalic patients depression rates are higher than in healthy people, even if remission had been attained. This indicates the need for an early diagnosis, before the development of advanced complications and significant changes in patients' appearance. In order to optimize the management, dimensions that reflect mental state and quality of life should be evaluated. In some cases providing emotional support to the patients could be very helpful or even necessary.

Giant prolactinomas in men: clinical features and therapeutic outcomes

Karina Arcano[1], Juan José Diez[2], Victor Rodriguez[2], Carmen Bernal[3], Carles Villabona[4] & Pedro Iglesias[2]
[1]Hospital Universitario Rey Juan Carlos, Móstoles, Spain; [2]Hospital Universitario Ramón Y Cajal, Madrid, Spain; [3]Hospital Universitario Doce De Octubre, Madrid, Spain; [4]Hospital De Bellvitge, Barcelona, Spain.

Aims
To evaluate the clinical features and long-term therapeutic outcome of giant prolactinoma (gPRLoma) in men and to compare them with those of a group of male patients with non-gPRL macroprolactinomas (non-gPRLomas).
Patients and methods
A retrospective and multicenter study of gPRLomas in men diagnosed in a 20-year period was performed. Clinical data and treatment outcome were registered. The diagnosis of gPRLoma was established when the maximal tumor diameter was $\geq$ 40 mm or the tumor had $\geq$20 mm of suprasellar extension associated to hyperprolactinemia (PRL > 1000 ng/ml). Non-gPRLoma was considered when tumor diameter was $\geq$ 10 mm and $<$40 mm associated to hyperprolactinemia (PRL $\geq$ 200 ng/ml).
Results
Twenty three patients with gPRLoma (age 38.3 ± 13.5 yr) followed for at least 3 mo were evaluated. A group of 42 patients with non-gPRLoma served as a control group. More than half (56.5%) of the gPRLoma patients were younger than 40 years at diagnosis. Visual disturbances were significantly more common in gPRLoma than in non-gPRLoma patients (65.2 vs 25.6%; $P = 0.004$). Prevalence of hypopituitarism was similar in both groups of patients (73.9% vs 80.9%; gPRLoma vs non-gPRLoma; NS). Serum PRL concentrations were significantly higher in gPRLoma than in non-gPRLoma patients [median (IR), 3978 ng/ml (1179-9012) vs 907 ng/ml (428-3119); $P < 0.001$]. Maximum tumor diameter in gPRLomas was 4.8 ± 0.8 cm and 2.4 ± 0.7 cm in non-gPRLoma ($P < 0.001$). All patients were treated with dopamine agonists (DA). Surgery was used in 12 (52.2%) gPRLoma patients and in 12 (28.6%) non-gPRLoma patients ($P = 0.054$). Lastly, radiotherapy was used in 5 (21.7%) gPRLoma patients and in 6 (14.2%) non-gPRLoma patients (NS). At last visit, PRL was similar in both groups of patients and tumor size decreased significantly ($P < 0.001$) in both groups of patients. Clinical cure (maintained normoprolactinemia without therapy for $>$ 1 yr and no radiological evidence of pituitary tumor) was achieved in 2 (8.7%) gPRLoma patients and in 2 (4.8%) non-gPRLoma patients (NS).
Conclusion
gPRLomas in men are usually diagnosed at the age of 40 yr, an age similar to that of non-gPRLomas. The only clinical difference with non-gPRLomas is their greater prevalence of visual disturbances. The therapeutic approaches and tumor outcomes were similar to those obtained in patients with non-gPRLomas. Complete cure in gPRLoma is rare, but similar to that achieved in non-gPRLomas, reaching in less than 10% of patients.

Static and dynamic balances in acromegaly and impact of exercise on balance

Ozlem Haliloglu[1], Nuri Topsakal[2], Filiz Camliguney[2], Ozge Polat Korkmaz[1], Serdar Sahin[1], Birol Cotuk[2], Pinar Kadioglu[1] & Oya Erkut[2]
[1]Istanbul University, Cerrahpasa Medical Faculty, İstanbul, Turkey; [2]Marmara University, İstanbul, Turkey.

Purpose
Patients with acromegaly may have changes in balance due to visual disturbances, musculoskeletal abnormalities and changes in body composition. We aim to compare static and dynamic balances in patients with acromegaly and healthy controls and to evaluate effects of exercise on balance in patients with acromegaly.
Methods
Twenty-two patients with acromegaly followed at the Endocrinology Outpatient Clinic of Istanbul University, Cerrahpasa Medical Faculty and 11 healthy volunteers were included in the study. The participants (all right-handed) who had vestibular or neurological diseases or physical disabilities were not enrolled in the study. The patients with acromegaly were divided into 2 groups. Eleven patients with acromegaly (group A) were attended to an exercise program which included 75 minutes exercise session, 3 days a week for 3 months whereas the remaining 11 patients with acromegaly (group B) and healthy volunteers (Group C) didn't take any exercise. Bipedal and unipedal stance static and dynamic balance tests were performed using Prokin 5.0 device.
Results
The ages, gender distribution and educational status were similar between groups. The disease remission status of Group A and B were also similar. The body mass indices of all patients with acromegaly were higher than the control group ($P = 0.017$). When all patients with acromegaly were compared with healthy controls; bipedal static balance values were similar but in unipedal stance analysis, displacement of center of pressure in anterior-posterior direction (C.o.P.Y) was seen in patients with acromegaly when left leg was used when compared with healthy controls ($P = 0.019$). In addition, dynamic balance measurements at forward-backward sway to the left direction were also different than normal ($P = 0.027$). When the exercise effect on balance were evaluated between Group A and group B; the eyes-open pre and post exercise bipedal stance values of patients were similar whereas post-exercise eyes-closed bipedal stance C.o.P.Y ($P = 0.01$) and right and left leg unipedal stance values ($P = 0.02$ vs $P = 0.03$) got better after exercise in Group A. Additionally, various parameters of dynamic balance measurements of both forward-backward and right-left sway also got better after exercise ($P = 0.01$ and $P = 0.006$ respectively).
Conclusions
Imbalances on unipedal stance static and dynamic measurements on left direction were detected in patients with acromegaly, when compared with healthy controls. In addition, eyes-closed anterior-posterior displacements, imbalances on unipedal stances and impairments on dynamic balances on both forward-backward and right-left sway got better with exercise.

Severe hypernatremia resulting in a locked-in syndrome

Julia Silva-Fernández[1], Rafael García-Ruiz[2], Francisco Javier Gómez-Alfonso[1], Florentino Del Val-Zaballos[1], Belvis Torres-Arroyo[1], Paloma González-Lázaro[1], Cristina Contreras-Pascual[1], Álvaro García-Manzanares Vázquez de Agredos[1] & Inés Gómez-García[1]
[1]Section of Endocrinolgy, Mancha Centro Hospital, Alcázar de San Juan, Spain; [2]Section of Neurology, Mancha Centro Hospital, Alcázar de San Juan, Spain.

Introduction
Osmotic demyelination syndrome (ODS) is a well described, potentially devastating consequence of rapid alterations in plasma osmolality, classically occurring secondary to the excessively rapid correction of chronic hyponatraemia. We describe a case of diabetes insipidus (DI) resulting in a Locked-in syndrome (LIS) caused by a rapidly developing severe hypernatremia.
Case report
A 43-year-old woman was admitted to the Internal Medicine ward with a clinical diagnosis of urinary tract infection. Her past medical history included panhypopituitarism, DI without adipsia and multiple meningiomas secondary to craniopharyngioma treated with surgery and radiotherapy during childhood, without difficulties to control sodium level. On admission, sodium level was within the normal range (138 mEq/L (135-145)). Three days later her level of consciousness was diminished. Lumbar puncture and electroencephalogram excluded both encephalitis and non-convulsive status epilepticus. Blood examination revealed high sodium level (180 mEq/L). The patient was aggressively fluid resuscitated with normal saline and was administered intravenous desmopressin. With 24, 48 and 72 hours, serum sodium decreased to 168, 159 and 151 mEq/L respectively. But despite achieving normal sodium levels, her neurological condition didn't improve. She could open her eyes spontaneously, but she couldn't speak or follow orders, and she was otherwise quadriplegic, so a suspicion of a LIS was raised. A brain MRI showing hyperintense lesions in the brainstem confirmed the ODS as the cause for the LIS.
Conclusions
Although reports of severe hypernatremia resulting in a ODS are few, rapid alterations in plasma osmolality – rather than only the correction of hyponatremia – are real cause for it. Physicians involved in the management of patients with difficulty control of plasma osmolality should be extremely cautious with rapid changes, as the consequences can be devastating.

Thyroid autoimmunity and euthyroid hashimoto thyroiditis frequancy in patients with pituitary adenoma

Mehmet Emin Budak[1], Mahmut Şenyurt[2], Ayse Carlioglu[3] & Senay Durmaz[4]
[1]Erzurum Regional Training and Research Hospital, Department of Internal Medicine, Erzurum, Turkey; [2]Erzurum Regional Training and Research Hospital, Department of Clinical Biochemistry, Erzurum, Turkey; [3]Erzurum Regional Training and Research Hospital, Department of Endocrinology, Erzurum, Turkey; [4]Kırıkkale University Faculty of Medicine, Department of Endocrinology, Kırıkkale, Turkey.

Purpose
The purpose of this study were to evaluate the relation thyroid autoimmunity and euthyroid hashimoto thyroiditis in patients diagnosed with pituitary adenoma and association of pituitary adenoma with clinical and laboratory findings
Materials and methods
The retrospective study population included a total of 230 participants. A total of 189 patients (67 with prolactinoma, 35 with acromegaly, 4 with cushing disease and 83 with non-functional pituitary adenoma) were included this study; 41 healthy subjects with similar age and sex and without pituitary adenoma in pituitary MR were used as the control group. This study was conducted at the Erzurum Regional Training and Research Hospital Endocrinology Medicine Clinic and all participants were tested for thyroid autoantibodies.
Results
Body mass index (BMI) ($P=0.005$, $p\leq0.001$, $P=0.027$, respectively),waist circumference (WC) ($P=0.001$, $P\leq0.001$, $P\leq0.001$, respectively), fasting blood glucose (FBG) values ($P=0.04$, $P=0.048$, $P=0.015$, respectively) of the patients with acromegaly were higher and HDL values ($P=0.035$, $P=0.012$, $P=0.007$, respectively) were lower than those of the control, non-functional pituitary adenoma and prolactinoma group. LDL values of the all patients with pituitary adenoma are significantly increased in cases than controls($P\leq0.05$). Anti-TG ($P=0.011$) and Anti-TPO ($P\leq0.001$) values were significantly higher in patients with pituitary adenoma compared to healthy subjects values. Anti-TPO and Anti-TG positivity was detected 7.3%, 4.9% in control group, 18.1%, 19.3% in patients with non-functional adenoma, 13.4%, 16.4% in prolactinoma group and 14.3%, 22.9% in acromegaly group. Anti-TG 18.5% positive and anti-TPO 15.9% positive were detected in all patients with pituitary adenoma. The frequency of euthyroid HT was significantly higher in the patients with acromegaly (22.9%), prolactinoma (14.9%) and non-functional adenoma patients (19.3%) than the control group ($P=0.006$, $P=0.037$ and $P=0.01$, respectively). Correlation analysis reveals significantly positive correlation of Anti-TPO ($r=0.210$; $P=0.001$) and Anti-Tg ($r=0.338$; $P\leq0.001$) with pituitary adenoma. The ROC showed that Anti-TPO (AUC = 0.66) with sensitivity (58%) and specificity (79.9%) and Anti-Tg (AUC = 0.76) with sensitivity (74%) and specificity (74.6%) levels could be used as markers to diagnose pituitary adenoma ($P=0.001$ and $P\leq0.001$).
Conclusion
Comparing the control group with pituitary adenoma, it was seen that the thyroid autoantibodies were significantly higher in the patient group. In our study, we found a strong association between euthyroid HT and pituitary adenoma and we think that thyroid autoantibodies may play a role in the etiopathogenesis of pituitary adenoma. We think that further, wide-ranging studies are needed.

Gonadotroph pituitary macroadenoma inducing ovarian hyperstimulation syndrome

Blertina Dyrmishi[1], Taulant Olldashi[1], Entela Puca[2], Ema Lumi[3] & Dorina Ylli[2]
[1]Hygeia Hospital Tirana, Tirana, Albania; [2]UHC "Mother Teresa", Tirana, Albania; [3]Regional Korca Hospital, Korca, Albania.

Case report
We report a young woman with ovarian hyper stimulation syndrome (OHSS), headache, visual field defect and pituitary macro adenoma. The patient was treated about four years ago as pituitary PRL-secreting adenoma with carbergoline. The evaluation of other hormones FSH, LH and Estradiol values wasn't done. The patient presented to our hospital with abdominal pain and headaches and amenohrrea. The pregnancy test was negative and pelcic ultrasound demonstrated enlarged ovaries with multiple cysts. The case was treated with GnRH agonist by gynecologist, but and the ovaries remain hyper stimulated and the estradiol and FSH values very high. The biopsy of ovaries was negative for malignancy (follicular luteinisation cysts. The pituitary macro adenoma secreting FSH was suspected. The laboratory results: β-HCG negative; Prolactine 83 ng/ml (N 4.3-32.3 ng/ml), FSH 103.3 IU/l (N 6.3-22 IU/l), LH 1.9 (N 1.5-8 IU/l), Estradiol > 3000 pg/ml (N 38-200). The other hormones normal. MRI of the pituitary gland: Pituitary macroadenoma $35\times20\times25$ mm with suprasellar extension, elevation and compression of the optic chiasm. Immunohistochemical staining of the pituitary adenoma specimen was positive for α subunit, FSHβ subunit and LHβ subunit; staining was negative for growth hormone, prolactin, adreno-corticotropic hormone and for TSH. The patient was diagnosed with gonodotrope cell adenoma with secondary ovarian hyperstimulation. After surgery of pituitary gland the gonadotropin and estradiol levels returned to normal range. Menstrual cycles resume and the ovaries revert to normal size with cyst remission.
Conclusion
Surgical resection is the definitive and primary therapy for OHSS due to gonadotropin-secreting adenomas. In those with recurrent tumors, radiation therapy may be required. In a patient with abdominal pain, irregular menses and multicystic ovaries the clinicians should measure the estradiol and gonadotropin levels to exclude OHSS.

Keywords: gonadotrope adenoma, ovarian hyperstimulation syndrome

Associated pituitary insufficiencies in children with growth hormone deficiency

Taieb Ach, Yosra Hasni, Asma Ben Abdelkarim, Amel Maaroufi, Maha Kacem, Molka Chaieb, Monia Zaouali & Koussay Ach
Endocrinology and Diabetology, University Hospital Farhat Hached de Sousse., Sousse, Tunisia.

Context
GH deficiencies could be associated with other pituitary insufficiencies. Our main objective is to assess othe pituitary secretion in short stature patients.
Patients and methods
Twenty three patients (17 boys, 6 girls) were included in the study for exploration of short stature, after oral and informed consent of their parents, from January 2016 to June 2017 in the Department of Endocrinology of the University Hospital of Farhat Hached Sousse. The mean age of the patients was 11.30 ± 2.83 years. Patients were excluded if they had a known chromosomal abnormality, untreated primary hypothyroidism, metabolic disease or disease associated with disordered glucose metabolism, MRI abnormalities, a known endocrine abnormality that could interfere with HPA axis function, were treated by any kind of steroid preparation, or had an anatomic abnormality or tumor of the central nervous system, a history of central nervous system irradiation, or documented central or primary hypothyroidism. The Inslin Tolerance Test (ITT) was performed by administering an IV bolus injection of 0.10 U/kg regular human insulin (Actrapid*). The Glucagon Stimulation Test (GST) was performed by intramuscular injection of 1 mg glucagon. We assessed the other pituitary axis by hormonal assays: TSH and T4 for the thyroid deficiency, ACTH and cortisol for adrenal insufficiency and Gonadotrophins for gonadic axis.
Results
From 23 children with short stature, 15 had GH deficiency (GHD) confirmed by both of Insulin tolerance test and Glucagon stimulation test. The mean age of the patients was 10.67 ± 3.24 yo. The mean height was 164.33 ± 4.22 cm, with a standard derivation (SD) of -2 DS for 53.3% and -3 DS for 46.7%. Hypophysary MRI performed in 6 children was normal. The bone age was of 10.13 ± 2.85 yo. They were 12 boys and 3 girls. The mean peak of GH under ITT and GST was respectively of 1.95 ± 1.04 ng/ml and 2.92 ± 1.7 ng/ml significantly lower than normal children ($P < 10^{-3}$). Of the children with GHD, 5 of them had secondary adrenal insufficiency confirmed by both of ITT and GST, 3 of them had hypogonadotropic hypogonadism and 1 of them had central hypothyroidism. None of them had hyperprolactinemia.
Conclusion
GH deficiency could be associated with other pituitary insufficiencies that may be asymptomatic in children with short stature. Assessing the entire pituitary secretion may discover these deficiencies and permit earlier treatment.

Metastasis – A rare cause of diabetes insipidus and pituitary insufficiency

Codruta Ioana Nemes
Emergency County Hospital, Satu Mare, Romania.

Introduction
Metastases in the pituitary gland are an uncommon presentation of carcinomas, lung and breast being the most common sites of the primary tumor. The most frequent clinical manifestations are diabetes insipidus, visual disturbances, cranial nerve paralysis and hypopituitarism.
Case report
We report the case of a 64 years old man, smoker, with no chronic illness, with one year history of headache, and more recent asthenia, weight loss, poliuria, polidipsia, loss of appetite. The MRI exam revealed a 20/14/12 mm sellar tumoral mass that interest the pituitary stalk. The endocrinological assessment confirmed diabetes insipidus, hypopituitarism and hiperprolactinemia (TSH = 0.5 uUI/ml, n.v = 0.4–4, FT4 = 0.6 ng/dl, n.v = 0.89–1.76; FSH = 0.32 U/l, n.v = 0.7–11.5, LH = 0.1 U/l, n.v. = 0.8–7.6; testosterone < 0.1 ng/ml, n.v = 1.3–8.53; cortisol = 4.46 mcg/dl, n.v = 5–25; PRL = 76.1 ng/ml, n.v = 2.5–17). He started treatment with Prednison 5 mg/day, Desmopresin 120 mcg/ twice daily, then Euthyrox 50 mcg/day and then he underwent surgery. The histological exam revealed a metastatic lesion of a poorly differentiated lung adenocarcinoma. The chest CT scan confirmed multiple pulmonary lesions and mediastinal lymph node metastasis. No secondary lesions on abdominal CT scan. The postoperatory hormonal assessment reconfirmed hypopituitarism, hyperprolactinemia and diabetes insipidus (STH = 2.09 ng/ml, n.v = 0–7; TSH = 0.5 uUI/ml, n.v = 0.4–4, FT4 = 0.98 ng/dl, n.v = 0.89–1.76; FSH = 0.28 U/l, n.v = 0.7–11.5, LH = 0.1 U/l, n.v. = 0.8–7.6; testosterone < 0.1 ng/ml, n.v = 1.3–8.53; cortisol = 1.47 mcg/dl, n.v = 4–25; PRL = 47.9 ng/ml, n.v = 2.5–17). He continued the same substitution therapy and he also underwent cranial radiotherapy.
Conclusion
Diabetus insipidus and pituitary insufficiency may be the first and only manifestation of malignancy. The detection and appropriate treatment of hormonal insufficiency are important to improve the quality of life.

Endocrine abnormalities in primary empty sella syndrome

Rym Belaid[1], Nadia Mchirgui[1], Imen Rojbi[1], Ibtissem Ben Nacef[1], Amel Jaidane[2], Karima Khiari[1], Haroun Ouertani[2] & Néjib Ben Abdallah[1]
[1]Departement of Endocrinology, Internal Medicine A, Charles Nicolle's Hospital, Tunis, Tunisia; [2]Department of Endocrinology, Military Hospital, Tunis, Tunisia.

Background
The term primary empty sella (PES) makes reference to the herniation of the subarachnoid space within the sella turcica in patients with no history of pituitary tumor,surgery or radiotherapy. The aim of our study was to evaluate hormonal abnormalities associated with PES.
Methods
Thirty-six patients with PES were retrospectively analysed over a 24-year period [1992-2016].Patients were evaluated for pituitary function with basal hormone levels (FT4, TSH, GH, IGF1, FSH, LH, cortisol,ACTH, prolactin) and dynamic testing when necessary.
Results
Our study included 26 women and 10 men with PES. The revealing symptoms were dominated by endocrine signs (52.7%). At least one pituitary hormone deficiency was found in 72% of cases. Secondary adrenal insufficiency was the most common hormonal abnormality (42.85%) followed by hypogonadotropic hypogonadism (34.2%). Central hypothyroidism,mild hyperprolactinemia and central diabetes insipidus were also recorded in 19.4%,19.4% and 5.5% of patients,respectively. Somatotrophic axis was not adequately assessed. The percentage of hypopituitarism in complete PES was significantly higher than that in partial PES ($P < 0.05$).
Conclusion
Our study showed that endocrine alterations are frequent in patients with PES syndrome and that the association of central diabetes insipidus with PES isn't a very rare event.Moreover, a correlation was found between the residual pituitary gland and the degree of pituitary dysfunction. Thus, a prompt evaluation and an early hormone replacement therapy are always recommended for better quality-of-life.

Long-term outcomes of different treatments for cushing disease: a retrospective study

Inmaculada Gonzalez Molero[1], Jose Abuin[1], Monserrat Gonzalo Marin[1], Viyei Doulatram[1], Juan Garcia Arnes[2], Miguel Angel Arraez[1] & Gabriel Olveira[1]
[1]CArlos Haya Hospital, Malaga, Spain; [2]Malaga University, Málaga, Spain.

Introduction
Cushing disease (CD) results from excessive exposure to glucocorticoids caused by an adrenocorticotropic hormone–secreting pituitary tumor. Inadequately treated CD is associated with significant morbidity and elevated mortality.
Objetive
The study purpose was to describe the long term treatment outcomes for CD patients in our hospital.
Methods
Retrospective analysis of the records of 36 patients with Cushing disease with more than 5 years of follow up. Descriptive statistical analyses were conducted to examine presenting signs, laboratory data and treatment outcomes.

Results
75% were female, median age at diagnosis 39.7 years (range:12–72 years). Pituitary adenomas size were 3–20 mm, 69.6% microadenomas, 21.7% macroadenomas. Blood test: Mean ACTH 68.04 pg/ml(normal range 5–52 pg/ml), 50% > 52 and 50% < 52 pg/ml. 85.7% had positive dexametasone 1 mg supresión test, 71.4% positive 8 mg supression test, 86.4% elevated UFC, 66.7% elevated salival nocturnal cortisol. 15% of patients had 3 positive test, 65% 2 positive test. Inferior petrosal sinus sampling (IPSS) were needed in 34.2%. First line Treatment: 100% underwent TSS (transesphenoidal surgery). The remission, recurrence and persistence rate were: 36.4%, 36.4% and 27.3% respectively. Remision rate after "normal anatomopathology" was 57.1%. Remission rates: in patients <30 years old remision rate was 12.5% vs >30 years 50%, micro 41.7% vs macro 33.3%,women 43.8% vs men 16.7%, early postsurgery cortisol < 10 μg/dL 100% vs cortisol >10 μg/dL 12.5%. Mean time between first treatment and first recidive: 6.7 years. Non cured patients in first line treatment: Mean time between second treatment and second recidive: 11.5 years. 70% had "normal conventional RM" and were diagnosed with ·3T RM/metionin PET, 69.2% underwent second TSS and 30.8% radiotheraphy. Remission, recurrence and persistence rate after second line treatment were: 50%, 7.1% and 42.9% respectively. After all treatments 68.2% are cured (13.3% with panhipopytuitarism)and 31.8% are non cured, with ketokonazol and waiting for definitive treatment).
Conclusion
Despite multiple treatments, at the end of follow-up, remission was still not achieved in 31.8% of patients. Early possurgery cortisol is the best predictor of remission after surgery.

Association between prolactin level and tumor size reduction at 3 months after cabergoline treatment in patients with macroprolactinoma

Daham Kim[1], Youngki Lee[1], Se Hee Park[1], Kyeong Hye Park[2], Cheol Ryong Ku[1], Sun Ho Kim[3] & Eun Jig Lee[1]
[1]Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Department of Internal Medicine, National Health Insurance Service Ilsan Hospital, Goyang, Republic of Korea; [3]Department of Neurosurgery, Yonsei University College of Medicine, Seoul, Republic of Korea.

Objectives
Prolactin (PRL) normalization after 3 months of Cabergoline (CAB) treatment are useful predictors of responsiveness in patients with prolactinoma. However, differences within the PRL normalization cut-off value have not been identified.
Methods
We reviewed the medical records of patients with prolactinomas who were treated with CAB as a primary drug at Severance Hospital. We included patients who had a full dataset of pituitary hormone assays and sella MRI at baseline, follow-up PRL assay and sella MRI at 3 months after CAB treatment.
Results
Among the 217 patients, 123 patients had macroprolactinoma. After 3 months of CAB treatment, PRL normalization was achieved in 109 (88.6%) of macroprolactinoma patients, the mean size reduction was 22.9%. We divided these patients into two groups according to the PRL level at 3 months. When we classified by 5 ng/ml, low normal group ($PRL \leq 5$, $n=82$) and high normal group ($5 < PRL \leq 20$, $n=27$) did not differ in baseline PRL, tumor size and size reduction. When we classified by 1 ng/ml, low normal group ($PRL \leq 1$, $n=49$) and high normal group ($1 < PRL \leq 20$, $n=60$) did not differ in baseline PRL and tumor size. However, size reduction was significantly different between the two groups (27.18 ± 18.31 vs. $19.46 \pm 13.87\%$, $P=0.014$). Even if we narrow down the high normal group ($1 < PRL \leq 10$, $n=50$ and $1 < PRL \leq 5$, $n=33$), similar results came back (27.18 ± 18.31 vs. $19.30 \pm 13.66\%$, $P=0.017$ and 27.18 ± 18.31 vs. $19.22 \pm 14.33\%$, $P=0.039$).
Conclusion
Prolactin drops to less than 1 ng/ml at 3 months after CAB treatment predicts better response of macroprolactinoma.

Predictors of clinical behavior of pituitary adenomas

Mirsala Solak[1], Tina Dušek[1], Ivana Kraljević[1], Tanja Škorić Polovina[1], Annemarie Balaško[1], Ante Melada[2], Vjerislav Peterković[2], Marcel Marjanović Kavanagh[3], Antonia Jakovčević[4], David Ozretić[5] & Darko Kaštelan[1]
[1]Division of Endocrinology, Center of Neuroendocrinology Zagreb, Zagreb, Croatia; [2]Department of Neurosurgery, Center of Neuroendocrinology Zagreb, Zagreb, Croatia; [3]Department of Otorhinolaryngology, Zagreb, Croatia; [4]Department of Pathology, UHC Zagreb, Zagreb, Croatia; [5]Department of Radiology, UHC Zagreb, Zagreb, Croatia.

The aim of this study was to investigate the expression of histological markers Ki-67, p53 and mitotic activity in pituitary adenomas and their correlation with the frequency of recurrence and progression of residual adenoma. The study comprised 94 patients treated at the Department of Endocrinology, University Hospital Center Zagreb in the period from 2005 to 2011. After the operation, 63.8% of patients had residual adenoma. In the minority of patients (12/60 patients, 20%) with residual adenoma we detected increase in size. In patients with complete adenoma resection, only few patienst had recurrence (3/34 patients, 8.8%). The size of the denoma had a significant prognostic value for residual tumor ($P=0.027$). In majority of adenoma samples (74.5%) expression of Ki-67 was less than 3%, 26.1% had positive p53 while only 9.6% had mitotic activity. Functional adenomas had significantly higher expression of Ki-67 compared to nonfunctional adenomas ($P=0.012$). The expression of the Ki-67 in the pituitary adenoma correlated positively with the recurrence of adenoma as well as the increase in residual adenoma ($P<0.001$). Cut-off value of Ki-67 $\geq 3\%$ was significant for the time of residual adenoma progression or adenoma recurrence after complete removal ($P=0.007$). All patients with residual adenoma, regardless of the clinical outcome, had a significantly higher expression of Ki-67 compared to patients without residue ($P=0.009$). Patients with residual adenomas had significantly larger and more invasive adenomas ($P<0.001$ and $P=0.002$, respectively). In patients with enlargement of residual adenoma or recurrence after complete removal, the expression of Ki-67 was higher compared to patients with stable residue or complete adenoma removal ($P<0.001$). Patients with increased residue size and recurrent adenomas had significantly larger initial size of the adenoma ($P=0.045$). Moreover, these patients had higher expression of Ki-67 compared only to the group of patients with stable residue ($P=0.005$). Based on this study we can conclude that patients with larger adenoma size and higher expression of proliferative marker Ki-67 have an increased chance of progression of residual adenoma or recurrence after complete removal.

The comparison of combination test either with 1 μg acth test and glucagon test for the evaluation of hypothalamo-pituitary-adrenal axis in patients with pituitary disorders

Kursad Unluhizarci, Emel Kokoglu, Zuleyha Karaca, Fatih Tanriverdi & Fahrettin Kelestimur
Department of Endocrinology Erciyes University Medical School, Kayseri, Turkey.

The low-dose (1 μg) ACTH stimulation test or glucagon stimulation test (GST) are candidate tests for hypothalamo-pituitary-adrenal (HPA) axis evaluation in patients with pituitary disorders. In this study, we aimed to compare the combination of low-dose ACTH and GSTs (named as combination test) with each test results alone in the evaluation of HPA axis in patients with pituitary disorders whether combination test may overcome the problems when the test results are equivocal.
Patients and methods
Forty-one adult patients with pituitary disorders and 20 healthy subjects were included in the study. Patients with diabetes mellitus or with the diagnosis of Cushing's syndrome were not included in the study. Low-dose ACTH test, GST and combination tests were performed on separate days. Blood samples for the measurement of cortisol were obtained in the basal state and at 30, 60, 90 and 120 min after the administration of 1 μg ACTH intravenously. The lowest peak cortisol value of control subjects (14.6 μg/dl) was considered as the cut-off value for adrenal insufficiency in low-dose ACTH test. The GST was performed by subcutaneous injection of 1 mg glucagon. Blood samples for measurement of cortisol were obtained at 90, 120, 150, 180, 210 and 240 min after glucagon injection. The lowest peak cortisol value of control cubjects (9.7 μg/dl) was considered as the cut-off value for adrenal insufficiency. Combination test was performed by injecting 1 μg of ACTH at the 180 min of GST and blood samples

for cortisol measurement were obtained at 210 and 240 minutes. For the determination of optimal cut-off value for diagnosing adrenal insufficiency, Receiver Operating Characteristics (ROC) analysis was performed and 12.4 μg/dl of cortisol value was obtained with a sensitivity of 83% and specificity of 100%.
Results
Ten patients with adrenal insufficiency in both tests also had adrenal insufficiency in the combination test. Twenty-eight patients with normal cortisol response to both tests also had normal cortisol response to combination test. Two patients with adrenal insufficiency (peak cortisol responses were 13.4 and 13.1 μg/dl) at ACTH test and a patient with adrenal insufficiency at GST (peak cortisol response 8.7 μg/dl) had normal cortisol responses to combination test.
Conclusion
The combination test gave an additional information in three (7.3%) patients who had equivocal results in ACTH and glucagon tests. Moreover, by performing the combination test, we can save a day of the patients and evaluate GH axis concomitantly.

Clinical parameters to distinguish silent corticotroph adenomas from other non-functioning pituitary adenomas

Daham Kim[1], Cheol Ryong Ku[1], Se Hee Park[1], Kyeong Hye Park[2], Ju Hyung Moon[3], Eui Hyun Kim[3], Sun Ho Kim[3] & Eun Jig Lee[1]
[1]Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Department of Internal Medicine, National Health Insurance Service Ilsan Hospital, Goyang, Republic of Korea; [3]Department of Neurosurgery, Yonsei University College of Medicine, Seoul, Republic of Korea.

Silent corticotroph adenomas (SCAs) are difficult to distinguish from other non-functioning pituitary adenomas (NFPAs) preoperatively. This study assessed the preoperative clinical parameters associated with SCAs. After excluding patients with increased 24-h urinary free cortisol, 341 patients who underwent surgery for NFPAs during 2011–2016 with available preoperative combined pituitary function test (CPFT) and immunohistochemical staining results were enrolled. The patients' medical records were retrospectively reviewed. The age and tumour size were similar between patients with SCAs and other NFPAs. The percentages of female patients (89.2 vs. 57.6%, $P<0.001$), cavernous sinus invasion (35.1 vs. 20.7%, $P=0.047$), and intra-tumoural haemorrhage on preoperative sella magnetic resonance imaging (32.4 vs. 9.2%, $P<0.001$) were higher in the SCA group. In the preoperative CPFT, the peak adrenocorticotropic hormone (ACTH) (67.80 ± 49.83 vs. 85.67 ± 78.97 pg/mL, $P=0.061$) tended to be lower, and the ΔACTH (53.71 ± 50.14 vs. 72.67 ± 75.82 pg/mL, $P=0.046$) was significantly lower in SCAs. After excluding patients with preoperative hypopituitarism caused by mass effects, the peak ACTH (69.39 ± 39.45 vs. 119.75 ± 89.84 pg/mL, $P=0.001$) and ΔACTH (58.58 ± 36.51 vs. 107.66 ± 86.05 pg/mL, $P=0.001$) were significantly lower in SCAs. Female sex, cavernous sinus invasion, intra-tumoural haemorrhage on sella magnetic resonance imaging, and decreased ACTH response are independent indicators of SCAs.

Male hypogonadism – when two endocrine causes merge in the same patient

Alexandra Novais Araújo, Ana Wessling & Maria João Bugalho
Centro Hospitalar Lisboa Norte - Hospital Santa Maria, Lisbon, Portugal.

Introduction
Male hypogonadism is defined by lower levels of testosterone than expected for age-matched individuals. In primary or hypergonadotropic hypogonadism, LH and FSH show a compensatory elevation to low testosterone levels, while in the secondary or hypogonadotropic hypogonadism the low testosterone levels are a result of insufficient gonadotropin levels. Hyperprolactinemia is a cause of hypogonadotropic hypogonadism. It is not only caused by lactotroph adenomas (prolactinomas), but may also develop due to pharmacological or pathological interruption of hypothalamic-pituitary dopaminergic pathways, sometimes also idiopathic. Klinefelter syndrome is a common sex-chromosome aneuploidy with clinical features that include the development of hypergonadotropic hypogonadism.
Clinical case
Case of an asymptomatic 57-year-old male patient referred to a Endocrinology department after the incidental diagnosis of a pituitary macroadenoma in a tomography of the paranasal sinus (pituitary mass with $23\times15\times13$ mm). He had no offspring. His medical history included heart failure secondary to idiopathic dilated cardiomyopathy, essential hypertension and chronic atrial fibrillation, medicated with furosemide 40 mg id, isosorbide mononitrate 5 mg id, captopril 50 mg id, spironolactone 25 mgid and warfarin. Clinical examination revealed a mild gynecomastia, a BMI of 32 and a 179 cm height. The initial lab results included prolactin level of 1155 ng/ml (4–15 ng/ml), FSH 8.5 U/L (1.5–12.9 U/l), LH 6.83 U/l (1.3–9.8 U/l) and a total testosterone of 241.1 ng/dl (190–740 ng/dl). He was started on bromocriptine 20 mg/day and, after 6 months, prolactin levels had lowered to 527.5 ng/ml, with increasing of FSH (13.7 U/L) and LH (8.47 U/l) and a total testosterone of 95 ng/dl. 3 Years later, bromocriptine was switched to cabergoline 1 mg/per week, with a sustained lab response (prolactin 107 ng/dl, 6 months after the switch) and tumor size reduction (absence of supra-selar extention in a CT 1 year after the switch). Despite the good responsiveness of prolactin levels to dopamine agonists therapy, testosterone levels remained low (88.1 ng/dl) with increased gonadotropins (FSH 26.3 U/l and LH 12.8 U/l). A karyotype was requested, and after the result of 47, XXY, the diagnosis of a Klinefelter syndrome was established.
Conclusion
The underlying hypergonadotropic hypogonadism was initially masked as a result of gonadotropin suppression by high levels of prolactin. The reduction of prolactin levels was accompanied by a paradoxical decrease of testosterone and increase of gonadotropin levels raising the clinical suspicion of a preexisting Klinefelter syndrome. The diagnosis of Klinefelter syndrome is important to alert the clinician to other common comorbidities.

The diagnostic utility of late night salivary cortisol (LNSF) and cortisone (LNSE) in Cushing's Syndrome and their relationship to metabolic markers

Aoife Garrahy, Hannah Forde, Patrick O'Kelly, Karen McGurren, William Tormey, Diarmuid Smith, Mohsen Javadpour & Amar Agha
Beaumont Hospital, Dublin, Ireland.

The diagnosis of Cushing's Syndrome (CS) requires demonstration of excess circulating cortisol. Measurement of late night salivary cortisol (LNSF) has been advocated as a simple, non-invasive and reliable outpatient diagnostic tool for patients with suspected CS but the usefulness of its metabolite cortisone (LNSE) remains unclear. LNSE levels are approximately six times higher than LNSF in saliva due to the rapid action of 11β-hydroxysteroid dehydrogenase type 2 (11βHSD), and have been shown to have a linear relationship with serum free cortisol. We hypothesised that LNSE concentrations may therefore correlate with degree of metabolic derangement resulting from hypercortisolemia. In this study, we investigated the sensitivity of LNSF and LNSE (measured using liquid chromatography-mass spectrometry, LCMS) as compared to the traditional urine free cortisol (UFC) and overnight dexamethasone suppression test (ONDST) in patients with confirmed CS. We also studied any association between LNSF or LNSE and metabolic parameters affected by cortisol excess including HbA1C, ALT and blood pressure (BP). Eighteen patients (15 female) with confirmed CS attending Beaumont Hospital were included. Sixteen patients had ACTH-dependent CS. Median age was 34 years (range 7 – 65). Both LNSF and LNSE were strongly correlated with UFC (R 0.53, $P=0.03$ and R 0.69, $P=0.01$ respectively). Sensitivity of ONDST was 100% (data for 17 patients). UFC was measured in 17 patients – median number of samples 1.5 (range1–6) with a sensitivity of 92%. One patient with confirmed CS had four measurements for UFC, all of which were negative. Median number of LNSF and LNSE samples measured was 3 (range 1–18). LNSF had a sensitivity of 91%, while LNSE had a sensitivity of 84%. Seventeen of 18 LNSF samples were positive in the patient with four negative UFCs. Serial LNSF and LNSE identified four patients with cyclical Cushing's Disease. Six patients (33%) had diabetes mellitus, 11 (61%) were hypertensive, and 11 (61%) were obese. On multivariate analysis, LNSF was not significantly associated with HbA1C, ALT or BP, while LNSE was negatively associated with HbA1C ($P=0.04$) but not with BP or ALT. When the ratio of LNSF to LNSE was studied, there was no significant effect on metabolic parameters. Late night salivary cortisol is more sensitive than salivary cortisone as a diagnostic test for CS and may identify cases of cyclical ACTH secretion. We did not identify an association between LNSF and metabolic parameters influenced by hypercortisolemia. The negative association between LNSE and HbA1C requires further elucidation.

Purpose
Acromegaly, an uncommon disease, is existed in the result of over production of growth hormone (GH). It is associated with increased cardiovascular risk factors and metabolic abnormalities. Urotensin II (UII), a secreted vasoactive peptide hormone, plays an essential role in the regulation of vascular tone, glucose metabolism and atherosclerosis. UII belonging to somatostatin superfamily activates somatostatin receptors as well. The aim of this study was to ascertain whether circulating UII levels are altered in subjects with acromegaly and to describe the relationship between UII and hormonal or cardio-metabolic parameters.
Methods
This cross-sectional study included 41 subjects with active acromegaly, 28 subjects with controlled acromegaly and 37 age- and BMI-matched controls without acromegaly. Hormonal and metabolic features of the subjects as well as carotid intima media thickness (cIMT) and epicardial fat thickness (EFT) were defined. Circulation of UII levels was determined via ELISA.
Results
Both active and controlled acromegalic subjects showed a significant elevation of circulating levels of UII with respect to controls. There was no remarkable difference in circulating levels of UII between active and controlled acromegalic groups. Both cIMT and EFT were remarkably increased in acromegaly subjects comparing to controls. UII positively correlated with cIMT, EFT, BMI and HOMA-IR. There was no correlation between UII and GH, insulin-like growth factor-1. According to the results obtained from regression models, UII levels independently predicted cIMT and EFT.
Conclusion
Elevated UII levels are associated with severity of cardiovascular risk factors including cIMT and EFT in acromegalic subjects.

The association between Ki-67 proliferation index, P53 expression, mitotic index, tumor invasion and the risk of recurrence in pituitary adenomas

Rovshan Hasanov, Berna İmge Aydoğan & Sevim Güllü
Department of Endocrinology and Metabolism, Ankara University Faculty of Medicine, Ankara, Turkey.

Background
The 4th edition of World Health Organization (WHO) classification of pituitary tumors recommended evaluation of tumor proliferation and invasion to identify aggressiveness. We aimed to assess the relationship between Ki-67, mitotic index, P53 expression, invasion and recurrence risk in pituitary adenomas.
Methods
Among 601 patients who underwent TN/TS adenomectomy between 2001 and 2016, 101 patients (16.8%) who had tumors with Ki-67 index ≥ 3 were included and categorized as Group A. The control group (Group B) consisted of 43 patients matched for age, gender and tumor type but had Ki-67 index $<3\%$. Mitotic index and p53 expression were evaluated in 81 tumors. Histopathology reports, pre/postoperative radiological findings, tumor type, recurrence of tumors were assessed retrospectively.
Results
The mean age of patients was 46.9 ± 12.7 years. The most frequent symptoms were visual disturbances (34.7%). Frequency of somatotroph, mammotroph, gonadotroph, ACTH-producing, TSH producing, non-secreting and plurihormonal tumors were 35.4%,20.1%, 16%, 12.5%, 2.8%, 11.8% and 1.4%, respectively. Mean tumor size was greater in Group A compared to Group B (25 ± 10.6 vs 18 ± 11 mm, $P<0.01$) and frequency of macroadenomas was higher in Group A (67.4% vs 94.1%, $P<0.01$). Frequency of invasion to adjacent tissue was higher in Group A when compared to Group B (75.8% vs 22%, $P<0.01$). Fifty-one tumors had invasion to adjacent tissue at MRI and the most frequent invasion site was cavernous sinus (58.8%). The mean follow-up period was 46.6 ± 34 months. One hundred seventeen patients who had postoperative MRI and follow-up data for at least 12 months were evaluated and recurrence risk was higher in Group A patients than Group B ($P=0.03$). Ki-67 index ≥ 2.7 was positively associated with recurrence risk. Frequency of recurrence was higher in adenomas with invasion at preoperative MRI ($P=0.03$). Tumor size and recurrence were not associated with P53 expression. High P53 expression was related with tumor invasion at MRI ($P=0.03$). Tumors with high ($\geq 2\%$) mitotic index was more frequent among macroadenomas ($P<0.05$). Mitotic index was not associated with tumor recurrence risk and invasion. Recurrence risk was higher in tumors with ≥ 2 histopathological atypia criteria ($P=0.01$).
Conclusions
High Ki-67 index is a reliable marker for predicting recurrence in pituitary adenomas. Recurrence risk is higher in tumors with two histopathological atypia criteria and invasion.

Pituitary enlargement due to the autoimmune thyroiditis mimicking a pituitary macroadenoma

Sinem Kiyici, Esen Onlen[2] & Metin Guclu[1]
[1]Department of Endocrinology and Metabolism, University of Health Sciences, Bursa Yuksek Ihtisas Education and Research Hospital, Bursa, Turkey; [2]Department of Internal Medicine, University of Health Sciences, Bursa Yuksek Ihtisas Education and Research Hospital, Bursa, Turkey.

Introduction
Pituitary tumorous hyperplasia with hyperprolactinemia has been described as a rare presentation of primary hypothyroidism. The loss of thyroxin feedback inhibition in primary hypothyroidism causes overproduction of thyrotropin-releasing-hormone (TRH), which results in secondary pituitary enlargement. TRH has a weak stimulatory effect on the lactotroph cells of the pituitary, so a mild to moderate increase in prolactin (PRL) levels is expected. This report describes an unusual case of primary hypothyroidism with pituitary hyperplasia mimicking a pituitary adenoma.
Case report
A 27 year old female patient admitted to the gynecology clinic with the complaint of infertility. A pituitary macroadenoma and mild hyperprolactinemia were detected after laboratory and radiological assessment and patient was referred to Endocrinology outpatient clinic. She had regular menstrual cycles and no galactorrhea. There were also no neurological symptoms such as headaches and visual disturbances. The patient had no known chronic disease and was not using any medication. Her hormonal profile showed raised thyrotrophin stimulating hormone (TSH) (44 μIU/ml, range 0.40–4.5) and low free T4 (0.78 ng/dl, range 0.88–1.72) and mildly elevated PRL levels (39.4 ng/ml, range: 5–25). The growth hormone and pituitary-adrenal axis were interpreted as normal. Magnetic resonance imaging (MRI) of pituitary showed 10×15 mm globular pituitary enlargement with a convex superior margin. Anti-thyroglobulin antibodies (>1300 IU/ml, range: 0–157) is found elevated while antimicrosomal antibodies was negative. Thyroid gland had a heterogeneous echotexture on the ultrasonography. A diagnosis of autoimmune thyroiditis and primary hypothyroidism with pituitary hyperplasia was suspected. Oral levothyroxine substitution treatment was started and the dose was increased gradually until euthyroidism was restored. After 6 months of follow-up, TSH and PRL levels dropped to their normal ranges and the pituitary enlargement was found regressed on MRI.
Conclusions
Pituitary enlargement secondary to primary hypothyroidism is known but uncommon entity and sometimes differentiation of pituitary gland enlargement from pituitary adenomas may be difficult. Interpretation of a pituitary mass without proper endocrine evaluation can lead to mismanagement and unnecessary treatment.

Intracranial germinoma with panhypopituitarism in a 18-year old patient

Semih Özyurt[1], Ozlem Celik[2] & Leyla Ozer[3]
[1]Department of Internal Medicine, Acibadem University School of Medicine, Istanbul, Turkey; [2]Division of Endocrinology and Metabolism, Department of Internal Medicine, Acibadem University School of Medicine, Istanbul, Turkey; [3]Division of Oncology, Department of Internal Medicine, Acibadem University School of Medicine, Istanbul, Turkey.

Intracranial germ cell tumors (GCTs) account for only 0.4–3.4% of all central nervous system (CNS) tumors. A 18 year old patient with an unremarkable medical history was presented to the ophtalmology outpatient clinic with a 2 month history of loss of vision at left eye and blurrred vision at right also headache and fatigue. Ophtalmological examination showed loss of visual acuity at left eye and decreased 0.05–0.1 at the right and bilateral optic atrophy. Further physical examination showed sexual infantilism (poor beard, pubic and axillary hair growth, small testis). The patient's skin was dry and pale. Endocrinological examination showed panhypopituitarsm. Pituitary MR imaging demonstrated contrast enhancing mass lesion at suprasellar cisternal region which outstrecthed to posterior perimesencephalic cisternal region. The mass resected by craniotomy and pathology showed germinoma.Chemotherapy and radiation therapy were administered. He is still using prednisolon, L-thyroxine and human chorionic gonadotropin treatment.

DOI: 10.1530/endoabs.56.P815

Primary pituitary abscess: an unexpected diagnosis

Semih Özyurt[1], Ozlem Celik[2], Cemal Ustün[3] & Savas Ceylan[4]
[1]Department of Internal Medicine, Acibadem University School of Medicine, İstanbul, Turkey; [2]Division of Endocrinology and Metabolism, Department of Internal Medicine, Acibadem University School of Medicine, İstanbul, Turkey; [3]Department of Infectious Diseases and Clinical Microbiology, Acibadem University School of Medicine, İstanbul, Turkey; [4]Department of Neurosurgery, Kocaeli University School of Medicine, Pituitary Research Center, Kocaeli, Turkey.

Pituitary abscess is a rare condition, with approximately 200 cases reported in the literatüre. Two-thirds of pituitary abscess which occurs without any of the aforementioned risk factors are primary type while remaining are secondary type-abscess. A 58 year old female patient presented with fatigue, headache and loss of appetite for two months. Laboratory analysis showed high ESR and CRP levels also hypocortisolism, hypothyroidism, hypogonadism. Pituitary MRI showed a mass measuring 30x20 mm dense, cystic, lesion on T2 weighted coronal view, which caused enlargement in the sella turcica, suprasellar cistern obliteration, indistinguishable from the pituitary gland, pushing the stalk to the superior and right posterolateral. She has no visual defect on ophtalmological examination. TSE surgery was done and purulent material was seen intraoperatively. No tumor or other associated lesion was detected. Culture of the specimen was negative. The patient treated with metronidazole,ceftriaxone and linezolid for 2 weeks and 4 weeks of metronidazole, ceftriaxone and sulfamethoxazole/trimethoprim. Her headache, fatigue, loss of appetite resolved. After surgery hypopituitarism continued and treated with oral prednisolon and L-thyroxine therapy.

Diurnal melatonin profile in patients with pituitary adenomas

Oksana Khyzhnyak[1,2], Miroslava Mykytyuk[1,2], Dina Kashkalda[3], Teona Gogitidze[1], Nadiya Barabash[1], Yurii Karachentsev[1,2], Katarina Manska[1] & Roman Nikolaiev[1]
[1]Institute of Endocrine Pathology Problems, Kharkov, Ukraine; [2]Academy of Postgraduate Medical Study, Kharkov, Ukraine; [3]Institute of Children and Adolescents Health Care, Kharkov, Ukraine.

Introduction
The role of the pineal gland and its hormone, melatonin, in the regulation of hypothalamo-adenohypophysial system activity is well known. At the same time, studies of the circadian rhythm of melatonin secretion in patients with pituitary adenomas are few in number, because the evaluation of pineal activity is not generally included in the clinical investigation of patients with pituitary tumors.

Aim
The present study analyzed the circadian diurnal melatonin profile, in patients with GH/prolactin (PRL) secretion adenomas.

Subjects and methods
Under investigation there were 69 patients aged 18–75 years with pituitary tumors: 52 acromegaly (ACRO) (female 32/male 20); 17 prolactinoma (PROL) (female 14/male 3), by comparing the results with those seen in 10 healthy controls. All the patients had active disease and were off treatment; none had overt hypopituitarism. Blood samples for GH and PRL were taken in fasting state. 6-Sulfatoxymelatonin (MT), the main melatonin metabolite, was determined by fluorometric assay by C. Druex in two separated urine portions: in the daytime (MTd) and nighttime (MTn) in the spring/autumn period. Data are given as M ± S.D., Me, [Mim – Max].

Results
Abnormally high serum levels of MT during the period of maximum light and abnormally low increases during the night were seen in 31/52 ACRO (GH-23.6 ± 24.1, Me = 14.0 [3.1-144.9] ng/l) and 12/17 PROL (PRL - 248.5 ± 551.4, Me = 61.2 [2.35 - 3857.9] ng/l) patients. Moreover, mean levels of MT were significantly lower in patients than in controls. In ACRO patients total diurnal MT (85.08 ± 62.65; Me = 70.3 [9.5–324.6] nmol/24 h) and MTd levels (43.04 ± 31.25; Me = 33.65 [6.3–155.4] nmol/24 h) were significantly higher comparing patients with PROL: MT total - 49.58 ± 20.71; Me = 53.2 [17.8–103.2] nmol/24 h, $P = 0.0001$; MTd – 30.0 ± 19.24; Me = 31.24 [5.4–82.5] nmol/24 h, $P = 0.03$. It was found that in ACRO patients with daily rhythm inversion of melatonin excretion (MT-Ratio night/day < 1), MTn level was also significantly higher in comparison with PROL: 28.4 ± 18.3, Me = 25.4 [3.2 – 77.8] nmol/24 h; 16.4 ± 5.8, Me = 16.7 [5.9 – 26.6] nmol/24 h, respectively; $P = 0.0003$.

Conclusion
This study demonstrates the existence of an altered pineal function in patients with pituitary tumors. Further studies will be required to establish the pathogenetic and prognostic significance of pineal disorders in neoplastic disease of the pituitary gland.

Diabetes insipidus due to hypothalamitis and infundibulo-neurohypophysitis

G Gonca Örük[1] & Melda Apaydın[2]
[1]Division of Endocrinology and Metabolism, Izmir Katip Celebi University Ataturk Training and Research Hospital, Izmir, Turkey; [2]Division of Radiodiagnostics, Izmir Katip Celebi University Ataturk Training and Research Hospital, Izmir, Turkey.

Autoimmune hypothalamitis has been implicated in idiopathic central diabetes insipidus (DI) due to antibodies against vasopressin producing hypothalamic cells. Lymphocytic infiltration of hypothalamus has been reported in patients with lymphocytic hypophysitis (LH) manifesting as hypopituitarism with DI. These patients can also have other associated autoimmune diseases. Here, we report a case of a male patient who presented with headache, poor orientation, partial hypopituitarism, diabetes insipidus, and whose MRI findings revealed involvement of hypothalamus, posterior pituitary and infundibulum. 40 years old male patient was admitted to the hospital with symptoms of polyuria (8–10 lt/day), polydipsia, headache. Urine density was low (1005). Hormonal testing revealed low IGF1, testosterone, normal cortisole levels, but thyroid hormone levels were in the normal range with high TSH and anti-TPO levels. Response to LHRH and ACTH stimulation tests were normal. Sellar fossa and pituitary gland size, pituitary gland enhancement were normal at MRI. Increased T2 signal intensity in the optic chiasm, hypothalamus, infundibulum and contrast enhancement in the T1-contrasted series were noted. This finding is most visible in 2016, but regressed in 2017. As the lesion did not cause any visual symptoms and did not have features typical of tumors of the suprasellar area, and the patient did not give consent for a pituitary biopsy, a strict follow-up and see policy was chosen. Polyuria improved after oral administration of desmopressin 2 × 120 μg. We did not give steroid treatment, levothyroxin was administered for the subclinical hypothyroidism. The symptoms improved in six months without steroid treatment, anterior pituitary functions returned to normal. The lesion spared the anterior pituitary. Hence, it is speculated that anterior pituitary dysfunction could be consequent to either deficiency of hypothalamic releasing hormones due to the involvement of hypothalamic nuclei or microscopic involvement of anterior pituitary. He is still being followed with desmopressin and levothyroxin. As far as we know this is the first case of hypothalamitis and infundibulo-neurohypophysitis presenting with symptoms of DI and partial hypopituitarism. To conclude, in a patient presenting with headache, hypopituitarism and a suprasellar mass, hypothalamitis also should be considered in differential diagnosis. Because it is a self-limiting condition, close follow-up with clinical and laboratory testing can be

sufficient for most of the patients. But also according to the literature, these patients may benefit from course of steroid and immunosuppressive drugs

Age and severity of hyperthyroidism are determinants of thoracic vertebral fractures in patients with TSH-secreting pituitary adenoma

Stefano Frara[1], Marco Losa[2], Mauro Doga[1], Anna Maria Formenti[3], Pietro Mortini[2], Gherardo Mazziotti[4] & Andrea Giustina[1]
[1]Chair of Endocrinology, Università Vita-Salute San Raffaele, Milan, Italy; [2]Chair of Neurosurgery, Università Vita-Salute San Raffaele, Milan, Italy; [3]Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy; [4]Endocrinology Unit, ASST Carlo Poma, Mantova, Italy.

Introduction
Osteoporosis and vertebral fractures (VFs) commonly occur in overt and subclinical primary hyperthyroidism. In this clinical setting, bone damage is caused by the direct effects of thyroid hormone in excess on bone remodeling, although there is also evidence that low thyrotropin (TSH) values may play a role in driving fracture risk. In fact, TSH was shown to have direct inhibitory effects on osteoclastogenesis and bone resorption. Based on these data, one could argue that primary and secondary hyperthyroidism may induce variable effects on bone in relationship to the different TSH values. In this cross-sectional study, we evaluated for the first time the prevalence and determinants of VFs in patients with TSH-secreting pituitary adenoma (TSH-oma).
Patients and Methods
Twenty-two patients (10 M, 12 F; median age 47.0 years) with TSH-oma were retrospectively evaluated for clinical and biochemical parameters as well as for thoracic VFs using a morphometric approach on lateral chest X-ray routinely performed in the pre-surgical diagnostic work-up.
Results
At the time of VFs assessment, 17 patients (77.3%) had an overt hyperthyroidism and five patients (22.7%) had thyroid hormone values in the reference ranges. TSH values were inappropriately normal in 17 patients and high in five patients. VFs were found in 13 patients (59.1%) in association with older age ($P=0.007$) and higher serum free-thyroxine (FT4) values ($P=0.02$). The prevalence of VFs was more frequent in patients with overt hyperthyroidism as compared to those with thyroid hormones in the reference ranges (70.6% vs. 20.1%; $P=0.04$), whereas no significant difference was found in patients with high vs. normal TSH values ($P=0.38$).
Conclusions
This study provides for the first time evidence that patients with TSH-oma may develop VFs in close relationship with the severity of hyperthyroidism. It is likely that elevated TSH levels do not protect bone in TSH-omas due to the predominant negative effect on bone of elevated circulating thyroid hormones.

P820

Cushing disease after remission and prevalence of cardiovascular risk factors

Paloma Moreno-Moreno, Ángel Rebollo-Román, María Rosa Alhambra-Expósito, Concepción Muñoz-Jiménez & María Ángeles Gálvez-Moreno
Hospital Universitario Reina Sofía, Córdoba, Spain.

Objective
Cardiovascular risk factors (CVRF) persist with notable prevalence in patients with Cushing's disease (CD) after remission: obesity/overweight up to 40%, hypertension (HTA) up to 60%, type 2 diabetes (DM-2) up to 60% and dyslipidemia up to 30% of cases. Persistence of metabolic syndrome in patients with controlled CD seems to be related to the duration of the disease before remission. The aim of this study is to describe the prevalence of CVRF in patients with CD in remission.
Patients and methods
Retrospective descriptive study of patients with CD (1995–2016). Variables analyzed: age, sex, body mass index (BMI), CVRF at diagnosis and after the remission of CD, treatment of CVRF. Statistical analysis (SPSS v.18.0 for Windows): t-student for comparison of means and McNemar for comparison of proportions.
Results
49 patients with CD. Age 44.43 ± 15.29 years. Women: 89.8%. Transsphenoidal surgery: 87.8%. Remission: 68.7%. Time from onset of clinical to diagnosis: 29.7 ± 30 months. At diagnosis of CD: 36% obesity and 16% overweight, 20% DM-2 [treatment with oral antidiabetics 40%: 20% metformin, 20% sulfonylureas; 60% insulinized (insulin dose 26 ± 16 IU/day)], 68% HTA (54% antihypertensive treatment with more than one drug) and 36% dyslipidemia. After remission of CD: 27% obesity ($P=0.8$), 25% overweight ($P=0.7$), 15.3% DM-2 persisted ($P=0.9$) [oral antidiabetics 100% (75% metformin and 25% metformin and secretagogue)], 46% HTA ($P=0.3$) and 50% dyslipidemia ($P=0.5$). BMI at diagnosis 32 ± 8 kg/m^2, after remission 30 ± 5 kg/m^2 ($P=0.8$).
Conclusions
CD is more frequent in the fourth decade of life and is more frequent in women. The prevalence of obesity, DM-2 and HTA is reduced after remission of CD, increasing the prevalence of overweight and dyslipidemia, without statistically significant differences.

DOI: 10.1530/endoabs.56.P820

Clinical relevance of metabolic phenotype in hypopituitarism: what really matters?

Dragana Miljic[1,2], Sandra Pekic[1,2], Mirjana Doknic[1,2], Marko stojanovic[1,2], Marina Nikolic-Djurovic[1,2], Milica Medic-Stojanoska[3,4], Verica Milosevic[5,6], Branka Sosic-Jurijevic[7,6], Vladimir Ajdzanovic[5], Zvezdana Jemuovic[1], Ivan Soldatovic[8,2], Vera Popovic[2] & Milan Petakov[1,2]
[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia; [2]Belgrade School of Medicine, Belgrade Univresity, Belgrade, Serbia; [3]Clinic of Endocrinology, Clinical Center of Novi Sad, Novi Sad, Serbia; [4]Medical Faculty, University of Novi Sad, Novi Sad, Serbia; [5]Department of Cytology, Institute for Biological Research 'Sinisa Stankovic', Belgrade, Serbia; [6]Belgrade University, Belgrade, Serbia; [7]Department of Cytology, Institute for Biological Research 'Sinisa Stankovic', Belgrade, Serbia; [8]Institute of Medical Statistics and Informatics, Belgrade, Serbia.

Previous studies reported increased prevalence of metabolic syndrome (MS) and mortality rates from cardiovascular causes in hypopituitary patients. Fatty liver disease was added recently to this unfavorable cardio-metabolic phenotype. We studied the prevalence of MS and non-alcoholic fatty liver disease (NAFLD) in unselected cohort of 282 hypopituitary patients (146 male), mean age 49.2 ± 15.1 years, on standard replacement therapy (76.4% received l-thyroxin, 76% hydrocortisone, 9.8% gonadal steroids, 4.6% desmopressin, 1.8% growth hormone). Surrogat marker of MS, lipid acummulation product (LAP) was calculated using gender specific formulas including waist circumference and triglyceride level. Marker of NAFLD, fatty liver index (FLI) was calculated using formula including body weight, height, waist circumference, triglyceride and gamma glutamyl transferase levels. Hepatic steatosis was assessed by ultrasonography and liver function tests. In this cross-sectional study, prevalence of MS was 57.1% (using IDF) and 48.6% (with ATP III criteria). MS was more common in females than males (IDF 63.2% vs 51.4%, $P=0.044$; ATP III 54.4% vs 43.2%, $P=0.059$) and significantly associated with unreplaced hypogonadism in female patients ($P=0.003$). Statistically significant associations ($P<0.001$) were found for MS and age, obesity, adult onset of hypopituitarism and NAFLD. Prevalence of NAFLD in the cohort was 20.6%, based on ultrasonographic features of hepatic steatosis, while in addition to this 7.1% had elevated liver enzymes. For NAFLD, statistically significant associations were found with MS ($P<0.001$), etiology of non-functioning pituitary macroadenoma ($P=0.006$) and growth hormone deficiency ($P=0.026$). Hypopitutary patients with NAFLD had more severe features of MS with significantly higher body mass index, waist circumference, cholesterol and triglycerides, LAP and FLI, but lower HDL compared to no-NAFLD patients ($P<0.001$). ROC analysis confirmed that LAP and FLI were reliable markers of hepatic steatosis and functional hepatic impairment resulting from NAFLD. MS is common in hypopituitarism, featuring NAFLD in one third of hypopituitary patients with MS. Hypopituitary NAFLD patients present with more severe MS and higher LAP and FLI indexes compared to no-NAFLD patients. LAP and FLI are reliable markers of hepatic steatosis and functional hepatic impairment, resulting from NAFLD. Complex interactions of multiple pituitary hormone deficiencies and balance in their replacement are very important for metabolic phenotype, as well as age, gender, obesity, adult onset and etiology of hypopituitarism.

TSH-secreting pituitary adenomas: clinical and morphological characteristics and outcomes of surgical treatment

Liudmila Astafyeva, Boris Kadashev, Pavel Kalinin, Maxim Kutin, Dmitriy Fomichev, Oleg Sharipov, Yuliya Sidneva, Irina Klochkova & Liudmila Shishkina
N.N. Burdenko National Medical Research Center Of Neurosurgery, Moscow, Russian Federation.

Objective
To study the clinical, diagnostic and morphological characteristics and treatment outcomes of TSH-secreting pituitary tumors.
Patients and methods
The study included 21 patients with pituitary adenoma and a normal or elevated TSH level and elevated fT_4 and fT_3 levels who were operated on at the Neurosurgical Institute in the period between 2002 and 2015. Before surgery, in the early postoperative period, and 6 months after surgery, the patients were tested for levels of TSH, fT_4, fT_3, prolactin, cortisol, LH, FSH, estradiol/testosterone, IGF-1. The thyroid status was evaluated using the following reference values: TSH, 0.4–4.0 mIU/l; fT_4, 11.5–22.7 pmol/l; fT_3, 3.5–6.5 pmol/l. An immunohistochemical study of material was performed with antibodies to TSH, PRL, GH, ACTH, LH, FSH, and Ki-67 (MiB-1 clone); in 13 cases, we used tests with antibodies to somatostatin receptors type 2 and 5 and to D2 subtype dopamine receptors.
Results
TSH-secreting tumors were detected in patients aged from 15 to 67 years (median 39 years), males (48%) and females (52%). Before admission to the Neurosurgical Institute, 11 (52%) patients were erroneously diagnosed with primary hyperthyroidism; seven of these patients underwent surgery on the thyroid gland and/or received thyrostatics (four cases). Hyperthyroidism symptoms were observed in 16 (76%) patients. The level of TSH was 2.47–38.4 mIU/l (median, 6.56); fT_4, 22.8–54.8 nmol/l (median, 36); fT_3, 4.24–12.9 pmol/l (median, 9.66). Tumors had the sellar localization in 4 (19%) cases and the parasellar localization in 17 (91%) cases. Total tumor resection was performed in 7 (33%) patients. All these tumors had the sellar and suprasellar localization. No total resection was performed in patients with infiltrative growth of adenoma (invading the skull base structures). An immunohistochemically study of tumor resection specimens detected TSH expression in 21 (100%) cases; 18 (86%) tumors were plurihormonal and secreted TSH and GH and/or PRL. Of 13 tumors, expression of the type 2 dopamine receptor was detected in 9 (69%) cases; expression of somatostatin receptors type 5 and type 2 was found in 6 (46%) and 2 (15%) cases, respectively.
Conclusion
The criterion for total tumor resection was a postoperative TSH level decrease to 0.1 mIU/l or less. Total resection was performed in 33% of patients with sellar and suprasellar tumors only. In most cases, tumors were plurihormonal secreting TSH and GH and/or PRL.

Recovery of the adrenal function after pituitary surgery in patients with Cushing Disease: remission or recurrence?

Andreea Serban[1], Elisa Verrua[1], Elisa Sala[1], Marco Locatelli[2], Maura Arosio[1], Giovanna Mantovani[1] & Emanuele Ferrante[1]
[1]Endocrinology Unit, Fondazione IRCCS Ca′ Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy; [2]Neurosurgery Unit, Fondazione IRCCS Ca′ Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy.

Background
The treatment of choice in patients with Cushing Disease (CD) is pituitary surgery (PS). A successful PS is generally followed by adrenal insufficiency (AI). Although the remission rate after PS may reach 96.6% of cases, approximately 1/3 of cured patients experience the recurrence of the disease during lifetime. The aim of this study was to analyze the duration of AI in relation with the recurrence of CD.
Materials and methods
We performed a retrospective analysis on patients with CD followed at our center between 1995 and 2017 and who met the following inclusion criteria: age above 18 years, presence of adrenal insufficiency 2–3 months after PS and a minimum follow-up of 3 years. Adrenal insufficiency was confirmed on either basal cortisol <3 μg/dl or a cortisol peak <18 μg/dl during consynthropin test (1 mcg or 250 μg). Recurrence was defined by high urinary free cortisol (UFC) levels and a positive dexamethasone suppression test (1 mg overnight or 2×2 mg: cortisol >1.8 mg/dl).
Results
According to the inclusion criteria we selected 54 patients. The mean follow-up was 6.6 years (median: 5 years, interquartile range (IQR): 4–9.25 years). The recurrence rate at 3 years was 11.1% (6/54) while the cumulative rate was 14.8% (8/54). Six out of eight patients experienced the recurrence in the first 3 years after PS, one patient at 4 years and one after 15 years. AI recovery rate without disease recurrence was 35.3% at 3 years with a cumulative rate of 48.8%. Comparison between the two groups (remission/recurrence) showed a similar gender ratio (F:M = 8:1), BMI (25.4 ± 4.1 vs.27.7 ± 6.6, $P=0.4$), age at PS (43.5 ± 16.1 vs 41.5 ± 14.3 years, $P=0.7$). Also hormonal characteristics and radiologic features did not show any significant difference between the two groups. The duration of AI was the only parameter significantly different (median 24.3, IQR: 11.9–40 vs 10.7, IQR: 8.1–17.2). In particular, the recovery time of adrenal function represented a significant predictor for persistent remission (OR: 1.14, CI: 1.003–1.313, $P=0.046$). Using the duration of AI as diagnostic test for persistent remission we observed a good accuracy (AUC 0.91, $P<0.001$). The persistence of AI after 22 months had a PPV of 100% and NPV of 47% for persistent remission.
Conclusion
Our study show that the duration of adrenal insufficiency after PS in patients with CD may be a useful predictor for persistent disease remission.

Hypothalamic involvement in diffuse large B-celllymphoma

Melda Apaydin[1], G Gonca Örük[2], Türkan Atasever Rezanko[3] & Asu Fergün Yılmaz[4]
[1]Izmir Katip Celebi University Ataturk Training and Research Hospital, Division of Radiodiagnostics, Izmir, Turkey; [2]Izmir Katip Celebi University Ataturk Training and Research Hospital, Division of Endocrinology and Metabolism, Izmir, Turkey; [3]Izmir Katip Celebi University Ataturk Training and Research Hospital, Division of Pathology, Izmir, Turkey; [4]Izmir Katip Celebi University Ataturk Training and Research Hospital, Division of Hematology, Izmir, Turkey.

Non-hodgkin lymphoma (NHL) is a hematological tumor caused by abnormal lymphoid proliferation. NHL can arise in any part of the body, including central nervous system (CNS). However, hypothalamus involvement is a rare presentation. Here, we report a case of hypothalamic infiltration of NHL Diffuse Large B-cell lymphoma (DLBCL) in a 21 years old male patient with panhypopituitarism and diabetes insipidus. The patient was admitted to the hospital with a history of nausea, vomiting, headache, asthenia, quickly worsening walking impairment and weight loss in two months. He denied neck stiffness and fever. Neurological examination showed global motor slowing, generalized weakness against resistance to head and limbs, no sensitive deficit or focal neurologic sign was recognizable. Hormonal evaluation revealed panhypopituitarism. Non-contrast computed tomography (CT) of the head was performed in the emergency department, showing hydrocephalus and a suprasellar mass. At further imaging a soft tissue mass with a maximum diameter of 14×16 mm on the axial plane, which was located in the infundibulum, optic chiasma and hypothalamus and extending into the third ventricle was also discovered with magnetic resonance imaging (MRI). Ependymoma, metastasis to the hypothalamus, primitive neuroectodermal tumor was speculated for differential diagnosis. Anterior and posterior pituitary was preserved. Lumbar puncture, blood tests, including serology for HIV and other infections, were negative. He was operated and immune histopathological examination of the specimen revealed DLBCL. He was treated with chemotherapy (rituximabe, methotrexate) and cranial radiotherapy. During hospitalization, hypotension, polydispsia, polyuria were observed. Hormonal and clinical evaluation was compatible with central diabetes insipidus and panhypopituitarism. He is still being followed with desmopressin, dexamethasone, levothyroxin and testosterone. The incidence of primary central nervous system lymphoma (PCNSL) has been increasing in recent years, accounting now for 2–6% of all intracranial tumors, although it is considered an uncommon aggressive tumor. Most PCNSL is diffuse large B-cell lymphoma ($>95\%$) whereas T-cell lymphomas are rare. Clinical presentation and imaging findings can vary according to the immune status of the patient. In order to treat the disease optimally, early diagnosis is important. In conclusion, hypothalamic infiltration of NHL on MRI is a rare finding. Diagnosis should be suspected after biochemical analysis and MRI results. Treatment consists of chemotherapy against NHL and hormonal replacement for pituitary dysfunction.

Iceberg alert: undetected health problems in adults with Prader-Willi syndrome – multidisciplinary care could prevent 'unexplained deaths'

Karlijn Pellikaan, Anna Rosenberg, Janneke Baan, Kirsten Davidse & Laura de Graaff
Erasmus Medical Center of Rotterdam, Rotterdam, Netherlands.

Introduction
A yearly mortality rate of 4% among young adult patients is unacceptable in any patient population. Nevertheless, in Prader-Willi syndrome (PWS), up to 4% of young patients die every year and this situation has been going on for decades. PWS is a complex hypothalamic disorder, combining hypotonia, intellectual disability (ID), pituitary hormone deficiencies and hyperphagia. Due to this lack of satiety, patients can literally eat themselves to death: overeating can cause morbid obesity, complicated by diabetes and secondary cardiovascular complications, or stomach rupture. The mean age of reported deaths in PWS is 29.5 years; 20% of deaths even occur below age 18 years and mortality is often unexpected. Autopsy reports show that in some cases, the cause of death is food-related, like gastrointestinal perforation and aspiration/choking due to rapid consumption of food. However, in half of the patients, the cause of death turns out to be cardiovascular origin or obesity-related respiratory failure. These severe complications can be prevented if Prader-Willi associated obesity is managed effectively in a multidisciplinary setting.
Methods
In order to optimize care for patients with this complex syndrome, we have launched a multidisciplinary outpatients clinic (OPC) for adults with PWS, consisting of an endocrinologist, an ID-physician, a physiotherapist, an ID-dietitian and a neuropsychologist. We have analysed the clinical data of the patients who visited the multidisciplinary OPC including medical histories and physical and biochemical measurements.
Results
Among the first 90 patients visiting the multidisciplinary OPC, we found a striking number of undetected and untreated health problems, like untreated hypogonadism (also present in lean PWS adults), untreated osteoporosis, untreated diabetes, untreated hypothyroidism and obesity. Although half of the patients was obese, 23% of patients exercised less than 30 min per day and one third was not on a diet. Caregivers often reported stealing and merchandising for food, meaning that diets are doomed to fail unless carefully supervised. Nevertheless, 25% of patients lived under incompetent supervision.
Conclusion
During the first two years of the multidisciplinary OPC, we detected a striking number of untreated health problems among adults with PWS. Most patients have at least 3 serious health problems. The combination of complex health issues among adults with PWS requires multidisciplinary care. The multidisciplinary OPC for adults with PWS will prevent painful and expensive complications and reduce mortality in this vulnerable patient population.

Pituitary apoplexy in pregnancy lead to empty sella

Ramazan Gen[1], Emel Avcı[2], Leyla Batmaz[1], Kerem Sezer[1] & Esen Akbay[1]
[1]Mersin University Endocrinology and Metabolism, Mersin, Turkey; [2]Mersin University Neurosurgery, Mersin, Turkey.

Pituitary apoplexy (PA) is an endocrine emergency characterized by acute, severe headache, visual disturbances, ophthalmoplegia, hypopituitarism and altered consciousness. This condition usually arises in an underlying pituitary adenoma. 27-year-old female without a known pitutary lesion presented to the emergency department in December 2015 with a 8-hour history of with sudden and severe frontal headache, fever, blurred vision, nausea, confusion at 36 weeks of gestation. The past history revealed that the patient had normal periods after puberty and no galactorrhea before pregnancy. Nothing was notable from her medical or family history; she did not smoke and was not taking any drugs.On admission her laboratory evaluation was revealed secondary hypothyroidism, and secondary adrenal insufficiency (Table 1).Non-contrast MRI demonstrated a macroadenoma, 2.2×2.1 cm in size with apoplexy and there were significant suprasellar extension and compression of the optic apparatus. The patient was admitted to the intensive care unit and put on intravenous steroids. She reported a dramatic improvement in her vision and headeche within 24 h after steroids treatment. After five days of hydrocortisone treatment L-thyroxine 25 μg/day treatment was given for secondary hypothyroidsm which dose increased gradually. She was treated conservatively and the clinical picture improved in a few days, followed by an uneventful pregnancy and delivery. Six month after delivery MRI report revealed empty sella and endocrinological investigation revealed secondary gonadal, thyroid and adrenal insufficiency (Table 1). Patient used hydrocortisone 20 mg/day and L-thyroxine 100 μg/day.
Conclusion
Pituitary apoplexy is a rare condition and it may manifest as the first presentation for the preexisting pituitary tumor.

Table 1 Endocrinological Evaluation

	On admission	6 monts after delivery	Normal reference value
ST4 (pmol/l)	9.0	16.5	12–22
TSH (mIU/ml)	0.064	0.151	0.4–4.2
PRL (ng/ml)	352	467	4.79–23
GH (ng/ml)	0.187	0.675	
IGF-1 (ng/ml)	298	287	116–358
Cortisol (nmol/l)	175	138	171–536
ACTH (pg/ml)	<5	<5	0–46
FSH (IU/l)	<0.1	<0.1	3.5–12.5

Benefits of pre-surgical treatment with somatostatin analogs in naive patients with acromegaly

Isabel M Cornejo-Pareja[1], Silvia Maraver-Selfa[1], Araceli Muñoz-Garach[1], Inmaculada Gonzalez-Molero[2], Isabel Mancha-Doblas[1] & Francisco Tinahones[1]
[1]Endocrinology and Nutrition Department, Virgen de la Victoria Hospital, Málaga, Spain; [2]Endocrinology and Nutrition Department, Regional Universitary Hospital, Málaga, Spain.

Introduction
Somatostatin analogs (SS-analogs) are the treatment option when there is a persistent disease despite surgical intervention. They can be also recommended as a first line treatment if surgery is not appropriate (non-curative or contraindicated surgery).
Objetive
To evaluate the effect of first-generation SS-analogs (lanreotide and octreotide) on tumour shrinkage and biochemical control in naive patients.
Methods
We performed a prospective study of 23 acromegalic patients (followed between years 2000 and 2015) treated with SS-analogs awaiting surgery. We evaluated mean age, associated comorbidities, growth hormone (GH), insulin growth factor 1 (IGF1), and prolactin (PRL) mean levels, also tumour volume (TV) and maximum tumour diameter (MTD) reduction, and repercussion of SS-analogs in the glicaemic metabolism; baseline and after 6 months of treatment. The differences between groups were calculated by Wilcoxon test.
Results
The mean age at diagnosis was 48±13 years, 39% men and 61% women. 87% were macroadenomas. BMI was 26±4 kg/m^2. Hypertension was found in 47%, glicaemic metabolism disorders in 47%, dyslipidemia in 26%, obstructive sleep apnea hypopnea syndrome in 17%, carpal tunnel syndrome in 30%. 57% of patients received high doses of SS-analogs, 34% medium doses and 9% low doses. 26% received concomitant treatment with cabergoline. After 6 months of treatment, we found significant differences in: MTD (18±9 previous vs 15±9 mm, $P=0.001$), TV (3098±4,829 vs 2,362±5,005 mm^3, $P=0.001$), GH levels (30±28 vs 12±20 ng/ml, $P=0.003$), IGF1 levels (1182±461 vs 661±50 ng/ml, $P=0.000$) and PRL levels (29±33 vs 7.4±5.4 ng/ml, $P=0.001$). After 6 months of treatment: 26% normalized IGF1, 13% had GH levels under 1 ng/ml and 61% achieved a TV reduction ≥ 20%. We did not find significant differences in glicaemic metabolism after receiving treatment with SS-analogs (glycemia 119±37 vs 114±17 mg/dl, $P=0.74$ and HbA1c 6±0.9 vs 6.1±0.8%, $P=0.66$).
Conclusions
Our results demonstrate the clinical benefit, in biochemical control and tumour shrinkage, of SS-analogs as a primary treatment for patients with acromegaly.

Temozolomide is effective for rapid control of hypercortisolism in aggressive acth-secreting pituitary tumors

Daniele Cappellani[1], Gabelloni Michela[2], Mirco Cosottini[2], Claudio Urbani[1], Giulia Marconcini[1], Luca Manetti[1], Claudio Marcocci[1], Fausto Bogazzi[1] & Isabella Lupi[1]
[1]Department of Clinic and Experimental Medicine, Unit of Endocrinology, University of Pisa, Pisa, Italy; [2]Department of Translational Research and New Technologies in Medicine and Surgery, Unit of Neuroradiology, University of Pisa, Pisa, Italy.

Background
Temozolomide is an alkylating chemoterapic agent that ties a methyl to guanine, causing a base-pair mismatch and a DNA damage, resulting in cell death. Due to its lipophilic nature and its ability to cross the blood-brain barrier, this drug was originally used for malignant gliomas and later for aggressive pituitary tumors and carcinomas. Temozolomide is now recommended as first-line chemotherapy by the recently published ESE Clinical Practice Guidelines. Here we present our experience with temozolomide in three patients with aggressive and invasive ACTH-secreting pituitary tumors.
Patients
PT1 (female, 65 years-old) after two surgical interventions (pathology: ACTH-staining pituitary adenoma) and several medical therapies, underwent a severe relapse in hypercortisolism associated with worsening of general conditions and increase in tumor remnants. Temozolomide was started, leading to a sudden control of hypercortisolism. One month later PT1 underwent gamma-knife radiosurgery. Temozolomide was withdrawn after five cycles for hematological side effects. After 5 years, hypercortisolism is still in remission and a signisficant reduction in tumor remnants was documented. PT2 (male, 50 years-old) a few months after pituitary surgery (pathology: ACTH-staining pituitary atypical adenoma, Ki-67 > 4–5%) underwent severe relapse of hypercortisolism; temozolomide (in association with capecitabine, 'CAPTEM') was started with pasireotide, leading to a rapid control of disease. Six months later PT2 was treated with external-beam radiotherapy. CAPTEM was withdrawn after 12 cycles, pasireotide was withdrawn 1 month later and hydrocortisone was started for the development of hypocortisolism. PT3 (male, 50 years-old) had been treated with four surgical interventions and a course of external-beam radiotherapy. MRI revealed tumor remnants in the right cavernous sinus and above the sellar region, compressing the right subnuclear and temporo-mesial regions and the right-inferior cerebellar pedunculus; furthermore a meningeal metastasis was spotted above the clivus, protruding in the prebulbar cysterna. PT3 underwent 15 cycles of CAPTEM gaining an overall good control in hypercortisolism and a reduction in tumor and metastasis size. PT3 remained in remission of disease for 3 years.
Conclusion
Therapy with temozolomide (alone or in combination with capecitabine) was highly effective in controlling hypercortisolism in the short term; moreover, in association with radiotherapy, temozolomide proved effective in reducing pituitary mass and prolonging remission of disease. It can be considered for different categories of patients: patients (as PT1) with severe/repeated recurrence of disease; patients (as PT2) with histologically aggressive tumors in whom surgery was not complete and hypercortisolism relapses; patients (as PT3) with pituitary carcinoma.

Cancer in acromegaly: a case-control study

Susana Mallea Gil[1], Graciela Stalldecker[2], Sabrina Diez[2], Adriana Palazzo[1], Bruno Peressotti[1] & Carolina Ballarino[1]
[1]Servicio de Endocrinologia, Hospital Militar Central, Buenos Aires, Argentina; [2]Servicio de Endocrinologia, Hospital Ignacio Pirovano, Buenos Aires, Argentina.

Carcinomas are the third most frequent cause of complications in acromegalic patients. It has been suggested that diabetes potentiates the risk of cancer. To assess the frequency and type of malignant neoplasms in acromegalic patients and control group; to evaluate, in both groups, the relationship between IGF-I/GH and the development of cancer, and between glucose metabolism and cancer in two centers of Buenos Aires, Argentina. Retrospective, cross-sectional study; medical records of patients with acromegaly and control group with pituitary illnesses with normal GH/IGFI, sex- and age-matched, 1985–2017, were reviewed in order to find information about the presence of any neoplastic diseases. Sixty-two acromegalic patients, 50% women; 51 controls, 55% women; mean time of follow-up was 10.2 years. Mean age of acromegalic patients and control group was: 59 ± 14 vs 58 ± 15 years. Nine acromegalic patients (14.5%) developed cancer; mean age when cancer appeared was 59 ± 14 years. In two patients both diseases were simultaneously diagnosed; in the remaining patients the mean time between the diagnosis of acromegaly and cancer diagnosis was 15.7 years. The types of cancer were: colon in three male patients (33%), prostate in 2 (22%), testicular teratocarcinoma in one, breast in one female, papillary thyroid carcinoma in one female, kidney in one male. IGF-I and GH at cancer diagnosis were elevated in three patients and normal in six. Eight patients had altered glucose metabolism, only one had normal glucose levels. In the control group, four patients developed cancer (7.8%), mean age when cancer appeared was $59 \pm$ 24 years, and the types of cancer were: in two men lymphoma and lung cancer; in two women rhabdomyosarcoma in mediastinum and colon cancer. None of these patients had altered glucose metabolism. The relative risk of developing cancer in acromegalic patients was 1.85, IC 95% 0.65–5.66. When we compared the disturbance of glucose metabolism in both groups with cancer, acromegalic vs control, it was 88,9% vs 0.0% ($P = 0.007$), respectively. In acromegalic patients, among those who developed cancer and those who did not, the glucose metabolism disorders were 88.9% vs 35.8% ($P = 0.008$), respectively.
Conclusions
In our study, the risk of developing cancer in acromegalic patients was 85% higher than in the control group. Although this trend is important, statistical significance was not reached due to the small sample size. In acromegalic patients, cancer was significantly associated with disturbance of glucose metabolism.

A rare case of acromegaly with normal IGF-1, severe chronic congestive heart failure, and impaired glucose tolerance

Maria Kurowska[1], Joanna Malicka[1], Agnieszka Zwolak[2] & Jerzy S Tarach[1]
[1]Department of Endocrinology, Medical University, Lublin, Poland; [2]Chair of Internal Medicine and Department of Internal Medicine in Nursing, Medical University, Lublin, Poland.

Introduction
Acromegaly with normal IGF-1level is rarely diagnosed and is difficult to recognize. In acromegalic pa-tients with poorly controlled diabetes, malnutrition, hepatic injury, hepatic congestion due to heart fail-ure, inflammatory diseases, renal dysfunction, and malignant neoplasm, IGF-1 synthesis is inhibited and thus in such cases normal IGF-1 levels may be observed. The aim of the study is to present a rare case of a patient with acromegaly and normal IGF-1 level, and to emphasize that low or normal concentrations of IGF-1 do not rule out the diagnosis of acromegaly.
Case report
A 75-year-old woman with pituitary macroadenoma was admitted to hospital with suspected acromegaly. The pituitary tumor was visualized 24 years earlier during CT performed because of headaches. 1 year later, without hormonal evaluation, the patient was disqualified from the neurosurgical treatment. For 23 years she had performed only periodic imaging controls. In 2012 CT revealed a focal lesion 17×15 mm within the Turkish saddle, suggesting the presence of craniopharyngioma. 28 years ago the patient had undergone partial thyreoidectomy due to nodular goiter. She also suffered from long-term arterial hypertension resistant to treatment, chronic heart failure, atrial fibrillation with ventricular extrasystolia and severe osteoarticular disorders. She had thickened facial features, enlarged tongue, hands and feet, and increased sweating. Basal GH level was 10.37 ng/ml (n:0.03–2.47) without GH suppression during OGTT (3.79 ng/ml, $n: < 0.4$), IGF-1 = 157.3 ng/ml (n: 29–204). The remaining pituitary functions were normal. On the basis of OGTT [96 mg%–150 mg%] an impaired glucose tolerance was diagnosed. In MRI pituitary tumor $17 \times 19 \times 14$ mm was detected. Renal insufficiency, malnutrition [BMI = 34.2 kg/m^2] or malignant neoplasms were excluded. Acromegaly was diagnosed and Lanreotyd Autogel 120 mg every 28 days was introduced. Because the patient refused neurosurgery, she remains on long-acting somatostatin analogue therapy.
Conclusion
Probably the low concentration of IGF-1 in the presented case was caused by liver damage secondary to long-term severe congestive heart failure, most likely caused by long-term untreated acromegaly and hyperglycemia.

Two-dimensional speckle tracking echocardiography showed a slight impairment of left ventricular deformability in acromegalic patients at diagnosis and during follow-up

Claudio Urbani[1], Iacopo Fabiani[2], Valeria Siciliano[1], Daniele Cappellani[1], Michele Mantuano[1], Nicola Riccardo Pugliese[2], Claudio Marcocci[1], Vitantonio Di Bello[2] & Fausto Bogazzi[1]
[1]Section of Endocrinology, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy; [2]Cardioangiology Departmental Section, Cardio-Thoracic and Vascular Department, University of Pisa, Pisa, Italy.

Introduction
Acromegalic heart disease is characterized by concentric left ventricular (LV) hypertrophy and impaired LV function. Speckle tracking echocardiography (STE) allows a non-invasive and reproducible study of myocardial strain, a marker of cardiac deformability and early ventricular systolic dysfunction.
Objectives
The aims of the study are: 1) evaluation of STE parameters in acromegalic patients at diagnosis and during the follow-up; 2) appraisal of the role of hypertension, diabetes or both on the STE parameters in acromegaly; 3) assessment of the impact of biochemical control and different treatments for acromegaly on global LV longitudinal strain (GLS) and other echocardiographic features.
Patients and methods
It was an historical-prospective study enrolling 111 acromegalics and 54 matched subjects with non-functioning pituitary adenoma used as controls. All subjects underwent clinical and biochemical evaluations and two-dimensional echocardiography using STE. LV mass index (LVMi), LV ejection fraction (LVEF), E/A ratio, and GLS were obtained. 53 patients were evaluated at diagnosis of acromegaly; 21 of them were also longitudinally reassessed after reaching disease control. 79 subjects were evaluated during the follow-up and classified according to treatment for acromegaly: adenomectomy ($n=11$), somatostatin analogs (SSA, $n=43$), Pegvisomant (Peg, $n=16$), SSA + Peg ($n=9$). 69/79 subjects appraised during the follow-up had complete control of acromegaly at the time of STE evaluation.
Results
At diagnosis, mean LVMi was increased and mean E/A ratio was decreased in acromegaly compared to controls (*t* test; $P=0.03$ and $P=0.009$, respectively). The mean GLS differed between acromegaly and control group at diagnosis (t-test; -18.12 ± 0.43 vs. -19.55 ± 0.35, $P=0.01$). The presence of hypertension, diabetes or both did not affect GLS at diagnosis of acromegaly (ANOVA, $P=0.81$). Any differences in LVMi, EF, E/A ratio, and GLS were observed during follow-up, either stratifying patients with biochemical disease control or the basis of the type of therapy. In the group of subjects evaluated longitudinally, GLS improved in 12 and worsened in nine after the achievement of disease control even if the mean GLS value did not significantly change (paired *t* test $P=0.62$).
Conclusions
Acromegalic patients are characterized by concentric LV hypertrophy and diastolic dysfunction at diagnosis. GLS study showed, for the first time, slight impairment of cardiac deformability in naive acromegalic patients that was not influenced by the presence of hypertension and diabetes. The therapies and the biochemical control of acromegaly do not seem to influence myocardial strain in acromegalic patients.

P832

Trabecular bone score as skeletal fragility predictor in patients with acromegaly

Laura Pérez-Olivares Martín, María Calatayud Gutiérrez, María Soledad Librizzi, Violeta González Méndez, Sonsoles Guadalix Iglesias, Federico Hawkins Carranza & Guillermo Martínez Díaz-Guerra
Hospital Universitario 12 de Octubre, Madrid, Spain.

Introduction
Several studies have demonstrated a high incidence of vertebral fractures (VF) in acromegaly, not always correlated with bone mineral density (BMD) value adquired by dual X-ray absorptiometry (DEXA). At trabecular level, GH may alter bone microarchitecture (BM) that predisposes to bone fragility. Trabecular Bone Score (TBS), a textural parameter applied to DEXA to evaluate BM, could be useful to predict VF risk in these patients.
Materials and methods
A cross-sectional study was carried out in acromegalic patients followed up at our hospital between 1989 and 2016. DEXA with Horizon DXA system (Hologic®) to assess lumbar (L1-L4) BMD and TBS value (TBS iNsight®), spine X-ray and blood tests to evaluate hormonal status and bone metabolism were performed. DXA and TBS results were compared with a healthy control group. TBS ≥ 1.35 corresponded to a normal BM (NBM), 1.2-1.35 to a partially degraded BM (PDBM) and ≤ 1.2 to a degraded BM (DBM).
Results
Twenty-six acromegalic patients meeting criteria of disease control by IGF1 levels (53.8% women; age 59.3 ± 15.6 and median BMI 28.4 kg/m^2) and 128 control subjects (53.1% women; age 50.9 ± 20.3 and median BMI 24.9 kg/m^2) were evaluated. TBS was lower in patients compared with control (1.26 ± 0.13 vs 1.35 ± 0.18; $P=0.01$), with no significant differences in BMD (g/cm^2), T-score and Z-score (0.99 ± 0.2 vs 0.96 ± 0.15; -0.63 ± 1.76 vs -0.95 ± 1.35 and 0.41 ± 1.67 vs -0.22 ± 1.44 respectively). In acromegalic patients no significant relationships were found between IGF-1, gonadal and adrenal status, TBS and lumbar BMD. Patients who had received radiotherapy (RT) had lower TBS than those who had not (1.15 ± 0.08 vs 1.31 ± 0.13; $P=0.017$). DBM was observed in 80% of acromegalic patients with diabetes mellitus vs 22% in non-diabetics ($P=0.05$). VF were found in 3 patients, all of them with TBS values corresponding to DBM (TBS 1.09, 1.2 and 1.08).
Conclusions
In our study, acromegalic patients show lower TBS than healthy controls, particulary in RT-treated and diabetic subgroups. This finding suggests alterations in BM that could explain the increased risk of fractures in these patients. More studies are needed, exploring the fracture predictive capacity of TBS in these patients.

Registry for central diabetes insipidus in Russia: prevalence and etiologies of the disease

Ekaterina Pigarova[1], Larisa Dzeranova[1], Zhanna Belaya[1], Liudmila Rozhinskaya[1], Alexander Lutsenko[1], Galina Melnichenko[1], Ivan Dedov[1] & The Consortium CDI[2]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]Endocrinologists, Regions, Russian Federation.

Introduction
Epidemiological data for central diabetes insipidus (CDI) are quite sparse.
Objectives
To provide an epidemiological data on CDI in different regions of Russia (20 from 83 Federal regions).
Materials and methods
We used the Russian Registry for Central Diabetes Insipidus (RCDI) to study the epidemiological features of CDI.
Results
A total of 2004 patients with CDI were recorded, 47% women and 59% men. The most common of identified etiologies for CDI were postoperative (13,1%), head trauma (7,4%), and pathology of development of hypothalamic-pituitary region (6,9%). Less common were tumors (4,3%) and hereditary forms of CDI (4,3%). Rare forms of CDI with less than 4% overall were neuroinfection, Langergans hystiocytosis, sarcoidosis, and Sheehan syndrome. Idiopathic CDI was considered in 37% of patients, which is lower than previously reported 51%. The prevalence between participating in RCDI regions was variable from 0,65 to 10,67 cases per 100 000 population. The prevalence in Moscow city which represents a multinational population was 4,5% per 100 000 population. Nine from 20 regions have higher prevalence than that in Moscow city, with 4 of them having the prevalence twice as higher which may represent ethnic differences.
Conclusions
There is a reduction of previously reported proportion of idiopathic form of CDI which represent a progress in diagnostics. High variability in prevalence of CDI may represent ethnic differences.

Two cases of silent corticotroph adenomas

Murat Cinel, Sule Canlar & Sevim Gullu
Ankara University Faculty of Medicine, Endocrinology and Metabolism Department, Ankara, Turkey.

Introduction
Pituitary adenomas are mostly benign tumors which may be clinically functioning or non-functioning and ACTH secreting tumors make up 15% of them. Up to 20% of corticotroph adenomas which don't have any biochemical or clinical evidence of hypercortisolism are known as silent corticotroph adenomas.
Case 1
A 54 years old male presented with blurred of vision and headache that increasing in severity within six years. Physical examination and visual field tests were normal. After initial evaluation, the brain MRI was performed and pituitary mass was detected 33x27x28mm diametered, heterogeneous in nature, extented to suprasellar region, infiltrates cavernous sinuses and contact with optic chiasma. Pituitary hormones were in normal range except high serum ACTH level. Twenty four hour urine free cortisol level and dexamethasone supression test are within normal range and physical examination did not show any cushingoid signs. Transnasal transsphenoidal surgery was performed and pathology reported as "densly granulated corticotroph adenoma, Ki 67: %3, p53 (-)".
Case 2
A 55 years old male admitted to hospital with a complaint of headache. Past medical history includes prior pituitary surgery, depression and hypertension. His arterial tension and neurologic examination was normal. Prior pituitary pathology report could not be reached. After first evaluation he underwent to brain MRI that revealed pituitary adenoma about 12x10x5mm in diametered, no sign for extension to optic chiasma and cavernous sinuses. Pituitary hormones were in normal range except high serum ACTH level. Twenty four hour urine free cortisol level and dexamethasone supression tests were in normal range, patient had also no cushingoid signs. Transnasal transspheonidal surgery was performed and pathologic examination revealed "corticotroph staining adenoma as Ki 67: %2 and p53 (-)".
Discussion
Cushing's disease are detected in 0.7 to 2.4 per million individuals per year. Most of the corticotroph adenomas are microadenomas. Silent ACTHomas are generally >1 cm in diameter. It is difficult to differentiate pre-perioperatively. Most of silent adenomas don't exhibit any hormonal and physical abnormalities except for serum ACTH level. But serum ACTH level is not enough alone to diagnose Cushing's disease. It is thought that high-measured ACTH is immunologically active but biochemically inactive. So clinicians must be avoided to make wrong diagnosis. Clinicians also should keep in mind that sometimes silent adenomas cause subclinical Cushing diseases during progression of disease and most of them are difficult to remove surgically because of extension to surrounding tissue.

IgG4-related neuroinfundibulo-hypophysitis treated by rituximab and corticosteroids

Isabella Lupi[1], Claudio Urbani[1], Luca Manetti[1], Mirco Cosottini[2], Alessandro Brancatella[1], Daniele Cappellani[1] & Fausto Bogazzi[1]
[1]Department of Clinical and Experimental Medicine Section of Endocrinology, University of Pisa, Pisa, Italy; [2]Department of Translational Research and New Surgical and Medical Technologies University of Pisa, Pisa, Italy.

IgG4-related hypophysitis, a type of IgG4-related disease, is a rare condition. It appears to be sensitive to glucocorticoids in most patients, but its recurrence is likely.
Clinical case
A 17 year-old girl was referred for hypotonic polyuria and polydipsia of 1 month duration. Water deprivation test was suggestive of central diabetes insipidus. Basal and dynamic assessment of pituitary anterior function were unremarkable. Patient did suffer from autoimmune thyroiditis and autoimmune gastritis. Serum IgG4 were found high [269 mg/dl (49-66)] as well as serum IgE [2600 U/ml (50-120)]. Magnetic resonance imaging (MRI) of the sella turcica showed a clear enlargement of the pituitary stalk with an intense and homogeneous contrast enhancement, the neurohypophysis bright spot, on pre-contrast images, could not be identified. IgG4-related neuroinfundibulo-hypophysitis was suspected on clinical grounds. Imaging studies, such as total body positron emitted tomography and abdomen ultrasound, excluded other localization of disease.B-cell depletion therapy with Rituximab was administered (1 g iv for two doses in 14 days), preceeded by metilprednisolone pulse therapy. Oral therapy with metilprednisolone, started at 40 mg/d, was continued for 6 months. To control polyuria, desmopressin was started at 180 mcg/d.Three months after first treatment, control MRI showed a normal sized pituitary stalk with normal enhancement after gadolinum, serum IgG4 and IgE were reduced (60% and 30%, respectively) although still above normal range. After 6 months, at the end of metilprednisolone therapy, sellar MRI still showed a normal pituitary and stalk. IgG4 and IgE were decreased, pituitary anterior function was normal. Diabetes insipidus was still present, however the dose of desmopressin needed to control polyuria was lower than at diagnosis (60 mcg/d).
Conclusion
IgG4 related hypophysitis is a rare condition that may benefit from B-cell depletion therapy. Goal of treatment is remission of pituitary inflammation and ultimately of diabetes insipidus. Careful follow-up is needed in order to spot recurrence of the disease, in the pituitary or in other sites.

Early postsurgery cortisol after transphenoidal surgery to predict adrenal insufficiency one year posturgery

Inmaculada Gonzalez Molero[1], Viyey Doulatram[1], Silvia Maraver[2], Montse Gonzalo Marín[1], Jose Abuin[1], Ignacio Ruiz García[1], Miguel Angel Arraez[1], Francisco Tinahones[2] & Gabriel Olveira[1]
[1]CArlos Haya Hospital, Malaga, Spain; [2]Hospital Clinico, Malaga, Spain.

Aim
To assess a perioperative glucocorticoid protocol in transsphenoidal surgery (TSS)and the performance of early post-TSS 08:00 cortisol measurement to detect/exclude secondary adrenal insufficiency.
Methods
We selected patients undergoing TSS.In patients with no cushing disease, we checked cortisol/Synachten presurgery, measured 3° postoperative 0800 a.m. cortisol(after 24 h without corticoids) and cortisol/Synachten 3-6 months post-surgery. We excluded patients with previous diagnosed and treated adrenal insuficiency.All included patients received perioperative glucocorticoid replacement (First and second days postsurgery) unless basal cortisol was >10 mcg/dL and cortisol after Synachten >23 mcg/dL previous to surgery (In these patients we measured cortisol in 1 day postsurgery). All patients with cushing disease received perioperative glucocorticoid. In patients with 1°/3° day cortisol lower than 15 we maintained glucocorticoid treatment until reevaluation with cortisol/Synachten 6 months post-surgery.In patients with 1°/3° day cortisol higher than 15 glucocorticoids were discontinued. We evaluated again patients after one year of surgery.
Results
Data were obtained from 52 patients (55,7% women, mean age 46,7+/-15,6 years), Mean tumour size:20.1+/-11.9 (5-51 mm). Diagnosis:40.4% non functioning adenomas, 17,3% acromegaly, 26,9% cushing disease, 7.7% prolactinoma, 7.7% others. 72.4% of patients were treated with glucocorticoids perioperative. Patients with adenomas no cushing: 85% of patients with 1°/3° day cortisol $>$ 15mcg/dL had normal cortisol/Synachten 6 months post-surgery vs 20% of patients with 1°/3° day cortisol <15 ($P<0.05$). After one year of surgery: 88,2% of patients with 1a/3° day cortisol >15mcg/dL had adrenal sufficiency, 40% of patients with 1a/3° day cortisol between 10 and 15 and 50% of patients with <5 mcg/dL had adrenal sufficiency. 9.1% of patients with adenomas <20 mm had adrenal insufficiency vs 46.2% of patients with adenomas >20 mm (100% if patients had other presurgery deficiencies) ($P<0.05$). None of the patients without perioperative glucocorticoids had adrenal insufficiency symptoms during perioperative period. Cushing disease: all patients with 3° day cortisol $<$ 5mcg/dL are in remission 1 year after surgery vs 33,3% of patients with 3° day cortisol >5 mcg/dL ($P<0.05$)
Conclusion
A 3° day post-TSS cortisol $>$ 15mcg/dL is a safe cutt off to discharge adrenal insufficiency. 100% of patients with 3° post-TSS $<$ 5 mcg/dL are in remission 1 year postsurgery. Our protocol to select patients who need or not perioperative glucocorticoids is safe to manage patients with TSS.

Cushing's disease with negative or inconclusive MRI: reassessment of transphenoidal surgery at the age of medical treatment. Post operative remission rate in 184 patients including 86 with negative or inconclusive MRI

Justine Cristante[1], Virginie Lefournier[2], Nathalie Sturm[1], Jean Guy Passagia[1], Emmanuel Gay[1] & Olivier Chabre[1]
[1]CHU Grenoble Alpes, Grenoble, France; [2]Clinique Mutualiste, Grenoble, France.

When pituitary MRI show a typical imaging of adenoma, it is agreed that transsphenoidal surgery is the reference treatment with remission achieved in about 80% of patients. If MRI is negative or inconclusive, some authors consider that the results of surgery are less successful, and propose medical treatment as a first line therapy, despite a disease control rate between 30 and 70%. Since 1990, our center chose to systematically explore patients with ACTH dependent hypercorticism by a Bilateral Inferior Petrosal Sinus Sampling (BIPSS) when MRI is negative or inconclusive, and to perform transphenoidal neurosurgery when BIPSS demonstrates that ACTH is of pituitary origin. The remission data and the characteristics of the adenomas were retrospectively collected from the computerized medical file of all our patients operated for Cushing's disease between 1992 and 2016. Our main objective was to evaluate the performance of neurosurgery in Cushing's disease in patients with normal or inconclusive MRI versus MRI with a typical adenoma image. 184 patients were operated: 82 microadenomas, 16 macroadenomas, 43 with inconclusive MRI and 43 negative MRI. The postoperative remission rates were not statistically different, 85.4%, 93.7%, 72.1% and 74.4% ($P=0.119$) respectively. A crude cost analysis comparison between expert neurosurgery and medical treatment shows that in our country the cost of drugs to treat only one patient for Cushing's disease for 30 years is equivalent to the cost of exploration and treatment of 30 to 60 patients in an expert center for pituitary surgery and neuroradiology. We conclude that even at the age of medical treatment neurosurgery in an expert center should be the first line therapy of patients with Cushing's disease and a negative or inconclusive MRI.

Simultaneous coexistence of Cushing's disease and renal cell carcinoma

Pinar Sisman[1], Ozen Oz Gul[2], Soner Cander[2], Canan Ersoy[2] & Erdinc Erturk[2]
[1]Medicana Hospital, Endocrinology and Metabolism Clinic, Bursa, Turkey; [2]Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey.

Background
After the diagnosis of corticotropin (ACTH) dependent Cushing's syndrome established, its cause must be determined. Cushing's disease (CD) is caused by corticotropin (ACTH) secreting adenomas and it accounts for roughly 75-80% of all endogenous Cushing's syndrome. These adenomas are almost always benign. Renal cell carcinoma (RCC) is the most seen kidney cancer. In this case report, a presentation of a patient who was diagnosed with concurrent CD and RCC was planned.
Case
A 40-year-old patient admitted to our hospital with complaint of abdominal pain. Abdominal MRI performed in the urology department revealed a 7.5x7 cm mass in the left kidney, which showed a close proximity to adrenal gland. Left partial nephrectomy was performed. Pathologic evaluation revealed papillary renal cell carcinoma. Tumor diameter was 6x5x4 cm. Positron emission tomography showed no pathological metabolic activity in the lymph nodes. There was no metastatic finding. She was referred to our polyclinic with the suspicion of Cushing's syndrome. She was diabetic and she had been using oral antidiabetic drugs for 4 years. On her physical examination she had findings of Cushing's syndrome. 1 mg dexamethasone suppression test was performed with the suspicion of Cushing syndrome. No suppression of cortisol levels was observed in the result of the test (cortisol level = 17 μg/dL). Cortisol levels were also higher than the reference values in 24 hour urine cortisol test. Basal ACTH was 47 pg/mL. Other anterior pituitary hormones were normal. The patient was evaluated as CD. Magnetic resonance imaging (MRI) of the sella revealed a 14x10 mm sized adenoma. Optic chiasm was normal. The patient underwent transsphenoidal surgery. Monitoring of the patient is continued.
Conclusions
In this case ectopic ACTH syndrome should be considered in differential diagnosis. Various tumors can cause ectopic ACTH syndrome. Small cell lung carcinoma, carcinoid tumors, islet cell tumors, pheochromocytoma and medullary thyroid carcinomas are the most frequent tumors. In ectopic ACTH syndrome circulating ACTH and corticol levels are extremely high, the duration of symptoms is short and the clinical phenotype is different from CH. The ectopic ACTH syndrome was excluded because of the presence of the pituitary adenoma, the fact that the ACTH levels were not too high and the phenotypic findings of the patient were incompatible with the ectopic ACTH syndrome. This case illustrates the importance of considering differantial diagnosis between ectopik ACTH syndrome and Cushing's disease accompanying renal cell carcinoma.

The relationship between sleep apnea syndrome and metabolic parameters in patients with acromegaly

Buket Biçer[1], Özen Öz Gül[2], Nermin Şen[1], Hikmet Öztop[1], Soner Cander[2], Canan Ersoy[2] & Erdinç Ertürk[2]
[1]Uludag University Medical School, Department of Internal Medicine, Bursa, Turkey; [2]Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey.

Background
Acromegaly is a rare endocrine disorder characterized by sustained hypersecretion of growth hormone (GH) with concomitant elevation of insulin-like growth factor I (IGF-I) associated with acral enlargement, sleep apnea, cardiovascular and metabolic disorders. Its annual incidence is approximately six per million people. The most common cause of acromegaly is a somatotroph (growth hormone-secreting) adenoma of the anterior pituitary.
Methods
A total of 28 patients diagnosed with acromegaly were included in this retrospective study. Seventeen of the patients were female and 11 of them were male. The clinical presentations, anthropometric measurements, fasting and postprandial blood glucose levels, triglyceride levels and polysomnography characteristics of patients were analyzed. The patients were divided into two groups according with and without sleep apnea syndrome.
Results
The mean age of these patients was 50.60 ± 13.92 years and 15 (53.6%) of the patients were sleep apnea syndrome. Of these patients, 63.6% of the women; 47.1% of the men had sleep apnea syndrome. 46.4% of patients with sleep apnea syndrome were diabetic. 66.7% of the patients without diabetes, did not have sleep apnea syndrome. As a result, a statistically significant difference was found between diabetic patients with and without sleep apnea syndrome ($P<0.05$). Serum triglyceride levels were examined when patients were diagnosed with acromegaly. Serum triglyceride levels were 161.53 ± 59.10 mg/dl in the group with sleep apnea syndrome and $99.15 \pm 38{,}58$ mg/dl in the group without sleep apnea syndrome. There was a statistically significant difference in serum triglyceride levels between these two groups ($P<0.05$).
Conclusion
In this study, we investigated the association of sleep apnea syndrome with metabolic disorders in acromegaly patients. It's revealed that diabetes and hypertriglyceridemia are more frequent in patients with sleep apnea syndrome in acromegaly.

Early postoperative GH level as biomarker for surgical outcome in patients with acromegaly

Alexander Tsiberkin, Uliana Tsoy, Vladislav Cherebillo, Natalya Gussaova, Anna Dalmatova, Andrej Polezhaev, Lidiya Belousova & Elena Grineva
Almazov National Medical Research Centre, St. Petersburg, Russian Federation.

Introduction
Persistence after transsphenoidal surgery remain a significant challenge in management of acromegaly. Value of basal growth hormone (GH) evaluation in early postoperative period as marker of acromegaly persistence has been proposed and discussed in the literature, but is not widely used in clinical practice.
Aim
The goal of our study is to specify the value of basal GH level measurement 24 hours later after transsphenoidal surgery as postoperative biomarker for surgical outcome in patients with acromegaly.

Materials and methods
A total of 18 patients (12 women and 6 men) with an average age of 48.9 ± 13.5 years (range 27-66 years) were enrolled in our study. All patients underwent total transsphenoidal adenomectomy performed by one neurosurgeon. All patients harbored macroadenomas, with average size of 18.3 ± 4.9 mm (range 11-29 mm). Measurement of a 24-hours postoperative GH level was performed in all patients. The outcome of surgery via OGTT and measurement of insulin-like growth factor 1 (IGF-1) was evaluated 6 months after surgery. The biochemical remission of acromegaly according to the 2010 remission criteria are defined as nadir GH level on an OGTT <0.4 μg/l along with age and gender normalized values of IGF-1.
Results
At baseline basal GH level was 36.4 ± 23.5 μg/l, IGF-1 was 2.5 ± 0.6 times the upper limit of normal. At 6 months after surgery, the remission of acromegaly was achieved in 8 patients (44%). A 24-hours postoperative GH level in patients with remission was 1.4 ± 0.5 μg/l, whereas in group with acromegaly persistence –5.3 ± 1.7 μg/l. All patients with persistence of the disease had a 24-hours postoperative GH level $\geq$ 2.0 μg/l.
Conclusion
Our study suggests that a 24-hours postoperative GH level above 2.0 μg/l associated with persistence of acromegaly 6 months after surgery.

Optimal follow-up strategy based on the natural history of nonfunctioning pituitary adenomas

Jung Hee Kim[1,2], Yun-Sik Dho[2,3], Yong Hwy Kim[2,3], Jung Hyun Lee[2,3], Ji Hyun Lee[1], A. Ram Hong[1], Min Kyong Moon[1] & Chan Soo Shin[1,2]
[1]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Pituitary Center, Seoul National University Hospital, Seoul, Republic of Korea; [3]Department of Neurosurgery, Seoul National University College of Medicine, Seoul, Republic of Korea.

Object
The natural history and proper algorithm for follow-up testing of nonfunctioning pituitary adenomas (NFPAs) are not well known, despite their relatively high prevalence. The aim of this study was to suggest the optimal follow-up algorithm for NFPAs, based on the natural history.
Methods
We followed up on 197 patients with NFPAs without any treatment (including surgery and radiation) at the time of detection, in a single center, between March 2000 and February 2017. We conducted a hormone test, visual field test and magnetic resonance imaging (MRI) at the time of diagnosis, and then, yearly.
Results
The overall median follow-up duration was 37 months. Microadenomas (n = 38) did not cause visual disturbance, pituitary apoplexy, or endocrine dysfunction. The incidence of patents with a 120% or larger tumor volume growth was higher in macroadenomas than microadenomas (13.8% vs. 5.0% per year). The overall incidence rate of worsening visual function was 0.69% per year. Patients with a tumor volume growth rate $\geq$ 0.35 cm^3/year (n = 38) showed higher incidences of worsening visual functions (3.52% vs. 0.16% per year) and endocrine dysfunction (4.40% vs. 0.49% per year). Based on the tumor volume growth rate, the median time for 10% of patients to grow more than 120% was 3.4 years in microadenomas and 1.9 years in macroadenomas.
Conclusion
The tumor volume growth rate was the strongest predictor of worsening visual functions or endocrine dysfunction. A follow-up strategy needed to be determined based on the tumor volume growth rate as well as initial tumor volume.

Thicknesses of Chorioretinal layers in Prolactinoma Patients: A Spectral Domain Optical Coherence Tomography Study

Berna Evranos[1], Sevgul Faki[1], Sefika Burcak Polat[1], Nagihan Ugurlu[2], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Yildirim Beyazit University Department of Endocrinology, Ankara, Turkey; [2]Yildirim Beyazit University Department of Ophtalmology, Ankara, Turkey.

Introduction
Prolactinoma is a type of pituitary tumor that produces excessive amount of the hormone prolactin. It is the most common type of hormonally-active pituitary tumor. These tumors can result in ocular complications such as vision loss and visual fields (VF) defect. In this study, we aimed to evaluate thicknesses of chorioretinal layers in patients with prolactinoma.
Material and method
We enrolled 21 prolactinoma patients (13 females, 8 males and mean age: 40.7 ± 8.1 years) and 18 age and gender matched healthy controls. All participants underwent complete hormonal and ophthalmological examination including thicknesses of chorioretinal layers and VF test. We used the Spectralis spectral domain optical coherence tomography for evaluation of chorioretinal layers in an outpatient setting. The seven layers were retinal nerve fiber layer (RNFL), ganglion cell layer (GCL), inner plexiform layer (IPL), inner nuclear layer (INL), outer plexiform layer (OPL), outer nuclear layer (ONL), and retinal pigment epithelium (RPE). Additionally, we calculated the mean thickness of two combined layers: inner retinal layer (IRL) and photoreceptor layer (PL). The results of prolactinoma patients were compared with the control group.
Results
There were no statistically significant differences in median right-left and mean RNFL, GCL, IPL, INL, OPL, ONL, and IRL measurements between prolactinoma and control groups ($P > 0.05$ for each). Median right and mean RPE were significantly low in the prolactinoma group ($P = 0.018$ and $P = 0.028$, respectively). Median right-left PL was similar in two groups, while mean PL was significantly lower in patients with prolactinoma compared to control group ($P = 0.04$) None of the patients had VF defect. When we compared two subgroups of prolactinoma patients (active/inactive), we found that the thicknesses of layers were not significantly different between the groups.
Conclusion
To our knowledge, this is the first study that evaluates thicknesses of chorioretinal layers in patients with prolactinoma. Thicknesses of many layers were similar with control group, while mean RPE and PL were lower in prolactinoma group.

Combined treatment of craniopharyngiomas

Maxim Kutin, Aleksander Konovalov, Boris Kadashev, Liudmila Astafyeva, Nataliya Serova, Pavel Kalinin, Dmitriy Fomichev, Nadezhda Mazerkina, Yuliya Sidneva & Yrii Trunin
N.N. Burdenko National Medical Research Center of Neurosurgery, Moscow, Russian Federation.

Introduction
Craniopharyngiomas (CF)- benign epithelial tumors that develop from the remnants of Rathke's pouch cells. Most often, CF manifest themselves in two age groups: in children 5–14 years old making 5.6–13% of intracranial tumors and in adults 50–74 years old making 2–5%.
Materials and methods
In the last decade, the Institute annually for the surgical treatment received 100–120 patients with CF. The total number of cases (given and repeated) exceeds 2500. For transcranial removal of CF we use different combinations of basal and transcallosal approaches. In pediatric patients this type of surgery reaches 60%, and in adult patients only 20%. Starting in 1987 we use transsphenoidal approaches (first microsurgically, from 2005 pure endoscopicaly). Extended endoscopic approach makes possible radical tumor removal. Now transsphenoidal operations for CF in pediatric group takes only 20%, instead 60% in adults. For cystic craniopharyngiomas in some cases, we use Ommaya systems. It takes 20% of both pediatric and adults group.
Results
In recent years, mortality in adults group after tarnscranial surgery does not exceed 8%, after transshenoidal and Ommaya system in both age groups mortality is zero. Tumor recurrence after total and subtotal removal takes 21.5%, and after a partial takes 53.2%. The recurrence rate of papilomatouse CF takes 7.8%. In the last decade we started using radiosurgery and stereotactic radiotherapy ("Gamma knife", "Cyber knife", "Novalis"). In cystic CF after irradiation we saw sharp reduction in production of cystic fluid. Nowadays we do not have sufficient statistics to estimate the effect of irradiation on the rate of tumor progression and the probability of formation of its recurrence, but we have the number of cases with significant reduction of tumor size.
Conclusion
Further development of a combined treatment of CF will be to improve surgical techniques such as endoscopic assistance in transcranial surgery and improvement of transsphenoidal endoscopic techniques. Future analysis of the effect of different variants of radiotherapy on recurrence rate will optimize surgical removal of CF, as well as irradiation regimes. Modern morphological studies will identify CF subgroups with the aggressive character of growth and a high risk of relapse.

Vitamin D status in acromegaly: a comparative study

Sana Mahjoubi[1], Hajer Kandara[1], Sabrine Mekni[1], Olfa Laajili[1], Sonia Nagi[2], Chayma Ben Amara[1], Ines Kamoun[1] & Leila Ben Salem[1]
[1]Endocrinology and Nutrition Departement, National Nutrition Institute, Tunis, Tunisia; [2]Neuroradiology Departement, National Neurology Institute, Tunis, Tunisia.

Background
The vitamin D is a pleiotropic hormone that plays a significant role on global health. However, vitamin D status in acromegaly has been poorly studied.
The aim
The aim of this study was to assess the vitamin D status in acromegaly and compare it to a control group. Then to analyse bone remodeling and density markers based on the vitamin D levels.
Methods
We conducted an evaluative cross sectional study in the Department of Endocrinology at the National Institute of Nutrition in Tunis comparing 2 groups of 25 acromegalic patients and 25 control subjects (age and sex matched).
Results
The average age was 50 ± 14.52 years [16–52]. The sex ratio was 9/16 (36% men and 64% women). The mean duration of the acromegaly was 8.6 ± 9.62 years. As for acromegalic repercussions patients presented with rheumatologic impacts in 80% of the cases, visual in 72%, respiratory in 68%, pituitary in 56%, metabolic in 56% and tumoral in 8%. Twenty-one subjects underwent surgical treatement, 24% were under somatostatin analogs, two patients had received radiotherapy. Acromegaly was active in 64% of the cases, controlled for 4 patients and cured for 5 (20%). The vitamin D status was similar between the acromegalic group and the control subjects: Thirteen acromegalic patients had deficiency, 9 (36%) had insufficiency and 3 patients (12%) had a normal level of vitamin D. The univariate study showed that, duration of sun exposure, exposed surface, score screening for vitamin D insufficiency, height, PTH, and GH were significantly associated with the vitamin D level in acromegalics.
Conclusion
The exploration of the vitamin D status in acromegaly should become a common practice. The management starts with the prevention of the defict, the screening and eventually a therapeutic supplementation.

Hypernatraemia and mental disorders

Yuliya Sidneva, Liudmila Astafyeva, Maxim Kutin, Pavel Kalinin & Irina Klochkova
N.N. Burdenko National Medical Research Center of Neurosurgery, Moscow, Russian Federation.

The problem of the influence of disturbances of Hyper- or Hyponatraemia is the most common disorder of body fluid and electrolyte balance encountered in clinical practice. Electrolyte disbalance affected on the formation of mental disorders, their structure and dynamics in the literature has not been sufficiently studied. Perhaps there are certain factors and patterns of the influence of hypo- and hypernatraemia on mental activity with various lesions of the brain, which requires study.
Purpose
To study the effect serum sodium concentration on the structure and dynamics of mental disorders on the model of a benign tumor of craniopharyngioma.
Material and methods
89 patients (18–65 years old, mean age 38 ± 2, 44 men and 45 women) were examined after removal of craniopharyngiomas in the early postoperative period. Methods: psychopathological, data from endocrinological, neurological, neuroimaging methods of research were used. Serum sodium concentration was determined in the norm of 135–145 mmol/l.
Results
1 group – 43 patients (48%) with hypernatraemia after removal: endo-suprasellar (10%), suprasellar (35%), extra-intraventricular (45%) and intraventricular (10%) craniopharyngiomas. Group 2 – 46 patients (52%) with normal serum sodium concentration after removal: endo-suprasellar (39%), suprasellar (37%), extra-intraventricular (11%) and intraventricular (13%) craniopharyngiomas. Analysis of mental disorders in patients revealed productive symptoms in 80%: motor excitement, affective disorders, delirium, visual hallucinations, amnestic confusion. These disorders occurred in patients with hypernatraemia more often ($P < 0.001$) (group 1) than in patients with normal serum sodium concentration (group 2). In the first group there was a subgroup of patients with persistent long hypernatraemia (lasting more than 5–7 days) in 22 patients (51%). In this subgroup there were negative (deficient) symptoms: Korsakov's syndrome, apathy, increased drowsiness in 15 patients (68%). It was significantly more frequent ($P < 0.001$) compared to patients with normal serum sodium concentration.
Conclusion
Serum sodium concentration affects a person's mental activity. Hypernatraemia can be a factor that causes productive symptoms and syndromes of mental disorders and adversely affects their dynamics, that it was revealed in patients after removal of craniopharyngiomas.

The use of colonoscopic screening in acromegaly in our everyday practice revisited: how compliant with guidelines have we been?

Ismene Bilbao, Nerea Egaña, Maite Perez de Ciriza, Izaskun Olaizola, Cristina Garcia, Leire Agea, Maite Aranburu, Alfredo Yoldi & Miguel Goena
Hospital Universitario Donostia, Donostia-San Sebastian, Spain.

Introduction
Although it has been suggested that there is a strong association between acromegaly and premalignant colonic lesions and colon cancer, it seems that in real – life practice the adherence to ACRO colonoscopy guidelines might be lower than expected (as recently shown by M.Parolin et cols).
Methods
We retrospectively reviewed the case records of the 54 patients with acromegaly seen in our center since 1994.We analyzed the findings of 27 patients who had undergone full length colonoscopy.
Results
Only 50% of our patients underwent at least one colonoscopy. 34 colonoscopies were performed since 1994 and the total number of colonoscopies increased from 0 in the period of 1994–1999, to 9 in the period of 2000–2005, and to 21 between 2012 to 2017.25% of the colonoscopies were performed at diagnosis and 75% during follow up. Diverticulosis and internal hemorroids were the most frecuent findings. In 33% of the screened patients (9/27) polyps were found. Among these patients 7 were women and 2 were men with a median age of 60.5 years (42–79) and a median IGFI level of 343,4 (126–761). A total of 18 polyps were found with a median size of 5 mm (2–11 mm), and the adenomatous polyps being the most frequent type. Pathological specimen results were Hyperplastic polyp (5/18), tubular adenoma (10/18), tubulovillous adenoma (1/18), villous adenoma(1/18), serrated adenoma (1/18). 1 female patient had colon adenocarcinoma (3.7%, 1/27). No complications related to the endoscopic examination were reported, such as perforation or bleeding.
Conclusions
The compliance to the guidelines in our center has been low with an increasing adhesion over the years. We do not know the reasons behind this change, but we are aware that due to the findings in our series, we will work towards a more proactive surveillance and improve the adherence to the guidelines.

The Secret of the Ophtalmopathy

Ilgin Yildirim Simsir, Utku Erdem Soyaltin, Banu Sarer Yurekli, Mumtaz Yilmaz & Fusun Saygili
EGE University, Izmir, Turkey.

Although the first line therapy for prolactinoma is medical. Visual field defect due to pituitary mass would lead to surgery. Herein, we share the post-operative follow-up of a macroprolactinoma case.
Case
A 57-year-old male patient was operated on for a giant pituitary adenoma, which was compressing the optic chiasm. The postop prolactin (PL) value was found to be higher than 200 ng/ml and cabergoline treatment was initiated. Two months after the operation, the patient was admitted to the hospital for complaints of exophthalmos, headache, fatigue and drowsiness. Blood pressure was 100/60 mmHg, laboratory values revealed Na 128 mEq/l and creatinine 1.82 mg/dl. Adrenal insufficiency was presumed and methylprednisolone was initiated. Cranial CT scan was obtained to exclude secondary complications of operation, and it revealed a 1.5 cm residual adenoma and pseudotumor orbita. When the persistent microscopic haematuria, elevated sedimentation rate (ESR) (80 mm/s) and proteinuria (1.3 g/24 h) were considered, with the clinical finding

of pseudotumor orbita, it was believed that all would be indicative of vasculitis and IgG4 related diseases. ANA was negative, PR3ANCA was 3(+) and IgG4 was 224 mg/dl (120–200). Steroid treatment resulted in a significant improvement of ocular and biochemical findings (creatinine 1.4 mg/dl, ESR 36 mm/h). We performed kidney biopsy to exclude Wegener granulomatosis (WG). Biopsy was compatible with WG; IgG4 staining was negative. Pulse steroid therapy and 1 g cyclophosphamide were administered. Haematuria disappeared, IgG4 normalized, creatinine and ESR decreased to 0.9 mg/dl and 29 mm/s, respectively. Cabergoline treatment was switched to bromocriptine to exclude the cabergolin induced vasculitis.

Conclusion

The patient did not have retroorbital biopsy, on the other hand the kidney biopsy supported WG. It has been reported that the PL elevation triggers autoimmunity and clinical remission can be achieved by treatment with dopamine agonist in patients with SLE and RA, whose PL levels are elevated. There are cases in which IgG4 related diseases were identified by the initiation of high dose cabergoline treatment and the relationship between IgG4-related diseases and WG has been firmly stated in the literature. Under the light of literature, vasculitis may have been triggered by prolactinoma and cabergoline treatment in our patient. The orbital pseudotumor may be associated with either IgG4-related disease or WG. A few cases have been reported about WG-associated pseudotumor orbita in adult patients. In this respect, our case remains exciting.

Tolvaptan usage in hyponatremic patients with syndrome of inappropriate secretion of antidiuretic hormone: a single-center experience

Suat Akgür[1], Ayşegül Oruç[1], Abdülmecit Yıldız[1], Canan Ersoy[2], Mustafa Güllülü[1], Mahmut Yavuz[1], Kamil Dilek[1] & Alparslan Ersoy[1]
[1]Uludag University Medical Faculty, Department of Nephrology, Bursa, Turkey; [2]Uludağ University Medical Faculty, Department of Endocrinology and Metabolism, Bursa, Turkey.

The syndrome of inappropriate secretion of antidiuretic hormone (SIADH) is a disorder of impaired water excretion caused by inability to suppress secretion of antidiuretic hormone. The therapy of SIADH varies with severity of hyponatremia and presence or absence of symptoms. Non-peptide vasopressin receptor antagonists (vaptans) are effective at increasing sodium in euvolemic and hypervolemic states and appear safe. We aimed to evaluate the efficacy of tolvaptan in euvolemic hyponatremic patients with SIADH.

Methods

The study included 13 euvolemic hyponatremic (serum sodium level <125 mmol/l) patients with idiopathic SIADH between January – December 2017. The diagnosis of SIADH was made with hyponatremia, hypoosmolality, urine sodium level above 40 mEq/l and urine osmolality above 100 mosmol/kg. Serum potassium levels of all patients were normal, there was no acid-base disturbance. Patients with hypervolemic or hypovolemic status and hepatic dysfunction were excluded from the study. All patients received 7.5 mg/day of tolvaptan therapy. Clinical and laboratory data of patients were obtained before and after treatment.

Results

The mean age of patients (11 females, 2 males) was 74.6 ± 10.9 years (range 57–95). There was type 2 diabetes mellitus in 5 (38.5) patients, hypertension in 12 (92.3%) patients and chronic kidney disease in 7 (53.8) patients. The mean sodium levels before tolvaptan treatment were 120.5 ± 2.2 mmol/l (range 116–124). The mean sodium levels increased to 132.6 ± 4.0 mmol/l (range 125–140) after tolvaptan treatment at 2.7 ± 1.3 days (range 2–6). This increase in the sodium levels was significant ($P<0.001$). In a patient, hyponatremia recurred after ten days and corrected with two doses of tolvaptan. We did not observe serious adverse event related with tolvaptan treatment.

Conclusion

Our study suggested that hyponatremia was a common problem in elderly patients who had co-morbidities. Tolvaptan can treat hyponatremia effectively and safely in euvolemic elderly patients with SIADH.

Real-world data from NordiNet International Outcome Study (IOS) and ANSWER Program provide new insights into the safety of growth hormone in a large cohort of children with Noonan Syndrome

Jovanna Dahlgren[1], Birgitte Tønnes Pedersen[2], Sebastian Roehrich[3] & M. Jennifer Abuzzahab[4]
[1]Department of Paediatrics, Institute of Clinical Science, University of Gothenburg, Gothenburg, Sweden; [2]Novo Nordisk A/S, Søborg, Denmark; [3]Novo Nordisk Health Care AG, Zurich, Switzerland; [4]Children's Minnesota, Saint Paul, Minnesota, USA.

Objectives

Congenital heart disease, especially pulmonary stenosis, is a frequent comorbidity in patients with Noonan syndrome (NS). Patients with NS are also at increased risk of childhood leukaemia and solid tumours. Among solid tumours, brain tumours, including glioneuronal tumours, have been described in younger patients but remain rare. Current safety data do not indicate an association of growth hormone (GH) therapy with increased risk for development or progression of tumours or worsening of congenital cardiac conditions, but available data are limited. This report describes long-term real-world safety data on GH therapy in paediatric patients with NS.

Methods

Two complementary non-interventional, multicentre studies, NordiNet IOS (NCT00960128; $n=154$) and the ANSWER Program (NCT01009905; $n=258$), evaluated the long-term effectiveness and safety of Norditropin (somatropin; Novo Nordisk A/S, Denmark) as prescribed by treating physicians in a real-life clinical setting. Safety data (serious adverse events [SAEs] [not related to therapy], non-serious and serious adverse drug reactions [NSARs/SARs]) were evaluated for GH-treated patients with NS ($n=412$) enrolled in these studies.

Results

Baseline characteristics (% or mean [SD]): female, 29.1%; age at treatment start, 9.48 (3.92) years, height standard deviation score (SDS), −2.65 (0.95), weight SDS −2.03 (1.31), insulin-like growth factor-I (IGF-I) SDS, −1.13 (1.62), IGF binding protein−3 SDS, −0.91 (1.72), GH dose (μg/kg/day), 43.9 (13.7), GH-naïve, 68.5%. Mean (SD) treatment duration, 3.1 (2.6) years. GH dose (μg/kg/day), during treatment, 46.6 (13.6). The most common cardiovascular comorbidities reported included pulmonary valve stenosis (20 patients) and atrial septal defect (five patients). Overall, 31 adverse events (AEs) were reported in 21 patients (#events/#patients): NSARs, 21/15, SARs, 2/1, SAEs, 8/5. Most patients with AEs reported one event (16/21). For patients with AEs, mean (SD) age at treatment start was 9.90 (4.13) years and height SDS at baseline was −3.14 (0.82). The most common NSARs were headache (six events/six patients) and arthralgia (five events/three patients). Two SARs (brain neoplasm; metastases to spine) were reported in one patient. The SAEs reported were giant cell epulis (one patient), scoliosis and spinal fusion surgery (both in one patient), moyamoya disease (one patient), glioneuronal tumour (one patient), and aggravated glioneuronal tumour and epilepsy (one patient). No cardiac AEs were reported.

Conclusions

These data further support a favourable safety profile of GH therapy in patients with NS, specifically the absence of any cardiac AEs. Glioneuronal tumours have previously been associated with Noonan syndrome and RASopathies.

Hypophysitis: Experience of a single tertiary center

Pinar Kadioglu, Ozge Polat Korkmaz, Hande Mefkure Ozkaya, Ozlem Haliloglu, Serdar Sahin, Fatma Eda Nuhoglu Kantarci & Tugce Apaydin
Istanbul University, Cerrahpasa Medical Faculty, İstanbul, Turkey.

Purpose

The authors review the clinical outcomes of patients with hypophysitis.

Methods

Medical records of hypophysitis patients who were followed between 2007 and 2018 at Cerrahpasa Medical Faculty were evaluated retrospectively. Clinical, endocrinological, pathological and radiological findings and therapies were assessed.

Results

Twenty patients (F/M:12/8) were identified with a mean age at diagnosis of 39.14 ± 17.78 years. The mean follow-up was 34.23 ± 14.12 months. Eleven out of 20 patients (55%) were diagnosed histopathologically, 9 patients (45%) were diagnosed clinically with typical MRI findings. Five of 20 patients (25%) were

secondary hypophysitis: 3 histiocytosis-X, 1 neurosarcoidosis and 1 Erdheim Chester disease. From 7 histologically diagnosed patients with primary hypophysitis, 5(25%) had lymphocytic, 1(5%) had lymphocytic-granulomatous and 1 (5%) had xanthomatous hypophysitis. None of the hypophysitis cases were diagnosed after pregnancy. The most commonly seen symptoms are headache (65%), polyuria/polydipsia (45%) and fatigue (%30). Pre-treatment endocrinological evaluation revealed that 9 (57%) patients had panhypophysitis, 9 (45%) had diabetes insipidus, 6 (30%) had hyperprolactinemia, 7 (35%) had isolated endocrine deficiencies with partial gland function and 2 (10%) had normal laboratory values. Radiologic findings of patients at the time of diagnosis revealed various results including large sellar mass (65%), thickened infundibulum (50%), uniform contrast enhancement (40%), loss of hypophysis bright spot on T1 imaging (20%) and partial empty cella (15%). Six out of 15 primary hypophysitis patients were treated conservatively and six of them had been operated. The remaining 3 out of 15 and 2 patients who didn't have remission after surgery were treated with steroid therapy. Two patients, who needed to take steroid therapy after surgery and didn't have remission despite these treatment modalities had radiotherapy. Sixty-six percent (4/6) of patients who were on steroid treatment experienced avascular necrosis. Overall, 55% of patients had radiographic improvement and 45% had stable or deteriorated imaging findings. Endocrinological evaluations revealed that 1 patient (5%) had improvement, 16 patients (85%) had stable findings, 3 patients (15%) had deteriorated endocrinological functioning and 1 patient didn't have any follow-up data. Six patients who were followed conservatively had no sign of worsening radiologically or endocrinologically.

Conclusion

It is a challenge to make the right diagnosis and also the appropriate treatment of hypophysitis. It is unclear whether active treatment with steroids improves clinical outcome. When the serious side effects of steroids are also taken into account, surgery and or radiotherapy can be appropriate treatment modalities for selected patients.

Pituitary adenomas in childhood and the transition period - clinical and genetic characterization of 49 patients at one tertiary care endocrine institution in Romania

Andreea Vladan[1], Serban Radian[1,2], Ionela Baciu[1,2], Iuliana Gherlan[1,2], Antonia Lefter[1], Simona Galoiu[1,2], Cristina Dumitrescu[1], Camelia Procopiuc[1], Corin Badiu[1,2] & Catalina Poiana[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Department of Endocrinology, C. Davila University of Medicine and Pharmacy, Bucharest, Romania.

Introduction

Pituitary adenomas (PAs) are rare in childhood and the transition period, can result from *AIP/MEN1* mutations, are difficult to manage and severely impair quality-of-life.

Aim

To describe the clinical and genetic characteristics of patients with PA onset before 21 years old.

Patients and methods

Retrospective study (1980–2015). Clinical, imaging and hormonal data, *AIP/MEN1* sequencing.

Results

We identified 49 patients (33 F/16 M), with onset age 18 (15–19) years, median (25th–75th percentile): 27 prolactinomas (5 micro, 20 macro, 2 giant adenomasn [>4 cm]; 3 clinical MEN1), 11 somatotropinomas (9 macro, 2 giant adenomas; 2 *somatolactotropinomas*; 2 patients with gigantism), 8 corticotropinomas (7 microadenomas), 2 nonfunctional PAs (NFPA, 1 mesoadenoma, 1 macroadenoma), 1 giant GH co-secreting, thyrotropinoma. From 34 patients tested, two (both with gigantism) had *AIP* mutations: c.940C>T (M-18yrs.), c.895dup (F-13yrs.). One patient with prolactinoma and primary hyperparathyroidism had a *MEN1* mutation: c.1446delC. Therapy included Dopamine agonists (DA): 27 prolactinomas, 8 somatotropinomas, 2 corticotropinomas, 1 NFPA, 1 thyrotropinoma; Somatostatin analogues: 11 somatotropinomas and 1 thyrotropinoma; Pegvisomant: 5 somatotropinomas; pituitary surgery: 10 somatotropinomas, 6 corticotropinomas, 1 NFPA, 1 thyrotropinoma; radiotherapy: 8 somatotropinomas, 3 corticotropinomas, 8 prolactinomas, 1 NFPA, 1 thyrotropinoma; Temozolomide: 2 giant PAs, multiply operated and irradiated (1 thyrotropinoma+1 DA-resistant prolactinoma). *AIP* mutations were associated with gigantism, giant adenomas ($rsquare = 0.59$, $P < 0.01$) and the absence of tumour growth control ($rsquare = -0.39$, $P < 0.05$). The number of treatment agents per patient was 1 (1–2), for prolactinomas and 5 (3–6) for somatotropinomas. At the last follow-up visit, 7 (2–10.5) years after diagnosis, 33/47 (70.21%) functional PAs were controlled biochemically.

Conclusions

Results of therapy in patients with PA onset before 21 years are suboptimal, despite aggressive therapy. Somatotropinomas are particularly resistant, partly due to *AIP* mutations.

Psychopathology in Cushing's disease and acromegaly

Alicia Santos[1], Eugenia Resmini[1], Iris Crespo[1,2], Elena Valassi[1], Ma Antonia Martínez[3] & Susan M Webb[1]
[1]Endocrinology/Medicine Department, Hospital Sant Pau, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBER-ER, Unit 747), IIB-Sant Pau, ISCIII and Autonomous University of Barcelona (UAB), Barcelona, Spain; [2]School of Medicine and Health Sciences, Universitat Internacional de Catalunya, Sant Cugat del Vallès, Spain; [3]Fundamental and Medico-Surgical Nursing Department, School of Medicine and Health Sciences, University of Barcelona, Bellvitge Campus, Hospitalet de Llobregat, Spain.

Introduction

Cushing's disease (CD) and acromegaly, despite their different specific symptoms, often present psychopathology (mainly depression and anxiety) even after hormonal normalization. However, their psychopathological profiles may be different. The aim of this study was to analyse the psychopathological profile in successfully treated Acromegaly and CD, and to compare both diseases. Current hormonal evaluation and time since endocrine control will also be analysed.

Methods

Twenty-one patients in remission of CD, twenty patients with controlled acromegaly for at least one year and 41 matched controls for age, sex and education years were included in the study. They completed SCL-90R, Beck Depression Inventory II (BDI-II), State- Trait Anxiety Inventory (STAI) and underwent endocrine evaluation.

Results

Patients with CD and acromegaly presented more psychopathology than controls in most of the areas evaluated (Depression, Anxiety, Somatization, Obsessive-Compulsive, Interpersonal Sensitivity, Hostility, Paranoid Ideation, Psychoticism, Global Severity Index, Positive Symptom Distress Index and Positive Symptoms Total $P < 0.05$ all). No differences were found between CD patients and controls for Phobic Anxiety, or between acromegalic patients and controls for Paranoid Ideation and Phobic Anxiety. When comparing both patient groups, scores were similar for BDI-II, STAI and most of the areas of the SCL-90 questionnaire. Only for Somatization ($P < 0.001$), Paranoid Ideation ($P = 0.036$) and Global Severity Index ($P = 0.036$) CS patients had higher scores, while in acromegaly scores were higher for Positive Symptoms Total ($P = 0.001$). In CD (excluding those taking hydrocortisone), correlations were found between psychopathology and both morning cortisol (STAI-State: $P = 0.027$, $R = 0.521$, STAI-Trait: $P = 0.037$, $R = 0.495$, Depression $P = 0.035$, $R = 0.513$, Hostility: $P = 0.041$, $R = 0.500$) and 24 hour urinary free cortisol (STAI-Trait: $P = 0.038$, $R = 0.521$, Depression: $P = 0.038$, $R = 0.539$, Hostility: $P = 0.007$, $R = 0.663$, Psychoticism: $P = 0.024$, $R = 0.578$, Global Severity Index: $P = 0.012$, $R = 0.629$, Positive Symptoms Total: $P = 0.040$, $R = 0.534$). No correlations were found between psychopathology and IGF1 or GH in acromegaly. No correlations were found in normal controls between psychopathology and hormonal parameters. Psychopathology did not correlate with time since endocrine control.

Conclusions

After at least 1 year of cure, patients with CD and acromegaly score higher on psychopathology than controls. Current cortisol evaluation, despite being within normal values, correlated with psychopathology in CD, but not in controls. Despite some similarities, CD showed more somatizations, paranoid ideation and higher severity of psychopathological symptoms, while acromegalic patients reported a higher number of psychopathological symptoms.

P853

Presence of empty sella in a patient with clinical and biochemical diagnosis of acromegaly

Nagihan Bestepe[1], Cevdet Aydin[2], Abbas Ali Tam[2], Karabekir Ercan[3], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Department of Endocrinology and Metabolism, Ataturk Education and Research Hospital, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Ankara Yildirim Beyazit University School of Medicine, Ankara, Turkey; [3]Department of Radiology, Ataturk Education and Research Hospital, Ankara, Turkey.

Introduction
Acromegaly is an acquired disorder related to excessive production of growth hormone (GH) and insulin-like growth factor-1 (IGF-1). It is characterized by progressive somatic disfigurement and systemic manifestations. Empty sella (ES) is an anatomical condition comprising sella turcica that is partially or completely filled with cerebrospinal fluid mainly due to intrasellar herniation of subarachnoid space. Primary ES may be associated with endocrine dysfunction and intracranial hypertension. Primary ES has to be distinguished from secondary ES, which has been linked to iatrogenic factors (surgery, radiation, medical treatment) or may be due to pituitary tumor apoplexy or autoimmune hypophysitis. Here, we describe a patient who presented with clinical and biochemical features of acromegaly and who had an empty sella on pituitary MRI.
Case
A 73-year-old male patient was consulted to our clinic for acromegalic phenotype while planning to be operated due to colorectal adenocarsinoma. The patient noticed gradual enlarging of his hands, feet, lips, and nose for 30 years, but never consulted to any clinician for this reason. Physical examination revealed typical acromegalic features. Visual field defect was not detected. Laboratory data showed elevated serum growth hormone (GH; 20.6 ng/ml)(normal <3 ng/ml) and insulin-like growth factor-1 (IGF-1; 531 ng/ml)(normal, 69–200 ng/ml). An oral glucose tolerance test (OGTT) showed no suppression of GH values. Serum levels of prolactin (PRL), adrenocorticotropic hormone (ACTH), cortisol (CS), thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), andluteinizing hormone (LH) were normal. T1-weighted magnetic resonance imaging (MRI) revealed an empty sella. Thorax computed tomography (CT), abdomen CT and 18F-FDG PET-CT did not have any finding consisted with ectopic GH secretion. Adenoma releasing growth hormone releasing hormone (GHRH) was not considered as GHRH was in the normal range (<100 mg/dl).He was treated with Octreotide LAR 20 mg per 28 days. At 6th month evaluation, serum GH and IGF-1 levels were decreased to 5.45 ng/ml and 274 ng/ml (normal, 69–200 ng/ml), respectively.
Conclusion
The mechanism underlying the association of acromegaly and empty sella remains unclear. However, our patient did not have a history of pituitary apoplexy, we should keep in mind that apoplexy on existing pituitary adenoma and then formation of necrosis can proceed empty sella. Yet, we have not found any reason for secondary empty sella in our patient. So, he has probably primary empty sella.

P854

The metabolic disturbances in acromegaly patients in relation to total, acylated and unacylated ghrelin

Hanna Komarowska[1], Barbara Bromińska[1], Nadia Sawicka-Gutaj[1], Magdalena Jaskuła-Świtek[1], Ryszard Waśko[1], Marek Ruchała[1] & Małgorzata Kotwicka[2]
[1]Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Science, Poznań, Poland; [2]Department of Cell Biology, Poznan University of Medical Sciences, Poznań, Poland.

Purpose
Acromegaly is a disease characterized by the excessive secretion of GH. Clinically, it is manifested by overgrowth of tissues and internal organs, which leads to characteristic phenotype. Patients with active acromegaly usually have impaired glucose metabolism. It significantly improves after achieving remission of the disease. Adversely, disturbances in lipid profile are not altering. Moreover, these parameters are even worse in successfully treated patients. Ghrelin strongly stimulates growth hormone secretion from anterior pituitary, as well as regulates the energy balance and various metabolic parameters. It is known that ghrelin affects glucose and lipid metabolism. It was shown that ghrelin level changes during treatment of acromegaly in earlier papers. Ghrelin occurs in acylated (AG) or unacylated (UG) form. Unacylated protein until recently was considered to be inactive. However, the latest research suggested that both forms may play biological functions. We aimed to evaluate the levels of total, acylated and unacylated ghrelin in medically naive and treated patients with biochemically active acromegaly in respect to variables of lipid and glucose metabolism.
Methods
The study group consisted of 24 patients diagnosed with active acromegaly. In study group nine patients were newly diagnosed and 16 patients received somatostatin analogs (9 lanreotide, 6 octreotide). Fifteen healthy volunteers served as controls. The physical examination of each subject was performed. Plasma levels of total ghrelin (TG), AG, calculated UG, GH, IGF1, insulin, glucose, total cholesterol, HDL cholesterol and calculated LDL cholesterol, triglycerides, apolipoproteins A-I (apoA-I) and B-100 (apo B-100) were measured.
Results
Total ghrelin levels in patients with acromegaly were decreased compared to healthy controls. In pooled data of all subgroups, simple linear regression analysis revealed that total ghrelin concentration was significantly associated with Apo-A1 concentration ($\beta=0.8087$; $P=0.0315$), and acylated ghrelin concentration was significantly associated with fasting insulin concentration ($\beta=15.5183$; $P=0.011$). We also observed an inverse association between unacylated ghrelin and patients' age, and its positive association with Apo-A1.
Conclusions
Ghrelin probably influences metabolic disturbances in acromegaly. We suggest to evaluate acylated and unacylated ghrelin in all patient. It seems to be probable that changes in ghrelin forms proportions are responsible for observed disturbances.

Hypopituitarism in primary empty sella

Karin Zibar Tomšić[1], Marin Deškin[2], Ivana Kraljević[3], Tina Dušek[3,4], Mirsala Solak[3], Tanja Škorić Polovina[3], Annemarie Balaško[3] & Darko Kaštelan[3,4]
[1]Vuk Vrhovac University Clinic for Diabetes, Endocrinology and Metabolic Diseases, Merkur University Hospital, Zagreb, Croatia; [2]General Hospital Bjelovar, Bjelovar, Croatia; [3]Department of Endocrinology, University Hospital Centre Zagreb, Zagreb, Croatia; [4]School of Medicine, University of Zagreb, Zagreb, Croatia.

Empty sella is characterized by the radiological appearance of an enlarged or deformed sella turcica which is completely or partially filled with cerebrospinal fluid resulting in a displacement of the normal pituitary gland. Primary empty sella (PES) refers to the empty sella appearance of unknown etiology, diagnosed after excluding a history of previous pituitary pathology. The prevalence of hypopituitarism in empty sella syndrome varies between 2 and 32% in different published series. The aim of this study was to investigate the incidence of hypopituitarism among PES patients. We conducted a retrospective analysis of the pituitary function in 46 consecutive patients (19 male, 27 female, median age 58 years (27–78)) with PES who were referred to the University Hospital Centre Zagreb between 2010 and 2016. Hypopituitarism was defined as the deficiency of one of the three hormonal axes (corticotroph, thyreotroph or gonadotroph). Hypopituitarism was present in 11 out of 46 PES patients (seven male, four female). Five patients had one pituitary axis insufficiency, four patients had two pituitary axis insufficiency and two patients had the insufficiency of all three pituitary axes. The insufficiency of the corticotroph, thyreotroph and gonadotroph axis was present in 17%, 17%, and 15% of patients, respectively. According to our results, every fourth patient with PES has at last one pituitary axis insufficiency. Therefore, in all PES patients regular endocrine work-up should be recommended.

A first-in-human pharmacokinetic, safety, and tolerability study of pasireotide subcutaneous depot

Fredrik Tiberg[1], Susanne Glantz[1], Kerstin Strandgården[1], Christelle Darstein[2], Johannes Eisinger[2], Libuse Tauchmanova[2] & Astrid Breitschaft[3]
[1]Camurus AB, Lund, Sweden; [2]Novartis Pharma AG, Basel, Switzerland; [3]PAREXEL International, Berlin, Germany.

Background
Pasireotide is available in twice-daily subcutaneous (sc) and long-acting intramuscular (im) formulations. Pasireotide sc depot is an investigational

extended-release sc formulation designed for improved handling and administration. Results are reported from a Phase I dose-escalating study.
Methods
All subjects received a single dose of pasireotide sc (600 μg) and were randomized 12:2:2 to pasireotide sc depot as a single upper-thigh injection (in five ascending-dose groups: 5, 10, 20 [another group of 12 subjects added at this dose level received a single buttock injection], 40, and 80 mg), long-acting pasireotide (60 mg), or pasireotide s.c. (900 μg) twice daily for 7 days.
Results
94 subjects (59 male, 35 female) were randomized; 90 (95.7%) completed the study. After pasireotide sc depot injection, pasireotide plasma profiles for all tested doses (5–80 mg) showed a relatively rapid initial release (median t_{max} 24–97 hours) followed by a slow decay with a half-life suitable for once-monthly dosing. Across the pasireotide sc depot dose range, AUC_{inf} increased dose proportionally and C_{max} slightly more than dose proportionally. AUC_{inf} and C_{max} for the 40 and 80 mg doses of pasireotide sc depot were within the exposure range for pasireotide im. Pasireotide pharmacokinetic parameters were comparable after buttock and upper-thigh injections of pasireotide sc depot (20 mg). The relative pasireotide bioavailability for pasireotide sc depot versus pasireotide im (60 mg) was 52–98% for the 5–40 mg doses, and 115% for the 80 mg dose. Mean values for maximum relative inhibition of insulin-like growth factor 1 versus baseline were similar for pasireotide sc depot 40 and 80 mg and pasireotide im 60 mg, but slightly lower for pasireotide sc depot 5, 10, and 20 mg. Overall, 76/94 (80.9%) subjects experienced adverse events (AEs). The incidence of AEs was 50%, 83.3%, 91.7%, 50%, 100%, and 100% for subjects in the 5, 10, 20 (upper thigh), 20 (buttock), 40, and 80 mg pasireotide sc depot dose groups, respectively, 100% for pasireotide sc, and 80% for pasireotide im. Diarrhoea (25/94 [26.6%]), injection-site pain (27/94 [28.7%]), and injection-site induration (21/94 [22.3%]) were the most commonly reported AEs. Most AEs were mild to moderate in intensity, with seven grade 3 AEs in five subjects (increased alanine aminotransferase [$n=3$], diarrhoea [$n=2$], increased gamma-glutamyl transferase [$n=1$], and vomiting [$n=1$]). There were no serious AEs, deaths, or AEs leading to discontinuation.
Conclusions
Pasireotide sc depot provides dose-proportional long-acting release of pasireotide with a safety and tolerability profile comparable to currently available long-acting im and sc formulations.

HLA celiac haplotypes and Primary Autoimmune Hypophysitis in Caucasian patients

Sabrina Chiloiro[1], Ettore Domenico Capoluongo[2], Tommaso Tartaglione[3], Antonio Bianchi[1], Antonella Giampietro[1], Chiara Bima[1], Flavia Angelini[4], Vincenzo Arena[5], Alfredo Pontecorvi[1] & Laura De Marinis[1]
[1]Department of Endocrinology, Catholic University School of Medicine, Rome, Italy; [2]Institute of Biochemistry and Clinical Biochemistry, Catholic University of Sacred Heart, Rome, Italy; [3]Institute of Radiology, Catholic University School of Medicine, Rome, Italy; [4]Laboratory of Vascular Biology and Genetics, Department of Medicine, Catholic University School of Medicine, Rome, Italy; [5]Department of Pathology, Catholic University School of Medicine, Rome, Italy.

Purpose
Primary hypophysitis is a rare disease, with an autoimmune etiology. As few papers have investigated its genetic, our aim was to evaluate HLA status in a single-center series of patients.
Patients and method
A retrospective, longitudinal and cross-sectional study was conducted. Consecutive Caucasian patients, with clinical or histological diagnosis of primary autoimmune hypophysitis (PAH), undergone determination of HLA genotype, anti-pituitary and anti-hypothalamus auto-antibodies were included. This cohort was compared with a control group.
Results
A total of 16 patients was enrolled. Fourteen patients were female (87.5%). According to HLA-DR status, we found the following 9 out of 16 patients (56.3%) haplotypes that were associated to celiac disease (CD). Among these, 5 carried the DR7-DQ2 heterozygote haplotype (55.5%) while the remaining ones only the following haplotypes: DR3-DQ2 homozygote (25%), DR4-DQ2 heterozygote (25%), DR4-DQ8 heterozygote (50%), DR4-DQ8 homozygote (25%), respectively. A total of 12 CD-associated haplotypes were identified. In PAH, we found a significantly higher frequency of patients carrying CD-associated HLA-haplotypes as compared to the control group (respectively 75% vs 48% $P=0.03$; OR: 3.25 95%IC:1.1–10.3), particularly, for DQ2 and DQ8 haplotypes. DQ2 haplotype was detected in 50% of PAH and 38.4% of control group ($P=0.3$), while DQ8 haplotype in 25% of PAH and 7.2% of control group ($P=0.01$ OR:4.3 95%IC:1.3–14.7).
Conclusion
Our data suggest that PAH and CD share some HLA haplotypes, reinforcing the knowledge of their association. HLA haplotypes, particularly DQ8, may play a role in PAH management and diagnosis, also suggesting the predisposition to other autoimmune diseases.

Consensus on the management of acromegaly in Spain

Ignacio Bernabeu[1,2], Rosa Camara[3], Mónica Marazuela[4] & Manel Puig Domingo[5,6]
[1]Servicio de Endocrinología y Nutrición, Complejo Hospitalario Universitario de Santiago de Compostela, Santiago de Compostela, Spain; [2]Fundación Publica Galega de Medicina Xenomica (Unidad de Medicina Molecular), Universidad de Santiago de Compostela, Santiago de Compostela, Spain; [3]Servicio de Endocrinología y Nutrición, Hospital Universitario y Politécnico La Fe, Valencia, Spain; [4]Servicio de Endocrinología y Nutrición, Hospital Universitario La Princesa, Madrid, Spain; [5]Servicio de Endocrinología y Nutrición, Hospital e Instituto de Investigación Germans Trias, Badalona, Spain; [6]Universitat Autònoma de Barcelona, Barcelona, Spain.

Objective
To find consensus on issues that may raise clinical doubts in the management of patients with acromegaly in Spain.
Methods
Nominal group and Delphi methodology was followed. Four experts on acromegaly were selected, who defined important clinical questions in the management of acromegaly. A set recommendations were proposed to solve these questions. Subsequently, a group of 30 additional endocrinologits from all over Spain was selected according to acromegaly expertise criteria. The level of agreement with the recommendations was tested through two Delphi rounds. A literature narrative review was performed in order to support the recommendations.
Results
The recommendations cover different aspects of clinical practice including: 1) Useful instruments for the individualization of treatment (predictive markers of treatment response, imaging techniques, etc.); 2) Specific clinical profiles of patients and relevant comorbidities for the individualization of the treatment; 3) Role of the patients in the treatment decision making; and 4) Access to treatments (accessibility and equity). In the first Delphi round, 35 recommendations were evaluated, reaching consensus in 6, 2 were eliminated and 2 reformulated. In the second Delphi round, 27 recommendations were included, reaching consensus in 24 (22 consensus in the agreement, 2 in the disagreement) and 3 were eliminated because they did not reach the level of agreement established. For example, consensus was reached to associate cabergoline in a partial response to 1st generation somatostatin analogs, before the use of other costly drugs. In the second line therapy, although the presence of a non-aggressive residual tumor mass following surgery does not contraindicate pegvisomant monotherapy, the experts consider that, if the residual tumor in close to the chiasm, pasireotide is the best choice. In addition, pasireotide may be indicated in case of partial tumor response with 1st generation somatostatin analogs. In diabetic patients with insufficient control, pegvisomant alone or associated with a 1st generation somatostatin analog is considered more adequate than pasireotide. However, diabetes is not considered a limiting factor for this treatment. On the other hand, the panel also consider that the acromegalic patients should be responsible for taking the treatment correctly, in order to obtain an adequate benefit. The same way, patients should have the possibility of a second opinion and to be treated in a reference center.
Conclusions
These recommendations aim to solve some common clinical questions and facilitate decision-making process in the management of patients with acromegaly in Spain.

PROMPT: a prospective study to assess efficacy and safety of metyrapone in endogenous Cushing's syndrome

Lynnette Nieman[1], Baris Akinci[2], Albert Beckers[3], Marek Bolanowski[4], Felicia Alexandra Hanzu[5], Emese Mezösi[6], Anke Tönjes[7], Martine Bostnavaron[8], Amélie Jaspart[8], Pascale Borensztein[8], Marco Boscaro[9] & Carla Scaroni[9]

[1]NICHD, Bethesda, MD, USA; [2]Dokuz Eylul University Medical Faculty, Izmir, Turkey; [3]CHU of Liége, Liége, Belgium; [4]Samodzielny publiczny hospital and clinic, Wrocław, Poland; [5]Hospital clinic, Barcelona, Spain; [6]University of Pecs, Pecs, Hungary; [7]Universitätsklinikum Leipzig, Leipzig, Georgia; [8]HRA-Pharma, Paris, France; [9]University of Padova, Padova, Italy.

Introduction

Metyrapone blocks cortisol production by inhibiting 11ß-hydroxylation of 11-deoxycortisol, the last step of cortisol synthesis. Based on observational retrospective studies published over more than 50 years metyrapone is approved for the treatment of endogenous Cushing's syndrome (CS) in 14 European countries. PROMPT is the first prospective study to document the safety and efficacy of metyrapone using modern assay techniques.

Design and inclusion criteria

This is a single arm, open-label, multicenter, international trial. Adult patients with a new diagnosis of endogenous CS of any etiology (except advanced adrenal carcinoma) or recurrent or persistent Cushing's disease (CD) after transsphenoidal surgery (TSS), are eligible if three baseline 24 h Urinary Free Cortisol (UFC) values are at least 50% above the upper limit of normal (ULN = 165 nmol/24 h). Metyrapone given three or four times daily is titrated over 12 weeks to achieve normal urine and serum cortisol levels. After 12 weeks, patients whose mean value of 3 UFCs (mUFC) is less than 2-fold the ULN, may continue to receive metyrapone for another 24 weeks. Cortisol is measured in a central laboratory by LC-MS/MS.

Objectives

The primary objective is to assess the efficacy of metyrapone to normalise mUFC after 12 weeks of treatment. Secondary objectives are: assessment of the efficacy of metyrapone to normalise serum and salivary cortisol after 12 weeks and UFC after 24 weeks; assessment of changes in clinical symptoms of CS, blood pressure, quality of life (CushingQoL and Tuebingen CD QoL inventory); assessment of tolerance including adverse events and Ferriman-Gallwey score of hirsutism in women. The impact of metyrapone blockade on circulating lipids, glucose, ACTH, 11-deoxycortisol, deoxycorticosterone, renin/renin activity, androstenedione, DHEA-S and total testosterone levels is assessed. Time to 50% reduction of UFC, eucortisolemia, clinical and biochemical improvements, will be estimated. Exploratory objectives include factors predicting success and response relationships.

Status

The study started in 2015 and is ongoing in Belgium, Germany, Spain, Italy, Hungary, Poland and Turkey. To date 32 patients were included: 22 women and 10 men, with a mean age of 45 years old [21–73]; 29 have Cushing's disease (20 had previous TSS, range [1–3]). Fifteen completed the 9 months therapy period. Nine patients stopped study at/or after the primary objective endpoint: 2 for inefficacy, 1 because mUFC was >2xULN despite improvement by 70%, 1 for hirsutism, 1 for SAE (severe hypotension, cellulitis, venous thrombosis, and renal insufficiency) and 4 underwent TSS.

Mind the gap between cortisol levels measured with second generation assays and current diagnostic thresholds for the diagnosis of adrenal insufficiency: a single center experience

Giorgia Grassi[1,2], Valentina Morelli[1], Elisa Polledri[3], Silvia Fustinoni[3], Iacopo Chiodini[1], Ferruccio Ceriotti[4], Simona D'Agostino[4], Giovanna Mantovani[1,3] & Maura Arosio[1,3]

[1]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]University of Milan, Milan, Italy; [3]Department of Clinical Sciences and Community Health University of Milan, Milan, Milan, Italy; [4]Laboratorio Analisi, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Milan, Italy.

Objective

The current cut-offs to diagnose adrenal insufficiency (AI) have been established using outdated immunoassays. More modern methods have demonstrated less cross-reactivity with other steroids. The aim of our study was to evaluate the correlation between the cortisol assay Roche Cortisol I (R1), the newly available Roche Cortisol II (R2) and liquid chromatography tandem mass spectrometry (LC-MS/MS), the gold standard procedure for the measurement of steroids.

Design

We enrolled 30 consecutive patients (age 47 ± 21 years) referred to our Center to undergo Synacthen test (1 or 250 µg). Blood samples were collected at 0, 30 and 60 minutes and cortisol was simultaneously measured with R1, R2 and LC-MS/MS. AI was diagnosed for R1 stimulated peak cortisol levels <18 µg/dl.

Results

Mean cortisol levels measured with R1, R2 and LC-MS/MS were respectively 14.9 ± 6.4, 10.4 ± 4.3 and 10.7 ± 4.3 µg/dl at basal conditions, 25.5 ± 7.4, 17.4 ± 4.8 and 18.1 ± 4.8 µg/dl at 30 minutes, 26.7 ± 10.9, 18.2 ± 7.1 and 18.8 ± 7.3 at 60 min after Synacthen test ($P \leq 0.01$ for R1 vs both R2 and LC-MS/MS; P = not significant for R2 vs LC-MS/MS at any time). Based on the correlation between R1 and R2 cortisol levels we calculated that the diagnostic threshold for AI would be 12.6 µg/dl if cortisol is measured with R2. Considering the 18 µg/dl cut-off AI was diagnosed in 5/30 patients using R1 and 12/30 using R2 (+140%).

Conclusions

The introduction of more specific cortisol assays results in lower cortisol levels and could lead to wrong diagnosis of AI. Cortisol levels by R2 method are similar to those found by LC-MS/MS. It could help clinician in the Synacthen test interpretation until new clinically-derived thresholds will be available.

An open-label, multicentre, single-arm, expanded-access study of subcutaneous (s.c.) pasireotide in patients with Cushing's disease (CD)

Maria Fleseriu[1], Chioma Iweha[2], Luiz Salgado[3], Tânia Longo Mazzuco[4], Heather Patino[5], Federico Campigotto[5], Ricardo Maamari[5] & Padiporn Limumpornpetch[6]

[1]Northwest Pituitary Center, Department of Medicine and Neurological Surgery, Oregon Health & Science University, Portland, OR, USA; [2]Panda Medical Associates, Peoria, AZ, USA; [3]Hospital das Clinicas da Faculdade de Medicina da USP Avenida Doutor Eneas de Carvalho Aguiar, Sao Paulo, Brazil; [4]Universidade Estadual de Londrina, Londrina, Brazil; [5]Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA; [6]Songklanagarind Hospital, Division of Endocrinology and Metabolism, Department of Medicine, Prince of Songkla University, Hat Yai, Thailand.

Introduction

Pasireotide sc has a proven favourable efficacy and safety profile in CD patients, as shown in clinical trials. Here, we report safety and efficacy results from an expanded-access study designed to allow CD patients to receive pasireotide until regulatory approval for commercial use and reimbursement was obtained in their country.

Methods

Pasireotide-naïve adults with CD (mean 24-hour urinary free cortisol [mUFC; of three samples] exceeding the upper limit of normal [ULN]) were enrolled and initiated pasireotide sc at 600 µg bid (EU countries) or 900 µg bid (non-EU countries; 600 µg bid in patients with impaired glucose metabolism). Pasireotide dose could be increased/decreased in 300 µg increments/decrements to a maximum of 900 µg or a minimum of 300 µg for sustained UFC normalization/tolerability issues. The primary objective was to document the safety of pasireotide (primary endpoint: proportion of patients with a grade 3/4 or serious drug-related adverse event [AE]). Key secondary objectives included assessment of mUFC normalization and changes from baseline in clinical signs and quality of life (QoL) to weeks 12, 24 and 48.

Results

104 patients received pasireotide: female, $n = 84$ (80.8%); median duration of pasireotide exposure, 25.1 weeks; median (range) baseline UFC, 321.2 nmol/24h (142–10,920). Sixty-four (61.5%) patients discontinued treatment, most commonly for unsatisfactory therapeutic effect (25.0%), AEs (19.2%) and consent withdrawal (13.5%). Drug-related AEs occurred in 102 (98.1%) patients. Most AEs were mild/moderate severity; grade 3/4 drug-related AEs or serious AEs were documented in 42 (40.4%) patients, primarily metabolism/nutrition ($n = 20$; 19.2%) and gastrointestinal ($n = 13$; 12.5%) disorders. Most common grade 3/4 drug-related AEs were diabetes mellitus (10.6%) and hyperglycaemia (7.7%). At weeks 12, 24 and 48, respectively, 36/66 (54.5%), 22/46 (47.8%) and 9/21 (42.9%) evaluable patients had mUFC ≤ ULN. Improvements were observed in clinical signs; mean percentage change from baseline to week 48 in weight and sitting systolic and diastolic blood pressure was –7.0% (95%CI –9.1, –5.0), –4.9% (95%CI –7.9, –1.9) and –3.8% (95%CI –7.3, –0.4), respectively. Patients experienced a favourable shift in clinical signs and QoL improvement; mean CushingQoL scores increased by 34.4% (95%CI 19.5, 49.4) from baseline to week 48.

Conclusions
This study demonstrates that pasireotide is generally well tolerated, effectively reduces UFC (normalization in ~50% of evaluable patients) and improves clinical signs and QoL of CD patients in a setting similar to 'real-world' clinical practice. AEs were frequent but manageable for most patients, with <20% discontinuing because of AEs.

Growth hormone secretion in children treated for medulloblastoma

Alexey Kalinin[1], Natalia Strebkova[1], Olga Zheludkova[2] & Maria Kareva[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]Russian Research Center of Rentgenradiology, Moscow, Russian Federation.

Medulloblastoma is the most common malignant brain tumor in childhood. Treatment of medulloblastoma includes surgery, radiation therapy and chemotherapy. Craniospinal radiation can cause adverse effects on the endocrine system, specifically on the hypothalamic-pituitary axis. Increasing survival rates of pediatric patients with brain tumors lead to increased concern regarding long-term quality of life, including the detection and correction of endocrine disorders. One of the most frequent signs of endocrine dysfunction is growth and/or growth velocity retardation. We present data of growth hormone secretion in 28 patients with medulloblastoma after combined treatment (including craniospinal radiation). There were 20 boys (71.4%) and eight girls (28.6%). The mean age at time of examination was 10.2±2.75 yrs (6.2–15.5) The mean age of disease onset was 6.4±2.8 yrs (ranged from 1.1 to 13 yrs) and the time from end of therapy to our examination was 4.36±2.43 (0.5–13.4) yrs. Height SDS at the moment of examination (adjusted to age and sex) was −1.25±0.9 (−3.35 ÷ 0,21). Growth velocity did not exceed 2.5–3 cm/year in most patients. Growth hormone secretion was assessed by GH-stimulation test (clonidine or insulin). Total growth hormone deficiency was observed in 26/28 patients (92.9%), another two patients had partial GH-deficiency. Mean IGF-1 S.D.S. level (adjusted for sex, age and Tanner stage) was −1.35±0.9 (−5.2 ÷ 1.22), nevertheless 64.28% of patients (18/28) had normal IGF-1 level (i.e. IGF-1 SDS level from +1.2 to −2).
Conclusion
In the group of children, treated for medulloblastoma (including craniospinal therapy) we received growth hormone deficiency (total or partial) in 100% of patients, whereas 64.28% of them had normal IGF-1 level. We conclude that all patients with a history of craniospinal radiation should be screened for growth hormone deficiency. IGF-1 level cannot serve as a sensitive additional marker in this case.

Interim results of a non-interventional, observational study evaluating the long-term safety and efficacy of pasireotide sc in Cushing's disease

Carla Giordano[1], Jochen Schopohl[2], Kevin C J Yuen[3], Ulrike Kriemler-Krahn[4], Jiang Li[4], Ricardo Maamari[5] & Luca Manetti[6]
[1]Section of Endocrinology, Dipartimento Biomedico di Medicina Interna e Specialistica (DiBiMiS), University of Palermo, Palermo, Italy; [2]Medizinische Klinik IV, Klinikum der Universität München, Munich, Germany; [3]Barrow Pituitary Center, Barrow Neurological Institute, Phoenix, AZ, USA; [4]Novartis Pharma AG, Basel, Switzerland; [5]Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA; [6]Dipartimento di Medicina Clinica e Sperimentale, Università di Pisa, Pisa, Italy.

Introduction
Subcutaneous (sc) pasireotide effectively reduces cortisol levels, improves signs/symptoms and is generally well tolerated in Cushing's disease (CD) patients, as shown in previous clinical trials. We report interim results from a multicentre, real-world observational study evaluating the long-term safety and efficacy of pasireotide sc in clinical practice in CD patients.
Methods
Adults with CD, for whom surgery has failed or is not an option, are being enrolled. Primary objective: document the long-term (3-year follow-up) safety and tolerability of pasireotide. Secondary objective: document the short- and long-term efficacy of pasireotide as measured by the proportion of patients achieving mean urinary free cortisol (mUFC) below the upper limit of normal (ULN) at months 1, 3, 6, 12, 24 and 36. Patients are grouped by whether pasireotide was started before (prior-use) or at (new-use) study entry.
Results
As of 1 October 2016, 99 patients have been recruited and received ≥1 pasireotide dose after enrolment: 78 prior-use (mean time from diagnosis, 81.3 months; female, 80.8%) and 21 new-use (mean time from diagnosis, 40.7 months; female, 66.7%). Median (range) exposure to pasireotide: prior-use, 7.2 months (0.1–36.3) on study, 25.3 months (2.0–108.5) from drug initiation; new-use, 2.9 months (0.1–12.1) on study. Eighty-nine (prior-use, $n=69$; new-use, $n=20$) patients had ≥1 safety assessment after enrolment, of whom 65 (73.0%) experienced ≥1 adverse event (AE). Forty-three patients (48.3%) had ≥1 drug-related AE, most commonly nausea (prior-use, $n=6$ (8.7%); new-use, $n=7$ (35.0%)), diarrhoea (prior-use, $n=5$ (7.2%); new-use, $n=3$ (15.0%)) and hyperglycaemia (prior-use, $n=3$ (4.3%); new-use, $n=5$ (25.0%)). Drug-related serious AEs were documented in 8/69 prior-use (11.6%; hyperglycaemia, $n=1$ (1.4%)) and 4/20 new-use (20.0%; hyperglycaemia, $n=3$ (15.0%)) patients. Of patients with a normal/pre-diabetic HbA_{1c} level at baseline, 3/15 (20.0%) prior-use and 4/6 (66.7%) new-use patients had a highest-reported level in the diabetic range during the study. Of evaluable patients in the prior-use and new-use groups, respectively, mUFC was ≤ULN in 23/34 (67.6%) and 1/10 (10.0%) patients at baseline, 9/16 (56.3%) and 7/14 (50.0%) at month 1, 18/22 (81.8%) and 1/3 (33.3%) at month 6, and 16/18 (88.9%) and 0/0 at month 12.
Conclusions
Results from this study demonstrate the favourable risk/benefit profile of pasireotide sc in CD patients, confirming findings from previous clinical trials. The lower incidence of hyperglycaemia in prior-use versus new-use patients indicates that glycaemic control does not deteriorate over time, which is potentially attributable to appropriate management at its onset.

An immunohistochemical study on pituitary adenomas

Iulia Florentina Burcea[1], Cristina Capatina[1,2] & Catalina Poiana[1,2]
[1]'C. I. Parhon' National Institute of Endocrinology, Bucharest, Romania; [2]'Carol Davila 'University of Medicine and Pharmacy, Bucharest, Romania.

Introduction
Pituitary adenomas (PA) represent approximately 15% of all intracranial neoplasms, with a global incidence of 15,20 per million per year. The immunohistochemical analysis of PA is necessary for diagnosis and plays an important role in the modern classification system of pituitary tumors.
Material and methods
Samples from 142 surgically resected PA were studied immunohistochemically using antisera for 6 anterior pituitary hormones. Reticulin fiber staining and routine hematoxylin-eosin staining were also used. There were 57 patients with acromegaly (ACM), 29 prolactinomas (PRM), 55 non-functioning PA (NFPA) and 1 PA with mixed secretion of growth-hormone (GH) and prolactin (PRL).
Results
Immunohistochemical staining was positive for one hormone in 44% cases, 34% staining positive for multiple hormones. 21% of tumors failed to stain for any of the main pituitary hormones (null-cell adenomas). Most PA were acidophilic (105/142), the rest being basophilic (14/142), chromophobe (7/142) or mixed (16/142). In patients with ACM, most tumors were GH- (54%), mixed GH and PRL-producing (23%) and plurihormonal PA (9%). In the other cases (14%) the immunostaining results were discordant with the clinicobiological data. Prolactinomas were 75% PRL-producing PA, the rest being mixed GH and PRL or plurihormonal (7% each); discordant results were obtained in 11%. In our study, 32/55 (58%) of NFPA showed hormonal immunoreactivity: 13.5% (5/37) for GH, 89% (16/18) for FSH/LH, 6/13 (46%) plurihormonal PA and 11% (2/18) mixed GH-PRL. TSH, PRL and ACTH exclusive immunoreactivity were found each in one case. Most tumors immunopositive for GH (28/37), GH and PRL (13/18) and plurihormonal (8/13) were positive for reticulin, while those positive for PRL (9/23), ACTH (1/2), FSH-LH (7/18) and null-cell adenomas (14/30) stained less for reticulin. The only TSH-producing adenoma in the study stained negative for reticulin.
Conclusion
The immunohistochemical characterization of PA is useful for an accurate diagnosis. However, the hormonal immunoreactivity of these tumors is not always correlated with the synthesis and the release rate of the hormones. That is why the revised classification of pituitary adenomas (WHO, 2017) recognizes the role of many other immunohistochemical markers and transcription factors. Their widespread use will hopefully aid in the early identification of aggressive pituitary adenomas and in improving management strategies.

Inferior petrosal or cavernous sinus sampling in ACTH-dependent Cushing's syndrome: a single center experience

Mirka Andrée Ruch[1], Antonios Valavanis[2], Christoph Schmid[1] & Oliver Tschopp[1]
[1]Clinic for Endocrinology, Diabetology and Clinical Nutrition, University Hospital, Zurich, Switzerland; [2]Department of Neuroradiology, University Hospital, Zurich, Switzerland.

Objective
Most patients with ACTH-dependent Cushing's syndrome have Cushing's disease, i.e. a pituitary corticotroph adenoma, but the presence of another tumor secreting ACTH (although the prevalence of ectopic ACTH syndrome is lower) needs to be considered in the differential diagnosis. Distinguishing between these two etiologies can be difficult despite biochemical and radiological examinations. Previous research showed that inferior petrosal/cavernous sinus sampling (IPSS/CSS) has the highest diagnostic accuracy in this differential diagnosis. The aim of this study was to determine the accuracy of IPSS/CSS in predicting the source of ACTH-dependent Cushing syndrome in a tertiary center in Switzerland.
Methods
Retrospective, single center study of 21 patients (seven male, 14 female; age 40.4 ± 16.8y) with ACTH-dependent Cushing's syndrome who underwent a selective bilateral inferior petrosal sinus ($n=6$) or superselective bilateral cavernous sinus ($n=15$) sampling at the University Hospital Zurich between 2000 and 2017 and provided written informed consent. ACTH levels were measured before and within 20 min after corticotropin-releasing hormone (CRH) administration, and the ratios of central-to-peripheral plus interpetrosal ACTH levels were calculated. A central-to-peripheral ratio ≥ 2 before and ≥ 3 after CRH is diagnostic of an orthotopic source of ACTH. A ratio ≥ 1.4 between the two sinuses predicted the tumor lateralization.
Results
IPSS/CSS confirmed orthotopic (pituitary) source of ACTH in 19 patients with Cushing's disease and correctly identified 2 patients with ectopic disease. A central-to-peripheral plasma ACTH ratio was diagnostic for Cushing's disease in 19 patients before CRH and in 19 patients after CRH-administration. Interpetrosal ratios for ACTH lateralization were found in 17 (pre-CRH) and 17 (post-CRH) patients. The IPSS/CSS pre- and post-CRH ACTH ratio was negative (close to 1) in both patients with ectopic Cushing's syndrome. There was no adverse event in the context of the catheterization procedure. Perioperative MRI ($n=18$) showed 1 macroadenoma, 12 microadenomas and no visible lesion in five patients. In patients with visible pituitary lesions, IPSS/CSS predicted correctly the localization to the left, right or paramedian side in seven cases. Judged by surgery, the IPSS/CSS predicted correctly the lateralization of the pituitary tumor in 14 of 19 patients. Pituitary surgery was successful in 14 patients; five had persistent cortisol excess.
Conclusion
Our results confirm previous reports that IPSS/CSS is an effective intervention to locate the source of ACTH production. IPSS/CSS was safe and useful in planning the surgical therapy in patients with Cushing disease.

Relationship between pituitary adenoma size and transsphenoidal pituitary adenoma surgery outcomes: single-centre experience

Martyna Ramanciuckaite[1], Robertas Knispelis[1], Rimantas Zalinkevicius[2], Birute Zilaitiene[1,2] & Rasa Verkauskiene[1,2]
[1]Department of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction
Stereotactic radiotherapy and more relevant pharmacotherapy are widely used for PA's treatment; however transsphenoidal surgery remains gold standard. Postoperative complications and endocrinological outcomes vary widely and are related with surgeon experience and tumor characteristics.
The aim of this study
To determine relationship between pituitary adenoma size and transsphenoidal pituitary adenoma surgery outcomes.
Materials and methods
We performed a retrospective analysis of medical records for patients with pituitary tumor, who underwent transsphenoidal pituitary surgery during 2007–2016 year period at the Hospital of Lithuanian University of Health Sciences Kauno Klinikos. Data consisted of 217 patients: 121 (55.76%) male and 96 (44.24%) female, with a mean age of 52.84 ± 15.70 yrs (range 18–84 yrs). Relationship between tumor size, postoperative complications and endocrinological outcomes has been evaluated. The difference between proportions was confirmed using the χ^2 criterion. The odds ratio was calculated using 2×2 table methodic. Results were interpreted as statistically significant when $P<0.05$.
Results
The study included 123 nonfunctioning and 94 functioning adenomas: 38 were prolactinomas, 12 growth hormone (GH) and four corticotropin (ACTH) secreting adenomas. The majority of tumors 174 (80.18%) were macro adenomas (>1 cm), 26 (11.99%) micro adenomas (<1 cm) and 18 (8.29%) giant adenomas (>4 cm). The most common presenting symptoms were visual disturbance 117 (53.91%) and headache 122 (56.22%). Possibility for visual disturbance before surgery was significantly higher in macro adenomas group (OR 1.89 (±95 CI 1.66–2.17); $P=0.038$). Hypopituitarism prior operation was reported for 7 (3.22%) patients, all presented with nonfunctioning macro adenomas. Postoperative complications were observed in 31 (14.28%) patients. We confirmed that after surgery in patients with macro adenomas visual field (VF) and visual acuity (VA) improvement chance was significantly higher (VF OR 2.28 (±95 CI 1.12–1.46); $P=0.03$), (VA OR 2.15 (±95 CI 1.89–2.46); $P=0.03$). Odds to have the same VF and VA parameters after micro adenomas surgery were the following: VF OR 1.28 (±95 CI 1.13–1.47); $P=0.03$), VA OR 2.40 (±95 CI 2.1–2.74); $P=0.03$. After surgery remission achieved for 81 (37.32%) patients. Hypopituitarism was observed in 21 (8.42) patients and risk was significantly higher after macro adenomas surgery (OR 1.25 (±95 CI 1.1–1.44); $P=0.05$).
Conclusions
Our study demonstrated significant improvement of VF and VA, but higher risk for postoperative hypopituitarism after pituitary macro adenomas trassphenoidal surgery.

Clinical and mri findings among 120 patients with macroprolactinemia: results from a retrospective study

Lucio Vilar[1,2], Clarice Vilar[2], Luciano Albuquerque[1], Ana Carolina Thé[1], Erik Trovao[1], Patricia Gadelha[1] & Ruy Lyra[1]
[1]Division of Endocrinology, Hospital das Clinicas, Federal University of Pernambuco, Recife, Brazil; [2]Pernambuco Endocrine Research Center, Recife, Brazil.

Background
Macroprolactinemia is a condition where more of 60% of circulating PRL is made up of macroprolactin. It may be observed in both sexes (although women represent about 90% of published cases), and at all ages. As macroprolactin has low biological active and low bioavailibility, most patients are asymptomatic. The Endocrine Society guidelines recommend screening for macroprolactin only in asymptomatic hyperprolactinemic patients. However, some data from the literature have challenged this recommendation.
Subjects and methods
The aim of this retrospective study was to evaluate clinical presentation and MRI findings among 220 patients with macroprolactinemia routinely followed at Division of Endocrinology, Hospital das Clinicas, Federal University of Pernambuco, and at Pernambuco Endocrine Research Center, Recife, Brazil.
Results
A total of 120 patients (100 women and 20 men; mean age, 32.5 ± 6.5 yrs; age range, 19–46) were included. The great majority of female patients had been referred by gynecologists. Overall, 69 patients (57.5%) were asymptomatic, whereas 51 (42.5%) presented with symptoms related to hyperprolactinemia. Among the 100 female patients, 13% had galactorrhea, 26% menstrual disorders, and 3% both, whereas 58% were asymptomatic. Among the 20 male patients, 5 (30%) had erectile dysfunction, 3 (15%) had decreased libido and 1 (5%) both, whereas 11 (55%) subjects were asymptomatic. Abnormal MRI findings were found in 28 patients (23.3%): microadenomas in 16 (13.3%), empty sella in 8 (6.7%), and macroadenomas in 4 (3.3%).
Conclusion
Our findings demonstrated that abnormal MRI findings and particularly symptoms related to hyperprolactinemia are frequent features in patients with macroprolactinemia. Therefore, screening for macroprolactin only in asymptomatic patients seems to be an inappropriate approach.

Hypothalamic-pituitary axis assessment in a clozapine treated patient with a pituitary adenoma

Fotini Adamidou, Paraskevi Komzia, Fani Kalograni, Panagiotis Anagnostis & Marina Kita
Ippokration General Hospital, Thessaloniki, Greece.

Background
Assessment of hypothalamic–pituitary adrenal axis in patients with schizophrenia is complex, as it involves both the disease process and antipsychotic medications. We present a case of a patient on long term clozapine with a concomitant pituitary adenoma who presented discordant responses to adrenal stimulation.
Case
A 38-year old male was referred with chronic symptoms of reduced libido and associated low testosterone levels. He was treated for paranoid schizophrenia with clozapine 100 mg q.am and 400 mg note for many years. On further assessment he was normally masculinized, with testes of normal size and texture and no galactorrhea. However, testosterone levels were confirmed low at 20 mg/dl with low gonadotropins (FSH 1.51 mIU/ml, LH 0.73 mIU/ml), normal prolactin 7.93 ng/ml, TSH 2.52 μIU/ml and fT_4 0.68 ng/dl (normal 0.84–1.76). IGF-1 and morning cortisol levels were frankly low, at 26 ng/ml (normal range for age and sex 94–360) and 3.44 μg/dl respectively, making the diagnosis of panhypopituitarism. MRI of the sella showed a pituitary adenoma 10×10.7 mm. He was placed on hydrocortisone, thyroxine and testosterone replacement and underwent a successful endoscopic transphenoidal adenomectomy six months later. Stimulation with 1 μg tetracosactrin six months postoperatively showed a peak cortisol response of 11.7 μg/dl. Glucagon stimulation test also showed an inadequate peak cortisol response (9.32 μg/dl at 180′). At the same time, the responses of ACTH and cortisol to corticotropin-releasing hormone stimulation were normal, with a peak of 132 pg/ml at 15′ and 19.90 μg/dl at 30′ respectively. One year after surgery, morning cortisol levels were restored and hydrocortisone replacement was stopped. Repeat stimulation with 1 and 250 μg tetracosactrin and 1mg glucagon, showed peak cortisol responses of 16.0 at 30′, 21.60 at 60′ and 20.5 μg/dl at 180′, respectively. The patient remains GH, gonadotropin and TSH deficient.
Conclusions
1) Clozapine may blunt glucagon-stimulated ACTH secretion
2) Currently employed dynamic tests of adrenal axis in patients with pituitary pathology in the presence of antipsychotic medications cannot accurately reflect true capacity for stress response).

Comorbidities and symptoms among patients with acromegaly in italy: a longitudinal retrospective chart review study

Annamaria Colao[1], Ludovica Grasso[1], Marialuisa Di Cera[1], Wendy Y Cheng[2], Philippe Thompson-Leduc[2], Hoi Ching Cheung[2], Mei Sheng Duh[2], Maureen P Neary[3], Alberto M Pedroncelli[4], Ricardo Maamari[3] & Rosario Pivonello[1]
[1]University Federico II, Naples, Italy; [2]Analysis Group, Inc., Boston, USA; [3]Novartis Pharmaceuticals, East Hanover, USA; [4]Novartis Pharma AG, Basel, Switzerland.

Acromegaly is a disorder characterized by overproduction of growth hormones (GH), which causes tissue growth in the body and comorbidities and symptoms. While prior studies examined comorbidities commonly associated with acromegaly, few have long follow-up periods necessary to characterize the long-term comorbidity profile of patients with acromegaly. There is limited literature on real-world treatment patterns of patients with acromegaly. This study describes the long-term prevalence of comorbidities and symptoms associated with acromegaly, as well as treatment patterns, in a major referral center in Italy. Medical records of adult patients with a confirmed acromegaly diagnosis, ≥2 valid readings of GH and IGF1, and ≥6 months of follow-up at the endocrinology center at the University Federico II in Naples, Italy, were reviewed. For this analysis, patients were followed from the 1st acromegaly diagnosis recorded by this study center until end of data availability, loss to follow-up, or death; some patients may have had an earlier diagnosis before referral to this center. Prevalence (i.e., ≥1 diagnosis during chart review period) of selected comorbidities and symptoms was described. Treatments with corresponding line of therapy was documented during the follow-up period. 150 patients met the eligibility criteria. Patients were on average 43.1 years old (range: 19–70) at diagnosis, 47.3% female, all Caucasian, and median follow-up time was 8.7 years (range: 0.8–35.5). 25.3% of patients had ≥15 years of follow-up. The 3 most prevalent comorbidities were 1) endocrine and metabolic system disorders (97.3% of patients), 2) cardiovascular system disorders ([CVsD], 76.0%) and 3) arthropathy (62.0%). Common endocrine and metabolic system component conditions included dyslipidemia (74.7%), nodular thyroid disease (72.3%), glucose metabolism abnormalities (50.0%), gonadal and menstrual disorders (50.0%) and obesity (40.7%). CVsD's component conditions included hypertension (59.3%), myocardial hypertrophy (50.0%) and other various CVsD's (45.5%). Cancer, cerebrovascular disease, colon polyps, metabolic syndrome and sleep apnea were reported in $<50\%$ of patients. 68.0% of patients underwent transphenoidal surgery during the chart review period. 85.3% of patients received somatostatin analogs (e.g., lanreotide [58.7%] and octreotide (54.0%)) at various treatment phases. Dopamine agonists were used by 34.0% of patients, mostly in 2nd, 3rd or 4th line of therapy. Pegvisomant was used by 30.0% of patients, mostly in 2nd or 3rd line of therapy. While these comorbidities and symptoms have been shown to be associated with acromegaly, this study provides further insight on their lifetime prevalence. Heterogeneity in the treatment patterns underscores real-world differences in patient management following diagnosis.

Safety and efficacy of long-acting Pasireotide monotherapy in acromegalic patients treated with a combination of first-generation somatostatin analogs and cabergoline or pegvisomant

Hélène Lasolle[1], Amandine Ferrière[2], Marie-Laure Nunes[2], Magalie Haissaguerre[2] & Antoine Tabarin[2]
[1]Hospices civils de Lyon, Bron, France; [2]CHU de Bordeaux, Pessac, France.

Introduction
Combination therapy using pegvisomant and cabergoline with first-generation long-acting somatostatin analogs (1GSSA) is a common procedure in acromegalic patients that are not fully controlled by surgery and 1GSSA. Pasireotide-LAR is a new multireceptor-targeted somatostatin receptor ligand that has superior efficacy over octreotide LAR to control GH and IGF1 levels. Little data is available about the efficacy and safety of pasireotide monotherapy in patients treated with a combination therapy.
Materiel and methods
Fourteen acromegalic patients (10 women, aged: 47 ± 11 y) treated with octreotide LAR (30 mg/Mo, $N=8$) or lanreotide SR (120 mg/Mo, $N=6$), and cabergoline ($N=4$, weekly dose $=3.5$ mg) or pegvisomant ($N=10$, weekly dose 40–200 mg) were prospectively enrolled in an open study and switched to pasireotide-LAR monotherapy (half with 40 mg and half with 60 mg/Mo). Seven patients already had diabetes mellitus, two patients had glucose intolerance. Clinical, biological and radiological evaluations were performed before (baseline), 3 months after the switch and at 6 Mo or later.
Results
IGF1 level at 3 Mo and baseline were similar (median $=1.1$ vs 1.1 ULN). Median GH was 1.54 ng/ml (min $=0.14$-max $=8.9$). As compared to baseline, six patients vs five had IGF1 below 1ULN. A significant increase in fasting blood glucose and HbA1c was observed at 3 Mo vs baseline: 1.15 g/l (0.82–1.6) vs 1.02 (0.9–1.78) ($P=0.05$) and 6.4% (5.4–8.4) vs 5.7% (5.3–7.2) ($P=0.002$) respectively. A new anti-diabetic treatment was initiated in six patients (including five with diabetes at baseline). During the follow-up, six patients stopped Pasireotide-LAR for lack of control of IGF-1 ($N=2$), intolerance despite control (dizziness $N=1$ and hyperglycemia $N=1$), and lack of control associated with hyperglycemia ($N=2$). Eight patients were treated with Pasireotide-LAR for a median duration of 8 months (2–17) with a controlled IGF1 (0.5–1.1 ULN) and acceptable glucose tolerance (median HbA1c 6.1% (5.4–7.4)). Three of these 8 patients required antidiabetic treatment intensification (increase in insulin dosage in 1) or initiation (oral antidiabetic treatments in two). Five patients had normal glucose tolerance without pharmacological treatment.
Conclusion
In this small series, Pasireotide-LAR is an efficient alternative with acceptable tolerance in a subset of acromegalic patients treated with a combination therapy involving 1GSSA.

Association between biochemical control and comorbidities and symptoms among patients with acromegaly in Italy: a longitudinal retrospective chart review study

Annamaria Colao[1], Ludovica Grasso[1], Marialuisa Di Cera[1], Wendy Y Cheng[2], Philippe Thompson-Leduc[2], Hoi Ching Cheung[2], Mei Sheng Duh[2], Maureen P Neary[3], Alberto M Pedroncelli[4], Ricardo Maamari[3] & Rosario Pivonello[1]
[1]University Federico II, Naples, Italy; [2]Analysis Group, Inc., Boston, MA, USA; [3]Novartis Pharmaceuticals, East Hanover, MA, USA; [4]Novartis Pharma AG, Basel, Switzerland.

Acromegaly is a rare disorder characterized by the overproduction of growth hormone (GH) and elevated insulin-like growth factor-1 (IGF1). While some studies have investigated the potential associations between biochemical control (i.e., normalization of IGF-1 and/or GH) and comorbidities/symptoms, few studies have long-term follow-up. This study assessed the association between biochemical control and selected comorbidities/symptoms in patients with acromegaly using real world longitudinal data. Medical records of adult patients with a confirmed acromegaly diagnosis, $\geq$2 valid readings of GH and IGF1, and $\geq$6 months of follow-up at an endocrinology center in Naples, Italy, were reviewed. For this analysis, patients were followed from the first medical encounter with a GH/IGF1 measurement at the center until the occurrence of comorbidities/symptoms (i.e., event), loss to follow-up, or death (i.e., censoring). Biochemical control was assessed annually and defined as having $>$50% days with IGF1 measurements $\leq$ the upper limit of normal, or GH measurements $\geq$2.5 µg/l when IGF1 was not available. Comorbidities/symptoms assessed included arthropathy, cancer, cardiovascular system disorders (CVsD) and component conditions, cerebrovascular disease, colon polyps, endocrine and metabolic system disorders and component conditions, and sleep apnea. Time-varying Cox models, adjusting for age and sex, were used to assess the association between biochemical control and comorbidities/symptoms. Hazard ratios (HRs) and confidence intervals (CIs) were estimated. Of the 150 eligible patients, all were Caucasian, 47% were female, on average 43.1 years old (range: 19–70) at diagnosis, with a mean follow-up time of 8 years (range: 0–31). The mean GH level during the follow-up was 8.3$\pm$11.9 µg/l and 367.7$\pm$154.2 µg/ml for IGF1. The three most commonly observed incident comorbidities/symptoms during follow-up were endocrine and metabolic system disorders (94.3%), CVsD (63.4%), and arthropathy (48.5%). Biochemical control was significantly associated with a lower hazard of CVsD (HR=0.54, 95% CI=0.31–0.93). While significance was not reached for endocrine and metabolic system disorders as a whole (HR=1.01, 95% CI=0.78–1.33), biochemical control was significantly associated with a lower hazard of diabetes (HR=0.36, 95% CI=0.15–0.83). Biochemical control was significantly associated with a higher hazard of certain types of arthropathy (HR=1.68, 95% CI=1.04–2.71), but not with the remaining comorbidities/symptoms assessed. These results highlight the importance of achieving biochemical control, since this may reduce the risk of costly conditions, including CVsD and diabetes. The association found for arthropathy may suggest the irreversibility of this acromegaly-related impairment.

Trends of insulin-like growth factor 1, growth hormone, and biochemical control of patients with acromegaly in italy: a longitudinal retrospective chart review study

Annamaria Colao[1], Ludovica Grasso[1], Marialuisa Di Cera[1], Wendy Y Cheng[2], Philippe Thompson-Leduc[2], Hoi Ching Cheung[2], Mei Sheng Duh[2], Maureen P Neary[3], Alberto M Pedroncelli[4], Ricardo Maamari[3] & Rosario Pivonello[1]
[1]University Federico II, Naples, Italy; [2]Analysis Group, Inc., Boston, USA; [3]Novartis Pharmaceuticals, East Hanover, USA; [4]Novartis Pharma AG, Basel, Switzerland.

Long-term biochemical control (i.e., normalization of growth hormone [GH] and insulin-like growth factor-1 [IGF1]) is the goal of treatment of acromegaly. Few studies have characterized the sustainability of GH/IGF1 levels in acromegaly patients. This study aimed to identify long-term time trends of GH, IGF1 levels, and biochemical control in patients with acromegaly using longitudinal real world data. Medical records of adult patients with a confirmed acromegaly diagnosis, $\geq$2 readings of GH and IGF1, and $\geq$6 months of follow-up at an endocrinology center in Italy, were reviewed. Patients were followed from first documented GH and/or IGF1 measurement at the study center until end of data availability, loss to follow-up, or death. Mean GH and IGF1 levels were obtained across multiple measurements per year. Biochemical control was assessed annually and defined as having $>$50% of IGF1 measurements $\leq$upper limit of normal, or GH measurements $\leq$2.5 µg/L (when IGF1 unavailable). Latent class growth analyses were conducted to identify different time trends of mean IGF1, mean GH, and probability of being biochemically controlled over 10 years, and to estimate the proportion of patients presenting with these time trends. Trend assignments were based on model fit. All 150 eligible patients were Caucasian, 47% female, with mean age of 43.1 years (range: 19–70) at diagnosis and a mean follow-up time of 9 years. 81 (54%), 84 (57%), and 81 (54%) patients had normal IGF1, GH, and biochemical control status, respectively, for $\geq$50% of the follow-up period. Four trends were identified for IGF1 (% of population; mean levels): one stable (15.3%; 186.5 ng/mL) and three declining ([1] 39.3%; initial [year 1]: 465.8, last [year 10]: 142.9; [2] 38.0%; initial: 576.8, last: 280.1; [3] 7.3% initial: 664.1, last: 403.4). Three declining trends were identified for GH ([1] 23.6%; initial: 1.63 µg/L, last: 0.32 µg/L; [2] 50.7%; initial: 4.57, last: 1.03; [3] 25.7% initial: 12.99, last: 3.34). Probability of achieving biochemical control followed two trends (% of the population; probability of control): one stable (26.7%; 20.4%) and one increasing (73.3%; initial: 33.1%, last: 98.0%). Results show that IGF1 and GH levels were initially elevated in the majority of patients, and declined over time. Biochemical control was reached by $\geq$70% of patients after 10 years. One-third of the population had low likelihood of achieving control at any time. Future research is warranted to understand the impact of long-term biochemical levels on patients' disease course.

Pituitary intensity at magnetic resonance imaging is reduced in obese patients: results from the CHIASM study

Giulia Puliani[1], Emilia Sbardella[1], Alessia Cozzolino[1], Carlotta Pozza[1], Tiziana Feola[1], Daniele Gianfrilli[1], Carla Lubrano[1], Marco Fiorelli[2], Andrea Lenzi[1] & Andrea M Isidori[1]
[1]Department of Experimental Medicine – Sapienza University, Rome, Italy; [2]Department of Neurology and Psychiatry – Sapienza University, Rome, Italy.

Introduction
Even if obesity has been associated to several hormonal imbalances, pituitary appearance at Magnetic Resonance Imaging (MRI) in obese patients is understudied.
Aim
To measure pituitary signal intensity and homogeneity at MRI in obese subjects free of focal pituitary disease, in the context of the CHIasM study (Changes in the Hypotalamic-pItuitary region of patients with Metabolic syndrome and obesity).
Materials and methods
Seventy-eight patients were prospectively enrolled and underwent metabolic, hormonal, body composition (DEXA scan) and pituitary MR assessment. Patients were divided in two groups according to BMI (study group $\geq$ 30 kg/m^2, 55 patients, control group $<$ 30 kg/m^2, 23 patients). Texture of the pituitary gland was quantified recording pixel density and distribution using ImageJ software. Two operators independently placed the region of interest to entirely cover the pituitary gland, calculating mean intensity and its standard deviation. All analyses were normalized for both white and grey brain matter intensity.
Results
In the study group, we demonstrated a statistically significant reduction in mean pituitary intensity in T1 weighted images both in basal (P=0.038) and contrast-enhanced sequences (P=0.002), trough analysis of covariance (ANCOVA). Moreover, pituitary intensity in T1-weighted basal and contrast-enhanced images was negatively correlated to truncal fat (P 0.008, P 0.011) and fibrinogen (P=0.011, P=0.005). Multiple regression analysis revealed that, after adjusting for age and sex, the percentage of truncal fat and fibrinogen were significant predictors of the mean intensity of coronal T1-weighted scans (P=0.001). The model explained up to 26% of variance of pituitary signal intensity, and in a step-wise R^2 analysis fibrinogen itself accounted for 9.6% of the variance.
Conclusions
This study describes a quantitative reduction in pituitary intensity in T1-weighted sequences in obese patients, that seems related to visceral adiposity and low-grade inflammation. Data could be explained by a relative change in pituitary stromal tissue in this cohort of patients.

The influence of levothyroxine (T4) treatment on metabolic parameters in central hypothyroidism (CH)

Milica Medic-Stojanoska[1,2], Bojan Vukovic[1,2], Ivana Bajkin[1,2], Jovana Prodanovic[1,2], Natasa Milosevic[2], Stefan Stojanoski[2], Jovanka Novakovic-Paro[1,2] & Nikola Curic[1,2]
[1]Clinical Center of Vojvodina, Novi Sad, Serbia; [2]Medical faculty University of Novi Sad, Novi Sad, Serbia.

Introduction
L thyroxin treatment of CH is monitored by free T4 (fT4) which should be above mid normal range for the assay. It is not clear whether these doses are adequate for regulating the metabolic disturbances accompanying CH.
Aim
To determine whether T4 therapy leads to improvement of metabolic parameters in CH.
Materials and methods
This was a retrospective study. Study group comprised of 60 hypopituitary patients with CH, controls were 18 patients with hypopituitarism without CH. We analyzed fT4 and freeT3 (fT3), daily T4 dose, duration of CH, number of pituitary deficits, body mass index (BMI), arterial blood pressure, total cholesterol (TC), triglycerides, HDL, LDL, fasting blood glucose (FBG) and insulinemia, HOMA IR, and spine and hip bone mineral density (BMD).
Results
fT4 was normal in both groups (13.55 ± 2.72 vs. 13.54 ± 1.86 pmol/l). FT3 was normal but significantly lower in CH group (3.76 ± 0.84 vs. 4.45 ± 1.16 pmol/l; $P < 0.028$). Average dose of T4 was 1.26 ± 0.54 µg/kg/body weight. Duration of CH was 10.36 ± 11.69 years. Number of pituitary deficits was significantly higher in CH group ($P < 0.001$). Triglycerides were elevated in the CH group, but the difference was insignificant (1.91 ± 1.07 vs. $1.45 \pm 1.45 \pm 0.86$ mmol/l, $P = 0.10$). HDL was low in CH group and difference was significant (1.07 ± 0.32 vs. 1.52 ± 0.54, $P < 0.001$). Other parameters were normal and did not differ. FT4 was significantly positively correlated with HDL and negatively with hip BMD ($P < 0.05$; $P < 0.01$; $P < 0.002$). FT3 was significantly negatively correlated with FBG ($P < 0.02$). T4 dose was significantly positively correlated with BMI, negatively with spine and hip BMD ($P < 0.04$; $P < 0.008$; $P < 0.004$; $P < 0.007$). Duration of CH was significantly negatively correlated with spine and hip BMD ($P < 0.03$; $P < 0.004$; $P < 0.001$).
Conclusion
Apart from fT4 metabolic parameters should be taken into account when treating CH.

Efficacy of pasireotide lar in first line somatostatin analogue resistant acromegaly patients: experience from a large and single centre Italian cohort

Sabrina Chiloiro[1], Antonella Giampietro[1], Antonio Bianchi[1], Tommaso Tartaglione[2], Chiara Bima[1], Serena Piacentini[1], Federica Mirra[1], Federico Donfrancesco[1], Liverana Lauretti[3], Carmelo Anile[3], Alfredo Pontecorvi[1] & Laura De Marinis[1]
[1]Pituitary Unit, Catholic University of the Sacred Heart, Rome, Italy; [2]Institute of Radiology, Catholic University of the Sacred Heart, Rome, Italy; [3]Department of Neurosurgery, Catholic University of the Sacred Heart, Rome, Italy.

Introduction
Pasireotide Lar is a new generation long-acting somatostatin multireceptor ligand, approved for the treatment of first line somatostatin analogue resistant patients. We aimed to review Pasireotide Lar efficacy data, in our series of patients affected by aggressive acromegaly.
Patients
A retrospective longitudinal study was conducted on patients with aggressive acromegaly, resistant to first-line somatostatin analogues (SSA) and on treatment with Pasireotide Lar for at least 6 months. Clinical and radiological data at baseline (Pasireotide Lar start) and at follow-up were collected.
Results
Thirty-one patients met the inclusion criteria. 21 patients were treated with Pasireotide Lar during CSOM230C2304 clinical trial, 3 patients started treatment as for compassionate use and 7 patients started treatment after Pasireotide Lar marketing. 20 patients were female. Mean age at Pasireotide Lar start was 42 years (SD:11.6). All patients were considered affected by active acromegaly at Pasireotide Lar treatment start (mean GH:24.5 ng/mL SD: 46.7; mean IGF-I: 3.58 xUNL SD:1.77). All patients had undergone previous pituitary neurosurgery for macroadenoma and at baseline carried residual disease with cavernous sinus invasion. Ki67 was higher than 1.5% in all patients (mean:2.5 SD:1.7). Types IIa and V Somatostatin analogues receptors (SSTRs) immunohistochemical study was available in 11 patients. Particularly we found a high (score 3) immunoistochemical expression of type V STTR in 2 patients, a mild SSTR5 (score 2) in 5 patients. With regard to SSTR2A, we found a high expression (score 3) in 3 patients and a mild expression (score 2) in 3 patients. In the remaining cases, both SSTR5 and SSTR2A expression was considered negative. Mean duration of Pasireotide Lar treatment was 173.6 months (SD: 650). 24 patients were treated with Pasireotide Lar 60 mg monthly and the remaining 7 patients with Pasireotide Lar 40 mg monthly. Among patients enrolled in CSOM230C2402 study, 14 cases reached the biochemical control of acromegaly. Among patients on post-marketing treatment with Pasireotide Lar, 4 patients were on combination therapy with Pasireotide Lar, Pegvisomant and Dopamine Agonist. At the last examination, 20 patients were on treatment with Pasireotide Lar: 10 patients who had started therapy during CSOM230C2402 clinical trial and all the patients started Pasireotide Lar as compassionate use or post-marketing. All 20 patients documented normalization of GH and IGF-I secretion. In a single case, at neuroradiological follow-up, volumetric reduction of residual pituitary adenoma occurred.
Conclusion
Our data confirmed the efficacy of Pasireotide Lar in aggressive acromegaly.

The change in metabolic parametres of prolactinoma patients after therapy intervention

Iffet Dağdelen Duran[1], Neşe Ersöz Gülçelik[2] & Dilek Berker[1]
[1]Ankara Numune Education and Research Hospital, Endocrinology And Metabolic Diseases Department, Ankara, Turkey; [2]Gülhane Education and Research Hospital, Endocrinology and Metabolic Diseases Department, Ankara, Turkey.

Introduction
Prolactinoma is the prolactin secreting tumor of the pituitary gland which exerts mainly hypogonadal complaints and sometimes symptoms due to mass effect. Meanwhile it was mentioned to cause metabolic abnormalities such as increased fasting plasma glucose (FPG), Low Density Lipoprotein(LDL) cholesterol and triglycerides(TG). We studied whether some of these metabolic parametres of prolactinoma patients could be changed after the therapy.
Methods
This study was in retrospective design, enrolled 100 prolactinoma patients who were admitted to our endocrinology department. 49 of them did not require any treatment. 51 patients who were administered only drug therapy or both surgery and afterwards drug therapy were included. The drugs were cabergoline and bromocriptine. Metabolic variables and tumor dimensions on magnetic resonance imaging (MRI) were studied at diagnosis and after therapy.
Results
Out of 51, 42 were female (82.4%) and nine (17.6%) were male. The age and disease duration did not vary according to sex. 4/9 (44.4%) of male and 7/42 (16.7%) of female harbored macroadenoma. Only three patients underwent pituitary surgery. Through whole group, LDL cholesterol (from 115.3 ± 10.7 to 84.6 ± 14.7, p:0.049) decreased significantly and TG level (from 150.5 ± 26.3 to 121.7 ± 18.5, p:0.30) decreased nonsignificantly accompanying a significant decrease in PRL levels (from 108.6 ± 13.0 to 13.6 ± 2.2, p:0.000) following treatment. The data were shown in detail in Table 1.
Conclusion
Metabolic variables such as FPG, HDL and TG did not show significant alteration while LDL decreased minimal significantly after achievement of PRL level's

normalization in our study. Previously, it was denoted FPG, TG and LDL decreased ($P<0.005$) after prolactinoma treatment, independent of BMI reduction or sex hormonal change. However, the initial metabolic conditions of their patients could be more undesired than our subjects', that might be one reason for much willingness of their values to improve by treatment. Therefore, more studies in prospective design with higher number of patients is required to deliver more accurate results about this scheme.

Table 1 The characteristics of prolactinoma patients before and after the treatment.

	Time of diagnosis	After the treatment	*p* value
PRL (mcg/l)	108.6±13.1	13.6±2.2	0.000
FPG (mg/dl)	94.4±22.6	95.5±16.3	NS
LDL cholesterol (mg/dl)	115.3±10.7	84.6±14.7	0.049
HDL cholesterol (mg/dl)	51.6±4.4	47.9±3.3	NS
TG (mg/dl)	150.5±26.3	121.7±18.5	NS

"Silent" ACTH-secreting pituitary carcinoma: case report

Ludmila Astafyeva, Pavel Kalinin, Nikita Mikhailov, Yuriy Trunin & Grigiriy Kobyakov
Burdenko Neurosurgical Institute, Moscow, Russian Federation.

Introduction
Pituitary carcinomas are extremely rare neoplasms and molecular events leading to malignant pituitary transformation are largely unknown.
Case report
36-year-old man turned to the clinic for visual and oculomotor disorders. A large endo-supra-latero(S)sellar tumor was found on MRI. There was also an increase in the level of ACTH in the blood (60,80 pmol/l (normal values 5–49)). The level of free cortisol in 24-hour urine was normal. Endoscopic transsphenoidal tumor removal was performed. Histological conclusion was pituitary adenoma (Ki67 10–15%). Immunohistochemical study revealed the expression of ACTH by a tumor. A month after the operation, MRI control was performed. A tumor recurrence was detected. PET-CT revealed metastases in the spine, liver and tubular bones. In the metastasis of the brachial bone, the expression of ACTH was also found. The patient was carried out the combined treatment including 18 courses of palliative chemotherapy (docetaxel, carboplatin, irinotecan, cisplatin, temodal), 3 courses of stereotactic irradiation for primary tumor and therapy with cabergoline and somatostatin analogues. The patient lived 2 years and 9 months after detection of the tumor was made.
Conclusions
There was a decrease in size of the primary tumor after radiotherapy, and chemotherapy resulted in a decrease in the metabolic activity of metastases which increased the life expectancy of the patient.

Radiotherapy for pituitary adenomas – safety and efficacy analysis

Sílvia Paredes, Rui Ramos, Rui Almeida & Olinda Marques
Hospital de Braga, Braga, Portugal.

Introduction
Radiotherapy (RT) has been proven to be effective in controlling hormone production and tumor growth in pituitary adenomas (PA). Still, RT adverse effects had turned it an unattractive choice of treatment. The aim of this study was to evaluate the efficacy and safety of RT for patients with PA.
Methods
We conducted a retrospective study of patients treated in our center, a central hospital, since 1998. Thirty-three patients were included, 67% female, with a medium time of follow-up of 85.5 months (P25-44/P75-133 range 11–279). Twenty-nine patients had macroadenoma and 16 cavernous sinus invasion. Eight patients had pituitary deficits before RT. In all but one patient, RT was a secondary treatment after surgery. Eighteen patients had functioning PA (FPA) (11-GH, 6-ACTH, 1-PRL) and 15 non-functioning PA (NFPA) (7 null-cell, 4-FSH, 4-ACTH, 1-PRL).
Results
Twenty-eight patients were submitted to conventional or fractioned stereotaxic RT (mean daily dose 2.26±1.1Gy; mean dose 46.50±9.2Gy) and 5 patients were submitted to radiosurgery (mean dose 23±6.2Gy). Mean age on 1st surgery was 43.31±13.4 years and at RT was 48.94±13.7 years. During follow-up patients presented: visual deficit deterioration ($n=1$,3.1%), new visual deficit ($n=2$,6.2%), hormonal deficit deterioration ($n=3$,37.5%), de novo hormonal deficit ($n=14$,58.3%), stroke ($n=2$,6.2%), cognitive impairment ($n=6$,18.8%) and death ($n=2$). Medium time to development of 1st pituitary deficit was 19 months (P25-9/P75-42). Hypocortisolism and hypothyroidism were the most common deficits ($n=13$). In respect to NFPA, 2 did not achieve tumor growth control and 1 presented tumor growth, requiring new surgery. In respect to FPA: 4 achieved remission, 6 control with pharmacological treatment, 6 did not achieve biochemical control, 1 was lost to follow-up and 1 died. Medium follow-up time to biochemical control was 24 months (P25-11.5 P75-66). Nowadays, 10 patients are under pharmacological treatment. The overall estimated 6-month, 30-months and 108-months pituitary function preservation rates were 87.5%, 57.5% and 30.7%, respectively.
Conclusions
After RT, 86% of NFPA patients presented tumor growth control and 62.5% of FPA presented remission or biochemical control. RT-induced hypopituitarism was the most common adverse effect and hypocortisolism and hypothyroidism were the most common deficits. RT demonstrated to be an effective treatment in PA, nevertheless, it also presented important adverse effects. Life-long follow-up is essential in these patients and a longer follow-up is needed to evaluate long-term outcomes of RT in PA.

Usefulness of stereotactic radiotherapy in acromegalic patient resistant to conventional treatment

Barbara Bromińska, Hanna Komarowska & Marek Ruchała
University of Medical Sciences in Poznań, Poznań, Poland.

Introduction
Acromegaly is a rare, chronic disease characterized by increased secretion of growth hormone, most commonly by autonomous adenoma of the anterior pituitary. Mortality is 2–3 times higher than in general population. So that, it is vital to achieve biochemical cure. We present a case in which patient was successfully treated with stereotactic radiotherapy (SRT)- CyberKnife and preserved pituitary function.
Case report
A 39-years old men was admitted to endocrinological outpatient department due to signs and symptoms suggestive for acromegaly. He noticed changes in his face shape, enlargement of hands and feet. He complained about excessive sweating and headache. Laboratory results confirmed diagnosis and excluded hypopituitarism. MRI of pituitary gland revealed microadenoma (8×6 mm), which did not

compress optic chiasm. Before transphenoidal resection of the lesion patient received three octreotide injections. After surgery due to persistent disease, octreotide was re-introduced (dose: 30 mg/monthly). Then, because of drug intolerance, it was replaced with lanreotide (120 mg/monthly). Still, we did not achieve treatment goals. Patient refused to be re-operated. Finally, he underwent stereotactic radiotherapy (CyberKnife). Lanreotide was withdrawn twelve months after SRT. On regular check-up, 18 months after radiotherapy, patient met the criteria of cured acromegaly. Function of other pituitary axes was preserved.

Conclusions

Radiotherapy in acromegalic patients might be useful in case of uncontrolled disease and drug intolerance after surgery. Radiotherapy may lead to biochemical control, thereby limiting the necessity of lifelong medical therapy. SRT is recommended over conventional radiotherapy due to lesser side effects, shorter time to achieving remission and shorter treatment duration.

Subclinical left ventricular dysfunction in patients with naive acromegaly assessed by two-dimensional speckle tracking echocardiography (2D-STE)

Agata Popielarz-Grygalewicz[1], Maria Ste[2], Jakub Gęsior[1,3], Aleksandra Konwicka[1], Paweł Grygalewicz[1], Wojciech Zgliczyński[2] & Marek Dębrowski[1]

[1]Cardiology Clinic of Physiotherapy Division of the 2nd Faculty of Medicine, Medical University of Warsaw, Warsaw, Poland; [2]Department of Endocrinology, The Centre of Postgraduate Medical Education, Warsaw, Poland; [3]Faculty of Health Sciences and Physical Education, Kazimierz Pulaski University of Technology and Humanities, Radom, Poland.

Introduction

Cardiac disease called acromegalic cardiomyopathy may be present in patients with acromegaly at diagnosis, however most echocardiographic studies showed that systolic function in these patients is normal. Speckle tracking echocardiography (STE) is a novel method that allows for the study of global longitudinal strain (GLS), a marker of early and subclinical left ventricular (LV) systolic dysfunction.

Objective

To evaluate left ventricular GLS in patients with naive acromegaly with normal LV systolic function.

Patients and methods

Fifty-one consecutive patients with naive acromegaly with normal systolic LV function measured by ejection fraction (EF), and a control group were matched for age and gender underwent 2D-STE.

Results

The mean GLS was significantly lower in acromegaly group than in the controls (in%, -17.28 ± 4.9 vs. -20.9 ± 3.2, $P < 0.01$). Majority of acromegalic patients (60.7%) had abnormal GLS. Patients with impairment in GLS had statistically significant longer duration of acromegaly symptoms compared to those with normal GLS values (years, 10.0 vs. 5.0, $P < 0.05$). Acromegalics with lower GLS had also statistically significant increase in parameters of LV thickness i.e. intraventicular septum (IVS) [in mm, 13 (8–19) vs. 11.5 (8–14), $P < 0.05$] and posterior wall (PW) [in mm, 13 (8–17) vs. 12 (9–13) $P < 0.05$] compared to those with normal GLS values. Mean left ventricular mass index (LVMi) was increased in the acromegaly group compared to controls (in g/m^2, 138.8 ± 36.5 vs. 99.4 ± 24.0, $P < 0.01$). There was a statistically significant negative correlation between LVMi and GLS ($R = -0.38$, $P < 0.01$)

Conclusions

Naive acromegalic patients presented with lower GLS compared to the control group. This finding indicates subclinical systolic dysfunction in the untreated acromegalic patients. It cannot be ruled out that the LV function measured with GLS improves as an effect of treatment; it requires further studies. We found longer disease duration in a group of acromegalic patients with impairment in GLS compared to those with normal values. Increased efforts should be made to diagnose acromegaly at early stage to prevent cardiac systolic dysfunction.

Efficacy and tolerability of cabergoline in a cohort of 160 prolactinomas at weekly doses of up to 9 mg

Lucio Vilar[1,2], Clarice Vilar[2], Luciano Albuquerque[1], Ana Carolina Thé[1], Erik Trovão[1], Patricia Gadelha[1], Icaro Sampaio[1], Barbara Gomes[1], Liana Ferreira[1], Priscila Aroucha[1], Raissa Lyra[2], Maira Fonseca[1] & Ruy Lyra[1]

[1]Division of Endocrinology, Hospital das Clinicas, Federal University of Pernambuco, Recife, Brazil; [2]Pernambuco Endocrine Research Center, Recife, Brazil.

Background

Dopamine agonists are the mainstay of treatment for prolactinomas. Cabergoline (CAB) is preferable to bromocriptine due to its greater efficacy and better tolerability.

Subjects and methods

The aim of this retrospective open trial was to evaluate the efficacy and tolerability of CAB in a cohort of 160 patients with prolactinomas routinely followed in Pernambuco Endocrine Research Center and Division of Endocrinology, Hospital das Clinicas, Federal University, Recife, Brazil.

Results

A total of 160 patients (100 women and 60 men; mean age, 31.1 ± 6.3 yrs; age range, 15–44; 86 micros and 74 macroprolactinomas) were enrolled. Overall, 7 patients (4.4%) were intolerant to CAB due to gastrointestinal and/or neurological side-effects (headaches and dizzness). Among the remaining patients, normalization of prolactin (PRL) levels was achieved by 115 patients (75.2%) at doses of up to 2 mg/week, whereas PRL normalization was found in 13 additional patients when CAB dose was increased to up to 3 mg/week. The remaining 25 patients were submitted to increasing doses of CAB up to 9 mg/week, 18 of whom (72%) reached PRL normalization. No patients benefited from weekly doses > 7 mg. Among responsive patients with macroprolactinomas, 82% experienced tumor shrinkage $>50\%$ whereas 55% had complete tumor disappearance. CAB doses > 3 mg/week were well tolerated and no significant valvular abnormalities were found despite the use of weekly doses as high as 9 mg.

Conclusions

In doses of up to 9 mg/week, longterm CAB therapy was well tolerated and enabled PRL normalization in 95% of patients with prolactinomas. No patients benefited from doses > 7 mg/week.

Pituitary apoplexy: 15 years of experience

Bernardo Marques[1], Diana Oliveira[2,3], Mara Ventura[2], Adriana Lages[2], Nelson Cunha[2], Diana Catarino[2], Lúcia Fadiga[2], Margarida Bastos[2,3], Sandra Paiva[2], Isabel Paiva[2], Leonor Gomes[2,3] & Francisco Carrilho[2]
[1]Endocrinology Department – Portuguese Institute of Oncology of Coimbra FG, EPE, Coimbra, Portugal; [2]Endocrinoloy, Diabetes and Metabolism Department, Centro Hospitalar e Universitário de Coimbra, EPE, Coimbra, Portugal; [3]Faculty of Medicine, Coimbra University, Coimbra, Portugal.

Introduction
Pituitary apoplexy (PA) is an endocrine emergency and usually presents with sudden headache and visual fields changes. Pituitary function assessment should be performed promptly and repeated throughout follow-up, regardless of the choice of treatment.
Methods/design
Retrospective analysis of patients diagnosed with PA admitted to an Endocrinoloy Department of a tertiary hospital between 2002 and 2017. Review of patients' medical records and assessement the following parameters: clinical evaluation, imaging, pituitary deficiencies and treatment at the time of the episode, two months later and by the last evaluation.
Results
We evaluated 17 patients (65% were male), mean age 55 ± 18 years, mean follow-up time 3 years. Four patients had personal history of pituitary adenoma, two of which were non-functioning and two, ACTH-secreting. Hypertension and antiplatelet therapy were the most frequently identified risk factors. Clinical presentation included sudden headache in all patients, decreased visual acuity (38%), visual field deficit (35%) and ophthalmoparesis (43%). A pituitary adenoma was identified in 11 of the 13 patients without known pituitary disease (median diameter: 25 mm). At the time of the apoplexy, hypogonadism was detected in 11/14 patients, hypothyroidism in 9/16, adrenal insufficiency in 5/13 and growth hormone deficiency in 6/13. Twelve patients underwent surgical treatment. Histological analysis revealed gonadotroph adenoma in 4 patients, corticotroph in 2, somatotroph in 2, lactotroph in 1, null cell in 1 and necrotic findings in 2. At the time of hospital discharge, 13 patients were receiving hydrocortisone and 7 levothyroxine. Most of the operated patients had persistence of disease on imaging test after 3–6 months (7/11). At the time of the last evaluation, most patients had insufficiency of two or more pituitary axes. The most common deficits were adrenal (11/16) and gonadal (10/16). There was recovery of ophthalmologic impairment in most operated patients who initially presented with ophtalmoparesis/visual field deficits (6/7).
Conclusion
In this study, surgical treatment was the preferred therapeutic option, which allowed for recovery of visual impairment, despite little recovery of pituitary insufficiency. Patients submitted to conservative treatment had a favourable outcome. Despite being an endocrine emergency, pituitary apoplexy can have a favourable outcome if correctly identified and treated.

Clinical and treatment outcomes in patients with craniopharyngiomas – single center experience

Tanja Skoric Polovina[1], Mirsala Solak[1], Ivana Kraljevic[1], Tina Dusek[1,2], Nemanja Spanovic[3], Anne-Marie Balasko[1] & Darko Kastelan[1,2]
[1]Department of Endocrinology, University Hospital Center Zagreb, Zagreb, Croatia; [2]School of Medicine University of Zagreb, Zagreb, Croatia; [3]Department of Internal Medicine, General Hospital Nova Gradiska, Nova Gradiska, Croatia.

Craniopharyngiomas are rare and histologically benign tumors that are associated with an unfavourable prognosis and controversial optimal treatment. The aim of this retrospective study was to review clinical presentation, natural history and therapeutic outcomes of patients with craniopharyngiomas treated in a single center between 1995 and 2017. In that period, 38 patients (16 children and 22 adults) were diagnosed with craniopharyngioma. Median age at the time of diagnosis in children and adults was 12.5 years (range 6–17) and 40 years (range 19–66), respectively. The most frequent presenting feature was visual field defect in adult patients and headache with intracranial hypertension in children (75% and 69%, respectively). In 16 adults and in 10 children hypothalamic invasion was present on initial MRI, whereas optic chiasm impingement was found in 20 adults and 11 children. Fifteen patients underwent gross total resection of the tumor, 13 patients had partial resection of the tumor combined with radiotherapy (RT), 4 patients had two partial resections together with RT, while 6 patients had partial resection of the tumor and are awaiting further treatment. During a follow-up period of 56.5 months (range 3–264) 10 out of 15 patients had tumor relapse after gross total resection, while 7 out of 17 patients had progression of residual tumor after the partial resection(s) combined with RT. There was no difference in recurrence/progression rate with regard to therapeutic approach (gross total resection vs. partial resection with RT). Median time to recurrence/progression was 36 months (range 8–156). There was no difference in time to recurrence/progression between patients who underwent gross total resection and those with residual tumor. Hypopituitarism and diabetes insipidus (DI) were found significantly more often after the treatment in all patients ($P < 0.001$), while body mass index (BMI) significantly increased one year after the treatment (22.4 kg/m^2 (15.3–26.1) vs 28.1 kg/m^2; $P < 0.001$). There were no statistically significant differences in the incidence of hypopituitarism, DI and obesity regarding therapeutic approach. Our results showed no differences in progression-free survival and the incidence of hypopituitarism, DI and obesity between gross total resection and partial resection with RT.

Very high prolactin levels associated to domperidone therapy

Lucio Vilar[1,2] & Clarice Vilar[2]
[1]Division of Endocrinology, Hospital das Clinicas, Federal University of Pernambuco, Recife, Brazil; [2]Pernambuco Endocrine Research Center, Recife, Brazil.

Introduction
Prolactin (PRL) levels $>$ 250 ng/ml are highly suggestive of prolactinomas though they may be also seen in other conditions, particularly macroprolactinemia, GH and PRL cosecreting tumors, and renal failure. Drug-induced hyperprolactinemia is typically associated with mild PRL elevation (usually $<$100 ng/ml). Higher levels (around 300 ng/ml) have been occasionally reported, particularly with risperidone, an atypical antipsychotic drug.
Case report
A 25 year old asymptomatic women was referred to the endocrinologist with the diagnosis of a microprolactinoma. In a routine lab evaluation, PRL levels of 720 ng/ml (15120 mIU/l) e 690 ng/ml (14490 mIU/l) were found (normal range, 2.8–29.2 ng/ml [59–613 mIU/l]). A 0.5 cm pituitary lesion was subsequently shown on a MRI scan. Macroprolactin screening was negative. Thyroid and renal functions were normal. The physical examination do not identify noteworthy findings. The patient has been treated with a combined oral contraceptive pill for 24 months and with domperidone (a prokinetic drug) over the past 3 months (in the treatment of functional dyspepsia). Two months after domperidone withdrawal, PRL levels dropped to 18 ng/ml (328 mIU/l).
Conclusion
This case shows that domperidone should be included in the list of drugs that may be associated with very high PRL levels. The lesion depicted on MRI scan was a nonfunctional pituitary microadenoma.

Acromegaly: surgical results and predictors for remission

Ana Amado[1], Gonçalo Figueiredo[2], Isabel Ribeiro[2], Cláudia Amaral[1], Fátima Borges[1] & Helena Cardoso[1]
[1]Endocrinology Department, Centro Hospitalar do Porto, Porto, Portugal; [2]Neurosurgery Department, Centro Hospitalar do Porto, Porto, Portugal.

Introduction
Acromegaly is a rare disease with significant morbidity and mortality. Surgical treatment is the first line treatment for these patients, with remission rates of $>$85% for microadenomas and 40–50% for macroadenomas.

Objectives
Our objective was to characterize patients with acromegaly followed in our department and evaluate remission status after surgery. We also aimed to determine remission related factors.
Methods
A retrospective study was performed. Patients diagnosed with acromegaly in the last 12 years and submitted to surgery were included. The following data was collected: age at diagnosis, gender, follow-up period, growth hormone (GH) and insulin-like growth factor 1 (IGF-1) values before and 3–6 months after surgery, adenoma size and invasion of the cavernous sinus, therapeutic strategies and response to therapy.
Results
We included 41 patients. 53.7% ($n=22$) were female. Mean age at diagnosis was 47.8 years (S.D. = 11.9). Mean follow-up was 6 years (S.D. = 3.3). Diagnosis was based on phenotypic alterations in the majority of patients (51.2%, $n=21$). At diagnosis GH value ranged from 0.4 to 80.2 ng/ml (median 11.9) and IGF-1 value ranged from 288 to 1610 ng/ml (median 646). The majority of patients had a macroadenoma (78%, $n=32$); 36,6% ($n=15$) had invasion of the cavernous sinus. After surgery, median levels of GH and IGF-1 were 1.9 (min. 0.05, max 37.4) and 333.5 (min. 33.5, max. 1130) respectively. 12.2% ($n=5$) were submitted to a second surgery and 7.3% ($n=3$) to radiotherapy. 56.1% ($n=23$) of the patients were treated with medical therapy after the surgery. During follow-up 1 patient was lost and two patients died. Of the remaining patients 44.7% ($n=17$) had remission criteria, 31.6% ($n=12$) had controlled disease under medication and 23.7% ($n=9$) had active disease. Remission status was significantly correlated with GH value before and after surgery ($P=0.016$ and $P=0.004$ respectively) and IGF-1 value after surgery ($P<0.001$). Invasion of the cavernous sinus was also associated with lower remission frequency ($P=0.004$).
Conclusion
Remission status after surgery for acromegaly was similar to that described in the literature. The main features correlated with remission were GH value before and after surgery, IGF-1 value after surgery and invasion of the cavernous sinus.

Investigation and initial management of hyponatraemia
Melina Kostoula, Vassiliki Bravis, Rozana Ramli, Edson Nogueira, Radhika Dua & Anna Daunt
St Mary's Hospital Imperial NHS Trust, London, UK.

Hyponatraemia is the commonest electrolyte disturbance in clinical practice and accounts for 15–20% of emergency admissions to hospital. It is thought that up to 30% of hospitalized patients develop a degree of hyponatraemia at some point during their admission. It is therefore an important problem. Management of inpatients with hyponatraemia remains problematic and an audit of our practice at St Mary's Hospital, Imperial College Healthcare NHS Trust, has confirmed that. The audit was conducted on the management of severe hyponatraemia (defined as serum sodium level 125 mmol/l) in medical and surgical adult inpatients over a 3-month period, between October 2012 and December 2012. The audit findings indicated the need for further education and training with regards to the management of hyponatraemia within the general medical and surgical specialties, as well as the need for the introduction of a guidance which includes helpful steps in the accurate assessment and initial treatment of patients with hyponatraemia. Our Endocrine team created a protocol that describes the early identification of hyponatraemia and management strategies, especially when it is severe. The guidance indicates that all patients with severe hyponatraemia should have their volume status established and documented clearly, appropriate biochemical assessment in the form of paired plasma and urine osmolalities and urinary sodium measurements and endocrine specialist input in some form, as inpatients, as well as a definitive diagnosis for the hyponatraemia prior to discharge. The guidance relates to all junior and senior medical staff that cares for adult inpatients. Dedicated training was provided to medical staff to familiarize themselves with the protocol. Following its implementation, we decided to audit the adherence to this guidance. The study included all adult medical and surgical inpatients at St. Mary's Hospital with sodium level equal to or less than 125 mmol/l during the period 1–31 March 2016. The results demonstrated that the patients' volume status was clearly established in 51% cases, osmolalities and urinary sodium were measured in 21% cases, endocrine review was performed in 13% cases and definitive diagnosis for the hyponatraemia was made in 60% cases. In the majority of cases the hyponatraemia was treated successfully. It is possible that following the implementation of the Hyponatraemia Guideline the non-endocrine teams feel more confident in managing the above electrolyte abnormality without seeking specialist advice. We plan to continue the training of our staff and re-audit in spring 2019.

Lanreotide autogel may be an effective approach for acromegalic patients who failed octreotide lar
Lucio Vilar[1], Clarice Vilar[2], Luciano Albuquerque[1], Erik Trovao[1], Ana Carolina Thé[1], Icaro Sampaio[1], Liana Ferreira[1], Izabela Cardoso[1], Thaise Borges[1], Priscila Aroucha[1], Patricia Gadelha[1] & Ruy Lyra[1]
[1]Division of Endocrinology, Hospital das Clinicas, Federal University of Pernambuco, Recife, Brazil; [2]Pernambuco Endocrine Research Center, Recife, Brazil.

Background
Growth hormone secreting pituitary gland adenomas specifically express somatostatin (SST)-2 and SST5 receptors. First-generation somatostatin analogs (octreotide and lanreotide) are the mainstay in the medical treatment of acromegaly, however the percentage of patients controlled with these drugs significantly varies in the different studies (20–70%). Many factors are involved in the resistance to SRL somatostatin analogs such as sst, AIP, E-cadherin, ZAC1, filamin A and β-arrestin expression in the somatotropinomas. With a higher affinity for the SST2 receptors and low affinity for the SST-5 ones, octreotide and lanreotide are thought to have a similar efficacy in normalizing IGF-1 and GH levels. However, their exact dose equivalence is not yet fully established.
Objective
To evaluate the effectiveness of Lanreotide autogel (LAN) 120 mg monthly in normalizing GH and IGF-1 levels in acromegalic patients who failed octreotide LAR (OCT-LAR) 30 mg monthly concerning hormonal normalization. These doses have usually been considered the maximal doses of these agents.
Subjects and methods
Twenty four patients (14 men and 10 women; mean age 42.3 ± 10.2 years [range, 25–62 years]) who do not reach normalization of IGF-1 levels while taking OCT-LAR 30 mg every 4 weeks intramuscularly were enrolled. These patients have been previously treated with OCT-LAR only ($n=15$) or OCT-LAR combined with cabergoline ($n=9$). They were given subcutaneous injections of LAN 120 mg every 4 weeks instead of OCT-LAR. The clinical and biochemical responses of patients were evaluated 3 months later.
Results
After 3 months of LAN treatment, normalization of IGF-1 levels and GH levels < 1 ng/ml were observed in 6 patients (25%). The response rate did not differ in patients previously submitted to OCT-LAR monotherapy or those receiving combined therapy. The LAN tolerability profile was similar to that of OCT-LAR.
Conclusion
Our results indicate that monthly injections of 120 mg of Lanreotide autogel may be an effectivel approach for one quarter of acromegalic patients partially responsive to 30 mg of OCT-LAR monthly.

Are there specific biomarkers able to differentiate non classical congenital adrenal hyperplasia (NCAH) due to 21-hydroxylase deficiency from non-NCAH in a population of naive hyperandrogenic women in the reproductive age?

Claudia Oriolo[1], Soara Menabò[2], Lilia Baldazzi[2], Silvia Castelli[1], Uberto Pagotto[1], Marco Mezzullo[1], Flaminia Fanelli[1] & Alessandra Gambineri[1]

[1]Endocrinology Unit, Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy; [2]Pediatric Endocrinology Unit, Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy.

Objective

This study was aimed to evaluate the prevalence of non classical congenital adrenal hyperplasia due to 21-hydroxylase deficiency (21-NCAH) in hyperandrogenic women in the reproductive age attending our Endocrinology Unit and to identify specific phenotypic traits among clinical, biochemical and hormonal features.

Setting

Outpatient Unit of Endocrinology, S. Orsola-Malpighi University Hospital of Bologna, Italy.

Patients and methods

Among a population of 1079 women who attended our Unit from 2003 to 2017 for hyperandrogenic complaints, we selected 70 subjects having basal 17 hydroxyprogesterone (17OHP) levels in the follicular phase of the menstrual cycle $\geq$200 ng/dl measured by immunoassay. All these 70 patients performed CYP21A2 gene analysis by direct DNA sequencing and multiplex ligation-dependent probe amplification (MLPA). They also performed an ovarian ultrasonography, a 1-24ACTH test, a complete basal steroid profiling measured both by immunoassay and by liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS), all in the follicular phase of the menstrual cycle.

Results

Twenty-three patients resulted affected by 21-NCAH, 15 were found to be heterozygotes for the 21-hydroxylase deficiency (21-HTZ) and 32 had no mutations for CYP21A2gene(C). As expected, these three groups resulted significantly different for basal 17OHP levels measured by immunoassay even though there was an overlap among them [21-NCAH:1971$\pm$2550 ng/dl (from 228 to 12,420); 21 HTZ: 287$\pm$85 ng/dl (from 196 to 452); C: 305$\pm$100 ng/dl (from 201 to 624)]. At variance, basal 17OHP measured by LC-MS/MS discriminated the 21-NCAH group from the others without any overlap [21-NCAH: 16.9$\pm$23.1 ng/ml (from 3.5 to 51.5); 21 HTZ: 1.7$\pm$0.9 ng/ml (from1.1 to 2.9); C: 1.4$\pm$0.3 ng/ml (from 1.1 to 1.8)]. Furthermore, in 21-NCAH patients 21-deoxycortisol levels were found significantly higher than in the other groups (0.58$\pm$0.32 ng/ml vs. 0.14$\pm$0.08 ng/ml in 21 HTZ and 0.11$\pm$0.06 ng/ml in C, $P<0.05$). In addition, cortisol and corticosterone measured by LC-MS/MS were significantly lower in 21-NCAH group (cortisol: 61.6$\pm$46.9 ng/ml; corticosterone 1.1$\pm$0.9 ng/ml) than in 21-HTZ (cortisol: 182$\pm$27 ng/ml; corticosterone: 12.1$\pm$9.7 ng/ml) and C (cortisol: 169$\pm$26 ng/ml; corticosterone 14.4$\pm$5.2 ng/ml) groups.

Conclusion

This study confirms that the prevalence of 21-NCAH of new diagnosis among hyperandrogenic women in the reproductive age is high accounting for 2.2%. In addition, it demonstrates that a basal blood steroid profiling measured by LC-MS/MS in the follicular phase of the menstrual cycle and composed by 17OHP, 21-deoxycortisol, cortisol and corticosterone is a valid diagnostic tool in 21-NCAH patients.

Bone mineral density in oligomenorrhoeic women with polycystic ovary syndrome

Dusan Ilic[1], Ivana Bozic-Antic[1], Tamara Bogavac[1], Jelica Bjekic-Macut[2], Danijela Vojnovic-Milutinovic[3], Olivera Stanojlovic[4], Bojana Popovic[1], Tatjana Isailovic[1], Valentina Elezovic-Kovacevic[1], Sanja Ognjanovic[1] & Djuro Macut[1]

[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinial Center of Serbia, Belgrade, Serbia; [2]CHC Bezanijska kosa, Belgrade, Serbia; [3]IBISS, University of Belgrade, Belgrade, Serbia; [4]Institute of Physiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction

Oligomenorrhoea have negative impact on bone mineral density (BMD). The aim of this study was to analyze BMD in oligomenorrhoeic women with polycystic ovary syndrome (PCOS), and healthy controls with regular menstrual cycles.

Methods

We analyzed 29 women with PCOS diagnosed using ESHRE/ASRM criteria (age: 23.6$\pm$4.7 years, BMI: 24.9$\pm$6.1 kg/m^2) and 22 healthy BMI-matched controls (HC) (age 31.6$\pm$6.3 years, BMI 24.9$\pm$6.1 kg/m^2). In follicular phase of menstrual cycle we determined BMD by osteodensitometry, fasting serum glucose (FG), insulin, lipids, calcium, phosphate, albumin, PTH, testosterone, SHBG, DHEAS, 17OH-progesterone, androstenedione, estradiol, TSH, fT4, fT3. HOMA, FAI and corrected calcium were calculated. Differences between groups were age-adjusted.

Results

There was no difference between groups in BMD measurements on L1-L4, total and neck femur. PCOS had higher testosterone (2.4$\pm$0.8 vs. 1.4$\pm$0.5 nmol/l, $P=0.002$), androstenedione (3.2$\pm$1.1 vs. 1.9$\pm$0.4 ng/ml), corrected calcium (2.2$\pm$0.9 vs. 2.1$\pm$0.9 mmol, $P=0.011$). There were no between-groups differences in other measurements. PCOS women showed significant correlation between L1-L4 BMD and LH ($r=0.49$, $P=0.04$), L1-L4 BMD and DHEAS ($r=-0.68$, $P=0.001$), total femur BMD and TSH ($r=-0.56$, $P=0.012$), and total femur BMD and PTH ($r=-0.65$, $P=0.022$).

Conclusions

Oligomenorrhoeic women with PCOS did not differ in BMD to the BMI matched healthy controls.

Effect of mifepristone on viability of cells of HECa10 line evaluated in real time depends on the duration of exposure and density of cells and allows choosing the proper time point to apoptosis assessment

Agata Niedziela & Gabriela Melen-Mucha

Department of Immunoendocrinology, Medical University in Lodz, Lodz, Poland.

Apoptosis is an important process influencing tissues growth, however the assessment of this process in monolayer culture is difficult because apoptotic cells disappear quickly due to secondary necrosis. Most of the methods used with success in vivo is useless in vitro. Our approach to evaluating apoptosis *in vitro* is based on the possibility to perform multiple assays on the same sample well. The aim of the study was to evaluate the effect of mifepristone (RU-486), a strong competitive antagonist of progesterone and glucocorticoid receptors, used at the previously selected concentration of 2×10^{-5}M on viability of cells of the HECa10 high endothelial line assessed in real time and on apoptotic intensity assessed in cultures carried out with different numbers of sown cells: 1000, 2000, 4000 and 8000 cells/well in a 96-well plate. Two compatible assays were used: luminescence method for assessment of cell viability in real time and fluorescence method for apoptosis detection based on activities of caspase-3 and 7 (Promega Corporation). It was shown that the longer the exposure time to mifepristone and the higher the cell density in the wells, the inhibitory effect of mifepristone on viability of cells is earlier and stronger (observed already after 2 hours for 8000 cells/well, after 4 hours for 4000 cells, and only after 24 hours for 1000 and 2000 cells/well). The inhibitory effect of mifepristone grew with the duration of the culture what allowed to choose the right time point for the assessment of the apoptosis intensity. After 26 hours mifepristone caused an increase in apoptosis e.g. by 19% for 8000 cells and by 15% for 1000 cells/well. At that time point mifepristone inhibited cell viability e.g. by 40% for 8000 cells and by 20% for 1000 cells/well. Tracing the viability of cells in controls found out that the luminescence signal remains linear for 1000 and 2000 cells/well over the 3 day period, whereas the signal from higher cell number (4000 and 8000 cells/well) lose linearity after 48 hours. Mifepristone, a drug commonly used as medical abortion, evokes strong antiangiogenic effect on HECa10 line via inhibition of cells viability and induction of apoptosis.Tracing the viability of cells in cultures in real time allows to choose the optimal time to complete the culture and to determine the apoptosis intensity under the influence of mifepristone.

An analysis of the cardiovasular risk factor profiles of patients with turner syndrome

Aoife Christine Newman & Sio McQuaid
Mater Misericordiae University Hospital, Dublin, Ireland.

Turner Syndrome (TS) is a genetic disorder which affects 0.5–1 in every 2000 females. It is a multi-systemic disease characterised by a deleted or partially missing X chromosome. This deletion results in a higher incidence of primary ovarian failure and removal of the cardio-protective presence of endogenous oestrogen. The aim of this study was to analyse the prevalence of cardiovascular risk factors in a TS cohort and to assess the steps taken to modify these risk factors. We retrospectively analysed the charts of 54 TS patients attending a university hospital endocrinology clinic. Data was collected on blood pressure (BP), lipid and Haemoglobin A1c profiles, statin and hormone replacement therapy (HRT) use, Body Mass Index (BMI), and the presence of structural heart disease. Data is expressed as mean $\pm$S.D. We aimed to assess the number of patients who reached targets of blood pressure (BP) less than 140/90 mmHg; BMI <25 kg/m^2 and Low density lipoprotein (LDL) less than 2.6 mmol/l. Fifty four patients with mean age of 35.1 ± 12.6 years had BMI of 28.54 ± 8.11 kg/m^2; 19 patients had a BMI within target. Mean BP was $121.6 \pm 13.3/73.7 \pm 10.5$ mmHg. Twelve patients were on anti-hypertensive agents (eight patients were on single agent treatment and four were taking two agents). Mean BP of those not on anti-hypertensive therapy was $117.3 \pm 12.2/72.2 \pm 10.5$ mmHg. Seven patients did not have blood pressure within target. Mean LDL level was 2.95 ± 1.31 mmol/l with mean total cholesterol of 5.11 ± 2.62 mmol/l. Only 12 out of 54 (22%) of patients achieved their LDL targets. Seven patients were on therapy while a further four declined therapy. Mean LDL of those on therapy (6 on statin therapies; one on ezetimibe) was 3.4 ± 0.6 mmol/l. One patient on statin therapy achieved the target LDL. Mean HbA1c for the cohort was 34 ± 3.6 mmol/mol. Four patients had impaired glucose tolerance (IGT). Three patients had confirmed type 2 Diabetes Mellitus (T2DM) with mean HbA1c of 54.0 ± 9.9 mmol/mol. Fourteen patients were not taking hormone replacement therapy; six patients were post-menopausal, three patients desired pregnancy, three patients had spontaneous menstruation, one patient declined therapy and one patient had severe liver disease. In summary, while the majority of patients in our cohort have a blood pressure within our recommended targets a significant number are above both their BMI and LDL targets. Further efforts will be concentrated on improving these metabolic goals.

A testicular mass in a patient with Klinefelter syndrome

Aoife Christine Newman & Siobhan McQuaid
Mater Misericordiae University Hospital, Dublin, Ireland.

A 35 year old gentleman with a history of 47 XXY Klinefelter Syndrome (KS) and previous orchidopexy presented to the endocrine service with a two-week history of left sided testicular pain. Examination revealed a tender left testicle. Testicular ultra-sound confirmed bilateral atrophic testes and a 5 mm hypoechoic lesion in the left upper pole. This patient presented with KS at the age of 15 years with gynaecomastia and elevated gonadotrophins. After urgent urological review a left radical inguinal orchidectomy was performed. Histology revealed a sex cord-stromal tumour, 20 mm in maximum measurement. The major pattern was multifocal Leydig cell tumour with additional glandular ductal components. There was no normal testicular histology and no evidence of malignancy. The patient remains clinically well six months post-operatively.

Discussion

KS is the most common sex chromosomal disorder in males, caused by the inheritance of at least one additional $\times$ chromosomes from either parent. Its prevalence is 1 in 660. Discovered in 1942 by Harry Klinefelter, it is characterised by gynaecomastia, aspermatogenesis and elevated gonadotrophins. Sex cord stromal tumours (SCST) are rare, accounting for only 5% of all testicular tumours in general populations. These tumours occur most commonly between 40 and 50 years of age and rarely metastasise. Patients who develop metastasis have an estimated prognosis of two years. Leydig cell tumours are the most common type of SCST. Approximately 30% present with virilising or feminising symptoms due to excess androgens or oestrogens. Two large epidemiological studies (Swederlow *et al*. 2005 and the Danish Cytogenic Registry), have demonstrated that KS is not associated with an increased risk of testicular tumours. Despite a 37% prevalence of crypto-orchidism, few testicular cancer cases are seen. These same studies confirmed the greatly elevated risk of lymphoma and breast cancer iin KS patients. Mediastinal germ cell tumours are also observed in KS patients despite being extremely rare in the general population. Two theories exist to explain the discrepancy between the perceived and the actual risk of testicular cancer in this group. One possible explanation is an unknown immunological process which has a net protective effect against testicular cancer. The second hypothesis postulates that patients with undiagnosed KS present with testicular cancer, however the diagnosis of KS is missed due to phenotypical variability and under-recognition. This case highlights the phenotypic variability and complexity of KS. In summary, greater awareness of KS, its potential complications and various manifestations, is needed to optimise patient outcomes.

Postmenopausal virilization with negative imaging

María Molina Vega, Isabel Mancha Doblas, Isabel Cornejo Pareja, Araceli Muñoz Garach, Silvia Maraver Selfa & Francisco Tinahones Madueño
Virgen de la Victoria Hospital, Málaga, Spain.

Introduction

After menopause, an abrupt drop in estrogen levels happens, while ovary androgens secretion declines gradually with aging. This relative hyperandrogenism may lead to the development of hyperandrogenic symptoms. However, the development of marked hirsutism and/or symptoms/signs of virilization, make necessary a detailed study in order to rule out tumorous cause (from adrenal glands or ovaries).

Case report

58 years old woman with progressive appearance of abundant terminal hairs in face, decrease in scalp hair and deepening of the voice during the last 5 years, worse in the last year. Medical history: smoker, no treatments. Menarche at age 13, regular periods. 4 pregnancies, 1 abortion. Hysterectomy at age 43 due to uterine fibroids. Physical examination: BMI 24.9 kg/m^2, blood pressure 140/80 mmHg; severe hirsutism (Ferriman-Gallwey scale: 32), male type balding, clitoromegaly and centripetal fat distribution without other signs of hypercortisolism. Laboratory evaluation: hematocrit 48.5%, TSH 2.7 μUI/ml (0.35–3.7), FSH 64 μUI/ml (>30), LH 22 μUI/ml (>14), prolactin 5.5 ng/ml (<25), estradiol 26 pg/ml (0–32.2), progesterone 0.7 ng/ml (<1), 17-hydroxy-progesterone 0.89 ng/ml (0.23–1.36), DHEA-S 57.9 μg/dl (80–560), androstenedione 0.83 ng/ml (0.6–3.5), testosterone 6.54 ng/ml (0.14–0.76), serum cortisol levels (after 1 mg overnight dexamethasone) 1.07 μg/dl (<1.8). With these findings, we suspected tumorous cause. However, abdominal MRI, adrenal CT scan, and gynecologic ultrasonography did not show any tumor. After excluding adrenal gland mass, due to the high levels of testosterone, the most reasonable diagnosis was an ovarian tumor eluding detection with imaging so, given the difficulty of performing an ovarian and adrenal venous sampling, Decapeptyl (a GnRH analogue) was prescribed to the patient. GnRH analogues have been shown to normalize testosterone levels in patients with ovarian hyperandrogenism. After Decapeptyl therapy, testosterone levels become normal (testosterone 0.14 ng/ml, FSH 9.33 μUI/ml, LH <0.07 μUI/ml) and we observe an evident clinical improvement, supporting ovarian origin. Therefore, oophorectomy was performed. Histopathology: 4 mm primitive rests in the hilus of right ovary, expecting determination of androgen receptor. Current laboratory evaluation: testosterone 0.16 ng/m, FSH 57 μUI/ml, LH 41 μUI/ml.

Conclusion

Despite it is usual to find hyperandrogenic symptoms after menopause, the development of severe hyperandrogenism or virilization should makes us rule out an organic cause, including tumoral origin. If imaging is inconclusive, GnRH

analogues would be an effective treatment for ovarian virilization in postmenopausal women.

Hypergonadotropic hypogonadism secondary to vanishing testes syndrome newly diagnosed in a 42-year-old male patient

Francisco Sousa Santos, Ricardo Capitão, Cátia Ferrinho, Clara Cunha, Clotilde Limbert & Carlos Vasconcelos
Endocrinology Department, Hospital Egas Moniz, Lisbon, Portugal.

Introduction
Cryptorchidism is the most common abnormality of male sexual development. Approximately 5% of cases of cryptorchidism are associated with vanishing testes syndrome. This rare condition occurs when an initially normal testicle that existed in fetal life subsequently atrophies. Affected patients usually have normal male external genitalia and hypergonadotropic hypogonadism. This disease is usually diagnosed in early childhood allowing for normal sexual development with timely testosterone therapy. Here we report the highly unusual case of a 42-year-old male patient with an early onset hypergonadotropic hypogonadism left undiagnosed and untreated for 4 decades, most probably secondary to vanishing testes syndrome.
Case report
Forty-two-year-old african male referred to Endocrinology outpatient clinic due to suspected hypogonadism. Phenotypical features included gynoid body fat distribution, gynecomastia, absent facial and truncal hair, micropenis and no palpable testicles in the scrotum. He denied ever experiencing development of male secondary sex characteristics. His medical/surgical history was unremarkable, to the best of his knowledge. Family history was unknown to the patient. Endocrine testing revealed low testosterone (total testosterone of 46 ng/dl and free testosterone of 1.04 ng/dl), elevated gonadotrophins (FSH 27.7 U/l and LH 15.7 U/L), AMH <0.01 µg/l and a normal thyroid and adrenal axis function results. Peripheral blood karyotype was 46, XY. Scrotal ultrasound confirmed cryptorchidism. Pelvic and abdominal echography and MRI did not suggest any ectopic gonadal structures. Skeletal X-Ray and DXA showed no signs of fractures or osteoporosis. The patient was started on monthly testosterone injections with great clinical benefit, namely: increased energy; improved muscular mass; increased penile length; lower voice pitch and development of axillary, facial and pubic hair with male distribution.
Conclusion
This male patient's clinical course, with failure of normal pubertal progression, along with his endocrinological and radiological presentation suggest a case of late diagnosed early childhood onset hypogonadism. The most likely diagnosis is vanishing testes syndrome, although surgical exploration is yet to be performed. The timing of his diagnosis – during the fourth decade of life – makes this case quite unique. Clinicians should be aware of this condition in face of a male hypogonadic patient, even when presenting during adulthood, if the disease course is suggestive of an early life onset.

Gender identity and assignment in a 46XY DSD-case report

Elena-Alexandra Vadana[1], Ioana Maria Lambrescu[1,2], Luminita Cima[2], Mona Zvanca[2,3], Sorina Martin[1,2] & Simona Fica[1,2]
[1]Department of Endocrinology, Elias University Hospital Bucharest, Bucharest, Romania; [2]Department of Endocrinology 'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania; [3]Department of Gynecology, Elias University Hospital, Bucharest, Romania.

Introduction
The term disorder of sexual development (DSD) refers to a congenital condition characterised by a discordance in the development of chromosomal, gonadal and anatomical sex. The inborn errors of metabolism in these disorders due to genetic mutations lead to anomalous genitalia.
Case report
A 16-year-old girl without significant family history was referred to our department for primary amenorrhea. The physical examination revealed: height of 167.5 cm, weight of 68 kg (BMI = 23.8 kg/m^2), Tanner stage 3 for breast development and 5 for pubic hair growth. Inspection of external genitalia showed normal appearance of labia majora with labia minora attached on the ventral side of the clitoris and no visible urethral opening. In addition, the patient had clitoromegaly-microphallus-like appearance and hirsutism. No inguinal masses were palpable. The laboratory findings showed basal plasma cortisol: 19 µg/dl, ACTH: 49.96 pg/ml, androstenedione: 2.65 ng/ml, DHEA-S: 191.9 µg/dl, 17-OH Progesterone: 2.38 ng/ml, FSH: 91.45 mIU/ml, LH: 15.18 mIU/ml, estradiol: 13.6 pg/ml, testosterone: 234.5 ng/dl, dihydrotestosterone: 120 pg/ml, inhibin B: <10 pg/ml, anti-Müellerian hormone: 0.24 ng/ml. The karyotype was performed, revealing a 46 XY male karyotype. An echogenic mass of 28/13 mm on the right inguinal side and the absence of uterus, ovaries and fallopian tubes was identified on abdominal ultrasound. The MRI scan confirmed two masses resembling testes located in both inguinal canals and associating yolk sack, outline of cavernous bodies with no external opening in the pelvic region and on the posterior side of the bladder a seminal vesicle-like mass. After careful expert evaluation performed by a multidisciplinary team, gender assignment decision as female was made, taking into account the patient's wish. In this context, we recommended gonadectomy due to the malignant potential of the abdominal testis-like masses. After surgery, she will receive hormone replacement therapy with estrogens to maintain secondary sexual characteristics.
Conclusions
A comprehensive multidisciplinary team is essential in order to provide the best of care for patient with DSD. Prioritizing patients wish coupled with the specialists' consensus regarding management is probably the best way to treat this medical entity.

DOI: 10.1530/endoabs.56.P896

P897

Type 1 autoimmune polyglandular syndrome – clinical case report

Paulo Carvalho Ferreira[1], Delfina Alvarez[2] & Filipe Mota[1]
[1]Endocrinology Service, Hospital Pedro Hispano, ULS Matosinhos, Matosinhos, Portugal; [2]Hospitais da Luz, Porto, Portugal.

Introduction
Type 1 autoimmune polyglandular syndrome is a rare entity, presenting typically during childhood and comprising a variable combination of autoimmune endocrine and non-endocrine diseases that differ in their immunological features. This phenotypical heterogeneity may difficult the identification of this syndrome.
Clinical case
33 year-old female, presenting with secondary amenorrhoea at the age of 13, and by that date diagnosed with hypergonadotropic hypogonadism (HH) and primary autoimmune hypothyroidism. By the age of 14 she was diagnosed with primary hypoparathyroidism. She has a family history of two maternal cousins presenting with primary hypothyroidism. The height and weight developments were normal. When she was 30 years old she was referred to the adult Endocrinology consultation for follow-up. The patient complained of progressive asthenia during more than one year. Physical examination did not show any relevant findings, namely skin and mucosal hyperpigmentation. The analytical results revealed serum cortisol – 3.7 µg/dl (3.7–19.4), ACTH – 451.7 pg/ml (7.2–63.3), TSH – 3.04 µUI/ml (0.35–4.94), free T4 – 1.42 ng/dl (0.7–1.48), free T3 – 2.34 pg/ml, (1.71–3.71), anti-thyroglobulin antibodies – 6.3 UI/ml (<4.11), anti-TPO antibodies – 14.7 UI/ml (<5.61), ionized calcium – 1.07 nmol/l (1.15–1.35), parathormone – 7.8 pg/ml (15.0–68.3), anti-parietal cell antibodies – positive, vitamine B12 – 328 pg/ml (189–883), creatinine – 1.1 mg/dl (0.6–1.1), urea – 41 mg/dl (15–40) and GFR – 66.20 ml/min/1.73 m^2. OC was temporarily suspended confirming the diagnosis of HH: LH – 39.23 mUI/ml (2.39–74.24),

FSH – 92.22 mUI/ml (3.35–20.82), oestradiol – 19 pg/ml (21–649). The renal echography did not reveal any abnormalities and the bone densitometry showed secondary spinal osteopenia. She is presently medicated with hydrocortisone 15 mg and fludrocortisone 0.05 mg daily due to the primary adrenal insufficiency. She maintains desogestrel 75 µg, L-thyroxine 112 µg, calcium carbonate and initiated calcitriol 25 µg every 12 h.
Conclusions:
Type 1 polyglandular autoimmune syndrome shows not only heterogeneity in respect to the nature of the several possible disease components, but also in regard to their temporal presentation, which in the past was admitted to be more predictable. The positivity to anti-parietal cell antibodies and the decline in the renal function underline the importance of monitoring for the development of pernicious anaemia and tubulointerstitial nephritis.

Triple X and premature ovarian insufficiency – case report

Claudia Matta-Coelho, Mariana Barbosa & Selma B Souto
Endocrinology Department, Hospital de Braga, Braga, Portugal.

Introduction
Triple X syndrome is the most common female chromosomal abnormality, with an estimated incidence of 1/1000 female newborns. Most of the women are phenotypically normal, apart from being taller than average. Possible additional problems are psychiatric disorders, genitourinary malformations, EEG abnormalities, scoliosis and premature ovarian insufficiency.
Case report
46-year-old female, referred to the Endocrinology department due to secondary amenorrhea since 30 years old. Obstetric history of one gestation/one liveborn at 21 years old. Personal history of androgenic alopecia without known aetiology. Irrelevant family history. Medicated with hormonal replacement therapy since last year. Unremarkable physical examination. Height 149 cm, Weight 60 kg. The biochemical study showed an elevated basal Follicle-Stimulating Hormone (FSH) level 43.59 mUI/mL (reference range 2.5–10.2) and Luteinizing Hormone (LH) 23.14 mUI/mL (1.9–12.5) with low estradiol 65.79 pmol/l (71.6–529.2). Further biochemical study was normal, namely sex hormone binding globulin, thyroid function and negative auto-immunity. A transvaginal pelvic ultrasound scan showed no alterations. No osteoporosis or osteopenia verified by DEXA. The karyotype revealed a mosaicism of 47, XXX/46, XX.
Discussion
Genetic defects are proposed to cause premature ovarian insufficiency by increasing atresia of ovarian follicules due to apoptosis or failure of follicle maturation and the decreasing the pool of primordial follicles. We aim to emphasize the need for chromosomal analysis in women with premature ovarian insufficiency leading to primary or secondary amenorrhoea.

A 25 years old male patient with Noonan syndrome and delayed puberty

Pinelopi Thoda, Dimitra Pappa, Anastasia-Konstantina Sakali, Eleni Georgioy, Ioannis Gkountios & Alexandra Bargiota
Department of Endocrinology and Metabolic Diseases, University of Thessaly, Larissa, Greece.

Introduction
Noonan syndrome is a genetic disorder that usually occurs on a sporadic basis (de novo mutuations) or with autosomal dominant inheritance. Patients present with dysmorphic facial features, cardiac disorders and short stature. Delay of puberty can also be noted. We present here an adult case of Noonan syndrome.
Presentation
A 25 years old male presented to our department with low stature, decreased libido and absence of any secondary sexual characteristic. Fifteen years ago, he was diagnosed with Noonan syndrome, but had no further management, because he was lost in follow up. On clinical examination his height was 156 cm and his weight 44 kg (BMI:18 kg/m^2). He had the distinctive facial features of the syndrome (triangle-shaped head, wide forehead, hypertelorism, and low-set posteriorly rotated ears), bilateral cryptorchidism, hypoplastic scrotumn, pennis length 5.5 cm, pubic hair Tanner stage II, and absence of facial hair. Laboratory evaluation revealed: testo:0.025 ng/ml, LH: 8.55 mIU/ml, FSH: 40.31 mIU/ml and normal IGF1 for his age (439 ng/ml). His bone age was delayed (12–13 years old), and had osteoporosis of the lumbar spine (T score: −3.1). Testosterone replacement therapy was initiated in order to promote the development of secondary sexual characteristics and the improvement of his muscle mass, bone density and libido.
Conclusions
In patients with Noonan syndrome delayed puberty should be treated in females after the age of 13 with estradiol or conjugated estrogens, and in males after the age of 14 with testosterone, as early as possible. Treatment with GH is also indicated, especially in patients with certain genetic mutations, starting at the prepubertal period to help patients to achieve an adult height and to promote bone growth.

Evaluation of pubertal development in young with type 1 diabetes mellitus: about 200 patients

Zineb Boulbaroud[1,2], Siham El Aziz[1,2] & Asma Chadli[1,2]
[1]Endocrinology, Diabetology and Metabolic Diseases Department Ibn Rochd University Hospital of Casablanca, Casablanca, Morocco;
[2]Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy-University Hassan II-Casablanca-Morocco, Casablanca, Morocco.

Introduction
Puberty is associated with various hormonal changes which can influence glycemic control in youth with type 1 diabetes mellitus, especially with the increase in growth hormone. Conversely, a poor control of diabetes can lead to delayed puberty.
Objective
To assess pubertal status in young patients with diabetes Type 1 and determineÂ factors that influence pubertal development.

Patients and methods
Analytical retrospective study of 7 years in the period ranging between January 2010 and November 2017, in young with type 1 diabetes aged between 14 and 20 years, collected in Endocrinology-Diabetology departement of the University Hospital of Casablanca. Puberty was compared at the stage expected for chronological age. Weight and size were measured and compared with targets (WHO curves). The listed according puberty Tanner was compared stadium expected for chronological age of puberty according to Tanner listed was compared stadium expected for chronological age of puberty according to Tanner listed was compared to the expected stage for chronological age Statistical analysis performed by the software SPSS.16
Results
During the studied period, 200 patients were studied (57% girls, 43% boys), average age of diabetes discovery was 10 ± 2 years. The mean HbA1c level was 11%. A low socioeconomic level was found in 62% of patients. A pediatric transition was noted in 15% of patients. An intensive insulin regimen was adopted in 115 patients (57%). Delayed puberty was found in 11 boys (13%) and in 4 girls (5.3%). Menarche average age was 12 (9–16) years. Irregular menstruations were found in 21% of girls with secondary amenorrhea reported in a girl. Short stature was found in 9 boys and 16 girls. Underweight was seen in 20% of patients, normal weight in 75% and overweight in 5% of cases. Delayed puberty was correlated to glycemic control ($P < 0.05$), with diabetes duration ($P < 0.02$), rural origin ($P < 0.05$) and to repeated hypoglycemic episodes ($P < 0.02$). No significant association regarding the insulin regimen and micro-angiopathy presence ($P < 0.2$) was found.
Discussion
Metabolic control of diabetes and age at diagnosis are major factors influencing growth and pubertal development in young diabetics. It is therefore essential to ensure close monitoring of young diabetics growth and pubertal development and good glycemic control must be maintained.

Comparison of diabetes mellitus screening methods for women with polycystic ovary syndrome

Gema López Gallardo
Santa Bárbara Hospital, Ciudad Real, Spain.

Objective
To compare screening strategies for type 2 diabetes mellitus (DM) and impaired glucose tolerance (pre-DM) in woman with polycystic ovary syndrome (PCOS).
Design
Prospective study.
Patient(s)
Adult women with PCOS ($n = 62$) according to NIH criteria.
Main outcome measure (s)
Subjects were screened for pre-DM and DM using a 2-hour glucose tolerance test (GTT), hemoglobin A1c (HbA1c), or fasting plasma glucose (FPG) according to ADA guidelines. Screening approaches were compared using Cohen's Kappa (κ) coefficient.
Result(s)
DM and pre-DM were diagnosed by GTT in 3 (4.8%) and 11(17.7%) of subjects, respectively. Screening with FPG and HbA1C failed to identify 100% of DM subjects. GTT and HA1c had only slight agreement ($\kappa = 0.075$)
Conclusion (s)
Women with PCOS should be screened for Pre-DM and DM using GTT. Fasting plasma glucose levels and HA 1c were suboptimal predictors of DM in our cohort.

Correlational evaluation of inflammatory biomarkers in polycystic ovarian disease: a case control study

G Gayathri[1], B Rajesh[1], B Ramesh[1], D Vignesh[1], M Venkateshwara Reddy[1], B Rajkiran Reddy[2], B Chakrapani[3] & PRK Bhargav[4]
[1]VMC, Kurnool, India; [2]SMART Sunshine Hospital, Hyderabad, India; [3]Neuro Hospital, Nizamabad, India; [4]Endocare Hospital, vijayawada, India.

Introduction
Contrary to the high prevalence of polycystic ovarian syndrome (PCOS) amongst reproductive age group women, there is disproportionate uncertainity over its etiopathogenesis. Substantial evidence suggests immunological-inflammatory role in causing this endocrine disorder. In this context, we set out study the role of inflammatory biomarkers in PCOS.
Material and methods
This prospective case-control study was conducted on PCOS patients diagnosed based on Rotterdam criteria). Institutional ethical committee approval was obtained. Exclusion criteria were women with galactorhea, hyperthyroidism, any systemic disease that affects their reproductive physiology, or any medication which interferes with the normal function of the hypothalamic-pituitary-gonadal axis. Serum samples were collected from 150 PCOS women and 150 age matched healthy controls. Interleukin-6 (IL-6), Tumour necrosis factor-alpha (TNF-α) and high sensitive C reactive protein (hsCRP) levels were measured in all serum samples. Statistical analysis was performed by one way ANOVA with Dunnet's test and Pearson correlation tests.
Results
The mean hSCRP levels was higher in 34% of PCOS woman and its level were 7.9 ± 0.05, 9.9 ± 0.04, 9.9 ± 0.6 and 12.3 ± 0.7 among PCOS (normal weight, obese and over weight) and control subjects respectively. 32% of PCOS women showed raised TNF-α levels and its mean were 159.3 ± 21.3, 302.0 ± 28.9, 202.7 ± 42.5 and 120.0 ± 14.7 among the PCOS (normal weight, obese and overweight) and controls respectively. There was no significant difference among the normal as well as the overweight patients (P value > 0.05), while the levels differed significantly between obese PCOS and controls (P value < 0.05). The IL-6 levels were considerably increased in all the PCOS cases, with the highest in over weight PCOS women. The IL 6 levels differed significantly between the groups (P value < 0.05).
Conclusions
This study shows that there is notable association between inflammatory markers – IL-6, TNF-α and hsCRP with obese PCOS. Intermarker correlation shows positive link between hsCRP and IL-6. The biomarkers appears to predict the metabolic dysfunction in asymptomatic women.

Tumor growth of breast cancer was enhanced by fludioxonil, an antifungal agent, via estrogen receptor-dependent pathways

Cho-Won Kim, Ryeo-Eun Go & Kyung-Chul Choi
Laboratory of Biochemistry and Immunology, College of Veterinary Medicine, Chungbuk National University, Cheongju, Republic of Korea.

Previous studies suggest that environmental factors such as high levels of meat consumption, caffeine, cigarette smoking, pesticides, and endocrine disrupting chemicals (EDCs) may enhance the risk of breast cancer. The fludioxonil is an antifungal agent used in agricultural applications and present at measurable amounts in fruits and vegetables. In this study, the effects of fludioxonil on cancer cell viability and migration ability were examined in MCF-7 and T47D breast cancer cell with estrogen receptors and MDA-MB-231 breast cancer cell without estrogen receptors. The MCF-7, T47D and MDA-MB-231 cells were cultured with 0.1% DMSO (control), 17β-estradiol (E_2; 1×10^{-9} M), or fludioxonil (10^{-5}–10^{-8} M). As results, in MTT assay for 9 days, E_2 as a positive control markedly increased MCF-7 and T47D cell viability about 3.5 times and 2.2 times, and fludioxonil (10^{-5} M) also increased cell viability about 1.2 to 1.5 times compared to control. When the respective treatment was co-treated with ICI 182,780, an ER antagonist, MCF-7 and T47D cells viability were reversed to the level of control. However, the cell viability of MDA-MB-231cells was not changed by treatment of fludioxonil and co-treated with ICI 182,780, as did E_2. In the migration assay for 48h, MCF-7 cells and T47D cells were migrated to low chamber from upper chamber via to 0.8 μm pore. And migration of MCF-7 cells and T47D cells by E_2 or fludioxonil were inhibited by co-treatment of ICI 182,780. Although, the cell number of migration in MDA-MB-231 cells by treatment of E_2 or fludioxonil were not had the significance of result compare with 0.1% DMSO including co-treatment of ICI 182,780. These results imply that the fludioxonil may have breast cancer progression effect by increasing cell viability and migration via estrogen receptor dependent pathway. Therefore, we will have to confirm the molecular mechanism for support the change of cell viability and cell migration. And, based on this result, we will identify the mechanism related with estrogen receptor and PI3K/AKT pathway *in vitro* and confirm their effect by using xenografted or orthotopic mouse models in which MCF-7 or T47D cells are subcutaneously injected or are injected into mammary fat pad for 90 days.

Key words: Endocrine disruption; cell cycle gene; cell migration; fludioxonil; breast cancer; estrogen receptor pathway

P905

Treatment with pesticides, fenhexamid and cyprodinil, resulted in an increase of cell cycle- and metastasis-related genes in an estrogen receptor-dependent pathway in cellular and xenografted mouse models with MCF-7 breast cancer cell

Ryeo-Eun Go & Kyung-Chul Choi
Laboratory of Biochemistry and Immunology, College of Veterinary Medicine, Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Fenhexamid (Fen) and cyprodinil (Cyp) are antifungal agents used in agricultural applications. In this study, to examine the effects of two-pesticides on cancer cell viability and metastasis via estrogen receptor pathway, the ER positive-MCF-7 and ER negative-MDA-MB-231 breast cancer cells were used. MCF-7 and MDA-MB-231 were cultured with 0.1% DMSO (control), 17β-estradiol (E_2; 1×10^{-9} M), Fen (10^{-5}–10^{-7} M), Cyp (10^{-5}–10^{-7} M) in the absence or presence of ICI 182,780 (ER antagonist). As results, in MTT assay, two-pesticides increased MCF-7 viability about two times compared to control like E_2 (about 3.5 times). But, when the respective treatment was co-treated with ICI 182,780, MCF-7 cell viability was maintained at the control level. However, MDA-MB-231 cell viability was not affected by E_2 or two-pesticides compared to control. In colony formation assay, MCF-7 cells did form the colony by treatment of E_2 and antifungal agents, but MDA-MB-231 cells did not form. However, E_2 and antifungal agents in the presence of ICI 182,780 did not induce the formation of MCF-7 colony. To examine the morphology change, MCF-7 and MDA-MB-231 cells were incubated on E_2 and two-pesticides in the absence or presence of ICI 182,780. As a result, morphology of MCF-7 cells was changed sharper by E2 and two-pesticides than control or group of co-treated with ICI 182,780. However, morphology of MDA-MB-231 cells by E2 and two-pesticides or co-treatment of ICI 182,780 was the same compared with control. In wound-healing scratch assay, the scratched distance was reduced by MCF-7 cells treated with E2 or two-pesticides compared with control. However, the scratched distance by MCF-7 cells co-treated with ICI 182,780 and MDA-MB-231 cells treated with E_2 or two-pesticides were maintained to the level of control. In migration assay, MCF-7 cells treated with E_2 or two-pesticides migrated more than 5 times compared with control and co-treatment with ICI182,780 inhibited migration of MCF-7 cells. The migration ratio of MDA-MB-231 cells by E2 or two-pesticides was similar to control. These results imply that the two-pesticides may have cancer progression effect by increasing cell viability and migration via ER dependent pathway. Based on this result, we will identify the mechanism related with metastasis of two-pesticides via ER pathway and confirm their effect by using xenografted mouse models in which MCF-7 cells are subcutaneously injected or are injected into mammary fat pad.

Relationship of urinary bisphenol A to metabolic and hormonal profile in PCOS women

Zora Lazurova, Jana Figurova, Beata Hubkova & Ivica Lazurova
Medical Faculty of PJ Safarik University, Kosice, Slovakia.

Objectives
Polycystic ovary syndrome (PCOS) is one of the most common endocrinopathies in women. Its increasing prevalence is probably related to environmental estrogens exposure, such as bisphenol A (BPA). BPA is considered to play an important role in the ethiopathogenesis of PCOS and can be responsible for various clinical symptoms. Aim of the study was to compare the levels of urinary BPA between PCOS women and healthy controls and to assess the relationship of BPA to sexual steroid hormones and metabolic parameters in the PCOS group.
Subjects and methods
Study included 86 Caucasian women with PCOS (age 28.5 + 5.1 years, range 19–43) and 32 controls (age 24.9 + 4.4, range 21–35 years). All subjects were examined for urinary BPA, sex steroid hormones and parameters of glucose and lipid metabolism.
Results
PCOS women had significantly higher BPA than controls (6.1 + 0.786 μg/g creatinine vs 1.65 + 1.2 μg/g creatinine, $P=0.0035$). BPA positively correlated with age ($P=0.01$; $R^2=0.1$), SHBG ($P=0.05$; $R^2=0.07$) and negatively with estrone ($P=0.005$; $R^2=0.12$), DHEAS ($P=0.033$; $R^2=0.18$) and free androgen index (FAI) ($P=0.05$; $R^2=0.08$), respectively. Other steroid hormones (testosterone, free-testosterone, androstenedione, estradiol) and metabolic parametres (BMI, glucose, insuline, HOMA-IR, total cholesterol, LDL, HDL and triacylglycerols) did not show any significant relations. When divided PCOS women into two subgroups according to BPA levels (group with normal BPA and group with elevated BPA, cut off value = 2.14 μg/g creatinine), there was found a significantly higher serum estrone (153.9 + 25.0 pg/ml vs 88.0 + 20.0 pg/ml; $P=0.05$) and FAI (13.23% + 1.7 vs 7.56% + 1.7; $P=0.029$) in the group with normal BPA, and higher SHBG (38.26 + 9.8 nmol/l vs 65.63 + 9.6 nmol/l; $P=0.046$) as well as insulin (10.46 + 1.8 mIU/l vs 15.2 + 1.5 mIU/l; $P=0.05$) in the group with elevated BPA.
Conclusion
We conclude that PCOS patients have higher urinary BPA levels than healthy controls. Increased urinary BPA is related to lower levels of some steroid hormones, such as estrone, DHEAS and FAI, indicating a possible suppressive efect of bisphenols on steroidogenesis.

Cross hormone therapy in transgender individuals: changes in lipid profile and other cardiovascular risk factor

Ma del Carmen Serrano Laguna[1], María Hayón Ponce[1], David Blanquez Martinez[2], Maria Dolores Avilés Pérez[1] & Elena Torres Vela[1]
[1]UGC Endocrinologia y Nutricion, Hospital Universitario San Cecilio, Granada, Spain, [2]Farmacia Hospitalaria, Hospital Universitario San Cecilio, Granada, Spain.

Background
Cross-sex hormone therapy (CHT) is known to lead to alterations in cardiovascular risk factor(CVRF).
Objective
To assess changes in lipid profile and other CVRF in transsexual subjects receiving CHT.
Materials and methods
Retrospective longitudinal study. We evaluated individuals with gender identity disorder following CHT, assisted in the Gender Identity Unit from 2015 to 2017.

Primary endpoint was lipid profile change from baseline at 24 months. Secondary endpoints included change in body mas index(BMI), weight, blood pressure(BP) and glycaemic parameters.Statistical analysis was performed with SPSS Statistics 20.0:t-Student to compare means for paired quantitative data and Chi-square for qualitative variables.
Results
40 transsexuals, 19 male-to-female (MtF: 47.5%) and 21 female-to-male (FtM: 52.5%). Mean age 23.86±11.25 years, mean duration of CHT 24.7±39.9 months.Mean age and mean duration of CHT was similar in both group. In the MtF group,weight and BMI increased significantly, from 72.12±19.04 to 75.17±19.96 kg ($P=0.01$) and from 23.84±5.79 to 25.02±5.85 kg/m^2 ($P=0.02$),respectively, as well as diastolic blood pressure(DBP)(from 71.80±15.59 to 75.60±14.72 mmHg ($P=0.03$)) and triglycerides(TG)(from 102.90±83.69 to 108.81±88.37 mg/dl ($P=0.035$). FtM transsexuals also presented an increase in weight(70.02±11.14 to 72.17±11.17 kg ($P=0.02$) and BMI (from 24.03±4.04 to 25.32±4.11 kg/m^2 ($P=0.035$)).No significant differences in lipid profile and blood pressure were observed in this group.Even though final levels were all within normal range.No significant differences were observed with regard to gender (MtF vs. FtM).
CONCLUSION
MtF transsexuals experienced alterations in weight, serum lipid profile and diastolic BP because of CHT while FtM only experience changes in weight and BMI, although final levels were all within normal range. No significant differences were observed with regard to gender (MtF vs. FtM).We suggest that clinicians should monitor glucose and lipid metabolism and blood pressure regularly according to established guidelines.

Patient perspectives on sexuality in hypopituitarism

Ida Björkman[1], Jenny Tiberg Persson[2,3], Eva Jakobsson Ung[1], Ann-Charlotte Olofsson[2,3], Gudmundur Johannsson[2,3] & Lisen Dellenborg[1]
[1]Institute of Health and Care Sciences and Gothenburg Centre for Person-centred Care, University of Gothenburg, Gothenburg, Sweden; [2]Institute of Medicine, Department of Internal Medicine, University of Gothenburg, Gothenburg, Sweden; [3]Department of Endocrinolgy, Sahlgrenska University Hospital, Gothenburg, Sweden.

Aim
The aim of the study was to explore patient perspectives on sexuality in hypopituitarism.
Background
Hypopituitarism usually leads to a complete loss of sex hormones and the condition has a negative impact on sexuality. Previous research has mainly focused on erectile functioning in men and fertility issues in women but little is known about their sexual wellbeing and experiences of hypopituitarism in relation to sexuality.
Design
An interpretative, qualitative methodology inspired by Gadamer's philosophical hermeneutics was carried out.
Methods
Individual interviews were conducted with 19 men and women with hypopituitarism. Data were collected between October 2011 and April 2012.
Findings
Four themes emerged that describe experiences of an altered sexuality in hypopituitarism: Desire, fatigue and lack of initiative, Intimate relationships and love, lust for life and self-perception and a public and private silence surrounding sexuality.
Conclusions
The altered sexuality included sexual functioning as well as wellbeing, which affected both self-perception and intimate relationships. The patient perspective on sexuality in hypopituitarism extends well beyond sexual functioning into issues of sexual wellbeing, intimate relationships, self-perception and cultural, gendered, norms. Nurses can aid patients in adapting to an altered sexuality but current health care practices focusing on sexual functioning and reproduction alone are insufficient.

Testosterone replacement: 'The best practice'

Anna Hawkins, Edel Casey & Khash Nikookam
King George Hospital, Barking, Havering and Redbridge University Hospitals NHS Trust, Ilford, UK.

Testosterone deficiency syndrome (TDS) may well contribute to a number of co-morbidities and multitude of symptoms which may affect one's daily activities adversely. TDS prevalence in UK is 5:1000 and certain groups of patient's are at higher risk of TDS, in particular elderly and patients with diabetes mellitus where 42% are known to have TDS. A retrospective audit was carried out to bench mark our practice in line with a publication of a recommended National/European guidelines of 'A practical guide for the management of men with suspected testosterone deficiency'. We obtained and analysed the medical records of 35 patients who attended our endocrine services over a 6 month period. 31 of them had already been started on testosterone from the year before. Seven patients were excluded due to lack of data availability. The age in our cohort ranged from 31 to 72 years with a mean age being 53 years. Initial testosterone and PSA results ranged between 0.4 and 9.4 nmol/l (normal 8.4–28.7 nmol/l) with mean of 5.9 nmol/l and 0.1 μg/l to 2.1 μg/l (normal 0–3.0 μg/l) with a mean of 0.7 μg/l respectively. We found the time lapse between initial blood results and testosterone initiation were from 1 to 18 months, with a mean of 7 months. The guidelines suggests; prior to testosterone initiation PSA and a rectal examination (PR) should be carried out. Within our patient group only 5/28 (18%) had a PR, 21/28 (75%) had PSA, 16/28 (57%) had ultra sound scan (USS) of prostate and 16/28 (57%) of our patients have had neither a PR nor an USS. 18/28 (64%) of the patients who had been started on testosterone were on Nebido 1g injection, 15 of whom had this administered by their GP, the other 3 by the hospital Endocrine Specialist Nurse (ESN). The 3 ESN treated patients had an USS before commencing treatment. Recommended on-going monitoring of 3–6 monthly intervals in the first year was achieved on 23/25 (92%) of our patients.
Conclusion
We recommend a dedicated andrology service and a shared care pathway with community colleagues to ensure all patients have received the best possible care by means of investigations, treatment and follow up care in line with National/European guidelines.

Resveratrol inhibits DHT-induced metastasis of prostate cancer through interfering with the AR and CXCR4 pathway

Yin-Gi Jang, Kyung-A Hwang & Kyung-Chul Choi
Laboratory of Biochemistry and Immunology, College of Veterinary Medicine, Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Prostate carcinoma is one of the most common malignancies and the second most common cause of cancer-related deaths in men world-wide and is affected by the action of dehydrotestosteron (DHT) via androgen receptor (AR). Resveratrol as a phytochemical in grapes and red wine has diverse effects such as anti-inflammation, anti-oxidant and anti-cancer. CXCR4 as a chemokine receptor has been found to be upregulated in cancer metastasis and has been used as a prognostic marker in various types of cancer, including leukemia, breast cancer, and prostate cancer. In this study, we focused on the role of DHT in the induction of prostate cancer progression by affecting the AR and CXCR4 pathway. Also, we investigated the inhibition effect of resveratrol on DHT - induced prostate cancer metastasis. In cell viability assay, DHT increased the cell viability of LNCaP prostate cancer cell on the other hand, resveratrol and its combination with bicalutamide (BCT) as an AR-antagonist or AMD3100 as a CXCR4 inhibitor significantly reduced the cell viability promoted by DHT. Trans-well migration assay and wound healing assay represented the similar results with cell viability assay. According to the results of tunnel assay, the apoptotic activity was induced by treatment of resveratrol. As results of western blot analysis, the expression of AR, CXCR4, and the downstream genes related with epithelial-mesenchymal transition (EMT) were decreased and the expression of the apoptosis-related genes was increased by treatment of resveratrol and its combination with BCT or AMD3100. This study would suggest that resveratrol and its combination with AR and CXCR4 antagonists can be used in order to suppress the metastatic behaviors of prostate cancer.

Assessment of insulin resistance in polycystic ovary syndrome: HOMA, QUICKI and McAuley indices have only moderate correlation with OGTT-based belfiore index

Krzysztof C Lewandowski[1,2], Justyna Plusajska[1], Ewa Bieniek[1], Wojciech Horzelski[3] & Andrzej Lewinski[1,2]
[1]Department of Endocrinology and Metabolic Diseases, 'Polish Mother' Memorial Research Institute, Lodz, Poland; [2]Department of Endocrinology and Metabolic Diseases, The Medical University of Lodz, Lodz, Poland; [3]Faculty of Mathematics and Computer Science, University of Lodz, Lodz, Poland.

Backgroud
Though insulin resistance (IR) is common in polycystic ovary syndrome (PCOS), there is no agreement as to what surrogate method of assessment of IR is most reliable.
Aim
We compared methods based on measurements of fasting insulin and either fasting glucose (HOMA-IR and QUICKI), or triglycerides (TAG) (McAuley index) with insulin resistance (Belfiore) index (IRI) derived from glucose and insulin during a 75-g oral glucose tolerance test (OGTT).
Subjects and methods
Glucose (G) and insulin (I) were measured during OGTT in 478 patients with PCOS (Rotterdam criteria). IR indices were calculated according to the formulae: HOMA-IR = [G] (mmol/l) × [I] (μU/ml)/22.5, QUICKI = 1/[log(I) + log(G)]; while IRI = 2/[(INSp x GLYp) + 1], where INSp, GLYp = insulinaemic and glycaemic areas during OGTT. McAuley index was calculated as Mffm/I = e [2.63–0.28 ln (I) – 031 ln (TAG)].
Results
There was a significant ($P<0.001$), but modest correlation between IRI and HOMA ($R=0.582$), IRI and QUICKI ($r=-0.580$), and IRI and McAuley index ($r=-0.614$). In contrast, there was an excellent correlation between HOMA-IR and QUICKI ($r=-0.999$, $P<0.001$), and HOMA & McAuley index ($r=-0.849$, $P<0.01$). Concordance between HOMA-IR and IRI was poor for subjects with HOMA-IR or IRI above 75th and 90th percentile i.e. those most insulin resistant. In particular, only 53% (70/132) women with HOMA-IR > 75th percentile had IRI value also above 75th percentile, while only 44% (24/54) of women with HOMA above 90th percentile, also had IRI value above 90th percentile. This discrepancy was even more striking for comparison between IRI and McAuley index, where 121/126 (96%), and 52/53 (98%) women with IRI above 75th, and 90th percentile had the value of McAuley index below 75th and 90th percentiles, respectively.
Conclusions
Significant number of women with PCOS can be classified as being either insulin sensitive, or insulin resistant depending on the method applied, with the greatest discrepancies existing for comparison of between IRI (Belfiore) and McAuley indices. Clinical application of surrogate indices for assessment of IR in PCOS must be therefore viewed with an extreme caution.

Presence of antiphospholipid antibodies is associated with increased failure rates of assisted reproductive techniques: a meta-analysis

Georgios Boutzios[1], Eirini Papadimitriou[1], Alexandros Mathioudakis[2], Panayiotis Vlachoyiannopoulos[1] & George Mastorakos[3]
[1]Department of Pathophysiology, Laiko University Hospital, Medical School, University of Athens, Athens, Greece; [2]Division of Infection, Immunity and Respiratory Medicine, The University of Manchester, Manchester, UK; [3]Endocrine Unit, Aretaieion University Hospital, Medical School, University of Athens, Athens, Greece.

Introduction
The presence of antiphospholipid antibodies is associated pathogenically with thrombotic vascular events and resulting pregnancy complications. Studies support that antiphospholipid antibodies (aPL) impair female fertility by interfering with endometrial decidualization and implantation. This meta-analysis aims to determine the prevalence of aPL in women undergoing assisted reproductive techniques (ART) for in Vitro Fertilization and Embryo Transfer (IVF-ET).
Material and methods
A systematic review of the literature was performed in PubMed regarding observational studies which reported prevalence of aPL among women undergoing ART for IVF-ET and implantation rate was included in their outcome. Studies included women failed to conceive and control women who conceived. A prospectively registered with structured search strategy was employed. The extracted data (patients' and control characteristics and outcomes) were transferred in a standardized form. Risk of bias was assessed by employing Newcastle-Ottawa Score and meta-analysis was performed only if the design of the studies were similar enough for data to be pooled together.
Results
Our systematic review yielded 14 studies, evaluating 3462 women of reproductive age. The prevalence of aPL among women experiencing IVF failure was compared with its prevalence among women who conceived following IVF (4 studies) or with matched women of reproductive age (11 studies). All results consistently showed significantly higher levels of aPL among women experiencing IVF failure. Our results were heterogeneous, due to differences in study designs and inclusion criteria. However, all included studies presented consistent results, supporting our protocol hypothesis.
Conclusion
These results strongly suggest that the presence of antiphospholipid antibodies in women ART for IVF-ET may reduce the rate of the implantation compared to controls and consequently impair the fertilization rate and pregnancy outcome.

Association between anthropometric parameters and lipid and carbohydrate profiles and CRP as inflammation indicator in women with polycystic ovary syndrome

Iwona Zieleń-Zynek[1], Joanna Kowalska[1], Justyna Nowak[1], Karolina Kulik-Kupka[1], Agata Kulpok[2] & Barbara Zubelewicz-Szkodzińska[1,2]
[1]Department of Nutrition-Related Disease Prevention; School of Public Health in Bytom, Medical University of Silesia, Katowice, Bytom, Poland, [2]Department of Endocrinology, Piekary Medical Center, St. Luke's Local Hospital in Piekary Śląskie, Piekary Śląskie, Poland.

Polycystic ovary syndrome is associated with lipid and carbohydrate metabolism disorders, leading to obesity and insulin resistance. The aim of the study was to asses the correlation among anthropometric parameters, metabolic markers (lipid and carbohydrate profiles) and CRP as inflammatory indicator in women with Polycystic Ovary Syndrome. The study consists of 43 women diagnosed with Polycystic Ovary Syndrome based on 2003 Rotterdam criteria. The patients were hospitalized in Endocrinology City Hospital in Piekary in 2016-2017. In order to estimate the anthropometric parameters: BMI, BAI, VAI, WHR and WHtR were used. Concentration of total cholesterol (TC), LDL cholesterol, HDL cholesterol, triglycerides (TGC) also glucose, insulin, HOMA-IR, QUICKI index and CRP were taken from the patients' medical records. CRP > 5 was adopted as the anomalous value. Statistically significant value $P \leq 0{,}05$ was assumed. In the examined group the average BMI (kg/m^2) was 28,0 ± 6,9, BAI 32,7 ± 6,4, VAI 1,7 ± 0,8, WHR 0,8 ± 0,1, WHtR 0,6 ± 0,1. The average concentration of TC (mg/dl) was 184,2 ± 40,2, LDL cholesterol (mg/dl) 99,2 ± 34,9, HDL cholesterol (mg/dl) 64,8 ± 20,6, TGC (mg/dl) 101,2 ± 58,3. The carbohydrate profile consisted of average concentration of glucose (mg/dl) 91,2 ± 13,2, insulin (uU/mL) 13,4 ± 10,9, as well as average values of HOMA-IR index 0,3 ± 0,0 and QUICKI index 3,3 ± 1,0. The average concentration of CRP (mg/l) was 3,4 ± 1,6. HDL cholesterol was statistically lower in patients with higher BMI ($P \leq 0{,}05$, $r=0{,}40$), BAI ($P \leq 0{,}05$ $r=0{,}3$), VAI ($P \leq 0{,}05$, $r=0{,}54$), WHR ($P \leq 0{,}05$, $r=0{,}25$) and WHtR ($P \leq 0{,}05$, $r=0{,}38$). TGC correlated positively ($P \leq 0{,}05$, $r \geq 0{,}16$) with BMI, BAI, VAI, WHR, WHtR. There were not significant correlation observed among TC, LDL cholesterol and studied variables. Fasting glucose and insulin correlated positively ($P \leq 0{,}05$, $r \geq 0{,}23$) with BMI, BAI, VAI, WHR and WHtR. Women with higher value of HOMA-IR index had statistically higher BMI ($P \leq 0{,}05$, $r=0{,}45$), BAI ($P \leq 0{,}05$, $r=0{,}27$), VAI ($P \leq 0.05$, $r=0{,}46$), WHR ($P \leq 0{,}05$, $r=0{,}40$) and WHtR ($P \leq 0{,}05$, $r=0{,}46$). There was negative correlation ($P \leq 0{,}05$, $r \geq 0{,}33$) between anthropometric parameters and the value of QUICKI index. Positive correlation ($P \leq 0{,}05$, $r \geq 0{,}23$) between CRP concentration and BMI, BAI, VAI, WHR and WHtR was observed in the examined group of women. Anthropometric parameters are functional indicators of carbohydrate and lipid metabolism disorders, (except TC and LDL cholesterol concentration) in PCO-S women. High BMI, BAI, VAI, WHR and WHtR might imply an inflammation in the examined group.

The risk of cardiovascular diseases in relation to anthropometric parameters and CRP concentration in a group of women with polycystic ovary syndrome

Iwona Zieleń-Zynek[1], Joanna Kowalska[1], Justyna Nowak[1], Karolina Kulik-Kupka[1], Agata Kulpok[2] & Barbara Zubelewicz-Szkodzińska[1,2]
[1]Department of Nutrition-Related Disease Prevention; School of Public Health in Bytom, Medical University of Silesia, Katowice, Bytom, Poland; [2]Department of Endocrinology, Piekary Medical Center, St. Luke's Local Hospital in Piekary Śląskie, Piekary Śląskie, Poland.

Polycystic Ovary Syndrome increases the risk of cardiovascular diseases. To factors predisposing to cardiovascular diseases belong: hypertension, lipid and carbohydrate profiles, smoking and reduced physical activity. The aim of this study was to determine the association between selected factors predisposing to cardiovascular diseases and anthropometric parameters and CRP concentration in women with Polycystic Ovary Syndrome. The study was conducted amongst 43 women, aged 18-39, diagnosed with Polycystic Ovary Syndrome based on the 2003 Rotterdam criteria. The patients were hospitalized in Endocrinology City Hospital in Piekary in 2016-2017. The selected factors predisposing to cardiovascular diseases (CVD) were: blood pressure different from 135/85mmHg, total cholesterol > 200mg/dl, LDL > 135mg/dl, HDL < 50mg/dl, triglycerides > 150mg/dl, HOMA-IR > 1,5, glucose > 100mg/dl, BMI > 24,9, smoking and reduced or very reduced physical activity and assigned 1 point for every existed factor. Body composition was measured with TANITA BC-420 Analyzer. The results were used to signify the anthropometric indicators (BMI, BAI, VAI, WHR, WHtR). To establish the statistical relationship statistically significant value $P \leq 0.05$ was accepted also to verify the power of correlation between two chosen variables r-Pearsona coefficient was used. Selected factors predisposing to CVD have been recognized in 90.7% of examined women, including at least 4 factors in 22 women. Positive correlation was observed between BAI and predisposing CVD factors ($P \leq 0.05$, $r = 0.35$), as well as between VAI and predisposing CVD factors ($P \leq 0.05$, $r = 0.26$), WHR and predisposing CVD factors ($P \leq 0.05$, $r = 0.38$), also WHtR and predisposing CVD factors ($P \leq 0.05$, $r = 0.46$). Higher numbers of predisposing CVD factors is connected to higher CRP concentration ($P \leq 0.05$, $r = 0.22$). The correlation between predisposing CVD factors and BMI (kg/m^2) was observed ($P \leq 0.05$, $r = 0.45$). Anthropometric parameters as well as CRP concentration are useful tool in determining the risk of cardiovascular diseases in women with Polycystic Ovary Syndrome.

Experience of managing primary hyperaldosteronism (HP) during pregnancy

Natalia Giraldo, Carmen Asensio, María Del Rio, Enric Cayuela & Lluis Vila
Hospital General de l'Hospitalet-Hospital Moises Broggi (Consorci Sanitari Integral), Hospitalet de Llobregat, Spain.

PH during pregnancy is a rare entity with no standardized practice management guidelines available. We report a case of a Latin American 40-year-old patient, with a history of arterial hypertension first diagnosed during her first gestation followed in Ecuador. She presented at 24 weeks' gestation with a fetal demise and high blood pressure, being diagnosed of severe preeclampsia. Cesarean section (CS) was performed. No further control of blood pressure after delivery was reported. Three years after she was referred to our unit at 10 weeks' gestation because of severe hypertension. She was treated with labetalol 600 mg and nifedipine 60mg reporting an optimal arterial blood pressure control until 38 weeks' when a CS was performed. The newborn was a male weighing 2850 g with good perinatal outcome. During her postpartum hospitalization hypertensive peaks and a hypokalemia was observed and treated with valsartan 320 mg and amlodipine 10 mg. PH was diagnosed with a confirmatory test of renin-aldosterone stimulation with furosemide-standing. An adrenal computed tomography (CT), demonstrated a left adrenal node, 20 mm in diameter. Catheterization was not required and treatment with spironolactone 100 mg/daily was started with an optimal control. Adrenalectomy was recommended but it was postponed since she became pregnant again. We visited her at 6 weeks' gestation. We decided to continue treatment with spironolactone at high doses (100 mg/daily) with the consent of the patient until week 20 and reduced the dose to 50 mg/daily due to the possible reported side effect of decrease placental flow. Labetalol 400mg/daily was added to keep blood pressure under optimal control. A CS was performed at 40 weeks' gestation. A female newborn was obtained, weight 3160 g, Apgar 9/10. At follow up, an uncomplicated laparoscopic adrenalectomy was performed, and no further antihypertensive treatment was needed.

Conclusion

Despite the few cases described in the literature, in our experience the treatment with spironolactone at high doses during the first half of gestation allowed a correct management of the blood pressure and probably had a role in preventing preeclampsia with no malformations or adverse effects perinatal. In our case, we didn't choose eplerenone, since the patient was already on spironolactone at time of consultation, was a female fetus and the lack of literature on eplerenone prenatal safety. However eplerone may be recommended in planned gestations to avoid the possible feminizing effect of spironolactone scarcely reported.

Beneficial effect of *Ecklonia cava* extract in Letrozole-induced polycystic ovary syndrome rats

Hyun Yang, Bo-Jeong Pyun, Hye Jin Kim & Hye Won Lee
Korean Institute of Oriental Medicine, Daejon, Republic of Korea.

Polycystic ovary syndrome (PCOS) is an endocrinal disorder afflicting women mainly during their childbearing age. The symptoms of PCOS are irregular menstrual cycles, weight gain, subfertility, and infertility. However, since the etiology is as yet unclear, the management and treatment are still not well established. Recently, natural substances have been used for PCOS therapy. *Ecklonia cava* is a well-known natural substance that attenuates inflammation, allergy and cancer. In this study, we investigated the effects of *Ecklonia cava* extract in PCOS rats. When Letrozole-induced PCOS rats were exposed to the *Ecklonia cava* extract, the regular estrus cycle was restored, similar to that in placebo rats. Hormone levels, including testosterone, estrogen, LH, FSH and AMH, recovered to their normal states. Histological analysis revealed that the polycystic ovary symptoms significantly decreased in the *Ecklonia cava* treated rats, comparable to normal ovaries. At the transcriptional and translational levels, Cyp19a1, Ar, Esr1, *Esr2* and aromatase were remarkably increased in the *Ecklonia cava* treated PCOS rats than those of Letrozole-induced PCOS rats. These results suggest that *Ecklonia cava* extract inhibits the symptoms of polycystic ovary syndrome through regulating imbalanced hormonal levels and irregular ovarian cycles in Letrozole-induced female rats.

The paracrine endometrium expression in women with autoimmune thyroid imbalance and spontaneous abortion

Ksenia Fris, Elena Andreeva, Nadezhda Platonova & Iya Voronkova
Endocrinology Research Centre, Moscow, Russian Federation.

Context

Autoimmune thyroid pathology can lead to serious complications of pregnancy and can be combined with generalized autoimmune imbalance, in particular, in the endometrium. The imbalance in the regulation of the immunocompetent cells activity and the increase of cytokines production are one of the reasons for the failed implantation or disruption of embryo development with future consequences

Objective

To assess the role of paracrine factors (expression of autoantibodies against cytokine receptors IL-1 alpha, IL-2, TNF-alpha, interferon-gamma) in the endometrium in women with autoimmune thyroid diseases and misscariages.

Methods

Immunohistochemical endometrium study was performed on the immunostimulator Leica Bond-Max (Leica Microsystems, Germany). The expression value of markers IL-2 receptor, IL-1α, TNFα, INF-γ was performed using mouse/monoclonal antibodies (Santa Cruz Biotechnology). The immunohistochemical reactions were assessed by a quantitative score method for immunointensity of 0 to 3 (0 - negative; 1 - weak; 2 - moderate; 3 - strong). For reliability of the differences was used Spearman's nonparametric rank correlation method. Statistically significant differences were considered for $P < 0.05$.

Patients

84 women, considering pregnancy, divided into 4 groups: 1- women with reproductive losses and hypothyroidism as outcome of Hashimoto disease, $n = 21$,

mean age - Me 34 [30; 37], 2- $TPOAb^+$ positive women with a history of reproductive losses, $n=21$, mean age - Me 33 [30; 38], 3- women with reproductive failures without autoimmune thyroid disease, $n=21$, mean age - Me 30 [26; 35], 4- healthy women of the control group, $n=21$, mean age - Me 29 [27; 34].
Main outcome Measures
In comparative analysis in all 4 groups was negative expression of IL- 1 alpha and IL-2/CD 25 ($P>0,05$). Significant differences in the expression level of IFN gamma were observed in glands in the group with hypothyroidism and $TPOAb^+$ positive women ($P=0,06$ and $P=0,001$ respectively) than in control group. Furthermore, a negative correlation of expression TNF alpha was observed between the group of women with autoimmune thyroid pathology and women with misscariage and normal thyroid function.
Results
In the course of the research work was revealed an increased level of IFN expression in the group of women with with both hypothyroidism and $TPOAb^+$ positive women.
Conclusion
Expression of IFN gamma is helpful to assess the risk of a possible complication of pregnancy in women with autoimmune thyroid disease, but further research is required. Supported by Grant of President of Russian Federation ND MK-4717.2012.7

Young lean women with evidence of both premature adrenarche and pubarche display a metabolic, hormonal and psychologic profile that is similar to that of their peers with polycystic ovary syndrome

Sarantis Livadas[1], Christina Bothou[2], Christina Kanaka-Gantenbein[3], Dimitrios Chiotis[3], Nicholas Angelopoulos[1], Djuro Macut[4] & George P. Chrousos[3]
[1]Endocrine Unit, Metropolitan Hospital, Athens, Greece; [2]Division of Endocrinology, Diabetes and Metabolism, Medical Department 1, University Hospital, Goethe University, Frankfurt am Main, Germany; [3]Division of Endocrinology, Diabetes and Metabolism, First Department of Pediatrics, Faculty of Medicine, National and Kapodistrian University of Athens, Medical School, "Aghia Sophia" Children's Hospital, Athens, Greece; [4]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Context
The early activation of adrenal *zona reticularis,* denoted by increased circulating levels of adrenal androgens before the age of eight years in girls is called premature adrenarche (PA), while the concomitant appearance of pubic hair is termed premature pubarche (PP). Girls with PA-PP display an unfavorable metabolic, hormonal and psychologic profile, compared to their normal peers and are also at an increased risk of developing polycystic ovary syndrome (PCOS) features peripubertally, especially those born small for gestational age. The natural history of these girls with PA-PP post puberty is unclear.
Aim of the study
To define the metabolic, hormonal, and psychologic profile of young lean women with a history of both PA and PP, born with a normal birth weight. These women were prospectively followed since childhood, did not seek medical assistance and their majority did not fulfill PCOS criteria.
Participants
21 PA-PP women (age: 21.35 ± 3.36 years, BMI: $23.59\pm4.40 kg/m^2$) were compared with 26 controls and 45 women with classic PCOS. Only three women (14%) in the PA-PP group had PCOS by the Rotterdam criteria.
Results
PA-PP women had significantly lower serum total cholesterol (165 ± 20 *vs.* 187 ± 28 mg/dl), LDL (87 ± 21 *vs.* 21 ± 12mg/dl) and higher HDL (65 ± 11 *vs.* 56.2 ± 10.9mg/dl) than controls. Insulin resistance index HOMA-IR was similar in PA-PP (2.09 ± 1.42) and PCOS (2.08 ± 0.83), and significantly higher than that of controls (1.13 ± 0.49). Serum delta 4-androstenedione levels (ng/ml)did not differ between PA-PP (3.22 ± 1.44) and PCOS (3.54 ± 1.14) but were significantly higher than controls (0.58 ± 1.42). Similar findings were obtained for DHEAS and 17OHP, however serum testosterone and free androgen index were comparable among all groups. Ovarian volume (cm^3) was similarly increased in PA-PP (11.14 ± 3.34) and PCOS (10.99 ± 4.61) compared to controls (6.74 ± 1.83). Regarding their psychologic profile, PA-PP women had a significantly higher score of state and trait anxiety, as well as of depressive and eating disorder symptoms than controls, with a pattern that was quite similar to that of PCOS.
Conclusions
Young lean women with a history of PA and PP displayed hormonal, metabolic and psychologic profiles similar to those of their peers with classic PCOS. These findings indicate that in women with PA-PP history, a thorough evaluation and long-term monitoring is needed.

DOI: 10.1530/endoabs.56.P918

P919

Endometrium steroid receptors expression in women with autoimmune thyroid pathology and reproductive failures

Ksenia Fris, Elena Andreeva, Nadezhda Platonova & Iya Voronkova
Endocrinology Research Centre, Moscow, Russian Federation.

The complex study of the endometrium, in particular, immunohistochemical (IHC), allows to determine the state of steroid receptivity and allows to choose the optimal way of examination in women with autoimmune thyroid diseases and miscarriages.
Aim
To evaluate IHC expression of steroid receptors (ERα, ERβ, PR) in endometrium in women with a history of reproductive loss and autoimmune thyroid diseases
Materials and methods
The study involved 63 women with a history of reproductive failures, divided in 3 groups: I ($n=21$) - primary hypothyroidism in the compensation stage, II ($n=21$) - $TPO-^+$ positive patients, III ($n=21$) - without an autoimmune thyroid pathology. The control group ($n=21$) included women planning pregnancy. The endometrium IHC expression of receptors for estradiol and progesterone in stromal and glandular cells was performed using mouse/ monoclonal antibodies to ERβ, ERα, PR (Leica, Germany). As an evaluation of immunohistochemical reactions was used AllRed Score evaluation method
Results
Was found the expression decrease of ERα in stroma in I and II groups compared with III ($P<0.001$ and $p=0.002$, respectively) and the control group ($P<0.001$). A lower expression level ERα in glands was observed in I and II groups, compared to III ($P<0.001$ and $p=0.03$, respectively) and IV ($P<0.001$). The ERα expression in stroma and glands between groups III and IV were not statistically different ($p=0.513$ and $p=0.07$, respectively). In the analysis of progesterone receptors, a significant increase in the expression of ERβ in stroma and glands was found in group III in comparison with IV ($P<0.001$). In addition, lower rates of ERβ expression in groups I and II were found, but statistical significance was confirmed only in women with primary hypothyroidism ($P=0.04$). The results of PR expression in stroma and glands indicated their decrease in the I group in relation to the remaining cohorts (PR stroma: $P<0.001$, PR of the gland: $p=0.03$).
Conclusions
The estimation of steroid receptors endometrium expression indicated a high degree of damage to the receptor apparatus in women with autoimmune thyroid diseases with imbalance of the secretory function of the endometrium glands. Early diagnosis of the combined immune disorders in this cohort of patients and the proper pre-gravity training will ensure greater effectiveness in the management of subsequent pregnancies.

Does Crohn's disease have an effect on female fertility?

Jana Kollerova[1], Tomas Koller[1], Barbora Kadlečková[2], Jozef Tóth[1], Anna Krajčovičová[1], Tibor Hlavatý[1] & Juraj Payer[1]
[1]5th Department of Internal medicine, University Hospital, Bratislava, Slovakia; [2]IBD Center Assiduo, Bratslava, Slovakia.

Introduction
Impaired fertility in women with Crohn's disease compared to healthy women seems to be a consequence of Crohn's disease, according to older studies. However, data are not consistent, and it is not clear why could the reduced fertility occur. Influence on ovarian reserve might be one of the answers.
Patients
The study group consisted of women with Crohn's disease. The control group consisted of age and BMI matched healthy women with no history of assisted reproduction.
Methods
All patients completed a personal questionnaire, focused on fertility parameters as well as the Crohn's disease phenotype, activity and treatment. Ovarian reserve was measured by the serum concentration of anti-mullerian hormone (AMH).

In patients with Crohn's disease, we investigated the effect of the Crohn's disease phenotype and prior treatment on the ovarian reserve.
Results
We included 50 women with Crohn's disease and 50 controls. Comparing two groups, we did not observe any difference in rates of birth, spontaneous abortion, contraceptive use and age of menarche. Serum AMH was not different between the groups (3.026 vs. 3.19, $P=0.74$), 54 vs. 52% of women had an optimal ovarian reserve (AMH >2.27), and 23.7 vs. 19.23% had low ovarian reserve (AMH <0.68), with no difference. Age was the strongest parameter affecting decline of the ovarian reserve, with not difference between patients with Crohn's disease versus controls. We did not detect any significant impact of disease duration, type of disorder, inflammatory activity, or type of treatment on the rate of age-related AMH decline. However, we found a more pronounced age-related AMH decline in patients with prior IBD surgery compared to no surgery (slope -0.12 versus -0.29, $P=0.04$) and the trend towards the more pronounced decline in L2 colic phenotype compared to L1 and L3 (slope -0.33 vs. -0.14, $P=0.12$). Finally, women older than 30 years had a more pronounced age-related AMH decline if Crohn's disease lasted for more than 5 years (slope -0.31 vs. -0.2, $P=0.029$).
Conclusion
We found that women with Crohn's disease as compared to controls had the same ovarian reserve and equal rate of its age-related decline. More pronounced age-related decrease in ovarian reserve was observed in women with prior IBD surgery and those over 30 years of age with Crohn's disease lasting for more than 5 years. In these cases, patients may be advised not to delay a pregnancy.

Effects of food restriction on estrous cycle and leptin hormone in mongolian gerbils (*Meriones unguiculatus*)

Gözde Gülşin & Bülent Gündüz
Department of Biology, Faculty of Arts and Sciences, Canakkale Onsekiz Mart University, Canakkale, Turkey.

Reproductive systems of the Mongolian gerbils are controlled by the photoperiod but body weight is independent of photoperiod. Food intake has an effect on reproduction and gerbils are very sensitive about food intake. Leptin hormone has controls on both food intake and body weight. Finding a link between changes in feeding behavior and reproductive activity in relation to obesity-related issues will play an important role. In this study, three groups were established; a) food was introduced as ad libitum, b) food was introduced only in dark period, c) food was introduced only in light period. Daily food consumption and weekly body weights were calculated. Estrus cycles have been observed by means of vaginal smears every day and preparations were photographed. Leptin measurement at each phase of the estrus cycle phases was evaluated separately. When all groups were compared in terms of food consumption, the control group was higher ($\sim$6.34 g/day) than in other groups however, other groups were found to be similar ($\sim$4.53 g/day). It was found that the weight variations of the three groups were similar. The leptin value in diestrus phase of both food restricted groups was higher ($\sim$24 ng/ml; $P<0.05$) than the control. The values in proestrus stage were similar ($P>0.05$), but the values in estrus stage had higher leptin when the animals were fed in the dark phase ($\sim$32 ng/ml; $P<0.05$). Leptin in metaestrus stage was lower in the group fed in the light phase but other groups had similar leptin values ($\sim$7 ng/ml; $P<0.05$). 4-day estrus cycles of the control group were prolonged in food-restricted groups ($\sim$7–8 days). As a result, feeding behavior has led to changes both in leptin values and in the estrus cycle. Since the relationship between nutrition and leptin in recent years is important in terms of obesity, changes in feeding rhythm may directly affect on the organism's reproductive system.

Amenorrhea and high intensity training

Vitoria Pires
Armed Forces Hospital, Lisboa, Portugal.

Introduction
Functional hypothalamic amenorrhea (FHA) is one of the most common causes of secondary amenorrhea. There are three types of FHA: weight loss-related, stress-related, and exercise-related amenorrhea. The latter is fairly common among competitive athletes. Currently the Olympic Committee includes amenorrhea in the "Relative Energy Deficiency Syndrome in Sport (RED-S)". The syndrome of RED-S refers to impaired physiological function including metabolic rate, menstrual function, bone health, immunity and cardiovascular health caused by relative energy deficiency. Admission to the Military Academy is a period of intense physical exercise where trainees are at risk for amenorrhea and consequently RED-S.
Objectives
To verify the prevalence of amenorrhea in high intensity training included in a military set and to identify possible predictors.
Material and methods
Observational, descriptive, cross-sectional and retrospective study of female soldiers who entered the Military Academy from 1992 to 2016. A questionnaire was formulated to analyze variables before admission (demographic data, sports federation, gynecological history, use of oral contraceptives (ACO)) and variables after admission (period in amenorrhea, sports injuries). Descriptive and statistical analysis was performed using the chi-square test.
Results
102 military personnel answered the questionnaire. At the time of entry, they had an average of 18.8 (17-25) years and 36.2% were federated in a sport. 37.3% took ACO, of the remaining 64 cadets, 43.8% (28/64) had menstrual dysfunction, and 35.9% (23/64) presented amenorrhea, on average 5 months. 78.3% recovered spontaneously, 17.4% resorted to ACO and 4.3% to other therapies. Of de total, 39.2% suffered injuries, and there was no difference between the group taking ACO, the group that had amenorrhea and the group without amenorrhea. No difference was found regarding previous sports history.
Discussion and conclusions
The prevalence of amenorrhea in women subjected to high intensity physical training (characterized in this study by military training) was 35.9%, and it was not possible to correlate it with previous sport history or with the presence of injuries. Studies show prevalence of amenorrhea in runners and dancers range from 20 to 66%, revealing that this condition is very common. However, investigations should include assessment of systemic and endocrinologic etiologies, as FHA is a diagnosis of exclusion.

Detection of SRY gene in patients with turner syndrome

Erdal Kurnaz, Semra Çetinkaya, Şenay Savaş-Erdeve & Zehra Aycan
Dr. Sami Ulus Obstetrics and Gynecology and Pediatrics Training and Research Hospital, Ankara, Turkey.

Background
The presence of the Y chromosome and Y-specific sequences (e.g: *SRY*, DYZ1, DYZ3, DYS132, *ZFY,* and *TSPY*, etc) in Turner syndrome patients is a risk factor for gonadal tumors (mostly gonadoblastoma) in dysgenetic gonads. Unfortunately approximately 60% of gonadoblastoma cases, there is a potential to progress towards invasive germ cell tumors (mostly dysgerminoma). Girls with Y chromosomal material also present a higher risk of virilization, because the stroma cells and granulosa/Sertoli cells present in the dysgenetic gonad can produce androgens. Therefore, TS patients Y chromosomal material should undergo prophylactic gonadectomy. In this study we aimed to share our clinical experience.
Methods
The SRY gene was investigated in 71 of 85 TS cases (aged 0.3 months-27 years) between 2005 and 2017. Fluorescent *in situ* hybridization (FISH) was used until 2014, after then SRY gene analysis was performed by polymerase chain reaction (PCR). In 25 cases with used FISH method, SRY gene analysis was investigated second times by PCR method.
Results
Pathologic findings were not found in terms of virilization, clitoromegaly, posterior labial adhesions in case of TS. SRY gene was found to be negative in all cases. Further studies did not require due to no pathologic findings normal over visualization in USG.
Conclusion
Routine testing for SRY or the presence of Y chromosome material in TS patients without masculinization is not clinically warranted. For these reasons, molecular screening to detect Y-chromosomal sequences is currently recommended in TS individuals with masculine features who are negative for Y material by conventional cytogenetic and FISH analyses. In these individuals, multiple sequences adjacent to the Y centromere should be amplified using PCR.

Time-dependent regulation of kisspeptin/Kiss1R and TAC3/TACR3 systems expression in human ovarian granulosa cells from polycystic ovary syndrome (PCOS) patients and non-PCOS patients

Yang Yu & Kai-Lun Hu
Peking University Third Hospital, Beijing, China.

The kisspeptin/Kiss1R and tachykinin 3 (TAC3)/tachykinin receptor 3 (TACR3) system in the hypothalamus are essential for reproduction. Recent study suggested that the two peptide systems are both expressed in the ovary, particularly in the granulosa cells. The expression profile of the two systems in human granulosa cells has not been fully investigated yet. We collected the granulosa cells from normal infertile control patients and patients diagnosed with PCOS in Peking University Third Hospital. The expression of *Kiss1*, *Kiss1R Tac3*, and *Tacr3* increased at 2000 when compared with 1000 in granulosa cells from normal control patients. While the expression of *Kiss1* and *Tacr3* increased, *Kiss1R* and *Tac3* decreased at 2000 when compared with 1000 in patients with PCOS. HCG had no significant effect on the expression of Kiss1, Kiss1R Tac3, and Tacr3, but significant promoted the expression of circadian time gene PER1. Kisspeptin-10 and Tacr3 antagonist, senktide decreased the expression of circadian gene *Bmal1* and *per2*, but it was not statistically significant. The expression of Kiss1 was related to the expression of *Bmal1* at different time within a day. Our results suggest that ovarian kisspeptin/Kiss1R system and Tac3/Tacr3 system have a different expression profile in patients with and without PCOS. The discrepancy may be related to the different circadian clock gene expression manner in the granulosa cells.

Hyperandrogenism in a postmenopausal woman:A clinical challenge

Tahir Omer & Ian Seetho
Cambridge University Hospital, Cambridge, UK.

Introduction
Hyperandrogenism is an uncommon finding in postmenopausal women. Possible sources of the elevated androgen levels include Cushing's syndrome, Polycystic ovarian syndrome, benign and malignant androgen secreting ovarian tumors, ovarian hyperthecosis, adrenocortical tumours and iatrogenic hirsuitism.
Case
A 65 year-old lady was referred with a raised testosterone level of 2.6 nmol/l [0–1.8 nmol/l]. She experienced weight gain and fatigue for over 6 months. She also had nail changes and hair loss, with increased hair growth on her face and acne that had gradually worsened in the last year. There were no changes to voice or muscle size. She experienced menopause in 2003 and received HRT therapy for a year then stopped it. Clinically she scored 15 on Ferriman Gallway score for hirsutism with no clinical features of Cushing's syndrome or Acromegaly.
Investigations
Testosterone of 2.7 nmol/l [0–1.8 nmol/l], Androstenedione 3.1 nmol/l [<3.0 nmol/l], LH 42.4 mIU/ml, FSH 104.0 mIU/ml, DHEAS 0.9 umol/L, Oestradiol<90, Prolactin 91 mU/l, 17-hydroxyprogesterone Progesterone < 1.6 nmol/l, Insulin growth factor-1: 25.6 nmol/l, overnight dexamethasone suppression test: Cortisol <25, TSH 0.71 mU/l [0.35–5.5 mU/L], T4 13.6 pmol/l [10.0–19.8 pmol/L]. Ultrasound pelvis showed a bulky right ovary. MRI pelvis was unremarkable with no worrying features. DEXA scan showed normal bone density. A CT adrenal scan showed a mildly nodular appearance to the left adrenal gland, however, there were no focal adrenal lesions. GnRH agonist suppression test: GnRH agonist administration resulted in a dramatic decline in testosterone levels with Testosterone level of 0.5 nmol/l, Androstenedione of 2.2 nmol/l, LH 1.4 mIU/ml, FSH 7.8 mIU/ml on the 4th week following the injection. There was dramatic improvement of her symptoms. She has now been referred for oophorectomy.
Discussion
Identification of the source of elevated androgens often creates a clinical challenge. Hyperandrogenism has virilizing physical effects but is also associated with dyslipidaemia, hypertension, insulin resistance, uterine and cardiovascular disease. If the source is identified, surgery (whether oophorectomy or adrenalectomy) is often curative. Medical management with GnRH agonist/analogues or antagonists has been reported in the literature but may have associated side effects.

Polycystic ovary syndrome and insulin-like growth factor (IGF) system.

Ivica Lazúrová, Jana Figurová, Zora Lazúrová, Silvia Toporcerová, Miroslava Rabajdová & Jana Mašlanková
Medical faculty of the P.J. Šafárik University, Košice, Slovakia.

Objectives
Insulin-like growth factors 1 and 2 (IGF1 and IGF2) are widely expressed mitogenic peptides playing a role in the fetal developement and differentiation. Evidence suggest their possible involvement in the pathogenesis of metabolic syndrome and probably in polycystic ovary syndrome (PCOS).
Aim
Aim of the study was to assess the relationship of serum IGF1, IGF2 and IGF binding protein 3 (IGFBP3) levels to steroid hormones and metabolic parameters in PCOS women.
Subjects and methods
The study included 56 Caucasian women diagnosed with PCOS (age 28.62±5,2 years, range 19-43). All patients were examined for parameters of glucose and lipid metabolism, sexual steroid hormones and serum IGF1, IGF2 as well as $IGFBP_3$ levels.
Results
Nonobese PCOS women had higher IGF1 than those with BMI>25 with borderline significance (211±15.6 v.s. 160.7±16, $P=0.06$). No significant differences in serum IGF2 and $IGFBP_3$ levels in women according to BMI have been detected. IGF1 negatively correlated with HOMA IR ($R^2=0.23$, $P=0.03$), waist circumference ($R^2=0.15$, $P=0.045$) and triacylglycerols ($R^2=0.23$, $P=0.02$), but not with sexual steroids. On the other side $IGFBP_3$ was in positive correlation with TAG ($R^2=0.22$, $P=0.0215$), total cholesterol ($R^2=0.2$, $P=0,028$), LDL cholesterol ($R^2=0.2$, $P=0.03$), dihydrotestosterone ($R^2=0.14$, $P=0.049$) and estrone ($R^2=0.21$, $P=0.014$). Neither correlation between serum IGF2 and metabolic variables nor between IGF2 and steroid hormones have been detected.
Conclusion
We conclude that higher IGFBP3 level is more related to metabolic parameters and steroid hormones in PCOS women than both serum IGF1 and IGF2. Further studies are needed.

DOI: 10.1530/endoabs.56.P926

Disentangling polycystic ovary syndrome (PCOS) components by liquid-chromatography – tandem mass spectrometry (LC-MS/MS) steroid profiling

Flaminia Fanelli[1], Marco Mezzullo[1], Laura Zanotti[1], Alessia Fazzini[1], Marianna Mastroroberto[2], Antonio Maria Morselli-Labate[2], Uberto Pagotto[1], Renato Pasquali[1] & Alessandra Gambineri[1]
[1]Endocrinology Unit and Centre for Applied Biomedical Research, Department of Medical and Surgical Sciences, University of Bologna – S.Orsola-Malpighi Hospital, Bologna, Italy; [2]Department of Medical and Surgical Sciences, University of Bologna – S.Orsola-Malpighi Hospital, Bologna, Italy.

Introduction
Clinical and laboratory hyperandrogenisms indistinctly contribute to PCOS diagnosis; however, they differ in hormonal and metabolic correlates and require proper therapeutic strategies. Circulating biomarkers of hirsutism were not identified so far, with elevated testosterone being observed only in half of hirsute patients. Reasons for such inconsistencies possibly relies in previously used immunoassays, nowadays recognized as not adequate because of poor reliability and limited steroid panel. The present study aimed at defining the circulating steroid fingerprint that specifically distinguishes hirsutism by LC-MS/MS profiling of a broad steroid panel.
Methods
Sixteen serum steroids were determined in 352 patients (age 14–49 years) in follicular phase. The independent effect of ovarian dysfunction (OD; oligo-amenorrhea and/or PCO morphology), hyperandrogenemia (testosterone≥1.56 nmol/L and/or androstenedione≥5.72 nmol/L) and hirsutism (modified-Ferriman-Gallway score≥8) on circulating steroids was valued. Moreover, hirsute ($n=74$) vs not-hirsute ($n=47$) women were compared within patients showing both OD and hyperandrogenemia.
Results
OD directly associated with LH ($P=0.048$) and LH/FSH ($P<0.001$), and negatively with FSH ($P<0.001$). OD positively associated with androstenedione ($P=0.002$), 17OHprogesterone/progesterone ($P<0.001$), 17OHprogesterone/17OHpregnenolone ($P=0.004$), androstenedione/dehydroepiandrosterone

($P<0.001$), and negatively with progesterone ($P=0.026$), dehydroepiandrosterone ($P=0.029$), dehydroepiandrosterone-sulfate ($P=0.034$) and 11deoxycortisol/17OHprogesterone ($P=0.003$). Hyperandrogenemia positively associated with mFG-score ($P=0.012$), ACTH, LH and LH/FSH (all $P<0.001$), insulin ($P=0.025$) and HOMA-IR ($P=0.045$). Hyperandrogenemia positively associated with 17OHpregnenolone, progesterone, dehydroepiandrosterone, 17OHprogesterone, estrone (all $P<0.001$), dehydroepiandosterone-sulfate ($P=0.004$), dihydrotestosterone ($P=0.009$), corticosterone, 11deoxycortisol, cortisol (all $P<0.001$), cortisone ($P=0.009$), 17OHprogesterone/progesterone ($P<0.001$) and androstenedione/dehydroepiandrosterone ($P=0.014$), and negatively with dehydroepiandrosterone-sulfate/dehydroepiandrosterone, testosterone/androstenedione, estrone/androstenedione, estradiol/testosterone, dihydrotestosterone/testosterone and cortisol/11deoxycortisol (all $P<0.001$). Hirsutism directly associated with BMI ($P=0.014$) and inversely with HDL ($P=0.041$). Hirsutism also associated with lowering progesterone ($P=0.007$) and 17OHprogesterone ($P=0.003$) and increasing androstenedione/17OHprogesterone ($P<0.001$) and 11deoxycortisol/17OHprogesterone ($P=0.021$). Compared with not-hirsute, hirsute women with OD and hyperandrogenemia exhibited higher BMI ($P=0.002$) and dehydroepiandrosterone/17OHpregnenolone ($P=0.011$), and lower SHBG ($P=0.001$), 17OHprogesterone ($P=0.030$), testosterone ($P=0.004$), androstenedione/dehydroepiandrosterone ($P=0.024$) and testosterone/androstenedione ($P=0.039$).

Conclusions

Androstenedione excess in OD apparently originates by gonads, as indicated by imbalanced gonadotropin, low progesterone, increased 17hydroxylase activity and reduced adrenal secretion. Hyperandrogenemia is featured by insulin resistance, combined ovarian and adrenal hypersecretion of the overall steroid profile, and reduced precursors' conversion in downstream active steroids. Hirsutism is characterized by obesity and dyslipidemia, by low 17OHprogesterone and, in the PCOS context, by mild hypertestosteronemia and reduced SHBG, overall suggesting that this phenotype could result by increased free-androgens at the pilosebaceous unit.

Anxiety and depression in patients with polycystic ovarian syndrome

Syed Muhammad Ali Shah, Ayesha Tariq & Amna Tariq
Nawaz Sharif Medical College/Aziz Bhatti Shaheed Teaching Hospital, Gujrat, Pakistan.

Background

Polycystic ovary syndrome (PCOS) occurs in women of reproductive age and is characterized by hyperandrogenism, polycystic ovaries, oligomenorrhea or amenorrhea. Estimated prevalence is at least 6.5%. Women having PCOS tend to be overweight or obese. In addition to endocrine, metabolic and gynecological, features of PCOS, a number of psychological problems add up which affect quality of life and psychological well-being in women with PCOS.

Materials and methods

Case-control study conducted from July 2017 to January 2018 at ABSTH Gujrat after ethical approval from IRB. Non-probability consecutive sampling was used. 50 patients having PCOS were included in study and compared to 50 healthy subjects after their consent. Clinical characteristics of PCOS were compared in both groups. Assessment of anxiety and depression was done using DSM-V criteria. Statistical analysis was done using SPSS 20.0.

Results

Mean age was $26.16+5.54$ and $25.48+6.27$ years, mean weight $72.26+16.53$ and $64.7+13.51$ kg and mean BMI was $28.96+5.87$ and $24.55+5.24$ kg/m^2 in cases and controls respectively. Hirsutism (72% vs 18%), oligomenorrhea or amenorrhea (98% vs 12%), hypertension (28% vs 6%), weight gain (50% vs 12%) , heaviness of voice (12% vs 6%), enlargement of clitoris (16% vs 6%), hair fall (74% vs 34%), acne (68% vs 16%) and hyperglycemia (4% vs 0%) were compared in both groups. Presence of hirsutism, oligomenorrhea or amenorrhea, hypertension, weight gain, hair loss and acne were significantly associated with PCOS ($P<0.05$). BMI was independent risk factor for development of anxiety ($P=0.001$) and depression ($P=0.000$). Relative risk of anxiety in cases was 3.3333 (95% CI, 0.9751–11.3954) while that of depression was 5.1667 (95% CI, 2.3652–11.2863). Depression was significantly associated with PCOS ($P<0.001$) but anxiety was not significantly associated ($P=0.055$).

Conclusion

Depression is significantly present in patients with PCOS as compared to healthy women with BMI as independent risk factor.

A retrospective analysis of the audiometric data of a cohort with turner syndrome

Aoife Christine Newman & Siobhan McQuaid
Mater Misericordiae University Hospital, Dublin, Ireland.

Turner Syndrome (TS) is a multi-systemic genetic condition in females caused by partial or complete deletion of one X chromosome. It affects approximately 25-50 per 100,000 live births. Recent data shows that up to 60% of patients with TS will experience recurrent otitis media and 30% will suffer permanent hearing impairment. International guidelines recommend audiometric screening at diagnosis, every three years in childhood and at least every five years in adulthood for TS patients. In this retrospective review we aimed to assess the patterns of hearing loss with formal audiometric analysis in a cohort of adult females with confirmed TS attending a tertiary referral centre. Of three patients only nine (16.7%) had unimpaired hearing. A total of 24 patients had some hearing abnormality and one patient failed to attend for assessment. The majority of patients ($n=18$) had a sensorineural hearing loss pattern. Only one patient displayed solely conductive hearing loss and five patients had a mixed pattern. Mean age of patients with hearing loss was $39.3+10.6$ years (versus $35.1+12.6$ years in the total population and $23.7+7.4$ years in the population with normal hearing). This is in keeping with the known natural history of TS where recurrent otitis media leads to eventual cochlear damage as the patient gets older. Patients with hearing loss were also more likely to have cardiac abnormalities (45.8% vs 22%; $P=0.67$) and thyroid function abnormalities (50% vs 44%; $P=0.77$) than TS patients with normal hearing profiles. Of the patients with normal hearing one patient had a 45XO karyotype and the remaining eight were all mosaic karyotypes. In the group with hearing impairment four patients had 45XO karyotype, twelve had mosaic patterns and the remainder had an unknown karyotype. Of 16 patients referred for hearing aids two patients declined them. In conclusion, greater awareness is needed among physicians regarding the prevalence, severity and prognostic implications of hearing impairment in patients with TS.

The relationship between uric acid levels and metabolic parameters in patients with polycystic ovary syndrome

Özen Öz Gül[1], Soner Cander[1], Buket Biçer[2] & Canan Ersoy[1]
[1]Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey; [2]Uludag University Medical School, Department of Internal Medicine, Bursa, Turkey.

Introduction

Polycystic ovary syndrome (PCOS) is a common, multifaceted endocrinopathy associated with metabolic alterations such as insulin resistance, hyperinsulinemia, dyslipidemia, and obesity, and thereby an increased risk of developing type 2 diabetes mellitus (T2DM) and cardiovascular disease (CVD). Endothelial dysfunction and chronic inflammation are early findings in the atherosclerotic process. Elevated serum levels of uric acid may reflect low-grade chronic inflammation. But there are controversial data whether increased the uric acid level in PCOS patients. This study was aimed to examine the relationship between uric acid, lipoprotein levels and insulin resistance in obese and non-obese patients with PCOS.

Methods

Eighty-three young women with PCOS were included this study. Plasma levels of glucose, insulin and uric acid were measured. The patients were divided into two groups according to a cut-off BMI value of 30 kg/m^2. Anthropometric variables, hormonal and metabolic profiles were evaluated in both groups. Insulin resistance was evaluated by homeostasis model assessment (HOMA-IR).

Results

A total of 83 premenopausal PCOS patients with ($n=37$, mean (s.d.) age: 24.3 (4.7 years) or without obesity ($n=46$, mean (s.d.) age: 29.4 (6.3) years) were included in this study. Plasma uric acid levels and HOMA-IR were significantly higher in women with obese PCOS patients than non-obese PCOS patients. Serum fasting total cholesterol and hemoglobin A1c levels were similar between obese and non-obese groups. Compared with non-obese PCOS subjects, obese PCOS subjects had high HOMA-IR, insulin, TG and uric acid levels. Plasma fasting glucose levels, postprandial glucose levels and androgen levels were similar between obese and non-obese women with PCOS.

Conclusion

Our findings revealed significantly higher levels for plasma insulin and HOMA-IR values in obese PCOS patients when compared to non-obese PCOS patients. Obesity is the main determinant of serum uric acid concentrations in PCOS

patients. Measurement of serum uric acid could help the detection of insulin resistance and related disorders in patients with PCOS.

Pure leydig cell tumor of the ovary in young premenopausal female

Liudmila Yesaulava[1], Jeffrey A Stinson[2] & Maya Y Peltsverger[2]
[1]Memorial University Medical Center, Savannah, Georgia, USA; [2]New Hanover Regional Medical Center, Wilmington, North Carolina, USA.

Background
Leydig cell ovarian tumors (LCOT) represent a rare type of sex-cord stromal tumors accounting for less than 0.1% of all ovarian tumors. (1) Although rarely described in young, LCOT most commonly occur in postmenopausal women (2). The prominent clinical features of LCOT are rapidly progressive virilization, recently described, secondary erythrocytosis and OSA (3). Suppressed plasma leptin has also been reported in patients with LCOT (4), however direct correlation of leptin with testosterone level is still debatable.
Clinical case
A 42-year old woman, presented for evaluation of hirsutism. Past medical history was significant for hypothyroidism, type 2 DM, obesity class II, OSA and secondary amenorrhea that started after the birth of her child at age 20. Previous biochemical studies demonstrated elevated testosterone leading to diagnosis of PCOS. Physical examination showed virilization, frontal alopecia, facial plethora, laryngeal hypertrophy, hirsutism (Ferriman-Gallwey score of 35), truncal obesity, acanthosis nigricans, and clitoromegaly. Laboratory studies revealed elevated total testosterone of 1242 ng/dl ($<$ 70 ng/dl), low normal estradiol of 40.6 pg/ml (11.0–462.1 pg/ml), suppressed LH and FSH, normal prolactin, 17-OH progesterone, 24 urine free cortisol, DHEA-S, and TSH. The patient had marked erythrocytosis (Hgb of 18.3 g/dl (11.2–15.7 g/dl) and hematocrit $>$53% (34.1–44.9%), and significant insulin resistance ($>$100 units of insulin a day and four other oral hypoglycemics; HOMA-IR 11.2). Furthermore, she had elevated fasting serum insulin of 57.1 uIU/ml (normal:2.6–24.9 uIU/ml), HgbA1C 9.7%, and suppressed serum leptin level of 4.2 ng/ml (14.1–78.4 ng/ml). Pelvic ultrasound and CT of abdomen and pelvis with intravenous contrast did not reveal an adrenal adenoma or pelvic mass. Ovarian vein sampling was considered, however patient elected for TAH-BSO. Intra-operatively, both ovaries were normal in appearance. Pathology revealed 3.4 cm right ovarian pure Leydig cell tumor. Postoperatively, serum testosterone, Hgb/Hct levels rapidly normalized. Nine months after the surgery, plasma leptin increased to 39.7 ng/ml (22–121 ng/ml).
Conclusion
Secondary erythrocytosis and OSA in premenopausal women, when associated with markedly elevated testosterone levels, warrant further investigation and a high degree of suspicion for LCOT. Furthermore, in this case study, we re-demonstrated that extremely high testosterone has a suppressive effect on leptin production, as reflected by circulating levels of this hormone, which normalized following the resection of the tumor, without significant changes in BMI. The mechanism of this effect remains to be elucidated.

Effect of maternal smoking on steroidogenesis

Monika Šrámková[1,2], Michaela Dušková[1], Karolína Adamcová[3], Lucie Kolátorová[1], Tereza Chlupáčová[1], Markéta Šimková[1], Hana Jandíková[1], Antonín Parízek[3] & Luboslav Stárka[1]
[1]Institute of Endocrinology, Prague, Czech Republic; [2]Department of Medical Chemistry and Clinical Biochemistry, University Hospital Motol, Prague, Czech Republic; [3]Department of Obstetrics and Gynecology of the First Faculty of Medicine and General Teaching Hospital, Prague, Czech Republic.

Objective
Smoking during pregnancy could have impact on steroidogenesis, with more marked changes in smokers carrying boys as well as in their newborns. The aim of study was compared steroid hormones between non-smokers, ex-smokers, which stop smoking in the beginning of pregnancy, and active smokers.
Method
We focused on changes in steroidogenesis in the blood of mothers in their 37th week of pregnancy and in mixed cord blood from their newborns. Because of difference in steroid hormones due to sex of fetus, it is necessary to analyze separately results according the fetus sex. We included 47 healthy women carrying female fetuses with physiological pregnancies (22 non-smokers, 11 active smokers and 14 ex-smokers). The group of women carrying male fetus were excluded due to low numbers in the subgroups. Seventeen steroids were measured by LC-MS/MS method.
Results
We found higher androstenedione in smokers and ex-smokers compared to non-smokers at the 37th week. We found no changes in the female newborns.
Conclusion
Smoking during pregnancy, but unfortunately also stop smoking in the beginning of pregnancy, induces changes in the production of steroids in the mother. Stop smoking is required, but much earlier could bring more benefit.

Fertility restoration in female patients with hypopituitarism

Irena Ilovayskaya[1], Tatiana Nazarenko[2], Yana Zaydieva[2] & Lidia Logutova[2]
[1]Moscow Regional Research and Clinical Institution, Moscow, Russian Federation; [2]Moscow Regional Research Institution of Obstetrics and Gynecology, Moscow, Russian Federation.

Hypopituitarism is relatively rare disorder characterized by different kind of pituitary deficit, and GH-deficiency as well as hypogonadotropic hypogonadism (HH) are the most often met ones. The prevalent cause of hypopituitarism is organic lesion of hypothalamo-pituitary region (pituitary tumors, craniopharyngiomas, empty sella turcica and etc). Successful neurosurgery and optimal replacement hormonal treatment allow patients to appeal to a doctor about pregnancy. Results of fertility restoration in 22 patients with hypopituitarism were compared in this study. Women 22–34 y.o. with duration of HH from 2 to 10 years were observed: 4 patients with isolated HH, 12 – with other adequately treated pituitary deficiencies. Before ovulation stimulation patients were treated with 17β-estradiol (2–4 mg) and dydrogesterone (10–20 mg) in sequence manner no less than for 12 months, this period was used for restoration of physiological endometrium function, increase of uterus volume, correction of treatment of other pituitary deficits (if needed). AMH levels were normal in 19 women and low in 3. In eight women there were 16 stimulations of superovulation according to standard 'long' or 'short' IVF protocols (group 1), 1–8 eggs were obtained per protocol. In other 8 women there were 12 ovarian stimulations using human recombinant gonadotropins with individualised dose titration (group 2), 1–3 ovulated follicles were usually observed per stimulation. In more 8 women (including 2 with previous unsuccessful ovarian stimulation) 12 mild stimulations of ovulation according to individualized IVF protocols were done (group 3), 1–3 eggs per protocol. Individual approach for groups 2 and 3 included: pre-treatment for 2–3 months with low (37.5 MU) rFSH doses in case of low number of antral follicles, estrogen treatment continuation during ovarian stimulation, addition of rLH to rFSH from 6–7 day of stimulation in case of retardation of follicle growth. Moreover, in group 3 GnRH agonists/antagonists were not used because spontaneous LH surge were not expected. Total doses of gonadotropins used for ovarian stimulation were same or below in groups 2 and 3 compared with group 1. During pregnancy replacement treatment of accompanying pituitary deficits were correlated. Rates of 'take-home-baby' were 56.25%, 66.67% and 66.67% accordingly. Main reasons for failure were other infertility factors (male, immunological, concurrent gynaecological). Thus, modern assisted reproductive technologies can help patients with hypopituitarism to restore fertility but individualized approach is highly recommended taking into account both assisted reproductive technologies features and hypopituitarism points. Pregnancy attainment in a woman with hypopituitarism is real ART of medicine.

The inflammatory markers and central obesity in policystic ovary syndrome

Małgorzata Kałużna[1], Adam Janicki[1], Magdalena Człapka-Matyasik[2], Katarzyna Wachowiak-Ochmańska[1], Jerzy Moczko[3], Katarzyna Ziemnicka[1] & Marek Ruchała[1]
[1]Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland; [2]Institute of Human Nutrition and Dietetics, Poznan University of Life Sciences, Poznan, Poland; [3]Department of Computer Science and Statistics, Poznan University of Medical Sciences, Poznan, Poland.

The waist-to-height ratio (WHtR) has recently gained attention as an anthropometric index showing the highest predictive value for cardiometabolic risk in PCOS and healthy women. Central adiposity is the key driving force behind a constellation of inflammatation linked to insulin resistance, metabolic syndrome and cardiovascular diseases. PCOS is also considered to be linked to chronic inflammatory processes. Platelet count ratio/mean platelet volume (PLT/MPV), lymphocyte–white blood cell count (L/WCC) and neutrophil to lymphocyte ratio (NLR) are the useful markers of the detection of systemic inflammation. Our aim was to investigate PLT/MPV, L/WCC, NLR, high-sensitive C-reactive protein (hsCRP), ferritin, lipid profile (cholesterol, LDL, HDL, TG) and insulin resistance index (HOMA-IR) in 265 patients with PCOS and with or without central obesity classified according to WHtR levels. PCOS was diagnosed according to Rotterdam criteria. A WHtR cutoff of 0.5 was used as an universal cutoff for central obesity in adults. Therefore 156 low-WHtR and 88 high-WHtR PCOS patients were included in the study. High-WHtR patients had statistically higher WBC, PLT, PLT/MPV, NLR, ferritin and CRP levels ($P > 0.05$, nonparametric Mann-Whitney test). Cholesterol, LDL and TG levels and HOMA-IR were also higher in high-WHtR PCOS patients. L/WCC was lower in high-WHtR vs. low-WHtR PCOS patients. There was positve correlation between PLT/MPV and CRP, cholesterol, LDL, TG levels and HOMA-IR in all PCOS patients. NLR positively correlated with CRP, LDL, TG and ferritin level, and HOMA-IR. L/WCC was negatively associeted with CRP, TG and ferritin level, and HOMA-IR (nonparametric Spearman monotonic correlation test). Central obesity in PCOS patients was associated with WBC, PLT, PLT/MPV, L/WCC and NLR levels. Further prospective studies concerning inflammation, central obesity and PCOS are needed.

The clinical utility of serum anti-Müllerian hormone (AMH) in patients aged over 40 with their first IVF treatment

Yubin Lee, Hee Jun Lee, Sang Woo Lyu, You Shin Kim, Woo Sik Lee & Tae Ki Yoon
Fertility Center of CHA Gangnam Medical Center, Seoul, Republic of Korea.

Objective
To evaluate the clinical significance of AMH in predicting IVF outcomes among patients over age 40 undergoing the first IVF cycle.
Design and methods
This is a retrospective study. Patients aged 40 or older who underwent their first IVF cycle from January 2013 to September 2014 in CHA Gangnam fertility center were included ($n = 201$). All patients received gonadotropin-releasing hormone (GnRH) antagonist protocol, with a starting dose of 75–225IU recombinant FSH. Serum samples were collected prior to IVF treatment. Serum AMH level and other patient characteristics were analyzed. The main outcome was total retrieved-oocyte number and clinical pregnancy.
Results
The mean age was 41.8 ± 2.1 years and the mean AMH level was 0.35 ± 0.17 ng/ml. The 76% ($n = 153$) of patients was diagnosed as poor responders, fulfilling the Bologna criteria. There was a positive correlation between serum AMH levels and the number of oocytes retrieved ($R^2 = 0.123$, $P < 0.0001$). 30 out of 201 patients achieved clinical pregnancy (14.9%) and the receiver operating characteristic (ROC) curve analysis for prediction of clinical pregnancy showed that AMH had an area under the curve (AUC) of 0.64. Both day 3 serum FSH and BMI had lower accuracy (AUC 0.50 and 0.43, respectively) than AMH. Furthermore, the optimum cut-off level of AMH was 0.27 ng/ml (sensitivity 93.3%, specificity 42.0%, respectively).
Conclusion
Serum AMH concentration is a promising biomarker for the prediction of the number of total oocytes retrieved and the clinical pregnancy in old aged patients, at the time of their first IVF cycle with GnRH antagonist protocol. The cut-off level of 0.27 ng/ml AMH can be used to predict clinical pregnancy.

Child wish and fertility preservation in assigned female at birth transgender persons living in Belgium

Justine Defreyne[1], Judith Van Schuylenbergh[2], Elia Wyverkens[3], Joz Motmans[2], Kelly Tilleman[4] & Guy T'Sjoen[1,2]
[1]Department of Endocrinology, Ghent University Hospital, Ghent, Belgium; [2]Center for Sexology and Gender, Ghent University Hospital, Ghent, Belgium; [3]HOWEST University of Applied Sciences, Brugge, Belgium; [4]Ghent University Hospital, Center for Reproductive Medicine, Ghent, Belgium.

Objectives
Gender affirming hormonal and/or surgical care is associated with reduced fertility. Over the last years, the options for transgender persons to fulfill their child wish have increased. Previous research (mainly focused on transgender persons visiting health care professionals) on fertility in transgender persons assigned female at birth (AFAB) shows low fertility preservation utilization. Ideas and concerns of AFAB transgender persons regarding fertility preservation and child wish have never been reported in a large, non-clinical sample.
Materials and methods
An anonymous web-based survey on fertility and parenthood was conducted in Belgium in 2017, which invited all persons aged ≥ 16 years who identified themselves as trans* to participate. AFAB transgender people were selected for this substudy, which included transgender men (TM) and gender non binary (GNB) persons).
Results
The questionnaire was filled out by 426 participants, of which 172 (40.4%) AFAB (141; 68.8% TM and 64; 31.2% GNB). Sixty-one (35.5%) respondents had a current/future child wish. Child wish was fulfilled in 14 (8.1%) and inexistent in 64 persons (37.2%) (other categories: 19.2%). Child wish did not differ between TM and GNB persons ($P = 0.304$). In total, 130 AFAB persons (75.6%; TM: 99; 85.3% and GNB: 31; 55.4%) had previously sought medical help for their gender identity, of which 27 (20.8%) considered the loss of fertility due to the transitioning process undesirable and of which half (75; 57.7%) did not wish for fertility preservation. Of the total AFAB population, 14 people (10.3% - 79 missing, TM: 12; 12.9%, GNB: 2; 4.8%) had frozen germ cells. The top three reasons not to proceed with fertility preservation included not feeling the need for this (52; 54.2%), having to take hormones for follicle development (27; 28.1%) and the price for freezing germ cells (27; 28.1%). Barriers encountered for fulfilling the child wish included: the assumed difficulties in the adoption procedure (38; 41.3%), fear of discrimination against the child (35; 38.0%), fear of being discriminated as a transgender parent (30; 32.6%) and the price for using own genetic material (30; 32.6%).
Conclusion
Although child wish in our AFAB population is comparable to earlier research, we report lower fertility preservation utilization rates, reflecting the barriers transgender persons face when considering fertility options (including the costs and the need to postpone hormone therapy). GNB persons' opinions regarding fertility are assessed here for the first time, showing different needs for gender affirming treatment and fertility preservation.

Oral glucose tolerance test vs fasting plasma glucose determination for the assessment of glucose metabolism disturbances in women with Polycystic Ovary Syndrome

Andrés Ortiz[1], Elena Fernández[1], Francisco Alvarez[1], Elisa Santacruz[1], Marta Rosillo[2], Héctor Escobar[1] & Manuel Luque[1]
[1]Diabetes, Obesity and Human Reproduction Research Group, Hospital Universitario Ramón y Cajal & Universidad de Alcalá & Instituto Ramón y Cajal de Investigación Sanitaria (IRYCIS) & Centro de Investigación Biomédica en Red Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Madrid, Spain; [2]Department of Clinical Biochemistry, Hospital Universitario Ramón y Cajal, Madrid, Spain.

Background
Polycystic ovary syndrome (PCOS) is a common endocrine condition in women at reproductive age, in whom, glucose metabolism disturbances are commonly observed. In addition, overweight and obesity, especially visceral obesity, are more prevalent in PCOS women, which enhances the resistance to insulin action,

and as consequence, the onset of impaired glucose tolerance (IGT) and/or type 2 diabetes mellitus (T2DM). Clinical guidelines recommend oral glucose tolerance test (OGTT) in all PCOS patients as a screening tool; however, other authors suggest that this test should only be considered in case of obese patients, older than 40 years, and/or in hyperandrogenemic phenotypes.
Methods
Observational transversal study that included 379 PCOS women, recruited between 1998 – 2017, in whom a 75-gr OGTT was performed for the assessment of glucose metabolism disturbances. Diagnostic agreement was observed between fasting and 120-min glucose concentrations in all patients, and after stratifying them by BMI, age and circulating androgen concentrations.
Results
14% of the patients showed impaired fasting glucose while OGTT detected IGT in 16% of the cases, and T2DM in 2%. When fasting glucose was normal, OGTT detected IGT in 13% of patients, percentage that rose to 50% when fasting glucose was $\geq$100 mg/dl. OGTT detected IGT in 6% of lean patients, 15% when overweight, and 18% in obese women with normal fasting glucose. Hyperandrogenemic phenotypes presented IGT in 14% of the cases, while 10% of non-hyperandrogenemic women showed values $\geq$140 mg/dl. In younger patients ($<$40-year-old) with normal fasting glucose, IGT was present in 13% of them, conversely, in women older than 40 years, glucose concentrations $\geq$140 mg/dl after OGTT was observed in the 66% of the cases who previously had glucose values $\leq$100 mg/dl. Finally, in the 95% of patients with normal fasting glucose values, a normal response after OGTT was observed in younger, non-hyperandrogenemic patients with normal BMI.
Conclusions
OGTT is the method of choice for IGT screening and should be performed in all overweight/obese PCOS women. A fasting glucose determination could detect 95% of pre-diabetic conditions in lean, younger and non-hyperandrogenemic PCOS women.

Potential toxicity of cefuroxime therapy on rats' ovary

Amal Tahri[1], Manel Naifar[2], Kamilia Kssouda[1], Tarak Rebai[3], Fatma Ayedi[2], Mohamed Abid[4] & Zouheir Sahnoun[1]
[1]Research Unit of Pharmacology and Toxicology of Xenobiotics (UR12 ES13) and laboratory of pharmacology-Sfax Medicine School, Sfax, Tunisia; [2]Biochemistry laboratory, Habib Bourguiba Hospital, Sfax, Tunisia; [3]Research Unit of Pharmacology and Toxicology of Xenobiotics (UR12 ES13) and laboratory of histo-embryology, Sfax Medicine School, University of Sfax, Tunisia, Sfax, Tunisia; [4]Endocrinology Department, Hedi Chaker Hospital, Sfax, Tunisia.

The aim of the present study was to evaluate the potential toxicity of Cefuroxime (CFR), a second-generation cephalosporin antibiotic, on ovary of 'wistar' rats. A total of 32 adult female rats (12 weeks old) were intraperitoneally injected with CFR at a dose of 0, 30, 60 or 120 mg/kg, divided into two equal doses daily, for 7 days and sacrificed 24 h after the last dose. Biochemical assays showed significant reduction in oestradiol and progesterone levels in comparison with the control group ($P<0.05$). In addition, ovarian levels of reduced glutathione (GSH) and glutathione peroxidase (GPx) activity were decreased in the CFR-treated groups in a dose dependent manner ($P<0.05$). However, ovarian malondialdehyde (MDA), superoxide dismutase (SOD) and catalase (CAT) seemed not to be influenced by this drug. In consistance with these results, histological investigation showed that the structure of the ovary was perfectly conserved among CFR-treated rats. In conclusion, CFR induced oxidative stress and disrupt hormonal balance in the rats' ovaries without disturbance of normal structure of ovaries.

Polycystic ovary syndrome (PCOS) associates with dissatisfied body image and weight loss attempts at age 31 and 46 – A prospective, population-based Cohort study

Fia Sundelin[1], Emilia Koivuaho[1], Marjo-Riitta Järvelin[2,3,4], Jaana Laitinen[5], Juha S Tapanainen[1,6], Stephen Franks[7], Laure Morin-Papunen[1] & Terhi T Piltonen[1]
[1]Department of Obstetrics and Gynaecology, University of Oulu and Oulu University Hospital, Medical Research Center, PEDEGO Research Unit, Oulu, Finland; [2]Institute of Health Sciences, University of Oulu, Oulu, Finland; [3]Department of Children, Young People and Families, National Institute for Health and Welfare, Oulu, Finland; [4]Department of Epidemiology and Biostatistics, MRC-PHE Centre for Environment and Health, School of Public Health, Imperial College London, London, UK; [5]Finnish Institute of Occupational Health, Oulu, Finland; [6]Department of Obstetrics and Gynaecology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland; [7]Institute of Reproductive and Developmental Biology, Imperial College London, London, UK.

Introduction
Being overweight or obese are common characteristic of women affected by polycystic ovary syndrome (PCOS). Indeed, 50–70% of the women are obese and more likely to present with higher growth rate and obesity already from early childhood compared with women without the syndrome. Obesity predisposes women with PCOS to adverse metabolic outcomes such as metabolic syndrome, insulin resistance and diabetes. Recent studies have also revealed a high prevalence of eating disorders and altered body image among women with PCOS, however, population-based data and longitudinal follow-up studies on body image and weight loss attempts are lacking.
Materials and methods
The present study assessed the association of body image and weight loss attempts with PCOS in a prospective, general population-based follow-up birth cohort ($n=5889$ females). Postal questionnaires were sent at age 31 (81% answered) and 46 (72% answered). Women reporting both oligoamenorrhea and hirsutism at age 31 and/or PCO/PCOS-diagnosis by age 46 were considered as having PCOS ($N=280$) whereas asymptomatic women at age 31 or without PCO/PCOS-diagnosis by age 46 comprised a control group ($N=1573$). Questions on body image and weight loss attempts and clinical examinations were performed at ages 31 and 46.
Results
Women with PCOS were more dissatisfied with their weight compared with controls both at age 31 and 46 (72.3% vs 52.4%, $P<0.001$ and 86.4% vs 69.0%, $P<0.001$). PCOS was associated with risk for body dissatisfaction at age 31 and 46 (Odds ratio, OR 2.39, 95% confidential interval, CI [1.691–3.63] and 2.92[1.901–4.476]) and the association remained statistically significant after adjusting for BMI and depression and anxiety score (Hopkins Symptom Checklist-25, HSCL-25) (31 years: OR 1.70[1.026–2.808]) and 46 years: OR 2.67[1.372–5.183]). Women with PCOS were more likely to have weight loss attempts compared with controls at age 31 and 46 (47.1% vs 34.0%, $P=0.001$ and 62.8% vs 47.5%, $P<0.001$, respectively). In regression analysis PCOS associated with weight lost attempts independent of BMI. There was a significant but unexpected weak association between waist circumference (WC) and BMI with weight lost attempts in the whole female population (WC: OR 1.11 [1.093–1.119], respectively and BMI: OR 1.40 [1.351–1.444]).
Conclusions
Women with PCOS were more dissatisfied with their weight compared with controls and they were more likely to attempt to lose weight by age 46. As the differences between the groups were independent from BMI, further studies to elucidate the reasons for body dissatisfaction are warranted.

Subchronic exposure to kalach 360 SL-induced endocrine disruption in female ovaryrats

Latifa Hamdaoui[1], Manel Naifar[2], Fatma Rahmouni[1], Fatma Ayedi[2], Zouheir Sahnoun[3], Mohamed Abid[4] & Tarek Rebai[1]
[1]Histology-Embryology Laboratory, Sfax Faculty of Medicine, Sfax, Tunisia; [2]Unit of Research 'Molecular Bases of Human Diseases',12ES17 Sfax Medicine College, Sfax 3029, Tunisia; [3]Research Unit of Pharmacology and Toxicology of Xenobiotics (UR12 ES13) and Laboratory of Pharmacology-Sfax Medicine School, Sfax, Tunisia; [4]Endocrinology Department, Sfax, Tunisia.

Kalach 360 SL (KL), glyphosate (G) surfactant-based herbicides, is a systemic herbicide effective against weeds. It was applied in agriculture in Tunisia and

throughout the world, which can represent a risk to non-target organisms. The aim of this study was to investigate the morphological and biochemical aspects of ovary injury after exposure to KL. Female Wistar rats were divided into three groups: group 1 was used as a control; group 2 orally received 0.07 ml of KL, (126 mg of G/kg) and group 3 orally received 0.175 ml of KL (315 mg of G/kg) each day for 60 days. The subchronic exposure of KL induces impaired folliculogenesis, ovary development, decreased oestrogen secretion, promoted oxidative stress and impairments of ovary histological aspects. Histological finding shows necrosis cell, vacuolisation of follicles, dissociated oocytes and granulosa cell, associated with several atretic follicles. We conclude that KL induces endocrine disruption and ovary damage in female rats.

Acute and delayed responses of steroidal hormones after a resistance training session: time-of-day effects.

Manel Naifar[1], Mouna Turki[1], Achraf Ammar[2], Faten Haj Kacem[3], Mohamed Abid[3] & Fatma Ayedi[1]
[1]Biochemistry Laboratory, Habib Bourguiba Hospital, Sfax, Tunisia; [2]Research Unit, Education, Motricity, Sport and health, UR15JS01, High Institute of Sport and Physical Education of Sfax, Sfax, Tunisia; [3]Endocrinology Department, Sfax, Tunisia.

The present study aimed to investigate the effect of time-of-days (TOD) on some biochemical and hormonal responses after resistance training sessions.
Methods
Ten trained subjects performed three resistance-training-sessions at 0700 h, 1300 h and 1700 h. Each training-session included six upper and lower body resistance exercises with 3×10 repetitions. Blood lactate (Lac), creatine kinase (CK), lactate dehydrogenase (LDH), cortisol (C) and testosterone (T) were collected at rest, 3min and 48h after each-session.
Results
At rest, steroidal hormones were higher in the morning compared to the evening ($P<0.01$), whereas, no significant TOD effect on Lac, CK or LDH was observed. 3min after training, whatever the TOD, Lac, CK and T increased significantly ($P<0.001$). However, a significant decrease in C and a significant increase of T/C ratio were registered only after morning training. 3 min and even 48 h after training, the diurnal variations (i.e. morning to evening) of CK and C have been altered with higher early evening values of CK and lower one of C; whereas, T, Lac and LDH conserved their resting diurnal variation. Additionally, 48 h after the morning session, CK and T/C ratio remained elevated compared to the baseline levels.
Conclusions
In conclusion, resistance exercises soliciting both lower and upper limbs seems to alter the diurnal variation of CK and Cortisol, to enhance the morning anabolism/catabolism status and to produce more favorable environment for muscular adaptation up to 48 h post-training.

Recombinant FSH and biosimilars result in different intracellular signaling

Laura Riccetti[1], Samantha Sperduti[1], Clara Lazzaretti[1], Simonetta Tagliavini[2], Manuela Simoni[1,3,4] & Livio Casarini[1,3]
[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Department of Laboratory Medicine and Pathological Anatomy, Azienda USL, NOCSAE, Modena, Italy; [3]Center for Genomic Research, University of Modena and Reggio Emilia, Modena, Italy; [4]Department of Medicine, Endocrinology, Metabolism and Geriatrics, Azienda Ospedaliero-Universitaria di Modena, NOCSAE, Modena, Italy.

Introduction
Follicle-stimulating hormone (FSH) biosimilars, differing for source cell and glycosylation pattern, are commercially available for therapy of hypogonadism and assisted reproduction techniques (ART). Although these molecules are commonly used in clinical practice, comparison of their action *in vitro* was poorly investigated.
Aim
The aim of the study is to compare recombinant FSH- and biosimilars-induced cell response *in vitro*.
Material and methods
Different batches of FSH and biosimilars were used, i.e. recombinant FSH Gonal-F® (Merck KGaA, Darmstadt, Germany), Bemfola® 150, 300 and 450 (Finox Biotech, Kirchberg, Switzerland) and Ovaleap® 450 and 900 (Teva Pharmaceutical Industries, Basel, Switzerland). Human primary granulosa lutein cells (hGLC), as well as FSH receptor (FSHR)-transfected HEK293 cells were stimulated by increasing doses of FSH or biosimilar (1-100 nM range). Intracellular cAMP and Ca^{2+} production as well as β-arrestin two recruitment were evaluated by BRET. Moreover, CREB and ERK phosphorylation was evaluated by Western blotting analysis. Finally, 8- and 24-h progesterone and estradiol synthesis were investigated by immunoassay.
Results
While no different cAMP and β-arrestin two recruitment were detected in FSHR-transfected HEK293 cells (cAMP EC50 range = 6 ± 0.09 – 19 ± 0.07 ng/ml; β-arrestin two EC50 range = 72 ± 0.27 – 489 ± 0.26 ng/ml; Mann-Whitney's *U* test; $P>0.05$; $n=4$), Ovaleap® induced lower levels of pCREB and pERK1/2 activation than other biosimilars in hGLC (Mann-Whitney's *U* test; $P<0.05$; $n=4$). Kinetics analysis revealed no intracellular Ca2+ increase upon treatment by 4.4 μg/ml Ovaleap® and Bemfola® (Mann-Whitney's *U* test; $P<0.05$; $n=4$), while treatment of FSHR-transfected HEK293 cells by 4.4 μg/ml Gonal-F® rapidly induced intracellular Ca^{2+} peak. In hGLC, FSH and biosimilars induced both 8- and 24-h progesterone and estradiol synthesis, but no differences were found between the EC50s and plateau levels ($n=4$).
Discussion
Preparation-specific intracellular signaling patterns were activated by recombinant FSH and biosimilars, but the downstream steroid synthesis was similar. Especially, biosimilars failed to induce intracellular Ca2+ increase.
Conclusions
Recombinant and biosimilar drugs used in clinical practice as equivalent, are linked to specific intracellular signaling in vitro. Results may be relevant for their use *in vivo*.

Two cases of Mayer-Rokitansky-Küster-Hauser syndrome type 2 with bilateral inguinal hernia

Gülay Karagüzel[1] & Hatice S Cömert[2]
[1]Karadeniz Technical University, School of Medicine, Department of Pediatric Endocrinology, Trabzon, Turkey; [2]Karadeniz Technical University, School of Medicine, Department of Pediatric Surgery, Trabzon, Turkey.

Background
Mayer-Rokitansky-Küster-Hauser syndrome (MRKHS) is defined as aplasia or hypoplasia of the uterus and vagina in female with normal 46,XX karyotype. Isolated congenital absence of the uterus and vagina is classified as MRKHS type 1 (typical form). If it is associated with at least one concomitant congenital malformation that mainly affect the renal and skeletal system, is classified as MRKHS type 2 (atypical form). We report here the cases of MRKH type 2 with inguinal hernia in a child and an adolescent in order to pay attention concomitant malformations for early diagnosis in childhood before the onset of amenorrhea.
Cases
Patient 1: 5-year-old girl was referred to our clinic for the absence of vaginal orifis. She had a history of inguinal hernia repair and operated for atrial and ventricular septal defect in infancy. She had also vesicoureteral reflux. Pelvic ultrasonography and magnetic resonance image (MRI) showed absence of the uterus and vagina. Lumbarization S1 was established as a skeletal anomaly. Patient 2: 15-year-old girl who presented a primary amenorrhea studied with transabdominal and pelvic ultrasonography and pelvic MRI, which demonstrated a complete agenesis of uterus, a functional cyst in the right ovary, and a left pelvic ectopic kidney. She had not a major skeletal anomalies. She underwent bilateral inguinal hernioplasty.
Conclusions
The concomitant malformations contribute to clinical profile heterogeneity of women with MRKHS. Our cases are to show the importance of further investigation in cases of inguinal hernia to diagnose other concomitant anomalies to establish earlier that patients have MRKHS type 2.

Mayer Rokitansky Küster Hauser syndrome: a case report

Bercem Aycicek, Ümit Çavdar, Nilüfer Özdemir Kutbay & Halit Diri
Gazi Yasargıl Education and Research Hospital, Diyarbakır, Turkey.

Objective
Mayer-Rokitansky-Küster-Hauser syndrome (MRKH) is a very rare congenital anomaly characterised by vaginal agenesis and a spectrum of different genitourinary tract anomalies. Typical form of this syndrome is characterised by congenital absence of the uterus and upper 2/3 vagina with normal ovaries and fallopian tubes and atypical form of the syndrome is associated with anomalies of the ovaries and fallopian tubes and renal anomalies.
Case report
18 years old patient with symptom of primary amenorrhea was admitted to our hospital. She developed clinical signs of puberty at 13 years old. Physical examination showed an average height and weight (160 cm/54 kilos) and normal breast examination (Tanner 5) and normal axillary and pubic hair. Normal clitoris, labia major and minor were also noted. The USG showed an ectopic right kidney with rotation anomaly and ectopic left kidney which are located in the pelvis, and uterus and ovaries were not found. Biochemical analyses were in normal limit ranges. Hormone profile included Follicular stimulating hormone (4.2 mUI/ml), Estradiol (98 pg/ml) and testosterone (0.2 ng/ml), which were all normal, indicating normal function of the hypothalamic-pituitary-ovarian axis. The karyotype was normal (46, XX). Because of the discrepancy between the clinical and laboratory findings and ultrasound examination, MRI was performed, and confirmed that right and left ectopic kidney and the absence of uterus, nevertheless could not show ovaries.
Conclusion
MRKH atypical form is should be in mind if there are features of its history, physical examination, US and MRI evaluations in a patient with primary amenorrhea.

Current situation of adult patients with Turner syndrome in Tenerife (Spain)Current situation of adult patients with Turner syndrome in Tenerife (Spain)

Elena Márquez Mesa, José Gregorio Oliva García, José Manuel Rial Rodríguez, Pilar Olvera Márquez & María Teresa Herrera Arranz
Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Spain.

Introduction/ objectives
Turner syndrome (TS) comprises a group of sex chromosomal abnormalities of heterogeneous clinical presentation. During the infant period, the pediatric endocrinologist coordinates their follow-up and it is important to ensure its continuation during the adult stage. The objective of this study is to know the current clinical situation, occupational, educational, social and medical monitoring of patients affected TS in Tenerife.
Material and methods
Retrospective study of the clinical parameters evaluated during the follow-up in consultation of the patients affected with TS in our center ($n=19$). Telephone interview in which demographic data, employment and educational status, current health and medical follow-up were asked.
Results
Age 36.3 ± 9.2 years. Karyotype: mosaicism (47.4%); 45X0 (52.6%). All patients were treated with growth hormone (GH): age of onset 10.1 ± 4.1 years, dose 40.2 ± 9.5 μg/kg per day; duration 6.5 ± 2.7 years, bone age of suspension 14.7 ± 0.7 years. Final adult size of 151 ± 7.9 cm. They received treatment with oxandrolone 36.8%. Pubertal induction was performed in 94.7% of patients: age of onset 11.9 ± 0.8 years, bone age of onset 13.4 ± 1.9 years, age of menarche 15.6 ± 2.7 years. Most common disorder: hypogonadism (94.7%), osteoporosis/ osteopenia (52.6%), hypothyroidism (52.6%), obesity (42.1%), dyslipidemia (42.1%), nephrolithiasis (26.3%), hypertension (21.1%), otitis of recurrence (21.1%), congenital lymphedema (21.1%). Clinical follow-up: endocrinology (47.4%), gynecology (31.6%), primary care (21%). Educational level: primary (23%), secondary/ vocational training (38.5%), university (38.5%). Occupationally active (92.3%). Residence: family (61.5%), couple (23.1%), single (15.4%). Couple currently (23.1%) and offspring (10.5%). Lifestyle: ex-smokers (21.1%), exercise (30.8%).
Conclusions
The results obtained in our sample of adult final height in patients treated with GH do not differ from the results described in other series. The doses of GH, duration of treatment and age of pubertal induction are adapted to the guidelines of management of patients with TS. The most prevalent pathology is hypogonadism followed by osteoporosis and hypothyroidism. The follow-up is heterogeneous. There is a greater tendency towards parental dependence and absence of a partner.

Primary amenorrhea due to gonadal gysgenesis in a girl with karyotype 46,XX

Dimitra Pappa, Pinelopi Thoda, Anastasia - Konstantina Sakali, Eleni Georgiou, Ioannis Gountios & Alexandra Bargiota
Department of Endocrinology and Metabolic Diseases, University Hospital of Larissa, Larissa, Greece.

Introduction
Gonadal dysgenesis is a rare cause of primary amenorrhoea, and refers to a number of conditions in which gonadal development is abnormal leading to streak or hypoplastic gonads. We present a rare case of a girl with primary amenorrhea, tall stature, gonadal dysgenesis and karyotype 46,XX. A 15 years old girl with primary amenorrhoea referred to our department for futher investigation. On clinical examination she was tall (height 1.74 m), her weight was 76 kg and BMI 25,10. She had normal intelligence and appearance with no dysmorphic features. External genitalia were normal but was at a prepubertal stage of sexual development. Laboratory investigations revealed hypergonadotrophic hypogonadism (FSH = 77.4 mIU/ml, LH = 42.32 mIU/ml, $E_2=5$ pg/ml), subclinical hypothyroidism (TSH = 5.1 μIU/ml) and hypoplastic uterous and small right ovary on an abdominal ultrasound. Bone age was delayed at 14 years and the karyotype was 46, XX. Hormonal replacement therapy was initiated in the begining with 17β-estradiol alone and then in combination with norethisterone. After nine months on treatment she developed breast and pubic hair (Tanner III and III-IV respectively) and an increased size of uterous and right ovary and visualization of the left ovarian tissue was observed on MRI Pelvis.
Conclusions
46,XX gonadal dysgenesis is a rare cause of primary amenorrhoea. It is important to be diagnosed as early as possible so that HRT treatment begins promptly. The kind of hormone replacement depends on the time of diagnosis and the status of secondary sexual characteristics.

Hormonal and metabolic differences between hyperandrogenic women with PCOS

Ivana Bozic-Antic[1], Dusan Ilic[1], Jelica Bjekic-Macut[2], Danijela Vojnovic-Milutinovic[3], Olivera Stanojlovic[4], Bojana Popovic[1], Tamara Bogavac[1], Tatjana Isailovic[1], Valentina Elezovic-Kovacevic[1], Sanja Ognjanovic[1] & Djuro Macut[1]
[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinial Center of Serbia, Belgrade, Serbia; [2]CHC Bezanijska kosa, Belgrade, Serbia; [3]IBISS, University of Belgrade, Belgrade, Serbia; [4]Institute of Physiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction
Hyperandrogenism (HA) is frequent but not universal characteristic in women with polycistic ovary syndrome (PCOS). According to the ESHRE/ASRM definition, hyperandrogenism criterion could be clinical (hirsutism) and/or biochemical (hiperandrogenemia). The aim of this study was to analyze metabolic and hormonal characteristics among women with PCOS with different forms of hyperandrogenism.
Methods
We analyzed 458 women with PCOS diagnosed using ESHRE/ASRM criteria and divided into three groups: 1) with clinical HA only (PCOS-CHA:N = 67, age: 26.7 ± 5.6 years, BMI: 23.6 ± 5.2 kg/m^2), 2) with biochemical HA only (PCOS-BHA:N = 151, age: 25.5 ± 5.3 years, BMI: 24.5 ± 6.5 kg/m^2), 3) with both clinical and biochemical HA (PCOS-CBHA:N = 240, age: 25.0 ± 5.2 years, BMI: 26.4 ± 6.2 kg/m^2), and 104 healthy controls (age:29.2 ± 5.8 years, BMI: 25.4 ± 16.8 kg/m^2). CHA was defined as Ferriman-Gallwey score ≥ 8, BHA as presence of FAI ≥ 6% and/or testososterone > 2 nmol/l. We measured fasting glucose (FG), insulin, lipids, FSH, LH, testosterone, SHBG, androstenedione, estradiol, DHEAS and 17OHprogesterone, while HOMA-IR and FAI were calculated. Differences between-groups were age and BMI adjusted.

Results
In comparison to controls, PCOS-BHA and PCOS-CBHA had higher total cholesterol (TC) ($P=0.031$ and $P=0.001$, respectively), LH ($P<0.001$ and $P<0.001$, respectively), DHEAS (both $P<0.001$), all PCOS groups had higher triglycerides ($P=0.006$, $P=0.004$, $P=0.001$ respectively), PCOS-CBHA had higher 17Ohprogesterone ($P=0.012$) and PCOS-CHA had higher androstenedione ($P=0.027$). In comparison to PCOS-CHA, PCOS-BHA and PCOS-CBHA had higher LH ($P=0.001$ and $P=0.026$, respectively) and PCOS-CBHA had higher 17OHprogesterone ($P=0.030$) and TC ($P=0.001$). There were no between-groups differences in HOMA-IR, FSH and estradiol. Significant correlations was found among CHA between androstenedione and HOMA-IR ($r=0.33$, $P=0.04$).
Conclusions
PCOS with different forms of hyperandrogenism present with different cardiometabolic risk factors and different hormone profiles. Women with hirsutism and without hyperandrogenemia have less severe metabolic and hormonal status.

Turner Syndrome and Abnormal liver function

Wajdi Safi[1], Dhouha Ben Saleh[1], Dorra Ghorbel[1], Fatma Mnif[1], Mouna Mnif Feki[1], Neila Belghith[2], Thouraya Kammoun[3], Mongia Hachicha[3] & Mohamed Abid[1]
[1]Endocrinology Department, Hedi Chaker Hospital, Sfax, Tunisia; [2]Human genetic laboratory, Hedi Chaker Hospital, Sfax, Tunisia; [3]Department of Pediatrics, Hedi Chaker Hospital, Sfax, Tunisia.

Introduction
Turner Syndrome (TS) is known to be associated with congenital malformations and a greater incidence of autoimmune disease. Many others organs systems are also affected to varying degrees and at different stages of life such as abnormal liver function. This disease is often detected on routine investigation and is not accompanied by signs or symptoms of liver disease. We report the case of a young Turnerian who presents a disruption of his hepatic balance with a strictly normal etiological investigation.
Case
A 10 years old girl was referred for short stature. Her past medical history was unremarkable. On examination, she had a height of 118 cm (-<3 S.D.). She had a female phenotype with female external genitalia (Tanner stage: stage 1). It presents a universal alopecia. Examination of cardiovascular, respiratory and neurological systems was normal. Hormonal investigations revealed hypergonadotropic hypogonadism with FSH level of 181.4 mIU/ml, LH level of 41 mIU/ml and a estradiol level <9 pg/ml. Pelvic ultrasonography showed a hypoplastic Uterus without visualization of the ovaries. Cytogenetic analysis of peripheral blood revealed a karyotype with 45 chromosome with one X chromosome missing (45, X). And the FISH (*fluorescence in situ hybridization*) analysis showing hybridization of x chromosome centromere probe to normal X and small ring X chromosome in a 46X,r(X) metaphase. Laboratory investigations revealed normal hematological and biochemical parameters except for Alanine aminotransferase (ALT) (87UI/l>45ui/l) and Alkaline phosphatase (AP) (819ui/l> 200ui/l), γ-Glutamyl transferase and serum bilirubin level were normal. Hepatotoxic medications and alcohol was ruled out and we have completed by abdominal ultrasound which showed no hepatic impairment. Viral hepatitis was suspected but the serologies were negative. Otherwise, autoimmune hepatitis was eliminated as the immunological survey showed negative anti-mitochondrial, anti-smooth muscle and anti-LKM1 antibodies. Finally the patient is treated with Ursodeoxycholic acid therapy. The evolution was marked by an improvement in liver function ALT (32ui/l), AST (40ui/l), AP (220 ui/l).
Conclusion
The incidence of biochemical liver abnormalities is frequent and should be investigated in any patient with TS. It appears that this is a benign condition which does not seem to reflect any liver dysfunction. The estrogen-progestin replacement therapy; should not be stopped because of its beneficial effects on the overall quality of life of these patients. Liver involvement in TS patients necessitates appropriate management and follow-up.

Association of hormonal and metabolic status with carotid intima-media thickness in women with polycystic ovary syndrome

Jelica Bjekic-Macut[1], Ivana Bozic-Antic[2], Snjezana Erceg[2], Milorad Civcic[2], Dusan Ilic[2], Danijela Vojnovic-Milutinovic[3], Olivera Stanojlovic[4] & Djuro Macut[2]
[1]CHC Bezanijska Kosa, Belgrade, Serbia; [2]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinial Center of Serbia, Belgrade, Serbia; [3]IBISS, University of Belgrade, Belgrade, Serbia; [4]Institute of Physiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction
Women with polycystic ovary syndrome (PCOS) have numerous risk factors that lead to higher risk for cardiovascular diseases (CVD) and stroke. Measurement of carotid intima-media thickness (CIMT) is a marker of CVD.
Methods
We analyzed 399 women with PCOS diagnosed using ESHRE/ASRM criteria (age: 25.5±5.1 years, BMI: 24.9±6.2 kg/m^2), and 82 BMI-matched healthy controls (age 29.2±5.9 years, BMI 25.3±8.6 kg/m^2). In follicular phase of menstrual cycle we determined fasting serum fasting glucose (FG), insulin, lipids, CRP, testosterone, SHBG, DHEAS, 17OH-progesterone, androstenedion, estradiol, TSH, fT4, CIMT and blood pressure (BP). HOMA and FAI were calculated. Differencies between groups were age adjusted.
Results
PCOS had higher total cholesterol-TC ($P=0.02$), LDL-C ($P=0.03$), triglycerides ($P=0.02$), HOMA-IR ($P=0.04$), testosterone ($P<0.001$), FAI ($P<0.001$), DHEAS ($P<0.001$), androstenedione ($P=0.02$), 17Ohprogesterone ($P=0.005$), systolic and diastolic BP ($P=0.004$ and $P=0.001$, respectively), and lower HDL-C ($P=0.02$), SHBG($P<0.001$) and estradiol ($P=0.04$). There were no between-group differences in CIMT, CRP, glucose, TSH, fT4. Significant correlations among PCOS were obtained for CIMT and BMI ($r=0.10$, $P=0.04$), triglycerides ($r=0.11$, $P=0.33$), estradiol ($r=-0.14$, $P=0.013$), systolic and diastolic BP ($r=0.13$, $P=0.01$ and $r=0.18$, $P=0.001$, respectively). There were no correlations between androgens and CIMT among PCOS.
Conclusions
Although women with PCOS have higher CVD risk, we did not show differences in CMIT in our PCOS women in comparison to respective BMI matched controls. Overall, there are no associations between CIMT and androgen status or insulin resistance in our examined group of PCOS women.

Oxidative stress markers in women with polycystic ovary syndrome without insulin resistance

Reveka Gyftaki[1], Sofia Gougoura[2], Nikolaos Kalogeris[1], Vasiliki Loi[1], George Koukoulis[2] & Andromachi Vryonidou[1]
[1]Department of Endocrinology Diabetes and Metabolism General Hospital Korgialenio-Benakio, Athens, Greece; [2]Department of Endocrinology Diabetes and Metabolism Henry Dunant Hospital Center, Athens, Greece.

Introduction
Polycystic ovary syndrome (PCOS) is usually accompanied by abdominal obesity and insulin resistance which are related with low-grade chronic inflammation, as evidenced by elevation of multiple markers of inflammation, among which is oxidative stress. However, as far as oxidative stress presence, the existing data are limited. The purpose of this study was the investigation of several oxidative stress markers in women with PCOS without insulin resistance.
Material and Methods
15 patients with PCOS according to NIH criteria (1990) and 10 women matched for age and BMI, with normal cycles and without clinical or biochemical hyperandrogenemia were studied. Somatometric parameters were recorded and androgen, SHBG, insulin and blood glucose levels were measured after an overnight fast. Free androgen index (FAI) and homeostatic model assessment of insulin resistance (HOMA-IR) were calculated. Among oxidative stress markers, catalase (CAT) and superoxide dismutase (SOD) activity were determined, total antioxidant capacity (TAC), glutathione levels (GSH), lipid peroxidation by thiobarbituric acid reactive substances (TBARS) and nitrogen monoxide (NOx) levels were assessed in peripheral blood. Statistical analysis was performed with logistic SPSS 16.0.
Results
Patients and controls were comparable regarding age, BMI (22.6±2.8 vs 20.5± 2.2 kg/m^2, $P>0.05$) and the level of insulin resistance as expressed by HOMA-IR (2.09±1.0 vs 1.6±0.5, $P>0.05$). As expected, androgen levels were higher while sex hormone-binding globulin levels were lower in patients with PCOS,

compared to control group ($P<0.01$). Oxidative stress as evidenced by lipid peroxidation and TAC was not different in women with PCOS compared to controls. However, a significant increase in CAT and SOD activity was observed, indicating an inner stress- counterbalanced effect ($P<0.01$). CAT activity was positively correlated with total testosterone ($P=0.019$) and D4-androstendione ($P=0.008$) levels, while SOD activity was positively correlated with total testosterone ($P<0.001$), D4-androstendione ($P=0.001$), DHEA-S ($P=0.023$) and glucose ($P=0.02$) levels and negatively with SHBG ($P=0.001$) levels.
Conclusions
These preliminary results show that, oxidative stress is not increased in women with PCOS without insulin resistance, probably due to its sufficient counter-balance by the inner antioxidant response. Insulin resistance may be a factor that is crucially involved in the aggravation of pro-inflammatory oxidative stress.

Thyroid axis in women with polycystic ovary syndrome

Tamara Bogavac[1], Ivana Bozic-Antic[1], Dusan Ilic[1], Jelica Bjekic-Macut[2], Danijela Vojnovic-Milutinovic[3], Olivera Stanojlovic[4], Bojana Popovic[1], Tatjana Isailovic[1], Valentina Elezovic-Kovacevic[1], Sanja Ognjanovic[1] & Djuro Macut[1]
[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinial Center of Serbia, Belgrade, Serbia; [2]CHC Bezanijska kosa, Belgrade, Serbia; [3]IBISS, University of Belgrade, Belgrade, Serbia; [4]Institute of Physiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction
Women with polycystic ovary syndrome (PCOS) often have other comorbidities and one of them is Hashimoto thyroiditis (HT). The aim of the sudy was to analyze metabolic and hormonal status among women with PCOS, with and without HT.
Methods
We analyzed 167 women with PCOS diagnosed using ESHRE/ASRM criteria divided on PCOS with HT ($PCOS_{with}HT$, $N=27$, age: 25.8 ± 5.2 years, BMI: 28.5 ± 7.3 kg/m^2) and without HT ($PCOS_{no}HT$, $N=140$, age: 25.1 ± 4.5 years, BMI: 24.5 ± 5.9 kg/m^2) and also 48 healthy controls (HC) divided on HC with HT (HC_{with} HT, $N=10$, age 32.6 ± 5.4 years, BMI 23.1 ± 3.8 kg/m^2) and HC without HT ($HC_{no}HT$, age 29.7 ± 6.3 years, BMI 23.6 ± 6.2 kg/m^2). In follicular phase of menstrual cycle we determined fasting serum glucose (FG), insulin, lipids, CRP, testosterone, SHBG, DHEAS, 17OH-progesterone, androstenedion, estradiol, TSH, fT4, fT3. HOMA and FAI were calculated. Differencies between groups were age-adjusted.
Results
$PCOS_{with}HT$ had highest BMI than all other groups (28.7 ± 1.2 kg/m^2) and significantly differed from all other groups: vs. $PCOS_{no}HT$ (24.7 ± 0.5 kg/m^2), $P=0.02$; vs. $HC_{with}HT$ (23.1 ± 3.8 kg/m^2), $P=0.02$; vs. $HC_{no}HT$ (23.7 ± 6.2 kg/m^2). There was no difference in any other measured parameter between $PCOS_{with}HT$ and $PCOS_{no}$ HT.
Conclusions
Women with PCOS and HT are more obese than PCOS without HT. However other metabolic and hormonal factors do not differ between examined groups of PCOS women.

Determinants of fatty liver disease in adult women with Turner syndrome

Antoinette Cameron-Pimblett[1,2], Gerard Conway[1,2], Melanie Davis[2] & Clementine De La Rosa[2]
[1]University College London, London, UK; [2]University College London Hospital, London, UK.

Introduction
Turner syndrome (TS), defined by the loss of X chromosome material, affecting 1/2500 females born. Associated with TS are a variety of comorbidities such as obesity and fatty liver disease, many of which increase in prevalence with age. The Turner Syndrome Life Course Project at UCLH has collected data on over 800 women over the last 20 years. Annual health surveillance in our adult TS clinic allows for screening for liver enzymes, such as Alanine Transaminase (ALT), Alkanine Phosphatase (AlKP) and Gamma-glutamyl transferase (GGT). Persistent elevation of liver enzymes may represent a risk for cirrhosis. Here we report regards to on the determinants of fatty liver disease in women with TS.
Methods
An analysis of 8,659 clinic visits from 829 women with TS and liver enzymes; ALT, AlKP and GGT. Factors affecting liver enzymes were examined such as hormone replacement therapy (HRT), age at visit and BMI. HRT was categorised as those receiving either *oral* oestrogens (oral contraceptive, oestradiol valerate & conjugated equine) or *transdermal* oestradiol. We assessed interactions between variables and liver enzyme parameters using a multiple regression. The first column of results shows the percentage of enzyme measurements that were above the reference range. Results for partial correlation coefficients on multiple linear regression are shown in the adjacent three columns with each enzyme tested separately as the dependent variable (* represents $P<0.05$).

	Number (%) values above the reference	Age	BMI	HRT (oral vs transdermal)
ALT	1494/4420 (43.8%)	0.17*	0.20*	0.08*
AlKP	1269/4603 (27.6%)	0.02	0.14*	0.06*
GGT	1080/2163 (49.9%)	0.31*	0.27*	0.03

Conclusions
BMI was the greatest influence on all liver enzymes with age showing a positive influence on ALT and GGT. With regard to oestrogen use, oral oestrogen was associated with lower enzyme levels compared to transdermal oestradiol as a weak independent influence on ALT and AlkP. Weight loss is a priority for adult women with TS and raised liver enzyme although extent of reversibility is get to be proven.

Is it all about deiodinase after all? Effects of correction normal high tsh in women with infertility on pregnacy outcome

Dusan Biukovic
Centre for Thyroid Gland, Banja Luka, Bosnia and Herzegovina.

Introduction
Progress in the field of infertility research and an increasing number of In Vitro Fertilizations (IVF) with intensive approach to sterility has opened new doubts about the impact of thyroid gland in the conception as well as pregnancy outcomes. Standard access to the levels of TSH and interpretation values as subclinical or clinical forms of hypothyroidism in this population has not proved to be quite correct.After the IVF guidelinesses begun to emphasize the amount of TSH of 2.5 mIU / l as the preferred upper limit for IVF, often have changes in thyrologists approach to this problem. The appearance of new organ (placenta) and intensive deiodinase activity is changing thyroid hormone metabolism.
Objective
Prove that correction of normal-high TSH values from 2.5 to 6.0 mIU /l with levothyroxine to below 2.5 mIU /l has an impact on the outcome of pregnancy. Discuss different mechanisms that might affect pregnancy outcome.
Materials and methods
Retrospectively in the last 8 years, a group of 60 patients who were at least two years in marriage and with the diagnosis of infertility, previously not given birth, were subjected to various procedures (VTO, insemination, etc.) and investigation group has not been previously treated for therapy thyroid gland diseases. From this group we excluded women with known tendency to thrombophilya and proven hyperprolactinemia. Patients had initial TSH levels (TSH1) of 2.5 to 6.0 mIU /l and normal T4 values, were treated with levothyroxine to TSH suppression below 2.5 mIU/l. Determined last TSH (TSH2) before pregnancy. During pregnancy, all patients maintained TSH levels below 2.5 mIU /l. Followed by the outcome of the pregnancy, which is regarded as: delivered, miscarriage, no pregnancy.
Results
Forty-three patients (71.6%) delivered successfully, 13 patients (21.6%) got pregnant but had a miscarriage, 4 had not got pregnant (6.66%) p(TSH1)=0,751 , p(TSH2)=0,580
Conclusion
During the follow-up of this group of respondents, obtained a high number of successfully conceived and delivered pregnancies (71.6%), the number of spontaneous miscarriages was discreetly higher than in the general population. It might happened that changes in deiodinase activity are the reason for these results or some other mechanism (TSH independent).

A case of 17 alpha-hydroxylase deficiency in a 46,XX patient: but where are Mullerian ducts?

Rezgani Imene, Ines Kamoun, Maroua Bennour, Olfa Hentati & Leila Ben Salem
Endocrinology and Nutrition Departement, National Nutrition Institute, Tunis, Tunisia.

Introduction
The 17 α-hydroxylase deficiency is a rare form of congenital adrenal hyperplasia. It is characterized by amenorrhea, impuberism, hypertension and hypokalemia. We report a case of 17α-hydroxylase deficiency in a patient with a 46,XX karyotype, which contrasted with the absence of Mullerian duct.
Case report
An18-year-old female was referred for primary amenorrhea. Her parents were cousins. Her sister, who had the same features, died suddenly at the age of 25. Physical examination showed hypertension (160/90 mm Hg), impuberism (S1P1 stage of Tanner classification) and normal female pre-pubertal external genitalia. The karyotype was 46, XX. Biological evaluation showed hypokalemia, primary hyperaldosteronism and low levels of all steroid hormones requiring α-hydroxylation (cortisol, 17α-hydroxy progesterone, dehydroepiandrosterone sulfate, 11 desoxycortisol, Δ4 androstenedione and testosterone). Thus, the diagnosis of 17 α-hydroxylase deficiency has been suspected. However, ultrasound and pelvic MRI did not show gonads or Mullerian ducts, which did not fit with the 46, XX karyotype. The patient was treated with hydrocortisone and spironolactone, with normalization of blood pressure and kaliemia. Estrogen replacement therapy was started to induce pubertal development. The genetic study is planned.
Conclusion
In contrast to other forms of congenital adrenal hyperplasia, the diagnosis of 17 α-hydroxylase deficiency is usually delayed to adulthood. It must be suspected in all young hypertensive patients with hypokalemia and amenorrhea. We have found no previous similar case with gonadal agenesis and absent Mullerian ducts in 46,XX subjects with 17 α-hydroxylase deficiency. Further exploration may be needed to explain this association.

Breast cancer in transgender persons receiving gender affirming hormone treatment: results of a nationwide cohort study

Christel JM de Blok[1], Chantal M. Wiepjes[1], Nienke M. Nota[1], Klaartje van Engelen[2], Muriel A. Adank[3], Koen M.A. Dreijerink[1], Ellis Barbé[4], Inge R.H.M. Konings[5] & Martin den Heijer[1]
[1]Department of Endocrinology and Center of Expertise on Gender Dysphoria, VU University Medical Center, Amsterdam, Netherlands; [2]Department of Clinical Genetics, VU University Medical Center, Amsterdam, Netherlands; [3]Department of Clinical Genetics, Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [4]Department of Pathology, VU University Medical Center, Amsterdam, Netherlands; [5]Department of Oncology, VU University Medical Center, Amsterdam, Netherlands.

Background
Transpersons can receive gender affirming hormone therapy (HT) to induce physical changes. Little is known about the effect of HT on breast cancer (BC) risk.
Objectives
To study the prevalence and characteristics of BC in transpersons with HT and to compare this prevalence with the general Dutch male and female population.
Methods
Adult transpersons who were seen after 1991 and started HT in the VUmc were included. This cohort was linked in August 2017 to the nationwide PALGA database, which registers histopathology and cytopathology in the Netherlands. Information about the date of diagnosis, type of BC, and hormone receptor status was retrieved.
Results
2,567 transwomen (median age at start of HT 30 years, inter quartile range (IQR) 23-41) and 1,324 transmen (median age at start of HT 23 years, IQR 19-31) were included with a follow-up time of 22,576 and 10,109 person-years, respectively. In transwomen, 18 BC cases were identified, while 72 BC cases (based on Dutch female reference rates) and 0.4 cases (based on Dutch male reference rates) were expected. In transmen, 4 cases were identified, while 21 and 0.1 cases were expected, respectively. Three transmen were diagnosed with BC several years after mastectomy. The median age at diagnosis was 51 years (range 30-73) in transwomen and 47 years (range 35-59) in transmen, which is lower than the average 61 years in the female reference population. Median number of years of HT before BC diagnosis was 222 months (range 79-490) in transwomen and 176 months (range 23-199) in transmen. In both groups, the most prevalent type of BC was ductal carcinoma, with 67% and 75%, respectively. In transwomen, 80% of the tumors were estrogen receptor positive (ER+), 67% progesterone receptor positive (PR+) and 7% human epidermal growth factor receptor-2 positive (HER2/neu+). In transmen, 50% was ER+, 50% PR+, and 25% HER2/neu+.
Conclusions
This study showed an increased risk of BC compared with the Dutch male reference population. Although the age at diagnosis was lower, the risk of BC in transpersons is still lower than in the Dutch female reference population.

The role of lipids in prediction of gestational diabetes mellitus

Emir Muzurovic, Olivera Boskovic & Snezana Vujosevic
Clinical Center of Montenegro, Podgorica, Montenegro.

Introduction
Gestational diabetes(GDM) is a kind of diabetes that can happen during pregnancy. Many women who have GDM, get type 2 diabetes later in life. GDM is more likely for women who are overweight, women with family members who have type 2 diabetes and women who are American Indian. During pregnancy of healthy women, it is usual for blood lipids to increase significantly. Total cholesterol, HDL- and LDL-cholesterol increase 25-50%, triglycerides increase twice to four times and there is also an increase of apolipoproteins B. High triglycerides prior to pregnancy may develop severe hypertriglyceridemia (third trimester).
Aim
The aim of the study is to estimate the predictive value of lipid levels at the beginning of pregnancy to the development of gestational diabetes mellitus.
Materials and methods
The study includes 114 pregnant women, without lipid disorders before pregnancy. In study, in first trimester of pregnancy(10-11 week of gestation), we measured: fasting lipid profile(cholesterol, tryglicerides, low density proteins, high density proteins), hsCRP, total weight, total height and body mass index. All pregnant women finished OGT test in 24-28 week of gestation (performed 75-g OGTT with plasma glucose measurement before, 1h and 2h after). Patients were divided into two groups: patients with developed gestational diabetes(GDM) and patients without gestational diabetes(nonGDM). The measured parameters(in first trimester), between GDM and nonGDM group were compared. We used Student's T test.
Results
In our study 12 patients develop GDM(10.25%), 102 patients(89.75%) were with normal OGTT. Patients with developed GDM were older(28.75±2.01 vs25.22±1.78 years), with higher BMI (28.57±4.02VS26.46±1.26 kg/m2), with higher levels of triglycerides (2.26±0.87vs1.87±1.12mmol/l), higher levels of hsCRP(2.32±0.99vs1.76±0.76) and lower levels of HDL (1.20±0.16 vs1.41±0.32 mmol/l) ($P<0.05$). The levels of cholesterole (4.24±1.24v4.27±0.85mmol/l) and LDLc (2.87±0.56 vs2.91±0.71 mmol/l) were similar ($p>0.05$). Seven(58.33%) of GDM patients have DM in family. Fifteen(14.7%) of nonGTT patients have DM in family.
Conclusion
Pregnant women who have higher values of triglycerides and lower HDL values, in first trimester of pregnancy, are more likely to develop GDM. Also, older pregnant women, those with higher BMI(in the first trimester) and those with DM history in family are at a greater risk of GDM.

Biological exploration of hirsutism: Tunisian experience

Rihab Makhlouf, Khansa Chaabouni, Manel Naifar, Mariem Dhieb & Fatma Ayedi
Biochemistry laboratory, HabibBourguiba Hospital, sfax, Tunisia.

Introduction
In women, androgens are produced by adrenal glands and ovaries. In peripheral tissues, they result from a conversion of present androgens in the blood circulation. Androgens measurement are of interest in the exploration of hirsutism.

Materiel and methods
Retrospective study was conducted over 12 months from January, 2016 to December 2017 in Biochemistry Laboratory of Habib Bourguiba Hospital. Testosterone and prolactin assay were performed using electrochemuluminescence technique (cobas 6000, Roche). S DHEA, delta 4 androstenedione (Δ4 A) and 17 OH progesterone (17 OHP) were performed using ELISA technique. Statistical analysis were performed using Epi Info 7.
Results
Fifty-four women with suspicion of hirsutism were included in the study. The average age of patients was 33 ± 14 ans. Prescriptions came mainly from Endocrinology (57.3%), dermatology(9.48%) , gynecology(8.2%), pediatrics(8.2%) departments. Mean value of Testosterone and prolactin were 0.49 ± 0.56 ng/ml and 21.85 ± 10.61 ng/ml respectively. 17 OHP level was 2.79 ± 4.42 ng/ml while s DHEA and Δ4 A were 1.81 ± 1 µg /ml (RR: 0.4- 2.17 ng/ml) and 3.44 ± 3.44 ng/ml (RR: 0.75 – 3.89 ng/ml) respectively. Testosterone values were upper than 0.6 ng/ml in only 2 cases while 17 OH progesterone values were upper than reference range in 80%.
Conclusion
17 OH P seems to be more sensitive in the diagnosis of hirsutism than testosterone but the biological interpretation of hormonal assays cannot be done without detailed patients' clinical information

A new balanced autosomal translocation as a cause of premature ovarian insufficiency

Nuria Perez[1], Mauro Boronat[2], Yaiza Garcia[3], Maria Pino Alberiche[4], Maria Lopez-Madrazo[5], Rosa Sanchez[6], Javier Novoa[6] & Carlos Rodriguez[6]
[1]Hospital Insular de Gran Canaria, Las Palmas de GC, Spain; [2]Hospital Insular de GC, Las palmas de GC, Spain; [3]Hospital Insular de GC, Las Palmas de GC, Spain; [4]Hospital Insular de GC, LPGC, Spain; [5]HUIGC, LPGC, Spain; [6]Hptal Insular de GC, LPGC, Spain.

Premature Ovarian Insufficiency (POI) is defined as impairement of ovarian function in women under 40 years, with a incidence between 1-4% in women of reproductive age. Among the major identified causes of Premature Ovarian Insufficiency, genetic factors related with X-chromosome are widely described. However, autosome defects are less common found and are related generally with genetic mutations instead of structural abnormalities of them. Thefor, we report a relevant case of POI with balanced translocation between chromosomes 9 and 10. Our patient had puberal development and her first menstrual period at the age of 12, both spontaneously. After 2 years of regular cycles, she stopped menstruation. Laboratory investigations showed FSH and LH within menopausal range, with estradiol <50 pg/ml. Ultrasonography demostrated small uterus and left ovary, right ovary was not seen. Genetic testing showed karyotype 46,XX,t(9;10)(p24;q23). It should be noted that 9p24.3 region codes for DMRT1 an DMRT2 genes, which encode for transcription factors involved in indifferent gonad formation. Finally, this autosomal translocation is not yet described as a cause of POI.

Infertility caused by Chapelle syndrome

Ivana Kavecan[1,2], Milan Obrenovic[2] & Boris Privrodski[2]
[1]Faculty of Medicine, University of Novi Sad, ivana.kavecan@mf.uns.ac.rs, Novi Sad, Serbia; [2]Institute for Children and Youth Health Care of Vojvodina, Novi Sad, Serbia.

Introduction
Testicular disorder of sexual development (XX male syndrome; Chapelle syndrome) is a rare clinical condition. Incidence is 1:20 000 in newborn males. Characteristics of syndrome include hypogonadism, gynecomastia, and infertility resulting from the azoospermia. Diagnosis is mainly established after puberty. Clinical manifestations could be heterogeneous, but external genitalia appear to be completely virilized in 90% of 46,XX males: SRY-positive. Other manifestations such as hypospadias, undescended testes, or various degrees of inadequate virilization in the external genitalia are seen in 10% of the cases: SRY-negative.
Case report
In this paper we described a 31-year-old male with complete masculinization referred to geneticist because of a history of several years of infertility and established azoospermia. He had hypergonadotropic hypogonadism. FSH was elevated, LH was elevated, testosteron was lower. Peripheral blood karyotype showed a normal female karyotype (46,XX). FISH analysis revealed that SRY locus had been translocated to the short (p) arm of the X chromosome. A testosterone replacement therapy was initiated.
Conclusion
Etiology of infertility is heterogeneous. Karyotype should be performed in all males with azoospermia or severe oligospermia. Also, there is necessity of multidisciplinary approach.

Background
In patients with testicular dysgenesis syndrome, reduced semen quality and testicular cancer are common. We report a case of a testicular tumour in a patient with a history of cryptorchidism and oligoasthenospermia. He had an unusual hormonal profile, which was not fully explained by the pathological findings.
Case
A 31-year-old man was referred to our tertiary care andrology unit for primary infertility with a history of bilateral orchidopexy during childhood. Testes were small (12 cc). Gynaecomastia was absent. Semen analysis repeatedly showed oligoasthenospermia (2.4 to 7.1 million/mL, 85 to 92% immotile). Gonadotropins (LH and FSH <0.1 U/L) were undetectable, but testosterone and estradiol were normal (850.7 ng/dL and 38.6 ng/L). Prolactin, other pituitary hormones, DHEAS, AFP, HCG and inhibin B were also normal. He denied using anabolic steroids. Suppressed gonadotrophins suggested a sex steroid producing testicular tumour. However, scrotal ultrasound only showed diffuse microcalcifications and three millimetric hypolucent lesions in the left testis, but no intratesticular mass. There were no suspicious lesions nor microcalcifications in the right testis. To further investigate the possibility of increased testicular sex steroid production, selective testicular venous sampling was performed. In the left spermatic vein, testosterone and estradiol levels were very high (3744 ng/dL and 378 ng/L), with a testis-to-periphery gradient of 4.4 and 9.0 respectively. There was no gradient in the right spermatic vein. These results confirmed increased sex steroid producing in the left testis. However, histopathological examination after orchidectomy revealed a multifocal seminoma (largest diameter 3 mm) and profuse germ cell neoplasia in situ. There were neither isolated syncytiotrophoblastic cells, nor choriocarcinoma. Leydig cell hyperplasia was present without Leydig cell tumour. HCG was remeasured with three different methods, all showing very low HCG between 0.6 and 1.1 IU/L. After orchidectomy gonadotrophin levels increased (LH 24.3 U/L, FSH 10.3 U/L), with normal total testosterone and estradiol, indicating recovery of suppression of the hypothalamic-pituitary-testis axis. Sperm concentration increased (10 million/mL.)
Key messages
Our case shows that endogenous testosterone may support spermatogenesis even without gonadotropins.
In patients with suppressed gonadotropins, normal sex steroid levels and no testicular mass, selective testicular venous sampling can be useful in identifying the site of hormonal overproduction.
Thus far, the pathology findings cannot explain the hormonal profile. Further investigations are therefore ongoing.

Differential effects of genetically inherited – and high fat diet induced – obesity on spermatogenesis in adult male rats

Sharvari Deshpande[1], Harishankar Nemani[2], Suresh Pothani[2] & Nafisa Balasinor[1]
[1]National Institute for Research in Reproductive Health, Mumbai, India; [2]National Institute of Nutrition, Hyderabad, India.

Obesity, a new world syndrome, is defined as excessive white adipose tissue accumulation, that may impair health leading to severe metabolic and reproductive complications affecting millions of people of different age groups. Recent studies have shown that incidence of male obesity induced fertility issues are rising in couples undergoing assisted reproductive technologies suggesting that obesity is emerging as an established risk factor for male infertility or subfertility. Obesity is a multifactorial condition with predominantly genetic and/or environmental causes. No studies have compared genetically inherited and high fat diet induced obesity effects on spermatogenesis. Thus, our present study aims to delineate effects of obesity on spermatogenesis using two male rat models: genetically inherited obese (GIO) – WNIN/Ob and diet induced obese (DIO) – High fat diet. Terminal body weights were similar in both groups, but, differential effects on adiposity index were observed in both the groups. We observed a significant decrease in caudal sperm counts in GIO group but not in DIO group despite body weights being similar in both the groups. To study the specific cause of reduced sperm counts in GIO group, not in DIO group, flow cytometry and germ cell specific marker expression studies in testis revealed that both genetically inherited and diet induced obesity affects mitosis process by increasing spermatogonial proliferation. In GIO group, both meiosis and differentiation process was affected by decreasing spermatocyte population and increasing round spermatid population as well as decrease in elongated spermatid population confirming the decrease in caudal sperm counts whereas in DIO group, it was unaffected. Further, gene expression studies in testis in GIO and DIO group revealed differential expression of genes involved in various aspects of spermatogenesis mainly primary spermatocyte progression and spermiogenesis process, reproductive hormone receptors, leptin signaling molecular players, pro-inflammatory cytokines and cell cycle mediators. Taken together, our study shows that the differences in the effects of genetically inherited and diet induced obesity on spermatogenesis is based on the difference in adiposity index and not due to high terminal body weights. This suggests that the discrepancies in the literature concerning human obesity induced fertility issues could be due to combination of both genetic and environmental factors as well as due to the difference in the amount and distribution of white adipose tissue which could be leading to infertility in some obese individuals but not in all.

Hematological indices in congenital hypogonadism and the effect of testosterone replacement therapy: A retrospective study

Cem Haymana[1], Ibrahim Demirci[1], Mustafa Dinc[1], Orhan Demir[1], Onur Akın[2], Coskun Meric[1], Aydogan Aydogdu[1], Alper Sonmez[1] & Omer Azal[1]
[1]Gulhane Training and Research Hospital, department of Endocrinology and Metabolism, Ankara, Turkey; [2]Gulhane Training and Research Hospital, department of Pediatric Endocrinology and Metabolism, Ankara, Turkey.

Introduction
Patients with hypogonadism are at increased risk for cardiovascular diseases. Mean platelet volume (MPV), platelet-to-lymphocyte ratio (PLR), and neutrophil-to-lymphocyte ratio (NLR) are hematological indices that are surrogate markers of adverse cardiovascular outcomes. This study investigated the platelet count, MPV levels, PLR, and NLR in patients with congenital hypogonadotrophic hypogonadism (CHH) and also studied the effect of testosterone replacement therapy (TRT) on these parameters.
Methods
A total of 67 young male patients with CHH (mean age: 21.5 ± 2.0 years) and 68 healthy control subjects (mean age: 21.9 ± 1.3 years) were enrolled in the study. The demographic parameters, homeostatic model assessment-insulin resistance (HOMA-IR), platelet count, MPV, PLR, and NLR were measured in patients with CHH and healthy controls before and after TRT.
Results
The patients had higher WC ($P=0.04$), triglycerides ($P=0.02$), insulin ($P<0.001$), HOMA-IR ($P<0.001$), platelet count ($P=0.001$), MPV ($P=0.004$), and PLR ($P=0.003$) levels and lower FSH, LH, and total testosterone ($P<0.001$ for all) levels than the healthy controls. After 5.85 ± 2.13 months of TRT, the patients had significantly elevated BMI, WC, total testosterone, and HOMA-IR ($P<0.001$, $P=0.001$, $P<0.001$, and $P=0.03$, respectively) and decreased HDL-C levels ($P<0.001$); however, the alterations in platelet count, MPV levels, PLR, and NLR were not significant. There was also a significant correlation between total testosterone level and platelet count ($r=-0.23$, $P=0.009$), MPV ($r=-0.0.22$, $P=0.013$), and PLR. ($r=-0.0.22$, $P=0.014$).
Conclusion
The present study showed that platelet activation may play a pivotal role in the pathogenesis of cardiometabolic risk of patients with hypogonadism. Moreover, the short time TRT in treatment naïve young patients with CHH did not have any effect on the platelet count and size.

Hypogonadism and mortality in type 2 diabetic men

Juan José Corrales[1,2,3], Ana Herrero[1,2], Rocío Cáceres[2], Ana Isabel Sánchez[1,2], Miguel Marcos[1,4], Jose María Recio[1,2] & Jose Manuel Miralles[1,2]
[1]Department of Medicine. University of Salamanca, Salamanca, Spain; [2]Service of Endocrinology and Nutrition. University Clinical Hospital of Salamanca, Salamanca, Spain; [3]Cancer Research Institute (IBMCC-CSIC/USAL) and Institute for Biomedical Research, Salamanca, Spain; [4]Service of Internal Medicine. University Clinical Hospital of Salamanca, Salamanca, Spain.

Introduction
Low testosterone serum levels are associated with increased mortality in non-diabetic males. However, knowledge about the association between male hypogonadism and mortality among type 2 diabetic (T2DM) men is limited due to short follow-up periods in the few existing studies.
Objective
To assess the association between hypogonadism and mortality in diabetic men.
Material and methods
263 unselected men with T2DM (mean age 63.9 ± 10.5 years) were followed prospectively until death or December 1, 2017, during a period of 8 ± 3.9 years. Diagnosis of hypogonadism was established adding low total testosterone (TT) serum levels and hypogonadal symptoms (positive ADAM questionnaire). Three different thresholds for low testosterone were used (TT <3.4, <3 and <2.3 ng/ml). The survival in hypogonadal vs eugonadal men was analyzed with Kaplan-Meier survival curves (univariate analysis) and Cox regression (multivariate analysis).
Results
A total of 56 patients (21.3%) died during follow-up. Lower levels of TT (3.9 vs 4.4 ng/ml, $P=0.044$), free testosterone (7 vs 8.9 ng/dl; $P=0.011$) and bioavailable testosterone (164.2 vs 218.9 ng/dl; $P=0.003$) were found in deceased diabetic patients than in the group of survivors. The percentage of patients who died was higher in the hypogonadal group than in eugonadal diabetic men for all three thresholds (TT <3.4 ng/ml: 31.4 vs 17.7%, $P=0.026$, OR = 2.1 (95% CI = 1.1–4); TT <3 ng/ml: 33.3 vs 18.8%, $P=0.044$, OR = 2.2 (95% CI = 1.1–4.4); TT <2.3 ng/ml: 46.7% vs 18%, $P=0.001$, OR = 4 (95% CI = 1.8–8.8)). Survival was significantly lower in hypogonadal than in eugonadal men, and that was also demonstrated by using the three thresholds: TT <3.4 ng/ml: 68.6% vs 82.7% (Log-rank 8.5, $P=0.004$); TT <3 ng/ml: 66.7% vs 81.6% (Log-rank 7.7, $P=0.005$) and TT <2.3 ng/ml: 53.3% vs 82.3% (Log-rank 21.4, $P<0.001$). In addition, the mean time of survival was lower in hypogonadal than in eugonadal men (TT <3.4 ng/ml: 11.3 vs 14.3 years, $P=0.004$; TT <3 ng/ml: 11 vs 14.1 years, $P=0.005$ and TT <2.3 ng/ml: 7.7 vs 14.2 years, $P<0.001$). In the multivariate analysis, hypogonadism increased the risk of mortality (HR = 2.3, 95% CI = 1.2–4.3, $P=0.01$) independently of age, poor glycemic control, renal failure and the presence of macrovascular disease.
Conclusions
In the longest follow-up study reported so far we show that hypogonadism is associated with decreased survival in diabetic men. Mortality rates and mean time of survival were associated with the severity of male hypogonadism.

Impact of testosterone administration to female-to-male transsexuals on cardiovascular risk factors

Eva María Riera Sabater[1], Marcelino Gómez Balaguer[1], Santiago García Torres[1], Francesca Lannatuoni[2], Celia Bañuls Morant[2], Felipe Hurtado Murillo[3,4], Cristina Del Castillo Villaescusa[5] & Antonio Hernández Mijares[1,6]
[1]Service of Endocrinology and Nutrition, University Hospital Doctor Peset, Valencia, Spain; [2]Service of Endocrinology and Nutrition, University Hospital Doctor Peset/FISABIO, Valencia, Spain; [3]Spanish Society of Endocrinology and Nutrition's Sexual Identity and Differentiation Group (GID-SEEN), Valencia, Spain; [4]Fuente de San Luis's sexual and reproductive health center, Valencia, Spain; [5]Pediatric service, University Hospital Doctor Peset, Valencia, Spain; [6]Department of Medicine. University of Valencia, Valencia, Spain.

Introduction
Cross sex hormonal therapy with testosterone is used in female-to-male transgender people to induce the desired secondary sexual features; this could lead to an increased risk of cardiovascular diseases. Data published on this subject is scarce and contradictory.
Objective
To evaluate effects on weight, inflammatory and prothrombotic parameters, lipid profile, and insulin resistance after 3–4 months of testosterone treatment in transsexual men.
Materials and methods
Prospective study including 25 transsexual men who started treatment with testosterone between 2016 and 2017. Average was 23 ± 9.6 years of age. Those with known dyslipidemia, diabetes or thrombophilia were excluded. All of them started the treatment with 250 mg of i.m. testosterone cypionate every 21 days, except for 5 patients who started with 50 mg a day of transdermal testosterone gel, remaining in amenorrhea. Dietary and increased physical activity measures were promoted in all cases.
Results
There was a mean increase in weight after 3–4 months of treatment (72.4 ± 23.4 vs 74.4 ± 24.6 kg, $P = 0.026$), although it was very individually variable. 56% of the participants gained weight (3.7 ± 3.3 kg), while the rest (44%) remained stable or lost weight (−1.5 ± 1 kg). Testosterone treatment was associated with an increase in LDL levels, from 99.4 ± 32 to 105.4 ± 32 mg/dl ($P = 0.017$) and TG levels, from 69.6 ± 28.5 to 86.0 ± 38.2 mg/dl ($P = 0.048$). HDL levels did also decrease (54.9 ± 14.1 vs 44.8 ± 10.6 mg/dl, $P < 0.001$), as those of Apolipoprotein A (161.5 ± 24.4 vs 141.7 ± 23.7 mg/dl, $P = 0.005$). No differences were observed both in CRPus and fibrinogen levels. Homocysteine levels did increase (8.6 ± 2.5 vs 12.1 ± 7.9 umol/l, $P = 0.037$). Fasting glucose level dropped from 87.6 ± 9.6 to 83.6 ± 10.0 mg/dl ($P = 0.01$), but no differences were found in glycosylated hemoglobin levels nor in the HOMA index. An increase in total hemoglobin (13.2 ± 1.0 vs 14.7 ± 1.4 mg/dl, $P < 0.001$) and hematocrit (40.7 ± 3.0 vs 44.9 ± 4.0%, $P < 0.001$) levels was observed, not reaching pathological values in any case. No differences were observed in the platelet count. No positive correlation was observed between higher testosterone or estradiol levels and the variables studied.
Conclusions
There is a worsening of analytical parameters related to cardiovascular risk. There is a weight gain that could be controlled by promoting dietary and physical activity measures.

Triglyceride-Glucose index levels in patients with congenital hypogonadism

İbrahim Demirci, Cem Haymana, Orhan Demir, Nazlı Gülsoy Kırnap, Coskun Meric, Yusuf Alper Sonmez, Neşe Ersöz Gülçelik, Aydogan Aydogdu & Omer Azal
Gulhane Training and Research Hospital, department of Endocrinology and Metabolism, Ankara, Turkey.

Introduction
It is well known that patients with hypogonadism are at increased risk for insulin resistance and cardiovascular diseases. In many studies homeostatic model assessment-insulin resistance (HOMA-IR) formulation is used for the evaluation of insulin resistance. Recently, a simple and inexpensive approach to evaluate for insulin resistance has been developed, the Triglyceride – Glucose (TyG) index. This particular index is based on measuring the levels of fasting triglycerides and glucose. This study investigated the TyG index as a useful surrogate marker of insulin resistance among patients with congenital hypo gonadotrophic hypogonadism (CHH).
Methods
A total of 154 young male patients with CHH (mean age: 21.54 ± 1.95 years) and 115 healthy control subjects (mean age: 22.81 ± 1.45 years) were enrolled in the study. The demographic and laboratory parameters, plasma ADMA, hsCRP, HOMA-IR levels and TyG index were measured in healthy controls and patients with CHH, before and after TRT.
Results
The patients had higher waist circumference (WC, $P = 0.011$), systolic blood pressure (SBP, $P = 0.011$), triglycerides (Tg, $P < 0.001$), insulin ($P < 0.001$), asymmetric dimethylarginine (ADMA, $P < 0.001$), HOMA-IR ($P < 0.001$) and TyG index ($P = 0.004$) levels and lower follicle stimulating hormone (FSH), luteinizing hormone (LH), and total testosterone ($P < 0.001$ for all) levels than the healthy controls. After 5.85 ± 2.13 months of TRT, the patients had significantly elevated BMI ($P < 0.001$), WC ($P < 0.001$), SBP ($P = 0.002$), Tg ($P < 0.001$), total testosterone ($P = 0.012$), HOMA-IR ($P < 0.001$), ADMA ($P < 0.001$) and TyG index ($P < 0.001$) and decreased HDL-C levels ($P < 0.001$). There was also a significant correlation between TyG index and BMI ($r = 0.15$, $P = 0.03$), WC ($r = 0.25$, $P < 0.001$), HDL-C ($r = -0.21$, $P = 0.001$), LDL-C ($r = 0.15$, $P = 0.032$) and ADMA ($r = 0.17$, $P = 0.03$) levels.
Conclusion
The results of the present study show that patients with CHH have elevated TyG index which is an easily calculated and inexpensive parameter that can indicate insulin resistance. TyG index is further increased after TRT and also related to surrogate marker of endothelial dysfunction. Prospective follow-up studies are warranted to clarify the role of TyG index in predicting cardiometabolic risk in patients with hypogonadism.

Effects of cross-sex hormone treatment on body composition in transgender persons

Maria Hayon, David Blanquez, Maria del Carmen Serrano, Maria Dolores Avilés & Elena Torres
Hospital Universitario San Cecilio, Granada, Spain.

Background
Cross-sex hormone treatments are used to masculinize or feminize the bodies of female-to-male (FtM) or male-to-female (MtF) transsexuals, respectively. Redistribution of fat mass is expected to occur during the first 1–6 months in transgender males and in the first 3–12 months in transgender females.
Objective
To examine the effects of cross-gender sex hormone therapy (CHT) on body composition in transsexual men and women.
Materials and methods
Observational study. 40 transsexual men and women assisted in the Gender Identity Unit of an endocrinology community from January to September 2017. We measured weight, body mass index(BMI) and body composition by bioelectrical impedance analysis(BIA) at baseline and after mean duration of CHT of 2 years.
Results
We evaluated 40 transsexuals, 19 male-to-female (MtF: 47.5%) and 21 female to male (FtM: 52.5%). Mean age 23.86 ± 11.25 years, mean duration of CHT of 24.7 ± 39.9 months. In MtF(68.8% oral estradiol, 31.2% estradiol transdermal patch,83.3% cyproterone acetate), weight(Kg) and BMI(Kg/m2) increased from 72.12 ± 19.04 to 73.17 ± 19.96 ($P < 0.03$) and from 23.8 ± 5.79 to 24.03 ± 5.85($P = 0.04$) respectively; difference in body composition by BIA were also observed: fat mass(Kg) from 9.79 ± 7.62 to 12.3 ± 0.43($P = 0.03$), muscle mass(Kg) 55.45 ± 9.24 to 56.05 ± 8.76 ($P = 0.015$), body water 40.60 ± 6.75 to 41.02 ± 6.42 ($P = 0.04$). FtM (76.9% testosterone cypionate,23.1% testosterone undecanoate) also presented significant difference in body composition:fat mass(Kg) from 18.50 ± 3.55 to 14.14 ± 3.95($P = 0.04$), muscle mass(Kg)

46.44 ± 2.27 to 49.70 ± 6.55($P = 0.026$), body water 36.55 ± 5.57 to 33.77 ± 1.84 ($P = 0.042$). No significant difference in weight and BMI were observed.
Conclusion
Oral estradiol is the most frequent estrogen preparation used in transgender woman and testosterone cypionate in transgender men. Testosterone treatment in transgender males resulted in increased muscle mass and decreased fat mass. In transgender females, CHT is associated with change in fat mass redistribution although no difference in weight and BMI were observed.

Erectile Dysfunction – The hidden sickness we don't seek

Catarina Roque, Ricardo Capitão, Cátia Ferrinho, Sequeira Duarte & Carlos Vasconcelos
Hospital de Egas Moniz, CHLO, Lisbon, Portugal.

Introduction
Erectile dysfunction (ED) is highly prevalent and negatively impacts the patient's and the partner's quality of life. It is a well-established red flag for ongoing neuro-vascular disease and a predictor of coronary, cerebral and peripheral arterial disease (PAD). Our aim was to document how often do clinicians investigate ED and use it as a predictor of neuro-vascular pathology to trigger a thorough revision of cardiovascular risk factors (CVRF). This assessment was indirectly performed, using an original questionnaire (Qr) aiming to identify the patient's/clinician's awareness of ED. The Qr ascertained self-considered ED; ED approach at any hospital visit; ED presence and degree by the IIEF-5 questionnaire and investigated hypogonadism, comorbidities and life-style. The participants filled the Qr voluntarily, autonomously and anonymously.
Results
Participants ($n = 52$) with mean age 52.5 (32–72) y.o., 65% within 40–70 y.o. range, self-reported ED in 40.6% cases. Of these, 6% said to have been questioned by their doctors about ED. The remaining 84%, though they answered they would have liked to have discussed ED in a visit, only 9% had ever had that initiative. Among all patients, only 9.6% had been interrogated by their physicians about ED. Of the patients self-reporting ED using drugs (11.5%), 5.7% did so with over the counter. Hypogonadism symptoms/signs were reported by 23% (50% self-considered to have ED) and only 6% had ever been questioned about related symptoms. Patients reporting 2 or more hypogonadism specific symptoms ($n = 3$), had moderate ED on the IIEF-5 questionnaire. IIEF-5 assessment revealed an ED prevalence of 60%. In 44% it was moderate-severe, 89% of these patients had self-reported ED but only 1 had been ever questioned about it and only 2 had ever had the initiative to mention it. Obesity, hypertension, dyslipidaemia, inactivity, smoking, alcohol consumption, stroke, AMI and PAD were more prevalent in the group with ED (IIEF-5), but not in the group who considered to suffer from ED.
Conclusions
The prevalence of ED was significant. Most clinicians didn't actively seek ED and most patients didn't inform their doctors about their problem. Self-reported ED validated by the IIEF-5 questionnaire was useful in the identification of patients with CVRF and established cardiovascular disease. The identification and treatment of ED impact positively not only quality of life but also cardiovascular mortality: an underestimated chance for intervention that shouldn't be missed.

Subfertility in male hypogonadotropic hypogonadism secondary to obesity: successful conception with novel use of aromatase inhibitor

Si Ling Young[1], Joan Khoo[2] & Troy Puar[2]
[1]Internal Medicine Residency, Singhealth – Changi General Hospital, 2 Simei Street 3 Singapore 529889, Singapore, Singapore; [2]Department of Endocrinology, Changi General Hospital, 2 Simei Street 3 Singapore 529889, Singapore, Singapore.

Background
Hypogonadotropic hypogonadism due to obesity in males can be challenging to treat, particularly when fertility is desired. Although weight loss is ideal, this is difficult to achieve quickly, while testosterone replacement further suppresses spermatogenesis. Aromatase inhibitors have been suggested to improve spermatogenesis in idiopathic male hypogonadism, but there are no large scale studies to support this. Aromatase inhibitors may be even more efficacious in obesity-related hypogonadism due to increased aromatase activity causing high estrogen levels and suppressed gonadotrophins. We describe a case of successful conception after letrozole was initiated.
Clinical Case
A 30-year-old gentleman with morbid obesity (BMI 43.7 kg/m^2) presented with subfertility. Secondary causes of obesity were excluded. Preliminary workup showed hypogonadotropic hypogonadism (repeated low 8-am testosterone, 3.70 nmol/L, calculated testosterone 148 pmol/L) with inappropriately normal FSH and LH levels (FSH 2.85 IU/l, LH 3.93 IU/l). The other pituitary hormones were normal and pituitary imaging did not show any lesion. Initial semen analysis done showed oligo-astheno-teratozoospermia (Density 4 mil/mL, Motility 10%), suggestive of impaired spermatogenesis. The patient was counselled on lifestyle changes to achieve weight loss. He declined pharmacological therapy for his obesity, as well as bariatric surgery. However, the patient was not able to achieve significant weight loss and the couple was keen to conceive soon. Letrozole, an aromatase inhibitor, was started at 1.25 mg once a week. After 7 weeks of treatment, there was a rise in FSH (from 2.53 IU/l to 7.11 IU/l) and LH (from 3.58 to 10.5 IU/l), and corresponding rise in 8 a.m. testosterone levels from 3.31 nmol/L to 14.04 nmol/L, without a significant change in weight. He noted increase in his libido and frequency of morning erections. Within another four months, the couple successfully conceived, notably during his wife's first cycle of assisted reproduction (IVF). Letrozole was discontinued soon after, with resumption of lifestyle measures to encourage weight loss.
Conclusion
Although aromatase inhibitors have been used sporadically to improve male hypogonadism, this unique case shows successful conception after a short course of letrozole, achieving rapid improvement in hypogonadism. Although they may not correct other important issues, such as metabolic complications in obesity, a course of aromatase inhibitors may be a useful adjunct to other measures like weight loss, in improving subfertility in obesity-related hypogonadotrophic hypogonadism.

Leptin targets in the male reproductive tract of mice

Robert Hart[1], Robin Dobos[2], Linda Agnew[1] & James McFarlane[1]
[1]University of New England, Armidale, Australial; [2]Department of Primary Industries NSW, Armidale, Australia.

Leptin is best known as an appetite and metabolic rate modulator secreted from fat, but it also has a range of other functions including modulation in reproductive physiology. To date, most studies examining the role of leptin in male reproduction have focussed on individual tissues, often *in vitro*. In the current report, a bolus physiological dose of iodinated leptin was administered intravenously to male mice to and samples collected over a one hour time course to determine potential targets for leptin action in the male reproductive tract. The testis and the epididymis accumulated approximately 0.3% of the administered dose, remaining relatively stable over the time course. In the seminal vesicles, the dose recovered increased from 0.35 ± 0.1% to 1.37 ± 0.3% of the dose from 5 to 45 min after administration. In terms of dose recovered per gram of tissue, recovery from testis and epididymis remained relatively stable at approximately 0.9% dose/g, 2.5% dose/g, respectively. Recovery from the seminal vesicles 5 min after administration was 1.14 ± 0.1%dose/g, increasing to 4.15 ± 0.4%dose/g 45 min after administration, before a decline to 3.10 ± 0.2% dose/g observed 60 min post-injection. Major targets for leptin binding have been characterised in previous studies including work from out lab. These studies showed that leptin was rapidly cleared from these tissues. In the male reproductive tract leptin appears to accumulate, with the seminal vesicles being a preferential target, although the testis and epididymis also accumulate leptin for a period of time. Leptin receptors are expressed in each of these tissues, and leptin signalling has been shown to attenuate testosterone secretion in the testis, while in the epididymis leptin increases spermatozoa differentiation. However, it is still

unclear why leptin would accumulate in the seminal vesicles. Leptin and the soluble leptin receptor (LepRe) have been recovered from ejaculate and, leptin is known to facilitate *in vitro* fertilisation and implantation, and LepRe increases the half-life of leptin. Thus, leptin in the male reproductive tract may play a role in the normal fertilisation and implantation processes.

A case of Wolfram syndrome with primary gonadal insufficiency

Serhat Ozcelik[1], Mehmet Sariyadın[1], Bunyamin Aydin[1], Sibel Temiz[2], Kenan Caglayan[2], Mehmet Celik[3], Muhammed Kizilgul[4] & Hulya Iliksu Gozu[5]
[1]Adıyaman Education Hospital, Endocrinology and Metabolism Section, Adıyaman, Turkey; [2]Haydarpaşa Education Hospital, Endocrinology and Metabolism Section, Istanbul, Turkey; [3]Trakya University, School of Medicine, Department of Endocrinology and Metabolism, Edirne, Turkey; [4]Kilis State Hospital, Endocrinology and Metabolism Section, Kilis, Turkey; [5]Marmara University, School of Medicine, Department of Endocrinology and Metabolism, Istanbul, Turkey.

Introduction
Wolfram syndrome is characterized by diabetes mellitus (DM), diabetes insipidus (DI), optic atrophy and sensorineural deafness. DM is the first manifestation and optic atrophy also onsets in the first decade of life. The onsets of DI and sensorineural deafness are in the second decade, urinary tract abnormalities are in the third decade and neurologic abnormalities are in the fourth decade respectively. Hypogonadotrophic hypogonadism is a usual manifestation of the syndrome, however, as in our case, hypergonadotrophic hypogonadism can be rarely seen.
Case report
A 24- year old male patient admitted to our clinic with the complaints of mouth dryness, polyuria and polydipsia. The onset of polyuria, polydipsia, and blurred vision was at the age of six. He was diagnosed with tip 1 DM at the age of seven and intensive insulin therapy was instituted subsequently. It was noticed that despite the good glycemic control, the daily liquid intake of the patient was 10 liter, and the urine output was 9.5 l. The visual complaints of the patient were thought to be related to myopia and diabetic retinopathy. Our patient had complaints of loss of libido, impotence, erectile and ejaculatory dysfunction for the last 6 months. The insulin therapy was started as insulin aspart 4 unit tid and insulin detemir 12 unit per day. In the physical examination; bilateral grade 3 gynecomastia was observed. In the hormonal panel; FSH: 45 U/l (N:1.5–12.7), LH:28.4 U/l (N:1.7–8.6), total testosterone: 3.83 ng/ml (N:3–10 ng/ml), free testosterone: 2.15 pg/ml (N:12,00–30,00 pg/ml). In the bone mineral densitometry, the Z scores were -2.3 S.D. and revealed low bone mass for chronologic age. Spermiogram was reported as azoospermia. In the cytogenetic studies male karyotype 46, XY was confirmed. The fluid deprivation test was done and according to the test results the patient was diagnosed with diabetes insipidus. In the fundus examination bilateral optic atrophy was diagnosed. In the audiogram, the hearing loss with high-frequency sounds which considered to be related to sensorineural deafness was observed. As the primary treatment of primary hypogonadism, testosterone was started. Because of the minimal regression of bilateral gynecomastia with testosterone therapy, the patient was consulted with plastic and reconstructive surgery.
Conclusion
As in our case, the patients diagnosed with Wolfram syndrome requires long-term follow-up. Early diagnosis and appropriate hormone replacement improve the quality of patients life.

Child wish and fertility preservation in assigned male at birth transgender persons living in Belgium

Justine Defreyne[1], Judith Van Schuylenbergh[2], Elia Wyverkens[3], Joz Motmans[2] & Guy T'Sjoen[1,2]
[1]Ghent University Hospital, department of Endocrinology, Ghent, Belgium; [2]Ghent University Hospital, center for sexology and gender, Ghent, Belgium; [3]HOWEST University of Applied Sciences, Brugge, Belgium.

Objectives
Transgender persons undergoing gender affirming hormonal and/or surgical care, are at risk of reduced fertility. Although theoretically, the options for assigned male at birth (AMAB) transgender people to fulfill their child wish are extensive, research in transgender women shows low fertility preservation utilization. Ideas and concerns of AMAB transgender persons regarding fertility preservation and child wish have never been reported in a large, non-clinical sample.
Materials and methods
A web-based survey on fertility and parenthood was conducted in Belgium in 2017, which invited persons aged ≥ 16 years who identified themselves as trans* to participate. AMAB transgender people were selected for this substudy, including transgender women (TW), transvestites and gender non binary (GNB) persons.
Results
The questionnaire was filled out by 426 participants; 254 (59.6%) AMAB (196; 77.2% transgender women (TW), 14; 5.5% transvestites and 44; 17.3% GNB persons). Fifty-five (21.6%) respondents had a current/future child wish, child wish was fulfilled in 81 (31.9%) and inexistent in 57 persons (22.4%) (other: 19.2%). Although TW were older than GNB ($P=0.14$), TW were more likely to have a child wish ($P=0.004$). In total, 196 AMAB persons (77.2%; TW: 167; 85.2% and GNB: 23; 52.3%) previously sought medical help for their gender identity, of which 30 (15.3%) considered the loss of fertility due to the transitioning process undesirable. The majority (75; 68.2% – 86 missing) did not wish for fertility preservation. Of the total AMAB population, 14 people (9.8% – 112 missing, TW: 12; 10.3%, GNB: 2; 7.7%) had frozen germ cells. The top three reasons not to proceed with fertility preservation included not feeling the need (70; 68.0%), not desiring a genetic link with (future) child(ren) (20; 19.4%) and having to postpone hormone treatment (15; 14.6%). Barriers encountered for fulfilling child wish included assumed difficulties in the adoption procedure (40; 16.1%) and fear of discrimination against the child (38; 15.3)
Conclusion
Child wish and fertility preservation utilization were lower in our AMAB population than in previous research on clinical samples. These low utilization rates reflect barriers transgender persons face when considering fertility options, including postponing hormone therapy. In the present study, TW more frequently visited a health care professional and were more likely to have a child wish, compared to GNB persons. Subsequently, TW were more likely to have germ cells frozen/consider doing so in the future, compared to GNB persons, but the use of fertility preservation remained low.

The relationship between PTEN mutations and resistance to androgen-deprivation therapy in prostate cancer

Abdallah Alzoubi, Aya Alsmairat, Samir Al Bashir, Mahmoud Alfaqih & Khalid Kheirallah
Jordan University of Science and Technology, Irbid, Jordan.

Background
Prostate cancer is the second leading cause of cancer-related deaths in men worldwide. A marker of poor survival in prostate cancer patients is the loss of the tumor suppressor gene *PTEN (*phosphoinositide-3-phosphatase). Deletion of PTEN occurs in approximately 40% of prostate cancer patients, and is associated with early biochemical recurrence, metastatic potential, and androgen-independence. Androgen-deprivation-therapy (ADT) remains the principal treatment of prostate cancer, despite the eventual resistance to treatment in most patients. The exact mechanism of such ADT resistance is yet to be confirmed. Thus, our study aimed to determine whether PTEN mutations play a role in ADT resistance in prostate cancer.
Methods
A case–control study was performed. Cases ($n=64$) were patients with confirmed diagnosis of prostate cancer treated with ADT, while controls ($n=58$) were subjects with benign prostatic hyperplasia. Prostate specimens were collected by needle core biopsy, or during transurethral resection of the prostate or radical prostatectomy. PTEN expression status was assessed by immunohistochemistry, and scores of 0 (no expression) and 1 (expression) were assigned to prostate tissues.

Results
Loss of PTEN expression (score 0) was 30 times more likely to occur in prostate cancer cases compared to controls. However, the presence of PTEN mutation was not significantly correlated with the pathological Gleason grade of prostate cancer severity. Mean time to ADT resistance in prostate cancer patients was 25.3 months, which was not significantly different between those with PTEN mutation (mean = 26.8 months) and those without mutation (mean = 23.5 months). However, there was a statistically significant difference in mean time to ADT resistance between those receiving the combined therapy (mean = 33.2 months) and those receiving either goserline alone (mean = 9 months) or triptoline alone (mean = 8.9 months).
Conclusion
Our results indicate that loss of PTEN expression is not sufficient to explain ADT resistance in prostate cancer patients. Combined hormonal therapy might be a promising strategy to slow the process of ADT resistance in these patients. However, further studies in larger prospective cohorts are warranted.

Male hypogonadism due to 46, XX Testicular disorder of sex development

Mercedes Noval Font, Guillermo Serra Soler, Ana Jiménez Portilla, Carlos Antich Barceló, Santiago Tofé Povedano, Elena Mena Ribas & Vicente Pereg Macazaga
Hospital Son Espases, Palma de Mallorca, Spain.

Introduction
46,XX testicular disorder of sex development (DSD) is a rare syndrome, which is characterized by a female karyotype in discordance with a male phenotype. It is presented with primary hypogonadism, gynecomastia and infertility. About 80–90% of 46,XX testicular DSD cases are positive for SRY gene. Appearance of external genitalia and masculinization are usually normal in 46,XX SRY-positive cases
Clinical case
A 41-year-old male came with his partner to the outpatient clinic because of low levels of testosterone detected in routine blood test. He complained about fatigue, low libido and some difficulties to maintain erections since one year. He had no history of mumps, trauma or surgery.He was 169 cm tall and he weighted 74 kg, BMI of 25.9 kg/m^2. The physical examination reveled a normal penis size, with small soft testis (2 ml). No gynecomastia was detected. Facial, body, and pubic hair were of normal density and distribution. He related his small size of testis since puberty. He had not consulted before for this Laboratoy test showed a low level of total and free testosterone, high levels of gonadotropins, normal levels of prolactin and estrogens. A karyotype and semen analysis were assessed. The karyotype analysis showed a 46,XX formula. The polymerase chain reaction analysis confirmed the presence of SRY gen. The semen analysis showed azoospermia. These results were consistent with 46, XX DSD. The diagnostic had a high emotional impact and he needed psychological support to accepted it and the fact that he was infertile He started testosterone replacement but he refused to do other tests: magnetic resonance imaging of the pelvis or bone densitometry.
Conclusion
It is important to diagnose as soon as possible this testicular DSD syndrome, to avoid its negative emotional impact and the consequences of a chronic testosterone deficiency.

DicentricisochromosomeYp in adolescent with azoospermia

Fatma Loukil[1], Mouna Elleuch[1], Wafa Ben Othmen[1], Fatma Mnif[1], Ikhlas Ben Ayed[2], Neila Belguith[2], Mouna Mnif[1] & Mohamed Abid[1]
[1]Endocrinology-Diabetology Department, CHU Hédi Chaker, Sfax, Tunisia; [2]Genetic Department, Medicine Faculty, Sfax, Tunisia.

Background
Azoospermia is present at approximately 1% of the man. karyotype can show number and structure abnormalities of the sexe chromosomes.
Case
16 years old boy,who was refered to the departement of endocrinology for a failure to growth since 8 years old. This patient was resulting from a marriage between blood relations. He had a congenital bilateral hip luxation diagnosed since birth but untreated.He had a gait disorder with a low weight 32 kg <3 erd percentile and a short stature 134 cm < -3 S.D., the physicalexamination of the external genital was without anomalies. He did not have a particular endocrinal clinical disorders. The skeletal age determination was without evidence of disease.The hormonal profile was normal except these rum concentartion of follicule-stimulating hormone wich increased from 22 mUI/ml to 32 mUI/ml.The testis ultrasonography showed bilateral testis hypotrophy. A semen analysis was then required. It showed a depletion of sperm production 1.3 ml and azoospermia. The cytogenetic analysis carried out on peripheral lymphocyts with G banding revealed a 46,X, idic(Yp)(q11q22) karyotype. The rearrenged Y chromosome was accompagnied by a total duplication of the short arm Yp and a partial deletion of the long armYq.
Conclusion
This is the first report document in isochromosome Y with disruption in the SHOX, AZFb, AZFc gene area.The study is in hand to show if AZF region deletion is complete or partial.

Prolactin concentration in male-to-female transsexual subjects following cross-sex hormone therapy

Maria Hayon, David Blanquez, Maria del Carmen Serrano, Maria Dolores Aviles & Elena Torres
Hospital Universitario San Cecilio, Granada, Spain.

Background
Male-to-female transsexual persons use estrogens + antiandrogens to adapt their physical bodies to the female sex.Estrogens are powerful stimulators of synthesis and release of prolactin and serum prolactin levels are usually somewhat increased following estrogen treatment.
Objective
To determine prolactin levels and to assess the risk of development of prolactinoma in male-to-female transgender subjects following cross-sex hormone therapy (CHT).
Materials and methods
Retrospective longitudinal study including all male-to-female transsexual persons assisted in the Gender Identity Unit from 2015 to 2017.Clinical and laboratory data were collected before and after a mean duration of CHT of 24 months.Radiologic examinations of the pituitary were performed in those patients whose prolactin levels persistently increase despite stable or reduced estrogen levels.Transgender individuals who receive psychotropic medications were excluded.
Results
Thirty-nine male-to-female transsexual persons were included (mean age 29.05 $\pm$ 11.63 years). 68.8% with oral estradiol mean doses 17.18 $\pm$ 5.74 mg/week, 31.2% estradiol transdermal patch mean doses 45.15 $\pm$ 36.85 mg/week and 78.3% plus cyproterone acetate mean doses 52.13 $\pm$ 22.99 mg/day.Prior to treatment, prolactin levels (PRL) were 13.97 $\pm$ 9.33 ng/ml,estradiol(E2) 43.90 $\pm$ 30.27 pg/ml,testosterone(T2) 274.88 $\pm$ 215.41 ng/dL, LH 4.78 $\pm$ 5.51mUI/ml and FSH 5.16 $\pm$ 6.44 mUI/ml.After a mean follow up of 24.7 $\pm$ 35.6 months, PRL increased to 23.54 $\pm$ 14.19 ng/ml ($P = 0.02$),E2 to 48.89 $\pm$ 24.92 pg/ml ($P = 0.03$), T2 dropped to 111.25 $\pm$ 160.03 ng/dL ($P = 0.023$), LH to 2.01 $\pm$ 3.42 mUI/ml ($P = 0.021$) and FSH to 2.60 $\pm$ 4.34 mUI/ml ($P = 0.025$). None prolactinomas were reported.
Conclusion
Transgender females treated with estrogens have elevations in prolactin levels although any case of prolactinoma was reported.Clinicians should measure prolactin levels in transsexual people and perform imaging techniques of the pituitary in those patients with high prolactin levels.

The placenta is a highly specialized organ, which ensures nutrient uptake, waste elimination, provides thermo-regulation, prevents passage of some xenobiotic molecules and regulates the quantity of thyroid hormones (TH) necessary for the fetal development. It is known, that even minor changes in maternal TH levels, can alter the fetal growth. Several factors can modify TH levels during pregnancy. Among them, increasing evidences show that prenatal exposure to persistent organic pollutants (POP), such as brominated flame-retardants (PBDE), polychlorinated dibenzo-*p*-dioxins and furans (PCDD/F), and polychlorinated biphenyls (PCB), could disrupt the maternal TH regulation system. Some years ago, we investigated the association between some POP measured in placenta and congenital cryptorchidism [1–3]. Congenital cryptorchidism is a genital malformation that occurs in 2-9% of newborns and it is associated with decreased semen quality and higher risk of testis cancer. Several factors seem implicated in such pathology; however, the possible relationship between cryptorchidism and thyroid hormone levels during the uterine life in boys born with such malformation has been poorly investigated. The aim of this study was to analyze the level of thyroxine (T4), 3,3′,5-triiodo-L-thyronine (T3), 3,3′,5′-triiodo-L-thyronine (rT3) in 58 placenta samples (28 cryptorchid boys, 30 controls) using a LC-MS method recently developed in our group [4]. The samples were randomly selected at the end of the 3rd trimester and collected at birth. The entire placenta was homogenized prior analysis and stored at -20° C.

Results

No difference was detected in thyroid hormone values between the case and control group. No differences between the two groups with respect to maternal smoking, maternal age, BMI, and birth weight was found. Only a difference was seen in gestational age between case and control. Although no association of placental thyroid hormone levels with congenital cryptorchidism was found, for more complete overview, future study should include TH measurement in maternal and fetal placenta as well as in the cord blood.

Abnormal uterine bleeding in adolescents: experience of a single center

Selin Elmaogullari & Zehra Aycan
Dr Sami Ulus Children's Hospital, Pediatric Endocrionology, Ankara, Turkey.

Introduction

Abnormal uterine bleeding (AUB) refers to uterine bleeding that is excessive or occurs outside of normal cyclic menstruation. The most common cause of AUB in adolescents is anovulatory cycles due to immature hypothalamic-pituitary-ovarian axis. Additionally, endocrinological problems (hypothyroidism, hyperprolacitenemia, etc.) and bleeding disorders may cause AUB. The management of AUB begins with an assessment of whether or not the patient is hemodynamically stable and then proceeding with medical management based on etiology and the severity of anemia. The aim of the study was to assess etiological factors and treatment of AUB in adolescents in our clinic.

Method

We evaluated the clinical and laboratory features of 29 adolescents with AUB referred to adolescent outpatient clinic within 2 years of time. Hemogram, TSH, free T4, beta HCG, FSH, LH, E2, prolactin and von Willebrand factor antigen, prothrombin time, partial thromboplastin time measurement and pelvic ultrasonography were done in all patients. The severity of bleeding was assessed as mild(Hb: $\geqq$12 g/dl), moderate(Hb: 10–12 g/dl) and severe(Hb: $<$10 g/dl).

Results

The mean age of the patients at menarche and admission were 12.1 ± 0.9 (10.5–14.0) and 13.7 ± 1.6 (11.3–16.9) years respectively (mean time between them 1.6 ± 1.3 (0.0–4.9) years). 55% of the patients had heavy and irregular menstrual bleeding and 45% of the patients had heavy bleeding since menarche. The severity of bleeding was assessed as mild in five patients, moderate in four patients and severe in 20 patients. None of them were found to have a bleeding disorder and one patient had uterus didelphys. One patient with severe AUB had hypothyroidism. In 93% of the patients AUB was due to anovulatory cycles. 25 (86%) patients were treated with oral contraceptives. Three patients were treated with tranexamic acid and six patients had to be given erythrocyte transfusion due to hemodynamic instability.

Conclusion

The most common cause of AUB in adolescents is anovulatory cycles. Once hemodynamic stability is controlled and provided, the patient must be evaluated for severity of anemia, possible bleeding disorders and causes of AUB.

Breast hypertrophy (macromastia) in puberty: case report

Gayane Bayburdyan, Lusine Arakelyan & Yelena Aghajanova
Yerevan State Medical University, Yerevan, Armenia.

Background

Virginal breast hypertrophy is a rare benign disease. It is a condition of abnormal enlargement of the breast tissue and is characterized by rapid and excessive growth of one or two breasts during peripubertal period. This condition causes significal psychological and physical discomfort to affected adolescents, such as feeling embarrassed, inability to find appropriate clothes, suffering from back and shoulders pain, perhaps the appearance of kyphosis under the weight of the breasts.

Case report

12 year old girl presented to the Endocrinology Department of our University clinic with the complaint of intensive breast growth for the past 5-6 months. Menarche at age 11 years old, regular menstrual cycles. Hormone levels, such as Prolactin, LH, FSH, estradiol, were within the normal range. Ultrasound of the mammary glands was only significant for dilated ducts up to 2.0 cm and small

pelvis without any abnormal features. Within one month of observation, foci of necrosis appeared on the skin mammary glands, with progressive involvement of previously unaffected areas, causing significant pain and suffering. Despite normal hormonal evaluation, a progestin therapy with dydrogesterone at a daily dose of 20 mg/day was initiated. Despite the therapy, the growth of the mammary glands and necrosis continued, therefore the decision was made to proceed with a mastectomy with further mammoplasty at age 18.

Conclusions and follow up

When considering mastectomy in a teenager, an accurate diagnosis and rigorous treatment plan require a team approach, including pediatric, medical and surgical disciplines. Outcomes data are scarce as most available data are limited to small case series or case reports.

In vitro characterization and comparison of commercial GnRH antagonists

Samantha Sperduti[1], Laura Riccetti[1], Clara Lazzaretti[1], Manuela Simoni[1,2,3] & Livio Casarini[1,2]

[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Center for Genomic Research, University of Modena and Reggio Emilia, Modena, Italy; [3]Department of Medicine, Endocrinology, Metabolism and Geriatrics, Azienda Ospedaliero-Universitaria di Modena, Modena, Italy.

Introduction

Hypothalamic gonadotropin releasing hormone (GnRH) regulates mammalian reproductive system. It binds receptors (GnRHRs) expressed in gonadotrope cells of anterior pituitary, regulating the synthesis and secretion of follicle-stimulating hormone (FSH) and luteinizing hormone (LH). GnRHR is a G protein-coupled receptor (GPCR) coupled to Gαq/11 protein and, to a lesser extent, to Gαi/Gαs proteins, simultaneously activating Ca^{2+}, β-catenin signaling and mitogen-activated protein (MAP)-kinases. GnRHR ligands were developed to be used as GnRH agonists and antagonists.

Aim

The aim of this study is to compare three GnRH antagonists, Cetrorelix, Ganirelix and Teverelix, in modulating GnRH-induced intracellular signaling *in vitro*. To this purpose, dose-finding and kinetics were evaluated.

Methods

Experiments were performed in GnRHR-transfected HEK293 cells, and in the human derived neuroblastoma (SH-SY5Y) cell line, naturally expressing GnRHR. GnRH-induced intracellular Ca^{2+} increase and cAMP production were evaluated by BRET, while CREB and ERK1/2 phosphorylation by Western blotting, in the presence or in the absence of GnRH antagonists.

Results

Upon stimulation by increasing doses of GnRH (pM-μM range), intracellular cAMP and Ca^{2+} accumulation occurred in HEK293 cells transiently over-expressing GnRHR (cAMP $EC_{50} = 11.58 \pm 0.29$ nM, $n = 3$; Ca^{2+} $EC_{50} = 25.97 \pm 0.15$ nM, $n = 3$). Moreover, 1 μM GnRH treatment produced a rise in intracellular cAMP sustained over 50 min ($n = 3$) in transfected HEK293, while it resulted in no significant cAMP accumulation in SH-SY5Y cells expressing endogenous GnRHR ($P < 0.05$, one-way ANOVA; $n = 3$). In GnRHR-transfected HEK293 cells, Ca^{2+} increase induced by treatment using concentration of 3-fold the EC_{50} GnRH was suppressed by 1 μM of antagonists ($P < 0.05$, one-way ANOVA; $n = 2$), while no significant inhibition was detected at lower doses of Ganirelix and Teverelix (pM-nM range). Only 100 nM Cetrorelix prevented GnRH-induced intracellular Ca^{2+} increase ($P < 0.05$, one-way ANOVA; $n = 2$). nM concentrations of GnRH failed to induce CREB and ERK1/2 phosphorylation in transfected HEK293 cells and in SH-SY5Y cells.

Discussion

Cetrorelix, Ganirelix and Teverelix have different *in vitro* activity, evaluated in terms of GnRH-induced intracellular Ca^{2+} increase, suggesting that these drugs may act differently at the molecular level.

Conclusions

Since GnRH antagonists may be not equivalent *in vitro*, drug-specific effects *in vivo* should not to be excluded.

Facial feminization/masculinization: the effect of hormone treatment in transpersons

Marieke Tebbens, Nienke Nota, Niels Liberton, Brigitte Meijer, Baudewijntje Kreukels, Tim Forouzanfar, Ruud Verdaasdonk & Martin den Heijer

VU University Medical Center, Amsterdam, Netherlands.

Background

Facial feminization or masculinization is particularly important in transpersons, both for self-image and social interaction. Females tend to have a smaller, rounder face, with more prominent cheeks and males tend to have a larger, more square face with frontal bossing. It is unknown whether cross-sex hormones can change these features. However, transgenders themselves often report facial changes due to hormone treatment. Therefore we aim to objectify if hormone treatment in transpersons can cause facial feminization and masculinization.

Design

In a single center cohort study, we studied persons diagnosed with gender dysphoria, transwomen and transmen, who were treated with a regimen of hormones according to protocol (estrogen and cyproterone acetate in transwomen and testosterone in transmen). 3D facial images were made with an Artec Spider scanner at baseline and after 3 months of treatment. The primary outcome was relative local shift of skin in millimeters after 3 months of treatment, measured in 22 soft tissue landmarks.

Results

We included 14 transwomen and 6 transmen, mean age 28.3(IQR 21.5–30.0 years). Face surface mappings (colormaps) in transwomen demonstrated a small shift of skin in the jaw and cheek region. The gonion landmark shifted towards the origin in the x-axis (mean = 1.19 mm; 95%CI, −0.46 to 2.43) and the cheek landmark shifted away from the origin in the z-axis (mean = 0.50 mm; 95%CI, 0.09 to 0.91). In transmen, the colormap showed a small increase in the cheek region, corresponding with a measured shift towards the origin in the z-axis (mean = −0.54 mm; 95%CI, −0.77 to −0.31).

Conclusions

In both transwomen and transmen the face shows changes in the first 3 months of treatment. In transwomen the shifts implicate a rounding of the jaw and an increase in cheek tissue. In transmen the shift implicates a decrease in cheek tissue. These changes suggest that hormonal treatment induces facial feminization in transwomen and masculinization in transmen. Furthermore, this research shows that 3D imaging is a promising tool for the evaluation of facial changes.

Polycythemia in transmen – Prevalence, determinants and outcome in a large cohort

Dennis van Dijk, Chantal Wiepjes, Christel de Blok, Maartje Klaver, Nienke Nota, Marieke Tebbens, Martin den Heijer & Elfi Conemans
VU Medical Center, Amsterdam, Netherlands.

Introduction
Testosterone is known to have an effect on hematocrit levels, with polycythemia as an unwanted side effect. An increase in hematocrit levels is also seen in transmen after starting cross-sex hormonal treatment (CHT) with testosterone. The aim of this study is to investigate the effect of cross-sex hormonal treatment with testosterone on hematocrit levels in the context of the safety aspects of this treatment. The prevalence, determinants and outcome of secondary polycythemia were studied in a large cohort of transmen.
Methods
Adult female-to-male transpersons who started cross-sex hormonal treatment with testosterone and were monitored with laboratory control of hematocrit levels at our center were included. Polycythemia was defined as a hematocrit > 50%, measured at any moment in treatment. The prevalence of a hematocrit > 50% and > 54% and thrombogenic complications were studied. Determinants in the development of polycythemia studied were age at start of hormonal treatment, tobacco use, medical history, testosterone levels and type of testosterone admission.
Results
Of the 1218 patients included, 24.8% developed a hematocrit (Ht) > 50%, 4.2% had a maximum hematocrit of > 54% during the median 60 months of follow-up. The relative risk for smokers to develop a Ht > 50% was 1.27 (95% CI 0.90–1.78) and 1.67 (95%CI 0.84–3.34) for a Ht > 54%. Compared to testosterone gel, for injection with esters the OR for the development of a Ht > 50% is 2.00 (CI 1.30-3.08) and for a Ht > 54% 4.46 (CI 1.29–15.4). Compared with testosterone undecanoate, the OR is 2.12 (CI 1.25–3.63) for the development of a Ht > 50% and 4.12 (CI 1.01–16.9) for the development of a Ht > 54% respectively.
Discussion
Polycythemia is seen as a frequent side effect of testosterone admission in transmen. The number in thrombogenic complications was low. Tobacco use increases the risk of developing high hematocrit levels. Compared to testosterone gel, both injections, testosterone esters and testosterone undecanoate, increased the risk to develop polycythemia.

17-Beta hydroxysteroid dehydrogenase 3 deficiency: Three case reports

Mehdi Kalthoum, Bochra Ben Rhouma, Mouna Elleuch, Faten Hadjkacem, Dorra Ghorbel, Mouna Mnif, Nabila Rekik & Mohamed Abid
CHU Hedi Chaker, Sfax, Tunisia.

Introduction
Deficiency of 17-βHSD3 is a rare autosomal recessive disorder of sex development manifesting in XY karyotype individuals. The presentation can range from partial or incomplete virilisation at birth to primary amenorrhoea and virilisation at puberty of an externally phenotypically female individual.
Case reports
Case1 A 2-year-old girl presented with ambiguity of external genetalia. She had no significant past medical or surgical history. On exam she had cliteromegaly measuring 2.5 cm and bilateral inguinal mass consistent with gonads (Prader stage4). Pelvic MRI showed inguinal testis, normal adrenal gland, a blind vagina and absent internal female structures. The serum testosterone (T) was 0.9 ng/ml and rose to < 3 ng/ml after HCG stimulation. The serum androstenedione(A) was 12 ng/ml (8–250). The T:A ratio was low 0.16 (< 0.8). The karypotype was XY. Gene analysis revealed a homozygous mutation of the 17-βHSD3gene, c618C > A. She underwent bilateral orchidectomy at at the age of 3, genitoplasty at the age of 8 and was commenced on oral estrogen. This resulted in satisfactory breast development and sexual intercourse was more comfortable. Case 2: (Cousin of the first patient) A 7-year-old girl presented with inguinal hernia. On exam she had cliteromegaly (Prader stage1). Pelvic ultrasound and MRI showed inguinal testis and absent internal female structures. The karypotype was XY and gene analysis showed the same mutation as the first case (heterozygous). Case 3: A 16 year old woman presented with primary amenorrhoea, poor breast development, hirsutism and cliteromegaly. She had increased hair growth on her abdomen and face as well as increased muscle mass and deepening of her voice. Pelvic ultrasound and MRI showed uterine and ovarian agenesis. The karypotype was XY. The serum testosterone was 2.82ng/ml. The serum androstenedione was high at 9.6 ng/ml (three times the upper limit of normal). The T:A ratio was 0.3 (< 0.8) after HCG stimulation. Diagnosis of 17-βHSD3 deficiency was confirmed with genetic mutation of the 17-βHSD3 gene.
Conclusion
We have described 3 patients with classic clinical and biochemical features of 17-βHSD3 deficiency in whom a mutation was identified in the 17-βHSD3 gene. Identification of affected individuals and molecular biologic studies may help elucidate the clinical conundrums of this disorder. For patients who have a female gender identity, management includes orchidectomy to reverse virilisation and to remove gonads with malignant potential. Estrogen replacement is provided to maximise female secondary sexual characteristics and to prevent bone loss.

Relationship between hypothyroidism and androgen deficiency in men in different periods of mature age

Taras Krytskyy
Ternopil State Medical University, Ternopil, Ukraine.

The aim of the present study is to determine the relationship between hypothyroidism and androgen deficiency in men of mature age.
Material and methods
60 men with primary hypothyroidism ranging in age from 21 to 60 years were studied. The men were divided into two age groups according to the periods of human ontogenesis – the group of the first period of mature age (from 21 to 35 years) and the second group of the mature age (from 36 to 60 years).
Results
Age-related changes in the hormonal status of the examined men in the first and second mature periods were related to the content of blood serum total and free testosterone. In the second period of mature age men, the content of total testosterone was 1.36 times lower and free testosterone – 1.54 times lower than in men in the first mature period. Reduction of testosterone levels in the older age group men were not accompanied by increased levels of gonadotropins in the blood. This fact may evidence the low sensitivity threshold of the pituitary-hypothalamic system to a decrease in the production of testosterone with age. In both men age groups with hypothyroidism the content of total testosterone in the blood serum was lower than in men without hypothyroidism. However, the influence of hypothyroidism was more expressed in men of the first mature period, in which the presence of hypothyroidism was associated with a decrease in the content of the hormone by 2.14 times. In addition the decreasing in this magnitude by 1.36 times was in men of the second period of mature age. The frequency of hypogonadism was 45.2% in men of the second period of mature age, including men without hypothyroidism – 32.9%, and with hypothyroidism – 61.7%. The correlation analysis established the presence of statistically significant ($P < 0.05$) feedbacks between the level of total testosterone and the values of indicators characterizing hypothyroidism.
Conclusions
The presence of hypothyroidism is associated with androgen deficiency in men of the second period of mature age in 60% of cases, but, in comparison with men of the first period of mature age, clinical features of androgen deficiency are more expressed in the second period.

A silent thyroiditis in the remission period of Graves' disease

Cem Onur Kirac, Suleyman Ipekci, Gonca Kara Gedik & Levent Kebapcilar
Selcuk University, Faculty of Medicine, Konya, Turkey.

Silent thyroiditis is characterized by the destructive thyroid inflammation and is considered to be a chronic autoimmune thyroid disease, although the etiology could not have been fully explained. On the other hand, Graves' disease is autoimmune phenomena as well as silent thyroiditis and silent thyroiditis has been classified as part of the spectrum of Graves' disease. Although, the thyroid stimulating antibody (TSAb) are found positive in most of Graves' disease but rarely in silent thyroiditis cases and the role of TSAb in the pathogenesis of these diseases has still been unknown. In this case report, we aimed to present a rare case in which repeated thyrotoxicosis as a silent thyroiditis was followed by Graves' disease. A 40 year old woman admitted to outpatient clinic with the complaint of palpitations, sweating and weight loss 3 years ago. Laboratory results were TSH: 0.005 μIU/ml (normal:0.56–5.57), sT3: 8.5 pg/ml (normal:2.3–4.2), sT4: 4.05 ng/dl (normal:0.93–1.7) and anti-thyroid peroxidase and anti-thyroglobulin antibodies were positive. Thyroid scintigraphy showed homogeneous increased uptake involving the whole thyroid gland and the patient was diagnosed with Graves' disease. Treatment of the patient with propylthiouracil was stopped at the 18th month of treatment. After the 18 months of untreated follow-up, she was referred to our hospital with complaints of palpitation, tremor and sweating. On the physical examination of the patient the painless thyroid gland was palpable. Laboratory findings were as follows; TSH: 0.006 mU/l, sT3: 3.54 ng/l, sT4: 1.6 ng/dl and ESR was normal. Thyroid scintigraphy revealed a decreased uptake in the thyroid gland. The patient was diagnosed with silent thyroiditis and propranolol was started for symptoms. One month later, laboratory findings were TSH: 10.08 mU/l, sT4: 0.894 ng/dl, sT3:2.59 ng/l and the propranolol therapy was withdrawn and low-dose levothyroxine therapy was started. In a study with the patients who were followed up Graves' disease in remission that developed thyrotoxicosis during pregnancy and postpartum period, postpartum thyroiditis was diagnosed in 44% of patients, and 28% of patients were evaluated as Graves' exacerbation. Although the relationship between Graves' remission and silent/postpartum thyroiditis is not fully demonstrated. In conclusion, other thyrotoxicosis causes should be excluded before the patient is accepted as Graves' recurrence after the thyrotoxicosis in patients who are followed up due to Graves' disease in remission.

Amyloid goiter secondary to rheumatoid arthritis

Randa Salam & Mona Hammady
Faculty of Medicine Cairo University, Cairo, Egypt.

Introduction
Amyloidosis refers to a variety of conditions in which amyloid proteins are abnormally deposited in organs and/or tissues. Clinically significant enlargement of the thyroid owing to amyloid deposition is a rare occurrence.
Case report
58-year-old female referred to endocrinology clinic presenting with increasing dyspnea, dysphagia and visible swelling at the base of the neck for the last 6 months. She had been diagnosed with rheumatoid arthritis six years ago but had not used the prescribed medication regularly; she is on regular nonsteroidal anti-inflammatory drugs. Physical examination revealed: BP, 130/70 mmHg; HR, 100 bpm; RR, 22/min. Temperature, 37°C. Enlarged thyroid gland firm in consistency with multiple nodules on palpation. Laboratory test results included: TSH, 1.24 IU/dl (normal range, 0.4–4.0); free T3,2.2 ng/dl, free (N,2.3–4.4) free T4, 1.21 ng/dl (normal range, 0.7–2) glucose, 90 mg/dl, albumin; 3.6 g/dl, creatinine, 1.7 mg/dl; 24-h proteinuria, 1.9 g/day. Both of the thyroid lobes are enlarged in the ultrasound examination. The right lobe showed multiple nodules of 45–50 mm size, with areas of cystic degeneration. Renal ultrasound examination revealed grade II nephropathy. Echo heart showed impaired left ventricular filling, sclerotic aortic valve, and normal ejection fraction.Because of compressive symptoms, a computed tomography (CT) scan was performed before surgery, showing multinodular goiter with no tracheal compression. Total thyroidectomy was done Microscopic study of the specimen showed extensive infiltration of thyroid parenchyma by an amorphous expansive amorphous eosinophilic substance deposition and lipid infiltration in the whole thyroid gland. On Congo red dye staining, amyloid deposition was stained red in the interstitial space and it showed an apple-green birefringence with the polarizing microscope with no neoplastic cells. Renal biopsy was performed due of kidney involvement, showing kidney infiltration by amyloid with marked tubulo- interstitial fibrosis.
Conclusion
Amyloid goiter is an atypical presentation of an already rare disease. A high index of attentiveness should be kept whenever amyloid deposits are seen on fine needle aspiration cytology, as they are also established in medullary carcinoma. The confirmative diagnosis rested on the histopathology of the specimen.

An uncommon but serious hematological manifestation of Grave's disease: Grave's disease induced bicytopenia

Pei Shan Yeo
Tan Tock Seng Hospital, Singapore, Singapore.

Graves' disease (GD) is a common cause of hyperthyroidism. Associated hematological complications rarely occur. Most review articles describe it as a rare manifestation and often reported as isolated cases or series. These disorders in hyperthyroidism may stem from the primary thyroid pathology or its treatment. In untreated primary hyperthyroidism, effects on hematological parameters range from mild single lineage involvement to pancytopenia. The most feared treatment related hematological disorder is drug induced agranulocytosis. We present a middle-aged gentleman with 10 year's history of GD. Over the last 2 years, he had repeated admissions for severe thyrotoxicosis, sepsis and recurrent pancytopenia. In end 2014, he was admitted for an episode of neck cellulitis. He was floridly hyperthyroidism and had developed new onset bicytopenia – leucopenia (neutropenia) and thrombocytopenia. He had stopped taking his regular dose of Carbimazole 30 mg OM for the last 2 weeks. The bicytopenia was unlikely drug-induced agranulocytosis due to his non compilance. A multidisciplinary team was involved including endocrinology, hematology and nuclear medicine. An attenuated dose of Carbimazole 20 mg daily was restarted with close monitoring of his cell counts. Cholestyramine was added as an adjunct. Granulocyte-colony-stimulating-factor (GCSF) injections were initiated to boost the neutrophil counts. The patient also underwent a bone marrow examination (BME). The BME showed quantitatively adequate granulopoiesis with normal neutrophil count and increased megakaryopoiesis. The mildly hypercellular marrow with adequate hematopoiesis in all 3 cell lines suggested that the ongoing neutropenia and thrombocytopenia is secondary to peripheral consumption and destruction. Carbimazole induced agranulocytosis would result in a hypocellular marrow. Thus, the most evident cause of the bicytopenia was an autoimmune cause from hyperthyroidism. The patient's neutrophil and platelet counts improved as he achieved an improved thyroid state. This improvement of cell counts together with his thyroid status further reinforced the hypothesis of hyperthyroidism induced bicytopenia. The patient discharged well with an outpatient appointment for definitive therapy with radio-iodine ablation. However, he remained poorly compliant. This resulted in three further admissions for similar presentations of sepsis, florid hyperthyroidism and bi- or pancytopenia. His recovery of his cell counts would always mirror the improvement of thyroid status. He eventually received two doses of RAI 6 months apart. Mr N responded adequately to the 2nd dose of RAI therapy. At 8 weeks' mark, he was euthyroid status. The hematological abnormalities had fully resolved along with this.

A rare cause of subclinical hypothyroidism: macro-TSH

Cem Onur Kirac[1], Sedat Abusoglu[2], Esra Paydas Hataysal[2], Ayse Gul Kebapcilar[3], Suleyman Ipekci[1], Ali Unlu[2] & Levent Kebapcilar[1]
[1]Selcuk University, Faculty of Medicine, Division of Endocrinology and Metabolism, Konya, Turkey; [2]Selcuk University, Department of Biochemistry, Konya, Turkey; [3]Selcuk University, Faculty of Medicine, Department of Gynecology and Obstetrics, Konya, Turkey.

Macro TSH is a large molecular-sized thyroid-stimulating hormone (TSH) that is including TSH and anti-TSH antibody. Patients with macro TSH have elevated serum TSH and normal free thyroxine levels similar to subclinical hypothyroidism. A 18-year old female patient was referred from gynecology and obstetrics to endocrinology clinic for evaluating of elevated TSH with normal free thyroxine levels. Laboratory and clinical investigations revealed that only discordant TSH levels (normal reference range: 0.25–4.2 μIU/ml; two times separately checked results; 5.65 μIU/ml; 5.47 μIU/ml; respectively) with electrochemiluminescence immunoassay method with no other any demonstrable hormonal or clinical findings. On admission to our endocrinology department, she was clinically euthyroid. She had no history of medication or ilness. The patient had normal thyroid ultrasound pattern with tested mildly positive for both thyroglobulin and thyroid peroxidase antibodies. Rheumatoid factor, which can act like heterophile antibodies, was undetectable in this patient. Polyethylene glycol (PEG) method for TSH measurement was planned to find out the macro-TSH. We have used the same blood samples which of the TSH levels were found to be high, while using the PEG method was found to be within normal ranges as 1.50 mIU/L (5.65 μIU/ml to 1.50 μIU/ml; decrease of 75%) and 1.26 mIU/l (5.47–1.26 μIU/ml, decrease of 77%); respectively. The TSH value was exhibited to be markedly low by PEG precipitation test in our patient that she had PEG-precipitable TSH ratios greater than 75% as well as it's supposed to be reported by Hattori et al study. Macro-TSH should be kept in mind in patients with high TSH levels without symptoms of hypothyroidism in the differential diagnosis before unnecessary investigations and treatment.

Manifestation of thyrotoxic crisis after delivery: clinical case report

Vilma Vezbaviciene[1] & Neli Jakuboniene[1,2]
[1]Department of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Thyrotoxic crisis is a manifestation of an extreme and rare state of thyrotoxicosis. It is an acute, life-threatening state. The mortality of thyrotoxic crisis is currently reported at 8–25% [1]. The clinical presentation includes fever, tachycardia, hypertension followed by congestive heart failure, neurological and mental disorders. We present a case of 34-year-old woman without any history of thyroid hyperactivity. She was admitted to hospital after premature amniotic fluid leakage in 34th week of her second pregnancy and complained of intensive dyspnoe. After patient full examination it was decided to deliver the baby by Caesarean section because of progression of cardiopulmonary failure (her heart rate was 156 bpm, blood pressure 181/91 mmHg, respiratory rate 44 bpm, O_2 saturation 91%, ejection fraction was 30%). After section her condition remained critically serious and she moved to intensive care. Her respiratory failure required ventilatory support for 11 days, she had fever (T 39.6 °C), uncontrolled tachycardia and hypertension despite treatment. Although she was initially thought to have severe preeclampsia with pulmonary oedema complicated pneumonia, but her thyroid function tests indicated severe thyrotoxicosis: TSH <0.01 (normal 0.4–3.6 mU/l), free T_3 35.35 (normal 3.34–5.14 pmol/l), free T_4 82.58 (normal 9–21.07 pmol/l). This clinical picture was consistent with a diagnosis of thyrotoxic crisis. Treatment was started with thiamazole 80 mg/d, intravenous hydrocortizone 200 mg/d, Lugol's iodine 5% 20–30 drops/d, propranolol 160 mg/d and supportive care. Despite thyroid decreasing function, 7th day after section patient state remains difficult and it was decided to increase thiamazole dose to 120 mg/d, hydrocortizone to 300 mg/d and change propranolol to metoprolol 200 mg/d. Following 2 weeks on intensive care she made a remarkable recovery. She was discharged home on the 32nd postoperative day with a healthy baby. Now she is on endocrinologist control, her last anti-TPO was 2354 (normal 0–12 kU/l), anti-Tg 51 (normal 0–100 kU/l), anti-TTH 15.2 (normal <9 U/l). Thyroid ultrasound – thyroid gland was enlarged, hypoechogenic and heterogeneous structure because of hypoechogenic zones. According to test results it was diagnosed Graves' disease. It is almost one year after thyroid storm, she still has persistent subclinical hyperthyroidism despite consistent treatment with thiamazole. So, we are considering thyroidectomy. Reporting this case we want physicians to be aware of this rare situation as symptoms of thyrotoxic crisis are similar to those of preeclampsia.

Sunitinib induced myxedema in a patient with metastatic gastrointestinal stromal tumor (GIST)

Maria Lavinia Popa & Ioan Horea Ursu
Parhon National Institute of Endocrinology, Endemic Goiter and its Complications Department, Bucharest, Romania.

Introduction
It is known that hypothyroidism has multiple etiologies including tyrosinkinase inhibitors (TKI) agents which can cause thyroid disfunction through different mecanisms, not fully defined yet- Vascular endothelial growth factor receptor (VEGFR) blockade, thyroiditis, iodine uptake blockade, increased activity of deiodinase 3, increased hormone clearance. Some recent trials suggest that there is a correlation between the incidence of hypothyroidism and the outcome of patients treated with TKI, therefore the occurrence of hypothyroidism during Sunitinib treatment is a predictive marker of a progression-free survival.
Case report
We report the case of a 62-year-old female, with a family history of hypothyroidism (daughter- Hashimoto's disease). The patient was diagnosed in 2007 with metastatic retroperitoneal tumor GIST and since 2010 she has been treated with Sunitinib. She was first referred to our Institute in June 2017, after being diagnosed with pericarditis (medium pericardial effusion, without cardiac tamponade). The patient complained about gaining weight (7 kg in the past few months), extreme fatigue, palpebral edema, dry skin and cold intolerance. The hormonal profile found a TSH level = 69 μUI/ml (normal range = 0.5–4.5) with FT_4 = 3.84 pmol/l (normal range = 10.3–24.4) and a negative ATPO. Biochemical tests revealed hypercholesterolemia (cholesterol = 227 mg/dl), hypertrigliceridemia (trygliceride = 258 mg/dl), increased serum creatinine level (creatinine = 1.63 mg/dl), moderate anemia (hemoglobin = 10.1 g/dl), neutropenia (1.6×1000/ul) and high inflammatory markers (VSH = 65 mm/h). Thyroid ultrasound revealed a typical pattern for atrophic thyroiditis and a group of macrocalcifications in the left lobe. We initiated the treatment with 37.5 μg levothyroxine for the first 10 days, then progressively raised at 50 μg/day for the next 14 days; then to 62.5 μg/day, 75 μg/day, 87.5 μg/day until the dosage of 100 μg/day, with a decline in TSH from 69–1.55 μUI/ml and an improvement in renal function from a 1.63 mg/dl creatinine level to 0.85 mg/dl. Also, the pacient has a good response to Sunitinib, based on the long progression free survival (2010–2018).
Conclusion
Hypothyroidism induced by Sunitinib is a common side effect of the molecule. It is important to recognize it in a patient who is being treated with TKI in order to prevent possible complications. In addition, this case report comes to strengthen some recent opinions regarding a longer progression free survival in patients who develop hypothyroidism during treatment with Sunitinib.

Tuberculosis abscess resembling thyroiditis

Ayşegül Oruç[1], Suat Akgür[1], Abdülmecit Yıldız[1], Canan Ersoy[2], Özen Öz Gül[2], Soner Cander[2] & Alparslan Ersoy[1]
[1]Uludag University Medical Faculty, Department of Nephrology, Bursa, Turkey; [2]Uludağ University Medical Faculty, Department of Endocrinology and Metabolism, Bursa, Turkey.

Tuberculosis (TB) infection incidence is still high among solid organ transplant recipients. TB in recipients can manifest several years after transplantation, especially in developing countries. Atypical clinical presentations and extra-pulmonary involvement are not uncommon in recipients. Herein, we reported a kidney transplant recipient with TB abscess who admitted with fever and swelling on thyroid gland region.

Case

A 57-year old female recipient underwent a successful deceased kidney transplantation 4 years ago. She applied to our outpatient clinic with fever and swelling on the thyroid gland region. She complained fever for 20 days without sweating and tender swelling with hyperemia in front of her neck. On physical examination there was only hyperemic, hard, fixed, 6×8 cm diameter swelling in the midline of the neck which was enlarged to the right side. The laboratory tests revealed neutrophilic leukocytosis (15.0 K/mm^3), elevated CRP (23.7 mg/dl), creatinine (1.5 mg/dl) and PTH (698 pg/ml); low 25-OH vitamin D (<8 µg/l), calcium (8.3 mg/dl) and TSH (0.269 µIU/l); normal free T4 (1.2 ng/dl) and thyroglobulin (32 ng/ml) levels. Ultrasonography revealed hypoechogenic nodular thyroid gland and a 7.5×7 cm heterogeneous cyst. Neck computed tomography showed a 7.5×7 cm diameter abscess on the right cervical region extending to the upper mediastinum. Thyroid and parathyroid scintigraphies (Tc-99m pertechnetate + Tc-99m MIBI) revealed that the mass was unrelated to these glands. Secondary hyperparathyroidism due to vitamin D deficiency was diagnosed. Empirically meropenem and teicoplanin were administered. The drainage of the abscess was performed with micropuncture. Because of the mediastinitis risk the abscess was drained totally. Mycobacterium tuberculosis was detected with polymerase chain reaction of suppurative drainage material. A four-drug regimen with isoniazid, rifampycin, ethambutol and pyrazinamide was initiated. The abscess resolved and she was discharged with anti-tuberculosis regimen and immunosuppressive drug dose arrangement.

Conclusion

Extrapulmonary or disseminated TB infection rate after transplantation is 30–50%. Although TB occurs within the first year of the transplantation in 95% of the cases, it may appear late as in the present case. Extrapulmonary TB infection should be kept in mind in recipients with atypical suppurative lesions in thyroid region as was the case in our patient.

Significant cardiac disease complicating Graves' disease in the young

Justyna Witczak[1,2], Ravikumar Ravindran[2,3], Sam Rice[1], Zahir Yousef[4] & Lakdasa DKE Premawardhana[2,3]
[1]Department of Diabetes and Endocrinology, Prince Philip Hospital, Llanelli, UK; [2]Centre for Endocrine and Diabetes Sciences, University Hospital of Wales, Cardiff, UK; [3]Department of Diabetes and Endocrinology, Ysbyty Ystrad Fawr, Caerphilly, UK; [4]Department of Cardiology, University Hospital of Wales, Cardiff, UK.

Introduction

Graves' disease (GD) is associated with cardiac complications like tachydysrythmias, coronary ischaemia and cardiomyopathy. They are uncommon in the young. We present three individuals without previous cardiac disease, who developed significant cardiac complications of GD.

Case presentations

Subject 1

A 34-year-old female smoker, presented with breathlessness, palpitations, tremors and agitation for several weeks. Her fT4 was 98.4 (11–25 pmol/L), fT3 46.9 (3.1–6.8 pmol/L), TSH<0.01 (0.27–4.2 mU/l) and thyrotrophin receptor antibody (TRAb) 34.8 (<0.9 U/l). A thyroid storm was diagnosed, and she was given carbimazole, betablockers, steroids, antibiotics and intravenous fluids. A few days later, she became breathless and on echocardiography, cardiomegaly and pericardial effusion (2.9 cm) was seen, despite improving thyroid function (fT4 27.8; fT3 12.8). She had steroids and nonsteroidal agents with good response. There were no other identifiable causes for her pericardial effusion.

Subject 2

A 28-year-old previously fit male presented with weight loss, palpitations, sweating and diarrhoea, with a goitre and bruit. His fT4 was 38, fT3 13.9, TSH< 0.01 (abnormal for over 6 months) and TRAb 9.3. He was given carbimazole, but one month later presented with acute heart failure (HF) despite improving thyroid function. Echocardiography revealed severe dilated cardiomyopathy (DCM) with an ejection fraction (EF) of 12% and lisinopril, bumetanide, epleronone and ivabradine were given. Echocardiography 4 months later (when euthyroid), showed improvement in EF to 21%. Further investigations (including angiography and MRI) ruled out other causes for DCM. He awaits thyroidectomy.

Subject 3

A 42-year-old previously healthy woman presented acutely with palpitations, breathlessness and leg swelling, and was found to be in fast atrial fibrillation and HF. She had been thyrotoxic for several months (free T4 54.3; free T3 >46.1; TSH <0.01; TRAb 4.5) and had bisoprolol, digoxin, propylthiouracil and HF treatment. Echocardiography at presentation showed cardiomegaly, pleural effusion, and EF of 29%. Myocardial perfusion scans did not show inducible ischaemia. She had early total thyroidectomy and remains in sinus rhythm with EF of 50%.

Conclusions

Significant cardiac complications of GD (pericardial effusion, DCM, and tachycardiomyopathy) may occur in fit young patients without previous cardiac disease, who usually have had thyrotoxicosis for several months. There should be a high index of suspicion in those who remain symptomatic despite control of their thyrotoxicosis. Though the majority of patients respond well to thionamides with reversal of cardiac abnormalities, definitive treatment should be discussed early to avoid GD relapse and a recurrence of cardiac decompensation.

Thyroiditis in patients with rheumatoid arthritis, related to rituximab

Vanessa Bedoya[1], Luis Miguel Osorio[2], Melanie Santrich[3], Orlando Castaño[1], Maria Eugenia Casanova[1], Margarita Velasco[1] & Alín Abreu[1]
[1]Libre University, Cali, Colombia; [2]Santiago de Cali University, Cali, Colombia; [3]Javeriana University, Cali, Colombia.

Introduction

Rituximab is indicated in patients with active rheumatoid arthritis (RA), which through the Fab domain, binds to the CD20 antigen on the surface of B lymphocytes, generating lysis of B cells, present in the thyroid, by cytotoxicity dependent on complement, as a result of the binding of C1q, mediated by the Fc domain, destroying the thyroid follicles, by infiltration of inflammatory cells (1) (2).

Objective

Describe the characteristics of patients with RA who presented thyroiditis, after treatment with rituximab.

Methods

Descriptive study case series. We reviewed 4 clinical histories of patients with RA with therapeutic failure to DMARDs and anti TNF, without previous autoimmune thyroiditis, from a high complexity clinic in Cali, Colombia.

Results

Three patients were women, median age was 50 years (37–61), DAS28 3 (3–5), CRP 15.5 (8–28), ESR 78 (55–120), TSH 0.095 (0.01–0.2), T4L 2 (2–4), thyroid antiperoxidase antibodies 235 (92–800), and thyroiditis evolution time of 2.5 months (1–4). All had diffuse goiter by ultrasound and the scintigraphy was hypocaptant, none had a history of respiratory tract infection; they reported odynophagia and malaise. The 4 patients received management with steroid and 2 with beta-blockers. At 8 months they presented symptom improvement and complete resolution (DAS28 1 (1–3), TSH 0.9 (0.6–1.2), T4L 1.095 (1–1.3)).

Discussion
Biological agents can induce autoimmune phenomena, the evidence so far with rituximab is limited (3). Hyperthyroidism can be explained by an increased activation of thyroid peroxidase (TPO), enzyme that catalyzes reactions for the synthesis of T3 and FT4. A plausible explanation for the elevated TPO activity is a drop in the level of antibodies against TPO by rituximab-induced depletion of plasma cell precursors has been described in the literature and differs from Graves' disease by lowering uptake in the scintigraphy (4). We observed in our patients complete resolution with tests of normal thyroid function at 8 months, probably due to recovery of B cells. It has been described that the B cell count in peripheral blood, begins to increase from week 24 and evidence of repopulation is observed in most patients, at week 40 (5).
Conclusions
Treatment with rituximab could be related to the presentation of thyroiditis in patients with active RA.

Pericarditis: uncommon onset of anti-neutrophil cytoplasmic antibody-associated vasculitis induced by methimazol
Manel Jemel, Hanene Sayadi & Ines Khochtali
Fattouma Bourguiba University Hospital Depatment of Endocrinology, Monastir, Tunisia.

Introduction
Anti-neutrophil cytoplasmic antibodies (ANCA) associated vasculitis drugs induced are a rare side effect of antithyroid drugs. It is more commonly associated with propylthiouracil (PTU). The clinical manifestations are polymorphic like in primary vasculitides, but less severe; ranging from less specifics syndromes to multiple organs injured and lifethreatening in rare case. Cardiac involvement is uncommon. Herby we present the first case report of a 25-yr-old woman wich developed a syndrome of pericarditis as the first sign of ANCA associated vasulitis induced by methimazol.
Observation
A 25-yr-old woman was admitted with a recent history of dyspnea. A Graves' hyperthyroidism was diagnosed 1 year before; she was clinically and biochemically euthyroid on Methimazol 20 mg daily 1 year before. The examination revealed blood pressure of 120/60 mmHg, pericardial rub, and no edema. GFR $>$ 60 ml/min/1.73m, and systemic/urine sediment showed no abnormalities. The chest radiography showed severe cardiomegaly. An echocardiography showed a moderate-to-severe pericardial effusion. Direct Coombs test was negative, C3 and C4 within the normal range, ANA was negative, ANCA was positive (1/300), with a p-ANCA pattern. Cryoglobulinemia was negative. Treatment was started with doses of steroids at 1mg/kg/day, and the patient's state start to improve considerably. Two days after her admission, she developped necrotic-looking vasculitic skin lesions on bilateral lower extremity and on her right ear. Skin biopsy showed leukocytoclastic vasculitis. The methimazol induced vascularitis was suspected, so we stopped the offending treatment. In her follow up, we noticed a progressively disappearance of the skin lesions and pericardial effusion. In the light of clinical and laboratory findings she was diagnosed leukocytoclastic vasculitis caused by MMI, with positive p-ANCA.
Conclusion
The importance of this case is to call attention to the possible occurrence of pericarditis as a first symptom of methimazol-induced ANCA vascullitis.

Coexistence of hashimoto thyroiditis and De Quervain's thyroiditis
Raimonda Klimaite[1], Ilona Banisauskaite[1,2] & Raimondas Valickas[3]
[1]Department of Endocrinology, Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Department of Radiology, Hospital of Lithuanian University of Health Sciences Kauno klinikos, Kaunas, Lithuania.

Introduction
De Quervain's Thyroiditis (DQT) is a self-restriction inflammatory disease of the thyroid gland that presents severe pain localized in the neck. But few cases of a painful variant of Hashimoto's thyroiditis (HT) have been described as well. Thyroid ultrasound (US) may reveal in homogeneous hypoechoic pattern in both conditions.
Case
A 51-year old woman was admitted to the Hospital of Lithuanian University of Health Sciences, Kauno klinikos with the pain in anterior region of the neck and throat. Laboratory tests: erythrocyte sedimentation rate (ERS) 34 mm/h (normal 0–13), C-reactive protein 3.82 mg/l (0–10), TSH 0.11 mIU/l (0.27–4.2), FT4 17.95 pmol/l (12–22), FT3 4.2 (3.34–5.14), anti-TSH-R 3.9 U/l ($n<9$), anti-TPO 7 kU/l (0–12), anti-Tg 316 kU/l (0–100). US revealed decreased echogenicity, nonhomogeneous thyroid parenchyma and heterogeneous hypoechoic focal areas in both lobes. The treatment with nonsteroidal anti-inflammatory drug (NSAID) was started with gradually reduced dose. However, mildly elevated ERS and suppressed TSH remained. US showed the same size of focal area 2 months later. For the differential diagnosis (DD) of thyroid cancer (TC), painful HT and DQT coexisting with HT, fine needle aspiration biopsy (FNAB) was performed. FNAB showed changes compatible with DQT. It was decided to continue the treatment with NSAID and prednisolone was prescribed while gradually reducing the dose. The patient's condition has improved significantly. During follow-up appointment, after 3 months, thyroid hormones were in normal range and US showed decreased size of heterogeneous hypoechoic focal areas in both lobes.
Conclusions
Coexistence of DQT and HT is very rare and the diagnosis can be challenging. Clinical manifestation and ultrasonography results may be similar in both conditions. FNAB may be required for DD. The complete establishment of US patterns may last for one or two years.

Tea and juice as a causes of levothyroxine malabsorption and intermittent hypothyreoidism: a case report
Dragan Tesic[1], Edita Stokic[1], Milica Medic/Stojanoska[1], Milena Mitrovic[1], Dragana Tomic-Naglic[1], Tijana Icin[1], Ivana Bajkin[1], Bozidar Dejanovic[1] & Mirjana Tomic[2]
[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Vojvodina, Novi Sad, Serbia; [2]Emergency Center, Clinical Centre of Vojvodina, Novi Sad, Serbia.

Introduction
Biological casuses of levothyroxine (LT4) malabsorption are well known. Congestive heart failure, gastrointestinal diseases, pregnancy, medication or dietary interference are the most commonly known causes of poor oral absorption of LT4. However, when substitution therapy with LT4 fails we need to be more exploratory.
Case description
Female, born in 1987, BH 164 cm, BW 73kg, in 2010 she was presented as M. Basedowi and in october 2011 near thyreodectomy was done. In 2012 despate 200 mgr LT4 her TSH had been always elevatred. She was admitted to hospital in december 2017 with levothyroxine dosage of 700 mgr. In the last few months she was treated with Novothyral preparation 100, 3 tablets per day (combination of levothyroxyn 100 mgr and liothyronin 20 mgr) but without success. During 6 years period patient did have 24 controls (four per year) by secondary ot tertiary level endocrinologists). Most of the time she has been felt, briefly described, not healthy''. In 2014.y. and 2016.y. she had two birds. During pregnancy levothyroxine dosage was 300-400 mgr. During all these years transient hypothyreoidism has been presented. Values of hormones were as follows:

	Admittance to Clinic	7.day in Clinic	Average $\pm$ SD	Median	MIN-MAX.	Reference values
TSH mIU/L	$>$100	9.4	55.7 $\pm$ 61.97	23.8	0.01-201	0.35-4.94
fT4 pmol/L	5.9	10.8	12.8 $\pm$ 7.8	11.4	1.98-31.8	9-19
fT3 pmol/L	-	7.4	3.8 $\pm$ 2.2	3.57	0.2-8.8	2.6-5.7

On 8.day of hospitalisation we performed:

Table: Levothyroxyne Absorption Test (LAT) with 1000mgr levothyroxine

	0.h	1.h	2.h	3.h	4.h	5.h	Reference values
TSH mIU/L	4.15	3.77	3.52	3.36	2.65	3.05	0.35-4.94
-relation to 0.h	1	0,91	0,85	0,81	0,54	0,73	
fT4 pmol/L	12.1	16.86	23.91	24.26	26.76	22.48	9-19
-relation to 0.h	1	1,39	1,96	2,00	2,21	1,86	
fT3 pmol/L	7.4	7.35	7.67	7.43	7.6	6.97	2.6-5.7
-relation to 0.h		0,99	1,03	1.00	1.03	0.94	

After the test we obtained the data that she was taking levothyroxin on empty stomac but frequently with juice or tea. After a few days of hospital stay she started using the drug with water. Her latest dosage of levothyroxine is 100 mgr and latest control of hormones in referente range.

Discussion

LAT in our testing excluded malabsorpition of levothyroxine. Pseudomalabsorption was not caused because of nonadherence. Our patient did have actually dietary interference of juice and/or tea of mint with levothyroxine absorption.

Thyroid-type malignancies in struma ovarii and thyroid gland of two different origins: case report

Egle Kreivaitiene[1], Milda Daneliene[1,2] & Dalia Kozloviene[1,3]
[1]Hospital of Lithuanian University of Health Sciences Kaunas Clinics, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction

Struma ovarii (SO) is a rare ovarian tumor that occurs as part of a teratoma or is found in serous or mucinous cystadenomas and consist of more than 50% thyroid tissue. More uncommon is to diagnose thyroid cancer in struma ovarii and thyroid gland of two different origins. We present a case of follicular thyroid carcinoma arising in struma ovarii of the right ovary and papillary thyroid gland carcinoma.

Case

A 70-year-old woman admitted to gynecology department with abnormal vaginal bleeding. Endometrial biopsy revealed endometrioid adenocarcinoma (G3). Abdominal computed tomography (CT) showed 10.3×7.6 cm cystic tumor arising from the right ovary. Also, multiple uterine myomas and 2.1×2.0 cm left adrenal adenoma were observed in the CT. Total hysterectomy and bilateral salpingo-oophorectomy with pelvic-aortic lymphadenectomy were performed. The histological examination reported vascular invasive with the restricted cellular growth within the capsule follicular thyroid carcinoma of the right ovary and confirmed endometrioid adenocarcinoma (G3) of the uterus body. External pelvic radiotherapy was used postoperatively, but systemic chemotherapy for uterus adenocarcinoma was not prescribed because of co-morbidities. Thyroid ultrasound showed multi-nodular goiter and thyroglobulin level was normal – 19.3 μg/l (0 – 50). Considering the possibility of synchronous tumor of thyroid gland patient underwent total thyroidectomy. Histopathological examination revealed papillary thyroid carcinoma in 3 mm and 5 mm size masses and on immunohistochemistry positive expression of CK - 19. A radiation oncologist decided not to administer radioiodine therapy as an adjuvant treatment because of a minor risk for recurrence. Adrenal adenoma was evaluated by the incidentaloma algorithm and no hormonal activity was detected. In her medical history, she had acoustic neurinoma operation and postoperatively uses small doses of bromocriptine because of hyperprolactinemia. Genetic analysis was performed but neurofibromatosis type 2 diagnosis and other genetical disorders were not approved. No further treatment was deemed necessary at this time and the patient was scheduled for follow-up.

Conclusion

There is no consensus about SO diagnosis and management in the literature because of its rarity, representing only 1% of all ovarian tumors. Therefore, it is important to remember that some of SO are associated with thyroid-type carcinoma and this may significantly alter patient management. Thyroglobulin measurement could be used as one of the follow - up markers evaluating the recurrence. Recurrences may be detected using iodine - 123 scanning, and repeat radioiodine ablation can lead to higher rates of survival.

Type 1 diabetes mellitus and sorafenib: coincidence or consequence?

Cristina Ribeiro, Diana Catarino, Diana Oliveira, Joana Saraiva, Miguel Melo, Sandra Paiva & Francisco Carrilho
Department of Endocrinology, Coimbra Hospital and University Center, Coimbra, Portugal.

Introduction

Differentiated thyroid carcinoma is usually associated with a good prognosis. However, some of these tumors (5%) are radioiodine refractory and have different progression, associated with poor prognosis. In these situations, some tyrosine kinase inhibitors (TKI) can be used. We present a clinical case showing the difficulties in the follow-up and treatment of these patients.

Clinical case

A 60 years old woman, with a "multicentric papillary cancer, with high cells", underwent total thyroidectomy in 2000, followed by I131 ablation. TG remained undetectable but TgAb progressively higher. In 2005, lymph node cervical metastases were excised. In February 2017, Tg was still undetectable with TgAb 773 UI/ml and the 18 FDG-PET showed: "Bilateral hypermetabolic pulmonary metastases". She started sorafenib (800 mg) in September and 4 weeks later, she presented at the emergency service with a diabetic ketoacidosis (glycemia – 895 mg/dl; pH - 6,99), and was treated with intravenous fluids and continuous insulin infusion. After stabilization, she performed blood tests: A1C - 16,2%; GAD-65 Ab - 4,48 U/ml (<1); IA-2A Ab - 2,87 U/ml (<1). As the presence of different autoantibodies suggests the diagnosis of polyglandular autoimmune syndrome (PAS), we're waiting for the results of blood tests to exclude other autoimmune diseases. Meanwhile the level of TgAb reduced (350 UI/ml) but an urticaria reaction to sorafenib forced its reduction to 200 mg and later it was stopped. She is starting now lenvatinib.

Discussion

We present a patient with a papillary carcinoma and PAS who underwent a serious clinical manifestation of type 1 Diabetes (ketoacidosis) a few weeks after starting sorafenib. There's some evidence about the possible effects of TKI in immunologic reactions and autoimmunity. So, we can't exclude that this manifestation of DM could be a possible effect of this drug.

Thyroid arterial embolization for the treatment of large multinodular goiter and hyperthyroidism

Özen Öz Gül[1], Soner Cander[1], Pınar Şişman[2], Aytül Coşar[3], Canan Ersoy[1] & Erdinç Ertürk[1]
[1]Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey; [2]Medicana Hospital, Bursa, Turkey; [3]Uludag University Medical School, Department of Internal Medicine, Bursa, Turkey.

Background

Although hyperthyroidism has many treatment options, hyperthyroidism is difficult to control in some patients. Hyperthyroidism has three main treatment

options: antithyroid drugs, radioactive iodine therapy and surgical treatment. However, in some cases none of these treatments can be used. However, there are some patients who failed to respond to radioactive iodine therapy, patients who choose not to receive any one of the options, and others who are poor surgical candidates. Thyroid arterial embolization can be used for the treatment of Graves' disease and other thyroid conditions requiring thyroid ablation. We describe the case of a patient with a large multinodular goiter that was with thyroid arterial embolization.

Case

Fifty six years old man has admitted to our hospital complaints of fatigue, dyspnea, growing cervical mass and swallowing difficulty. When the patient's anamnesis was taken, it was learned that 20 years ago, the patient had subtotal thyroidectomy due to a nodular goiter. Patient who had not been followed for a long time, because of the current complaints increased in the last 2–3 months. On physical examination he presented a large, firm multinodular goiter that occupied the entire anterior cervical area. At admission, laboratory tests revealed normal sT4: 1.17 ng/dl (Normal Range: 0.89–1.37) and sT3: 2.45 pg/ml (Normal Range: 2.25–3.85), and decreased TSH: 0.017 μIU/mL (Normal Range: 0.47–3.41) levels. On ultrasound, a large goiter was visualized with multiple nodules of different sizes in both lobes. Thyroid scintigraphy showed irregular uptake with a large thyroid gland. Fine-needle aspiration biopsies performed in nodules were reported to be negative for malignancy. On neck computed tomography (CT) scan, the thyroid gland extended to the mediastinum and compressed the trachea. The patient was offered surgery because of symptoms of compression and extension of the gland to the mediastinum. Because the patient did not accept the operation, it was decided to thyroid arterial embolization to the patient. After embolization, no fever developed but the patient complained of mild anterior neck pain that regressed after therapy with standard anti-inflammatory treatment. At 30 days after embolization, thyroid hormone levels normalized and the thyroid ultrasound can showed that the thyroid gland had shrunk. The patient's complaints have improved substantially.

Conclusion

Thyroid embolization may be the treatment of choice in large multinodular goiter where the surgery is not accepted or the surgery is contraindicated.

Thyroid hormone resistance and pituitary macroadenoma: is there a connection? – case report

Anamaria Hrisca[1,2], Georgiana Tudurean Olteanu[1], Mirela Nechita[1], Stefana Bilha[1,2], Daniel Rotariu[2,3], Letitia Leustean[1,2], Cristina Preda[1,2] & Maria Christina Ungureanu[1,2]

[1]"Saint Spiridon" Clinical and Emergency Hospital, Department of Endocrinology, Iasi, Romania; [2]University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania; [3]"Nicolae Oblu" Clinical and Emergency Hospital, Department of Neurosurgery, Iasi, Romania.

Introduction

Inappropriate secretion of TSH, despite elevated levels of T4, is due to either a TSH-secreting adenoma (TSHoma) or thyroid hormone resistance (RTH). RTH is a rare disorder, usually caused by mutations in the thyroid hormone receptor beta, characterized by a variable tissue hyporesponsiveness to thyroid hormone. The increased level of TSH may predispose to thyrotroph hyperplasia and possible adenoma formation.

Case report

A 21 years old female patient adresses for the first time in 2011 for primary amenorrhea. The clinical features like short stature (−2.3DS), obesity, round face and short fourth metacarpal, along with the primary amenorrhea raised the suspicion of Turner syndrome or pseudohypoparathyroidism, excluded by genetic tests (karyotype 45, XX), normal phospho-calcic profile but without the posibility for GNAS1 testing. Subsequent investigations revealed an elevated TSH (7.1 μUI/ml, N: 0.4-4) with normal fT4 (1.44 ng/dl,N:0.89–1.76), FSH and LH at the upper limit (16 mIU/ml, respectively 26 mIU/ml) and the pelvic ultrasonography revealed 3–5 bilateral follicular cysts. Treatment with progesterone and 50 μg of levothyroxine was initiated, but despite treatment TSH remained unsupressed with high fT4. Five years later, after therapy had been discontinued for 3 months, she was admitted for reevaluation: tahycardia (100/min), persistent high TSH (7.88 μUI/ml) and fT4 (2.13 ng/dl) and low IGF1 (101 ng/ml, N:116-358). The rest of the hormonal profile including FSH, LH, estradiol, ACTH, cortisol, PRL were normal. The magnetic resonance imaging revealed a 11/10 mm adenoma witch raised the suspicion of a TSHoma or an incidental macroadenoma. Sex-hormone binding globulin, feritin and thyroglobulin were normal and the ultrasonography showed no goiter. On the TRH stimulation test, the brisk response of TSH (from 6.59 μUI/ml to 37.1 μUI/ml at 20 min) was suggestive for RTH. In January 2018, the patient underwent transsphenoidal pituitary adenomectomy and after removal of the tumor TSH value suddenly decreased to 0.2 μUI/ml.

Conclusions

This case highlights the difficulties in distinguishing the cause of inappropriate TSH secretion when a pituitary adenoma coexists. None of the investigations are entirely pathognomonic but a combination of tests can be suggestive of either RTH or TSHoma. In our case, although biological examination strongly suggested that this patient was suffering from RTH (normal SHBG and feritin, brisk response to TRH), the decrease in TSH value after surgery was suggestive for TSHoma. This case, along with previous reports and animals models, suggest that RTH may lead to the development of TSH-omas.

Thyrotoxic hepatitis

Lamia Gargouri[1], Faten Hadjkacem[2], Dorra Ghorbel[2], Faiza Safi[1], Manel Hsairi[1], Mohamed Abid[2] & Abdelmajid Mahfoudh[1]

[1]Pediatrics Department, Emergency and Intensive Care Unit Service, CHU Hedi Chaker, Sfax, Tunisia; [2]Endocrinology-Diabetology Department, CHU Hédi Chaker, Sfax, Tunisia.

Introduction

Liver abnormalities are rarely observed in thyrotoxicosis. Diagnosis should be considered only after outruling other possibilities of hepathic pathology, especially autoimmune disaese. We report the case of a 6-year-old girl with Graves' disease who presented a liver dysfuntion.

Case report:

A 6-year-old girl with a history of Graves' disease diagnosed and treated 15 days before, was admitted for jaundice and pruritus. The interrogation finds the notion of dark urine and partially discolored stool. On physical examination, there was significant jaundice and an hepatomegaly. Laboratory exploration showed an elevated serum level of Aspartate aminotransferase at 53 IU/l, alanine aminotransferase at 68 IU/l, gamma-glutamyltransferase at 16 IU/l, alkaline phosphatase at 959 IU/l and total bilirubinemia at 48 mmol/l. Abdominal ultrasound revealed hepatomegaly with a hetero-micronodular appearance. Cholangi-MRI was normal. After excluding other etiologies for her liver injury (Obstacles to the bile ducts, viral or autoimmune hepatitis and sclerosing cholangitis) she was treated with antithyroid medications (thiamazole (thyrosol®)).The thyroid status was corrected and normalization of liver tests was observed after one month. The diagnosis of "thyrotoxic hepatitis" has been retained.

Conclusion

Hépatic manifestations of hyperthyroidism are both polymorphic and non-specific. It is essential to know how to interpret the liver manifestations that occur during the follow-up of hyperthyroidism. Although the mechanism is not completely understood, antithyroid drugs are crucial in this life-threatening hepatitis.

Digestive system diseases associated with Turner's syndrome in 3 pediatric cases

Lamia Gargouri[1], Faten Hadjkacem[2], Dorra Ghorbel[2], Faiza Safi[1], Manel Hsairi[1], Mohamed Abid[2] & Abdelmajid Mahfoudh[1]
[1]Pediatrics Department, Emergency and Intensive Care unit Service, CHU Hedi Chaker, Sfax, Tunisia; [2]Endocrinology-Diabetology Department, CHU Hédi Chaker, Sfax, Tunisia.

Objective
Considering that the patients with Turner syndrome (TS) have a high prevalence of autoimmune disease, an early investigation for digestive system diseases should be carried out in those with TS.
Case 1
A 13-year-old girl, followed for Turner's syndrome with characteristic facial dysmorphia, developed glaring diarrhea. Colon and endoscopic endoscopic examinations have led to ulcerative colitis. It was put pentasa with a favorable evolution. With a pubertal delay at the age of 15, thyroid assessment was performed concluding hypothyroidism secondary to Graves' disease. Replacement therapy with thyroid hormones has been prescribed.
Observation 2
An 11-year-old girl without dysmorphia is followed for celiac disease. The evolution under a well-monitored gluten-free diet was marked by the persistence of a weight-loss delay at −3 DS. The search for other associated pathologies has been carried out. The blood karyotype concluded that mosaic Turner syndrome was present and the patient was put on growth hormone therapy.
Observation 3
A 10 years old girl was consulted for short stature. She had also a minor dysmorphic syndrome. Hormonal investigations revealed hypergonadotropic hypogonadism. Pelvic ultrasonography showed a hypoplastic Uterus without visualization of the ovaries. Cytogenetic analysis of peripheral blood revealed a karyotype with 45 chromosomes with one X chromosome missing (45, X). Laboratory investigations revealed normal hematological and biochemical parameters except AST (107 UI/l > 45 ui/l), ALT (87 UI/l > 45 ui/l) and ALP (819 ui/l > 200 ui/l). Hepatotoxic medications and alcohol was ruled out. Abdominal ultrasonography was normal. Serology Hepatitis B and C was negative. Immunological survey showed a Anti-mitochondrial antibodies, Anti-smooth muscle antibody and Anti-LKM1 antibody were negative. But she had a positive Anti-TPO antibody with normal thyroid function tests.
Conclusion
Continuous long-term follow-up is required in patients with Tuner's disease in order to detect early the associated diseases and to prescribe appropriate treatment.

Subacute thyroiditis in a patient with Epstein-Barr virus (EBV) meningitis

Athanasios Siolos, Alexandra Terzaki & Stelios Tigas
Department of Endocrinology, University of Ioannina, Ioannina, Greece.

Introduction
Viral infections have been implicated as a possible predisposing factor in the pathogenesis of subacute thyroiditis (ST). The seasonal distribution and the common clinical presentation of ST following upper respiratory track infections suggest a possible causative association. Direct serological or thyroid tissue evidence of viral infection during ST is however limited to a few case reports.
Case presentation
We present the case of a 59-year-old woman with ST 2 weeks following acute viral meningitis due to Epstein-Barr virus infection. Two weeks prior to admission, the patient developed malaise, myalgia, sore throat and mild fever. One week prior to admission she deteriorated and complained of headache, neck pain and fever up to 38.5°C. On examination there was neck stiffness and marked tenderness on palpation of the thyroid gland. Cerebrospinal fluid analysis was consistent with lymphocytic meningitis. Biochemical tests revealed elevated liver enzymes, hyperthyroxinemia (FT4 4.86 ng/dl, 0.6–1.37) with suppressed TSH and negative thyroid autoantibodies. Thyroid scintigraphy with 99mTc showed reduced uptake, consistent with thyroiditis. Serological tests were indicative of acute Epstein-Barr virus infection (positive VCA IgM and IgG antibodies). CSF culture was negative for common bacteria and PCR testing failed to detect CMV,HSV-1,HSV-2,VZV,HHV-6, enterovirus or parechovirus DNA. A month later, the patient developed hypothyroidism and was started on thyroxine replacement.
Conclusion
Only two cases of EBV associated thyroiditis have been reported so far, based on a positive titer of anti-EBV Abs or the detection of EBV DNA by PCR. We present the case of a 59-year-old woman with concomitant viral meningitis and ST and serological tests indicating acute Epstein-Barr virus infection.

Right heart failure in patient with resistant thyrotoxicosis due to Graves' disease

Cvetanka Volkanovska Ilijevska[1] & Irina Tonovska[2]
[1]City General Hospital 8th September, Department of Endocrinology and Diabetes, Skopje, Macedonia, the Former Republic of Yugoslav; [2]City General Hospital 8th September, Depratment of Cardiology, Skopje, Macedonia, the Former Republic of Yugoslav.

Introduction
Resistant thyrotoxicosis is condition in which patients fail to respond to maximal doses of antithyroid drugs. Definitive treatment is radioactive ablation and operative treatment. However, achievement of euthyroid status before definitive treatment is important in patients with underlying cardiovascular disorder in whom thyroid crises can be detrimental.
Case report
We describe a case of resistant thyrotoxicosis and right heart failure. A 55-year-old lady presented to our emergency center with complaints of chest pain, shortness of breath and distended stomach. On examination, she had blood pressure 140/80 mmHg, heart rate 40 bpm, jugular venous distension, pretibial edema, pansystolic murmur in the left paratsternal region and diffuse goitre. The abdomen was distended and the liver was palpable 2 cm below the right costal margin. The patient was diagnosed with Graves' disease 15 days previously in another institution and had already started taking high doses of methimazole (60 mg) and propranolol (60 mg). Blood analysis confirmed a severe hyperthyroidism with a thyroid-stimulating hormone (TSH) <0.004 uIU/ml and elevated fT4–4.03 ngl/dl (N 0.90–1.80), fT3–9.94 pg/ml (N1.80–4.20) and normocytic anaemia. Electrocardiogram showed bradicardic (40/min) sinus rhytam. Transthoracic echocardiography revealed a dilated right ventricle (52 mm) with a normal function and dimensions of left chambers. A severe tricuspid valve insufficiency was detected and estimated pulmonary artery systolic pressure was 60 mm Hg. The vena cava inferior was dilated and non-collapsing (24 mm). There was a mild mitral regurgitation grade III-IV. The methimazole was discontinued and treatment with maximum doses propylthiouracil (PTU) (300 mg three times a day), spironolacton and furosemid were initiated. The dose of propranolol was reduced (10 mg two times a day). After 2 weeks, fT4 and Ft3 were still significantly elevated and prednisolone (40 mg) was given in addition to the antithyroid drug. Four months later the patient clinically improved, but biochemical hyperthyroidism was still present. Definitive operative treatment was scheduled and in order to reduce the risk of precipitating thyroid crises the patient was given potassium iodide (150 mcg) in the next two weeks. Biochemical euthyroid state ensued and patient underwent total thyroidectomy. Thereafter tyroxine replacement therapy was started and pulmonary hypertension, atrial fibrillation and anemia resolved.
Conclusion
Addjunctive drugs like prednisolone and potasium iodide play an important role in preparing patients with resistent thyreotoxisocis for more definitive treatment.

Pharmacologic interference as a contributory factor for spuriously elevated TSH levels

Sofia Gouveia
Amato Lusitano Hospital, Castelo Branco, Portugal.

Introduction
TRH, thyroid hormones, dopamine, somatostatin and glucocorticoids have a recognized influence on TSH secretion. On the other hand, serotoninergic, histaminergic, catecholaminergic, opioidergic and GABAergic systems establish connections with hypophysiotropic neurons involved in TSH regulation; their relative contribution to TSH secretion is unknown. Still, there are a few reports of H1 receptor antagonists impact on TSH levels.

Case report
Thirty-years-old woman with autoimmune hypothyroidism. She had been pregnant the previous year; two months after delivery she remained on euthyroidism on 112 mcg levothyroxine [TSH-1.07 μUI/ml; FT4-1.11 ng/dl]. Nine months after delivery she repeated laboratorial evaluation [TSH-16.3 μUI/ml); FT4-1.04 ng/dl] and her general practitioner increased levothyroxine dose to 137 mcg. However, two months later her TSH was still high [TSH-14.62 μUI/ml; FT4-0.91 ng/dl] and levothyroxine dose was further increased (retrospectively, she had been taking metoclopramide/betahistine on a regular basis for the previous 2 weeks). When she presented to endocrinology appointment, her pharmacologic habits included 150 mcg levothyroxine, COCP and dimenhydrinate (prescribed 3 weeks earlier for vertiginous syndrome). On that occasion, she disclaimed intermittent compliance with levothyroxine therapy. Her laboratorial re-evaluation revealed a TSH of 159.43 μUI/ml and FT4 of 1.04 ng/dl. She was summoned to repeat analysis and advised to withhold dimenhydrinate. She denied exposure to other medicines, St.John's wort, iodine supplements, iodinated contrast or amphetamines, but admitted sporadic levothyroxine omission. The following blood sample was collected one week after the former and over 24 hours off dimenhydrinate: TSH-31.86 μUI/ml; FT4-1.38 ng/dl. The laboratory was requested to exclude macro-thyrotropin: serial dilutions revealed a linear recovery. The sample was also analysed by a different method/laboratory: TSH-38.46 μUI/ml; FT4-1.45 ng/dl; rheumatoid factor assay was negative. Five weeks after dimenhydrinate withdrawal and reinforcement of the importance of medication adherence, she presented a TSH of 3.84 μUI/ml and FT4 of 1.79 ng/dl.
Discussion
A normal FT4 with a very high TSH level on a patient with a personal history of hypothyroidism might be ascribable to intermittent compliance, iatrogenic or analytical interference factors. It is important to clarify pharmacologic habits, namely exposure to dopamine antagonists, amphetamines and drugs that impair levothyroxine absorption. Likewise, methodologic interference factors such as macro-thyrotropin, rheumatoid factor and heterophile antibodies should also be regarded. Considering dimenhydrinate actions and temporal coincidence between drug exposure/withdrawal and TSH levels increase/normalization, this H1 receptor antagonist might be an important interference cofactor in the reported case.

Subacute thyroiditis with coexisting papillary carcinoma – A case report

Ema Lumi[1], Eda Stase[2], Ornela Ruco[3], Blertina Dyrmishi[4], Entela Puca[5], Thanas Fureraj[6] & Agron Ylli[7]
[1]Endocrinologist, Department of Internal Medicine, Regional Hospital "Teni Konomi", Korce, Albania; [2]General Physician, Faculty of Human Science, Nursing Department, University "Fan S.Noli", Korce, Albania; [3]Infecionist, Department of Infectious Disease, Regional Hospital "Teni Konomi", Korce, Albania; [4]Endocrinologist, Hygea Hospital, Tirana, Albania; [5]Endocrinologist, American Hospital, Tirana, Albania; [6]Endocrinologist, Endocrine Department, UHC "Mother Teresa", Tirana, Albania; [7]Endocrinologist, Head of Endocrine Department, UHC "Mother Teresa", Tirana, Albania.

Introduction
Subacute thyroiditis-SAT is an acute inflammatory disease of thyroid. It is presumed to be caused by viral infection or a postviral inflammatory process. Whatever factors initiate subacute thyroiditis, the resulting thyroid inflammation damages thyroid follicles and activates proteolysis of the thyroglobulin stored within the follicles. Papillary thyroid carcinoma typically presents as a thyroid nodule. Thyroid nodules come to clinical attention when noted by the patient; during routine physical examination; or when incidentally noted during a radiologic procedure. The diagnosis of thyroid cancer is usually made by fine-needle aspiration (FNA) biopsy. SAT associated with papillary thyroid carcinoma is very rare. Only few case reports of SAT associated with papillary thyroid carcinoma have been reported in the literature.
Case report
A 49-year-old woman was admitted to hospital. She complained of fever, fatigue, malaise, anorexia, and myalgia during the last month. She had a mild pain on both side of the neck that radiated to the jaw. Physical examination revealed diffuse enlargement and mild tenderness of the thyroid gland. There were no palpable cervical lymph nodes. The rest of the exams were normal. On thyroid US, the right lobe was diffusely hypoechogenic with low flow. A hyperechogenic nodule (2.32–1.73 cm) was found in the left lobe. On laboratory investigation: TSH was 0.01 μIU/l (normal range: 0.27–4.2 μIU/l), FT4 was 23.29 pmol/l (normal range: 12–22 pmol/l), erythrocyte sedimentation rate (ESR) was 45 mm/h (normal range: 0–20 mm/h), and C-reactive protein (CRP) was 78.38 mg/l (normal range: 0.0–5.0 mg/l). A Tc-99 imaging study was done, showing low uptake in both sides of thyroid gland. FNA of the thyroid nodule on the left lobe was performed, revealing a high suspicious for malignancy (Bethesda class V). We started oral Ibuprofene 400 mg bid, and the anterior neck pain and tenderness improved within several days. Total thyroidectomy was performed and the nodule was confirmed to be papillary carcinoma, while the rest of the tissue showed granulomatous thyroiditis.
Conclusion
The ultrasound features of the nodule in our patient were not suspicious for malignancy. Despite this we performed the FNA biopsy, which revealed a Bethesda class V, confirmed by postsurgical biopsy as papillary thyroid carcinoma. Therefore, when SAT is clinically suspected, thyroid US is a useful tool for diagnosing this disorder and it may help identify a hidden thyroid malignancy.

Association of Pro-inflammatory cytokines and Benign Thyroid nodules: A prospective case-control study

B Rajkiran Reddy[1], B Ramesh[2], B Rajesh[2], D Vighnesh[2], G Gayathri[2], M Venkateshwar Reddy[2], B Chakrapani[3] & PRK Bhargav[4]
[1]SMART Sunshine Hospital, Hyderabad, India; [2]VMC, Kurnool, India; [3]Neuro Hospital, Nizamabad, India; [4]Endocare Hospital, Vijayawada, India.

Introduction
Nodular thyroid disease (NTD) is one of the commonest endocrine disease with incidence ranging from 5–30% in various populations Worldwide. They often require surgery for indications such as pressure symptoms or size related reasons. The natural history and etiopathogenesis are largely unclear except in few endemic regions. Immunomodulatory role has often been implicated in their pathogenesis. In this context, we set out study the association between Pro-inflammatory cytokines and NTD.
Material and methods
This prospective case-control study was conducted on surgically managed NTD patients. Institutional ethical committee approval was obtained. Diagnosis of NTD was based on thyroid function tests, imaging, fine needle aspiration cytology and histopathology. Exclusion criteria were subjects any systemic or chronic inflammatory disease or any medication which interferes with the normal function of the hypothalamic-pituitary-gonadal axis. Serum samples were collected from 100 HT subjects and 98 age matched healthy controls. Interleukin-6 (IL-6), Tumour necrosis factor-alpha (TNF-α) and high sensitive C reactive protein (hsCRP), Leptin levels were measured in all serum samples. Statistical analysis was performed by one way ANOVA with Dunnet's test and Pearson correlation tests.
Results
The mean hSCRP level in NTD and controls were 11.7 ± 1.8 mg/mL and 6.2 ± 1.3 mg/mL respectively. The mean TNF-α level, IL-6 level and Leptin levels were 198.4 ± 18 pg/mL, 15.3 ± 3.2 pg/mL and 2.9 ± 1.8 ng/mL respectively. Serum leptin level in controls was 3.8 ± 2.1 ng/mL. There was statistically significant difference of all the pro-inflammatory cytokines compared to controls (P value < 0.05).
Conclusions
This study shows raised titers of pro-inflammatory markers – IL-6, TNF-α and hsCRP correlated with NTD suggesting a contributory role. Leptin appears to have no definitive correlation with NTD. But, the exact immuno-modulatory role and pathogenetic mechanism needs active research.

Thyroid hormones (TH) of maternal origin are critical for the proper fetal development, especially during early pregnancy. Even minor changes in maternal TH circulation can lead to various adverse outcomes. Recent studies found that the metabolites of thyroxine (T_4) also play an important physiological role. For example, 3,5-diiodo-L-thyronine (T_2) and 3,3′-diiodo-L-thyronine (rT_2) can suppress the thyroid stimulating hormone (TSH) level and increase the resting metabolic rate. 3-iodothyronamine (T_1AM) administration in mice leads to a hypometabolic state. These metabolites may have influences on the fetus. Having the capacity to make a comprehensive analysis of T_4 and the metabolites in placenta provides a diagnostic tool for the placental TH homeostasis. Routine TH assessment has long been achieved by measuring T_4, triiodo-L-thyronine (T_3), and TSH in blood using immunoassay (IA) method, which is of high sensitivity, but is prone to nonspecific interferences. Methods based on liquid chromatography-mass spectrometry (LC-MS) and tandem mass spectrometry (LC-MS/MS) showed better accuracy and reliability. In this study, we report a method for the determination of T_4, T_3, 3,3′,5′-triiodo-L-thyronine (rT_3), T_2, rT_2, 3-iodo-L-thyronine (T_1), and T_1AM in the placenta. The method was optimized using isotope (^{13}C-T_4, ^{13}C-T_3, ^{13}C-rT_3, ^{13}C-T_2) dilution methodology and determined by liquid chromatography quadrupole time-of-flight mass spectrometry (LC-Q-TOF-MS). The calibration ranges from 0.5 to 150 ng/ml with R^2 values > 0.99. The method detection limits (MDLs) and the method quantification limits (MQLs) were 0.01–0.2 ng/g and 0.04–0.7 ng/g, respectively. The spike-recoveries for THs (except for T_1 and T_1AM) were between 81.0% and 112%, with a coefficient of variation (CV) of 0.5–6.2%. The intra-day CVs and inter-day CVs were 0.5% – 10.3% and 1.19% – 8.88%, respectively. The method was adopted for TH measurement in human and mouse placenta. The concentrations of T_4, T_3, rT_3, and T_2 were 22.9–35.0 ng/g, 0.32–0.46 ng/g, 2.86–3.69 ng/g, and 0.16–0.26 ng/g in human placenta, and 2.05–3.51 ng/g, 0.37–0.62 ng/g, 0.96–1.3 ng/g, and 0.07–0.13 ng/g in mouse placenta, respectively. The presence of T_2 was tracked in placenta tissue for the first time, indicating improved selectivity and sensitivity of our method. The validated method allows comprehensive evaluation of total T_4 and metabolites in the placenta.

Bethesda System for Reporting Thyroid Cytopathology (BSRTC): Category III and IV Frequency and Risk of Malignancyin the Era of Molecular Testing and after the Reclassification of Non Invasive Follicular Thyroid Neoplasms with Papillary-Like Nuclear Features (NIFTPs)

Rachel Chava Rosenblum[1], Alexander Shtabsky[2], Silvia Marmor[2], Leonor Trejo[2], Iris Yaish[2], Moshe Yehuda[2], Sophie Barnes[2], Naftali Stern[2], Zmira Silman[3] & Karen Tordjman[2]

[1]Meir Medical Center, Kfar Saba, Israel; [2]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; [3]Israel Academic College, Ramat Gan, Israel.

Background

The BSRTC aimed to standardize thyroid cytopathology reporting while enabling stratification of risk of malignancy (ROM) in thyroid nodules. Observational studies have demonstrated varying ROM for the Bethesda III and IV categories, further affected by the recent exemption of NIFTP. Finally, molecular testing is becoming a reasonable alternative for evaluating ROM in categories III and IV.

Objective

To retrospectively establish the use of Bethesda categories III and IV in specimens obtained from FNAs at Tel Aviv Sourasky Medical Center over a 3 year period, to assess the ROM in these categories in the era of molecular testing and NIFTP, and to examine clinical correlates that might affect the ROM.

Methods

Aspirated thyroid nodules between January 2013 and December 2015 were reviewed. Files of patients with nodules classified as category III and IV were searched for downstream surgical procedures, repeat FNA and/or Afirma® gene classifier testing, in order to determine their outcome. Confirmed NIFTPS were considered benign lesions. Sonographic characteristics and potential clinical risk factors for malignancy were evaluated for category III and IV nodules.

Results

Of 3701 nodules aspirated on 2674 subjects (80% women/20% men, age 56.7 ± 15.5 y), 6.5% were Bethesda-I, 72.8% Bethesda-II, 7.7% Bethesda-III, 3.6% Bethesda-IV, 2.3% Bethesda-V, and 7.2% Bethesda-VI. A diagnostic outcome was available for 128 of the 284 category III nodules: 18 (14.0%) were malignant (16.4% if NIFTP included), and 109 (86.0%) were benign. The outcome was known for 60 of the 132 category IV nodules, 17 (28.3%) were malignant (31.7% if NIFTP included), and 43 (71.7%) were benign. Male gender and smoking were significant and independent risk factors for malignancy in Bethesda III, but not in Bethesda IV nodules. Age, country of birth, family history of thyroid cancer, nodule size, and a cumulative score of 5 suspicious sonographic characteristics were not predictive of malignancy in either category.

Conclusion

The distribution of the various Bethesda categories in our study, and specifically categories III and IV, was consistent with previous published reports. The ROM for Bethesda III and IV nodules was also in line with recent reports. Exclusion of NIFTP from malignancy did not significantly affect these figures. Although we identified several factors that increased the ROM, their predictive value was not powerful enough to be acted upon. Better molecular tools are needed to further reduce the number of unnecessary surgeries in this age of epidemic of incidentally discovered thyroid nodules.

Thresholds of basal and calcium stimulated calcitonin for diagnosis of medullary thyroid carcinoma

Mara Baetu[1,2], Cristina Gheorghiu[2], Cristina Corneci[2], Dumitru Ioachim[2], Andra Caragheorgheopol[2], Ruxandra Dobrescu[2] & Corin Badiu[1,2]

[1]"C. Davila" University of Medicine and Pharmacy, Bucharest, Romania; [2]National Institute of Endocrinology, Bucharest, Romania.

Introduction

The current revised medullary thyroid carcinoma (MTC) guidelines don't specify reference ranges of basal (bCT) or stimulated serum calcitonin (sCT) levels for the diagnosis of MTC. These are important for early diagnosis and correct management.

Objective

We aimed to set gender specific thresholds for bCT and sCT for MTC diagnosis.

Patients and methods

CT samples during calcium-stimulation test (25 mg/kgBW adapted on ideal body mass index) before and at 2, 5 and 10 minutes after administration were measured before thyroidectomy in 31 patients with thyroid nodules: 21 Females(F) – 10 Males(M), aged 47 y (23–67). bCT and sCT were compared with histological results. CT was measured by immunochemiluminescence.

Results

The test was well-tolerated, with minimum side-effects. For 8 patients with bCT < 10 pg/ml (8F), the mean peak sCT was 106.6 pg/ml ± 197.12 (range:1.02–576). We identified 2 MTC, 1 papillary thyroid carcinoma (PTC) and 5-benign lesions. For 23 patients with bCT > 10 pg/ml (13F–10M), the mean bCT and peak sCT were:28.49 ± 26.9 pg/ml (range:11.57–104.4), respectively 356.35 ± 206.07 pg/ml (range:98.1–724.6) in F, and 26.99 ± 17.4 pg/ml (range:10.86–67.2), respectively 465.71 ± 440.43 pg/ml (range:73.07–1571) in M. Histologically, we identified MTC in 6F and 1M, associated with C-cell hyperplasia (CCH) in 2 and with PTC in 3 cases. For the remaining cases, CCH in 1F and 2M; PTC in 4F and 3M; 1 follicular thyroid carcinoma in 1M and benign lesions in 2F and 3M. The best CT thresholds to discriminate normal cases from patients with either MTC or CCH were: 19.85 pg/ml for bCT (sensitivity – 66.7%; specificity-89.5%), AUC 0.77 (CI:0.60–0.95), $P = 0.01$, and 244.65 pg/ml for sCT (sensitivity – 75%; specificity – 63.2%), AUC 0.73 (CI:0.55–0.91), $P = 0.03$. For F, the best thresholds to discriminate normal cases from patients with either

MTC or CCH were: 13.15 pg/ml for bCT (sensitivity – 77.8%; specificity – 75%), AUC 0.82 (CI:0.64–1), $P=0.01$, and 208.2 pg/ml for sCT (sensitivity – 77.8%; specificity – 75%), AUC 0.78 (CI:0.58–0.98), $P=0.02$. Genetic results are awaited and other histopathologic evaluations are scheduled.
Conclusions
Our study found bCT and sCT cut-offs for discriminating MTC or CCH from normal subjects. The calcium gluconate test is well tolerated and safe to use. Larger studies are needed for accurate cut-offs that may improve diagnosis not only of MTC in early stages, but, interestingly enough, for PTC.

Are benign adenoma and papillary thyroid carcinoma related? A linkage study from BRAF and NIS gene mutation point of view

B Ramesh[1], B Rajesh[1], M Venkateshwar Reddy[1], D Vighnesh[1], B Rajkiran Reddy[2], G Gayathri[1], B Chakrapani[3] & PRK Bhargav[4]
[1]VMC, Kurnool, India; [2]SMART Sunshine Hospital, Hyderabad, India; [3]Neuro Hospital, Nizamabad, India; [4]Endocare Hospital, vijayawada, India.

Introduction
The adenoma – carcinoma sequence in thyroid nodules is a enigmatic phenomenon. There are conflicting reports on development of papillary cancer from benign adenomas. Genomics is the only definitive modality to resolve this hypothesis. Adenomas and papillary carcinomas tend to have mutations in Sodium Iodide symporter gene (NIS) and highly specific BRAF gene respectively. In this context, we set out study the prevalence of these somatic mutations in surgical tissue samples.
Material and methods
This prospective study was conducted on surgically managed thyroid nodule patients. Institutional ethical committee approval was obtained. Diagnosis was based on biochemical confirmation, imaging, fine needle aspiration cytology and later confirmed by histopathology. All cases underwent total thyroidectomy along with additional neck dissection in cancer cases. We selected 25 benign thyroid adenomas (BTA) and 20 papillary thyroid carcinoma (PTC) cases. Tumour tissue samples were taken from *ex-vivo* specimen within operation theatre. After appropriate processing of samples, DNA extraction, cDNA preparation, PCR amplification, application of 6 sets of Primers were performed as part of mutational analysis of NIS and BRAF genes.
Results
Heterozygous mutations in NIS were found in 11/25 (44%) of BTA and 5/20 (25%) of PTC cases. A recessive heterozygous mutation in BRAF was found in PTC cases (9/20) only. No BRAF mutations were noted in BTA.
Conclusions
NIS mutations were prevalent in both benign and malignant thyroid nodules giving some evidence for linkage between them. Though not robust, we opine that there is possibility of adenoma- carcinoma sequence in thyroid nodules. BRAF mutations appear to be specific to PTC. We need larger, robust and consistent studies to justify this observation in future.

Characteristics of thyroid dysfunction in children with turner syndrome

Nadzeya Peskavaya, Anzhalika Solntsava & Katsiaryna Shlimakova
Belarusian State Medical University, Minsk, Belarus.

Objectives
To evaluate the prevalence and characteristics of thyroid diseases in children with Turner syndrome (TS).
Methods
This is a retrospective study, analyzing clinical data from medical records of 19 patients with TS from 3 to 17 years (average age 12.02 ± 4.0 years), who were regularly followed-up in the University hospital (Minsk). Depending on the karyotype, 3 groups of patients were identified: the first group with karyotype 45, X ($n=8$), the second group with mosaic variant 45,X/46,XX ($n=3$), the third group with structural anomalies of X chromosome ($n=8$). All patients were evaluated for thyroid function (TSH and free T4) and autoimmunity (anti-TPO antibodies (ATPO)), thyroid ultrasound examination was performed. The results were processed using SPSS.22.
Results
TS was diagnosed in patients with characteristic phenotypic signs according to the results of karyotyping at the age of 3.78 ± 3.48 years. 42% of girls ($n=8$) had normal thyroid function with TSH level of 2.61 ± 0.76 μIU/ml, 58% ($n=11$) had subclinical hypothyroidism (TSH – 7.5 ± 1.78 μIU/ml and normal level of fT4). Subclinical thyroid dysfunction was revealed in 66.7% girls with mosaic karyotype ($n=2$, TSH – 6.36 ± 0.79 μIU/ml), in 62,5% girls with monosomy X ($n=5$; TSH – 7.45 ± 1.92 μIU/ml), less often (50%, $n=4$) in girls with a mutation of the X chromosome (TSH 8.14 ± 2 μIU/ml). The prevalence of ATPO positivity was found to be 31.6% ($n=6$). Most of ATPO positive patients were girls with structural anomalies of the X chromosome (50% of patients, $n=4$). All patients with thyroid dysfunction are treated with levothyroxine, the average daily dose is 1.07 ± 0.53 μ/kg. There were no changes in the structure and size of the thyroid gland in 68.4% of girls ($n=13$) according to ultrasound. Sings of autoimmune thyroid disease (AITD) were found in 26.3% ($n=5$), nodal pathology – in 5.3% ($n=1$). Ultrasound symptoms of AITD were more common in girls with structural anomalies of the X chromosome (37.5%, $n=3$).
Conclusions
Our data showed high frequency of subclinical hypothyroidism in girls with TS. Thyroid autoimmunity in TS patients is more often detected in the presence of structural anomalies of the X chromosome.

Assessment of radioiodine treatment for hyperthyroidism

Emna El Feleh[1], Sana Mahjoubi[2], Ali Sellem[2] & Haroun Ouertani[1]
[1]Endocrinology Department, Military Hospital, Tunis, Tunisia; [2]Nuclear Medinice Department, Military Hospital, Tunis, Tunisia.

Introduction
Hyperthyroidism owing to Graves' disease or toxic nodular goiter is a common condition seen in clinical practice. The available modes of therapy are antithyroid drugs, surgery and radioiodine (RAI) therapy. Radioiodine is an effective, safe and relatively inexpensive form of therapy in patients suffering from hyperthyroidism. The aim of our study is to assess the effectiveness of radioactive iodine (RAI) treatment in patients with hyperthyroidism.
Methods
We retrospectively analyzed 70 patients suffering from hyperthyroidism and receiving RAI treatment. They were diagnosed as having hyperthyroidism based on clinical symptoms, elevated thyroid hormone levels and suppressed thyroid-stimulating hormone levels.
Results
The mean age of the study population was 38.33 ± 13.11 years. Forty-seven patients were female (67.1%) and 23 were male (32.9%). Sixty-five percent had Graves 'disease, 32% had toxic multinodular goiter and 3% had toxic single nodule. Sixty-five percent had been pre-treated with anti-thyroid medications. The mean duration of follow-up was 25.14 ± 14.25 months. The average dose of I131 used for therapy in our patients was 14.15 ± 0.34 mCi. Mean serum levels of free thyroid hormones were significantly lower in patients with toxic multinodular goiter compared to patients with Graves' disease (38.2 vs 58.6 pmol/l, $P=0.04$). Mean thyroid volume, as assessed by ultrasonography, was larger in patients with toxic multinodular goiter than in patients with Graves' disease (61.2 vs 24.2 ml, $P<0.01$). Patients with toxic multinodular goiter received a significantly higher dose of iodine than patients with Graves' disease (14.2 vs 12.3 mCi, $P<0.01$). The incidence of hypothyroidism was 52% at 6 months and 61% at one year. The response rate was significantly higher in the group without pre-treatment with anti-thyroid medications.The levels of serum thyroid hormone at presentation were correlated with the development of hypothyroidism after RAI treatment.
Conclusion
Radioactive iodine treatment is an effective modality for definitive treatment of hyperthyroidism. Response rate was not related to gender, etiology or RAI dosage. Pre-treatment with anti-thyroid medication reduces the response rate.

Dyslipidemia in subclinical hypothyroidism: a case–control study

Bayar Qasim[1], Sardar Arif[1], Ayad Ahmad[1] & Rezvan Abduljabbar[2]
[1]Department of Medicine, College of Medicine, University of Duhok, Duhok, Iraq; [2]Directorate of Health of Duhok, Duhok, Iraq.

Background
Subclinical hypothyroidism (SCH) is a common condition affecting 7.5–8.5% of women and 2.8–4.4% of men. Overt hypothyroidism is characterized by dyslipidemia, however the controversy persists regarding the lipids level in subclinical hypothyroidism (SCH) and its clinical significance. Recent evidence also shows that T4 replacement therapy may improve lipid profile.
Aim
The aim of this study is to assess the prevalence of dyslipidemia in subclinical hypothyroidism, to the best of our knowledge; this is the first study to assess dyslipidemia among patients with subclinical hypothyroidism in Duhok, Iraq.
Methods
This is a case-control study, consisted of a total 120 individuals, the case group composed of 60 patients diagnosed with subclinical hypothyroidism, while control group composed of 60 healthy individuals (matched for age and gender). The study conducted at the endocrine clinic at Azadi Teaching Hospital in Duhok Governorate, Kurdistan Region, Iraq from from 1st June 2016 to 1st June 2017.
Results
Dyslipidemia was much more prevalent in patients with subclinical hypothyroidism in comparison to control group (P value <0.001). In further analysis of dyslipidemia total cholesterol and triglyceride levels were statistically higher among cases in comparison to controls (P value <0.001) for both. LDL level was higher among cases in comparison to controls; however it didn't reach statistical significance (P value of 0.087). While there was significant difference regarding HDL level among female gender cases and Controls (P value of 0.003), there was no significant difference regarding difference in HDL level among male gender cases and Controls (P value is 0.653).
Conclusion and recommendations
SCH is considered atherogenic condition as it increases dyslipidemia and it increases overall cardiovascular risk. It's reasonable to assess lipid profile and CVS risk in these patients and to treat with levothyroxine when it's clinically applicable.

An eleven–year–old girl presenting with Graves' ophtalmopathy

Rym Belaid, Amel Jaidane, Insaf Oueslati, Chadia Zouaoui & Haroun Ouertani
Department of Endocrinology, Military Hospital of Tunis, Tunis, Tunisia.

Introduction
Graves' ophthalmopathy (GO) is an autoimmune disorder affecting the retro-orbital tissues. It represents the main extra- thyroidal expression of Graves' disease (GD). In children, GO is less common and less severe than in adults. Herein we report a case of GO in a child.
Case report
An 11-year-old girl with family history of autoimmune thyroid disease was referred to our department for evaluation of suspected hyperthyroidism. She presented with heat intolerance, diaphoresis, palpitations, mood disturbances, tearing, photophobia, gritty eyes as well as a history of weight loss over the past few months. On physical examination, she had a body weight of 40 kg, a BMI of 16.65 kg/m^2. The pulse rate was 110 beats per minute (bpm). A diffuse goiter and a mild bilateral exophthalmos were also found. At the admission, laboratory tests revealed decreased TSH (<0.005 μIU/ml) and increased free T4 of 26.9 pmol/l. TSH receptors antibodies were positive. Doppler Ultrasonography revealed enlarged thyroid without focal lesions, with increased vascular flow in both lobes. The diagnosis of Graves' disease was established. Treatment with Methimazole (15 mg) and propranolol (20 mg*3) was then initiated. Lubricating eye drops were prescribed for the ocular symptoms. Thyroid hormone levels normalized after 2 weeks and the girl was discharged from the hospital in good condition.
Conclusion
Although rare in childhood, GD remains the most prevalent cause of hyperthyroidism. Its ocular manifestations are much milder than in adult GO and their management requires, in the majority of cases, only a local treatment. A regular follow up is always needed.

Choroidal thickness changes in Graves' ophthalmopathy

Eylem Cagiltay[1] & Fahrettin Akay[2]
[1]Medical Sciences University, Sultan Abdulhamid Khan Education and Research Hospital, Istanbul, Turkey; [2]Izmir Katip Celebi University Ataturk Training and Research Hospital, Izmir, Turkey.

Introduction
Graves' ophthalmopathy (GO) may develop nearly 25–50% in Graves' Disease (GD). Clinical manifestations of GO are caused by the over compression of orbital tissues within the restricted orbital bone cavity. Impaired ocular blood flow may disrupt the retinal microstructure and functions. Early recognition of retinal and choroidal changes may alert the physicians for preventing ocular complications of GO. In this study we aimed to investigate the macular and choroidal thickness changes in GO compared with healthy subjects.
Materials and methods
The study group comprised 50 adult patients with previously diagnosed Graves' Disease with ophthalmopathy who were on anti thyroid treatment, compared with controls. For the assessment of GO activity, VISA (vision, inflammation, strabismus, and appearance) inflammatory score was used. When euthryoidism was achieved without side effects, the patients were referred to the ophthalmology clinic for Spectral-domain optical coherence tomography (SD-OCT) evaluation. SD-OCT is a non-invasive method that is used for quantitive assessment of retinal morphology and choroidal thickness.
Results
Subfoveal, mean and temporal choroidal thicknesses were increased significantly in study group according to the controls. But nasal, peripapillary and choroidal thickness minimal increased in study group and there was no statistical difference. None of our patients had severe GO, and the mean intraocular pressure (IOP) was within the normal limits. However, the mean choroidal thickness was elevated.
Conclusions
We think that this elevation is because of the retroorbital inflammation even in this non-severe GO group. We also suggest that choroidal thickness might be affected from the venous obstruction and congestion in patients with GO. The elevation of the choroidal thickness might be an early sign of venous congestion that occurs before the elevation of IOP (Table 1).

Table 1 Choroidal thickness differences between groups.

	Study group n = 50	Control group n = 50	P value*
Subfoveal	304.22 ± 36.09	275.54 ± 34.20	$P<0.001$
Temporal, 500 μm	311.06 ± 38.18	274.22 ± 34.92	$P<0.001$
Temporal, 1000 μm	309.68 ± 36.83	272.98 ± 33.24	$P<0.001$
Temporal, 1500 μm	302.00 ± 32.44	267.64 ± 31.77	$P<0.001$
Nasal, 500 μm	294.10 ± 34.74	270.76 ± 34.66	$P=0.001$
Nasal, 1000 μm	274.50 ± 38.92	263.50 ± 34.06	$P=0.13$

Post-operative hypocalcaemia following open thyroidectomy for benign multinodular goiters using FOCUS harmonic scalpel versus conventional suture ligation technique for hemostasis – a prospective, single-blind, randomized controlled trial

Sadaf Zehra[1] & Sughra Parveen[2]
[1]Royal College of Surgeons, Dublin, Ireland; [2]Jinnah Post Graduate Medical Center, Karachi, Pakistan.

Background
Vessel hemostasis during thyroidectomy is the mainstay of reducing the risk of post-operative hypocalcaemia, which can be achieved by using several techniques. The aim of this study was to compare the occurrence of hypocalcaemia 24–48 hours following total thyroidectomy by using FOCUS harmonic scalpel (HS) vs the conventional suture ligation (CSL).

Patients and methods
A prospective, single-blind, randomized trial in which 76 patients with benign multinodular goiters scheduled to undergo total thyroidectomy, were randomized into two groups: to receive HS ($n=38$) or CSL (38). Patients were monitored for hypocalcaemia at 24 and 48 h post-operatively and the lengths of post-operative hospital stay. Statistical analysis to detect between-group difference was based on student's *t*-test performed using SPSS.
Results
The incidence post-operative hypocalcaemia was 15.79% and 36.84%, in HS and CSL groups, respectively ($P=0.033$). Length of hospital stay was 2.63 ± 0.85 and 1.37 ± 0.67 days, respectively ($P<0.001$), identification of parathyroid glands was significantly associated with hypocalcaemia in the CSL group ($P=0.019$) but not in the HS group ($P=0.372$).
Conclusions
FOCUS HS is a reliable and safe technique, with the potential of achieving hemostasis in total thyroidectomy for benign thyroid disease. The conventional suture ligation technique should be replaced with FOCUS HS in thyroid surgery practice.

Thyroid disorders and gestational diabetes mellitus: more common than we thought

Sebai Imen, Ben Brahim Asma, Ben Abdessalem Haifa, Oueslati Insaf, Ben Cheikh Marwa, Ounaissa Kamilia, Yahiaoui Rim & Amrouche Chiraz
National Institute of Nutrition, Tunis, Tunisia.

Aim
Thyroid disorders are very common in women of reproductive age. The aim of this study was to determine the prevalence of different biological thyroid disorders during gestational diabetes mellitus (GDM).
Methods
This was a retrospective observational study carried out between March and June 2017 in the day hospital of the National Institute of Nutrition. Pregnant women referred for the management of GDM and who have no history of prior thyroid disorders were included. Five forms of thyroid disorders have been identified: Isolated hypothyroxinemia, Overt Hypothyroidism, Subclinical Hypothyroidism, Overt hyperthyroidism and Subclinical hyperthyroidism. Clinical and bio-chemical data were obtained by review of medical records.
Results
We included 100 pregnant women with a mean age of 32.4 ± 5.3 years. Of them, 4% were in the first, 35% in the second and 61% in the third trimester of pregnancy. Mean gestational age at time of screening for GDM was 22.3 ± 6 weeks. Approximately 47% of pregnant women were euthyroid, 20% were hypothyroid and 4% were hyperthyroid. Isolated hypothyroxinemia was detected at 29% of women. Hypothyroidism, defined as an elevated TSH level above the trimester-specific reference range, was associated with a decreased level of free T4 (overt hypothyroidism) in 16% and with a normal level of circulating free T4 in 4% of the population (subclinical hypothyroidism). The incidence of overt and subclinical hyperthyroidism in pregnant women was around 1% and 3%, respectively.The presence of thyroid disorders was noted in 40% of pregnant women during the first trimester, in 53% of pregnant women during the 2nd trimester and in 54% during the 3rd trimester.
Conclusion
Our results showed that thyroid disorders are common in our study population. A reassessment of the iodine status of Tunisian women is interesting to detect a possible deficit and therefore introduce targeted supplementation.

Characteristics and outcome of patients with hyperthyroidism attending a hospital endocrine clinic- a retrospective study

Sing Yang Sim, Claudia Lethem & David Coppini
Poole Hospital, Poole, UK.

Aims
A study looking at the incidence, presentation, diagnosis, management strategies and outcomes following anti-thyroid drug treatment and radio-iodine therapy in a cohort of patients presenting with hyperthyroidism.
Methods
Retrospective longitudinal study of all patients ($n=442$) who received treatment for a new diagnosis of hyperthyroidism (Grave's disease (GD), multinodular goitre (MNG), Toxic nodule) in a secondary care outpatient setting over a 15 year period (2002-17). All patients are initially treated with thionamides for at least a 6 month period, and up to 2 years until a biochemical remission (TSH level within the normal range) is observed for at least 6 months after cessation of drug treatment. A second course of treatment is offered to patients in cases of relapse, but treatment is individualised depending on personal circumstance, aetiology and patient preference.
Results
442 patients were treated with thionamides between 2002 and 2017. Mean duration of treatment was 295 days (range min-max). The age of diagnosis ranges between 17 and 91 years (mean 52.6 ± 17.1 years) with female (74.4%) to male (25.6%) ratio of 3:1. 78.5% ($n=347$) of subjects had Graves disease, 8.4% ($n=37$) had multinodular goitre (MNG), 6.6% ($n=29$) had amiodarone induced thyrotoxicosis and $n=16$ (6%) had toxic nodule. A biochemical cure on drug treatment was achieved in 161 patients (37%), and of these 93% ($n=150$) had Graves, 4.4% (N=7) had multinodular goitre 2.5% ($n=4$) had thyroid nodule. In 122 patients who received radioiodine, 70% ($n=85$) had Graves disease, 15% ($n=18$) had multinodular goitre, 13% ($n=16$) had toxic nodule, 2% ($n=3$) were of indeterminate aetiology. In 18 patients who received a 2nd dose of radioiodine, 67% ($n=12$) had Graves disease, 11% ($n=2$) had multinodular goitre, and 22% ($n=4$) had toxic nodule. 50% ($n=61$) patients developed permanent hypothyroidism within 6 months of radioiodine therapy. Of these 65% ($n=56$) had Graves disease, 22% ($n=4$) patients had MNG and 25% ($n=1$) had toxic nodule. In 8 patients who underwent a thyroidectomy, 6 had Graves' disease and 2 had amiodarone induced thyrotoxicosis.
Conclusions
This is the first study to report characteristics of patients with hyperthyroidism in a UK population managed in the outpatient setting. Although the data may be limited by some incomplete records commonly encountered in retrospective series, we present some interesting findings showing the likely clinical response rates to various established treatment modalities used.

How evolve antithyroperoxydase antibody in Hashimoto thyroiditis in time: Study on 450 patients: January 2018

Mihaela Ratcu[1], Mara Carsote[2], Cosmina Ilie[1], Payman Gharibafshar[1], Dana Cristina Staicu[1], Dan Peretianu[1] & Bogdan Oprisan[3]
[1]Medical Center 'Povernei', Bucharest, Romania; [2]Institute of Endocrinology, Bucharest, Romania; [3]Department of Biophysics Univ.Med.Gr.T.Popa, Iassi, Romania.

Aim
Most research teams analyze the evolution of patients with Hashimoto thyroiditis (HT) on syndromal basis, not on pathogenetic basis. Thus, most researchers refer to thyroid function evolution. In this study we tried to show how evolve the antithyroid antibodies. Therefore, we analyzed ATPO evolutive patterns.
Method
(1) ATPO levels were analyzed in several accreditated Bucharest laboratories. (2) Only patients with minimum 3 investigations were considered for interpretation. (3) We considered 5 ATPO evolutive patterns: (a) undulatorious; (b) decreasing; (c) increasing; (d) unmodified, (e) disappearance. (4) Unmodified pattern was considered if ATPO level did not differed by 5%. (5) Disappearance pattern was considered if ATPO decreased under the cut off level (=34 ui/ml).
Results
(A) Patients: 450; women – 421, men – 29 (6.89%). (B) The reinvestigation final time was: average: 5.37 years; median: 4.75; minimum: 2 months, maximum: 22 years. (C) ATPO level at onset (diagnostic time): average: 854 ui/ml, standard deviation: 2508. (D) The evolution patterns were: (a) undulatorious – 313 patients (69.5%); 5 without thyroid; (b) decreasing (ATPO over cut off limit) – 76 (17%); 3 no thyroid (1 – atrophy, 2 thyroidectomy/TX); (c) increasing: 36 (8%); (d) unmodified: 12 (2.67%), 2 no thyroid (1 after 131-I, 1 TX); (e) disappearance: 13 patients (2.9%), 8 no thyroid (3 atrophy, 5 TX). (E) ATPO patterns in patients (no. 68) seen after 10 years: (a) undulatorious: 51 (75%); (b) decreasing: 11 (16%) ; increasing: 1; unmodified: 1; (e) disappearance: 4 (6%). (F) There was no clear correlation with thyroid function at onset: Hypothyroidism vs euthyroidism vs hyperthyroidism: (a): 153-113-47; (b): 31-30-15; (c): 16-13-7; (d): 3-7-2; (*z* test, $P>0.005$); (e): 13-0 – significant difference.
Conclusions
(1) In most patients (c. 70%), ATPO evolve undulatorious. (2) When thyroid is missing, ATPO decreased level were registered till disappearance.

Hyperemesis gravidarum mimicking thyroid storm- A diagnostic dilemma in early pregnancy

Yingshan Lee
Tan Tock Seng Hospital, Singapore, Singapore.

Introduction
The thyrotrophic effects of human chorionic gonadotrophin (HCG) are responsible for a physiological rise in fT4 and suppression of TSH in early pregnancy. Hyperthyroidism in this period is mostly due to gestational transient thyrotoxicosis (GTT) which is frequently mild and resolves spontaneously by 18 weeks, or due to Graves' disease (GD) which would require closer monitoring through pregnancy (1). The pathophysiology of hyperemesis gravidarum is unclear, although it has been associated with higher HCG and fT4 levels. Here, a case of severe hyperemesis gravidarum (HG) presenting with features of thyroid storm is described.
Case
A 24 year-old primip with singleton pregnancy and no previous thyroid disease presented at 9 weeks gestation with a 3-week history of nausea, vomiting, anorexia, lethargy and 10% weight loss. Additional symptoms included palpitations and heat intolerance. Clinically, she was thin, dehydrated and anxious. She was afebrile, BP 110/76 mmHg with tachycardia at 150 per minute. Fine tremors were present. She had neither goitre nor other features of Graves' disease. Hyperthyroidism was confirmed biochemically – fT4 50.6 pmol/l [Reference Interval (RI): 8–21 pmol/l], fT3 14.6 pmol/l [RI 3.5–6.0 pmol/l], TSH 0.01 mIU/l [RI: 0.34–5.60 mIU/l]. LFT showed a mixed picture with bilirubin 3 times elevated and transaminases raised between 5 and 9 times. White cells count and erythrocyte sediment rates were normal. ECG showed T inversions. Burch-Wartofsky score was 50. She was supported with intravenous infusion and anti-emetic which stabilized her pulse to 120 per minute. In view overt clinical features of hyperthyroidism, carbimazole 30mg was given daily. Daily fT3 showed an improving trend and she was discharged on day 4 when fT4 31.4 pmol/l, fT3 8.6 pmol/l, TSH <0.01 mIU/l. Carbimazole was stopped 2 weeks later. Her thyroid antibodies eventually returned as negative. She delivered a healthy baby girl at term and post-partum thyroid tests were normal.
Discussion
While GTT is largely a benign condition, serious complications had been reported. Confident differentiation of GTT from GD relies on evidence of thyroid autoimmunity. Delaying definitive treatment while awaiting antibody testing results may expose the patient to adverse effects of hyperthyroidism. In cases with features of severe hyperthyroidism, a short course of ATD may be necessary to avoid further end-organ deterioration while maintaining close monitoring of thyroid levels to avoid over-treatment.

Correlation between cytologic results and thyroid autoantibodies, calcitonin, and thyroid function tests in patients with thyroid nodules

Pinar Karakaya[1], Bahar Pehlivan[2], Meral Mert[1], Bülent Yaprak[2], Yildiz Okuturlar[2], Sema Doğançiftçi[1], Cevher Akarsu[3], Ahmet Cem Dural[3] & Abdülbaki Kumbasar[2]
[1]Bakırköy Dr. Sadi Konuk Training and Research Hospital Endocrinology Department, Istanbul, Turkey; [2]Bakırköy Dr. Sadi Konuk Training and Research Hospital Internal Diseases Department, Istanbul, Turkey; [3]Bakırköy Dr. Sadi Konuk Training and Research Hospital General Surgery Department, Istanbul, Turkey.

Aim
Fine needle aspiration biopsy (FNAB) is currently a widely accepted screening procedure in diagnosis of thyroid nodules, there has been confusion related to diagnostic terminology in the assessment of samples. This confusion has been caused by multiple category names, descriptive reports without assigning to a category, and different terminologies used for surgical pathology. We aimed to evaluate correlations between US characteristics, cytologic results of FNAB, and thyroid antibodies, calcitonin, and thyroid function tests in patients presented with thyroid nodules, and to contribute in diagnosis, treatment, and patient follow-up.
Methods
A total of 1639 patients with thyroid nodules who applied to outpatient clinic of endocrinology between dates April and May 2017, had FNAB under US guideline, and their pathologic evaluation was performed according to Bethesda classification. Serological and hormonal tests were also performed for each patient.
Results
The mean age of study group was 50 (range interval = 14–90) years. The median of node-diameter1 was 17.5 (range = 1–51) mm, and median of node-diameter 2 was 12 (range = 8–33) mm. Of US characteristics, echogenicity, microcalcification, irregular borders, and solitary nodules were determined in 4.4%, 54%, 71.2%, and 86.6% of cohort respectively. Elevated anti-TPO was determined in 64.6%. Cytologic readings were reported as 15.8% nondiagnostic, 53.8% atypia of undetermined significance/follicular lesion of undetermined significance, 28.8% benign, 0.4% suspicious for follicular nodule, and 1.2% malign.
Conclusion
FNAB, high resolution US findings, and sensitive thyrotropin levels are the mainstay to determine further clinical approach in patients with thyroid nodules.

P1023

Percutaneous ethanol injection for benign cystic and mixed thyroid nodules

Aysenur Ozderya, Kadriye Aydin, Naile Gokkaya & Sule Temizkan
Department of Endocrinology and Metabolism, Kartal Dr. Lutfi Kirdar Research and Training Hospital, Istanbul, Turkey.

Background/aim
We aimed to determine the effect of percutaneous ethanol injection (PEI) on volume of cystic and mixt thyroid nodules, thyroid function tests (TFTs), antibody titers and cytological changes for 1 year.
Methods
Fifty-five nodules of 53 patients with cystic and mixt properties treated with PEI were included. Nodule volumes, TFTs, thyroid autoantibodies were analyzed at baseline, 6^{th} and 12^{th} months. Fine needle aspiration biopsy (FNAB) was performed to PEI applied nodules in the 12^{th} month. Thyroid nodules were grouped into three by structural properties (pure cystic, predominant cystic, predominant solid). By calculating volume reduction between initial and final volume, we defined response to PEI in three categories as complete response ($\geq$90%), partial response ($<$90% to $\geq$50), and no response ($<$%50).
Results
PEI caused a volume reduction of 80.7% at 6^{th} month and 82.1% at 12^{th}month without any serious complication. PEI was repeated 1.4 ± 0.4 times with a mean total ethanol amount of 3.6 ± 3.1 ml. Volume reduction in the pure cystic nodules at 6th and 12th months after PEI was greater than the volume reductions in predominant cystic and predominant solid nodules. We detected that smaller nodules have greater volume reductions after PEI at 12th month. During the study, patients remained euthyroid. Anti-thyroglobulin levels were decreased at 12^{th} months. None of the FNAB results was compatible with a malignant or suspicious for malignancy cytology at 12^{th}month.
Conclusion
PEI is an effective way of treatment for benign cystic and mixt thyroid nodules without any serious side effects. We can also assume that PEI is not a trigger for autoimmunity and carcinogenesis for short term.

Post partum and non-post partum relapsing Graves' hyperthyroidism display different response to anti-thyroid drugs

Valentina Capelli[1,2], Mario Rotondi[3], Francesca Coperchini[3], Sara Pinto[3], Laura Croce[3], Massimo Tonacchera[4] & Luca Chiovato[3]
[1]Department of Internal Medicine and Therapeutics, University of Pavia, Pavia, Italy; [2]Department of Medical and Surgical Sciences, University of Pavia, Pavia, Italy; [3]Unit of Internal Medicine and Endocrinology, ICS Maugeri I.R.C.C.S., University of Pavia, Pavia, Italy; [4]Endocrinology Section, Department of Clinical and Experimental Medicine, University Hospital of Pisa, University of Pisa, Pisa, Italy.

Background
Graves' disease (GD) female patients in remission after a full course of methimazole (MMI) therapy are at risk for a relapse of hyperthyroidism during the post-partum (PP) period, but whether this relapse may display any peculiarity is still unknown.
Aim
To compare GD patients undergoing a relapse of hyperthyroidism either in the PP period or not.

Subjects and methods
Fourty-three female patients of childbearing age experiencing a relapse of GD hyperthyroidism were retrospectively evaluated. In 18 of them the relapse occurred in the PP period (i.e. within 12 months after delivery, PP group); in the remaining 25 the relapse occurred elsewhere during life (NPP group).
Results
At the time of the relapse, patients in the PP and NPP group were similar in terms of: age (34.4 ± 6.0 years versus 36.9 ± 5.7 years NS), thyroid volume (17.4 ± 6.9 ml vs 17.4 ± 6.1 ml, NS), thyroid function tests (FT3 7.64 ± 4.05 pg/ml vs 8.07 ± 3.67 pg/ml, NS) TRAb titers (4.37 ± 2.95 U/l versus 7.25 ± 7.22 U/l NS) and MMI starting dose (20.3 ± 8.0 mg/day vs 20.6 ± 9.01 mg/day, NS). However, the remission rate after a 12-month of MMI course was much greater (79%) in the PP as compared with the NPP (32%) group ($P = 0.002$). Throughout the study span, a significant reduction in TRAb levels was observed in the PP ($F = 9.016$; $P = 0.001$), but not in the NPP group ($F = 2.433$; NS). At 12 months the PP group also showed significantly lower mean TRAb levels (0.6 ± 1.1 U/L vs 4.5 ± 4.7 U/l, for PP and NPP, respectively; $P = 0.029$).
Conclusions
Relapsing Graves' hyperthyroidism in the PP period is more prone to undergo a remission of hyperthyroidism after a second course of MMI. A conservative therapeutic approach seems than to be more appropriate in GD patients experiencing a relapse of hyperthyroidism in the PP period.

Rare association of primary hyperparathyroidism and toxic multinodular goiter

Hamza Elfekih, Mouna Elleuch, Dorra Ghorbel, Faten Hadjkacem, Mouna Ammar, Mahdi Kalthoum, Nadia Charfi & Mohamed Abid
Hedi-Chaker University Hospital, Sfax, Tunisia.

Introduction
The association of primary hyperparathyroidism (PHPT) and hyperthyroidism secondary to toxic multinodular goiter (TMNG) is rarely described in the literature. Hereby, we describe the clinical, biological, and radiological characteristics of two patients having this rare association.
Observations
First case: A 66 years-old female was diagnosed with primary hyperthyroidism. Her thyroid antibodies were negatives. During the follow-up, she presented a high serum calcium level (2.95 mmol/l) and high Parathormone level (141.3 pg/ml) persisting after the correction of initial low 25-hydroxyvitamin D3. Her PHPT was complicated by osteoporosis and recurrent urolithiasis. Cervical ultrasonography and thyroid scintigraphy affirmed the presence of TMNG and bilateral lower parathyroid adenoma. She underwent a thyroidectomy and parathyroidectomy of the two adenomas. Histopathological examination confirmed the presence of a benign multinodular goiter (MNG) and two parathyroid adenomas. Second case: A 56 years-old female was followed-up for 18 years for MNG. She developed hyperthyroidism (FT4 = 35 mIU/l) followed by PHPT with hypercalcemia (2.79 mmol/l) and elevated Parathormone level (147 pg/ml) persisting after the correction of initial low 25-hydroxyvitamin D3. Her PHPT was complicated by osteopenia. Cervical ultrasonography and thyroid scintigraphy affirmed the TMNG without finding a parathyroid adenoma.
Conclusion
PHPT associated with thyroid nodules is rare. Hypercalcemia can be found up to a quarter of patients with hyperthyroidism. PHPT should be considered once hypercalcemia persists after correction of the thyroid status and parathyroid hormone should be determined.

The thyrotoxicosis in patients with amiodarone induced thyrotoxicosis may not respond totherapeutic plasmapheresis like patients with Graves' disease

Ismail Yildiz[1], Gulsah Elbuken[1], Sibel Ozkan Gurdal[2], Tugay Atasever[3] & Sayid Zuhur[1]
[1]Namık Kemal University, Faculty of Medicine, Department of Endocrinology and metabolism, Tekirdag, Turkey; [2]Namık Kemal University, Faculty of Medicine, Department of General Surgery, Tekirdag, Turkey; [3]Namık Kemal University, Faculty of Medicine, Department of Internal Medicine, Tekirdag, Turkey.

Introduction
Due to the risk of thyroid storm, achievement of euthyroid state is necessary in patients with thyrotoxicosis undergoing surgery. However, euthyroid state could not be always achieved by antithyroid drugs. Therefore, therapeutic plasmapheresis (TPE) can be used for this purpose.
Case 1
A-58-year old male patient was admitted to emergency department with diabetic ketoacidosis (DKA) induced by amiodarone induced thyrotoxicosis (AIT). He had a history of Tip2 diabetes and ventricular arrhythmia which were treated with intensive insulin therapy and 200 mg amiodorone/day. His plasma glucose, arterial pH, serum TSH, fT3, fT4 and TRAb levels were 613 mg/dl, 7.19 log [H^+], <0.005 mIU/ml (0.4–4), 5.47 pg/ml (1.57–5.3), 5.3 ng/dl (0.8–1.9), 5.3 U/l (0–14), respectively. After appropriate treatment for DKA, propronolol 80 mg/day, methimazole 40 mg/day and methylprednisolone 60 mg/day were started. However, fT4 levels increased to >7.7 ng/dl 3 weeks after treatment. Therefore, thyroidectomy and preparation with TPE was planned. TPE was performed with plasma exchange method by Spectra Optia Apheresis System and %5 albumin and isotonic saline were used for replacement of plasma. After two sessions, fT4 and fT3 levels decreased only to 5.15 ng/dl and 2.22 pg/ml, respectively, consistent with a 35% decrease. A thyroidectomy was performed without any complication.
Case 2
A 74-year-old male patient with acute antertior myocardial infarction (AMI) induced by Graves' disease was admitted to emergency department. On biochemical analysis his serum TSH, fT3, fT4 and TRAb levels were <0.005 mIU/ml, 10.6 pg/ml, 4.5 ng/dl and 24 IU/l (0–14), respectively. Treatment with propranolol 80 mg/day, methimazole 40 mg/day and ten drops of lugol solution was started. A primer percutanous coronary anjiography revealed multiple vessel disease and an emergent coronary artery bypass grafting (CABG) was planned. So, a TPE was performed. After one session, fT4 and fT3 decreased to 2.48 ng/dl and 2.96 pg/ml, respectively, which were consistent with a 45% and 72% decrease in fT4 and fT3 levels. The patient underwent CABG surgery without any complication.
Conclusion
Although only one session of TPE was effective to achieve euthyroid state in a patient with Graves' disease, euthyroid state coud not be achived after two sessions of TPE in a patient with AIT. So, the thyrotoxicosis in patients with AIT may not respond to TPE like patients with Graves' disease.

Effect of metformin therapy on thyroid stimulating hormone and BMI in hypothyroid egyptian patients

Eman Fahmy[1], Mohamed Mashahit[2] & Ghada Mohamed[3]
[1]Helwan Unversity, Helwan, Egypt; [2]Fayoum Unversity, Fayoum, Egypt; [3]Assiut Unversity, Assiut, Egypt.

Back ground and objectives
Relation between thyroid function with respect to insulin resistance has been a field that is rich and captivating for research and further examination. Few studies have suggested that metformin, the first-line in diabetes management, may lower thyroid-stimu-lating hormone (TSH). Owing to Paucity of studies regarding the effect of metformin on TSH in hypothyroidism patients, this study compares the effect of metformin on TSH and BMI in Egyptian naïve hypothyroid patients.
Methods
This cross-sectional prospective study recruited 200 patients with newly diagnosed hypothyroidism (86 male and 114 female). Patients divided in to two groups; Group 1 include 100 patients receive metformin 1000 mg beside thyroxine therapy and Group 2 (100 patients) treated only by thyroxine therapy. The height, weight, BMI, waist circumference (WC) and thyroid hormone levels were assessed at baseline and after 4 months of metformin treatment.
Results
BMI and WC decreased significantly after metformin therapy (27.8 ± 2.2, 97.2 ± 6.7) and (28.8 ± 1.8, 104.8 ± 5.4) ($P < 0.0001$) in group 1 vs group 2 respectively. No significant difference between two groups as regard to TSH ($P = 0.881$).
Conclusion
It has been established that metformin decrease body mass index and waist circumference in naïve hypothyroid Egyptian patients with no influence on TSH levels.

IgM thyroglobulin autoantibodies are detectable in serum of patients with subacute thyroiditis

Alessandro Brancatella, Debora Ricci, Michele Marinò, Paolo Vitti & Francesco Latrofa
Department of Clinical and Experimental Medicine, Endocrinology Unit, University Hospital of Pisa, Pisa, Italy.

Context
Subacute thyroiditis (SAT) is an inflammation of the thyroid, likely caused by a viral infection. IgG Autoantibodies (Ab) to the main thyroid antigens, including thyroglobulin (Tg) (TgAb) have been reported in a few patients with SAT and their appearance is usually transient. We investigated whether IgM TgAb can be detected in sera of patients with SAT.
Design
Serum samples were collected from 17 patients with SAT, ten with Graves' disease (GD) and 10 with Hashimoto's thyroiditis (HT). GD and HT sera were selected because of positive IgG TgAb (by AIA-PACK 2000, Tosoh Biosciences) . Samples of SAT patients were collected 1–9 months after the onset of SAT. IgG and IgM TgAb were measured in ELISA. Wells coated with human Tg were incubated with sera and IgG and IgM TgAb were detected with biotin-conjugated anti human IgG or IgM. HRPO- conjugated streptadivin was then added. The substrate was o-phenylene diamine $+H2O2$. ODs were read at 490 nm. To rule out non-specific binding, ELISA for IgM was performed with BSA, keyhole limpet hemocyanin (KLH) and glucagon (Gluc); sera showing BSA binding were considered as IgM TgAb negative.
Results
IgG TgAb were positive in 14/17 SAT, 10/10 GD and 10/10 HT. IgM TgAb were positive in 10/17 SAT, 0/10 GD and 0/10 HT. Seven SAT sera were IgG TgAb positive and IgM TgAb negative, 5 IgG TgAb negative and IgM TgAb positive and 5 IgG TgAb positive and IgM TgAb positive. Median titer was 1/100 (IQR: 1/33-1/1000) for IgG TgAb and 1/3300 (IQR: 1/3300-1/3300) for IgM TgAb. The duration of SAT did not correlate with positive IgM TgAb. All SAT sera did not bind KLH and Gluc in IgM ELISA.
Conclusions
IgM TgAb can be detected in sera of SAT patients with or without IgG TgAb. They do not correlate with the duration of SAT.

Single session treatment of benign thyroid nodules with radiofrecuency ablation: results at 6 months in 17 patients

Cristina Familiar, Salome Merino, Tomas Ganado, Ines Jimenez & Concepcion Sanabria
Hospital Clinico San Carlos (Madrid), Madrid, Spain.

Introduction
Radiofrecuency ablation (RFA) represents an alternative to surgery for benign thyroid nodules with pressure symptoms or evident progressive growth.
Objetives
To analyze in our center the efficacy and safety at 6 montns of a single session treatment of RFA performed in predominantly solid thyroid nodules.
Patients and methods
17 patients with citologically benign thyroid nodules with pressure symptoms (dysphonia, dyspnea, dysphagia, foreign body sensation) or evidence of growth ($>$ 2 mm in two diameters or $>$ 50% of volumen) who refused surgery were treated with RFA using the moving-shot technique. Patients were evaluated at month 1, 3 and 6 of the procedure. Porcentual change form the basal volumen, pressure symptoms,TSH, FT4, Tiroperoxidase antibodies and potential minor complications (hematoma, pain requiring analgesic medication) and major complications voice change, nodule rupture, thyroid disfunction and brachial plexus injury) were recorded.
Results
Mean basal volumen decreased from 26.6 ± 14.8 to 9.9 ± 9.1 ml at month 6 ($P < 0.05$). Percentage of volumen decrease was significant since the first month of RFA ($30.3 \pm 9.7\%$) reaching $58.8 \pm 21.1\%$ at month 6.Therapeutic success defined as more than 50% in volumen reduction was achieved in 11/17 cases. Presssure symptoms basally recorded in eight patients disappeared in all cases since the first month from RFA and antithyroid drugs could be removed in 2/3 patients with initial subclinical hyperthyroidism. There were no changes in hormonal and antibodies values. Minor complications were reported in ten subjects (five transient paint and five local minor hematomas)and there was only one major complication consistent with a nodule rupture observed at month 1 recovering spontaneously.
Conclusion
One single session treatment of RFA is an effective and safe outpatient procedure in shrinking thyroid benign predominantly solid nodules and in controlling pressure related symptoms. A second session of RFA and a better selection of candidate nodules (obviating those in a confluent nodule background) could improve the percentage of volumen reduction and the prorpotion of patients with successful ablation.

Fibroblast growth factor 23 is elevated in patients with euthyroid Graves' disease

Chia-Hung Lin, Shyang-Rong Shih & Keh-Sung Tsai
National Taiwan University Hospital, Taipei City, Taiwan.

Background
Graves' disease (GD) is associated with accelerated bone turnover and elevated fibroblast growth factor 23 (FGF23). FGF23 is involved in the mineral homeostasis, especially the regulation of serum phosphate. Literatures showed that FGF23 decreased along with treatment of GD. It remains unclear whether FGF23 becomes normal after euthyroid status achieved.
Methods
A total of 64 patients with euthyroid GD and 64 healthy control subjects were enrolled. Endocrine profiles including thyroid autoimmune profiles, FGF23 and bone turnover markers were obtained and compared between two groups and within each group.
Results
Euthyroid GD patients have significantly higher FGF23 and phosphate, and lower 25-hydroxyvitamin D (25OH-VitD) and intact parathyroid hormone (iPTH) levels than the control group. FGF23 was significantly and negatively correlated with phosphate level after adjusted for age, gender, calcium, iPTH and 25OH-VitD in euthyroid GD group.
Conclusion
Serum FGF23 levels remain higher than normal in GD patients even after euthyroid status achieved. Underlying mechanisms warrant further investigations. Data are presented as mean $\pm$ S.D. if the continuous variable is normally distributed, and as median (interquartile range) if not normally distributed. Corrected calcium was calculated as follows: serum calcium (mg/dL) $+0.8$ * (four – albumin). *P* values were calculated by t-test for continuous variables and by chi-squared test for categorical variables. FGF23 was log-transformed to become normally distributed for *t*-test.

Table 1 Clinical characteristics of study subjects.

	Euthyroid GD	Control	*P*
N	64	64	
Age (years)	47.6 ± 10.9	48.0 ± 10.8	0.8523
Gender (female: male)	51:13	50:14	0.828
Corrected calcium (mg/dl)	9.12 ± 0.48	9.23 ± 0.29	0.1874
Phosphate (mg/dl)	4.24 ± 0.78	3.84 ± 0.51	0.0044
25-OH Vitamin D (ng/dl)	16.40 ± 5.52	23.20 ± 5.24	<0.0001
iPTH (pg/ml)	15.39 ± 8.82	25.79 ± 11.25	<0.0001
FGF23 (pg/ml)	59.10 (45.18–95.09)	46.00 (27.21–60.55)	0.0003
PINP (ng/ml)*	49.70 ± 19.65	54.12 ± 20.65	0.5293
CTX (ng/ml)*	0.21 ± 0.12	0.23 ± 0.09	0.5995

*Data of PINP and CTX were analyzed in 23 euthyroid GD subjects and 13 control subjects.

Table 2 The relationship of FGF23 and phosphorous in linear regression model, using FGF23 as the dependent variable and serum phosphate as the independent variable.

	Euthyroid Graves' disease group	Control group

Evaluation of the iodine sufficiency of pregnant women in Belarus

Sergei Petrenko[1], Boris Leushev[1], Vladimir Mojeiko[2], Tatiana Mokhort[3], Natalia Kolomiets[4], Ekaterina Fedorenko[5] & Alena Mokhort[3]
[1]International Sakharov Environmental Institute of Belarusian State University, Minsk, Belarus; [2]Osrovets Hospital, Minsk, Belarus; [3]Belarusian State Medical University, Minsk, Belarus; [4]Belarusian Medical Academy of Post-Graduate Education, Minsk, Belarus; [5]City Centre for Hygiene, Epidemiology and Public Health, Minsk, Belarus.

Republic of Belarus belongs to the iodine-sufficient countries. However, the subject of the study is to assess iodine status of pregnant women as the critical group of the population. Iodine deficiency has a negative impact on the level of pregnancy complications and childbirth, increasing the risk of babies with low birth weight, adverse effect on newborn and children of early age health.
The purpose of this study
To assess iodine sufficiency of pregnant women in 2nd trimester of pregnancy (random sampling).
Material and methods
The study included 100 pregnant women in the 2nd trimester of pregnancy. For an objective assessment of iodine status the following methods were used: estimation of urinary iodine excretion (by spectrophotometric cerium arsenite method adopted by the WHO) and thyroid dimensioning and estimation of iodine supplements (%).
Results
The table shows results for urinary iodine concentration in pregnant women.

Table 1

	The distribution of patients (%) in urinary iodine concentration (μg/l)						Me UIC,	Me, thyrod gland
Number	<20	21–50	51–100	101–250	251–300	>300	μg/l	volume, ml
100	0	6	33	23	11	27	157.3	16.4

The results indicate that only 38% of pregnant women reach the target level of urine iodine excretion. This value is consistent with the questionnaire data, which indicates that only 47% of pregnant women take potassium iodide, despite the recommendation of taking iodine-containing drugs to all pregnant women. The median thyroid gland volume corresponds to the normal values, which indirectly indicate a short period of iodine insufficiency.
Conclusion
Despite the achievement of target levels of iodine sufficiency in a population of children and adults, it is necessary to use of potassium iodide in pregnant women.

Thyroid disease in PHPT: a single centre study

Elena Castellano, Laura Gianotti, Adele Latina, Flora Cesario, Claudia Baffoni, Micaela Pellegrino, Francesco Tassone, Giampaolo Magro & Giorgio Borretta
Department of Endocrinology, Diabetes and Metabolism, Santa Croce and Carle Hospital, Cuneo, Italy.

Objective
Primary hyperparathyroidism (PHPT) and thyroid diseases are common in the general population. It is difficult to establish whether they occur in the same patient because of a direct relationship or just due to the widespread prevalence of both conditions. The reported prevalence of the concomitant occurrence of these two clinical conditions is widely scattered (ranging 17–84%), especially due to the heterogeneous criteria for patient selection. We aimed to evaluate in a large series of PHPT patients the prevalence of thyroid diseases and the clinical and biochemical presentation of PHPT in patients without or with concomitant thyroid diseases.
Methods
We retrospectively evaluated an unselected and monocentric series of 434 outpatients with PHPT, attending our hospital between 1998 and September 2017. Patients with neither bone or kidney involvement, nor hypercalcemic symptoms were considered asymptomatic. The US thyroid pattern was considered abnormal if nodules or features of chronic lymphocytic thyroiditis were found. The histological report of patients submitted to thyroidectomy was then evaluated.
Results or Case Presentation
Thyroid diseases were found in 263/434 (60.6%) PHPT patients. Among them, over than 80% were affected by nodular goiter, that was toxic in almost 10% of cases. Thyroid autoantibodies were positive in 50 (19%) patients, all with an autoimmune US pattern. Thyroid cancer was diagnosed in 11/85 patients (12.9%) and it was a papillary microcarcinoma in all cases but one. Patients with thyroid diseases were older and more frequently female than the others, despite no difference in serum calcium, creatinine, 25OHD and TSH levels. PTH levels result significantly higher in patients without thyroid abnormalities. Anyway, no difference were found in the PHPT clinical presentation nor in the presence of osteoporosis at any site between the two groups.
Discussion
Thyroid diseases, mostly nodules, were present in 60% of our patients with PHPT,consistently with the goiter endemic area where our study has been conducted. Moreover, a thyroid carcinoma was found in more than 10% of patients. The predominantly histotype was papillary microcarcinoma, in agreement with literature data. PHPT characteristics resulted biochemically and clinically similar in patients with or without thyroid abnormalities.
Conclusion
In conclusion, the majority of PHPT patients have a thyroid disease. Our data confirm that thyroid diseases and PHPT are two conditions prevailing in specific population, thus making their association more frequent. Thyroid nodules could interfere in the diagnostic and therapeutic PHPT work up.

Clinical importance of incidentally discovered thyroid nodule by carotid artery ultrasonography

Mi Young Lee[1], Eun Hee Cho[2], Ji Yun Jeong[3], Jung Min Kim[4] & Mi Seon Shin[5]
[1]Department of Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea; [2]Department of Internal Medicine, Kangwon National University School of Medicine, Chuncheon, Republic of Korea; [3]Department of Internal Medicine, Soonchunhyang University, Gumi, Republic of Korea; [4]Department of Internal Medicine, Sanggye Paik Hospital, Inje University College of Medicine, Seoul, Republic of Korea; [5]Department of Internal Medicine, Hanil General Hospital, Seoul, Republic of Korea.

Thyroid nodules were frequently incidentally discovered during radiologic studies of chest or neck. We investigated the prevalence and clinical importance of thyroid incidentaloma during carotid artery ultrasonography in patients with diabetes. We retrospectively reviewed the data of enrolling all diabetic patients who were performed carotid artery ultrasonography at the Diabetes Center of Wonju Severance Christian Hospital from January to December 2013. Chart reviews of all eligible patients were performed. For those diagnosed with thyroid nodules, ultrasonographic findings and diagnosis of the thyroid nodules were reviewed. Total subjects enrolled this study were 1,518 patients and mean age was 59.98 ± 11.15 years. The prevalence of thyroid nodules discovered by carotid artery ultrasonography was 46% (803 of 1,518) and total 1,542 thyroid nodules were seen in the study. In these thyroid nodules, 157 cases (10.2%) were underwent fine needle aspiration biopsy (FNAB). The results of diagnosis of fine needle aspiration biopsy were benign 73%, atypical cells with unsignificance 12.6%, papillary carcinoma 6.3%, and material insufficiency 8.2%. The prevalence of thyroid nodule was linearly increased by age. Routine carotid IMT measurement in diabetic patients may discover thyroid nodules more frequently than in healthy population, so clinicians should pursue further investigation of these nodules by clinical guidelines for thyroid nodules.

Thyroid function in relation to pregnancy outcome

Violeta Mladenovic[1,2], Marija Andjelkovic[2,3], Zoran Gluvic[4,5], Aleksandar Djukic[1,2] & Djuro Macut[6,7]
[1]Department of Internal Medicine, Faculty of Medical Sciences, University of Kragujevac, Serbia, Kragujevac, Serbia; [2]Clinical Center «Kragujevac», Serbia, Kragujevac, Serbia; [3]Department of Biochemistry, Faculty of Medical Sciences, University of Kragujevac, Serbia, Kragujevac, Serbia; [4]Division of Internal Medicine, Dept of Endocrinology, Zemun Clinical Hospital, Zemun, Serbia; [5]School of Medicine, University of Belgrade, Belgrade, Serbia; [6]School of Medicine, University of Belgrade, Belgrade, Serbia; [7]Clinic for Endocrinology, Clinical Center Belgrade, Belgrade, Serbia.

Introduction
Thyroid disease in pregnancy is a common clinical problem, at least 2–3% of women have thyroid dysfunction, and it is estimated that about 5–20% of women of reproductive age suffer from autoimmune thyroid disease. Subclinical thyroid disease during pregnancy may be associated with adverse outcomes. In the first trimester, the 'normal' range for TSH is reduced to 0.1–2.5 mIU/l, and in the second and third trimester is 3.0 mIU/l.
Aim
The aim of this study is to analyse concentration of thyroid hormones and the presence of TPOAb, and determine thyroid function in relation to pregnancy outcome.
Matherial and methods
This study included 77 healthy pregnant women in the first trimester of pregnancy registered in Center for endocrinology CC Kragujevac. Blood samples were collected for fT4, TSH and TPOAb and measured by RIA method. As parameters of adverse outcomes we included: premature labor (before 37 gw., Low Apgar score (<8), neonatal malformations, respiratory complications, hypoglycemia, birth body weight $>$ 4000 g or $<$2500 g, hyperbilirubinemia
Results
The mean age of patients was 30.8 ± 4.7 years. The prevalence of autoimmune thyroid disease was 25.9%, positive family history for thyroid disorder was in 9%, smoking in 23.4% patients. The average serum level in patients with adverse outcomes ($n=41$) for fT4 was 10.7 ± 2.46 pg/ml, for TSH was 2.52 ± 1.1 mIU/l, and for TPOAb was 737, while in group with a favorable outcome ($n=36$) average serum level for fT4 was 10.2 ± 2.1 pg/ml, for TSH was 2.25 ± 1.2 mIU/l, and for TPOAb was 474. It has been shown that the number of risk factors significantly affect the outcome of pregnancy ($P<0.005$, χ^2 test), and that the presence of TPOAb as marker of autoimmune thyroid disease during pregnancy affect the outcome of pregnancy (24,4% patients with a favorable outcome and 27,7% patients with adverse outcomes had positive TPOAb). It has been shown that patients without TPOAb usually have a favorable outcome of pregnancy, and a growing number of pregnancies with an adverse outcome in patients with TPOAb.
Conclusion
This study demonstrates that the presence of TPOAb as marker of autoimmune thyroid disease during pregnancy predicts unfavorable adverse outcome.

The assessment of vitamin D3 deficiency in patients with Hashimoto's disease and the relationship between the disease duration and 25OHD3 levels

Katarzyna Lizis-Kolus[1], Alicja Hubalewska-Dydejczyk[2], Anna Sowa-Staszczak[2], Anna Skalniak[2], Aldona Kowalska[1,3] & Pawel Lizis[4]
[1]Holycross Cancer Center, Kielce, Kielce, Poland; [2]Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland; [3]The Faculty of Health Sciences, Jan Kochanowski University, Kielce, Poland; [4]Department of Education and Health Protection, Holycross College of Kielce, Kielce, Poland.

The observed increase in the incidence of Hashimoto's thyroiditis (HT) requires the research on environmental factors that may initiate or model its course. There have been reports of the impact of vitamin D3 deficiency on HT development.
Objective
To assess the degree of deficiency of 25OHD3 and the relationship between the disease duration and 25OHD3 levels in patients with HT.
Material and methods
310 people were enrolled in the study: 155 patients with HT-144 women (93%), 11 men (7%) and 155 healthy volunteers-139 (90%) women and 16 men (10%); mean age: 49 ± 18, 58 ± 17, 49 ± 17 and 56 ± 16 years respectively. Serum 25OHD3 concentration was measured in all subjects. The relationship between HT duration and 25OHD3 concentrations was evaluated in HT group. The analysis was also performed in HT subjects and the disease duration of $<$ 1 year and $<$ 2 years. Vitamin D deficiency was defined as 25OHD3 $<$ 30 ng/ml.
Results
In HT patients 25OHD3 level was lower than in the control group: 23.2 ng/ml (Q_1-Q_3: 18.6-29.0) vs 25.6 ng/ml (Q_1-Q_3: 21.0–31.4; $P=0.006$).There was a significant correlation between the disease duration and 25OHD3 concentrations in HT patients ($R=-0.32$; $P<0.001$). The correlation was moderate and negative. The regression coefficient of impact the disease duration on the mean 25OHD3 values in the HT group was -0.615. The adjusted coefficient of determination was 8.4%. Analysis in HT group and duration of disease $<$ 1 year ($n=30$) and $<$ 2 years ($n=46$) showed no significant correlation between duration of HT and 25OHD3 concentrations respectively: $R=0.23$; $P=0.223$; and $R=0.16$; $P=0.295$.
Conclusions
Vitamin D3 deficiency is more prevalent in HT patients, and may adversely affect and enhance the abnormal response of the autoimmune process in later stages of the disease without significant impact of its initiation.

Hypothyroidism treated with weekly intramuscular thyroxine injections

Kevin Kwek, Xuyan Teoh & Winston Kon
Tan Tock Seng Hospital, Singapore, Singapore.

Background
Oral levothyroxine (LT4) is usually an effective treatment for hypothyroidism. However, timing of meals, concurrent medications and gastrointestinal diseases causing malabsorption may impair absorption of oral LT4. We present a patient with Hashimoto's thyroiditis on LT4 replacement through a gastrostomy tube causing the problem of erratic thyroid function test (TFT) results, successfully managed through the use of once-weekly intramuscular LT4 injection.
Clinical case
A 65-year-old Chinese male was on follow-up with our clinic for multi-nodular Hashimoto's goiter requiring thyroxine replacement, 125ug/d, resulting in serum free thyroxine (fT4) 15 pM (RR 8–21 pM), and thyroid stimulating hormone (TSH) 1.12 mIU/L (RR 0.34–5.6 mIu/L). His co-medications were aspirin, famotidine, lisinopril, atenolol, trimetazidine and simvastatin. He was diagnosed with squamous cell carcinoma of the tongue and lip in 2006, requiring multiple surgeries, radiotherapy and eventually on 24/2/17, permanent gastrostomy tube feeding. However, he experienced multiple episodes of blocked gastrostomy tube due to luminal obstruction by residual feeds requiring urgent tube change. Despite a body weight of 50kg (BMI 19.1 kg/m2), the patient required increasing doses of levothyroxine up to 100mcg daily. Despite the high dose of levothyroxine, he continued to experience fluctuating fT4 levels, ranging from 4 to 13 pM, and TSH levels, ranging from 2.04 to 69.52mIU/L. As he was compliant and administered his doses of medication correctly through the PEG (via crushing of tablets and suspension in plain water), we hypothesized that his labile TFT results were due to poor enteral delivery of LT4 through the gastrostomy tube. Thereby on 16/11/17, the patient was started on intramuscular LT4 400mcg injection once weekly. At the 8th cycle, serum fT3, fT4 and TSH levels were measured pre-dose (trough), 4 hours post-dose (peak), and on day 1, day 3 and day 6.

	UoM	Trough	Peak	Day 1	Day 3	Day 6
fT3	pmol/L	3.9	3.7	3.7	3.8	3.5
fT4	pmol/L	8	15	13	11	9
TSH	mIU/L	30.06	20.86	9.66	17.91	26.25

His fT3 levels remained stable throughout the entire duration. His trough fT4 of 8 and peak fT4 of 15 were adequate and appropriate. He remained free of symptoms of hyperthyroidism and hypothyroidism and reported no side effects from the intramuscular levothyroxine regime.
Conclusion
This case demonstrates that in hypothyroid patients with impaired enteral delivery of LT4, once-weekly intramuscular injection of LT4 can safely and effectively provide stable serum fT4 and fT3 levels.

Evaluation of thyroid nodule, volume and arterial stiffness in euthyroid individuals

Yasemin Aydoğan Ünsal[1], Mustafa Altay[2], Oktay Ünsal[3], Veysel Kaplanoğlu[4], Yavuz Çağır[5], Canan Yıldız[6], Esin Beyan[3] & Selma Uysal Ramadan[4]
[1]Keçiören Training and Research Hospital, Ankara, Turkey; [2]Kecioren Training and Research Hospital, Department of Endocrinology, Ankara, Turkey; [3]Kecioren Training and Research Hospital, Department of Internal Medicine, Ankara, Turkey; [4]Keçiören Training and Research Hospital, Department of Radiology, Ankara, Turkey; [5]Halil Şıvgın Çubuk State Hospital, Ankara, Turkey; [6]Didim State Hospital, Aydın, Turkey.

Aim
Overt/subclinic hypothyroidism and hyperthyroidism are known to be associated with cardiovascular risks. There have been no studies evaluating the relationship

between nodule presence and arterial stiffness in individuals with euthyroid nodular goitre. Our aim in this study is to demonstrate whether nodule presence and nodule stiffness affect arterial stiffness in individuals with euthyroid nodular goitre by using pulse wave analysis (PWA).
Materials and methods
In our study, 50 patients with eutyhroid nodular goitre and 50 healthy volunteers were included. All participants were evaluated by B-mod thyroid ultrasonography (USG) and the individuals in the nodular goiter group were also performed strain elastography (SE) by one experienced radiologist. Strain indices of nodules classified according to Rago scoring system were calculated. As well as waist and hip circumference, insulin, fasting plasma glucose (FPG), lipid parameters, free T3(sT3), free T4(sT4), TSH, anti-thyroglobulin antibody (anti-TG) and anti-thyroid peroxidase antibodies (TPO) levels were measured. The levels of insulin resistance calculated by homeostasis model assessment-IR(HOMA-IR) were evaluated. Evaluation of arterial stiffness was performed with the Mobile-O-Graph 24h PWA device.
Results
When comparing two groups with respect to data of PWA, pulse wave velocity was found to be statistically significantly higher in the group with nodular goitre ($P<0{,}001$). Other data of PWA were similar among the groups. There was no difference in HOMA-IR and insulin levels between the two groups. FPG levels were higher in the group with nodular goitre ($P=0{,}03$). There was no correlation between HOMA-IR and thyroid volume, nodule volume, nodule number ($P>0{,}05$). Also, correlation was not seen between HOMA-IR and strain index and data of PWA.
Conclusion
Detection of high levels of pulse wave velocity and fasting plasma glucose in patients with nodular goitre suggests that individuals with euthyroid nodular goitre should be followed closely for cardiovascular and metabolic risks.

Iron deficiency, a risk factor for thyroid dysfunction and autoimmunity in the second trimester of pregnancy in China

Yanan zhang & Bingbing Zha
Department of Endocrinology, Fifth People's Hospital of Shanghai Fudan University, Shanghai, China.

Ferritin is a universal intracellular protein that acts as an iron carrier. Several studies have indicated that iron deficiency affects thyroid function in non-pregnant women. Our objective was to assess the relationship between serum ferritin levels and thyroid function along with thyroid autoimmunity in pregnant women during the second trimester. 1592 pregnant women were recruited from the obstetric outpatient department during the second trimester. Serum ferritin (SF) levels, thyroid function, TPOAb and TGAb were determined by electrochemiluminescence immunoassay. Age, BMI and pregnant week were recorded. Iron deficiency (ID) was defined as ferritin <12 μg/L, and subclinical hypothyroidism (SCH) when TSH was >4 mIU/L. The percentage of ID and SCH were 11.87%, 9.17% respectively. Serum FT4 levels were significantly lower in the ID group as compared with the non-ID group [13.82(8.91–25.04) vs 14.60 (8.22–47.24) mIU/L; $P=0.000$],TSH levels were similar in the ID and non-ID group [1.78(0.01-7.13) vs 1.71 (0.01–10.2) pmol/L; $P=0.520$] and The prevalence of abnormal elevated TPOAb and/or TGAb, and SCH were comparable between both groups. SF levels were negatively correlated with serum TSH levels ($r=-0.112$, $P=0.000$), and positively correlated with FT4 levels ($r=0.201$, $P=0.000$). Linear regression analysis showed SF, age, week of gestation were significant predictors of regression with TSH as the dependent variable (β: -0.002, -0.026, and 0.061 respectively; all $P<0.05$), or with FT4 as the dependent variable (β: 0.005, -0.054, and -0.24 respectively; all $P<0.05$). Interestingly, in the logistic regression model, ID remained associated with abnormal elevated TGAb after correction for confounding factors [OR = 2.84, 95%CI (1.385, 5.825), $P=0.004$], but not correlated with abnormal elevated TPOAb. Therefore, maternal ID was a determinant of higher serum TSH, lower FT4 levels, and abnormal elevated TGAb in pregnant women during the second trimester.

A rare case of amyloid goiter with concomitant papillary thyroid microcarcinoma in a patient with HIV

Rujuta Katkar, Thinzar Lin & Antoine Makdissi
University at Buffalo, Buffalo, USA.

Introduction
Amyloid goiter (AG) may be associated with either primary amyloidosis (deposit of amyloid protein AL) or secondary amyloidosis (deposit of amyloid protein AL) in chronic inflammatory diseases including tuberculosis, cystic fibrosis, ulcerative colitis, ankylosing spondylitis and familial Mediterranean fever. To our knowledge, this is the first case of AG concomitant with PTC in a patient with HIV infection.
Case presentation
67-year-old male immigrant from Somalia with past medical history of HIV with CD4 count of 427/ml complained of painful progressive enlargement of neck mass for three months with dysphagia, dyspnea on exertion associated with weight loss and generalized weakness. A diffuse non-tender asymmetrically enlarged goiter was palpated with no cervical lymphadenopathy. Ultrasonography revealed diffusely echogenic heterogeneous significantly enlarged thyroid gland without discrete cystic or definable mass. Right lobe measured $96\times38\times58$mm, left lobe $76\times38\times42$mm, and Isthmus 20mm. Free T4: 0.93 ng/dl (0.80–1.80ng/dl), TSH: 0.067 munit/ml(0.40–5.00), TSI:151%(0–139). CT showed asymmetric enlargement of the right thyroid lobe and isthmus with deviation of the trachea and esophagus without retrosternal extension or significant cervical lymphadenopathy. FNA showed deposition of AA Amyloid localized in thyroid gland with positive Congo red staining. Surgical pathology revealed the same in addition to a small focus of 0.3 cm PTC. Further evaluation confirmed that patient's amyloidosis is localized only to thyroid without systemic involvement.
Discussion
Endocrinopathy is well recognized in relation to HIV infection itself or as a side effect from HAART. However, the association of HIV infection with AG is not well established. The patient presented in this case has AG localized amyloid deposition in thyroid gland without systemic amyloidosis and no clear chronic inflammatory condition other than HIV infection. Another unique feature is the presence of PTC as apposed to what has been described of AG being mostly associated with medullary carcinoma. There is no specific treatment for AA amyloidosis but treating primary underlying condition can halt the progression. Due to compressive symptoms, surgery was offered in this case.
Conclusion
AG should be included as differential diagnosis of rapid enlargement of thyroid gland in HIV patients.

Background
Numerous animal models have shown impressive beneficial metabolic effects of the putative thyroid hormone (TH)-derivative 3,5-diiodothyronine (3,5-T2),

including the prevention of insulin resistance or the reversal of hepatic steatosis, in the absence of thyrotoxic side effects. In contrast, the endogenous fate of 3,5-T2 in humans is still unclear. Comprehensive molecular profiling holds promise to gain deeper insights in metabolic alterations associated with serum 3,5-T2.
Methods
Among 856 participants of the Study of Health in Pomerania (SHIP-TREND) serum 3,5-T2 concentrations determined by chemiluminescence immunoassay were available. Metabolomics data were obtained using mass spectrometry and nuclear magnetic resonance spectroscopy, comprising 613 and 578 metabolites in plasma and urine, respectively. Linear regression analyses with either continuous or categorized 3,5-T2 concentrations were used to detect significant associations. Controlling for age, sex, waist circumference, thyrotropin and free thyroxine allowed assignment of thyroid function independent effects. Results were replicated in an experimental model of thyrotoxicosis comprising 16 male volunteers.
Results
Serum 3,5-T2 concentrations were not associated with thyroid function parameters nor altered during experimental thyrotoxicosis. The molecular fingerprint of 3,5-T2 comprised 15 and 73 significantly associated metabolites in plasma and urine, respectively. Metabolites related to coffee metabolism, including caffeine or paraxanthine, represented the most obvious molecular signature. This association was replicated under experimental thyrotoxic conditions.
Conclusion
The TH-independent molecular fingerprint of serum 3,5-T2 concentrations showed a clear and strong interference with coffee metabolism and points to the liver as potential target organ in the focus of local 3,5-T2 generation/action. Translating the beneficial effects seen in animal models, 3,5-T2 might provide a link between (high) coffee consumption and the decreased risk of metabolic diseases.

The benefits of the thyroid disease screening program in pregnant women in Slovakia

Matej Bielik[1], B Ja[2], Vladimíra Kmečová[3] & Marián Faktor[3]
[1]KAMEAT, Endocrinology Outpatient Department, Nové Mesto nad Váhom, Slovakia; [2]Faculty of HealthCare, Trencin University, Trenčín, Slovakia; [3]Health Insurance Company Dôvera, Bratislava, Slovakia.

Objectives
Screening of thyropathies in Slovakia began in 2009 on the basis of the expert guideline of the Ministry of Health of the Slovak Republic for the diagnosis and treatment of autoimmune thyroid diseases in women during pregnancy (Public Health Ministry 39, 2009, No. 33–39)
Methods
The records of pregnant women insured by the health insurance company Dôvera, who had their first documented gynecological visit due to pregnancy in 2011, while they had no records of an endocrinology visit in 2010. Women had blood taken for TSH and aTPO at the gynecologist and were subsequently examined by an endocrinologist, were involved in the study. An individual group that was monitored by an endocrinologist under diagnoses E.00 to E.07 by the end of 2013.
Results
Overall, 13,876 pregnant women insured by the health insurance company Dôvera, a.s. (27.50 market share) who have undergone the first examination in 2010 with confirmed pregnancy, were registered. Of this group 294 (2.19%) had a record of repeated endocrinology visit with dg. E.00 to E.07. 5,143 (37.06%) of 13,876 women women had blood taken for TSH (aTPO could not be identified), and 275 (5.35%) had at least two endocrinological examinations by the end of 2013. In 2011 207 (75.50%) women were prescribed at least 1 pack of thyroxin, in 2012 151 women (55.11%) and in 2012 195 women (70.80%). Of the thyreostatic drugs - thiamazole a prescription was documented only in two cases (0.70%) in 2013.The total cost for 2011-2013 was € 114,915. The cost of one case of the screening of trapped thrombotic pathology was € 399.50, the cost of one case of treated hypothyroidism was € 638.70. The cost for 1 case of hyperthyroidism was € 57,457.5.
Conclusions
The screening of thyroid pathology, evaluated in the 2 years of the MZ SR expert's guide, show its low feasibility by gynecologist in the population of pregnant women - 37.06%. The prevalence of documented thyreopathies in pregnant women was found to be 2.19%, while the prevalence of newly diagnosed thyreopathies was 5.35%. The overall prevalence of thyropathy in the 30–35 year-old women category can be estimated at about 7.54%. From newly diagnosed thyreopathies was in the first year after the detection of thyreophaty therapy needed in 70%–76%. An identical study for the years 2016–2017 is planned to assess the state of the screening program after 5 years.

Level of awareness in hypothyroid patients

Nilgün Şeşen Öncül & Mine Adaş
University of Health Sciences, Okmeydanı Education and Research Hospital, Istanbul, Turkey.

Aims
Hypothyroidism is a common disease and important in terms of community health. To increase the awareness of patients is an important issue in the healthcare process. In this study, it was aimed to determine the level of awareness and the factors affecting the awareness in the patients with hypothyroidism.
Methods
A questionnaire was conducted to patients diagnosed with hypothyroidism who were applied to the Okmeydanı Education and Research Hospital internal medicine and endocrinology outpatient clinics, aged over 18 years, diagnosed at least three months ago, had no thyroid malignancy and weren't pregnant. The relationship between awareness level and follow-up/treatment parameters and sociodemographic characteristics is examined.
Results
A total of 258 patients were included in the study, 221 (85.7%) female and 37 male (14.3%). The mean age was 53 ± 14.3 years and the TSH mean level was 5.8 mIU/l. The majority of the participants were primary school graduates, low-income and have disease duration over 5 years. There was no statistically significant difference between the number of total correct answer and follow-up frequency, family history of thyroid disease, marital status and smoking status ($P > 0.05$). There was a statistically significant difference between the level of awareness and age, sex, education level **and** income level ($P < 0.05$). The younger age group with higher education and income levels answered more questions correctly, a higher level of awareness was found in female patients. 54.7% of patients answered more than half of the questions incorrectly. While 70.5% of the participants knew the definition of hypothyroidism, only 42.6% had information about iodine deficiency. The rate of those who knew that thyroid replacement should not be stopped during pregnancy was 27.5% and who knew that thyroid hormones affected fetal intelligence development was 21.7%. Patients considered that levothyroxine should be used in the morning (84.1%) and on an empty stomach (88.4%), while they thought that it could be used in combination iron products (72.1%) and proton pump inhibitors (64.7%).
Conclusions
As a result of our study, it was concluded that there is not enough level of awareness about the diseases in hypothyroid patients. In order to increase the level of awareness, it has come to the conclusion that there should be a period of time for informing during the outpatient visits and this process should be supported by other methods like web pages, brochures, patient education programs, media programs.

Predictive value of HLA variants for Graves' disease recurrence – pilot study in Czech patients

Daniela Vejrazkova, Josef Vcelak, Eliska Vaclavikova, Marketa Vankova, Petra Lukasova & Bela Bendlova
Institute of Endocrinology, Prague, Czech Republic.

Introduction
Graves' disease (GD) is the most common cause of hyperthyroidism. The first-choice therapy is administration of thyreostatic drugs. However, approximately half of patients relapse within two years of discontinuation. It is then necessary to decide whether to re-initiate thyreostatic treatment, which may have serious side effects, or to choose a radical approach (TTE, radioiodine). Familial forms of GD indicate that the disease has a significant genetic component. The autoimmune nature of GD refers to the human leukocyte antigen complex (HLA). Within HLA, some variants of DRB1, DQA1 and DQB1 genes appear to be possible predictors of GD development and recurrence. The aim of our work was to introduce a reliable methodology for testing the HLA background of GD. Assessment of its predictive potential on the disease recurrence in long-term follow-up would make it easier for physicians and patients to choose an optimal therapeutic approach.
Methods
In 50 patients treated in the Institute of Endocrinology with GD, the sequencing was chosen as the most reliable haplotyping method. In the three HLA candidate genes (DRB1, DQA1 and DQB1), exon 2 was amplified as the part of the HLA molecule determining its antigenic properties. Amplification of DNA sequences required the group-specific S2, S3 and S4 kits (PentaGen, Protrans - Germany). NGS was performed on MiSDefault (Illumina).
Results
Concerning the patients with recurrence ($n=24$), the predisposing allelic groups were equally distributed ranging from no risk allele to four risk alleles. Unfortunately, patients who have not yet relapsed and whose remission lasts for more than 2 years are represented by only two individuals, one carrying no risk allele and the other carrying one risk allele. Fisher's exact test identified allelic group DQA1*05 to be close to statistical significance in terms of the ability to predict the recurrence ($P=0.06$). The remaining patients in the current cohort ($n=24$) can not yet be included in the statistical analysis as they are still being treated or their remission period has not yet reached two years of duration.
Conclusion
We reliably classified the HLA DRB1, DQA1 and DQB1 allelic groups in first 50 patients with GD. Low number of patients in long-term remission does not yet allow to quantify the allele-associated risk of the disease relapse. However, the DQA1*05 appears to be the most promising recurrence predictor.

Usefulness of ultrasound evaluation of thyroid nodules in predicting malignancy

Elena Atienza, Daniela Stefania Trifu, Clara Tasende, Pablo Escribano, Pilar Saavedra, Jose Antonio Rubio & Concepcion Blanco
Hospital Principe De Asturias, Alcala De Henares, Spain.

Introduction
Ultrasound (US) thyroid examination is the most common method to assess thyroid nodules risk of malignancy and select nodules for fine-needle aspiration biopsy (FNAB). Thyroid US evaluation performed by endocrinologists has recently increased in Spain.
Objectives
To evaluate the predictive value of US features of malignancy in differentiating benign and malignant thyroid lesions in a Thyroid Nodule Clinic.
Patients and methods
Retrospective analysis of 296 patients referred to an Endocrinology Department for US thyroid nodule evaluation, between October 2016 and October 2017. US features assessed in each nodule were: size, hypoechogenicity (HE), shape taller than wide (T > W), irregular margins (IM), intranodular vascularity (IV) and microcalcification (MC). A total of 337 nodules were selected for FNAB and were classified based on the Bethesda system. Thirty-three cases with Bethesda categories different from benign without histological diagnosis, were excluded for accuracy study. The sensivity (Se), specifity, negative (NPV) and positive (PPV) predictive value and accuracy of US features were evaluated.
Results
A total of 296 patients (250 women), median age 55 years old were included. TSH median was 1.6 mcUI/ml, 31% with positive thyroid antibodies. The median nodule size was 1.8 cm. In 119 nodules (35%) there were no sonographic malignancy features. In these cases, the US assessment of malignancy had a NPV of 99%. In 218 nodules (65%) there was one or more US malignancy feature: HE (42%), T > W (5.6%), IM (15.7%), IV (22%) and MC (12%).A Hypoechogenicity had the highest Se (56%) but its PPV was low (7%). Microcalcification had the highest PPV (19.4%) for malignancy diagnosis with a Se 37.5%.
Conclusion
Nodules with at least one US malignancy feature, specially microcalcification, should undergo FNAB. In nodules without any US malignancy feature, histological malignancy diagnosis is highly improbable.

Ultrasound in stages of surgical treatment of patients with thyroid diseases

Sergey Pamputis, Artem Dyakiv & Yuri Aleksandrov
Yaroslavl State Medical University (YSMU), Yaroslavl, Russian Federation.

The results of Surgeon-Performed Ultrasound before and after operations have evaluated at the 207 patients with pathology of the thyroid gland. Comparative assessment made between ultrasound at out-patient phase and Surgeon-Performed by ultrasound. Ultrasound at the outpatient stage in the screening mode does not provide a sufficient level of diagnostics. Causes of errors at this stage are a short time of the inspection, insufficient expertise, wrong interpretation of the image ignorance of the standards of diagnosis, lack of the resolution of the instrument, the subjectivity of assessment, depending on the qualification and integrity of the doctor. It is established that regardless of the nature of thyroid diseases carried out by the preoperative Surgeon-Performed Ultrasound has better results in comparison with the outpatient stage: fewer differences with the real picture when assessing the volume of the organ, the size, number and localization of nodules. Accounting surgeon features of the structure and location of the thyroid gland gives him the opportunity of planning the operation with minimal trauma to the patient. Conducted Surgeon-Performed Ultrasound of the organs of the neck in addition to the standard Protocol included inspection of the larynx. Ultrasonography of the larynx (for her vizualisation) before operation allowed to take into account the preconditions for the development of complications and to identify already existing pathological changes. Surgeon-performed ultrasound examination in the early postoperative period can visually assess the dynamics of wound process, to identify complications of the soft tissues and eliminate them. Ultrasound allows to objectively assess the condition of the abandoned tissue of the thyroid gland in organ-saving operations. Surgeon-Performed Ultrasound of the larynx in the postoperative period allows the high percentage of reliability to detect in the early stages of paresis of the larynx.

Active surveillance of indeterminate thyroid nodules beyond cytological diagnosis, ultrasound evaluation and molecular analysis

Graziana Santamorena[1], Stefano Gay[1], Miranda Mittica[1], Eleonora Monti[1], Barbara Massa[2] & Massimo Giusti[1,3]
[1]Endocrine Unit, Policlinico Hospital San Martino, Genoa, Italy; [2]Cyto-histopathological Unit. Policlinico Hospital San Martino, Genoa, Italy; [3]For the Thyroid Team at the Policlinico Hospital San Martino, Genoa, Italy.

Most thyroid nodules are benign after fine needle aspiration biopsy (FNAB). Nevertheless approximately 10–25% of nodules are classified in indeterminate classes. Literature reports different risks of malignancy in Thy 3 – Thy 4 nodules. In our center malignancy was observed in 26% of Thy 3a nodules and 14% of the Thy 3f nodules (Giusti *et al.* 2017) while it was >75% in Thy 4 nodules. Strategies for nodules stratification according to risk are now needed to reduce thyroidal surgery. The aim of the study was to report results of active surveillance in Thy 3 nodules in which thyroidectomy was refused or delayed. Sixty-five nodules (patients) with indeterminate thyroid cytology at the 1st FNAB ($n=33$ Thy 3a, $n=12$ Thy 3f, $n=10$ Thy 3) underwent active surveillance. Active surveillance includes: calcitonin and thyroid blood tests, neck ultrasonography (US), elastosonography (USE), contrast enhanced US (CEUS), BRAF mutation analysis and a 2nd FNAB. BRAF analysis was negative in all nodules and all

patients showed normal hormonal levels. At present the active surveillance period is of 48 months. Eight of the 65 nodules receded from surveillance for thyroid surgery ($n=1$: 1 NIFPT; 1 follicular adenoma), severe cardiac failure ($n=1$), change of geographical area ($n=1$) or retire of consensus ($n=4$). Twelve patients (18%) did not perform/refused 2nd FNAB. The 2nd FNAB showed down classification to Thy 2, stable Thy 3 category and subcategories, and non-diagnostic information in 64%, 29% and 7%, respectively. US score doesn't show significant changes from the baseline ($n=65$; 1.95 ± 1.08) compared to the last examination ($n=38$; 1.87 ± 1.07). In average, nodules were not significant in maximal diameter from the baseline (25 ± 12 mm) compared to the last examination (23 ± 13 mm) even if in 16% of nodules there was a change ($>20\%$) in size [increase (10%), decrease (6%)]. All the nodules with an increase in size were Thy 2 at the 2nd FNAB evaluation. USE and CEUS did not add further information after inclusion of patients under active surveillance. In conclusion our prospective study suggest that active surveillance can be proposed to patients with indeterminate cytology when no BRAF mutation is found from FNAB. The down classification to Thy 2 class is a frequent phenomenon when further information and material are collected for the pathologist. Simple changes in diameter of the nodule do not suggest surgical decision. However more data need to be collected.

A case of subacute thyroiditis associated with adalimumab

Serife Mehlika Kuskonmaz[1], Gonul Koc[1], Tahsin Ozenmis[1], Muhammed Mustafa Ince[2], Mehmet Kirnap[3] & Cavit Culha[1]
[1]Ankara Education and Research Hospital Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Education and Research Hospital Department of Internal Medicine, Ankara, Turkey; [3]Erciyes University Faculty of Medicine Department of Physical Therapy and Rehabilitation, Ankara, Turkey.

Subacute thyroiditis is a painful disease of the thyroid gland characterized with granulomatous inflammation. Adalimumab is a human monoclonal anti TNF antibody used in the treatment of several autoimmune diseases. Here we report a case of subacute thyroiditis associated with adalimumab treatment for ankylosing spondylitis. A 42 year old female patient was admitted to the hospital for fever, chills and neck pain radiating to the right ear. She was diagnosed with ankylosing spondylitis 9 years ago and was on adalimumab treatment (40 mg every 15 days) for the last 7 years. On physical examination her body temperature was 38.2 °C. Thyroid was diffusely enlarged and tender to palpation. Laboratory evaluation of the patient is summarized in table 1. A thyroid scintigraphy showed a diffusely supressed gland. Ultrasonography of the thyroid revealed diffuse enlargement of the gland with interspersed hypoechoic areas (figures A and B). The patient was diagnosed with subacute thyroditis. Serum Ig M for CMV and EBV were negative. Adalimumab treatment was stopped and prednisolone 32 mg/day was started. Four weeks later, she consulted again with relapse of fever and neck pain due to noncompliance with the steroid treatment. She was hospitalized and 48 mg/day prednisolone was given. Her neck pain subsided and her fever responded dramatically to steroid treatment. She was discharged on steroid treatment. When the patient came for a control at 6 weeks her thyroid function tests were normal and CRP decreased to 5.6 mg/dl. Adalimumab is a biologic agent used in the treatment of autoimmune diseases. To date three cases of subacute thyroiditis are reported with adalimumab. Subacute thyroiditis is histopathologically characterized with granuloma formation. TNF-α plays an important role in regulation of T cell function and granuloma formation. Adalimumab is implied in the paradoxical development of pulmonary sarcoidosis and granulomatous skin reactions.The precise mechanism underlying the association between adalimumab and the onset of subacute thyroiditis remains unclear.

Table 1 Laboratory values of the patient at diagnosis.

C reactive protein	132 mg/dl
ESR	56 mm/h
WBC/PMNL	15,700/mm^3/83.4%
TSH	0.09 mIU/l
Free T3	3.78 ng/l
Free T4	1.72 ng/dl
Anti TPO	9.0 IU/ml
Anti TG	18.14 IU/ml
Thyroglobulin	500 ng/ml

Correlation of recommended diagnostic tools with pathological findings in the thyrotoxic patient

Carolina M Perdomo, José Joaquin Paricio, María Llavero, Javier Gargallo, Marta García, Raquel Miralles, María I Morales, Juan Alcalde, Miguel Ángel Idoate, Javier Arbizu & Juan C Galofré
Clínica Universidad de Navarra, Pamplona, Spain.

Aim
A key diagnostic step to determine the cause of hyperthyroidism is the measurement of circulating thyroid-stimulating immunoglobulin (TSI). High levels are associated with Graves' disease (GD). A thyroid scintigraphy (TRS) is recommended when TSI is absent or its measurement unavailable, as TRS is capable of differentiating between GD (diffuse uptake) and toxic goitre (TG) (patchy uptake). Nevertheless, and while rarely necessary, histopathology remain the best method for obtaining an accurate aetiology. Our purpose was to compare TSI vs. TRS sensitivity and specificity in the differential diagnosis of thyrotoxicosis.
Methods
We retrospectively studied 235 outpatients with hyperthyroidism (overt or subclinical) admitted in our Centre from 2006 to 2016 from whom TSI and TRS were performed at the time of diagnosis. Subsequently, we selected a sample of thyroidectomised patients in whom a histological specimen was available. A pathologist reviewed the samples. SPSS 23.0 was used for statistical analysis. Pearson's correlation was used to quantify the relationship between the diagnostic tests.
Results
A total of 45 patients met the inclusion criteria. We divided the sample according to the histopathology diagnosis of GD: Group A: 14 patients (31.1%) consistent with GD; Group B: 31 patients (68.9%) without features of GD. In Group A, one patient (7.1%) had negative TSI and two patients (14.3%) did not have a TRS with a high diffuse uptake. In Group B, 10 patients (32.2%) had positive TSI and 6 patients (19.3%) had a TRS with a high diffuse uptake. In comparison with histopathology, the TRS yield offered better diagnostic precision than TSI in both accuracy (82.2% vs. 75.5%) and specificity (80.6% vs. 67.7%) although inferior sensitivity (85.7% vs. 92.8%). The Positive Predictive Value (PPV) for TSI was 56.5% and the Negative Predictive Value (NPV) was 95.45%, whereas the PPV for TRS was 66.7% and the NPV was 83.3%. Pearson's correlation between TSI and histology was 0.561 ($P<0{,}001$) versus 0.556 ($P<0.001$) between TRS and histology.
Conclusions
TRS has higher accuracy and specificity when compared to TSI in the differential diagnosis of thyrotoxicosis. These results suggest that the differential diagnosis of thyrotoxicosis cannot rely initially or solely on TSI, as this approach may result in misdiagnosis. Our results lend support to the value of both TRS and TSI as the first step in differential diagnosis, owing to the fact that TRS may detect 7.1% of mild GD with negative TSI and TSI alone may leave 32.3% of patients misdiagnosed.

Dependency between vitamin D3 and serum titers of the thyroid autoantibodies in smoking cigarettes patients with Graves' disease - one year follow-up - preliminary study

Maria Teresa Płazińska[1], Agata Czarnywojtek[2,3], Małgorzata Zgorzalewicz-Stachowiak[4], Nadia Sawicka-Gutaj[2], Barbara Czarnocka[5], Kosma Woliński[2], Adam Maciejewski[2], Hanna Komarowska[2], Maria Maria Karlińska[6], Marek Ruchała[2] & Leszek Królicki[1]
[1]Nuclear Medicine Department, Medical University of Warsaw, Warsaw, Poland; [2]Chair and Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland; [3]Department of Pharmacology, Poznan University of Medical Sciences, Poznan, Poland; [4]Laboratory of Medical Electrodiagnostics, Department of Health Prophylaxis, University of Medical Sciences in Poznan, Poznan, Poland; [5]Department of Biochemistry and Molecular Biology, Centre of Postgraduate Medical Education, Warsaw, Poland; [6]Department of Medical Informatics and Telemedicine, Medical University of Warsaw, Warsaw, Poland.

Purpose
The aim of this study was to evaluate the association between the serum vitamin D level and changes in the titers of the anti-TSH receptor (TSHR), antithyroglobulin (Tg), and antiperoxidase (TPO) autoantibodies (Abs) in smoking cigarette Graves' disease (GD) patients, with and without the vitamin D supplementation.

Methods
The study was performed from January 2015 to December 2016. It consisted of 136 patients. The intensity of nicotinism was assessed based on the Fagerström Test for Nicotine Dependence. Serum vitamin D level and the titers of TSHR-Abs, TPO-Abs, and Tg-Abs were analyzed retrospectively. Studied parameters were analyzed at entry and 1, 6 and 12 months following baseline.
Results
The titers of TSHR-Abs were significantly higher at baseline in GD patients treated with vitamin D3 {D3(+)} than in patients not receiving vitamin D3 {D3(−)} (8.9 vs 0.7 IU/ml, $P<0.001$); at the remaining time points, no statistically significant differences were noted. Among the GD D3(−) patients, the titers of TSHR-Abs were statistically significantly lower at baseline (Me: 0.7 IU/ml) than for each subsequent time of point (Me: 7.8, 6.6, 6.2 IU/ml; $P<0.05$). In the group of GD D3(+) patients, the titers of TSHR-Abs at baseline were comparable to the level after 1 (Me: 8.9 vs 18.5 IU/ml, $P=$NS) and 12 months (Me: 6.1 IU/ml, $P=$NS) of follow-up. There was a significant difference between 1 and 6 (Me: 18.5 vs 11.8 IU/ml, $P<0.001$), 6 and 12 months (Me: 11.8 vs 6.1, $P<0.001$) of observation. The titers of TPO-Abs at baseline in the GD D3(+) patients were significantly higher than in GD D3(−) patients (290 vs 38 IU/ml, $P<0.001$). At all subsequent time points, we noticed no significant difference. In the GD D3(+) patients, the titers of Tg-Abs at baseline were significantly higher than in GD D3(-) patients (97 vs 24 IU/mL, $P=0.002$). At all subsequent time points, there were statistically significantly smaller differences after one month (243 vs 92 IU/ml, $P=0.03$), and after 6 (220 vs 104 IU/ml, $P=0.009$), and 12 months (200 vs 52 IU/ml, $P=0.001$) of the follow-up.
Conclusion
In almost all cases, we observed that vitamin D does not have a strong association with the titers of thyroid autantibodies. Nicotine does not allow the reduction of the titers of TSHR-Abs in GD patients supplemented with vitamin D3.

Visual evoked potentials in the diagnosis of orbitopathy during the course of Graves' disease

Maria Teresa Płazińska[1], Małgorzata Zgorzalewicz-Stachowiak[2], Agata Czarnywojtek[3,4], Krzesisława Komar-Rychlicka[5], Krystyna Zeńczak-Praga[2], Nadia Sawicka-Gutaj[3], Barbara Czarnocka[6], Kosma Woliński[3] & Marek Ruchała[3]
[1]Nuclear Medicine Department, Medical University of Warsaw, Warsaw, Poland; [2]Laboratory of Medical Electrodiagnostics, Department of Health Prophylaxis, University of Medical Sciences, Poznan, Poland; [3]Chair and Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland; [4]Department of Pharmacology, Poznan University of Medical Sciences, Poznan, Poland; [5]Department of Ophthalmology, Poznan University of Medical Sciences, Poznan, Poland; [6]Department of Biochemistry and Molecular Biology, Centre of Postgraduate Medical Education, Warsaw, Poland.

Graves' disease (GD) is an autoimmunological disorder leading most often to hyperthyroidism and invasive-edema ophthalmopathy (Graves ophthalmopathy – GO).
Aim
Estimation of visual evoked potentials (VEP) results with the indicators of activity and advancement of the progress of GO.
Materials and methods
The examined group consisted of 100 patients between the ages of 31 and 77, hospitalized in the Department of Endocrinology and Metabolism. The duration of GD from the first clinical signs to the start of treatment was between 3 months to 20 years. Changes in the eye due to GO occurred from 3 months to 6 years. VEPs were carried out according to the recommendations of the International Federation of Clinical Neurophysiology. Latencies and amplitudes of VEP components were compared to normal values in a group of 30 healthy person without an autoimmunological thyroid disorder.
Results
According to the NOSPECS scale, 9 patients showed no visual symptoms. In 17 cases, class 1 or 2 was diagnosed. Furthermore, in 74 patients classes between 3 and 6 were observed. A possible loss of vision due to the visual nerve damage (class 6) was found only in 4 patients. The CAS criteria in 8 patients were equal to 0, and in the remaining 14 patients from 1 to 3. Active GO was diagnosed in 47 patients. In 74 patients, abnormal VEPs were recorded. Normal parameters of VEP were observed only in 26 patients. These were patients with inactive or mild processes involving eye balls. Changes in the latency of P100 increased from 125 ms in mild to 127 ms in intermediate and 129 ms in intense GO. Referring to the control group, a statistical change was observed in the latency of P100 and N145. It was prolonged already in the mild occurrence of GO which confirmed subclinical visual nerve involvement.
Conclusions
VEP can be helpful in the diagnosing of visual nerve neuropathy in patients with GD. The clinical interpretation of changes of P100 and N145 latency is very important in patients with GO.

Thyroid ultrasound alterations occurrence in patients with previous negative examination: A 6-years observational follow-up trial

Maria Laura Monzani[1,2], Giulia Brigante[1,2], Michela Locaso[1,2], Daniele Santi[1,2], Luigi Graziadei[1], Valentina Luisa Gnarini[1], Manuela Simoni[1,2] & Bruno Madeo[2]
[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Unit of Endocrinology, Department of Medicine, Endocrinology, Metabolism and Geriatrics, Azienda Ospedaliero-Universitaria di Modena, Modena, Italy.

Background
Thyroid nodules represent a common clinical finding and their prevalence is increasing worldwide. However, the most recent international guidelines do not give indications on the need to retest adults with previous negative neck ultrasound (US).
Aim
To evaluate the incidence of thyroid US abnormalities in patients with previous negative thyroid US and identify patient's characteristics able to predict the risk of developing thyroid disease.
Methods
In 2011, 291 subjects were enrolled in a prospective clinical trial conducted in the Endocrine Unit of Modena to detect the prevalence of thyroid disease in adults unaware of thyroid pathology. Among these, 136 patients did not shown any US thyroid alteration. Up to now, 99 of these patients (61 females and 38 males, mean age 51 ± 12 years) were prospectively examined with thyroid US after six years with the same US device. Each patient was further clinically evaluated, updating anamnesis, physical examination and anthropometric measurements.
Results
During a mean interval between the first and the second US evaluation of 72.4 ± 6 months, 51 subjects (51.5%) developed thyroid US alterations, specifically 46 (46.5%) subjects developed thyroid nodules and 5 (5%) a US pattern of thyroiditis. According to the American Thyroid Association nodular sonographic pattern classification, among patients with nodular pathology we have found 26 subjects (56.5%) with at least one benign or very low-suspicion nodule, 9 (19.5%) with at least one low-suspicion nodule and 11 (24%) with at least one intermediate or high suspicion nodule. The incidence of US thyroid alterations is not significantly different among subjects with (49%) or without (51%) family history positive for thyroid disease ($P=0.366$). Moreover, thyroid abnormalities occurrence was not predicted by smoking habit ($P=0.615$), age ($P=0.826$), weight ($P=0.960$), BMI ($P=0.546$) and thyroid volume ($P=0.114$). These results were confirmed considering males and females separately.
Conclusions
These preliminary data show that more than 50% of patients have developed US abnormalities in a mean period of 6 years. Interestingly, among patients with thyroid nodular pathology, 24% of subjects have developed at least one intermediate or high suspicion sonographic thyroid nodule. This result justifies the need to retest patients, even when no US alterations have been detected during first examination. Currently, we are not able to predict thyroid alterations occurrence, since positive family history for thyroid disease, smoking habit, age, weight, BMI and thyroid volume seem to be not related to the incidence of US abnormalities.

Evaluation of 32 patients with subacute thyroiditis

Guven Baris Cansu & Bengur Taskiran
Yunus Emre State Hospital, Eskisehir, Turkey.

Aim
Thyrotoxicosis is a clinical status related to increased thyroid hormones. It is caused by either hyperfunctioning thyroid tissue or destruction of thyroid. Subacute thyroiditis, also known as De Quervain or granulomatous thyroiditis, is an acute inflammatory disease of thyroid causing thyrotoxicosis. Clinical and laboratory features vary according to the course of disease. In this study, we

aimed to study clinical and laboratory features of the patients who were referred from internal medicine outpatient clinics to endocrinology department due to thyrotoxicosis.
Methods
We retrospectively evaluated electronic data of 32 patients who were followed-up by endocrinologists due to subacute thyroiditis in 2013–2018. Thyroid function tests, presence of antibodies, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), onset of disease, achievement of euthyroidism, department of initial admission, and thyroid scintigraphy results where available.
Results
Twenty six (81.2%) patients were female. Twelve patients (37.5%) first attended to ear-nose-throat department, 8 (25%) to family medicine practitioner, 6 (18.8%) to internal medicine specialist, and 6 (18%) to general surgery departments due to complaints. Eight (25%) were attended to the outpatient clinics in spring, 7 (21.9%) in summer, 12 (37.5%) fall, and 5 (15.6%) in winter. Mean age was 42.9 ± 9.1 (33–69). Four patients' sera (12.5%) were positive for anti thyroglobulin antibody. Mean TSH level was 0.015 ± 0.024 μIU/ml (0.35–4.94), free T4 level 2.17 ± 0.77 ng/dl (0.7–1.48), free T3 level 5.74 ± 2.53 ng/dl (1.71–3.71), ESR 73.3 ± 17.3 mm/h (0–20), and CRP 55.5 ± 37.3 mg/l (0–8). Nineteen patients had scintigraphy. All yielded suppressed uptake in thyroid bed. Two (6.3%) patients developed permanent hypothyroidisim. Mean time lapse till achieving euthyroidism was 3.8 ± 2.9 months in 29 patients.
Discussion
Subacute thyroiditis must be kept in mind in differential diagnosis of thyrotoxicosis for correct diagnosis ve management.

Cryoablation of goiter irrespective of thyroid profile

Mohamed Hamed, Sherif Mansour, Mohamed Halawa, Ahmed Bahaaeldin, Nesma Ibrahim & Ashraf Ghoneim
Ain Shams University, Cairo, Egypt.

Introduction
Thyroid nodules are extremely common. By age 60, about one-half of all people have a thyroid nodule. Cryoablation is used in a variety of clinical applications, using hollow needles (cryoprobes). Cryoprobes are inserted into or placed adjacent to diseased tissue which is desired to be ablated.
Objectives
To evaluate the effect of Cryoablation on the size & function of thyroid nodule, which may replace the need for surgery or radiotherapy.
Patients and methods
This is an interventional therapeutic study, conducted in Ain-Shams University hospitals; endocrinology clinic. Our study sample included 80 subjects, age between 20 & 60, having thyroid nodule diagnosed by ultrasound. Subjects were divided into 2 groups: Group 1 included 40 subjects 'control group' who were not subjected to cryoablation. Group 2 included 40 subjects 'cases' upon which cryoablation was done. Neck ultrasound were done for subjects & they were sampled for their TSH, free T4 & free T3 levels at start and after 3 & 6 months.
Results
There was high statistical significant difference between group 1 & group 2 regarding nodule size, after 6 months. Group 1 showed median nodule size after 6 months (0.85 cm) (IQR: 0.7–1.05)while cases showed (0.6 cm) (IQR: 0.3–0.9) (*P*-value 0.001). Females are more liable than males, to show nodule size reduction.
Conclusions
Cryoablation causes nodule size reduction, especially after 2nd session. Cryoablation does not affect thyroid function tests, all through our study.

Keywords: Cryotherapy, Thyroid nodule, Size reduction, TSH variation.

Prevalence and clinico-epidemiology of hypothyroidism in Indian patients with type-2 diabetes mellitus and hypertension

Talwalkar PG[1], Vaishali Deshmukh[2], Milind Bhole[3] & Rashmi Hegde[3]
[1]Talwalkar's Diabetes Clinic, Mumbai, India; [2]Deshmukh Clinic and Research Centre, Pune, India; [3]Abbott India Ltd, Mumbai, India.

Introduction
Among the most common chronic non-communicable diseases in India, Type-2 Diabetes mellitus (T2DM) and hypertension (HT) are increasingly becoming a matter of public health importance. Hypothyroidism is also believed to be a common health issue in India, with one out of 10 people in the country diagnosed with the condition. Hence the objective of this cross-sectional, clinico-epidemiological, Pan-India study was to evaluate the prevalence of hypothyroidism in patients with T2DM or HT or both T2DM and HT and to understand the management practices in Indian real-world setting.
Methods
Adults (≥18 years) with a diagnosis of T2DM or HT or both (established or newly diagnosed), visiting physician for routine check-up, were enrolled in this study. Overt hypothyroidism was defined as TSH >4.50 μIU/ml (FT4: <0.8 ng/dl; FT3: <1.4 pg/ml); subclinical hypothyroidism (SCH) as TSH >4.50 μIU/ml (FT4: 0.8–1.8 ng/dl; FT3: 1.4–4.4 pg/ml). Descriptive statistics was used for statistical analysis.
Results
A total of 1501 (99.5%) patients completed the study (T2DM:500 [99.2%]; HT:499 [99.6%]; both T2DM and HT: 502 [99.8%]). Mean (±S.D.) age of the population was 52.9 ± 12.49 years. In patients with known case of hypothyroidism, 86 (17.1%), 111 (22.2%), and 87 (17.3%) patients had history of T2DM, HT and both T2DM and HT, respectively. In patients with T2DM, the newly diagnosed cases of hypothyroidism were 38 (7.6%; SCH: 5.2%) versus 86 (17.2%) previously diagnosed cases. In patients with HT, newly diagnosed cases of hypothyroidism were 58 (11.6%; SCH: 8.2%) versus 109 (21.8%) old cases. Among patients with T2DM and HT, the newly diagnosed cases of hypothyroidism were 58 (11.6%; SCH: 6.4%) versus 87 (17.3%) previously diagnosed cases. Overall prevalence of hypothyroidism in T2DM ($n = 1002$) and HT ($n = 1001$) was 26.85% and 31.17% respectively. In T2DM patients with newly diagnosed SCH, 16 (61.5%) patients were prescribed with thyroxine. In HT patients with newly diagnosed SCH, 25 (61.0%) patients were prescribed with thyroxine. In patients with T2DM and HT, newly diagnosed with SCH, 20 (62.5%) patients were prescribed with thyroxine. Most commonly prescribed dose of thyroxine was 25 μg for SCH in all cohorts.
Conclusion
We conclude that screening for thyroid disease among patients with T2DM and HT should be routinely performed considering the prevalence of newly diagnosed cases in the study. This study thus emphasizes on the extent of overlap between these diseases and highlights the need for early diagnosis for effective management/better outcome.

Pos-thyroidectomy hypoparathyroidism: The role and timing of calcium determination

Gloria Baena-Nieto, Rosa Márquez-Pardo, Mercedes Díaz-Oteros & Lourdes García-García-Doncel
Jerez Hospital, Cádiz, Spain.

Introduction
Postoperative hypocalcemia is among the most frequent morbidities after total thyroidectomy. Although most postoperative hypocalcemia is temporary, it causes prolonged hospitalization and a decrease in quality of life. For all this, early diagnosis is essential to start treatment as soon as possible. In this study, we determined whether early serum calcium levels can predict the development hipoparathyroidism.
Methods
A total of 122 patients underwent total thyroidectomy with or without neck dissection between 2016 and 2017 were reviewed. Total calcium levels were evaluated at 6 h, 1 day an 1 month postoperatively. Serial serum calcium measurements were recorded as well as details of the operation, pathology, demographic and clinical data. To assess the value of the most appropriate test for the diagnosis of hypoparathyroidism, the sensitivity and specificity of calcium at 6 and at 24 h was studied and the area under the receiver operating characteristic (ROC) curve (AUC) was used to measure the relative predictability of these variables or criteria.
Results
63.9% patients did not develop hypocalcaemia but 29.5% were found to have temporary hypocalcaemia and 6.6% had permanent hypocalcaemia. No differences were observed for sex, age, neck dissection types and pathology between normocalcemic and hypocalcemic patients. The average calcium was 8.4 mg/dl at 6 h and 8.05 at 1 day postoperatively ($P < 0.05$). For the diagnosis of transient hypocalcemia, AUC from 6 and 24 h calcium levels was 0.724 and 0.963 respectively ($P < 0.001$). The threshold of 7.75 mg/dl was obtained by means of the ROC curve analysis, with 98% of sensitivity and 66% specifity from 6 h calcium, and 8 mg/dl with 89% of sensitivity and 68% specifity from 1 day postquirurgical calcium. However for the diagnosis of permanent hypocalcemia, AUC from 6 and 24 h calcium levels was 0.797 and 0.691 respectively

($P<0.001$) and the calculated threshold of 7.45 mg/dl (94% sensitivity and 75% especifity) from 6 h calcium and 6.95 mg/dl (93% sensitivity and 87% specificity) from 1 day postquirurgical calcium.
Conclusion
Post-thyroidectomy hypocalcemia is a common complication of total thyroidectomy. Our results suggest that the calcium levels on day 1 postoperatively are useful in predicting the development of hypocalcemia and the hypoparathyroidism diagnosis.

Adaptation and cross-cultural validation of the Spanish version of the Thyroid-Related Quality-of-Life Patient-Reported Outcome (ThyPRO) questionnaire

Ana María González Lleó[1], Mauro Boronat Cortés[1], Ulla Feldt-Rasmussen[2], Carlos Rodríguez Pérez[1], Åse Krogh Rasmussen[2], Yaiza López Plasencia[1], Laszlo Hegedüs[3], María del Pino Alberiche Ruano[1], Steen Joop Bonnema[3], Dunia Marrero Arencibia[1], Mogens Groenvold[4], Jakob Bue Bjorner[4] & Torquil Watt[2,5]
[1]Department of Endocrinology and Nutrition, Hospital Universitario Insular de Gran Canaria, Las Palmas de Gran Canaria, Spain; [2]Department of Medical Endocrinology, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark; [3]Department of Endocrinology and Metabolism, Odense University Hospital, Odense, Denmark; [4]Department of Public Health, University of Copenhagen, Copenhagen, Denmark; [5]Department of Internal Medicine Herlev Gentofte, Copenhagen, Denmark.

Introduction
The thyroid-related quality-of-life patient-reported outcome ThyPRO questionnaire is the most widely used tool for measuring health-related quality of life (QoL) in patients with benign thyroid diseases. The aim of this study was to adapt and validate a Spanish version of the ThyPRO.
Methods
The ThyPRO consists of 85 items, grouped in 13 scales and one single QoL item. Scales cover physical and mental symptoms, well-being and function, social and daily function, cosmetic concerns and overall QoL-impact. ThyPRO39 is a short version of the ThyPRO consisting of 39 items grouped in 11 scales and one single item. The Spanish version of the ThyPRO was developed using the forward-backwards translation: 1) forward translation from English to Spanish by two independent native Spanish translators; 2) reconciliation of both versions in a preliminary consensus-translated draft; 3) back-translation by an English native translator not familiar with the original version of the questionnaire; 4) comparison and discussion of the back-translated version and the master English questionnaire; 5) preparation of a new draft translation containing appropriate changes; 6) second back-translation by a different English native translator; 7) discussion of the second back-translation and approval of the final Spanish draft. The translation was pretested on five representative individuals with different thyroid diseases, by cognitive interviewing. The definitive questionnaire (ThyPROes) was completed by 155 patients with benign thyroid diseases attending the Endocrinology Department in a single hospital in Spain. Equivalence between the Spanish version and original (Danish) questionnaire was assessed using tests for differential item functioning (DIF) by means of ordinal logistic regression, controlling for specific diagnosis. The independent variables were language group and scale score, and an interaction term scale score*language group. Non-uniform DIF was considered when the interaction term was significant. DIF magnitude was considered substantial if it could explain more than 2% of the variance in the item score (R^2 difference >0.02).
Results
Eight items were flagged with DIF in the ThyProes (one with non-uniform DIF) and two items in the ThyPro39es. Eight scales of ThyPROes and nine scales of ThyPRO39es were free of DIF. The magnitude of DIF was small in most of cases (explained variance in the item score $<3\%$ in seven items of ThyProes and in one of ThyPro39es), with probably minor impact in scales scores.
Conclusion
The presented Spanish versions of the ThyPRO and the ThyPRO39 show a good cross-lingual validity and are suitable for use in clinical studies.

Antithyroid drugs can be associated with increased frequency of antibodies against type 2 5'-deiodinase enzyme influencing their therapeutical effectiveness in hyperthyroid Graves' ophthalmopathy

Ildikó Molnár[1], József A Szentmiklósi[2], Rudolf Gesztelyi[2] & Éva Somogyiné-Vári[1]
[1]Immunoendocrinology and Osteoporosis Centre, EndoMed, Debrecen, Hungary; [2]Department of Pharmacology and Pharmacotherapy, University of Debrecen, Debrecen, Hungary.

Antithyroid drugs represent mainly the first choice therapy in hyperthyroid Graves' disease. Their therapeutical ineffectiveness can lead to the onset or the severity of ophthalmopathy associated with Graves' disease. Type 2 5'-deiodinase enzyme (DIO2) plays a crucial role besides type 1 5'-deiodinase enzyme in the development of Graves' hyperthyroidism. Anti-thyroid drugs inhibit the activity of both type 5'-deiodinases blocking the synthesis of thyroid hormones and can induce antineutrophil cytoplasmic antibodies. In this study, the frequency of antibodies against type 2 5'-deiodinase and their effects on the inhibition of thyroid hormone synthesis were investigated during antithyroid drug therapy. Antibodies against DIO2 peptides (cys- and hom-peptides) were studied in 78 patients with Graves' disease (58 females and 20 males, mean age of 43 ± 14 years, 39 had ophthalmopathy) and 30 healthy controls (27 females and 3 males, mean age of 47 ± 16 years) using ELISA. The thyroid hormone and antibody serum levels were measured with chemiluminescence immuno-assay and ELISA. In hyperthyroid patients treated by propylthiouracil (PTU), a greater frequency of antibodies against DIO2 peptides was demonstrated compared with those treated by methi-ma-zole (MMI) (3/3 vs 5/23 cases, $P<0.002$ for cys-peptide and 2/3 vs 2/23 cases, $P<0.027$ for hom-peptide antibodies). The patients, who were treated with PTU and had cys-peptide anti-body positivity, demonstrated significantly increased TSH receptor antibody levels compared with those treated with MMI (26.4 ± 10.57 vs 6.96 ± 4.85 IU/l, $P<0.011$). In hyperthyroid Graves' ophthalmopathy, the patients were hom-peptide (0/12 vs 3/11, $P<0.05$) and cys-peptide (0/12 vs 5/12, $P<0.012$) antibody negative after MMI therapy in comparison with patients without ophthalmopathy. In hyperthyroid Graves' ophthalmopathy, the occurrence of hom-peptide antibodies was associated with elevated FT_4 (3.08 ± 0.86 vs 2.02 ± 0.49 ng/dl, $P<0.013$) and FT_3 (10.44 ± 6.02 vs 5.36 ± 1.42 pg/ml, $P<0.003$) serum levels compared with those who were antibody negative. In summary, an increased presence of antibodies againts DIO2 peptides could be demonstrated after PTU therapy in hyperthyroid Graves' disease. None of hyperthyroid cases with ophthalmopathy had antibodies against DIO2 peptides after MMI therapy. The presence of DIO2 peptide antibodies was associated with a prolonged hyper-thyroidism and increased TSH receptor antibody levels declining the therapeutical effective-ness of antithyroid drugs.

The thyroid gland in acromegaly

Roxana Dumitriu, Eugenia Petrova, Andra Buruiana & Adina Ghemigian
National Institute of Endocrinology 'C. I. Parhon', Bucharest, Romania.

Objective
Acromegaly is frequently associated with thyroid diseases. In this study we evaluated the incidence, morphology of the thyroid and the influence of surgery, iradiation and medical therapy used in acromegaly on thyroid function.
Methods
We evaluated 20 patients diagnosed with acromegaly using thyroid ultrasonography and measurement of IGF1, GH, TSH, free T4. 65% of the patients had active disease and were under medical therapy.
Results
35% of the patients had multinodular goitre assesed by thyroid ultrasonography, one patient was diagnosed with papillary thyroid carcinoma and another with medullary thyroid carcinoma. 20% had autoimmune chronic thyroiditis with hypothyroidism. We did not find a relation between the duration of the disease and nodular goitre. After one year of treatment with ocreotide or lanreotide there was a reduction in the thyroid volume ($P=0.05$). The majority of patients (30%) had indication for surgical treatment based on the ultrasonographic characteristics of the goitre.
Conclusions
Goitre is a common finding in acromegaly. In our study, diffuse goitre appeared in the early course of the disease. Nodul formation, enlargement of the thyroid gland may occur independent of TSH. Long-term stimulation by GH can be responsable for the thyroid enlargement.

Metabolic profile in patients with subclinical hypothyroidism

Mirjana Stojkovic[1,2], Slavica Savic[1], Jasmina Ciric[1,2], Biljana Nedeljkovic-Beleslin[1,2], Milos Stojanovic[1,2] & Milos Zarkovic[1,2]
[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia; [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Background
Thyroid function regulates a wide array of metabolic parameters and significantly affects lipoprotein metabolism. Subclinical hypothyroidism (SCH) is the most common thyroid disorder, with a prevalence up to 10% in adult populations. Subclinical hypothyroidism is defined as mild elevation in thyroid stimulating hormones (TSH) in presence of normal free thyroxine (fT4) and free triiodothyronine (fT3). This mild elevation of serum TSH is caused by a minor initial decrease in thyroidal secretion of thyroxine (T4) which activates piruitary-thyroid axis. The reason for maintaining T4 values within the reference range is the exquisite sensitivity of the pituitary thyrotroph for even very small decreases of serum T4.
Objectives
The aim of this study was to compare metabolic profile in patients with SCH and healthy controls.
Methods
The study group consisted of 75 patients with SCH (group 1, TSH 4.6–24.49 mIU/L) and 47 healthy controls (group 2, TSH 0.4–4.2 mIU/L) who were matched by age and weight. We compared glucose, HbA1c, HOMA index, cholesterol, HDL, LDL and trigyceride levels between groups. The data were analyzed by Welch Two Sample *T*-test with 95 percent confidence interval.
Results
There were no statisticaly significant difference in glucose levels, as well as in HbA1c and HOMA index between groups (glucose 5.249 vs 5.198 mmol/l; $P=0.725$; HbA1c: 5.55% vs 5.42%; $P=0.126$; HOMA 2.51 vs 2.48; $P=0.959$). Also, there were no statisticaly significant difference in cholesterol levels, HDL, LDL and trigyceride levels between groups (cholesterol 5.527 vs 5.563 mmol/l; $P=0.872$; HDL 1.522 vs 1.579 mmol/l; $P=0.411$; LDL 3.407 vs 3.414 mmol/l; $P=0.968$; Tg 1.317 vs 1.194 mmol/l; $P=0.34$).
Conclusions
These data suggest that activation of pituitary-thyroid axis and increase of TSH levels does not affect metabolic profile in patients with subclinical hypothyroidism.

The efficacy of intrathyroid injected steroids for painful lymphocytic thyroiditis

Miguel Paja[1] & Jose L Del Cura[1,2]
[1]Basurto University Hospital, Bilbao, Spain; [2]Basque Country University, Bilbao, Spain.

Thyroidal pain is usually due to subacute thyroiditis. It seldom occurs in patients with Hashimoto's thyroiditis (HT), and then its name is painful HT (PHT). Differently from subacute thyroiditis, occasional PHT patients show no benefit from medical treatment so that thyroidectomy is frequently needed. We report two women diagnosed of PTH and successfully treated with intrathyroidal corticosteroid injection after initial unsuccessful treatment with L-thyroxine replacement and oral corticosteroids.
Case 1
A 36-year-old woman presented in January 2015 with a 9-month history of episodic pain on the anterior neck and otalgia. Physical examination showed diffusely enlargement of both thyroid lobes with a firm consistency and marked tenderness in right lobe. Thyroid function tests revealed subclinical autoimmune hypothyroidism (TSH 6.57; FT4 12.0 pmol/l, AcTPO > 600 UI/l). Thyroid ultrasound (US) revealed a diffusely enlarged thyroid gland with heterogeneously hypoechoic pattern involving the entire area of both lobes. She received a short course of prednisone without relief, and substitutive thyroxine was started, with initial improvement and greater interval between episodes. Two years later, euthyroid (TSH: 1.23) pain flared-up, and intrathyroid corticosteroid injection was proposed. US-guided injection of 40 mg of triamcinolone was performed in both lobes aimed to the areas of hypoechogenicity. After treatment, the patient experienced almost total relief of pain and tenderness, and thyroid became less consistent at palpation.
Case 2
A 47-year-old woman, consulted on December 2016 because of 6-month thyroidal pain. Before the pain appeared, she was taken levothyroxine for 8 years because autoimmune hypothyroidism, with normal TSH. Pain had been attributed to subacute thyroiditis, although she had normal sedimentation rate and lymphocytic infiltration on FNAC, and was treated with oral corticosteroids (up to 45 mg of prednisone) and NSAIDs without success. Thyroid ultrasonography revealed marked hypoechogenity and high vascularization on Doppler exam. Intrathyroidal corticosteroids were proposed. US-guided injection of 40 mg of triamcinolone throughout the gland was performed. After first injection, pain was relieved, with residual tenderness. As she had residual discomfort that limited her to speak loudly, treatment was repeated at six and eleven months improving with every injection. After last injection the pain relief was complete.
Conclusion
US-guided intrathyroidal injection of corticosteroids can be an effective to treat painful HT. This technique can avoid surgery to treat this rare presentation of Hashimoto's thyroiditis.

The peripheral blood and thyroid compartment in patients with Graves' disease: helper and regulatory T-cells and decreased B-lymphocytes

Margarita Dudina[1,2], Andrey Savchenko[1,3], Sergey Dogadin[1,2], Alexandr Borisov[3] & Vladimir Man'kovsky[2]
[1]Krasnoyarsk State Medical University named after Prof. V.F. Voino-Yasenetsky, Krasnoyarsk, Russian Federation; [2]Krasnoyarsk State Regional Clinical Hospital, Krasnoyarsk, Russian Federation; [3]Federal Research Center 'Krasnoyarsk Science Center' of the Siberian Branch of the Russian Academy of Sciences, Scientific Research Institute of Medical Problems of the North, Krasnoyarsk, Russian Federation.

Graves' disease (GD) has been recognised for more than 100 years, its pathophysiological mechanisms are incompletely understood.
Aim
To investigate the helper- (Th-cells) and regulatory T-cells (Treg) influence on B-lymphocytes phenotypic composition of blood and thyroid tissue in GD.
Materials and methods
The study included 43 women with GD, mean age 39.95 ± 14.38, who were performed the epifascial thyroidectomy and 67 healthy women were examined as a control. The median of thyroid stimulating hormone, autoantibodies to TSH receptor, free thyroxine and triiodothyronine level was respectively 0.08 (0.01; 0.58 mIU/l, 10.25 (6.85; 24.68) IU/ml, 16.89 (11.39; 31.5) and 5.93 (4.6; 7.7) nmol/ml. Phenotypic composition of Th-cells, Treg and B-lymphocytes were measured by flow cytometry, using direct immunofluorescence, respectively, of whole peripheral blood and lymphocytes isolated from thyroid tissue.
Results
In patients with GD in peripheral blood increased the level of B1-cells. In thyroid tissue of GD patients we observed high level of memory B-cells, but decreasing the relative number of B1-cells, in contrast to its level in peripheral blood ($P<0.001$). In healthy control increasing the content of activated B-lymphocytes in the blood accompanied by a co-directional reaction from Treg, but in patients with GD such mechanism is disrupted. In peripheral blood of GD patients we revealed the positively interaction between the relative amount of B-lymphocytes with Treg and activated T-helper cells ($r=+0.39$, $P=0.009$), B2-cells and naïve B-lymphocytes with $CD3^+CD4^+CD25^+$- ($r=+0.49$, $P<0.001$ and $r=+0.42$, $P=0.003$, respectively) and $CD3^+CD4^+CD127^{Low}CD25^{High}$-cells ($r=+0.49$, $P<0.001$ and $r=0.37$, $P=0.012$, respectively). In thyroid tissue of GD patients the relative number of $CD3^+CD4^+$-cells interact with the level of $CD19^+CD5^+CD23^+$-lymphocytes ($r=+0.79$, $P=0.036$) and the percentage number of $CD3^+CD4^+CD25^+$-cells with $CD19^+CD23^+$- ($r=+0.85$,$P=0.014$), $CD19^+CD5^-CD23^+$- ($r=0.80$,$P=0.034$), $CD19^+CD5^+CD23^+$- ($r=+0.93$, $P=0.025$) and $CD19^+CD27^+CD23^+$-lymphocytes ($r=+0.82$, $P=0.023$).
Conclusion
It is assumed that in patients with GD and thyrotoxicosis decreased not only the content of Treg in peripheral blood, but also a violation of their functional activity. In patients with GD the ac ivated B lymphocytes and Treg does not involve in correlation system, respectively, in peripheral blood and thyroid tissue.

Influence on remission rates of hyperthyroid periods during anti-thyroid drug therapy of Graves' disease: retrospective study of $N=301$ patients

Natalie Wojciechowski[1], Harald Brix-Samoylenko[2] & Wolfgang Raber[1]
[1]Department of Medicine IIII, Division Endocrinology and Metabolism, Medical University of Vienna, Vienna, Austria; [2]Verein Grüner Kreis, Vienna, Austria.

Introduction and aims
Thionamide may have immunosuppressive mechanisms. However, data suggest restoration of the immunological regulation as patients return to the euthyroid state may better explain remission, How successfully patients are kept euthyroid during a course of antithyroid drug therapy for Graves' hyperthyroidism, and whether not continuously maintaining normal thyroid function is associated with a worse prognosis, is not known.
Aims
1) assessment of duration of euthyroid, subclinical and overt hyperthyroid periods during thionamide therapy of newly diagnosed Graves' disease, 2) thyroid function with shorter (2–4 weeks) compared to longer (5–6 and >7 weeks, respectively) intervals between out-patient visits, and 3) whether periods of hyperthyroidism are associated with lower remission rates.
Methods
Retrospective anaylsis of $N=301$ patients treated with thionamides for ≥ 10 months at a single thyroid out-patient unit from 2010 to 2015, patients in remission ($N=156$) compared to those with relapsing hyperthyroidism ($N=145$) – median follow-up after stopping thionamides 20 and 14 months, respectively. Multivariant regression analysis including length of different thyriod functions, scheduled intervals between visits, and other factors such as age, TRAb, degree of hyperthyroidism at first diagnosis, time to normalization of fT4 after initiation of antityhroid drug therapy, or smoking status to define independent predictors of remission.
Results
Median treatment duration (15.0 vs. 15.6 months) was comparable ($P=$n.s.). Relapsing patients displayed longer ($P<0.0001$ and $p<0.05$, respectively) periods of overt (11 ± 3.5 vs. 2.6 ± 3.3 weeks) and subclinical (10.4 ± 2.3 vs. 8.3 ± 4.2 weeks) hyperthyroidism, and shorter ($P<0.0001$) periods with normal thyroid function (33.9 ± 12.4 vs. 46.8 ± 12.1 weeks). Scheduled intervals differed widely within patients (2 to >7 weeks), were not different between groups, and did not influence thyroid function. Normal thyroid function at $>50\%$ of all visits was observed more frequently (92.3 vs. 64.1%) and at $\leq 5\%$ and 6–20% of all visits less ($P<0.0001$, respectively) frequently (0% and 0% vs 3.4 and 4.8%, respectivley) in remitting patients than in those who relapsed. Overt hyperthyroid and euthyroid periods were independent (opposing) predictors of remission, respectively, as were age, TSHR-Ab, fT4 at first visit, and time to first normalization of thyroid function.
Conclusion
Continuously maintaining normal thyroid function during antithyroid drug therapy may be associated with increased remission, whereas overt hyperthyroid periods with higher relapse rates. Intervals between visits >7 weeks were not associated with unfavourable outcome and identified, on an individual patient's basis, more often with patients in remission.

The accuracy of diagnostic tests in amiodarone-induced thyrotoxicosis; a case-series

Martin Cuesta[1], Cristina González Ruiz[2], Inés Jiménez Varas[1], Luis Lapeña[2], Tomás Ganado[3], Salomé Merino[3], Alejandro Santiago[4], Lourdes Recio[4], Alfonso Luis Calle Pascual[1] & Isabelle Runkle de la Vega[1]
[1]Servicio Endocrinología y Nutrición Hospital Clínico San Carlos, Madrid, Spain; [2]Servicio Medicina Nuclear Hospital Clínico San Carlos, Madrid, Spain; [3]Servicio de Radiología Hospital Clínico San Carlos, Madrid, Spain; [4]Servicio Farmacia Hospitalaria Hospital Clínico San Carlos, Madrid, Spain.

Introduction
Amiodarone-induced thyrotoxicosis (AIT) can present a high morbi-mortality.Initial subtype identification facilitates appropriate management.We describe the utility of diagnostic tests in a cohort of patients with AIT.
Material and methods
Retrospective, observational study of 59 patients attended from 2007 to 2018 in outpatient clinic. Differential diagnosis: type I if FT4 and FT3 (TH) were normalized following therapy with antithyroid drugs (ATD)-methimazole alone or with potassium-perchlorate (*KClO4*); Type 2 if TH were reduced following oral prednisone (Pred) initiation and/or there was a hypothyroid phase following Pred discontinuation without prior AT; Mixed-AIT if patients needed both types of therapy to control TH. Most patients were initially treated with methimazole 30 mg daily unless diagnostic tests (thyroid scintigraphy and Doppler ultrasound) suggested type-2 AIT, where Pred was initiated. KClO4 (1 g/day 6–8 weeks) was associated when other medication was insufficient. Student's t test, χ^2 or non-parametric tests.
Results
Males 36 (61%). Mean age: 70 (SD12). Mixed-AIT: 44 (74%) patients, type 1-AIT: 9 (14%), five with prior subclinical hyperthyroidism. Type 2: 6 (10%) patients. Interleukin-6 levels elevated in 50%, 40% and 58% patients in type 1, type 2 and mixed AIT respectively ($P=0.7$ among groups). Thyroglobulin and/or thyroid-peroxidise antibodies raised in 11% with type 1, 16% with type 2, and 8% with mixed-AIT ($P=0.5$).Tc-99m-pertechnetate-thyroid scan: no uptake in 39/40(97%). Technetium-99m–sestamibi (Tc-MIBI) thyroid scintigraphy: uptake in 1/3 (33%) type-2 patients, 5/5 (100%) type-1 patients ($P=0.035$) and 23/27(85%) mixed-AIT patients ($P=0.3$) showed patchy, diffuse or localized uptake. Colour-Doppler ultrasound: absent vascularity in 2/5 (40%) type-2 patients, 1/7 (14%) type-1 patients, and 23/40 (57%) mixed-AIT patients ($P=0.35$). Initial FT3/FT4 ratio was higher in type I;median 0.2 (IQR:0.18–0.33) compared to type II, 0.14 (IQR:0.13–0.15) ($P<0.0001$) and to mixed-AIT:0.16 (IQR:0.12–0.19) ($P=0.007$). Optimal FT3/FT4 cut-off in *ROC-curve* to define those who required ATD (type I or mixed-AIT) vs. those only requiring Pred (type II-AIT) was 0.14;sensitivity: 0.65, specificity: 0.6. 17/53 (32%) patients with type I or mixed-AIT required *KClO4* to control TH,15/17 (88%) normalising TH with no severe adverse events. In 7/59 thyroidectomy was performed. One patient died from post-operative sepsis.
Conclusions
Diagnostic tests were of limited value for initial AIT classification, showing significant overlap. Initial FT3/FT4 ratio could potentially be useful for differential diagnosis. Response-to-therapy indicated mixed AIT was the most frequent form. KClO4 association was safe and effective in Type I and mixed forms.

Arterial stiffness in hyperthyroid patients is deteriorated due to thyroid hormones

Canan Yıldız[1], Mustafa Altay[2], Sedat Yıldız[3], Yavuz Çağır[4], Tolga Akkan[5], Yasemin Aydoğan Ünsal[6] & Esin Beyan[6]
[1]Didim State Hospital, Aydın, Turkey; [2]Universities of Health Sciences Keçiören Practice and Research Center, Clinic of Endocrinology, Ankara, Turkey; [3]Söke Fehime Faik Kocagöz State Hospital, Aydın, Turkey; [4]Çubuk Halil Şıvgın State Hospital, Ankara, Turkey; [5]Van Çaldıran State Hospital, Van, Turkey; [6]Universities of Health Sciences Keçiören Practice and Research Center, Clinic of İnternal Medicine, Ankara, Turkey-.

Aim
It is aimed to evaluate whether arterial stiffness, which is an independent risk indicator for hyperthyroid cardiovascular diseases, is affected by pulse wave analysis (PWA) and to observe changes in patients treated with hyperthyroidism.
Methods
A total of 102 volunteers were included in the study (30 in the overt hyperthyroid group, 28 in the subclinical hyperthyroid group and 14 with euthyroidism by antithyroid therapy and 30 healthy). The arterial stiffness measurements of the subjects participating in the study were performed with the PWA device, which measures the sleeve-based oscillometric measurement of the brachial artery.
Results
Systolic blood pressure, pulse rate, central systolic blood pressure, cardiac output, augmentation index and PWV measurements were significantly higher in the hyperthyroid group than in the control group. The heart rate and PWV in the subclinical hyperthyroid group was significantly higher than the control group. In the euthyroid group, systolic blood pressure, central systolic blood pressure, cardiac output, cardiac index and PWV were found significantly higher than the control group. There was also a negative correlation between Aix@75 and TSH, and a positive correlation between Aix@75 and free thyroid hormones.
Conclusion
In our study, we observed that arterial stiffness was adversely affected by an overt or subclinical increase in thyroid hormones and this correlated with thyroid hormones. We recommend that PWV measurement, which is a simple method for detecting CVD risk, can be used in these patients.

Keywords: Arterial stiffness, augmentation index, hyperthyroidism, pulse wave analysis

Gestational and postpartum complications in women with chronic autoimmune thyroiditis receiving iodine and selenium therapy

Zsuzsanna Szanto[1], Attila Csiszer[2] & Zsuzsanna Croitorescu[3]
[1]Endocrinology Out-patient Unit, Tirgu Mures, Romania; [2]Regional Center of Public Health Tîrgu Mures, National Institute of Public Health, Tirgu Mures, Romania; [3]Central Laboratory of Mures County Clinical Hospital, Tirgu Mures, Romania.

Introduction
Iodine may aggravate maternal autoimmune thyroid diseases during and after pregnancy, but selenium could defend against it's harmful effect. Objective: to study the course and complications of Hashimoto's thyroiditis in pregnant and lactating women receiving iodine and selenium therapy. Material and method. Serum TSH, free-T4 and anti-thyroid peroxidase-antibody were measured in 30 women with chronic autoimmune thyroiditis in every gestational trimester, on the 6th-7th postpartum week and at 6–9 months after delivery. They received 100 mcg/day selenium and 100–200 μg/day iodine ± L-thyroxine during the studied period. The results were compared to those of 30 women without chronic autoimmune thyroiditis, receiving 100–200 μg/day iodine ± L-thyroxine during pregnancy and lactation.
Results
In the thyroiditis group nine women were known with thyroid disease before pregnancy, and hypothyroidism developed in other 20 cases during pregnancy (27 hypothyroidism and two isolated hypothyroxinaemia). Thyroid function has not normalized yet in any of these cases. One imminent abortion and one imminent preterm delivery were noticed. In the postpartum period two cases of postpartum thyrotoxicosis with autolimited course and two cases of severe hypothyroidism developed. In women without chronic autoimmune thyroiditis no gestational or postpartum complications, no postpartum thyrotoxicosis appeared. In the second group nine cases of isolated hypothyroxinaemia were recorded, their proportion being mildly higher, at the limit of significance compared to the thyroiditis group ($P = 0.04$). Conclusions. Hypothyroidism developed frequently among pregnant women with Hashimoto's thyroiditis receiving iodine with selenium, but gestational and postpartum complications were not observed significantly more frequently in these women compared to those without chronic autoimmune thyroiditis.

The effects of exenatide treatment on thyroid

Derya Köseoğlu[1], Özden Özdemir Başer[2] & Dilek Berker[2]
[1]Çorum Erol Olçok Education and Research Hospital, Department of Endocrinology and Metabolism, Çorum, Turkey; [2]Ankara Numune Education and Research Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey.

Glucagon-like peptide-1 (GLP-1) is an increatin hormon with various glucoregulatory effects, and exenatide is a GLP-1 receptor agonist used in the management of type 2 diabetes mellitus. C cell hypertrophy was seen in animals treated with GLP-1 receptor agonists, but the effects of GLP-1 agonists on C-cell proliferation or neoplasia in humans have not been documented formerly. The aim of this study was to evaluate the impact of exenatide on structural and functional features of the thyroid in patients with T2DM treated with exenatide. Fourty-eight patients with T2DM were included in the study. 5 μg exenatide was started to all patients twice daily.After 4 weeks the dose was increased to 10 μg twice daily.Four patients who had severe vomiting were excluded. Serum free triiodothyronine (T3), free thyroxine (T4), thyrotropin (TSH), anti-thyroid peroxidase (anti-TPO), anti-thyroglobulin (anti-Tg), carcino-embryonic antigen (CEA) and calcitonin were measured and thyroid ultrasonography was performed before the treatment was started and after 6th month. Fourty-one women and three men were included in the analysis with a mean age of 47.84 ± 7.37 years. The laboratory parameters and thyroid ultrasonographic features are summarized in the table. A significantly statistically decrease was achieved in TSH ($P < 0.001$) and thyroid volume (P:0.047). The statistical analysis was performed with 32 patients who were not using levothyroxine at the beginning, and TSH decrease was still statistically significant (P:0.022), whereas the reduction of the thyroid volume lost its significant difference (P:0.130). In conclusion, our study showed no difference in serum CEA and calcitonin level after 6 months of exenatide therapy, whereas a reduction in the thyroid volume was achieved for the first time in the literature .

Table 1 Demographic features and laboratory parameters at the beginning and after 6 months

	Before exenatide	6 months after exenatide	P
Weight	112.79 ± 14.73	102.98 ± 14.73	< 0.001
BMI	44.41 ± 6.63	40.18 ± 6.08	< 0.001

Evaluation of anti-thyroglobulin antibodies in pregnant women in Area IV of Asturias

Silvia González[1], Fernando García[1], Raúl Rodríguez[1], Alicia Martín[1], Lucía Díaz[2], Jessica Ares[1] & Edelmiro Menéndez[1]
[1]Hospital Universitario Central de Asturias, Oviedo, Spain; [2]Hospital Uniersitario de Cabueñes, Gijón, Spain.

Introduction
Hypothyroidism in pregnancy is a topic widely studied in recent years, especially in those women with positive autoimmunity. However, usually the only determination of antibodies that is made is the thyroid antiperoxidase antibodies (anti-TPO). In this study we wanted to know what incidence of anti-thyroglobulin antibodies (anti-Tg) our pregnant women present and what repercussion they can have on thyroid function.
Materials and methods
Anti-TPO and anti-Tg antibodies were analyzed in plasma of 147 consecutive women in her first trimester of pregnancy seen in the sanitary area of Oviedo in Asturias. Thyroid function was also evaluated, using the normal reference values for our area (TSH:0.2–4.5).
Results
Anti-TPO positive antibodies were detected in 14 (9.5%) of the 147 women and anti-Tg antibodies in 12 (8.2%) of them. In 87.07% of the patients none of the antibodies were detected, 4.76% had positive anti-TPO antibodies and negative anti-TG, and 3.40% presented positive anti-TG with negative anti-TPO. The thyroid function of these pregnant women according to their autoimmunity was as follow : In the case of patients with negative anti-TPO and positive anti-TG, 2 of 5 presented normal TSH, but in the range between 2.5 and 4.5, who would require treatment following 2017 ATA recommendations.
Conclusion
In our area, 12.92% of pregnant women have positive thyroid autoimmunity. Just 3.40% women presented only anti-Tg positive antibodies. Our patients with negative anti-TPO and positive anti-Tg antibodies had normal thyroid function, but 40% of them could require levothyroxine treatment. So we recommend the evaluation anti-Tg antibodies in those pregnant women who show negative anti-TPO antibodies.

First extracervical (remote-access) thyroid lobectomy for large specimen without a visible scar via a transoral vestibular and retroauricular approach (TOVARA)

Stefan Schopf[1], Elias Karakas[2], Günther Klein[3] & Hans Martin Schardey[1]
[1]Krankenhaus Agatharied, Hausham, Germany; [2]Hospital Maria Hilf, Alexianer GmbH, Krefeld, Germany; [3]Landeskrankenhaus Wiener Neustadt, Wiener Neustadt, Austria.

Background
Both Transoral (TOETVA) and several Retroauricular approaches (e.g. EndoCATS) are described as feasible and safe procedures in the literature. The TOETVA enables angulation of instruments and provides a good working space by dividing the strap muscles in the first step. Therefor one should be able to dissect even larger specimen than the short incision in the lip allows to remove. However EndoCATS is a single port access with limited working space, but with good potential to increase incision length along the hairline without leaving a visible scar to remove large specimen.
Methods
In December 2017 a patient with a 65 ml nodule in the right thyroid lobe asked for an endoscopic resection without a visible scar in the décolleté. She rejected ABBA because of the areolar incisions. As EndoCATS has a limited working space, we decided to improve our technique by a combination with TOVARA which provides a better angulation and an increased working space.
Results
The operation was performed as planned in January 2018, by first dissecting the specimen with TOVARA and removing it via EndoCATS on the ipsilateral side. The operation time was 165 min. There were no complications except of a mild hypocalcemia on the first postoperative day. A numbness of 5 cm in diameter at the chin vanished within 14 days. The patient had a VAS for pain of 2 at the first day and 1 for the next 3 days. RLN and EBSLN were proven intact by laryngoscopy. Wound healing was primarily and without infection. The patient was highly satisfied with the procedure.
Conclusions
This is the first report about a hybrid operation of the two endoscopic techniques TOVARA and EndoCATS. Only extracervical endoscopic thyroid surgery provides the benefit of an unscathed décolleté. It is the next step in endoscopic thyroid surgery to combine safe techniques to enlarge the number of possible indications.

Study of possible relation between thyroid volume, nodule formation and glucose metabolism disordersin egyptian population

Ahmed Bahaaeldin, Alyaa El-sherbeny, Manal Mohsen,
Emad Abd e-lmohsen & Mahmoud Nafie
Ain Shams University, Cairo, Egypt.

Insulin resistance (IR) with compensatory hyper-insulinemia are key factors involved in the pathogenesis of glucose metabolism disorders (including impaired fasting glucose and glucose tolerance and frank diabetes mellitus) as well as increased thyroid gland volume and nodule prev-alence in patients with metabolic syndrome. On the other hand, thyroid hormone contributes to the regulation of carbohydrates metabolism and pancreatic function. This cross-sectional study investigated the possible association between the different glucose metabolic disorders (GM) and thyroid gland volume. The study was conducted on 400 subjects over one year duration, divided into 50% diabetic patients in comparison to 25% pre-diabetics and 25% cross-matched control. All the subjects were investigated by fasting and postprandial blood sugar and fasting insulin level (for HOMA-IR calculation) as well as TSH assay combined with thyroid ultrasound. The results showed that thyroid volume was significantly larger in patients with diabetes com-pared to the control as well as significant positive correlation between thyroid volume and FBS, fasting insulin, HOMA-IR, 2-h pp BS and HbA1cin. Besides, there was significant association between serum TSH levels and thyroid volume. The main regulator of thyroid cell growth and differentiation is TSH. The elevated insulin levels due to IR lead to an increase in IGF-1 levels (which is an important hypertrophic and progression factor for a series of cell types including thy-roid cells with increased risk of malignancy in such patients).

Final diagnosis of thyroid nodules classified as Bethesda-4 after Fine-needle aspiration

Ana Barrera Martín[1], María Alcántara Laguna[2], Ángel Rebollo Román[2], María Rosa Alhambra Expósito[2], Paloma Moreno Moreno[2], Pedro Seguí Azpilcueta[3] & María Ángeles Gálvez Moreno[2]
[1]UGC Endocrinology and Nutrition, Hospital Reina Sofía, Córdoba, Spain; [2]UGC Endocrinology and Nutrition, Hospital Universitario Reina Sofía, Córdoba, Spain; [3]UCG Radiodiagnosis. Hospital Reina Sofía, Córdoba, Spain.

Introduction
Fine-needle aspiration (FNA) is indicated in suspicious thyroid nodules or big ones. Bethesda system classifies them according to the cytological malignancy risk. Bethesda category 4 (B4) comprises follicular neoplasms and suspicious follicular neoplasms. *Aim*: Determine final diagnosis of B4 nodules and study associations between malignancy and other variables.
Methods
Retrospective study of patients with nodules classified as B4 after FNA in our hospital between 2013 and 2017. Statistical analysis: SPSS v.19.0 (Student's *t* test to compare means and χ^2/Fisher's test for proportions).
Results
141 patients, 73.8% women, mean age: 53.33 ± 14.90. 76.6% evaluated by the Endocrinology service prior to the FNA (21.3% previous thyroid pathology; 87.2% normal function). Symptoms: 88.7% asymptomatic. 5.7% cervical pain, 3.5% dysphonia, 3.5% dysphagia. Nodule discovery: 49.6% accidentally discovered in imaging studies done for other reasons, 35.5% palpation, 8.5% symptoms related to the nodule and 6.4% in routine follow-up sonography (US). Sonography characteristics: maximum diameter: 30.93 ± 16.88 mm. 82.3% solid, 56.7% hypoechoic, 30.5% hypervascular, 9.2% coarse calcifications, 4.3% suspicious adenopathies and 1.4% microcalcifications (In the US 9.9% suspicious, 11.3% non-suspicious, 78.8% undetermined). 20.5% of them with previous FNA (1.4% B2, 7.8% B1, 11.2% B3). 84.4% patients underwent surgery (39.5% total thyroidectomy), 114.54 ± 84.97 days after FNA. Final diagnosis: 77.3% benign (73.9% adenoma, 15.2% noninvasive follicular thyroid neoplasm with papillary-like nuclear features [NIFTP], 10.9% nodular goiter) and 22.7% malignant (51.9% follicular carcinoma, 40.7% papillary carcinoma, 7.4% medullary carcinoma). Most prevalent diagnosis after surgery: 33.6% folicular adenoma, 21.8% Hürthle adenoma, 11.8% NIFTP. Incidental microcarcinoma in 12.6% of interventions. Association with malignancy: Cervical pain (1.8 vs 20%, $P = 0.010$), bigger maximum diameter (15.88 ± 1.72 vs 18.27 ± 3.23 mm, $P = 0.009$). Tendency to association with malignancy: microcalcifications (0 vs 7.1%, $P = 0.068$), hypoechogenicity (65.3 vs 89.5%, $P = 0.076$).
Conclusions
1) Incidentally discovered nodules equals clinically discovered ones.
2) Prevalence of malignancy in nodules classified as B4 is similar to the one reported in previous publications.
3) There is a statistically significative association between malignancy and clinical finding (cervical pain) and sonographic findings (bigger nodule size), as previously reported in the literature.

Thyroid autoantibodies and quality of life in patients with benign thyroid diseases

Gesthimani Mintziori, Stavroula Veneti, Athanasios Panagiotou, Thomas Georgiou & Marina Kita
Department of Endocrinology, Diabetes and Metabolism, Hippokration General Hospital of Thessaloniki, Thessaloniki, Greece.

Objective
Thyroid autoimmunity has been proposed as a risk factor for impaired health-related Quality of Life (HRQoL), depression and anxiety, though evidence is still limited. The aim of the current study is to assess the association of thyroid autoimmunity with quality of life in patients with benign thyroid disease.
Design
A cross-sectional study was implemented, that included consecutive patients with benign thyroid diseases who visited the outpatient clinics of the Department of Endocrinology, 'Hippokration' General Hospital, Thessaloniki, Greece, between September 2016 and June 2017. Patients were excluded if they had a thyroid cancer or if they were not able to communicate in Greek. The Greek, cross-cultural validated, version of ThyPRO questionnaire was used, as it comprises a reliable and validated instrument to measure thyroid-related quality of life. The 84 questions of ThyPRO are categorized in 13 scales that involve: goiter,

hypothyroidism, hyperthyroidism and eyes symptoms, tiredness, cognitive impairment, anxiety, depressivity, emotional susceptibility, cosmetic complaints and impaired social, daily and sex life. The scales were all scored and the final scores were transformed to a scale from 0 to 100. Lower scores reflect a better thyroid-related quality of life, whereas higher scores reflect a worse quality of life. Thyroid hormones were measured and thyroid autoimmunity was assessed in all patients while their thyroid disease history was also recorded. IBM SPSS was used for Statistical Analysis.
Results
Two hundred and three ($n=203$) consecutive patients (183 women and 20 men) with benign thyroid diseases were included in the study. Of them, 81 patients (39.9%) had Hashimoto thyroiditis. When compared with patients with benign thyroid diseases but no thyroid autoimmunity, patients with Hashimoto thyroiditis had surprisingly lower scores in the impaired sexual life scale ($26.6\pm3\%$ vs $34.8\pm3\%$ respectively, $P=0.05$) but no difference in all other scales.
Conclusions
The current study did not demonstrate significant differences between patients with Hashimoto thyroiditis and patients with other benign thyroid diseases in regard to patient-reported quality of life, questioning the role of thyroid antibodies per se, on the quality of life.

Iodine deficiency in pregnancy – is the situation in poland improving?

Malgorzata Trofimiuk-Muldner[1], Grzegorz Sokolowski[2], Joanna Konopka[3], Agnieszka Dubiel[2], Malgorzata Kiec-Klimczak[1], Lukasz Kluczynski[1], Marcin Motyka[2], Ewelina Rzepka[1], Agnieszka Stefanska[2], Joanna Walczyk[2], Malgorzata Wilusz[2], Andrzej Lewinski[4], Arkadiusz Zygmunt[4], Dorota Pach[1] & Alicja Hubalewska-Dydejczyk[1]
[1]Chair and Department of Endocrinology Jagiellonian University Medical College, Krakow, Poland; [2]Department of Endocrinology, University Hospital in Krakow, Krakow, Poland; [3]University Hospital in Krakow, Krakow, Poland; [4]Department of Endocrinology and Metabolic Diseases, the Polish Mother's Memorial Hospital- Research Institute, Lodz, Poland.

Iodine deficiency is considered the most common preventable cause of brain damage worldwide. It is particularly important during pregnancy, as it influences not only mothers but their fetuses as well. The Polish model of iodine prophylaxis is based on obligatory household salt iodization and recommendation of iodine-containing supplements for pregnant women. The aim of the study was to assess the current iodine status of pregnant women and to compare it with earlier results.
Material and methods
1208 pregnant women aged 16-46 years (median 29 years) were included. 911 of them (75.4%) were investigated between 2007 and 2011, remaining 297 (24.6%) were studied in 2017. Signed informed consent was obtained from every participating woman. The urinary iodine concentration (UIC) in casual morning sample was assessed by Sandell-Kolthoff reaction. Thyroid volume was measured by ultrasound. Iodine supplements intake was assessed by a questionnaire. The study protocol was approved by the Local Ethics Board.
Results
The studied population of pregnant women proved to be iodine insufficient: median UIC was 94.9 mcg/l (lower quartile – 61.85 mcg/l, upper quartile – 149.0 mcg/l). The UIC significantly increased between 2007-2011 and 2018 (median 92.47 mcg/l and 111.45 mcg/l, respectively; $P=008$), but still did not meet iodine sufficiency criterion (between 150 and 249 mcg/l). In only 17.4% of investigated women, UIC value was within the optimal range of 150 to 249 mcg/l: 17.3% between 2007 and 2011, and 17.5% in 2018. 62.2% of pregnant women were taking iodine supplements: 63.3% of women investigated between 2007 and 2011, and 58.6% in 2011 ($P=0.14$). The median thyroid volume in the investigated group was 11.8 mL (lower quartile 9.2 mL, upper quartile 15.0 mL). There was no significant difference in thyroid volume between two groups: 11.9 mL between 2007 and 2011, and 11.6 mL in 2017.
Conclusions
Although during last 5 years iodine status of Polish pregnant women has improved, it has not reached a sufficiency level. Therefore the current Polish iodine prophylaxis model should be adjusted to provide pregnant women with adequate iodine intake.

P1073

Serum thyroglobulin as a biomarker of iodine status in pregnant women

M. Dolores Ollero[1,2], Emma Anda[1,2], Marta Toni[2,3], Juan Pablo Martinez[3], Mercedes Espada[4] & J. Javier Pineda[1,2]
[1]Complejo Hospitalario de Navarra, Pamplona, Spain; [2]IdisNa, Pamplona, Spain; [3]Hospital Garcia Orcoyen, Estella, Spain; [4]Laboratory of Public Health, Vizcaya, Spain.

Serum thyroglobulin (Tg) is a biomarker used to assess iodine nutrition status, but data in pregnant women are scarce.
Objectives
To determine serum Tg concentration in Spanish healthy pregnant women, and to evaluate its relation with yoduria (UIC), thyroid volume, iodine intake and thyroid function throughout pregnancy.
Methods
Longitudinal study in pregnant women with no history of thyroid disease, recruited in 2 obstetric centers of Pamplona (Spain) at the first antenatal visit. We performed anamnesis, iodine intake questionnaire, thyroid ultrasound, and UIC in a single visit. Thyrotropin (TSH), free thyroxine (fT4), antiperoxidase and antithyroglobulin (anti-Tg) antibodies were determined in the three trimesters, and Tg in the first and third trimesters. We compared Tg concentrations in women according to the consumption of iodized salt, milk intake and pharmacological iodine supplements.
Results
We evaluated 100 pregnant women in the 10th gestational week, 92% Caucasian. To establish thyroglobulin values we excluded multiple pregnancies ($n=2$), women with positive anti-Tg antibodies ($n=14$) and/or nodular goiter ($n=2$), leaving a population of 82 women. The median Tg was 14.1 µg/l. Only 1 woman had Tg$>$ 40 µg/l (Tg 42.3 µg/l in the third trimester). Tg at 9th gestational week ($n=65$) was lower compared with Tg at 37th gestational week ($n=20$): 12.4 vs 22.8 µg/l; $P<0.001$. Women with anti-Tg antibodies had lower Tg values than those with negative antibodies (Tg 6.44 vs 14.1 µg/l; $P=0.007$). Five of the 14 women (35.7%) with positive anti-Tg antibodies, had undetectable Tg concentrations (<0.2 µg/l). The median yoduria was 251 µg/l (188.5-368.5). No correlations between serum Tg concentrations and UIC, thyroid volume, TSH or T4l concentrations were found. Women who started iodine supplementation (200 µg/daily) at least 1 month before pregnancy, had lower median Tg, compared to those who started at the detection of pregnancy, and those with no iodine supplementation (Tg 10.8 µ/l vs 13.4 µ/l vs 23.4 µg/l respectively; $P=0.030$). We found no statistical differences in Tg concentrations according to the consumption of iodized salt (no consumption, since pregnancy detection or pre-pregnancy) or according to milk intake (<1, 1–3 or >3 daily servings).
Conclusions
In our population serum Tg does not correlate with yoduria, thyroid volume, thyroid function, use of iodized salt or milk intake. Starting iodine supplements at least 1 month before pregnancy is associated with lower Tg.

Metabolic signature of hypothyroidism indicating higher cardiovascular risk

Stefano Massarini[1], Anna Ferrulli[2] & Livio Luzi[2]
[1]University of Milan, Milan, Italy; [2]IRCCS Policlinico San Donato, San Donato Milanese (MI), Italy.

Hypothyroidism is associated with higher risk of cardiovascular disease and increase of blood lipids. Previous evidence indicates that high dosage of levothyroxine could be cardiotoxic. There are fewer data describing mortality in subjects after treatment and stabilization of thyroid diseases and there are no data related to subjects with treated hypothyroidism. Aim of this study was to investigate correlations between the cardiovascular risk and metabolic status [Resting Energy Expenditure (REE),and Respiratory Quotient (RQ)], body composition and levothyroxine dosage in a population of patients affected by hypothyroidism. Twenty-five subjects (BMI$=28.4\pm5.5$ kg/m^2, range: 52.3–112.9 kg; age 52.6 ± 13.1 years) affected by hypothyroidism were analyzed. The cardiovascular risk was evaluated using skin autofluorescence via Age Reader instrumentation as well as estimated by Procam and Framingham index. Anthropometric and hormonal parameters (TSH, FT4 and FT3) were evaluated at baseline. REE was measured by indirect calorimetry and fat mass was evaluated by Air Displacement Plethysmography. Fourteen subjects had a high

cardiovascular risk (HCVD group) and 11 had a low cardiovascular risk (LCVD group). Comparing REE (measured vs predicted, %), fat mass (kilograms) and levothyroxine dosage (mcg) in HCVD and in LCVD group, a significant difference ($P < 0.05$) was found at baseline. The HCVD group showed lower REE %, higher fat mass and higher dosage of levothyroxine, compared to LCVD group. No significant differences were found in metabolic parameters (TSH, FT4, FT3) and in lipid profile (total cholesterol, HDL, LDL, triglycerides) between HCVD and LCVD. Patients with hypothyroidism treated with high dosage of levothyroxine had a major risk to develop a cardiovascular disease, a reduced REE and an excess of fat mass. Therefore, this study suggests that, among subjects affected by hypothyroidism, a reduced REE, an increased fat mass and a higher dosage of levothyroxine could be predictive of an increased cardiovascular risk.

Effectiveness of radioiodine treatment for toxic adenoma

Ana Sofia Osório[1], Ana Filipa Martins[1], Raquel Vaz de Castro[1], Vânia Gomes[1], Carolina Faria[1], Ema Nobre[1], Mickael Antoine Ferreira[2], Guilhermina Cantinho[3] & Maria João Bugalho[1]
[1]Endocrinology Department, Hospital de Santa Maria, Centro Hospitalar Lisboa Norte EPE, Lisbon, Portugal; [2]Statistical Independent, Lisbon, Portugal; [3]Instituto de Medicina Nuclear da Faculdade de Medicina de Lisboa, Lisbon, Portugal.

Objective
The purpose of this study was to assess clinical outcomes of patients with toxic adenoma (TA) treated with Radioactive Iodine (RAIT) in a tertiary hospital over a period of 8 years. We also analysed the influence of age, gender, TSH at diagnosis and anti-thyroid drugs (ATD) previous to RAIT on the cure rate.
Methods
Retrospective analysis of clinical records of all patients with TA submitted to RAIT between 2008 and 2015. The influence of demographic variables (age and gender) as well as clinical ones (TSH at diagnosis, iodine activity administered and previous ATD) on effectiveness of RAIT, 1 year after last treatment, was tested. Treatment success was defined by the achievement of euthyroidism or hypothyroidism 1 year after the last RAIT administration. For statistical analysis we considered a confidence interval of 95% ($sig < 0.05$).
Results
Over 8 years, 138 patients (female 110; male 28) mean age of 60.3 ± 14.6 years-old with TA were submitted to radioiodine treatment. Most patients were submitted to 10 or 5 mCi (61.8%–10 mCi; 35.8%–5 mCi) in a total of 145 treatments. Thirty-nine patients were lost for follow-up (28.3%). The global cure rate was of 82.8%. Hypothyroidism was observed in 32.3%. Age, gender and TSH at diagnosis had no influence on the outcome. Previous ATD was negatively correlated with the effectiveness of the radioiodine treatment. The cure rate achieved with activities of 5 and 10 mCi was slightly different, 75.6% and 88.7% respectively, but not statistically significant.
Conclusion
One year after RAIT, the cure rate of TA patients treated with an activity of 10 mCi was of 88.7% (euthyroidism 54.7% + hypothyroidism 34.0%); with an activity of 5 mCi was of 75.6% (euthyroidism 51.2% + hypothyroidism 24.4%). It is likely that for a longer period of follow-up these results might be different. Administration of ATD before radioiodine had a negative impact in therapy effectiveness.

Effective complex treatment of endocrinous ophthalmopathy (EO) with ophthalmic hyperthyroidism resistent to steroid therapy

Kulshara Yerdesova & Aknur Myrzabaeva
Asfendiyarov Kazakh National Medical University, Almaty, Kazakhstan.

Methods
With the purpose of evaluation of the condition of microlymphocirculation and the efficacy of lymph-stimulating medicines patients are divided into 2 groups: the reference group (p41) - traditional treatment (Thyrozol, Anaprilin). The main group (p16) – traditional treatment + Dalargin (Tyr-D-Ala-Gly-Phe-Leu-Arg, equivalent of leu-enkephalin) 1mg (per 2.0 0.9% NaCl) SC into the lateral part of the eyes No.7. Fluorescent lymphangiography, lymphoscopy, determination of the volume of lymphocirculation were performed before and after the treatment (3, 6, 12 months) for the purpose of comparative evaluation of the efficacy of the treatment.
Results
Already 3 months after the treatment with Dalargin, results in the main group reached the indicators of healthy people: reduction of the volume of lymphocirculation by 32% in the reference group and 72% in the main group; improved microlymphocirculation by 21.7% compared to the reference group; exophthalmometric values 3 months later approached the normal ones, and the effect was maintained during 12 months of observations.
Conclusion
1) dysfunction of the filtration and circulatory functions of the local and systemic lymphatic systems is observed in case of EO.
2) application of Dalargin in case of EO which is resistent to steroid therapy is effective, safe and pathogenetically substantiated.
3) lymphotropic subcutaneous periorbital application of the medicine increases the efficacy of traditional therapy.
4) the efficacy of the medicine in case of lymphotropic method of injections lasts 4-8 times longer and reduces the aggravation of the symptom by 6%.

Diminished levels and defective suppression function of Tr1 cells is observed in patients with autoimmune thyroiditis

Miguel Sampedro-Núñez[1,2], Marlen Vitales-Noyola[3], Ana Serrano-Somavilla[1,2], Rebeca Martínez-Hernández[1,2], Nerea Aguirre[1], Elena Fernández[1], Ana María Ramos-Leví[1,2], Roberto González-Amaro[3] & Mónica Marazuela[1,2]
[1]Service of Endocrinology, Hospital Universitario de la Princesa, Madrid, Spain; [2]Immunology and Molecular Biology Unit, Instituto de Investigación Princesa, Universidad Autónoma de Madrid, Madrid, Spain; [3]Department of Immunology, Research Center of Health Sciences and Biomedicine, Universidad Autónoma de San Luis Potosí, San Luis Potosí, Mexico.

Context
T regulatory type 1 (Tr1) cells are a subpopulation of T lymphocytes (CD4 + CD49 + LAG-3 + IL-10 +) lymphocytes that exerts a significant immunosuppressive effect. However, its possible role in autoimmune thyroid disease (AITD) had not been explored so far.
Objective
To analyze the levels and function of Tr1 cells in peripheral blood and thyroid tissue of patients with AITD.
Design
Cases and controls, observational study.
Setting
Department of Endocrinology, Hospital Universitario de la Princesa, Madrid, Spain.
Patients
Thirty-eight patients with AITD (23 with Grave's disease and 15 with Hashimoto thyroiditis) and twenty-six controls.
Intervention
Multi-parametric flow cytometry and immunofluorescence techniques were used to analyze the levels in peripheral blood ($n = 38$) and thyroid mononuclear cells ($n = 5$). An *in vitro* assay of suppression of cellular activation and cytokine release was performed to study the function of Tr1 cells. Main Outcome Measure: Levels and function of Tr1 cells in AITD patients and controls.
Results
Levels of Tr1 cells were significantly diminished in peripheral blood from AITD patients. Functional studies showed that Tr1 cells from AITD patients exhibit a diminished suppressive function compared to healthy controls. Tr1 levels were associated with disease severity, and auto-antibody titers.

Conclusions
The low levels of Tr1 cells and its diminished function may have a relevant role in the defective immune-regulatory function characteristic of AITD patients.

Thyroid amyloidosis mimicking medullary thyroid carcinoma

Sevgül Faki[1], Cevdet Aydin[1], Berna Ogmen[2], Ahmet Dirikoç[1], Haci Mehmet Inan[3] & Bekir Çakir[1]
[1]Department of Endocrinology and Metabolism, Yıldırım Beyazıt University Faculty of Medicine, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Ataturk Training and Research Hospital, Ankara, Turkey; [3]Atatürk Education and Training Hospital, Pathology Clinic, Ankara, Turkey.

Introduction
Amyloid accumulation in the thyroid gland leading to a clinically detectable mass is a rare clinical entity. The diagnosis of thyroid amyloidosis can be confused clinically as well as cytologically with both colloidal goiter or neoplastic processes of the thyroid. We report a case of thyroid amyloidosis that was initially misinterpreted as medullary thyroid carcinoma (MTC) clinical and cytological examination.
Case
A 24 years old man with chronic renal failure admitted to our hospita with rapidly progressive enlargement of a neck mass. He was suffering from renal failure for at least 10 years secondary to nephrolithiasis and was on 3 day/week hemodialysis after the rejection of renal transplantation 2 years before. He had dysphagia and dyspnea for about 5 months. Further workup demonstrated multinodular goiter with compressive symptoms and substernal extension. He had multiple nodules with the largest diameter of 80 mm in ultrasonography. Serum TSH was1.68mIU/L (0.27–4.2), free T4 was1.01ng/dL (0.9–1.7), free T3 was2.84ng/dL (1.8–4.6) and thyroglobulin was 758 ng/mL (0–78). Anti-thyroglobulin and anti-thyroid peroxidase antibodies were negative. His calcitonin level was high which was suggestive for possible diagnosis of MTC (12.6 pg/mL normal:2-8 pg/mL). Fine needle aspiration cytology of the largest nodule displayed MTC. 24 hour urine catecholamine levels were within the normal range and computerized tomography of adrenal glands revealed no pathology. Total thyroidectomy was performed and the final histopathological diagnosis was thyroid amiloidosis.
Conclusion
Although amyloid deposition in thyroid is a well known fact in MTC, it should be remembered that it is not a histological finding exclusive of this disease. In patients with a rapidly enlarging thyroid gland presenting with dysphagia, dyspnea, or hoarseness, amyloid goiter should be included in the differential diagnosis particularly when the patient has a chronic disease that might be associated with amyloidosis.

EMPATHY: a new tool for identifying the most suitable thyroxin formulation in hypothyroid patients

Giuseppe Bellastella[1], Mariangela Caputo[1], Maria Ida Maiorino[1], Miriam Longo[1], Lorenzo Scappaticcio[1], Dario Giugliano[1] & Katherine Esposito[2]
[1]Endocrinology and Metabolic Diseases Unit, Department of Medical, Surgical, Neurological, Metabolic, Geriatric Sciences and Aging, University of Campania 'L. Vanvitelli', Napoli, Italy. [2]Diabetes Unit, Department of Medical, Surgical, Neurological, Metabolic, Geriatric Sciences and Aging, University of Campania 'L. Vanvitelli', Napoli, Italy.

Hypothyroidism therapy is based on the administration of appropriate dose of L-thyroxine (L-T4). Absorption of L-T4 takes place in the duodenum and upper tract of the small intestine (jejunum), is maximal when stomach is empty, and is affected by a number of gastrointestinal disorders, including Helicobacter pylori–related gastritis, as well as ingestion of drugs, dietary fibers, and herbal remedies. Failure to achieve a good control of disease may be due to malabsorption in 40% of cases, or to poor compliance to L-T4 therapy in 60% of cases. During the past few years, various L-T4 formulations (in tablets, soft-gel capsules and liquid solution) have become available for clinical use. Liquid or gel formulations may be considered in subjects with hampered L-T4 absorption or who are not adherent to breakfast waiting time after L-T4 administration. Questionnaires to assess adherence to therapies are available and also adapted to patients with hypothyroidism. On the contrary, there are no tools available to detect malabsorption disorders and then addressing the endocrinologist in choosing the most appropriate therapy. Here we present EMPATHY (Evaluation of Malabsorption in PATients with HYpothyroidism): a questionnaire consisting of 13 questions which may help the endocrinologist to identify malabsorption disorders and then choose the most appropriate L-T4 formulation for each patient. EMPATHY allows to evaluate not only lactose and gluten intolerances but also some other allergies (nickel, histamine, citric acid, cornstarch) and alcohol intolerance. We administered EMPATHY to 150 newly diagnosed hypothyroid patients (50 males and 100 females). Exclusion criteria were previous thyroidectomy for thyroid cancer, central hypothyroidism, diabetes, obesity, current L-T4 therapy and pregnancy. We recorded more than 3 dose adjustments in six months in 21 out of 150 (14%) patients completing questionnaire and in 42 out of 150 (28%) not completing questionnaire ($P=0.01$). After two months of replacement therapy, most of patients in the group completing questionnaire (110 out of 150, 73%) and 82 out of 150 (54%) in the other group achieve a good control of disease ($P=0.001$). EMPATHY resulted extremely useful in the clinical practice allowing a better personalization of L-T4 replacement therapy and then a more rapid achievement of good control of the disease with smaller need of subsequent dose adjustments.

Coincidental prolactinoma and parathyroid adenoma in a patient with negative MEN1 and MEN4

Sevgül Faki[1], Cevdet Aydin[1], Muhammet Cuneyt Bilginer[1], Bagdegül Yükselgüler[2], Ali Abbas Tam[1], Mehmet Kilic[3] & Bekir Çakir[1]
[1]Department of Endocrinology and Metabolism, Yıldırım Beyazıt University Faculty of Medicine, Ankara, Turkey; [2]Atatürk Education and Training Hospital, Internal Medicine Clinic, Ankara, Turkey; [3]Yildirim Beyazit University, Ataturk Education and Research Hospital, General Surgery Department, Ankara, Turkey.

Introduction
Multiple endocrine neoplasia type 1 (MEN 1) is associated with neoplasia and hyperfunction of the parathyroid and pituitary glands, pancreatic islet cells, and neuroendocrine cells of the gut. Many authors advocate routine subtotal or total parathyroidectomy and autotransplantation for these patients. Here we demostrate negative MEN1 and MEN4 gene mutation analysis in a case with prolactinoma and a large parathyroid adenoma that could not be localized with preoperative imaging techniques.
Case
A 21-year-old man applied with a 8 years history of recurrent renal stones and increased serum calcium (11.25 mg/dl [Normal–9-10.5mg/dL]), alkaline phosphatase (147 U/L [Normal-30-120U/L]), serum parathyroid hormone (137 pg/l[Normal–10-60pg/mL]) and low phosphorus (2.1 mg/dl[Normal 3–4.5mg/dL]). Localization studies by imaging techniques (neck ultrasonography, Computed tomography and Tc-99m MIBI scintigraphy) failed to determine the number and location of diseased parathyroid glands. In addition, laboratory studies demonstrated elevated serum prolctine (246, Normal - 4.79-25.3 ng/mL). Other pituitary hormones were normal. Pituitary magnetic resonance imaging revealed 7.5 mm pituitary adenoma. He was started on cabergoline. Germ-line mutation analysis for *MEN1 and* Multiple endocrine neoplasia type 4 (MEN4) genes were negative and he had no familial history of endocrine tumors. Intraoperative parathyroid exploration demostrated a 3 cm paratyhroid adenoma. Histopathpolohical diagnosis was compatiel with parathyroid adenoma. There was no hypocalcemia or recurrence with a follow-up of 14 months.
Conclusion
Coexistence of hyperparathyroidism and prolactinoma in a young patient might not be always related to MEN1. A careful intraoperative exploration by an experienced parathyroid surgeon can be the best approach when hyperparathyroidism is diagnosed biochemically despite negative localization.

How should thyroid-related quality of life be assessed? Standard recall measures compared with here-and-now measures

Victor Brun Boesen[1], Ulla Feldt-Rasmussen[1], Jakob Bue Bjørner[2], Per Cramon[1], Mogens Grønvold[2,3], Birte Nygaard[4], Åse Krogh Rasmussen[1], Tina Vilsbøll[5] & Torquil Watt[1,4]
[1]Department of Medical Endocrinology, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark; [2]Department of Public Health, University of Copenhagen, Copenhagen, Denmark; [3]Department of Palliative Medicine, Copenhagen University Hospital Bispebjerg, Copenhagen, Denmark; [4]Department of Internal Medicine, Copenhagen University Hospital Herlev Gentofte, Copenhagen, Denmark; [5]Clinical Metabolic Physiology, Steno Diabetes Center, Copenhagen, Denmark.

Introduction
Some methodologists have raised concern about the validity of the standard method of assessing patient-reported outcomes, i.e. retrospective questionnaires. Repeated momentary measurements have been introduced to avoid recall bias and provide ecological validity. Although having theoretical advantages, the measurement properties remain unsubstantiated. This study examines the relationship between the retrospective thyroid-related quality of life patient-reported outcome measure ThyPRO and a momentary version of ThyPRO.
Methods
Eighty-three hyperthyroid patients were included to answer questions about their thyroid-related quality of life. Twelve momentary items from four multi-item scales were administered thrice daily via a smartphone application during 28 days. On day 28, the original retrospective ThyPRO was administered, thus the same period was covered by two different measurement methods, enabling head-to-head comparison. Correlations, differences, and levels of agreement were examined across all four scales. Further, it was explored if the two most substantiated forms of recall bias were evident (the peak effect and the end effect).
Results
Retrospective and averaged momentary ThyPRO ratings were highly correlated with Pearson correlations of 0.74–0.88. However, retrospective ratings provided significantly higher results, i.e. worse quality of life, on all scales with varying magnitude. Bland-Altman plots showed a skewed distribution, indicating low levels of agreement. Results supported the presence of the peak effect when measuring tiredness, but not on the remaining scales. There was partial support for the presence of an end effect, which was found in two of four scales.
Conclusion
Retrospective ThyPRO ratings and the average of momentary ThyPRO ratings were highly correlated, but provided significantly different results on the four tested scales, with higher scores in the retrospective rating. Only limited evidence was found to support the peak effect and the end effect. Thus, other possible explanations for the observed differences should be examined. The differences in scores were of clinically relevant magnitudes, why the two measures should not be interchanged. In most clinical studies the retrospective rating will be useable, however when designing clinical studies the measurement method should be carefully selected depending on the aim of measurement. To identify the most valid measurement method prospective analysis will compare responsiveness to change.

Radiofrequency ablation of the autonomously functioning benign thyroid nodules: 5-years follow-up

Viacheslav Solovov
Samara Oncology Centre, Samara, Russian Federation.

Introduction
The aim of this study was to evaluate the safety, efficacy and side effects of radiofrequency (RF) ablation for treating autonomously functioning thyroid nodules (AFTN). The study included the data of single centre.
Material and methods
The analysis included the results of the treatment of 127 patients with autonomously functioning benign nodules, received in the Samara Oncology Center in 2012–2015 years. All patients had high level of thyroid hormones and low level of thyreotropin. In all of them scintigraphy determined hot nodules. All the patients underwent fine needle biopsy twice. During the follow-up nodule volume and thyroid function were evaluated.
Results
The mean follow-up was 47.2 ± 13.5 months. 61 (48.0%) patients underwent 1 session of RFA, 54 (42.5%) patients – 2 sessions due to the big initial nodule size (more than 3 cm). In 12 (9.4%) patients after ablation and normalization of hormones levels during 3–6 months the minor nodule became active. That patients underwent ablation of this nodule too. Levels of triiodothyronine, free thyroxine, and thyrotropin reached normal in 2–3 weeks after RFA. During 5-years of follow-up hormone status remained normal. No serious complications such as thyroiditis, voice change, and hematomas were observed. RFA was an effective method for treating hot nodules.
Conclusion
RFA was effective, safe and repeatable procedure for treating autonomously functioning benign thyroid nodules.

Clinical and genetic study of autoimmun thyroid disease in a Tunisian multigenerational family

Noura Elleuch[1], Dorra Ghorbel[2], Faten Hadjkacem[3], Mouna Elleuch[3], Marwa Chiboub[2], Salwa Sessi[3], Mouna Mnif[3] & Mohamed Abid[3]
[1]Department of Life Sciences, Faculty of Sciences, Sfax, Tunisia; [2]Endocrinology-Diabetology Department, CHU Hédi Chaker, Sfax, Tunisia; [3]Endocrinology Department, Hedi Chaker Hospital, Sfax, Tunisia.

Autoimmune thyroid diseases (AITD), which include Hashimoto thyroiditis (HT), Graves' disease (GD) and primary idiopathicmyxoedema (PIM), are recognized by their clinical and genetic heterogeneity. In this study, we have carried on a global approach gathering 20 year genetic and clinical data on a Tunisian multigenerational family (Akr). Our purpose was search for a combined genotype involved in AITD susceptibility using 33 gene polymorphisms. The Akr pedigree is composed of more than 400 members distributed on 10 generations. Clinical follow-upwas performed by appreciation of the thyroid gland and measurement of both thyroid hormone and auto antibody levels. We used FBAT software to test for association between gene polymorphisms and AITDs. Clinical follow-up has showed that the number of AITD patients has increased from25 to 78 subjects subdivided on 51 cases of GD, 22 PIM and 5 HT. Concerning genetic analysis, our study has revealed new gene association when compared with our previous analysis (considering single genes). Thus, PTPN22, TG and VDR gene polymorphisms have became associated with p-values ranging from4.6 10^{-2} to 4 10^{-3} when consideredwith other genes on the same chromosome; giving evidence for gene interaction. The most significant association was found with the MHC region (p7.15 10^{-4}). Moreover, and among gene polymorphisms explored, our analysis has identified some of them as AITD biomarkers. Indeed, PDS gene polymorphisms were associated with either exophthalmia or goiter (p-values from 10^{-2} to 10^{-3}). In conclusion, our study gives evidence for gene interaction in AITD development confirming genetic complexity of these diseases.

High endocan level is associated with Graves' disease

Sami Aksan[1], Mehmet Muhittin Yalcın[2], Alev Eroglu Altınova[2], Mujde Akturk[2] & Fusun Balos Toruner[2]
[1]Gazi University Faculty of Medicine Department of Internal Medicinel, Ankara, Turkey; [2]Gazi University Department of Endocrinology and Metabolism, Ankara, Turkey.

Endocan has been suggested as a marker for endothelial dysfunction. Some evidence exists that Graves' disease may be associated with impaired endothelial function. The aim of the study was to evaluate serum endocan, endothelial growth factor (VEGF) and carotid intima media thickness (CIMT) in patients with Graves' disease. Thirty one newly diagnosed patients with Graves' disease and 31 healthy volunteers with similar age and sex were examined. Serum endocan, VEGF levels and CIMT were measured in the patient group both before antithyroid treatment and after euthyroidism achieved and compared with the control group. Serum endocan levels were higher in the hyperthyroid Graves' group than the control group (0.68 (0.18-1.21) vs 0.49 (0.11-1.88) pg/ml, $P = 0.002$). There was no significant difference in Graves' group after euthyroidism was achieved and the control group (0.57 (0.14-0.96 vs 0.49 (0.11-1.88) pg/ml, $P > 0.05$). Serum VEGF levels were not significantly different in the Graves' and control group ($P > 0.05$). CIMT was higher in the hyperthyroid Graves' group than the control group (0.68 ± 0.07 vs 0.47 ± 0.06 mm, $P < 0.001$). Decrease in CIMT was observed after euthyroidism achieved, however, it was still higher than the control group (0.59 ± 0.05 vs 0.47 ± 0.06 mm, $P < 0.001$). Serum endocan levels were correlated negatively with TSH ($P < 0.01$); positively with fT3 ($P = 0.01$), fT4 ($P < 0.01$), Anti-Tg ($P < 0.05$) and Anti-TPO

($P<0.001$). In multiple linear regression analysis fT3 level was the most important predictor for endocan levels ($F=5.664$, $R^2=0.106$, $P<0.05$). In conclusion, our findings suggest that serum endocan levels are increased and associated with fT3 in patients with Graves' disease.

Segregation of S292F TPO gene mutation in three large Tunisian families with thyroid dyshormonogenesis: evidenceof a founder effect

Dorra Ghorbel[1], Faten Hadjkacem[1], Fatma Mnif[1], Fatma Loukil[1], Mouna Mnif[1], Noura Elleuch[2] & Mohamed Abid[1]
[1]Endocrinology-Diabetology Department, CHU Hédi Chaker, Sfax, Tunisia. [2]Department of Life Sciences, Faculty of Sciences, Sfax, Tunisia.

We aimed to identify causal mutation(s) in 13 patients with thyroid dyshormonogenesis (TD) from three consanguineous Tunisian families. A 12-year clinical follow-up showed phenotypic variability ranging from the presence to the absence of goiter, sensorineural deafness, and mental retardation. Genetic analysis using microsatellite markers within two candidate genes (TPO and PDS) gave evidence of linkage with the TPO gene. Sequencing of its 17 exons and their flanking intron-exon junctions revealed the previously described c.875C>T (p.S292F) mutation in homozygous state. No additional mutations were found in either a 900 bp of the TPO gene promoter or PDS gene. In silico analysis showed that p.S292F mutation might reduce the catalytic cavity of the TPO which would restrict access of a potential substrate to the catalytic pocket. Using 4SNPs and one microsatellite marker in the TPO gene, an associated haplotype: G-C-G-G-214 was found, giving evidence of a founder mutation.

Conclusion

This is the first description of a TD causing mutation in Tunisia and thus may help to develop a genetic screening protocol for congenital hypothyroidism in the studied region. Although structural modeling suggested a pathogenic effect of this mutation, functional studies are needed. Additional causing and/or modifier genes, together with late diagnosis could explain the clinical variability observed in our patients.

When thyroid pathology becomes an emergency: about four cases

Habra Bahia, Elmghari Ghizlane & El Ansari Nawal
Department of Endocrinology diabetology and metabolic diseases. Laboratory FIPM, FMPM, Cadi Ayad University. CHU Mohamed VI., Marrakesh, Morocco.

Introduction

The thyroid emergency is a rare and life-threatening condition. These are severe complications of benign thyroid disease.

Patients and method

We report cases of thyroid pathology constituting an emergency and have been collected over 2 years in the department of endocrinology of the CHU Mohammed VI of Marrakech.

Results

Four cases of thyroid emergency were reported: three cases of acute thyrotoxic crisis (CAT) and one case of thyroid abscess. All patients were young, aged 20, 32, 40 and 45 years and were all female. The first case of CAT had complicated a disease of basedow, the other two were on multi-hetero-nodular toxic goiter. All three were revealed by an acute polymorphic table evoking the CAT. The case of thyroid abscess was revealed in a postpartum patient by a sudden increase in the volume of a pre-existing goitre with inflammatory signs. Evolution was good in all patients.

Discussion

Thyroid emergency is a serious pathology involving CAT and myxoedematous coma in addition to infectious pathology. The latter remains exceptional. A rare occurrence in developed countries, it is still present in disadvantaged areas and remains subject to significant mortality if there is no diagnosis and early and adequate management.

Dysthyroidism and chromosomal aberrations

Dorra Ghorbel, Fatma Mnif, Donia Chebbi, Dhouha Ben Salah, Nabila Rekik & Mohamed Abid
Endocrinology-Diabetology Department, CHU Hédi Chaker, Sfax, Tunisia.

Introduction

Dysthyroidism is not uncommon during chromosomal aberrations. The objective of this work is to study the characteristics of this association at the epidemiological and clinical levels.

Methods

This is a retrospective study of 27 cases of patients with trisomy 21 chromosomal abnormalities (6 cases), klinefelter syndrome (4 cases) and Turner syndrome (17 cases) genetically confirmed, collected at endocrinology service at Sfax University Hospital (CHU) over a period of 20 years (1997–2017) during which we selected patients with thyroid disease.

Results

Six out of 27 patients had a dysthyroidism with a prevalence of 22.2%. Hypothyroidism was found in 5 patients. The average age was 19.6 years old. The mean FT4 was 5.75 pmol/l and the average TSH was 113.1 µmol/l. Only one case of hyperthyroidism was collected in a 9-year-old trisomy 9 with a FT4 of 24.3 pmol/l and a TSH of 0.015 µmol/l. Antithyroid antibodies was positive.

Conclusion

The prevalence of dysthyroidism during chromosomal aberrations is estimated at 25% to 60% in the literature, dominated by hypothyroidism and autoimmune origin in most cases. Thus systematic evaluation for thyroid dysfunction should be made in this population to detect such anomalies.

DOI: 10.1530/endoabs.56.P1088

Riedel's Thyroiditis with Hypothyroidism and Hypoparathyroidism

Isilay Taskaldiran[1], Sevde Nur Firat[1], Gonul Koc[1], Pelin Demirturk[2], Cavit Culha[1] & Murat Faik Erdogan[3]
[1]Department of Endocrinology and Metabolizm, Ankara Reserch and Education Hospital, Ankara, Turkey; [2]Department of Pathology, Ankara University Faculty of Medicine, Ankara, Turkey; [3]Department of Endocrinology and Metabolizm, Ankara University Faculty of Medicine, Ankara, Turkey.

Riedel thyroiditis (RT) is a rarest form of thyroiditis, and characterized by dense fibrosis of the throid gland and infiltration into surrounding tissues. RT generally presents with local symptoms association with compression and also fibrotic process can impact thyroid and parathyroid functions. We report a case with RT which presents with compression findings and also hypoparathyroidism and hypothyroidism. 30 year old women visited our outpatient clinic with a complaint of neck mass and hoarseness. The symptoms had begun 20 days ago and had been followed by dyspnea. This patient had previously diagnosed with hypothyroidism and after hypoparathyroidizm approximately 6 mounths before and she had underwent treatment. She had been taking L- thyroxine, vitamin D3 and calcium preparat. Thyroid examination revealed a diffuse thyroid enlargement with very firm tissue. She had also stridor in rest. Thyroid function tests revealed thyroid stimulation hormone of 13.22 mIU/l (normal range, 0.4–3.7), showed hypothyroidism. Levels of thyroid antibodies were negative. Blood calcium was 7.8 mg/dl (normal range:8.8–10.6 mg/dl). Her parathyroid hormone level was12.7 ng/l(-normal range:15–65). Other biochemical tests were normal. Thyroid ultrasound demonstrated asymetrically enlarged thyroid gland with decreased vascularity, and showed a 4 cm mass in the left lobe and 3 cm mass in the right lobe. There was right shift of the trachea. There were no enlarged pathologic lymph nodes in the neck. Computerized tomography (CT) scan suggested that multinoduler guatr with a largest mass in the left lobe of the thyroid which push the trachea and caused tracheal stenosis. USG-guided tru-cut biopsy was performed on the nodule of greatest size. Histopathology exam showed that the thyroid gland was destroyed and extensively replaced by dense kollogen fibrous tissue with mononuclear cells infiltration. There was no evidence of malignancy and resultly riedel thyroiditis was confirmed as a diagnose. Prednisolon 40 mg/day was started and has been tapered during six months. After six month of treatment the symptoms improved and neck mass size decreased, and in ultrasound examination trachea was normal. After 6 months of follow up, now the patient is euthyroid with levothyroxine replacement (her needs reduced with time), and pth level was increased. In conclusion the appearance of hypoparathyroidism in Riedel's thyroiditis is a rare situation. Clinicians should be aware of RT, which presents as

stony hard thyroid with hypothyroidism and unexpected hypoparathyroidism. The response to treatment was good with prednisolon.

Our experience in the first year of radiofrequency ablation of benign thyroid nodules

Raul Rodriguez Escobedo[1], Silvia Gonzalez Martinez[1], Fernando Garcia Urruzola[1], Soraya Lanes Iglesias[1], Alicia Martin Nieto[1], Lucia Diaz Naya[2], Jessica Ares Blanco[1], Bonel Argüelles Garcia[2], Ana Maria Montes Garcia[1], Cecilia Sanchez Ragnarsson[1] & Edelmiro Luis Menendez Torre[1]
[1]Hospital Universitario Central de Asturias, Oviedo, Spain; [2]Hospital Universitario de Cabueñes, Gijon, Spain.

Purpose
At the beginning of 2016, radiofrequency ablation of benign thyroid nodules began to be carried out at the Central University Hospital of Asturias (Spain). The aim of this study was to evaluate the results obtained by the moment with the aforementioned technique.
Methods
It is a descriptive study carried out through the data obtained during the process and the subsequent analytical and ultrasonographic follow-up. In addition, patient surveys have been conducted, mostly by telephone.
Results
• *General data.* 24 patients undergoing treatment (18 women and 6 men), with a mean age of 52.7 (minimum 36 and maximum 83).
• *Evolution of size. Revision to the first month (n=20):* average reduction of 35.765% (median: 36.5, maximum: 69, minimum: 7). *Revisions at 3-6 months (n=10):* average reduction of 59.7% (median: 65, maximum: 88, minimum: 33). *Review at 8-9 months (n=10):* average reduction of 50.7% (median: 54, maximum: 84, minimum: 15). *Review at 11-14 months (n=2)*: average reduction of 89%.
• *Thyroid function.* 94.7% of euthyroid patients prior to radiofrequency remained euthyroid.
• *Pain during the intervention*. 89.47% of patients said they did not feel pain. 5.25% moderate pain and 5.25% intense pain.
• *Complications.* Local discomfort 63%, (83.33% mild, 16.67% moderate). Hematoma in 26.31% (80% mild, 20% moderate). Mild dysphagia 5.26%. There was no dyspnea or serious complications in any patient.
• *Subjective improvement.* 100% presented subjective improvement. In sensation of cervical bulk 84.21%, aesthetically 73.68%, dysphagia 63.15%, dyspnea 36.86%.
• *Satisfaction.* 78.94% were very satisfied with the treatment, 10.52% satisfied, 10.52% intermediate satisfaction. None was dissatisfied.
• *Repetition.* 100% of patients would repeat the radiofrequency treatment if necessary
Conclusion
• There have been marked reductions in the size of the nodules. This decrease is echographically appreciable from the first month, showing in most cases an increase in the reduction in subsequent revisions.
• Thyroid function is not affected by the use of radiofrequency therapy.
• The technique, in most cases, is not painful.
• No serious complications have occurred. It is seen as the main complication local discomfort, being mild in the vast majority of occasions.

Utility of 99 Tc-MIBI scintigraphy for the assessment of thyroid nodules with bethesda III cytologies

Marta Sánchez Pérez[1], Lola Santos Rey[1], Ana Gloria Villas Tome[2], Ma Jesús Díez Castro[2], Teresa Canela Coll[2], Marta Hernández García[1], Chadia Mizab Mellah[1], Liliana Patricia Gutiérrez Carrasquilla[1] & Ferran Rius Riu[1]
[1]University Hospital Arnau De Vilanova, Lleida, Spain; [2]Idi-Nuclear Medicine University Hospital Arnau De Vilanova, Lleida, Spain.

Introduction
Up to 30% of the thyroid nodules studied with fine needle aspiration biopsy (FNAB) are reported as Bethesda III, a category that does not rule out malignancy. One technique that could help to decide if there is a surgical indication is (99 m) Tc-sestaMIBI scintigraphy (MIBI).
Material and methods
All patients with a Bethesda III result were prospectively included, and 99 Tc-MIBI scintigraphy was performed prior to surgery. All exams, including ultrasonography, FNAB, cytological diagnosis and scintigraphic exams were perfomed in our hospital. (99 m) Tc-sestaMIBI scintigraphy reports were based on contrast retention at 10 minutes and 3 hours after the radiolabeled compound injection, with gradation of intensity in both moments, considering pathological uptake a moderate-intense retention in any of them. These results were eventually compared with the histological results after surgical intervention.
Results
Eighty-four patients with a 99Tc-MIBI scintigraphy underwent surgery, 68 (80.9%) women, mean age 52.4 ± 13.8 years. 99Tc-MIBI scintigraphies results were reported as benign in 39 (46.4%) and pathological in 45 (53.6%). After surgery 19 (22.6%) cases were reported as thyroid cancer (TC) (12 papillary, 5 follicular and 2 poorly differentiated) and 65 (77.4%) as benign. 38 (58.5%) patients with histological result of benignity did not show pathological uptake in MIBI and 27 (25.6%) did (59,2% at 10 minutes and the rest at both phases). Only one patient with TC (5.3%) did not show a pathological uptake in MIBI. With these results the pathological uptake in MIBI shows a sensitivity of 94.7% and a specificity of 58.5%, with a positive predictive value of 40% and negative predictive value of 97.44%($p < 0.001$ in chi square test).
Conclusion
We confirm that 99 Tc-MIBI scintigraphy is a useful technique for the identification of benign nodules after the Bethesda III result in cytology with a high negative predictive value. We think that patients with a Bethesda III cytological in a thyroid nodule FNAB and a non pathological MIBI uptake could be undergo clinical follow up without performing surgery.

Shopping trip and a thyroid storm

Ankit Kumar, Sreekanth Sakthibalan, Caoimhe Bonner, Bonnie Grant, Shazia Hussain, Anna Hawkins, Edel Casey & Khash Nikookam
Barking Havering and Redbridge University Hospitals NHS Trust, Greater London, UK.

A previously fit and well 27 year old Ghanaian male was brought to hospital by his cousin due to new behavioural changes. The patient was described by his cousin as a normally reserved, self-sufficient man who had become a polar opposite 'irritable' personality that 'spent extravagantly'. He repeatedly claimed to be 'God's protection' and responded aggressively to visual hallucinations. This had resulted in social exclusion and loss of employment. There was no significant family history or history of substance or alcohol misuse. Physical assessment was limited due to poor patient co-operation. Bedside observations revealed a marked resting tachycardia (121 bpm). Oxygen saturations, blood pressure and temperature were all normal. There was no apparent focal neurological deficit or neck rigidity. The remaining physical examination was positive only for a non-tender goitre and hand tremors. Electrocardiography confirmed sinus tachycardia. Computerised tomography (CT) head scan was normal and lumbar puncture was unsuccessful despite sedation. Initial investigations revealed a mild inflammatory response without electrolyte disturbances. He was treated empirically for meningoencephalitis, however, further urgent investigations confirmed marked hyperthyroidism with free T4 95 pmol/l (10–19.9 pmol/l) and TSH < 0.01 mU/l (0.35–5.5 mU/l). A diagnosis of thyrotoxic psychosis was made. He was commenced on high-dose carbimazole and propranolol 160mg daily in divided doses with little effect. Hydrocortisone, lithium and cholestyramine were subsequently added to help achieve euthyroidism with a consequential improvement in his mental state. A total thyroidectomy was performed to achieve definitive control. He was successfully discharged a few days later on levothyroxine and was given a supporting medical letter to help to cancel the multiple phone contracts and loans that he had accumulated during his thyrotoxic state. Histological evaluation of the excised thyroid gland confirmed Graves' thyrotoxicosis.
Conclusion
Thyrotoxic psychosis, although rare, should be considered in all patients with behavioural disturbances to allow early treatment, prompt control and improved outcomes.

Should tocilizumab be a second-line treatment of active, moderate-to-severe Graves' Orbitopathy?

Rocío Cáceres, Ana Herrero, José María Recio-Córdova, Ana Sánchez-Marcos, Cecilia Higueruela, Myriam Beaulieu, Rosana Iglesias, Cristina Robles, María García-Duque & Juan José Corrales-Hernández
Service of Endocrinology and Nutrition. University Healthcare Complex of Salamanca, Salamanca, Spain.

Introduction
Graves' orbitopathy (GO) is the most common extrathyroidal manifestation of Graves' disease. The first-line treatment are intravenous corticoids in active moderate-severe GO. Tocilizumab is a humanized monoclonal antibody against the IL-6 receptor which has been approved for the treatment of rheumatoid arthritis and is in its research stage for patients with corticosteroid-refractory GO.
Objectives
To assess the experience with tocilizumab in patients with GO at the University Clinical Hospital of Salamanca.
Material and methods
Retrospective analysis of four patients treated with tocilizumab for GO since 2014. The CAS was ≥ 3 and TSI antibodies were positive. An intravenous dose of 8 mg/kg was administered every month. The end of the treatment was dependent on clinical improvement (CAS ≤ 2) or negative results for TSI antibodies.
Results
The average age was 45 ± 9.5 years, and 50% of the patients were male. Half of the patients were active smokers and the rest were ex-smokers. Two of them were diabetic. They all presented bilateral moderate-severe GO and three of them had previously received corticoids (4.5 g doses) without any improvement. One patient had received treatment with rituximab, with no results. The average time from the last dose of corticosteroids and the administration of tocilizumab was 5 months. After 6.5 ± 2.6 cycles all the patients showed an improvement of the CAS (6 ± 2.3 before the treatment and 2.3 ± 0.5 after the last cycle ($P = 0.036$)). All the patients showed an improvement of exophthalmos, visual acuity and ocular motility. Two patients required decompression surgery and one patient required radiotherapy. TSI antibodies returned to normal values in all cases. The follow-up since the last dose was 18.3 ± 6.3 months, without any recurrence. None of the described secondary effects were observed, although two of the patients showed asymptomatic CK elevation.
Conclusions
Tocilizumab may be an alternative to corticoids in patients with GO who do not respond to them or who have a contraindication. More studies are necessary to assess the effectiveness and safety of this drug.

Features and determinants of hypothyroidism in patients with major beta thalassemia from Algeria.

Abderahman Youssouf Belazzouz[1], Malha Azzouz[1], Ziane Khouja[2], Ahmed Nacer[2], Aissa Boudiba[1] & Ilyes Yargui[3]
[1]Mustapha Pacha Hospital Diabetologia Departement, Algiers, Algeria; [2]Pierre Marie Curie Center Departement of Hematology, Algiers, Algeria; [3]Mustapha Pacha Hospital Biochemistry Departement, Algiers, Algeria.

Introduction
Hypothyroidism is the most common endocrine pathology during Major Beta Thalassemia (MBT). The geographic area is considered a factor in establishing the prevalence and form of hypothyroidism in MBT. We have tried through this study to establish features and determinants of hypothyroidism in Algeria.
Patients and methods
Twenty patients middle-aged 27 years (20–46 years) (10 males/10 Females) hospitalized in Pierre Marie Curie Center, Hematology unit, Algiers. All patients have been tested for thyroid hormones levels: TSH/FT4/FT3. Results have been correlated with ferritin and hemoglobin levels, the type of chelation (Deferoxamine/Deferasirox) as well as the viral serology.
Results
The prevalence of hypothyroidism is 25%. In 15% it is a subclinical hypothyroidism (1M/2F) who have benefited from antibody dosing (Ab TPO, Ab TG), while 10% have a central hypothyroidism, it is about two sisters without statural or weight delay having a gonadotropic deficit among them one died by hypersplenism having refused the splenectomy. No correlation was noted between ferritin and TSH (P: -0.06) nor FT4 (P: -0.05). Neither the Beta thalassemia duration nor the degree of anemia nor the type of chelator nor hyperferitemia appears to be risk factors for hypothyroidism with respectively Odds ratio (0.16/0.23/0.73/0.73). Subjects with viral hepatitis are more exposed, but not significantly, to hypothyroidism regardless of its form compared to unaffected individuals (odds ratio: 1.67).
Conclusion
In this sample of the North African MBT form, hypothyroidism seems to be heterogeneous between borderline primary hypothyroidism and the central form rarely described in the published series of the South European MBT, which demonstrates the main role of the geographical factor. Furthermore, an association of central and peripheral form of hypothyroidism in the same patient is not to eliminate. The treatment of subclinical hypothyroidism is often necessary especially in patients inadequately controlled under chelation treatment which are at high cardiovascular risk by iron overload.

Serum chemerin and other dyslipidemia markers in patients with autoimmune thyroiditis

Eszter Berta, Mariann Harangi, Viktória E Varga, Hajnalka Lőrincz, Ildikó Seres, Sándor Halmi, Endre V Nagy, György Paragh & Miklós Bodor
Institute of Medicine, University of Debrecen, Faculty of Medicine, Debrecen, Hungary.

Aim
Chemerin, a recently discovered adipokine produced by the adipose tissue and liver, along with other atherosclerosis markers, was associated lately with metabolic syndrome and acts as chemoattractant for immune cells may also regulate immune cell properties. Autoimmune Hashimoto's thyroiditis even with sTSH levels corrected to be within the normal range values may be accompanied by dyslipidemia presenting increased total-C, TG, LDL-C, and Lp(a), all of which are potential risk factors for developing atherosclerosis. Previously we found significant correlations between serum chemerin levels and lipid and lipoprotein subfractions in nondiabetic obese patients. However, chemerin level and its association with serum lipid levels in Hashimoto's thyroiditis has not been fully investigated.
Methods
In the present study we measured the serum chemerin and other atherosclerosis marker levels by ELISA in 52 patients with Hashimoto's thyroiditis and in 34 age, gender and BMI matched controls.
Results
We did not find significant difference in serum chemerin levels between the patient and control groups (88.7 ± 16.8 vs 91.5 ± 15.9 ng/ml). However, significantly higher sTSH, LDL-C, Lp(a), apoA1 and apoB levels were found in patients compared to the controls. We found significantly positive correlations between serum chemerin levels and TG, non-HDL, leptin and CRP, age and BMI. In this study chemerin level negatively correlated with the HDL-C level. There was no correlation between chemerin and sTSH, fT3 and fT4, and anti-TPO levels. These findings were consistent even when comparing the subgroups of patients having their sTSH levels above and under 4 mU/l, nor when considering these groups and the controls. Leptin was found to be an independent predictor of chemerin in both patient and control groups.
Conclusions
Although serum chemerin is not elevated in patients with Hashimoto's thyroiditis, regardless their actual sTSH levels, patients with higher chemerin levels present impaired dyslipidemia markers associated with increased risk for atherogenesis. Therefore, chemerin may be a useful marker in atherosclerotic risk assessment in patients having Hashimoto's thyroiditis.

Current iodine status in a Romanian school-aged children

Daniela Nuta[1,2], Michaela Nanu Nanu[3], Florentina Moldovanu[3], Ioana Nanu[3] & Ioana Sonia Ardeleanu[3,2]
[1]National Institute of Pubic Health, Bucharest, Romania; [2]University of Medicine and Pharmacy 'Carol Davila', Bucharest, Romania; [3]National Institute for Mother and Child Health 'Alessandrescu – Rusescu', Bucharest, Romania.

Introduction
Iodine deficiency is one of the most important cause of mental and physical disorders and is considered a public health issue. Previous studies reported the existence of iodine deficiency in several regions in Romania and its related

negative side effects on children's health. Therefore, Romania has implemented the universal salt iodisation (USI) since 2002.
Aim
The present study aimed to assess the current iodine status in Romanian school-aged children.
Subjects and methods
The study analysed data from a nationally representative sample – 624 children, aged 6–7 years old, covering 15 Romanian counties. Urinary iodine was measured using spectophotometric method, with ceramic ammonium sulphate. The iodine status of the target population was apreciated comparing the median urinary iodine value of the urine samples with WHO standards. The study was approved by the Local Ethics Committee. An informed consent from the parents was obtained.
Results
The median iodine value of 255.3 μg/l reflects a more than adequate iodine status of the surveyed population. The mean value of urinary iodine (275.6 μg/l) and its standard deviation (133.22 μg/l) showed a large dispersion of the results. Data were analysed and disscused in the context of previous studies. We report here a significant improvement in the iodine status of the children in Romania, reflecting an appropriate iodised salt household consumption.
Conclusions
In Romania, there is currently no iodine deficiency among school children in the context of the universal salt iodisation. In order to ensure an adequate prophylaxis of mild iodine deficiency, continuous iodine monitoring is required among schools in all urban and rural areas, and to correlate the iodine values with the other markers of iodine deficiency (neonatal TSH, thyroid volume).

Primary thyroidal paraganglioma in a 60 years old female with thyroid goiter

Spyridon Sapounas[1], Christos Manthakos[2], Maria Pissia[1], Katerina Saltiki[1], Eleni Anastasiou[1] & Evangelia Zapanti[1]
[1]Endocrinology Department Alexandra Hospital, Athens, Greece; [2]Endocrinologist Private Practice, Tripoli Arkadia, Greece.

Primary Paraganglioma of Thyroid Gland is an extremely rare neuroendocrine tumor. Less than 50 cases have been reported up to date and its rarity is the reason why it's often mistaken for thyroid nodule or other thyroid neoplasms. In this case we describe the misleading results of ultrasonography followed by FNA-biopsy, which led to a total delay of two years until final diagnosis. A 60 year old female presented with a 38 mm right-sided thyroid module. An ultrasound guided FNA-biopsy was performed and the cytology report was suggestive of a follicular adenoma. A total thyroidectomy was suggested because of the large size and hyper vascularity of the nodule, which was performed two years after initial examination. The results of histological examination revealed a neoplasm morphologically following a nesting pattern (zellballen) with rich capillary network. Immunohistochemical staining of the neoplasm was positive for chromogranin, synaptophysin and CD56. Sustentacular cells were positive for S-100 and Ki-67 was lower than 1%. Staining was negative for thyroglobulin and calcitonin. Neck-adrenal MRI as well as chest CT were normal. She underwent blood tests for gastrin, chromogranin A, calcitonin, tumor markers and 24 h catecholamine urine test (CATU) along with 5HIAA and VMA, all of which were also normal except from chromogranin A: 487 ng/ml (normal values: <120 ng/ml). We have no evidence of recurrence up to date and we suggested to the patient to undergo molecular analysis for germline mutations of the genes encoding succinate dehydrogenase subunits, SDHD, SDHAF2, SDHC, SDHB and SDHA. Diagnosis of TP is always confirmed postoperatively and differential diagnosis also includes medullary thyroid carcinoma and hyalinizing trabecular adenoma. These three conditions need completely different surgical approach and a close post-operative follow-up testing. Despite its rare frequency thyroid paraganglioma should always be included in the differential diagnosis of hypervascular thyroidal lesions especially those with indeterminate or undefined cytological results.

Management particularities of substernal goiter

Halwani Chiraz, Zoghlami Imène, Zgolli Cyrine, Akkari Khmaies & Ben Mhamed Rania
ENT Department – Military Hospital, Tunis, Tunisia.

Introduction
The definition of a substernal goiter is not univocal, several definitions have been advanced. It poses difficulties by its therapeutic features and management. The aim of this presentation was to detail the particularities of the management of substernal goiters and their therapeutic difficulties.
Methods
This is a retrospective study carried out on 40 patients with substernal goiter admitted to our department and treated during a period of 5 years (from 2012 to 2017).
Results
They were 13 men and 27 women. The average age was 52 years. The main complaint was a cervical mass found in all cases, associated with signs of compression in 15 cases. The size of the mass ranged from 3 to10 cm with an average of 7 cm. The patients were in clinical euthyroidism in 33 cases. The radiological assessment included cervical examination ultrasound and cervico-mediastinal CTscan in all cases. A total thyroidectomy was performed in 26 cases and a loboisthmectomy in 14 cases. The cervical approach was sufficient in the majority of cases. We used sternotomy in two cases. The malignancy rate was 12%. It was a papillary carcinoma in four cases and medullary in one case. A central compartment dissection was practiced in five cases and lateral in 1 case. I^{131} remnant ablation was performed for papillary carcinomas with a dose of 50 to 300 mci. External radiotherapy was performed for the case of medullary carcinoma for curative purposes. All patients with benign goiters had a good outcome over the course of follow-up time.
Conclusion
Generally benign, the surgery of substernal goiter is more difficult than that of cervical goiter. The cervical approach is often sufficient; however, a sternotomy is sometimes needed. The prognosis depends on a good preoperative preparation and rigorous postoperative follow-up.

A case of respiratory arrest associated with sepsis induced myxoedema coma

Edson Nogueira[1], Kyaw Khin[2], David Hope[1], Oluwagbemiga Idowu[1], Vivian Sathianathan[2], Daniel Darko[1] & Mushtaqur Rahman[1]
[1]Department of Endocrinology & Diabetes, Northwick Park Hospital, London, UK; [2]Intensive Care, Northwick Park Hospital, London, UK.

A 58-year old previously independent man with background of poorly-controlled hypothyroidism, T2DM, hypertension, ischaemic cardiomyopathy, and CKD presented to hospital feeling generally unwell, with a dry cough. His regular medications included anti-hypertensives, L-thyroxine 50 μg daily, linagliptin, insulin, aspirin, atorvastatin, and thiamine. On admission, the TSH was 83 mIU/l, free T4 6.5 pmol/l and free T3 was 1.9 pmol/l; four months earlier, the TSH was 58 mIU/l. He was noted to have staphylococcal septicaemia and acute kidney injury; bacterial endocarditis was excluded. He developed a pruritic, maculo-papular rash that was thought due to dry skin. There was a history of non-compliance with L-thyroxine. Despite increasing the dose to 150 μg od, the TSH continued to rise to >100; the free T4 rose to 14.7, but the fee T3 was 2.0. Over the next two weeks, he became more confused, hypothermic, had a respiratory arrest and was admitted to ITU. Infective and paraneoplastic causes of encephalopathy were excluded. A diagnosis of myxoedema coma was made: L-thyroxine 200 μg was administered daily via a nasogastric tube along with IV liothyronine 10 μg 8-hourly; the total daily dose of hormone was based on weight. IV hydrocortisone was commenced until normal adrenal function was confirmed. TSH was monitored every 48 hours until reduction was noted (it halved every 48 h), then weekly. Improved thyroid function was allied to improvement in consciousness, body temperature, blood pressure and renal function. He was moved to a general ward where he able to make a good recovery, including resolution of his dermopathy. Thyroid hormone replacement was then maintained on L-thyroxine 175 μg od alone. This case illustrates how myxoedema coma may occur following a non-thyroidal illness on a background of hypothyroidism. We believe this was due to reduced conversion of T4 to T3 due to sepsis, leading to myxoedema with reduced absorption of L-thyroxine, setting up a cycle that led to myxoedema coma. This case also illustrates the protean manifestations of severe hypothyroidism. Patients with encephalopathy should be screened for hypothyroidism and thyroid function closely monitored if conscious level deteriorates in patients with pre-existing hypothyroidism.

Prevalence of thyroid dysfunction in Catalonia from two different registers: pharmaceutical delivery records and diagnostic records (EUthyroid project)

Sara Torrejón[1], Berta Soldevila[2], Montse Martín-Baranera[3], Manel Puig-Domingo[4], Inés Velasco[5], Lluís Vila[6] & Thyroid Area of Spanish Society of Endocrinology and Nutrition[7]
[1]Endocrinology and Nutrition Service, Hospital of Sant Joan Despí Moisès Boggi, Sant Hoan Despí (Barcelone), Spain; [2]Endocrinology and Nutrition Service, Hopital of Germans Trias i Pujol, Badalona, Spain; [3]Clinical Epidemiology Service, Consorci Sanitari Integral, Hospitalet del Llobegat, Spain; [4]Germans Trias i Pujol, Research Institute, Badalona, Spain; [5]Obstetrics and Gynecology Service, Hospital of Riotinto, Huelva, Spain; [6]Endocrinology and Nutrition Service, Hospital of Sant Joan Despí Moisès Boggi, Sant Joan Despí (Barcelone), Spain. [7]SEEN, Madrid, Spain.

Background
Cross-sectional studies performed to estimate the prevalence (Prev) of thyroid dysfunctions are expensive and involve a great effort. Diagnosis and therapeutic prescription records may be a good alternative to monitor such prevalence. They also allow to easily compare the thyroid dysfunctions prevalence of among different populations (EUthyroid Project).
Objective
1) To estimate the Prev of hypothyroidism (hypoT) and hyperthyroidism (hyperT) based on Pharmaceutical Delivery records (PHDR) and on Diagnostic Records (DR) of the population of Catalonia; 2) To analyse the concordance of the results between both registers.
Methods
The population officially insured in the Public Health System (CatSalut) in 2014 was the basis for the calculations of the Prev. The information contained in the PHDR of the CatSalut on the number of DDD dispensed (HO3A: preparations of levothyroxine and HO3B: preparations of antithyroid medication) and the number of patients in treatment (NPT) was used. For the calculation of the prevalence based on the diagnoses, the "Minimum basic data set" registry of CatSalut was used, choosing the ICD-9 codes include 242 code for hyperT and in 244 and 243 codes for hypoT.
Results
The total of Catalan population insured in 2014 (from 0 to 108 years) was 7, 556 330 people. The global Prev of hypoT and hyperT based on NPT with levothyroxine or with antithyroid treatment was 3.07% and 0.14% respectively. The Prev of hypoT estimated by the registered codes 244 + 243 was 2.54%. The prev of hyperT based on the registered code 242 was 0.35%.
Conclusions
The Prev of hypoT is higher based on the PHDR than on the DR. The estimate of hyperT Prev is higher based on DR than on PHDR, probably because the subclinical hyperT is included in DR. Both the DR and the PHDR underestimate the Prev of both diagnoses (HypoT and HyperT) compared to cross-sectional studies of Spain and Catalonia. This discordance might be explained by the difficult record of subclinical dysfunction according to the ICD-9 (and also ICD-10).

Dysthyroid optic neuropathy in Grave's disease: two case reports

Júlia Vieira Oberger Marques, Caio Cesar Cervi Lagana, Neudir Frare Junior, Patrícia Oliboni Do Amaral, Marcela Robl, Débora Cristina Besen, Cleo Mesa Junior, Gisah Do Amaral & Hans Graf
Endocrinology and Metabolism Service, Hospital de Clínicas, Universidade Federal do Paraná (UFPR), Curitiba, Brazil.

Introduction
Ophthalmopathy is the most common extrathyroidal manifestation of Grave's disease, with 3–7% evolving to Dysthyroid Optic Neuropathy (DON), which requires urgent treatment to avoid permanent or progressive visual loss. We describe two cases of DON evaluated at Endocrinology and Metabolism Service of Paraná (SEMPR).
Case 1
Male, 70 years old, previously diagnosed with hypertension, type 2 diabetes with insulin use, microvascular complications and cataracts (corrective surgery 8 years before). Presented with 1 week history of visual loss, conjunctival hyperemia and bilateral periorbital edema to the ophthalmologist, treated with photocoagulation on the left eye for diabetic retinopathy. Progressive visual loss persisted, and the patient was admitted to the hospital for evaluation after NMR of the orbits was compatible with Grave's ophthalmopathy (bilateral periorbital muscle swelling). Endocrinology was consulted and laboratory showed TSH 0.00 mUI/ml (0.35–4.94), free T4 1.8 ng/dl (0.7–1.48), total T3 133.03 ng/dl (58–159) and TRAb 6.66 U/l (< 1.75); clinical evaluation demonstrate a CAS of 6, with visual acuity 20/200 on right eye and 0 on left eye. Pulse therapy with 1 g/d methylprednisolone was initiated, for 3 days, alongside with thiamazole 10mg/day. Patient was discharged for ambulatory treatment with 500mg methylprednisolone per week. Visual acuity improved to 20/60 and 20/160 at 3 g cumulative dose for right and left eye respectively, and 20/60 and 20/40 at 6 g, with a CAS of 3.
Case 2
Women, 44 years old, Grave's disease for 7 years in use of thiamazole 30 mg/day for the past 2 years reached our service with thyrotoxicosis symptoms and progressive visual loss for the past 2 years. Clinical evaluation revealed diffuse goiter, bilateral proptosis of 24 mm, divergent strabismus, CAS 1 (palpebral edema). Laboratory evaluation showed TSH < 0.005 U/l, total T3 133.73 ng/dl and free T4 1.87 ng/dl. Ophthalmology consultation showed reduced visual acuity bilaterally (20/400), lagophthalmos, diffuse keratitis, optic disc hypoplasia and important atrophy of the pigmented cells of retina. Pulse therapy with 1gr methylprednisolone a day was initiated, for 3 days, but without improvement, patient was referred for surgical decompression of the optic nerve. Improvement of the visual acuity was referred by the patient on the second post operatory day.
Conclusion
In order to prevent permanent visual loss, DON must be diagnosed and treated aggressively. Patient 1 showed improvement, but is still on activity, with a planned 8gr of cumulative dosing and reevaluation. Patient 2, probably because of the delay reaching proper treatment, needed decompressive surgery.

Conversion from thyroxine-treated autoimmune hypothyroidism to Graves' disease

Monica Livia Gheorghiu[1,2], Sofia Maria Lider Burciulescu[2], Mariana Purice[2] & Florin Alexiu[2]
[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania.

Graves' disease (GD) and Hashimoto's thyroiditis (HT) are both autoimmune thyroid diseases. While transition from GD to hypothyroidism has been more frequently reported, conversion of hypothyroidism to GD is uncommon. We describe a series of 3 patients diagnosed with HT and hypothyroidism, treated with L-thyroxine (LT4), who developed persistent hyperthyroidism with increased thyrotropin receptor antibodies (TRAb) levels and, in two of the patients, Graves' ophtalmopathy.
Case 1
A 46 year-old woman with primary hypothyroidism (TSH 169 mIU/l, normal values 0.5–4.5) treated for 3 years with LT4 50 μg/day, develops hyperthyroidism (TSH 0.013 mIU/l, FT4 2.69 pmol/l (0.6–1.76), TPOAb 260 U/ml (0–35), TRAb 27 IU/ml (< 1.75). Although LT4 was reduced and eventually discontinued, the patient developed mild unilateral exophthalmos and diplopia, with a normal-sized highly vascularized thyroid. She was treated with methimazole and i.v. methylprednisolone pulse-therapy. Her TSH level is still suppressed after 5 months.
Case 2
A 54 year-old woman with chronic hepatitis C, treated with pegylated interferon for 3 months, developed overt hypothyroidism with a small diffuse goiter 3 months after IFNα withdrawal (TSH 63.7 mIU/l, FT4 5.38 pmol/ml (10–28.2), TPOAb 3815 U/ml. LT4 was gradually increased up to 100 μg/day. Two months later, despite progressive LT4 withdrawal, the patient developed hyperthyroidism with mild bilateral exophthalmia (TSH < 0.005 mIU/l, FT4 39.6 pmol/l, TPOAb = 434 IU/ml, TRAb 15.5 IU/ml), increased homogenous uptake of ^{99}Tc pertechnetate at thyroid scintigraphy. On methimazole she had rapid oscillations of TSH levels and was treated with radioactive iodine 1 year later.
Case 3
A 39 year-old man with HT, hypothyroidism and intermittent mildly increased calcitonin levels (TSH 12.9 mIU/l, FT4 0.71 ng/dl (0.7–1.48), TPOAb > 1000 U/ml, calcitonin 9.01 pg/ml (1–8.4), with a small micronodular goiter, has been treated with LT4 50 μg/day for 14 months, when he developed progressive hyperthyroidism with increased ^{131}I uptake and TRAb 1.87 IU/ml (< 1.75). He was started on methimazole which normalized TSH levels in 5 months.
Conclusion
Conversion of LT4-treated hypothyroidism to GD is very rare (i.e. three cases in a 20 year- experience of a single clinician). Conversion of blocking- to stimulating-TRAb or distinct immune paradigms for GD and HT may account for this switch, while interferon treatment may be a trigger in some cases.

Cholestyramine: a useful therapeutic adjunct in severe thyrotoxicosis

Mohit Kumar
WWL Foundation Trust, Wigan, Greater Manchester, UK.

Case 1
A 32 year old fit and well female presented with symptoms of thyrotoxicosis and goitre. Her initial investigations revealed fT4 45 pmol/l (10–20) and fT3 26 pmol/l (3.5–6.5), with undetectable TSH. TSH receptor antibodies were positive. She was commenced on beta blockers and carbimazole and increased to 60 mg daily, with the fT4 improving only to 34.4 and fT3 to 13.8. Cholestyramine was commenced and titrated to a dose of 4 g twice daily, with resultant normalisation of free thyroid hormones levels. Vitamin D deficiency developed which was treated, but no coagulopathy. Planned thyroidectomy was reconsidered by the patient in view of the clinical response.
Case 2
A 39 year old male gave a history of Graves thyrotoxicosis 4 years earlier for which he was treated with carbimazole for 2 years before defaulting attendance. He represented with severe thyrotoxic symptoms affecting his physical, personal and professional life. Investigations showed fT4 61.6, fT3 29.4, TSH suppressed and TSH receptor antibodies positive. Despite 60 mg of carbimazole daily the fT4 improved only to 37.6 and fT3 to 16.4. Addition of cholestyramine was well tolerated and resulted in further improvements in thyroid hormone levels and considerable symptomatic improvement. Surgery is planned with Lugol's iodine pretreatment.
Discussion
Cholestyramine is a bile acid sequestrant that is predominantly used in the treatment of cholestatic pruritus and dyslipidaemias. The thyrotoxic state leads to an increased enterohepatic circulation, and cholestyramine can bind to thyroid hormones and lead to their increased excretion via the intestinal system. These two cases illustrate its clinical utility as a well tolerated adjunct to thionamides in severe thyrotoxicosis, and its use can buy time for more considered long term management.

Elevated level of serum calcitonin of unknown origin

Jitka Cepkova
Faculty Hospital, Hradec Kralove, Czech Republic.

We describe a case of a 59-years old man, in whom a thyroid nodule with a size of 16 mm and an elevated serum calcitonin level 29 ng/l (upper limit 21 ng/l) was incidentally found. The size of a nodule did not increase in time, serum level of calcitonin was stable and cytology from the nodule was benign. In January 2016, calcium stimulation test was performed with a positive result (baseline calcitonin 31.5 ng/l, stimulated calcitonin 417 ng/l), CEA was low. The patient was refered for thyroidectomy and after the surgery calcitonin level decreased to normal values, calcium test was negative. Histology revealed focal lymphocytic thyroiditis with macrofolicular hyperplastic nodule with regressive changes. Imunohistochemistry detected diffuse and locally nodular hyperplasia of C-cells with a strong expression of calcitonin.
Conclusion
C-cell hyperplasia with an increased secretion of calcitonin is considered to be a preneoplastic lesion associated with a medullary carcinoma of a thyroid gland. Its occurence can be sporadic, or familial in isolated forms or as a part of MEN syndrome. In our case, calcium stimulation test was helpful in differential diagnosis of an elevation of calcitonin of unknown etiology.

Prevalence of thyroid nodules in thyrotoxicosis detected in pregnancy

Ana Irigaray, Maria Dolores Ollero, Ana Iriarte, Amaya Sainz de los Terreros, Patricia Munarriz, Nerea Eguilaz, Ander Ernaga & Juan Zubiria
Hospital of Navarre, Pamplona, Spain.

Introduction
The aim of our study was to evaluate the causes of thyrotoxicosis detected during pregnancy as well as to determine the prevalence of thyroid nodular disease (TND) in our population and which factors are associated with this condition.
Methods
We performed a retrospective review of 1,760 patients between April 2014 and September 2017 remitted from the gynecology department due to thyroid dysfunction detected in the 9th week of pregnancy (universal screening of TSH). Among these patients, 131 presented thyrotoxicosis, defined as TSH <0.13 (reference range of TSH in the first trimester of gestation in our center: 0.13–4.16 mU/l). Patients with known TND ($n=9$), hyperemesis gravidarum ($n=5$) and multiple pregnancy ($n=17$) were excluded. All the patients received iodine supplementation during pregnancy. Thyroid function was evaluated throughout pregnancy and thyroid ultrasound was performed if the TSH remained decreased after the 20th week or if cervical palpation was abnormal. Comparisons within the group were done by T-student test or U-Mann Whitney using STATA program.
Results
Of the 100 patients studied, four were diagnosed with Graves' disease (TRAb-positivity) and 96 with gestational thyrotoxicosis (GT). Among patients with GT, the mean age was 34.3(5.4) years and there were 30 nuliparous (31.2%), 49 uniparous (51.1%) and 17 multiparous (gravidity ≥ 2, 17.7%). The sample consisted predominantly of Caucasians ($n=76$, 79.2%). The level of TSH in the first trimester was undetectable in 55.2% of patients. There was positive thyroid autoimmunity (defined as the presence of TgAb or TPOAb) in 16 patients (16.7%). There were 9 patients (9.4%) who had received treatment with *in vitro* fertilization. In 50 women, thyrotoxicosis was transient (TRAB-negativity, normal TSH $>$ 20th week and normal thyroid palpation). In the other cases ($n=46$), thyroid ultrasound was performed. Thyroid nodules (>2 mm) on ultrasonography were detected in 26 patients, (giving a TND prevalence of 56.5%), with 21 subjects having a nodule >10 mm. Fourteen women had clinically palpable nodules. Women with thyroid nodules were older (36.6 ± 4.9 vs 32.8 ± 5.0 yr, *P*:0.02) and had higher gravidity (*P*:0.04) compared with women having no thyroid nodules. The subject with TND also had higher positive rate of autoimmunity, (26.9% vs 5%, *P*:0.05). No difference in TSH and FT4 was detected throughout pregnancy.
Conclusions
The main cause of hyperthyroidism in pregnant women is gestational thyrotoxicosis. In our population, the prevalence of TND in these women is high, so ultrasound should be considered. TND is associated with older age, greater gravidity and positive autoimmunity.

Analysis of association of vitamin D receptor gene Cdx2 (rs11568820) polymorphism with autoimmune thyroid diseases

Adam Maciejewski[1], Michał J Kowalczyk[2], Teresa Gasińska[3], Waldemar Herman[4], Anna Szeliga[5], Jolanta Dorszewska[6], Ryszard Żaba[2] & Katarzyna Łęcka[1]
[1]Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznań, Poland; [2]Department of Dermatology and Venereology, Poznan University of Medical Sciences, Poznań, Poland; [3]Department of Internal Diseases and Oncological Chemotherapy, Medical University of Silesia, Katowice, Poland; [4]Outpatient's Unit of Endocrine Diseases, Wschowa, Wschowa, Poland; [5]Student Scientific Society, Poznan University of Medical Sciences, Poznań, Poland; [6]Department of Neurology, Poznan University of Medical Sciences, Poznań, Poland.

Introduction
Vitamin D is postulated to play a significant role in the immune system modulation and its deficiency has been reported in some autoimmune disorders. Polymorphisms of different vitamin D-related genes, among them vitamin D receptor gene (*VDR*), could either be a risk factor for autoimmune diseases. Therefore the aim of the study was to assess the association between *VDR* Cdx2 (rs11568820) polymorphism and autoimmune thyroid disease (AITD) among the Caucasian-Polish population.
Studied group
272 subjects diagnosed with AITD (mean age 50.55) and 119 healthy age and sex matched controls. AITD group comprised of 166 patients with autoimmune thyroiditis (AIT) and 106 patients with thyroid associated orbitopathy (TAO) in the course of Graves' disease. In the control group AITD and other autoimmune diseases or neoplasms were excluded.
Methods
Cdx2 polymorphism genotyping was performed with the use of real-time PCR with TaqMan probes, randomly selected samples were additionally analyzed by direct sequencing. The statistical significance of differences in allele and genotype distribution between AITD and controls, as well as in subgroups of AITD were evaluated by χ^2 or Fisher's exact test, where appropriate. A *P* value of <0.05 was considered significant.

Results
Observed allele frequencies were in Hardy-Weinberg equilibrium, except of TAO subgroup. In both AITD and the control group G allele and GG homozygote predominated, as expected for Caucasian population. The observed allele and genotype frequencies did not differ significantly between AITD and controls ($P=0.30$ and $P=0.56$, respectively). When analyzing AIT vs. controls, differences in allele or genotype distribution were also not significant ($P=0.41$ and $P=0.54$, respectively). In TAO group frequency of genotype AA was higher comparing to controls (6.60% vs. 1.68%), but without statistical significance ($P=0.09$; OR $=4.14$; 95% CI: 0.89–19.96). We also analyzed TAO vs. AIT and found significantly higher AA homozygote in TAO group comparing to AIT (6.60% vs. 1.20%; $P=0.03$; OR $=5.80$; 95% CI: 1.25–27.9).
Conclusions
There is no statistically significant difference in allele or genotype distribution of *VDR* Cdx2 polymorphism between AITD and the control group and between AIT or TAO and the control group among the Caucasian-Polish population. However, we found that TAO patients differed significantly from AIT group in *VDR* Cdx2 genotype distribution.

P1107

A case of severe hypothyroidism, correcting to euthyroidism through Graves' disease associated with refractory thyroid eye disease

Ali Al Nasser[1], Nida Chammas[2] & Natalie Maalouf[3]
[1]Royal College of Surgeons in Ireland, Manama, Bahrain; [2]Bupa Cromwell Hospital, London, United Kingdom; [3]University of Oxford, Oxford, UK.

A 54-year-old female presented to the neurologist in December 2017 with neuromuscular right arm weakness, lethargy and fascial swelling. She had a normal MRI head before being referred to the endocrine clinic with a TSH >125 mIU/l (0.27–4.2 mIU/l). Free T4 was 0.3 pmol/l (12.0–22.0) with a free T3 of <0.4 pmol/l (3.1–6.8). The thyroglobulin antibody was 1366 IU/ml (0–115) with a normal thyroid peroxidase level (TPO) 29.7 (0–34). No previous thyroid disease or a preceding viral illness and no thyroid eye signs. A thyroid ultrasound scan showed features consistent with autoimmune thyroiditis. She was diagnosed with primary autoimmune hypothyroidism and treated with levothyroxine 100 mcg daily with resolution of her neuromuscular weakness. She was discharged in June 2016. She presented in June 2017 to the ophthalmologist with a 3-month history of periorbital oedema. She had a TSH$<$ 0.01, free T3 10.03, free T4 36, TPO 13.25, TG Ab 3508 and a TSH receptor antibody >40 (0–0.8) IU/l indicative of Graves' disease. Levothyroxine was stopped and a thyroid ultrasound scan showed the thyroid gland was markedly heterogeneous with a mildly increased doppler vascularity. A technetium scan showed increased uptake (1.7%) in the right thyroid lobe relative to the left (0.8%). The patient was clinically euthyroid with some mild periorbital oedema. Carbimazole 5 mg was commenced in view of the suppressed TSH and an MRI of the orbits showed diffuse enlargement of extraocular muscles with bilateral proptosis, compatible with thyroid ophthalmopathy. Her thyroid eye disease was refractory to IV methylprednisolone 4.5 g over a period of 12 weeks. She proceeded to radiotherapy with some initial response and may require orbital decompression. At present, she remains off Carbimazole and levothyroxine (TSH 4.14, free T3 3.3, free T4 10.6, TG Ab 913).

Changes of visfatin/NAMPT serum concentration and its leukocyte expression in hyperthyroidism

Nadia Sawicka-Gutaj[1], Ariadna Zybek-Kocik[2], Michal Kloska[3], Agata Czarnywojtek[1,4], Jerzy Sowinski[1], Bartlomiej Budny[1], Kosma Wolinski[1], Katarzyna Ziemnicka[1], Dorota Mankowska-Wierzbicka[5] & Marek Ruchala[1]
[1]Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland; [2]Department of Endocrinology, Metabolism and Internal Medicine, Poznan Univeristy of Medical Sciences, Poznan, Poland; [3]Department of Gastroenterology, Internal Medicine, Metabolic Diseases and Dietetics, Poznan University of Medical Sciences, Poznan, Poland; [4]Department of Pharmacy, Poznan Univeristy of Medical Sciences, Poznan, Poland; [5]Department of Gastroenterology, Internal Medicine, Metabolic Diseases and Dietetics, Poznan Univeristy of Medical Sciences, Poznan, Poland.

Purpose
The aim of the study was to investigate changes of visfatin/NAMPT serum concentration and its leukocyte expression in hyperthyroid patients.
Material and methods
The study was designed as a single-center, cross-sectional with consecutive enrollment. We included all patients with newly diagnosed overt hyperthyroidism (Graves' disease or toxic nodular goiter). Each subject underwent physical examination, laboratory investigation, body composition analysis, and thyroid ultrasound. *NAMPT* mRNA leukocyte expressions were measured using RT-qPCR.
Results
Initially, 173 patients were eligible for the study, and due to exclusion criteria 95 were enrolled in further analysis (67 patients with Graves' disease (GD) and 28 with toxic nodular goiter (TNG)). Forty three healthy volunteers adjusted for age, sex and BMI served as a control group. We found higher NAMPT/visfatin serum concentration in patients with GD than in patients with TNG ($P=0.03855$). *NAMPT* leukocyte expression was significantly higher in GD patients ($n=32$) as compared to TNG patients ($n=18$) and euthyroid controls ($n=24$)($P=0.005965$). Simple linear regression analysis revealed that NAMPT/visfatin serum concentration was significantly associated with *NAMPT* leukocyte expression, thyroid autoimmunity, age, HOMA-IR, and fat mass percentage (FM%). *NAMPT* leukocyte expression was associated with thyroid autoimmunity, age, and TRAb levels. The stepwise multiple regression analysis confirmed FM%, HOMA-IR as independent predictors of visfatin/NAMPT serum levels. In a separate stepwise e multiple regression analysis, we confirmed the association between *NAMPT* leukocyte expression and TRAb levels.
Conclusions
We found that visfatin/NAMPT serum elevation in hyperthyroid patients is related to fat mass percentage together with HOMA-IR. Observed *NAMPT* leukocyte overexpression in GD patients and its association with TRAb levels suggest potential involvement of visfatin/NAMPT in pathogenesis of thyroid autoimmunity.

Congenital hypothyroidism: genes involved in organogenesis disorders

Rim Chaabane[1], Imen Gargouri[2], Faten Hadjkacem[2], Houssem Mrabet[2], Mouna Elleuch[2], Dorra ghorbel[2], Mouna Mnif[2], Nadia Charfi[2], Neila Belguith[1] & Mohamed Abid[2]
[1]Genetic Lab of Medecine Faculty, Sfax, Tunisia; [2]Endocrinology Department, Sfax, Tunisia.

Introduction
Congenital hypothyroidism (CH) is the most common congenital endocrine disease since it affects 1/3000–1/4000 births. The involvement of genetics is no longer discussed and several genes have been implied in the different clinical forms of thyroid dysgenesis.
Patients and methods
We report ten cases of thyroid dysgenesis collected at the pediatric and endocrinology departments of Sfax in Tunisia. The diagnosis was based on clinical, biological, morphological investigations of the thyroid gland. To investigate genetic abnormalities involved in the onset of CH in Tunisian families, first, we investigated the case of non-syndromic CH, by looking for mutations in the TSHR gene. Then we look for correlation genotype – phenotype for this gene and other genes involved thyroid development.
Results
Our study consisted of six girls and four boys of 22 months average age at the time of diagnosis. Parental consanguinity was noted in 80%. Three cases of familial form were recored with an autosomal recessive mode of transmission for two and autosomal dominant for the remaining case. The signs of dysthyroidism and delayed stature were the main circumstances of discovery. The non-syndromic form was the most common form. The syndromic associations noticed in the remaining cases were renal impairment, facial dysmorphism. Biologically, thyroid status confirmed peripheral hypothyroidism in all cases. At the end of this assessment, five of our patients had hypoplasia suggestive of TSH resistance syndrome. A mutation of the TSHR is evoked for four4 of these patients. However the molecular analysis TSHR revealed a known polymorphism (c.561T> C (rs 2075179) in exon 7 of the TSHR gene in a homozygous state in a patient with CH and in a heterozygous state in a another patient. No mutation was revealed at that time and the study of other exons is still being analyzed. For the remaining case, resistance to TSH due to Gs protein deficiency was strongly suspected in the presence of pseudohyperparathyroidism. For the three cases of ectopia, the NKx2-5 and TTF-2 genes can be incriminated. A mutation of the PAX8 gene is strongly suspected in association with a renal

anomaly in one case. For the facial dysmorphism noticed in one case, we will complete with FISH study in search of microdeletion7q11.23.
Conclusion
In this work, we have illustrated the contribution of molecular diagnosis of thyroid dysgenesis to establish adequate genetic counseling for families at risk in the lack of systematic neonatal screening.

Technique of recurrent laryngeal nerve liberation for phonation recovery
Radan Dzodic[1,2], Ivan Markovic[1,2], Nada Santrac[1], Marko Buta[1,2] & Silvana Lukic[3]
[1]Surgical Oncology Clinic, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia; [2]Medical Faculty, University of Belgrade, Belgrade, Serbia; [3]Department of Pathology, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia.

Background
Recurrent laryngeal nerve (RLN) injury is a major complication in thyroid surgery. It occurs more frequent during operations and reoperations of thyroid cancer and recurrent goiter. Techniques of nerve liberation and reconstruction can provide improvement in phonation, even complete voice recovery. The aim of this study was to analyze usefulness of the RLN liberation technique through level of improvement of symptoms after reoperation on patients who had injury of RLN during previous surgery.
Methods
From 2000 to 2017, we performed reoperations for RLN liberations in 18 patients who had RLN paresis/paralysis on laryngoscopy after initial surgical treatment. Reoperations were performed 2 months to 16 years after RLN injury. The *original Dzodic's technique* (first reported in 2008, published in *World J Surg in 2016*) consists of removing misplaced ligations, granulomas or adhesions from nerves, with its preservation. We use intraoperative neuromonitoring to asses RLN function intraoperatively. After surgery, voice quality was assessed by qualitative scoring system and laryngoscopy in 1st, 6th and 12th postoperative month.
Results
Majority of patients had oncological indication for reoperation. Six patients had reoperation for alleviating the symptoms of severe dysphonia or stridorous breathing. In two patients that had bilateral RLN paralysis and high risk for urgent tracheostoma, we performed a two-step surgery: 2 and 6 months after injury. RLN liberations provided complete voice recovery within 3 weeks in all patients. In 15 patients, score 4 on perceptual voice quality scale was achieved. Three patients, who had RLN liberation 6 months, 3 years and 16 years after the injury, restored normal vocal cord movements on laryngoscopy (score 5). One of them had injury of the non-recurrent laryngeal nerve.
Conclusion
The *original Dzodic's technique of RLN liberation* enables patients with paresis/paralysis due to surgical RLN injury a significant improvement in phonation, even complete voice recovery.

Intrathyroidal cyst with squamous metaplasia
Dubravka Brdar, Gordana Soso, Ana Baric, Sanda Sladic, Tina Majstorovic & Ante Punda
Department of Nuclear Medicine, University Hospital Split and Split University School of Medicine, Split, Croatia.

The occurence of multiple squamous cells in thyroid fine needle aspirate is rare.
Aim
We report a case of multiple squamous cells in thyroid aspiration specimen in a patient with chronic lymphocytic thyroiditis.
Case report
A 56-year-old woman has been observed for several years because of chronic lymphocytic thyroiditis and hypothyroidism. She was on levothyroxine supstitution therapy. Six years ago ultrasonography revealed inhomogeneous thyroid, predominantly hypoechogenic with hypoechogenic nodule, measuring 15 mm in diameter, in the right lobe close to isthmus. The FNAC of that nodule revealed chronic lymphocytic thyroiditis. Four months ago we performed control ultrasonography: hypoechogenic, cystic nodule in the right lobe close to isthmus measured 8×9×8 mm. A sonographically guided fine-needle aspiration yielded 1 ml of yellowish material and cytological analysis revealed multiple squamous cells, colloid, macrophages single and in clusters.
Conclusion
Our opinion is that multiple squamous cells in this case originated from metaplasia and degeneration, because fine needle aspiration 6 years ago of the same nodule revealed only chronic lymphocytic thyroiditis.

Levothyroxine absorption test: a safe help for difficult cases
Ana Lopes[1], Maria Teresa Pereira[1], Pedro Lito[2], Cláudia Freitas[1], Sofia Teixeira[1] & Helena Cardoso[1]
[1]Serviço de Endocrinologia, Centro Hospitalar do Porto, Porto, Portugal; [2]Serviço de Medicina Interna, Centro Hospitalar da Cova da Beira, Covilhã, Portugal.

Levothyroxine (L-T4) is the mainstay of treatment of hypothyroidism. Marked elevation of thyrotropin (TSH) in patients on high replacement doses is rare and can result from malabsorption, drug interaction or poor compliance. The levothyroxine absorption test is required to distinguish these causes and has proved to be safe. This test measures the serum free thyroxine (FT4) response to 1 mg of oral L-T4 over 4–24 h.
Clinical cases
Case no 1: A 28-year-old woman presented with congenital primary hypothyroidism, being supplemented since the neonatal period. She has no other relevant medical history and denies additional medications. Review of old records revealed marked elevation of TSH despite L-T4 supplementation at progressively higher doses. In October 2017 she had TSH 182 μUl/ml while taking 112 mcg daily of L-T4 (1.5 mcg/kg). The patient reported taking L-T4 every morning in the fasting state. We performed the L-T4 absorption test with 1 mg of L-T4: TSH 33,3 μUl/ml and FT4 1,01 ng/dl at baseline; TSH 32,1 μUl/ml and FT4 2,12 ng/dl after 4 h. This result confirmed the diagnosis of non-adherence.
Case no 2: A 36-year-old woman with primary hypothyroidism (antibody-negative thyroiditis) presented with uncontrolled hypothyroidism. She has history of Sjogren's syndrome. Medications in addition to L-T4 include hydroxychloroquine, methotrexate and folic acid. In December 2017 she had TSH 58.5 μUl/ml while taking 375 mcg daily of L-T4 (5.3 mcg/kg). She reports taking the levothyroxine regularly in the fasting state. The possibility of a malabsorption state was considered. Autoimmunity for celiac disease was normal, but gastric parietal cell antibodies were positive. Vitamin B12 levels were normal. Although it is recognised that there may be an increased need for L-T4 in patients with atrophic gastritis, this patient is already taking a very high dose. We are going to perform a L-T4 absorption test to exclude non-adherence.
Conclusion
The levothyroxine absorption test allows to distinguish between malabsorption and non-adherence. This test may be particularly useful in cases where malabsorption and noncompliance are likely to explain the failure of therapy. Testing over 4 h offers a safe alternative to longer protocols.

Pasireotide and Graves' orbitopathy: outcome in terms of efficacy compared to parenteral metilprednisolone; a pilot study
Rosario Le Moli[1], Carlotta Castoro[1], Maarten Mouritz[2] & Maarten Souters[2]
[1]Department of Clinical and Experimental Medicine University of Catania, Catania, Italy; [2]Academical Medical Center – University of Amsterdam, Amsterdam, Netherlands.

Objective
Graves' orbitopathy (GO) is an autoimmune disease that affects about 25% of the patients with Graves' disease. The thyrotropin receptor (TSHR) is the main autoantigen of GO. Somatostatin receptors (SSR) are expressed by orbital fibroblasts (OB) of GO patients. Pasireotide (SOM230) is a somatostatin analog that has a great affinity for the type 1 and type 5 SSRs and inhibits both orbital human lymphocyte and OB proliferation in vitro. Therefore it is interesting to investigate the effect of SOM230 on predefined endpoints in patients with active moderate to severe GO (MSGO).

Methods
This pilot study evaluated 10 patients with active MSGO treated with SOM230 compared to 10 patients with MSGO treated with methylprednisolone (MPNS). They received 4500 mg of intravenous MPNS or 180 mcg of SOM230 for 12 weeks. Clinial endpoints and quality of life (GOQUOL) were evaluated at time 0 and at 12 weeks. GO activity scored by clinical activity score (CAS) was evaluated at time 0, after they received about half of SOM230 or MPNS total dose and at 12 weeks.
Results
The efficacy of SOM230 and MPNS was similar accordig to overall clinical criteria evaluation and GOQUOL: in both groups 50% and 60% of patients improved respectively. Eyelid aperture improved in the SOM230 group compared to the MPNS group althougth not significantly: $-0.7(-2–4.5)$ vs. $-0.15(-3–2)$, $P=0.7$. Hertel absolute decrement was not different in the MPNS group compared with the SOM230 group: 0.75 ± 0.8 vs 0.67 ± 0.7, $P=0.7$, Hertel improved in 3(30%) patients of MNPS group, no patients improved in SOM230 group according to a single point clinical evaluation. CAS absolute decrement at 12 weeks was not different between the groups: -2 (3.2) vs -2 (1.2), $P=0.6$.
Conclusions
SOM230 showed to be as effective as MPNS to improve GO clinical signs and symptoms in MSGO patients when evaluated by overall clinical criteria.

Prediabetes and cardiovascular risk factors in patients with autoimmune thyroiditis

Celestino Neves[1,2], Sofia Castro Oliveira[1,2], João Sérgio Neves[1,3], Oksana Sokhatska[4], Miguel Pereira[1], Ana Oliveira[1], José Luís Medina[5], Luís Delgado[4] & Davide Carvalho[1,2]
[1]Department of Endocrinology, Diabetes and Metabolism, São João Hospital Center, Porto, Portugal; [2]Instituto de Investigação e Inovação em Saúde da Universidade do Porto, Porto, Portugal; [3]Department of Surgery and Physiology, Cardiovascular Research Center, Faculty of Medicine, University of Porto, Porto, Portugal; [4]Service and Laboratory of Immunology, São João Hospital, Faculty of Medicine, University of Porto, Porto, Portugal; [5]Faculty of Medicine of University of Porto, Porto, Portugal.

Introduction
Thyroid hormones modulate the insulin sensitivity and glucose metabolism. The interrelation between thyroid autoimmunity, thyroid function, glucose metabolism and cardiovascular risk factors remains uncertain.
Methods
We recorded thyroid function tests, BMI, IR markers comprising the Homeostasis Model Assessment for insulin resistance (HOMA-IR and HOMA-B), the Quantitative Insulin Sensitivity Check Index (QUICKI), HISI (Hepatic Insulin Sensitivity Index), WBISI (Whole-Body Insulin Sensitivity Index), IGI (Insulinogenic Index) and the levels of total cholesterol (TC), HDL, LDL-cholesterol, triglycerides (TG), apolipoprotein B (ApoB), ApoA1, lipoprotein (a) (Lp[a]), homocysteine, CRP (C-reactive protein), folic acid and vitamin B12 levels, in 354 patients with AIT, 93.5% woman, with a mean age of 46.0 ± 15.5 years. A 75-g OGTT was performed and measurements of plasma glucose, insulin, and C-peptide were obtained. Statistical analysis was performed with the Mann-Whitney test and the Spearman's correlations test. A two-tailed $P\leq0.05$ was considered significant.
Results
After dividing the OGTT sample in 3 groups (IFG-16.6%, IGT- 24.2% and diabetes DM-9.6%), we found that patients with IFG had significantly higher levels than IGT patients in homocysteine (9.50 ± 2.09 vs 7.24 ± 1.33 µmol/l; $P=0.002$) and HOMA-IR (3.86 ± 2.76 vs 2.14 ± 1.00; $P=0.01$). The levels of CRP were significantly higher among patients with prediabetes comparing with normoglycemic patients (0.552 ± 1.053 vs 0.346 ± 0.467 mg/dl, $P=0.003$). In patients with prediabetes, we found lower levels of HISI (120.63 ± 289.16 vs 59.00 ± 65.91, $P<0.001$) and WBISI (7.30 ± 5.66 vs 4.06 ± 2.67, $P<0.001$), and higher levels of IGI (0.57 ± 0.38 vs 1.16 ± 0.77, $P<0.001$). Patients with prediabetes presented higher levels of TC (211 ± 49 mg/dl vs 196 ± 35 mg/dl, $P=0.016$) and LDL (133 ± 37 mg/dl vs 120 ± 28 mg/dl, $P=0.002$). In the whole sample we observed significant correlations between TSH and insulin ($r=0.20$; $P=0.02$), total cholesterol ($r=0.10$, $P=0.04$) and apoB ($r=0.18$, $P=0.02$). In the IFG group we found significant correlations between FT3 and TC ($r=-0.53$; $P=0.01$), LDL ($r=-0.57$; $P=0.006$) and ApoB ($r=-0.53$; $P=0.03$). In IGT group we detected correlations between insulin and CRP ($r=0.61$; $P=0.002$), and between homocysteine and anti-TPO antibodies ($r=0.46$; $P=0.02$).
Conclusions
In patients with AIT, the presence of prediabetes is associated with higher cardiovascular risk. The screening of prediabetes with OGTT may be important in this group of patients to stratify the cardiovascular risk.

The significance of rare genetic variants in the thyroid autoimmunity – brief review and our own results on *SLC26A4* variants in Hashimoto's thyroiditis

Agata Jabrocka-Hybel[1], Anna Skalniak[1], Jakub Piętkowski[2] & Alicja Hubalewska-Dydejczyk[1]
[1]Department of Endocrinology Jagiellonian University Medical College, Krakow, Poland; [2]Unit of Endocrinology, University Hospital in Krakow, Krakow, Poland.

Identified genetic players for most common diseases are not sufficient to explain their heritability. This situation is known as the missing heritability problem. One among the possible explanations is the impact of rare variants. We present our own results of rare variants in the gene *SLC26A4* in Hashimoto's thyroiditis (HT), which were not found in controls, and therefore confirm the possibility of their impact on this disease. We genotyped 147 Hashimoto's thyroiditis cases (10.2% men) and 147 controls (13.6% men) matched for age, gender, marital status, education, monthly income, and size of the city they live in. The gene *SLC26A4* encoding for a iodine transporter was Sanger-sequenced in 20 HT cases, in order to identify new rare variants in this gene. We identified 2 new variants, which have not been previously reported. Two among the investigated SNPs were not differentially represented in both groups: c.-103T>C, previously associated with Pendred syndrome, and c.1708-18T>A, previously proven as benign. In contrast, variants located in the coding region, which have previously been assigned as benign or likely benign. Those included p.Ser190Arg ($n=4$ cases), p.Ile300Leu ($n=3$), p.Phe354Ser ($n=3$), p.Ala456Ala ($n=2$), p.Leu597Ser ($n=4$), p.Val609Gly ($n=2$) and p.Asp772Tyr ($n=1$). It seems very probable that rare variants are at least one of the reasons for missing heritability. It seems possible that the variants we identified in HT may play a joint role in HT, as most of them co-occurred in the same patients. Future studies should target genome-wide rare variants, as probably different genes will have a combined role in the risk of those diseases.

High dose metformin in obese PCOS patients with subclinical hypothyroidism

Aurelian Emil Ranetti[1,2] & Anca Pati Cucu[1]
[1]"Dr. Carol Davila" Central University Emergency Military Hospital, Bucharest, Romania; [2]"Carol Davila" University of Medicine and Pharmacy, Endocrinology Department, Bucharest, Romania.

Background
Polycystic ovarian syndrome (PCOS) diagnosis is set based on Rotterdam criteria, including hyperandrogenism, chronic anovulation and typical ultrasound appearance. 65–70% of women with PCOS have insulin resistance. Metformin, an oral antidiabetic agent, was the first drug used to treat insulin resistance in PCOS patients.
Material and method
Twenty non-diabetic women between 25–35 years old, with PCOS untreated prior to presentation, with a BMI >30 kg/m^2, were included in our study. Ovarian, thyroid ultrasound, BMI, TSH, fT4 levels were evaluated at baseline, at 3 and 6 months of treatement. All patients received metformin administered daily on a weekly increased dose up from 500 mg/day to a total of 2 g/day. 9 patients had subclinical hypothyroidism (SCH) (TSH levels 4.5–6 mUI/l). 11 patients were euthyroid. None of the patients had received levothyroxine treatment before the inclusion in our study. None of the patients were on a meat and dairy free diet.
Results
TSH levels decreased from a median of 4.9 mUI/ml at baseline to a 2.8 mUI/l after 3 month of treatment. Levothyroxine was added after 3 months of treatement in 4 of the patients (TSH >4.5 mUI/l). At 6 months all SCH patients had normal TSH levels (<3.1 mUI/l). No significant changes in TSH levels were noticed in euthyroid patients.

Conclusions
Metformin use induced an TSH lowering effect in obese patients with PCOS and SCH, reducing the need for levothyroxine replacement in selected patients.
Keywords: metformin, pcos, subclinical hypothyroidism.

Selenium supplementation and progression of Graves orbitopathy

Zelija Velija Asimi[1,2], Azra Burekovic[3,4], Amela Dizdarevic-Bostandzic[3,4], Amina Godinjak[3] & Amela Tuco[3]
[1]Faculty of medicine, University of Sarajevo, Sarajevo, Bosnia and Herzegovina; [2]Polyclinic and Daily Hospital "dr Al Tawil", Sarajevo, Bosnia and Herzegovina; [3]Clinical Centre University of Sarajevo, Sarajevo, Bosnia and Herzegovina; [4]Faculty of Medicine, University of Sarajevo, Sarajevo, Bosnia and Herzegovina.

Selenium (Se) is a micronutrient of vital importance to human health. It acts as an antioxidant, immunomodulator and also it is involved in the control of specific endocrine pathways. In adults, the thyroid is the organ with the highest amount of selenium per gram of tissue. The literature suggests that selenium supplementation of patients with Hashimotos thyroiditis is associated with a reduction in antithyroperoxidase antibody levels. Selenium supplementation also in mild Graves orbitopathy is associated with delayed progression of ocular disorders. The aim of this work is to evaluate the effect of selenium supplementation on progression of Graves Orbitopathy.
Design
An open-label, randomized controlled study was performed in 40 Graves-Basedows disease patients with mild form of Graves orbitopathy (GO) divided in to two groups: 1) Selenium group patients ($n=18$) received methimazole and selenium 200 ug for 6 months and 2) Control group patients ($n=22$) received methimazole alone for 6 months. Methimazole was discontinued at 24 weeks in euthyroid patients.
Results
After six months of treatment 12 of 18 (66.6%) in selenium group and 7 of 22 (31.8%) had no progression of orbitopathy (OR 1.18; $P<0.05$). Serum levels of free triiodothyronine/free tetraiodothyronine, thyroid-stimulating hormone receptor antibody, prevalence of moderate to severe Graves orbitopathy, thyroid volume were significantly lower in group treated with selenium than in control group after six months of treatment.
Conclusion
These results indicated that methimazole and selenium combination is more effective in reduction of Graves orbitopathy than the methimazole monotherapy.
Keywords: Graves orbitopathy, Hashimoto thyroiditis, selenium supplementation.

Mixed medullary–papillary carcinoma of the thyroid: a case report

Rym Belaid, Amel Jaidane, Insaf Oueslati, Chadia Zouaoui & Haroun Ouertani
Department of Endocrinology, Military Hospital of Tunis, Tunis, Tunisia.

Introduction
The coexistence of two types of tumors of different origins in the same thyroid is a rare phenomenon. Its etiopathogenesis remains unknown. We report the case of a mixed papillary and medullary carcinoma of the thyroid revealed by a compressive goiter.
Case report
A 70-year old woman with a history of right lobo-isthmusectomy for a toxic solitary adenoma, presented 30 years later with a chief complaint of a cervical mass accompanied by difficulty in swallowing. Her family history was free of any endocrine or non-endocrine malignant tumors. On physical examination, she had a left thyroid nodule of 4 cm in the greatest dimension without palpable cervical lymph nodes. Laboratory tests indicated hyperthyroidism with a decreased TSH of 0.002 μUI/ml and an increased free T4 of 26.6pmol/l. Thyroid scintigraphy showed a toxic multiheteronodular goiter. Cervico-thoracic CT scan showed an intrathoracic goiter exerting a mass effect on the trachea and the esophagus. The serum calcitonin assay was not performed preoperatively. The patient underwent a left thyroid lobectomy without lymph node dissection. Permanent histopathologic analysis revealed mixed papillary and medullary thyroid carcinoma in a multinodular adenomatous goiter. The immunohistochemical study confirms the histopathological examination by showing a calcitonin and a thyroglobulin staining. The patient was planned for a cervical lymph node dissection followed by a radioiodine therapy.
Conclusion
The simultaneous occurrence of medullary and papillary thyroid cancer is the result of a simple coincidence due to the high frequency of papillary micro carcinomas of the thyroid. This case illustrates the importance of the thyrocalcitonin assay in presence of any thyroid nodule.

Epidemiology of thyroid nodules in the United Arab Emirates: five-years tertiary center analysis

Eiman Alseddeeqi[1], Raqwana Baharoon[1], Abeer Al-Helali[1], Rawia Mohamed[1], Jinan Ghaith[1] & Luai Ahmed[2]
[1]SKMC, Abu Dhabi, UAE; [2]CMHS, Al Ain, UAE.

Background
Thyroid malignancy is the sixth common cancer type in the United Arab Emirates (UAE) where its incidence is increasing worldwide. There are no epidemiological data outlining the prevalence of cancer in thyroid nodules, nor previous analysis of ultrasonographic features correlating with thyroid malignancy in the UAE.
Aim
To report the prevalence of thyroid malignancy in thyroid nodules and correlate it with demographic data. A secondary aim is to define some ultrasonographic features that could predict thyroid malignancy.
Methods
Retrospective electronic medical records review of patients with thyroid nodules aged 18–80 years with a normal TSH who underwent ultrasound guided fine needle aspiration biopsy (UG-FNA) at Sheikh Khalifa Medical City (SKMC) during 2011–2015.
Results
A total of 573 nodules with normal Thyroid Stimulating Hormone (TSH) underwent UG-FNA cytological examination. Nodules were more frequent in females (59.2%) between 30–49 years of age and in males, (48.4%) between 40–59 years of age. The overall crude prevalence of thyroid cancer in thyroid nodules was 8.8% (95% Confidence Interval (CI) 6.5%–11.2%). The prevalence was 8.3% (95% CI 5.8–10.8) in females and 11.9% (95% CI 5.0–18.8) in males. The prevalence among UAE nationals, Arabs, and Far East Asians was 8%, 9.5% and 13.3% respectively. Classical papillary thyroid cancer was found in 46.9% of all cancerous nodules. Of all malignant nodules, 36.2% were complex and 36.2% were of hypoechoic echogenicity. 41.7% of cancerous nodules were between 2–4 cm size.
Conclusion
Cancer rate was higher in males (11.9%) compared to that in females (8.3%). Among the heterogenous population in the UAE, East Asians had the highest prevalence malignancy in examined thyroid nosules. The most common histological type is papillary thyroid cancer. Ultrasonographic features associated with malignancy are nodular size between 2–4 cm and echogenicity of either hypoechoic or complex.

Thyroid ultrasonographic characteristics and Bethesda results after FNAB

Fotini Kanouta[1], Eleni Triantafillou[1], Georgios Papadakis[2], Styliani Kalaitzidou[1], Aspasia Drosou[1], Aggeliki Sapera[1], Dimitra Tampouratzi[1], Michalis Kotis[1], Taxiarchis Kyrimis[1], Anna Drakopoulou[1], Victoria Kaltzidou[1], Eirini Veniou[1], Chrysa Karavasili[1], Styliani Plyta[3] & Athanasia Tertipi[1]
[1]Endocrinology Department, Metaxa Anticancer Hospital, Piraeus, Greece; [2]STEPS Stoffwechselzentrum, Biel/Bienne, Switzerland; [3]Cytology Department, Metaxa Anticancer Hospital, Piraeus, Greece.

Objectives
Fine needle aspiration biopsy (FNAB) is the initial investigation of choice for thyroid nodules. The Bethesda System (B) classifies thyroid cytological patterns into six categories (B1-6) according to risk for malignancy.
Methods
A total of 1113 patients (210 males/903 females) underwent FNAB for the same number of thyroid nodules. Their mean age was 56.2 ± 21.6 years $\pm$ S.D. We

correlated the demographic profile (age and gender) and sonographic features of these nodules with the FNAB outcome. The Bethesda system for reporting thyroid cytopathology was used.
Results
Out of total 1113 cases, 255 (22.9%) cases were diagnosed as non diagnostic (B1), 780 (70.1%) were diagnosed as benign (B2), 35 (3.1%) as B3 (atypia/follicular lesion of undetermined significance), 10 (0.9%) as B4 (follicular neoplasm or suspicious for follicular neoplasm), while 13 (1.2%) cases were categorized as B5 (suspicious for malignancy) and 20 (1.8%) as B6 (malignant). Remarkably, 11 nodules of 33 of category B5 and B6 each had a maximum diameter of less that 1 cm. When comparing benign result (B2) vs. result of category B3–6 irregular shape (6.5% in B2 vs. 15.4% in B3–6, $P=0.004$), ill-defined margins of the nodule (10.6% in B2 nodules vs. 20.5% in B3-6 nodules, $P=0.033$), the presence of calcifications (24.2% in B2 nodules vs. 65.4% in B3-6 nodules, $P<0.001$) and the hypoechogenity of nodule (41.9% in B2 vs. 65.4% in B3-6, $P<0.001$) decreased significantly the possibility for benign (B2) result, whereas features such as the size of nodule, the presence of central vascularity, the composition and the heterogeneity of parenchyma did not affect the possibility for B2 vs. B3–6 result ($P>0.05$). Finally, there was no association of gender and age with the Bethesda category result.
Conclusions
Our study supports that the irregular shape of a nodule, ill-defined margins, the presence of calcifications and the hypoechogenenity of a nodule decrease the possibility of a Bethesda benign result. FNAB of nodules <10 mm may reveal suspicious or positive for malignancy cytology.

The diagnostic value of elastography score and strain indexfor the evaluation of thyroid micronodules

Erman Cakal[1], Melia Karakose[1], Ilknur Unsal[1], Mustafa Sahin[2], Bekir Ucan[1] & Mustafa Ozbek[1]
[1]Diskapi Training and Research Hospital, Ankara, Turkey; [2]Ankara University, School of Medicine, Ankara, Turkey.

Background and aim
In the general population, the frequency of thyroid micronodules is increasing and the prevalence of malignancy is higher in nodules at this size. The ultrasonographic features of these nodules are neither spesific nor sensitive Elastography gives information about the degree of hardness at the tissue level and provides assessment of malignancy risk of the nodule. The aim of the study was to investigate the diagnostic value of elastography in patients with thyroid micronodules.
Methods
Two hundred and twenty-four patients with thyroid micronodules were recruited in this prospective study. All patients underwent a thyroid fine-needle aspiration biopsy (FNAB). Elastography scores and indexes were measured with real-time ultrasound elastography (Preirus HV machine with 13 MHz linear transducer).
Results
The outcome of our study shows that malignant micronodules compared the bening micronodules, malignant micronodules were with higher elastography scores (ES) and strain indexes (SI) values ($P<0.001$). When we use ES to diagnose malignancy that ES is >3 providing 79.4% sensitivity and 98.1% specificity for diagnosing malignancy. The area under the curve (AUC) for the ES was 0.888 ($P<0.001$). The best cut-off point for strain index which differentiates benign from malignant micronodules was 3.06 with 98% sensitivity, 91% specificity. AUC for the SI was 0.970 ($P<0.001$).
Conclusions
Elastography score and strain ratio of the thyroid micronodules are beneficial markers during malignancy investigation. According to our study, the strain index is better than elasto score when assessing the malignancy in thyroid micronodules.

Radiofrequency ablation for micropapillary thyroid carcinoma: evaluation of clinical efficacy

Aleksandr Makhonin, Mikhail Vozdvizhenskii, Andrey Orlov, Vladimir Stadler & Yana Matyash
Samara Regional Clinical Oncology Center, Samara, Russian Federation.

Purpose
Papillary thyroid cancer is the most common type of thyroid carcinoma and represents approximately 80% of all thyroid cancers. The aim of the study is an evaluation of the treatment results of micropapillary thyroid carcinoma by the radiofrequency ablation (RFA).
Materials and methods
Fourteen patients with papillary thyroid carcinoma T1aN0M0 with wild type of BRAF (V600E) were included in this research: 12 women and 2 men. The median age of the group was 36 (24–42). The mean nodule size was 0.7 (0.3–1.0) cm. In 12 cases nodules had solid content, in 1 case – mixed solid and cystic content. The mean duration of RFA was 7 (3–12) min. All the procedures were performed under local anesthesia with real time ultrasound control. Technique of dynamic RFA was applied. Internally cooled 7–10 cm length, 0.5, 0.7, 1.0 cm active tip electrodes were used. During the procedure permanent control of hoarse voice was carried out to avoid complications. The follow-up period of patients was 2–15 months.
Results
An ultrasound was used for evaluation of the efficacy of RFA at the first month of the follow-up. An elevation of echogenicity in the ablation area and the loss of Doppler signals were seen. None of the patients experienced any major complications.
Conclusion
RFA is a minimally invasive technique for treatment of micropapillary thyroid carcinoma with high clinical efficacy.

Prevalence and clinical significance of *BRAF*^{V600E} mutation in patients with papillary thyroid cancer

Alejandra Williams[1], Almudena Santón[2], Héctor Pian[2], Eva Cristóbal[2], Pedro Iglesias[2] & Juan J Díez[1,2]
[1]Universidad de Alcalá de Henares, Alcalá de Henares, Spain; [2]Hospital Universitario Ramón y Cajal, Madrid, Spain.

Background
The *BRAF*^{V600E} mutation is the most common mutation in papillary thyroid carcinoma (PTC). Its presence has been associated with extrathyroid invasion, lymph node metastasis, and tumor recurrence. Recently, assessment of the *BRAF*^{V600E} mutation status in patients with PTC has been used as a method to predict tumor aggressiveness.
Objective
Our aim has been to analyze the prevalence of *BRAF*^{V600E} mutation in a cohort of patients with PTC in our geographical and its relationship with poor prognostic factors or aggressiveness of the disease. We also investigated whether this mutation is related to the persistence of the disease 12 months after initial therapy.
Patients and methods
We retrospectively studied patients older than 18 years who underwent surgery for PTC at our centre from 2011 to 2017. Clinical, analytical, histological and molecular data were obtained from all patients with assessed *BRAF*^{V600E} mutation ($n=159$). In patients with more than 12 months of follow up after initial therapy data on the dynamic risk stratification results were recorded.
Results
The prevalence of *BRAF*^{V600E} mutation was 58.3% (95% confidence interval, 49.6–66.5). No differences in patients classified by gender or age groups were found. We could not find any significant association between *BRAF*^{V600E} mutation status and the evaluated clinical and analytical parameters (including radioiodine remnant ablation and postsurgical serum thyroglobulin levels). Tumor size, multifocal disease, extrathyroidal extension, or the presence of lymph node metastases were not related to the presence or absence of *BRAF*^{V600E} mutation. A significant association between this mutation and the histological variants of PTC was found. *BRAF*^{V600E} mutation was found in 71.4% of patients with the classical variant of PTC and only in 44.2% of those with the follicular variant of PTC ($P=0.002$). Twelve months after initial therapy 66% of our patients showed no evidence of disease according to the criteria of dynamic risk stratification (excellent response). We did not find any relationship between *BRAF*^{V600E} mutation and the persistence or remission of disease at this time.
Conclusion
BRAF^{V600E} mutation is very common (58.3%) in our population of patients with PTC. In this cohort of patients the presence of *BRAF*^{V600E} mutation is related with the histological variant of PTC, but we could not find any significant relationship with other histopathological features or with the response to treatment one year after initial therapy.

Association of pro-inflammatory biomarkers in papillary thyroid cancer: a prospective study

D Vignesh[1], B Ramesh[1], B Rajesh[1], M Venkateshwar Reddy[1], G Gayathri[1], B Rajkiran Reddy[2], B Chakrapani[3] & PRK Bhargav[4]
[1]VIMS, Kurnool, India; [2]SMART Sunshine Hospital, Hyderabad, India; [3]Neuro Hospital, Nizamabad, India; [4]Endocare Hospital, Vijayawada, India.

Introduction
Papillary thyroid carcinoma (PTC) is the commonest endocrine malignancy. Apart from genetic role in its pathogenesis, autoimmunity has been implicated in certain papers. But, reports have been tripolar ranging from causative, protective and neutral role of immunomodulation. In this context, we set out study the role of Pro- inflammatory cytokines in PTC in South Indian population.
Material and methods
This prospective case-control study was conducted on surgically managed PTC patients. Institutional ethical committee approval was obtained. Diagnosis of PTC was based on imaging, fine needle aspiration cytology and later confirmed by histopathology. Exclusion criteria were subjects with any systemic or chronic inflammatory disease or any medication which interferes with the normal function of the hypothalamic-pituitary-gonadal axis. Serum samples were collected from 53 PTC subjects and 51 age matched healthy controls. Interleukin-6 (IL-6), Tumour necrosis factor-alpha (TNF-α) and high sensitive C reactive protein (hsCRP), leptin levels were measured in all serum samples. Statistical analysis was performed by one way ANOVA with Dunnet's test and Pearson correlation tests.
Results
The mean hSCRP level in PTC and controls were 17.9 ± 3.1 mg/ml and 5.8 ± 1.3 mg/ml respectively. The mean TNF-α level, IL-6 level and Leptin levels were 294 ± 33 pg/ml, 13.9 ± 4.7 pg/ml and 1.9 ± 0.8 ng/ml respectively. Serum leptin level in controls was 3.4 ± 1.6 ng/ml. There was statistically significant difference of all the pro-inflammatory cytokines compared to controls (P value < 0.05) with negative correlation for leptin levels.
Conclusions
This study shows raised titers of pro-inflammatory markers – IL-6, TNF-α and hsCRP, while reduced leptin levels correlated with PTC suggesting a contributory role. But, the exact immuno-modulatory role and pathogenetic mechanism needs more investigational research.

An unusual association of three endocrine diseases: pheochromocytoma, hyperparathyroidism and papillary thyroid carcinoma

Laura Iconaru, Felicia Baleanu & Rafik Karmali
CHU Brugmann, Brussels, Belgium.

Introduction
Pheochromocytoma, papillary thyroid carcinoma and primary hyperparathyroidism have been reported rarely together. Whether the association is coincidental or results from an underlying unique genetic process is difficult to ascertain.
Case description
We report a case of a 59-year-old woman without a family history who had a personal history of multinodular goiter known for the ten last years and pheochromocytoma diagnosed and operated in 2008. In 2015 thyroid scintigraphy reveals a cold nodule in the left lobe. Fine needle aspiration shows benign follicular lesion. Calcitonin and thyroid function were normal. In addition, blood tests revealed hypercalcemia secondary to primary hyperparathyroidism. Due to tracheal compression seen on a neck CT-Scan, she underwent total thyroidectomy and intraoperative parathyroid exploration. Pathological examination showed bilateral papillary carcinoma in follicular presentation with vascular invasion and parathyroid gland hyperplasia. Tumor cells were negative for calcitonin and CEA. The patient was screened for germline variants for several candidate genes: RET (exons 8, 10, 11, 13, 14, 15 and 16), VHL, SDHB, SDHC, SDHD, SDHA. This search did not show any mutation. The genetic study by "Next Generation Sequencing" searching for 50 genes linked to cancer was performed in the thyroid tumour. There was a mutation in the HRAS gene (mutation pG13R in exon 2).
Conclusions
This is the rare reported case of the unusual combination of pheochromocytoma, bilateral papillary thyroid carcinoma and primary hyperparathyroidism with parathyroid gland hyperplasia**.** The genetic abnormality of this rare association needs further studies but may lie in the HRAS gene although a coincidental association cannot be excluded.

Coexistence of well differentiated, poorlydifferentiated and anaplastic thyroid carcinoma in a male patient with neurofibromas: A case report

Georgios Boutzios[1], Eleni Papaoiconomou[1], Andreas Pikoulis[2], Despoina Pouloudi[3], Anastasia Pikouli[2], Eleni Koukoulioti[1], Andreas Lazaris[3] & Emmanouil Pikoulis[2]
[1]Department of Pathophysiology, Laiko University Hospital, Medical School, University of Athens, Athens, Greece; [2]First Department of Surgery, Laiko University Hospital, Medical School, University of Athens, Athens, Greece; [3]First Department of Pathology Medical School, National and Kapodistrian University of Athens, Athens, Greece.

Introduction
Poorly differentiated thyroid carcinoma (PDTC) and anaplastic thyroid carcinoma (ATC) have been conjectured to arise from well differentiated thyroid carcinoma (WDTC) due to frequently reported synchronous and metachronous occurrence. We demonstrate the simultaneous presence of divergent histological subtypes in a single thyroid gland, with escalating loss of p53 expression in more aggressive variants.
Material and methods
A 60-year-old male with multiple neurofibromas presented with a palpable anterior neck mass, firm and fixed to underlying structures. Hormonal evaluation was conducted to evaluate thyroid function and rule out the presence of a pheochromocytoma, on grounds of unproven von Recklinghausen disease. Ultrasound revealed a hypoechogenic nodule on the left lobe, measuring 5.84×2.81 cm, with peripheral vascularity, which comprised a 2.24×1.28 cm area with suspicious calcifications. Three smaller hypoechogenic nodules with peripheral vascularity, 3.26, 3.18 and 0.83 cm respectively, were also observed. On the right lobe three isoechogenic nodules, 2.19, 1.47 and 0.73 cm, with cystic areas and no remarkable vascularity were noted.
Results
Histopathological examination revealed three foci at the right lobe, with characteristics of predominantly papillary but also follicular carcinoma growth pattern, with infiltrating margins and foci of extrathyroidal extension. At the left lobe two lesions were described, which presented with histologic features of insular and trabecular variant of PDTC. The larger tumor showed foci of anaplastic transition, with diffuse growth pattern, nuclear pleomorphism and areas of necrosis. Both tumors invaded thyroid capsule and displayed extrathyroidal extension reaching the inked surgical margins. Vascular emboli were also identified. Poorly differentiated tumor area appeared with reduced nuclear p53 protein accumulation.
Conclusion
We present a case of progressive decline of p53 expression in multifocal thyroid tumor areas consisting of WDTC, PDTC and ATC histologies, highlighting the possibility that WDTC can progress to PDTC and then ATC through an intricate procedure involving loss of p53.

Incidence of recurrent nerve paresis and hypocalcemia after total thyroidectomy – A retrospective Analysis

Jindrich Lukas[1,2], Tomas Kuderjavý[3], David lukas[4], Barbora Hintnausova[5], Jiri Drabek[6] & Martin Syrucek[7]
[1]Department of Otolaryngology – Head and Neck Surgery, Na Homolce Hospital, Prague, Czech Republic; [2]Department of Otolaryngology, Charles University in Prague, Faculty of Medicine in Pilsen and Faculty Hospital, Pilsen, Czech Republic; [3]Department of Otolaryngology – Head and Neck Surgery, Na Homolce Hospital, Prague, Czech Republic; [4]Department of Surgery, 3rd Faculty of Medicine, Charles University and University Hospital, Prague, Czech Republic; [5]Department of Internal Medicine, Endocrinology Centre, Na Homolce Hospital, Prague, Czech Republic; [6]IMTM, Faculty of Medicine and Dentistry, Palacky University Olomouc, Olomouc, Czech Republic; [7]Department of Pathology, Na Homolce Hospital, Prague, Czech Republic.

The aim of this study was to investigate: the incidence of postoperative paresis of the recurrent laryngeal nerve (RLN) and hypocalcemia; the frequency of incidental parathyroidectomy and the occurrence of hypocalcemia, and to find possible risk factors for hypocalcemia and RLN paresis.
Material and methods
Retrospective analysis of 550 patients after total thyroidectomy (TT) or completion thyroidectomy (CT) after histologically confirmed thyroid carcinoma. Postoperative RLN paresis was determined by postoperative laryngoscopy, and the index of recurrent injury (IRI) was calculated. Patients were monitored for postoperative clinical and biochemical hypocalcemia. Total calcium levels in plasma $<$ 2.0 mmol/l were regarded as hypocalcemia. Incidental parathyroidectomy (IPT) was identified by histology.
Results
Postoperative unilateral RLN paresis occurred in 15 patients (2.7%), of which 4 cases were permanent (0.7%), and IRI was 8. Postoperative transient hypocalcemia was observed in 32 (5.8%) and permanent hypocalcemia in 2 patients (0.3%). The occurrence of RLN pareses and incidence of hypocalcemia was significantly higher in patients with malignant tumors than in benign lesions: 7.1% vs. 1.6% RR = 4.47; 95% CI: 1.66–12.06; (P = 0.004) and 9.8% vs. 4.8% RR = 2.05; 95% CI: 1.00–4.12 (P = 0.041), respectively. IPT was reported in 67 patients (12.2%). IPT/ non IPT and CT/TT patients had significantly higher incidence of transient hypocalcemia 13.4% vs. 5.2% RR = 2.82; 95% CI 1.36–5.84 (P = 0.015) and 27.3% vs. 5.8% RR = 5.69; 95%CI: 1.58–20.48 (P = 0.025), respectively.
Conclusion
Risk factors of transient hypocalcemia and unilateral RLN paresis were thyroid malignancies, extend of lymph node dissection, surgical technique and mainly the surgeon's experience. Incidental parathyroidectomy and completion thyroidectomy significantly correlated with transient hypocalcemia. A higher frequency of incidental parathyroidectomy was observed in patients younger ($\leq$45 years).

Highly sensitive Thyroglobulin assay in monitoring patients treated for differentiated thyoid cancer in 26 consecutive patients
Ines Jimenez, Cristina Familiar, Anne Azcutia, Elvira Ramos & Elvira Barrio
Hospital Clinico San Carlos (Madrid), Madrid, Spain.

Introduction
Guidelines suggest that serum basal (nonstimulated) thyroblobulin (bTg) with sensitive assays (Functional Sensitivity-FS- below 0.1 or 0.2 ng/ml) could substitute the measurement of serum Tg levels after TSH stimulation during the follow-up of patients with differentiated thyroid cancer (DTC) when basal results fall below the FS.
Objective
A sensitive assay for Tg was incorporate in our center (Chemiluminiscent Tg Access; Beckam Coulter; Brea; CA) with FS of 0.1 ng/ml coexisting with an older traditional assay (Inmunoradiometric SelcoTg assay; Berlin) with higher FS (0.5 ng/ml). The aim of this study was to verify that sensitive bTg values below FS could obviate the need of stimulation with recombinant (rTSH) in patients consecutively seen for the follow-up of CDT in one endocrinology office between January and June 2017.
Patients and methods
Patients with DTC from one endocrinology office were included if:
– They underwent total thyroidectomy usually followed by 131 iodide ablation.
– They had a recent documented bTg determined with the sensitive assay (provided that Tg antibodies were negative) and a recent stimulated Tg (sTg) after rTSH administration determined with the IRMA assay.

Patients were classified in 3 categories:
– Excellent treatment responders: no clinical, biochemical or structural evidence of disease and sTg (IRMA method) below 1 ng/ml.
– Patients with structural disease cytologically or hystologically evidentiated.
– Incomplete biochemical responders: sTg above 1 ng/ml (IRMA method) in the absence of localizable disease.

Results
Study included 26 patients (4 men), mean age (DS): 49(15) years with DTC treated with total thyroidectomy (some of them with central and lateral neck dissection) followed by an ^{131}Iodide ablative dose in 25 cases. 4 patients had been reoperated and 3 received a second ^{131} Iodide dose because of recurrent nodal disease. Among Excellent treatment responders (n = 21), bTg was lower than 0.1 ng/ml in all but one case (0.2 ng/ml). In the case with structural disease (metastatic nodal recurrence) bTg raised above FS level (3.4 ng/ml). Among Incomplete biochemical responders (n = 4), 3 had bTg $>$ 0.1 ng/ml and that one with bTg $<$ 0.1 ng/ml had a marginally sTg (1.2 ng/dl) with the traditional assay of doubtful clinical significance.
Conclusion
Sensitive Tg methods could obviate the need for sTg in a majority of DTC patients and therefore could simplify the follow-up and alleviate the costs of rTSH.

Hounsfield unit value has null effect on thyroid nodules at 18F-FDG PET/CT scans
Filiz Eksi Haydardedeoglu[1], Gülay Simsek Bagir[1], Nese Torun[2], Nazım Emrah Kocer[3], Mehmet Reyhan[2] & Melek Eda Ertorer[1]
[1]Department of Endocrinology and Metabolism, Başkent University Faculty of Medicine, Adana Teaching and Research Center, Adana, Turkey; [2]Department Of Nuclear Medicine, Başkent University Faculty of Medicine, Adana Teaching and Research Center, Adana, Turkey; [3]Department of Pathology, Başkent University Faculty of Medicine, Adana Teaching and Research Center, Adana, Turkey.

Objectives
Detection rate of thyroid nodules is increasing with use of new imaging modalities, like 18F-fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT). To avoid unnecessary operations, differentiating between benign and malignant 18F-FDG PET/CT-positive thyroid nodules is essential. Many authorities recommend fine needle aspiration biopsy (FNAB) for exclusion of malignancy in thyroid nodules. Although FNAB is a simple, easily performed procedure, less invasive diagnostic approaches are required. Malignant thyroid nodules tend to have higher maximum standardized uptake values (SUVmax) but there is no clear information about the utility of Hounsfield Unit (HU) values for the prediction of malignancy. This study evaluated the HU values beside SUVmax for detecting malignancy risk of PET/CT-positive thyroid nodules.
Methods
We retrospectively studied 98 patients who had FNAB for thyroid nodules detected on PET/CT within the period; January 2011 to December 2015. The FNABs and surgical pathological results were recorded. On non-contrast CT scans taken during PET imaging, the HU of the nodules were calculated besides SUV max values of the nodules.
Results
The mean age of the study population was 57.6 $\pm$ 13.8 years, and 75 (76.5%) of the patients were women. The most common primary malignancy detected in these patients was breast cancer. If more than one nodule was detected on a PET/CT scan, FNAB was performed on the nodule that had the higher $SUV_{max.}$ FNABs revealed benign results in 32 patients (32.7%), malignant in 18 (18.4%), non-diagnostic in 20 (20.4%), indeterminate in 28 (28.5%). 24 patients underwent thyroidectomy due to their inconvenient general health conditions. When the FNAB and postoperative pathological results of nodules evaluated together, 38 of them were considered as benign and 25 of them were malignant. Only 24.5% of the cases were subjected to thyroidectomy, the malignancy rate was 25.5% in our cohort. Mean SUVmax was significantly higher ($P <$ 0.001) in malignant versus benign nodules. Area under curve (AUC) was 0.824 for SUVmax; the cut-off value was over 5.55 ($P <$ 0.001), with 80% sensitivity, 84.5% specificity. But mean HU values were not significantly different (P = 0.73).
Conclusions
We defined a SUVmax cut-off value of 5.5 for malignant potential of thyroid nodules detected on PET/CT. However; we did not find any merit in using HU values for discriminating between malignant and benign nodules.

Follicular thyroid carcinoma with late metastasis to kidney in a patient with elevated thyroglobulin levels of unknown source
Rujuta Katkar, Manasi Shah, John A Ryan & Amy Odonnell
University at Buffalo, Buffalo, New York, USA.

Here we present a case of follicular thyroid cancer with elevation of thyroglobulin (Tg, in ng/ml) detected almost 10 years after initial surgery and radioactive iodine therapy (RAI). The elevated Tg persisted for years before he was found to have a metastasis in his kidney 16 years after his initial cancer treatment. A 78 year old male had a total thyroidectomy followed by RAI therapy in 2001 for a 2.4 cm

follicular thyroid cancer. His Tg became mildly elevated in 2009, and continued to rise gradually. Body scan, PET scan and neck ultrasound did not find a source for the Tg. In 12/12 his Tg was 49.4 with a suppressed TSH. A thyrogen stimulated Tg in 2/13 was 930 and again ultrasound, body scan and PET scan were unremarkable. He was treated empirically with 210 mCi 131-I. His Tg level came down and remained <2 but a thyrogen stimulated Tg was 8.8 in 10/14. Tg antibodies have always been undetectable. Tg continued to rise to 96.5 on levothyroxine in 6/15. Again ultrasound, body scan and PET scan were unremarkable. On an abdominal CT scan for appendicitis in 10/15 a 1.4 cm right renal lesion was observed which remained stable on active surveillance. An increase in size of the renal mass was noted in Sept 2017 leading to radical nephrectomy. The pathology of the right kidney showed a lobulated $2.7\times2.4\times2.0$ cm mass, and histologic appearance and immunostains led to diagnosis of metastatic thyroid follicular carcinoma. Tg in 3/17 on levothyroxine was 63.4, and rose to 95.4 in 6/17, 267.5 in 9/17 and 190.9 in 10/17 before his nephrectomy. Interestingly, the presence and change in the renal mass corresponded to his Tg levels all along. In retrospect the small renal mass could be seen on his PET CT films from 2012. The increased FDG uptake in the kidney appears to have been missed due to normal FDG uptake in the urinary tract. At the time of his last body scan in 2015 the renal mass was only 1.4 cm on CT and likely below the detection of the 131-I. A Tg level after kidney surgery is 1.1 Conclusion: Given the rarity of thyroid cancer metastases to the kidney, and the uptake of FDG in the urinary tract, a renal metastasis may be missed during evaluation of patients with persistent elevations of thyroglobulin.

The role of platelet activation and inflammation in patients with differentiated thyroid cancer

Sorina Martin[1,2], Oana Ion[3], Andreea Grigore[4], Oana Enache[2], Anca Sirbu[1,2], Carmen Barbu[1,2], Cosmin Giulea[5,6], Adrian Miron[5,6], Florin Andrei[7] & Simona Fica[1,2]
[1]Carol Davila University of Medicine and Pharmacy, Endocrinology Department, Bucharest, Romania; [2]Elias Hospital, Endocrinology Department, Bucharest, Romania; [3]Fundeni Clinical Institute, Nephrology Department, Bucharest, Romania; [4]Fundeni Clinical Institute, Gastroenterology Department, Bucharest, Romania; [5]Elias Hospital, Surgery Department, Bucharest, Romania; [6]Carol Davila University of Medicine and Pharmacy, Surgery Department, Bucharest, Romania; [7]Elias Hospital, Pathology Department, Bucharest, Romania.

Background
The role of inflammation in the pathogenesis of cancer and the mechanisms through which platelets can influence the aggressive behaviour of different types of cancer have been highlighted by a few studies.
Methods
We retrospectively analysed the files of 493 patients submitted to thyroidectomy in our surgery department between 2012 and 2015. We assessed the relationship between differentiated thyroid cancer (DTC) and mean platelet volume (MPV), platelet count and serum fibrinogen level in a case-control study.
Results
The study included 86 patients with DTC (mean age 53.99 ± 13.91 years, 83.7% females) and a control group of 66 patients with histologic benign thyroid disorders (mean age 50.14 ± 13.05 years, 83.3% females). Patients with DTC had a higher level of serum fibrinogen compared to patients in the control group ($P=0.033$). We did not find any significant differences between case and control groups regarding MPV ($P=0.150$) or platelet count ($P=0.342$) levels. MPV was not significantly different between histologycal subgroups of DTC patients depending on: TNM staging ($P=0.308$), tumor subtype ($P=0.108$), vascular invasion ($P=0.829$), capsular invasion ($P=0.357$), extracapsular extension ($P=0.161$), local lymph nodes metastasis ($P=0.362$). In DTC patients, the platelet count was higher in patients with higher tumour diameters ($P=0.024$) and capsular invasion ($P=0.044$). In DTC patients platelet count was significantly lower after the surgery compared to preoperatory values ($P=0.050$).
Conclusions
Our data showed that, when compared to benign thyroid disorders, DTC was associated with a higher level of inflammation. In DTC patients, platelet count can be associated with aggressive tumor behaviour.

Incidental thyroid microcarcinoma in benign thyroid diseases: can it encourage total thyroidectomy as the first choice of surgical treatment? (A retrospective study)

Dimitrios Askitis[1], Eleni I Efremidou[1], Alexandra Giatromanolaki[2], Agis Esebidis[1], Vasiliki Vamvakerou[1], Alexandros Polychronidis[1] & Nikolaos Liratzopoulos[1]
[1]First Surgical Department, University Hospital of Alexandroupolis, Faculty of Medicine, School of Health Sciences, Democritus University of Thrace, Alexandroupolis, Greece; [2]University Pathology Department, University Hospital of Alexandroupolis, Faculty of Medicine, School of Health Sciences, Democritus University of Thrace, Alexandroupolis, Greece.

Aim
Well-differentiated thyroid cancer (TC) comprises the most common endocrine malignancy, featuring very good prognosis and 5-year survival rate of nearly 100% after total thyroidectomy. However, the prevalence of incidental thyroid microcarcinoma (mITC) is continuously rising during the last decade. One obvious reason is the high prevalence of total thyroidectomy (TT) as the preferred operation for otherwise benign nodular or diffuse thyroid diseases. The current retrospective study aims to evaluate the prevalence of mITC (max. diam. ≤1 cm) in benign thyroid diseases as a potential parameter for surgical decision regarding the type of thyroidectomy.
Patients-methods
In one Surgical Department, with specialty interest in Neck Endocrine Surgery, a cohort of 793 patients (660 females/133 males; mean age 51,1 years), underwent TT for benign thyroid diseases, during 13 years (1.1.2004-31.12.2016). All patients were referred for surgical treatment from MDs of Internal Medicine or Endocrinology. Patients with positive/suspicious or non-inclusive cytology, or history of TC, were excluded. Pathological report of mITC was recorded and evaluated according to preoperative diagnosis.
Results
The prevalence of mITC was 14.5% (115/793 patients: females/males: 88/27), while 678 patients (85.5%) were free of malignancy. Evaluation regarding the type of thyroid disease revealed that a percentage of 32.3% (40/124 patients) with solitary thyroid nodule-STN and another of 12.8% (68/530 patients) with multinodular goiter-MNG, were harboring an incidentally detected TC. Thyroid diseases with hyperthyroidism, such as Graves' disease and toxic multinodular goiter featured malignancy in 8.1% (3/37 patients) and 4.6% (4/87 patients) respectively. Interestingly, mITC was diagnosed in 15.4% (2/13 patients) with previous thyroid lobectomy or subtotal thyroidectomy; among them there was a case of mITC with foci of anaplastic TC.
Conclusions
Incidental thyroid microcarcinoma was identified in a significant proportion of patients with otherwise benign thyroid diseases subjected to TT. The vast majority presented in non-toxic disorders, while mITC was detected in nearly 1/6 of patients with nodular recurrence after previous non-total thyroidectomy. These findings can support the choice of TT as the optimal surgical procedure even in benign thyroid diseases with indication for surgery. Moreover, the first choice of TT leads simultaneously to permanent cure of a potential concomitant thyroid carcinoma, excluding the possibility of future neck re-operation and/or complex longtime follow-up.

Incidental thyroid microcarcinoma diagnosed after total thyroidectomy for non-toxic solitary thyroid nodule: A 13-year single surgical-center experience (A retrospective study)

Dimitrios Askitis[1], Eleni I Efremidou[1], Alexandra Giatromanolaki[2], Alexandros Polychronidis[1] & Nikolaos Liratzopoulos[1]
[1]First Surgical Department, University Hospital of Alexandroupolis, Faculty of Medicine, School of Health Sciences, Democritus University of Thrace, Alexandroupolis, Greece; [2]University Pathology Department, University Hospital of Alexandroupolis, Faculty of Medicine, School of Health Sciences, Democritus University of Thrace, Alexandroupolis, Greece.

Aim
Thyroid cancer (TC) is the most common endocrine malignancy, presenting a rising incidence during the last decade, due to continuously rising prevalence of incidental thyroid microcarcinomas (mITCs; ≤1 cm) in benign thyroid diseases treated with total thyroidectomy (TT). Solitary thyroid nodule (STN) is a thyroid condition, which remains under debate regarding the extent of thyroidectomy

needed (total or near-total thyroidectomy vs unilateral lobectomy). Objective of the current retrospective study was the assessment of the prevalence of mITC in patients with non-toxic STN subjected to TT, within a time period of 13 years.
Patients-methods
In one Surgical Department, with specialty interest in Neck Endocrine Surgery, a total of 124 patients (90 females/34 males; mean age 47.1 years), underwent TT for solitary thyroid nodule, from 2004 to 2016. Type of thyroidectomy is a choice of the surgical team. All patients were referred for surgical treatment from MDs of Internal Medicine or Endocrinology. Patients with positive/suspicious or non-inclusive cytology, or history of TC, were excluded. Pathological report of mITC was recorded and evaluated according to location of nodule and special features of detected TC.
Results
The prevalence of mITC was 32.3% (40/124 patients), while 84 patients were free of malignancy. Specifically, in 72.5% (29/40 patients) a papillary mITC was diagnosed, while the other types of thyroid carcinoma were: 15% (6/40 patients) follicular mITC, 5% (2/40 patients) papillary + follicular mITC, 5% (2/40 patients) medullary mITC and 2.5% (1/40 patients) foci of anaplastic TC. Interestingly, the case of anaplastic mITC referred to recurrent STN in the remnant lobe after previous lobectomy. Regarding the location and type of pathologically detected mITC, in 7.5% (3/40 patients; 2 papillary/1 papillary + follicular TC), there was multifocal carcinoma in both thyroid lobes. Surprisingly, in 22.5% (9/40 patients; 8 papillary/1 follicular TC) the malignancy was contralateral to STN.
Conclusions
Incidental thyroid microcarcinoma was identified in a significant proportion, nearly 1/3, of patients with solitary thyroid nodule, subjected to total thyroidectomy. More than 1/5 of patients featured mITC at the contralateral lobe. Although the small number of study group comprises a limitation, findings can support the choice of total thyroidectomy as a safe procedure in STN, giving the advantage of treating the disease and also diminishing the possibility of non-detected thyroid cancer or disease recurrence and need for neck re-exploration

The relationship between clinical, morphological and prognostic characteristics of papillary thyroid carcinoma with *BRAFV600E* mutation assessed immunohistochemically

Aleksei Sidorin[1], Aleksandr Abrosimov[2,3], Tatiana Rogounovitch[4], Pavel Rumyantsev[2], Kseniya Nizhegorodova[2], Pavel Isaev[1], Anna Shinkarkina[1], Shunichi Yamashita[4] & Vladimir Saenko[4]
[1]A. Tsyb Medical Radiological Research Center – branch of the National Medical Research Radiological Center of the Ministry of Health of the Russian Federation, Obninsk, Russian Federation; [2]Endocrinology Research Centre, Moscow, Russian Federation; [3]National University of Science and Technology, Moscow, Russian Federation; [4]Atomic Bomb Disease Institute, Nagasaki, Japan.

Background
Papillary thyroid carcinoma (PTC), especially its classic papillary, oncocytic, Warthin-like, tall and columnar cell variants, is characterized by a high frequency of BRAFV600E mutation that varies in different studies from 36 to 85%. Prognostic significance of the mutation remains controversial.
Objective
Aim of the study was an analysis of relationship between clinical, morphological and prognostic characteristics of PTC with BRAFV600E assessed immunohistochemically.
Material and methods
Histological and immunohistochemical study of formalin-fixed paraffin-embedded sections of primary, metastatic and recurrent (if available) PTC was conducted with mouse monoclonal antibodies to protein products of mutated BRAF in 74 patients (18 males and 56 females aged from 9 to 80 years. at the time of first operation). Results of immunohistochemistry were scored by three pathologists, and agreed opinion was considered for analysis of relationship between BRAF mutational status and clinical, morphological and prognostic features of PTC.
Results
Mutant BRAF status was observed in 29 of 74 PTC (39%). BRAF positive group of PTC was characterized by higher proportion of male patients (37.9 vs 15.5%, $P=0.050$), older age at the time of operation (39.3 vs 28.4 years., $P=0.005$), and higher frequency of advanced clinical stages (37.9 vs 13.3%, $P=0.023$). Classic papillary histotype of PTC was diagnosed more often (65.5 vs 35.5%, $P=0.017$), and frequency of tumor post-operational relapses was higher (62.1 vs 33.3%, $P=0.018$) in BRAF positive group in comparison with BRAF negative. BRAF negative group displayed a higher frequency of distant metastases, the volume of surgical operation was generally larger. No significant difference with regard to BRAF status was found for pT, pN categories, extrathyroidal tumor extension, multifocality, and encapsulation. Analysis of disease-free survival based on multivariate proportional hazard models demonstrated significantly elevated rate of relapse in the BRAF positive group, and that BRAF mutation was a prognostic factor of time-related tumor relapse independent from the extent of surgery.
Conclusions
The BRAF mutation is an important risk factor for PTC relapse that may be useful for prognostication during post-operational follow up.

Improved prognostic value of the eighth edition of the AJCC/TNM staging system for differentiated thyroid cancer

Evert van Velsen[1], Merel Stegenga[1], Folkert van Kemenade[2], Boen Kam[3], Tessa van Ginhoven[4], W Edward Visser[1] & Robin Peeters[1]
[1]Department of Internal Medicine, Academic Center for Thyroid Diseases, Rotterdam, Netherlands; [2]Department of Pathology, Academic Center for Thyroid Diseases, Rotterdam, Netherlands; [3]Department of Nuclear Medicine, Academic Center for Thyroid Diseases, Rotterdam, Netherlands; [4]Department of Surgery, Academic Center for Thyroid Diseases, Rotterdam, Netherlands.

Background
In January 2018, the 8th edition of the AJCC/TNM staging system for differentiated thyroid cancer (DTC) was introduced in clinical practice. Studies evaluating this 8th edition so far only comprised patients with papillary thyroid cancer (PTC) or made no distinction between PTC and follicular thyroid cancer (FTC). Therefore, we evaluated the prognostic value of the AJCC/TNM 8th edition in a European population with DTC, and subsequently distinguished PTC and FTC patients.
Methods
Adult patients diagnosed and/or treated for DTC at the Erasmus MC between January 2002 and April 2016 were included. For both editions, overall survival (OS) and disease specific survival (DSS) were analyzed using the Kaplan-Meier (KM) method. The Cox proportional hazards model was used to compare the effect of PTC and FTC on survival. The statistical model performance of the 7th and 8th edition was assessed using the C-index, AIC and BIC.
Results
We included 792 patients (69% women) with DTC (79% PTC, 21% FTC). Mean age was 49 years and median follow-up 86 months. Reclassification with the 8th edition resulted in down-staging of 282 (36%) patients, an increased number of patients in stage I (431 to 575) and II (82 to 129), and an equivalent decrease in stage III (96 to 30) and IV (183 to 58). For DTC, as well as for PTC and FTC separately, stage at diagnosis was significantly related to both OS and DSS ($P<0.001$) in the 7th and 8th edition. However, examination of the KM survival curves showed better separation of the stage curves for the 8th than for the 7th edition. In contrast with the 7th, no significant differences regarding survival rates per stage between PTC and FTC were seen using the 8th edition. Furthermore, the statistical model performance was better for the 8th than for the 7th edition.
Conclusion
We showed that the 8th edition of the AJCC/TNM staging system is a better predictor for both OS and DSS than the previous 7th edition in a European population of patients with PTC or FTC. Furthermore, differences in survival rates between PTC and FTC that were present using the 7th edition disappeared using the 8th edition, implicating that this new edition is predicting well regardless of DTC subtype.

Quantitative asessments of normal cervical lymph nodes using shear-wave ultrasound elastography

David Emilio Barajas-Galindo[1], Luna Florencio-Ojeda[2], María Sevillano-Jiménez[2] & Tomás Martín-Hernández[2]
[1]Complejo Asistencial Universitario de León, León, Spain; [2]Hospital Universitario Virgen Macarena, Sevilla, Spain.

Purpose
The aim of this study was to evaluate the reference values of quantitative shear wave elastography (SWE) for cervical lymph nodes with normal ultrasound

characteristics, and assess if there are differences according the location and other characteristics of patients.
Methods
67 cervical lymph nodes from 52 patients with thyroid nodules that were diagnosed previously as different thyroid disease had been imaged with SWE. The shear elasticity modulus, which indicates the stiffness of the lymph nodes, was measured in transverse position in three locations from medial to distal and in longitudinal position from cranial to caudal also in three locations on each lymph nodes, both the second measure corresponds the location of hilum.
Results
All the lymph nodes fulfilled all the ultrasound characteristics of benignity. Mean transverse value of elasticity of the lymph nodes were significantly different ($P=0.005$) by location (II: 20.97 KPa; III: 18.09; IV: 16.41 KPa; V: 26.99 KPa). The longitudinal mean measure was significantly higher than the transversal mean measure (29.58 KPa vs 15.39 KPa; $P=0.013$). There were no differences by measurements from the medial to the distal or from the cranial to the caudal. Also, no difference by volume, diagnosis, age or gender.
Conclusions
SWE may be valuable quantitative indicators for characterizing cervical lymph nodes, but there are differences by location of lymph node and the position of ultrasound probe that need to be standardized.

ABO blood groups, Rh factor and thyroid cancer risk: To 'B' or not to 'B'

Abbas Ali Tam, Didem Ozdemir, Sevgul Fakı, Muhammet Cuneyt Bilginer, Reyhan Ersoy & Bekir Cakir
Department of Endocrinology and Metabolism, Yıldırım Beyazıt University Faculty of Medicine, Ankara, Turkey.

Aim
In this study, we aimed to evaluate ABO blood groups and Rh factor in patients with thyroid cancer. We also assessed whether the ABO/Rh factor had any effect on prognosis, agressive features and advanced stage of thyroid malignancies.
Methods
Medical records of patients who underwent thyroidectomy between December 2006 and September 2014 were evaluated retrospectively. Demographical and clinical features, cytological results (according to Bethesda classification), ABO blood groups and Rh factor status of patients with benign and malignant thyroid disease were compared. Additionaly, in malignant group, histopathological features were compared in patients with different ABO blood groups, and Rh positive and negative patients.
Results
Histopathological diagnosis was benign in 1299 (63.5%) and malignant in 744 (36.5%) patients. There were no significant difference in age, sex, thyroid autoantibody positivity and ABO blood groups in benign and malignant patients ($P>0.05$ for each). Ratio of Rh positive patients was significantly higher in malignant compared to benign group (91.8% vs 88.1%, $P<0.046$). In all subgroups of cytology, malignancy rates were similar in different ABO blood groups, and Rh positive and negative patients. Considering malignant patients, extrathyroidal extension and advanced stage (3–4) were more prevalant in patients with B compared to non-B blood groups ($P=0.028$ and $P=0.042$, respectively). Patients with O blood group had lower rate of capsular invasion than patients with non-O blood groups ($P=0.018$). ABO blood groups or Rh status were not associated with thyroid cancer in this study. However, patients with B blood group had higher risk of extrathyroidal extension and advanced stage compared to patients with non-B blood group.
Conclusion
For the first time in our study, we evaluted the association of Rh factor status and thyroid cancer, and found no significant relation. ABO blood groups also did not increase malignancy risk in thyroid nodules. In malignant patients, extrathyroidal extension and advanced stage were higher in B compared to non-B blood groups. Our findings can be considered as a preliminary to investigate ABO blood groups and Rh status as factors that can identify patients with higher risk.

A case of anaplastic thyroid carcinoma complicated with thyrotoxicosis

Daisuke Hashimoto, Shuichi Nakayama, Mitsuru Nishiyama, Shinpei Fujimoto & Yoshio Terada
Department of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi University, Nankoku, Japan.

Background
Anaplastic thyroid carcinoma (ATC), which is one of the most aggressive endocrine tumors. Primary thyroid carcinoma typically does not interfere with thyroid function and presentation of ATC with thyrotoxic state is extremely rare. We present here an ATC patient who is complicated with thyrotoxicosis.
Case
A 69-year-old man presented with neck swelling and pointed out thyroid tumor with calcification two years ago. He appeared general fatigue, body weight loss and palpitation with elevated thyroid hormone, therefore he was transferred to our hospital for further examinations. Laboratory data showed thyrotoxicosis (TSH <0.05 μIU/ml, fT_3 5.5 pg/ml, fT_4 2.3 ng/dl) with negative TSH receptor antibody (TRAb <0.7 U/l), and a low grade uptake of ^{123}I scintigraphy in thyroid gland (0.2%). Ultrasonography showed diffuse goiter with low-echo levels and a 2.4 cm tumor with eggshell-like calcification at right lobe. Spontaneous remission was observed in thyrotoxicosis and it was consistent with destructive thyroiditis. One month later, he complained back pain and rib bone destruction was pointed out. Diffuse goiter was enlarged and diagnosed as ATC according to histological examination (TTF1 positive, p53 positive, MIB-1 index 30%). FDG-PET showed abnormal accumulation in thyroid, lung, bone and adrenals, which corresponded with multiple metastasis of ATC (Stage IVC). Multi-kinase inhibitor (Lenvatinib) was prescribed as treatment of ATC and RANKL inhibitor (Denosumab) was used against bone metastatic regions. However, these treatments were not effective and he moved to palliative care.
Conclusion
Thyrotoxicosis in ATC is very rare and only ten cases have been reported previously. Several explanations have been discussed in this phenomenon, and a representative theory is thyroid hormone leakage due to rapid tissue destruction, which is considered as same mechanisms in the present case.

Tyrosine kinase inhibitor (TKI) treatment outcome of stage IV-C thyroid differentiated cancer (analyzed by lesion evaluation)

Hiroyuki Iwasaki[1], Haruhiko Yamazaki[1], Nobuyasu Suganuma[1], Yuko Sugawara[1], Naoki Gotoh[2], Shinsuke Hatori[3], Hirotaka Nakayama[4] & Katsuhiko Masudo[5]
[1]Kanagawa Cancer Center, Yokohama, Japan; [2]Atami Hospital, IUHW, Atami, Japan; [3]Hiratsuka Kyosai Hospital, Hiratsuka, Japan; [4]Yokohama City University, Yokohama, Japan; [5]Yokohama City University Center Hospital, Yokohama, Japan.

Introduction
The standard treatment for differentiated thyroid carcinoma (DTC) with distant metastasis comprises complete total thyroidectomy and lymph node dissection, followed by radioactive iodine (RAI) ablation for metastatic lesions. However, between 2014 and 2015, sorafenib and lenvatinib have been approved for treatment of RAI-refractory advanced thyroid cancer in Japan. We retrospectively analyzed how the treatment results have changed after the approval of tyrosine kinase inhibitor (TKI) treatment.
Patients and methods
Among patients currently followed at outpatient clinics, 111 diagnosed with stage IV-C DTC who underwent surgery at our hospitals were included. A total of 48 patients with disease progression and an estimated lesion size ≥ 15 mm were treated with sorafenib and/or lenvatinib. The approval rate was 43.2%. Lesion evaluation was performed to compare and study these prognoses among 21 patients with lung metastasis, 18 with unresectable local recurrence, and nine with bone metastasis.
Results
Treatment results were classified as partial response (PR), stable disease (SD), not evaluable, and progressive disease (PD) in 16 (33.3%), 18 (37.5%), five (10.4%), and nine (18.8%) patients, respectively. The disease control rate (PR + SD) was 34/48 (70.8%) patients. Lesion evaluation showed that the disease control rate for pulmonary metastasis was the best (81.0%) and for bone metastasis (66.7%) and unresectable local recurrence (61.1%) was the worst (Table 1).
Conclusion
Because disease progression of pulmonary metastasis can be identified on a computed tomography image, the timing of TKI treatment was easy to determine

and the treatment outcome was satisfactory. However, in some cases, local recurrence involved large blood vessels, or therapy was interrupted due to tumor-skin fistula or bleeding. Eventually, some patients died due to an adverse event (AE) or PD. Some cases of bone metastasis were initially diagnosed with large metastatic lesions, and the treatment outcomes were considered worse. Our results suggested that an appropriate timing of TKI administration and the control of its AEs can improve the prognosis of patients with stage IV-C DTCs with PD.

Table 1

Lesion	N	PR	SD	NE	PD	Death
Pulmonary	21	10	7	2	2	4
Local rec.	18	6	5	3	4	6
Bone	9	0	6	0	3	4
Total	48	16	18	5	9	14

Expression of VEGFR2 and clinical response of anaplastic thyroid cancer to lenvatinib

Haruhiko Yamazaki[1], Hiroyuki Iwasaki[1], Nobuyasu Suganuma[1], Tomoyuki Yokose[1], Hiroyuki Hayashi[1], Sachie Osanai[1], Katsuhiko Masudo[2], Hirotaka Nakayama[3], Kaori Kohagura[3], Yasushi Rino[3] & Munetaka Masuda[3]
[1]Kanagawa Cancer Center, Yokohama, Japan; [2]Yokohama City University Medical Center, Yokohama, Japan; [3]Yokohama City University School of Medicine, Yokohama, Japan.

Introduction
Angiogenesis is known to play an important role in the development, growth, and metastasis of carcinomas. The vascular endothelial growth factor (VEGF) and VEGF receptor (VEGFR) are major molecules involved in angiogenesis. The VEGF family includes seven members, respectively named VEGF-A (often simply denoted as VEGF), VEGF-B, VEGF-C, VEGF-D, VEGF-E, VEGF-F, and placental growth factor. The VEGFR is a tyrosine kinase receptor with one to three types and is activated by binding to the VEGF. Among these receptors, the VEGFR2 has an important role in angiogenesis. It is suggested that the expression of VEGF correlates with advanced tumor stage in papillary thyroid cancer (PTC). Anaplastic thyroid cancer (ATC) accounts for 2% of all thyroid cancers but is one of the most lethal neoplasms in humans, with a median survival of 4–6 months. Conventional ATC therapy uses a multimodal approach with radiation therapy and conventional chemotherapy. Some patients survive for a fairly long time after receiving this therapy. A monoclonal antibody against VEGF has been developed for cancer treatment, and its antitumor effect has been reported. The effectiveness of lenvatinib, which mainly inhibits the VEGFR2, has been shown for PTC. Lenvatinib also has significant antitumor effects for ATC and is used in clinical practice. However, few studies report the expression of VEGF or VEGFR in ATC. Here, we studied the expression of VEGFR2 in ATC and the therapeutic effect of lenvatinib on ATC.
Materials and methods
Primary tumors were obtained from 12 patients with ATC (five males, seven females; age range, 63–89 years)[Editor1] who underwent surgery or core needle biopsy of a thyroid tumor at the Department of Breast and Endocrine Surgery, Kanagawa Cancer Center, Kanagawa, Japan. The protein expression of VEGFR2 in ATC was analyzed using immunohistochemical analysis. Furthermore, the therapeutic effect of lenvatinib was evaluated in seven patients who underwent the same tissue biopsy and lesion evaluation.
Result
All 12 patients had no expression of VEGFR2. The therapeutic effect of lenvatinib was classified as a partial response in four patients and as a stable disease in three patients.
Conclusion
There was no correlation between the expression of VEGFR2 in ATC tissues and the therapeutic effect of lenvatinib. Further studies are required to improve the overall survival of patients with ATC by investigating clinical predictive factors or new therapeutic target molecules.

Medullary thyroid carcinoma: a case report on the efficacy and safety of combined treatment with Vandetanib and Lanreotide Autogel

Athanasia Kalantzi[1], Labrini Papanastasiou[1], Liana Charalabidou[1], Konstantinos Lyberopoulos[2] & Theodora Kounadi[1]
[1]Department of Endocrinology and Diabetes, General Hospital 'G, Gennimatas', Athens, Greece; [2]Department of Radiology, General Hospital 'G, Gennimatas', Athens, Greece.

Introduction
Treatment options for progressive metastatic unresectable medullary thyroid carcinoma (MTC) include tyrosine kinase inhibitors (TKIs) or somatostatin analogues (SSA), although the efficacy of the latter is debatable. In such cases, combined treatment of TKIs and SSAs has not previously been reported.
Aim
To present a metastatic MTC case successfully treated with a combination of Vandetanib and Lanreotide Autogel.
Case report
A 67-year-old patient presented with progressively exacerbated anorexia, 40 kg weight loss and chronic diarrhoea. Abdominal CT scan demonstrated a hilus hepatic mass of 5.4 cm and multiple hepatic metastases. Hepatic biopsy revealed a well-differentiated neuroendocrine tumour. Octreoscan showed increased uptake in the liver and left thyroid lobe. Neck/chest CT scan revealed a mass of 4.46 cm in the left thyroid lobe. One month later, upon referred to our department, abdomen MRI showed enlargement of the hilus hepatic mass up to 10.5 cm and multiple hepatic metastatic lesions the greater of which 11 cm, located in the right lobe, suggesting rapid progression of the disease. Thyroid FNA confirmed an MTC. Calcitonin (60 300 pg/ml) and CEA (851 μg/l) levels were elevated. Based on hormonal, radiological and cytological findings an unrespectable rapidly progressive metastatic MTC was diagnosed. Given the rapid progression of disease combination treatment with Lanreotide Autogel 120 mg s.c. monthly and Vandetanib 300 mg daily was initiated, hoping to hamper further progression. In view of the possible synergic action of the above-mentioned drugs on QTc prolongation, the patient was kept under close electrocardiographic monitoring. No signs of QTc prolongation were marked. The patient experienced rapid remission of the diarrhoeic syndrome and shrinkage of the thyroid mass, which became almost impalpable within 4 weeks. Six months later, a new Abdomen MRI and neck/chest CT showed a significant shrinkage in size and number of the above-mentioned lesions. No new lesions were observed. The majority of hepatic metastases was non-measurable, the metastatic hilum mass became 4.5 cm and the thyroid mass 2.9 cm. Overall tumour burden reduced $>30\%$ according to RECIST criteria. Calcitonin levels fell to 125 pg/ml, while CEA unexpectedly elevated to 1528.5 μg/l, regardless of clinical and radiological remission. No adverse effects requiring dose adjustment were observed.
Conclusions
Combination of Vandetanib and Lanreotide Autogel could be considered as a safe and effective treatment for metastatic, rapidly progressive, unresectable MTC. Further studies comparing combination treatment to Vandetanib monotherapy are needed to validate the efficacy of this approach.

Increased incidence of thyroid cancer in a spanish tertiary hospital, valladolid, spain: evolution and clinical characteristics, 2002–2016

Susana Garcia Calvo[1], Gonzalo Diaz-Soto[1], Maria Alvarez-Quiñones Sanz[2], Isabel Martinez-Pino[3], Beatriz Torres[1], Juan Jose Lopez[1], Juan Jose Mateos[2] & Daniel de Luis[1]
[1]Servicio de Endocrinología y Nutrición, Hospital Clínico Universitario de Valladolid, Instituto de Endocrinología y Nutrición, Universidad de Valladolid, Valladolid, Spain; [2]Servicio de Anatomía Patológica, Hospital Clínico Universitario de Valladolid, España., Valladolid, Spain; [3]Sección Promoción de la Salud. ST Sanidad Valladolid JCYL. CIBERESP-ISCIII, Valladolid, Spain.

Introduction
Thyroid cancer is the most frequent malignant endocrine neoplasia. Its incidence has significantly risen worldwide in the last decades.
Objective
To estimate the incidence of thyroid cancer in Valladolid's east area population, Spain, over the period 2002–2016.

Methods
A retrospective descriptive research was performed in the Clinical Universitary Hospital of Valladolid (HCUVa). Clinical data was obtained from Anatomical Pathology Registry of HCUVa from 2002 to 2016. At diagnosis, the age, sex, histological features, size and stage of the thyroid tumor were analyzed. Incidence diagnosed rates were calculated adjusted to reference European Population by sex and age in three-year periods.
Results
398 patients were diagnosed of Differentiated Thyroid Cancer from 2002 to 2016; 78.6% were women with a mean age of 52.44 years (DS 15.20). The overall incidence of thyroid cancer increased over the last 15 years, from 5.2 to 25.7 per 10^5 population/year in women and from 2.3 to 8.8 per 10^5 population/year in men ($P<0.0001$). Incidence rates were significantly higher in males compared to females. Mean age at diagnosis increased from 45.54 years (DS 15.94) to 54.53 years (DS 15.61) ($P<0.01$). There were no statistical differences in tumor size at diagnosis. However, a size increment trend in papillary macrocarcinomas from 1.8 cm (DS 0.77) to 2.49 cm (DS 1.54) – ns – was observed. Gender and papillary and follicular carcinoma rates kept stable over the period (19.2–21.4%) and (92.3–97.1% and 7.7–3.3%), respectively -ns-. An increase in micropapillary thyroid cancer (<1 cm) from 29.4% to 52.1% -ns- was observed throughout the period. Finally, the distribution of papillary carcinomas over the whole period was: 51.21% of classic variant of papillary thyroid cancer, 42.98% of follicular variant and 5.8% of aggressive variant. An increment of follicular variant and aggressive papillary carcinoma from 29.2% to 50.7% and from 4.2% to 8.2% was observed from 2002 to 2016, respectively ($P<0.05$).
Conclusions
During the period studied, the incidence of thyroid cancer increased in Valladolid in both sexes. The increase in micropapillary thyroid cancer diagnose was mainly responsible for this rising trend. These results suggest an increase of thyroid cancer in the diagnosis due to changes in clinical practice and the extensive introduction of new diagnostic techniques, such as neck ultrasonography.

DOI: 10.1530/endoabs.56.P1142

P1143

The significance of postoperative calcitonin (CT) levels in the evaluation of disease course in medullary thyroid cancer (MTC) patients

Katerina Saltiki, George Simeakis, Evangelia Vogiatzi, Eva Kassi, Evangelia Zapanti & Maria Alevizaki
Endocrine Unit, Department of Clinical Therapeutics, Medical School National Kapodistrian University, Athens, Greece.

Aim
Postoperative calcitonin (postCT) is a prognostic factor for disease progression in MTC patients. We evaluated the disease course in patients with persistently elevated post-CT.
Methods
Of all MTC patients ($n=273$) followed-up in our Unit (for 1–37, median 7 years), 140 (39.3% men, 67.1% sporadicMTCs) had persistently elevated postCT (≥2.0 pg/ml). Clinical and biochemical data were recorded. Patients were classified in four groups according to postCT: group1: (2–12 pg/ml, $n=34$, 24.3%), group 2: (13–50 pg/ml, $n=26$, 18.6%), group 3: (51–200 pg/ml, $n=30$, 21.4%), group 4: (>200 pg/ml, $n=50$, 35.7%).
Results
Men had post-CT>50 ($P=0.005$) more frequently. SporadicMTCs had post-CT>200 more frequently than familialMTC (43.6% vs 19.6%,$P=0.019$). With increasing postCT, unfavorable histopathological features and multiple surgeries ($n\geq2$) were more frequent ($P<0.001$), tumor size was larger (median (IQR) 1.0(1.8), 1.25(1.23), 1.5(0.9), 2.5(1.8) cm, $P<0.001$) and preoperative-CT was higher (200(334), 17.9(732), 455(1011), 2500 (>10.000), $P=0.002$) in the four groups respectively. Distant metastases at diagnosis were present only in group4 patients (31.3%, all with post-CT>400). Metastatic disease appeared in 8% of group 1, 8% of group 2, 29.6% of group 3 and 68.9% of group four during follow up; progression was recorded in 5.9%, 19.2%, 26.7% and 78.0% while disease remission at last follow-up (after multiple interventions) was recorded in 71.0%, 27.3%, 14.3% και 0.0%, in the four groups respectively ($P<0.001$). The 10-year probability of absence of disease progression differed significantly between the four groups (group1: 94.1%, group 2: 80.8%, group 3: 73.3%, group 4: 22%, $\chi^2=30.3$, $P<0.001$ Log Rank). In Cox-proportional hazard analysis when age, sex, histological features, disease stage at diagnosis and postCT group were taken into account, the only predictor for disease progression were postCT ($P=0.037$), familial disease ($P=0.016$) and stage ($P=0.05$).
Conclusions
This study confirms that postCT are significant predictors of the clinical course in MTC patients. Approximately 20% of patients with postCT>200 showed slow disease progression. Increased awareness is required for patients with low-CT-secreting MTC as their levels may not reflect the disease extent.

Changing treatment trends with radioiodine in thyroid carcinoma at the beginning of 21st century in Castilla-La Mancha (Spain)

Manuel Delgado[1], Julia Sastre[2], Ivan Quiroga[3], Javier Gonzalez[4], Belvis Torres[5], Silvia Aznar[6], Visitación Alvarez[7], Sandra Herranz[7], Jesús Moreno[1] & Paz Gómez[1]
[1]Hospital General Universitario de Ciudad Real, Ciudad Real, Spain; [2]Complejo Hospitalario de Toledo, Toledo, Spain; [3]Hospital General Nuestra Señora del Prado, Talavera de la Reina, Spain; [4]Hospital Virgen de la Luz, Cuenca, Spain; [5]Hospital General La Mancha Centro, Alcázar de San Juan, Spain; [6]Complejo Hospitalario Universitario de Albacete, Albacete, Spain; [7]Hospital Universitario de Guadalajara, Guadalajara, Spain.

Background and objective
The incidence of differentiated thyroid carcinoma (DTC) is increasing worldwide. Radioiodine (RAI) ablation is one of the main elements in the therapy of DTC after surgical removal of the gland. This study aims to compare the use of I131 in a Spanish Cohort of DTC before and after the American Thyroid Association (ATA) 2009 guidelines.
Patients and methods
The Cadit-CAM study was designed to evaluate retrospectively characteristics of patients diagnosed of DTC in Castilla-La Mancha (CAM), a region in the central part of Spain, from 2001 to 2015. The cohort in Cadit-CAM study included 1434 patients from seven hospitals. We studied the use of RAI ablation therapy n this cohort. Patient recurrence risk was assessed using ATA risk stratification system (Low, Intermediate and High risk).
Results
1426 patients were analyzed (77% women, 92% papillary carcinomas). 1183 of them received RAI ablation (83.4%). The mean initial activity of I131 was 101.3 mCi. The mean accumulated activity was 148.7 mCi, only 21.7% of the patients received more than one RAI ablation therapy. Before 2010, RAI was used in 565 of 639 patients (88.4%). Between 2010 and 2015, 618 of the 779 patients diagnosed with DTC received RAI ablation therapy (79.3%, $P<0.01$). 81.1% of patients in the Low Risk category received I131 before 2010 and after this year only 66.5% were submitted to RAI ($P<0.01$). In Intermediate and High risk patients there were no differences in RAI therapy (99.0% vs 97.8% and 98.3% vs 90.7%, respectively) between the two periods. In microcarcinomas I131 was used in 65.9% before 2010 and in 46.7% after ($P<0.01$). Mean initial activity in low risk patients was significantly different before and after 2010 (99.3 vs 68.9 mCi, $P<0.01$). The recurrence rate of microcarcinomas and low-risk DTC was less than 1.5% in patients without RAI therapy in this Spanish Cohort.
Conclusion
There is a trend in using less RAI ablation in low-risk DTC after the 2009 ATA guidelines. In our cohort the prognosis of microcarcinoma and low-risk DTC was excellent in patients treated and not treated with RAI ablation therapy. We recommend risk-based selection of patients candidates for RAI, according to international guidelines.

Chronic lymphocytic thyroiditis is associated with decreased staging of differentiated thyroid cancer

Martyna Borowczyk, Adam Janicki, Grzegorz Dworacki, Ewelina Szczepanek-Parulska, Mateusz Danieluk, Jonathan Barnett, Magdalena Antonik, Małgorzata Kałużna, Barbara Bromińska, Rafał Czepczyński, Maciej Bęczyk, Katarzyna Ziemnicka & Marek Ruchała
Poznan University of Medical Sciences, Poznan, Poland.

Introduction
Despite numerous studies, the biological association between chronic lymphocytic thyroiditis (CLT) and differentiated thyroid cancer (DTC) has not been elucidated yet. The aim of the study was to assess whether the presence of CLT exerts any influence on clinical or histological presentation of DTC.
Materials and methods
Complete medical records of 907 consecutive patients with DTC treated at a single tertiary care department of endocrinology in the years 1998–2016 were subjected for analysis. The patients were divided into two groups according to the presence (studied group) or absence (control group) of concomitant CLT. Particular parameters were evaluated and compared between the groups. The statistical differences were analysed.
Results
Out of 907 patients included in the study, 331 were diagnosed with DTC and CLT (studied group) while 576 patients with DTC but without CLT constituted a control group. There was no difference in the distribution of papillary and follicular thyroid cancer in both groups. Patients from the studied group were younger than controls at the moment of diagnosis. The prevalence of pT1 was greater than for pT2-pT4 DTC ($P=0.0003$; OR = 1.69, range: 1.27–2.24) in the studied group compared to controls (68.3% vs 56.1% respectively). The thyroid capsule infiltration without extrathyroidal invasion was more frequent ($P<0.0001$) and post-thyroidectomy TgAb levels were greater ($P<0.0001$) but Tg levels were lower ($P<0.0001$) in the studied group. The presence of multifocal lesions was similar in both groups. Multivariate regression analysis confirmed that the protective factors against higher tumour staging (pT2-pT4) were female sex, papillary, unlike follicular, thyroid cancer and the co-occurrence of CLT.
Conclusions
The collected data indicate a protective role of CLT in preventing spread of the DTC. The presence of CLT might possibly limit tumour growth to primary site.

Clinical characteristics and prognostic factors in patients with follicular thyroid carcinoma

Ander Ernaga Lorea, Iranzu Migueliz Bermejo, Nerea Eguílaz Esparza, Emma Anda Apiñániz, Javier Pineda Arribas, Ana Irigaray Echarri, Marta Toni García & Juan Pablo Martínez De Esteban
Complejo Hospitalario de Navarra, Pamplona, Spain.

Objective
The aim of this study is to evaluate clinical characteristics of patients diagnosed of follicular thyroid carcinoma and to study factors that are associated with a worse prognosis of the disease.
Methods
We included 153 patients diagnosed of follicular thyroid carcinoma in our centre between January 1985 and December 2016. The baseline characteristics of the patients, and their long-term outcomes were collected. The mean follow-up was 15.2 years.
Results
The mean age of the patients was 45.6 ± 15.2 years and we found a higher prevalence of women (79.1%, $n=121$). The mean tumor size was 36.3 ± 17.8 mm. According to the AJCC/TNM classification, we observed 94 patients (61.4%) in stage I, 36 patients (23.5%) in stage II, 18 patients (11.8%) in stage III and three patients (2%) in stage IV. There was a higher prevalence of minimally invasive tumors (84.3% vs. 15.7%). In the follow-up, 3.9% of the patients died due to the tumor or had recurrence or persistence of the disease at the end of the study. In the univariate analysis the presence of persistence/recurrence or death was associated with an increased age, TNM classification at diagnosis and histological subtype (minimally or widely invasive). Using a multivariate model (logistic regression) only the histological subtype was associated with a worse tumor prognosis ($P=0.041$).
Conclusion
- In our study, the 10 years disease-free survival rate of patients diagnosed of follicular thyroid carcinoma was 96.4%.
- The most important predictor of persistence/recurrence of the disease or mortality was the histological subtype.
- The 10 years disease-free survival of widely invasive tumor was 80.2%

Association between Hashimoto's thyroiditis and thyroid lymphoma

Ilona Banisauskaite[1], Lina Barsiene[1], Robertas Pranevicius[2], Gintaras Kuprionis[3], Albertas Dauksa[4] & Milda Rudzianskiene[5]
[1]Lithuanian University of Health Sciences, Kaunas Clinics, Department of Endocrinology, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Kaunas Clinics, Department of Cardiology, Kaunas, Lithuania; [3]Lithuanian University of Health Sciences, Kaunas Clinics, Department of Radiology, Kaunas, Lithuania; [4]Lithuanian University of Health Sciences, Kaunas Clinics, Department of Surgery, Kaunas, Lithuania; [5]Lithuanian University of Health Sciences, Oncology Institute, Kaunas, Lithuania.

Introduction
Lymphoma usually occurs within lymph nodes, but in rare cases, it arises from lymphocytes that are presented within the thyroid gland**.** Thyroid lymphoma is rare, representing less than 5% of thyroid malignancies and less than 2% of all lymphomas occurring outside of the lymph nodes and it is more likely to occur in people with Hashimoto's thyroiditis. In this case we present a patient with Hashimoto's thyroiditis (HT) and thyroid lymphoma (TL).
Case
63 years women presented to the outpatients clinic with complains of fatigue, weakness of voice and enlargement of the neck. She has autoimmune thyroiditis (anti-TPO 53 kU/l) for 10 years. She has been taking Levothyroxin 50 μg per day for 5 years. Few weeks ago, she had noticed painless fast swelling left side of the neck and after 2 weeks the enlargement of the right side of the neck. Physical examination showed a large palpable mass on the both sides of the neck and an enlarged thyroid. Laboratory studies showed elevated sedimetation rate 34 mm/h (normal <13 mm/h), elevated anti-TPO antibodies 689kU/l (0–12) and anti-Tg 682 kU/l (0–100). Other laboratory measurements, including haemoglobin and leukocytes, thyroid hormones (FT4 15.22 pmol/l (12–22), TSH 0.72 mU/l (0.27–4.2), anti-TSH-R 3U/l (<9)), calcitonin <0.42 pmol/l (0–2.8), were normal. In the thyroid ultrasound examination thyroid enlarged, hypoechoic, heterogeneous, in the left side pathological lymph nodes – suspicion of lymphoma or anaplastic carcinoma. Other radiological tests, including abdomen ultrasound, chest X-ray and mammography, evaluating the spread of oncological process, were normal. Core needle biopsy of the thyroid was taken and showed a Diffuse large B-cell lymphoma (DLBCL). PET-CT scan showed metabolically active lymphoproliferative process in the thyroid, in the lymph nodes of mediastinum, in the small intestine and in the mesenteric lymph nodes. The patient was diagnosed with DLBCL (non Hodgkin's lymphoma) stage IV IPI 4 of the thyroid with hypothyroidism. Treatment with R-CHOP21 (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisolone) chemotherapy was started. After the first course of chemotherapy thyroid enlargement regressed, after the third course of chemotherapy anti-TPO antibodies decreased to 85kU/l, anti-Tg decreased to 55 kU/l, the thyroid function remained stable and in the thyroid ultrasound only the signs of thyroiditis is observed.
Conclusions
This case proves that TL, although rare, should always be considered in the differential diagnosis of patients with fast thyroid enlargement, nodules, goiter and carcinomas, because its prognosis and treatment differ substantially from the other disorders.

P1148

Prediabetes and type 2 diabetes mellitus and risk of thyroid cancer

Tereza Grimmichová[1,2] & Petr Matucha[1]
[1]Institute of Endocrinology, Prague, Czech Republic; [2]2nd Department of Internal Medicine, University Hospital Královské Vinohrady and Third Faculty of Medicine, Charles University, Prague, Czech Republic.

Background
Increasing incidence of thyroid cancer may be attributable to sensitive diagnostic tools as well as changes in exposure to certain environmental factors. Type 2 diabetes mellitus (DM) reaches high prevalence worldwide. DM is a risk factor for many chronic disorders including cardiovascular disease and cancer. Insulin resistance (IR) is a fundamental aspect of the etiology of DM and compensatory

hyperinsulinemia could promote cancer growth. The association between DM and thyroid cancer is inconclusive.
Methods
Case–control prospective study in 698 randomly selected patients without history/treatment of thyroid disease in iodine sufficient area. The patients were screened for DM, underwent thyroid ultrasound and laboratory tests. The patients were assigned to group of prediabetes (PDM) ($n=53$; 7.6%), DM ($n=64$; 9%) and non-DM (NDM) ($n=581$). FNA (fine needle aspiration biopsy) was carried out in 224 patients.
Results
Thyroid size (ml) in DM 15.1 (9.59–21.57), PDM 13.35 (8.94–17.88), NDM 10.87 (7.94–16.2); ($P=0.001$; after adjustment for age $P=0.062$). TSH (mUI/l) in DM 2.4 (1–6.7), PDM 1.2 (0.7–2.45) and NDM 1.6 (0.85–3.6) ($P=0.65$). PDM/DM were in 40% of patients diagnosed by our screening. FNA Bethesda I ($n=22$; 9.8%), II ($n=169$; 75.5%), III ($n=13$; 5.8%), IV ($n=7$; 3.1%), V ($n=8$; 3.6%), VI ($n=5$; 2.2%). Histological examination was done in 37 patients, 19 findings were malignant (2.72%). Rate of thyroid malignancy was similar in PDM/DM 3.42% vs NDM 2.58%. In both groups the most common type of thyroid tumor was papillary carcinoma (50%; $P=0.668$). Advanced differentiated thyroid carcinoma and other histological types including poorly differentiated tumors were just in NDM group. TSH correlated negatively with thyroid size in all study groups ($r=-0.474$; $P=0$), and with thyroid nodule size just in NDM ($r=-0.357$; $P=0$). This relation remained identical after exclusion of patients with Graves-Basedow thyrotoxicosis ($r=-0.459$; $P=0$). Just in NDM and PDM groups, the thyroid size was positively correlated with HOMA IR ($r=0.303$; $P=0.001$ vs $r=0.414$; $P=0.013$), BMI ($r=0.201$; $P=0$ vs $r=0.330$; $P=0.025$) and C-peptide ($r=0.266$; $P=0.004$ vs $r=0.437$; $P=0.009$).
Conclusion
In the most insulin resistant subjects, diabetic and prediabetic group, we did not observe significantly increased risk of thyroid cancer. Thyroid cancer types with poorer prognosis were observed just in NDM. Thyroid gland is larger in DM, but ageing is essential part of this growth. TSH represents major stimulus of thyroid growth. However, other growth factors besides TSH must be involved.

The mitochondrial DNA control region might have useful diagnostic and prognostic biomarkers for thyroid tumors

Rıfat Bircan[1], Hülya Ilıksu Gözü[2], Esra Ulu[1], Şükran Sarıkaya[3], Duygu Yaşar Şirin[1], Serhat Özçelik[4] & Cenk Aral[1]
[1]Namık Kemal University, Arts and Sciences Faculty, Department of Molecular Biology and Genetics, Tekirdağ, Turkey; [2]Marmara University, School of Medicine, Department of Endocrinology and Metabolism, İstanbul, Turkey; [3]Kartal Dr. Lütfi Kırdar Education and Research Hospital, Department of Pathology, İstanbul, Turkey; [4]Hardarpaşa Education andResearch Hospital, Section of Endocrinology and Metabolism, İstanbul, Turkey.

Background
It is currently present in the literature that mitochondrial DNA (mtDNA) defects are associated with a great number of diseases including cancers**.** The role of mitochondrial DNA (mtDNA) mutations/variations in the development of thyroid cancers is a highly controversial topic. In this study, we aimed to investigate the role of mt-DNA control region (CR) variations in thyroid tumor occurrence and the influence of mtDNA haplogroups on susceptibility to thyroid tumors in Turkish population.
Material and method
For this purpose, totally 108 hot thyroid nodules (HTNs), 95 cold thyroid nodules (CTNs), 48 papillary thyroid carcinoma (PTC) samples with their surrounding tissues and 104 healthy control subject's blood samples were screened for entire mtDNA CR variations. MtDNA D-loop CR was screened by using Sanger sequencing. The obtained DNA sequences were evaluated and mitohaplogroups were determined with the mitomaster, a web-based bioinformatics tool.
Results
MtDNA haplogroup U was significantly associated with susceptibility to benign and malign thyroid entities on the other hand J haplogroup was associated with a protective role for benign thyroid nodules. Besides, 10 SNPs (T146C, G185A, C194T, C295T, D568, G16129A, C16292T, T16304C, A16343G and T16362C) in mtDNA CR were associated with the occurrence of benign and malign thyroid nodules in Turkish population. By contrast with the healthy Turkish population and HTNs, the frequency of C7 repeats in D310 polycytosine sequence was found higher in CTN and PTC samples (χ^2 test; $P=0.04$) Beside this, the frequency of somatic mutations in MSI regions including T16189C and D514 CA dinucleotide repeats were found higher in PTC samples than the benign thyroid nodules (χ^2 test; $P<0.0001$, $P=0.0003$ respectively). Conversely, the frequency of somatic mutations in D310 MSI was detected higher in HTNs than CTNs and PTCs ($P=0.04$).
Conclusion
This study reveals that U haplogrup is associated with the susceptibility to benign and malign thyroid tumor occurrence in Turkish population. Although mtDNA D310 instability does not play a role in tumorigenesis of the PTC, the results indicates that it might be used as a diagnostic clonal expansion biomarker for premalignant thyroid tumor cells. Beside this, D514 CA instability might be also used as prognostic biomarker in PTCs.

Papillary carcinoma detected incidentally in a patient with Graves' disease

Elif Sevil Alaguney[1], Goknur Yorulmaz[1], Evrim Yılmaz[2], Bartu Badak[3], Nur Kebapci[1] & Aysen Akalin[1]
[1]Eskisehir Osmangazi University Division of Endocrinology, Eskisehir, Turkey; [2]Eskisehir Osmangazi University Department of Pathology, Eskisehir, Turkey; [3]Eskisehir Osmangazi University Department of General Surgery, Eskisehir, Turkey.

Introduction
Graves' disease is an autoimmune thyroid disease presenting with hyperthyroidism. In Graves' disease, there may be diffuse enlargement in the thyroid gland, as well as nodular appearance. The risk of papillary carcinoma should always be kept in mind while the risk of malignancy is low in Graves' disease.
Case presentation
A 50-year-old woman was admitted to our center for a second-time exacerbation of hyperthyroidism in 2015. Her history revealed a diagnosis of Graves' disease in 2008 and her disease was in remission in the first year of treatment. She was referred to our center with the reason that the remission cannot be achieved after starting propylthiouracil treatment. In admission the ultrasound findings are,the right thyroid lobe was $19\times14\times45$ mm, left lobe was $24\times19\times53$ mm, and isthmus was 2.2 mm. It also showed heterogeneous parenchyma echogenicity for both thyroid lobes, due to the millimetric hypoechoic areas compatible with thyroiditis while there was no nodular appearance. Thyroid stimulated receptor antibody levels were 2.54 U/l(0–1.5). Ophthalmologic examination did not suggest thyroid ophthalmopathy. We stopped propylthiouracil treatment and started methimazole. In the follow-up of the first year euthyroid state was achieved with methimazole treatment, however hyperthyroidism emerged when methimazole dose reduced. In this period, increased levels of thyroid stimulated receptor antibody were detected (4.2 U/l). Euthyroid state could not be established despite the maximal dose of methimazole. Thyroid stimulated receptor antibody levels were 12 U/l. Surgery was planned after establishing euthyroid state with plasmapheresis therapy. Total thyroidectomy was performed and pathology revealed papillary microcarcinoma with follicular variant in a 0.5 cm lesion in the left lobe under the capsule without invasion of vascular system or the capsule. The patient is followed with thyroid suppression therapy.
Discussion
It is important to follow patients with Graves Hyperthyroidism with physical examination and ultrasound in order to assess nodules. Our patient was operated because of uncontrolled hyperthyroidism, not for malignancy. Sporadic cases of thyroid carcinoma can be seen in patients with Graves Hyperthyroidism.

Determination of the BRAF V600E mutation prevalance at papillary thyroid carcinomas (PTCs) in Turkish population

Serhat Özçelik[1], Rıfat Bircan[2], Şükran Sarıkaya[3], Büşra Aydın[2], Mehmet Çelik[1], Akın Dayan[1], Nimet Karadayı[3], Yasemin Tütüncü[1], Hasret Cengiz[1], Melike Özçelik[4] & Hulya Ilıksu Gözü[5]
[1]Haydarpaşa Education Hospital, Endocrinology and Metabolism Section, İstanbul, Turkey; [2]Namık Kemal University, Arts and Sciences Faculty, Department of Molecular Biology and Genetics, Tekirdağ, Turkey; [3]Kartal Dr. Lütfi Kırdar Education and Training Hospital, Pathology Department, İstanbul, Turkey; [4]Kartal Dr. Lütfi Kırdar Education and Training Hospital, Department of Medical Oncology, İstanbul, Turkey; [5]Marmara University, School of Medicine, Department of Endocrinology and Metabolism, İstanbul, Turkey.

Introduction
BRAF V600E substitution is one of the most common mutation in PTC in different populations, and is associated with poor prognosis of the classical

variant of PTC (CVPTC) such as extrathyroidal expansion, vascular invasion, lymph node metastasis and recurrence of the disease. The purpose of this study is to determine the prevalence of BRAF V600E mutation in subcell- types of the PTCs in Turkish population.
Materials and methods
A total of 191 patients diagnosed with PTC admitted to Dr. Lutfi Kirdar Kartal Education and Research Hospital, Istanbul, were retrospectively analyzed. Clinical and pathologic factors including age, gender, PTC subtype, thyroid capsule invasion, extrathyroidal tissue invasion, and lymph node metastasis were obtained from patients' medical records. DNA was extracted from FFPE tissue samples. The BRAF gene region including V600E mutation was screened by using high resolution melting curve analysis (HRMA) and the precise localisation of mutations were confirmed by using DNA sequencing with Sanger method.
Results
One hundred and nine patients were diagnosed as CVPTC, 37 were macrocarcinoma and 72 were microcarcinoma. Sixty-five were diagnosed as Follicular variant of PTC (FVPTC), seventeen were diagnosed as Oncocytic variant of PTC (OVPTC). A mutation at 15th exon of the BRAF gene was detected in 23 of the 37 macroCVPTC patients. Nineteen out of twenty- three of these mutations were BRAF V600E, 1/23 was BRAF V600V and 3/23 were BRAF F583Y. Seventeen of the 72 microCVPTC cases were harbored with one of the BRAF mutations. Fifteen of them were BRAF V600E (20.8%) and only two of them were V600V mutation. Two mutations were detected in 37 macroFVPTC patients, one being BRAF V600V, while the other was BRAF V600E mutation (2.7%). Besides, two of the 28 microFVPTC cases (7.1%) were harbored with BRAFV600E mutation. Four of 12 macroOVPTC cases had one of the BRAF mutation. One of them was BRAFF595L and the others were BRAFV600E (25%). One of the microOVPTC case had BRAFV600V mutation. When mutation positive tumor samples were compared with mutation negative ones in classical variant group(CVPTC), thyroid capsule invasion, extrathyroidal tissue invasion, and lymph node metastasis were associated with BRAF mutations independent from tumor size ($P < 0.05$ for each).
Conclusion
Considering that BRAF V600E mutation is correlated with poor prognosis of the disease according to the obtained data, larger population based studies are necessary in order to follow up the prognosis of the PTC patients in Turkish population.

Association between Ospital ng Makati-based thyroid ultrasonography descriptive findings and fine-needle aspiration biopsy with histopathology in the diagnosis of thyroid malignancies

Jose Antonio Bautista, Rosa Allyn Sy, Buena Sapang & Chritopher Cipriano
Ospital ng Makati, Makati, Philippines.

Statement of the problem
Thyroid nodules are one of the most common clinical problems encountered today. Detection of these nodules have been augmented with ultrasonography and fine needle aspiration biopsy (FNAB). Worldwide, the use of international standards of reporting such as the American Thyroid Association (ATA) Sonographic Pattern Risk Assessment and the Bethesda System for Reporting Thyroid Cytopathology have been proven to detect thyroid malignancies. However, ultrasonographic descriptions and FNAB reports are different at the Ospital ng Makati (OSMAK), wherein these are described in ways that deviate from international standards. Thus, the study aimed to validate the association of these OSMAK-based reports with the histopathology results, and to determine their accuracy in detecting malignancy as confirmed by histopathology.
Methodology
A retrospective cohort study was utilized among patients 20 years old and above with thyroid malignancies who had thyroid ultrasonography and FNAB done at OSMAK between January 2012 and January 2017. Descriptive statistics were utilized to present the variables. Review of thyroid ultrasound descriptions and FNAB were done based on common descriptive findings seen on reports. The association between these findings and the histopathologic findings were done through Fisher's Exact Test. The accuracy of these OSMAK-based descriptions and reports were then analyzed.
Findings
It was determined that there was not enough evidence to conclude that OSMAK-based thyroid ultrasonography was associated with histopathologic findings ($P = 0.135$) and the test had an accuracy of detecting malignancy at 40.5%. Also, there was also not enough evidence to conclude that OSMAK-based FNAB was associated with histopathologic findings ($P = 0.083$), and the test had an accuracy of 56.8%.
Conclusion & Significance
The use of OSMAK-based ultrasonography and FNAB reporting are not accurate in detecting thyroid malignancies. Hence, the use of validated, internationally-accepted guidelines should be implemented to help physicians provide the most appropriate care for these patients.

Thyroid gland metastasis from a laryngeal mucinous adenocarcinoma: a case report

Daphne Gayle Galang, Nerissa Ang-Golangco &
Joseph Ray Richard Cedeno
Makati Medical Center, Makati City, Philippines.

Introduction
Despite its high vascularity, metastases to the thyroid is rare. The frequency of metastasis in routine practice is less than 0.2% of thyroid malignancies.
Clinical case
An ambulatory 48-year-old male presented with a two-month history of enlarging anterior neck mass that moves with deglutition, slowly growing in size, associated with hoarseness later in the course of the disease. He had no pertinent past medical history. Fine needle aspiration biopsy report: papillary thyroid cancer. CT scan was done and revealed a $5 \times 3 \times 5$ cm mass occupying almost the entire thyroid gland, but protruding to the lumen of the trachea and obliterating the upper portion of esophagus. The patient underwent total thyroidectomy, laryngectomy with tracheostomy. Pathological examination revealed the presence of abundant mucus secreting agglomeration of large atypical cells. Findings were consistent with mucinous adenocarcinoma involving the right thyroid lobe, isthmus and larynx. There was noted lymph node metastasis involving 15 out of 19 level II to V neck lymph nodes. Immunohistochemistry showed that the tumor stained negative for thyroid transcription factor-1 and thyroglobulin. This is consistent with a metastatic tumor rather than a primary thyroid cancer. CK 7 was positive, CK 20 was negative, consistent with a pulmonary origin of the tumor. A PET scan was done a month after surgery, which showed extensive metastatic disease. There was noted FDG positivity of bilateral noncalcified pulmonary nodules, cervical lymph nodes at all levels, esophagus, liver, gastric wall and mesenteric soft tissue masses and nodules. Due to the widespread metastases he opted to be treated with palliative radiotherapy. Two months later, the patient died.
Conclusion
Metastasis to the thyroid is rare but may indicate extensive disease. In patients presenting with an anterior neck mass, an FNAB may not be sufficient to clinch the diagnosis and staining for specific cancer markers may be necessary.

Circulating thyroid autoantibodies are more sensitive than fine needle aspiration in detecting metastatic thyroid cancer

Federica Ferrari, Laura Agate & Francesco Latrofa
Endocrinology Unit University Hospital of Pisa, Pisa, Italy.

Introduction
Follow up of differentiated thyroid cancer requires periodic measurements of thyroglobulin (Tg) and Tg autoantibodies (TgAb) and neck ultrasound. Recurrence is suspected in presence of rising levels of Tg and/or TgAb. Positive cytology or detectable Tg in washout of fine needle aspiration (FNA) of neck lymph nodes or 131-I neck uptake confirm the diagnosis of metastatic lymph node.
Case report
We report on a 25 year-old Caucasian man, affected by a classic variant papillary thyroid carcinoma with lymph nodal involvement and lymphocytic thyroiditis who underwent total thyroidectomy plus central compartment lymph node dissection. Three months later he underwent residual thyroid tissue ablation by 131-I activity (30 mCi). A neck ultrasound performed 6 months later showed two lymph nodes suspicious for metastatic disease. In the following four years lymph

nodes did not enlarge. Both cytological examination and measurement of Tg in washout turned out negative in two occasions. Tg remained undetectable while TgAb rose from a pre-surgical level of 16 IU/mL to 259 IU/mL. We treated the patient with a second 131-I activity (140 mCi). Whole body scan turned out negative. Because of this we decided to perform FNA of the suspicious lymph node which in the meanwhile was slightly enlarged (16 mm). Cytological examination was diagnostic for metastatic disease and Tg in washout fluid was 123 ng/mL. The patient subsequently underwent lymphoadenectomy. The histological examination confirmed the diagnosis of metastatic lymph node.
Conclusion
In this patient the rising of serum TgAb was the most sensitive marker predicting the recurrence of differentiated thyroid cancer. Indeed TgAb rise, in spite of constantly undetectable serum Tg and repeatedly negative FNA of neck lymph nodes, suggested the correct treatment.

Are there any differences between hot and cold nodules according to cytology and histopathology results?

Husniye Baser[1], Oya Topaloğlu[2], Muhammet Cuneyt Bilginer[2], Serap Ulusoy[3], Aydan Kılıcarslan[4], Elif Ozdemir[5], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Atatürk Education and Research Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Yildirim Beyazit University Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey; [3]Atatürk Education and Research Hospital, Department of General Surgery, Ankara, Turkey; [4]Yildirim Beyazit University Faculty of Medicine, Department of Pathology, Ankara, Turkey; [5]Yildirim Beyazit University Faculty of Medicine, Department of Nuclear Medicine, Ankara, Turkey.

Introduction
Many recent studies have shown that detection of an incidental thyroid cancer among patients operated for a toxic thyroid disease is not infrequent. We aimed to compare cytology and histopathology results of cold, warm and hot nodules in patients who had thyroidectomy due to toxic multinodular goiter (TMNG).
Methods
The cytology, histopathology and scintigraphy records of 1069 thyroid nodules from 413 patients who had operation with TMNG were reviewed in this study. The nodules were categorized as hypoactive (cold), normoactive (warm) and hyperactive (hot) groups according to scintigraphy. 0f 1069 nodules, 560 with undetermined scintigraphic activity were excluded. The cytology and histopathology results were compared.
Results
Of these 413 patients (118 men, 295 women), 23 (5.6%) had malignant and 390 (94.4%) had benign histopathology. In malignant group, 16 patients had papillary thyroid carcinoma (PTC), 3 had follicular thyroid carcinoma (FTC), 1 had an undifferentiated thyroid cancer (UTC), and 3 had thyroid tumors of uncertain malignant potential (TT-UMP). The 509 thyroid nodules were grouped as normoactive [$n=23$ (4.5%)], hypoactive [$n=122$ (24.0%)], and hyperactive [$n=364$ (71.5%)] according to scintigraphy. Cytological evaluations of 23 normoactive nodules were as follows: 7(30.4%) nondiagnostic (ND), 15(65.2%) benign, 1(4.3%) suspicious for follicular neoplasia (SFN). The cytology of 122 hypoactive nodules were ND in 25(20.5%), benign in 86(70.5%), atypia of undetermined significance (AUS) in 5(4.1%), follicular lesion of undetermined significance (FLUS) in 3 (2.5%), SFN in 1(0.8%), and finally suspicious for malignancy (SM) in 2 (1.6%). The 364 hyperactive nodules were determined as ND, benign, AUS, FLUS, SFN, SM, and malignant in 80 (22%), 259(71.2%), 10(2.7%), 7(1.9%), 2 (0.5%), 2 (0.5%) and 4 (1.1%), respectively. There were no differences according to cytological results between groups ($P=0.616$). Histopathology of normoactive nodules were PTC in 1(4.3%) nodule and benign in 22 (95.7%) nodules. However, 7 (5.7%) nodules had PTC and 1 (0.8%) nodule had FTC, 114 (93.4%) nodules had benign histopathology in hypoactive group. Histopathologies of the hyperactive group were as follows; 8 (2.2%) nodules with PTC, 2(0.6%) with FTC, 1(0.3%) with UTC, 3 (0.8%) with TT-UMP, and 350 (96.1%) nodules with benign pathology. There were no differences according to histopathological results between groups ($P=0.905$).
Conclusion
Recently, incidental papillary carcinomas originating from hot nodules have been reported. Contrary to conventional knowledge, we demonstrated similar malignancy rates in hot nodules when compared with cold and warm nodules.

DOI: 10.1530/endoabs.56.P1155

P1156

Diagnostic accuracy of CNB in tyroid nodules smaller than 1 centimeter

Miguel Paja[1], Aitziber Ugalde[1], Igone Korta[1], Rosa Zabala[1], Adela L Martínez[1], Alba Zabalegui[1], Cristina Arrizabalaga[1], Laura A Calles[1], Eider Etxebarría[1] & Jose L Del Cura[1,2]
[1]Basurto University Hospital, Bilbao, Spain; [2]Basque Country University, Bilbao, Spain.

Current guidelines suggest sonographic follow-up in thyroid nodules smaller than 10 mm with intermediate or highly suspicious features as ultrasound-guided FNAC has poor results in these nodules, and the risk of non-diagnosed thyroid carcinoma is very low. CNB has proved superior to repeated FNAC in case of insufficient or indeterminate first FNAC.
Objective
Evaluate diagnostic accuracy of CNB in nodules smaller than 10 mm with intermediate or high suspicious ultrasound (US) features.
Methods
Retrospective evaluation of all nodules CNB performed to thyroid nodules smaller than 1 cm in a tertiary center between 2006 and 2015. Evaluation included demographic data, US features, histological result, and surgical result when operated.
Results
CNB on 245 nodules, all with suspicious features on US, were included: size 3–9 mm (41 of them ≤ 5 mm); 230 solid; 88.6% in women; 166 (67.8%) in multinodular goiters, 89 of them with simultaneous CNB in a different nodule. Histological study showed: 11 insufficient samples (4.5%); 176 benign (71.8%, 26 inflammatory); 12 follicular proliferation (4.9%, 3 of them oxyphilic), and 46 malignant (18.8%, one medullary thyroid cancer and 45 papillary thyroid cancer, PTC). All non-operated nodules with insufficient or benign CNB and three with follicular proliferation were controlled 2–10 years after first CNB, 7 of them with a second benign CNB, and there was not US changes in this period. On surgery, all cases of malignant diagnosis were confirmed, 1 PTC was diagnosed among 9 resected nodules with diagnosis of follicular proliferation on CNB and 2 PTC were diagnosed among 19 resected nodules with benign CNB. The false negatives were one case of painful Hashimoto's disease that required surgery in which CNB missed the target, and a case that was operated by other nodule with follicular proliferation in the same gland in which the CNB showed subtle atypia but was not enough to diagnose malignancy. Sensitivity to detect malignancy was 95.9% and positive predictive value 79.7%. Specificity was 94% and negative predictive value was 98.9%. C- CNB may be a useful and feasible technique to study suspicious thyroid nodules smaller than 10 mm. This technique shows high sensitivity and PPV to detect malignancy and very high specificity and NPV, making follow-up unnecessary in most of cases.

Serum thyroglobulin (sTg) before surgery in euthyroid patients with differentiated thyroid cancer (DTC)

Miguel Paja[1], Aitzol Lizarraga[1,2], Amaia Expósito[1], M Teresa Gutiérrez[1], Borja Barrios[1], Natalia C Iglesias[1], Alba Zabalegui[1], Cristina Arrizabalaga[1], Adela L Martínez[3] & Amelia Oleaga[3]
[1]Basurto University Hospital, Bilbao, Spain; [2]Basque Country University, Biilbao, Spain; [3]Amelia Oleaga., Bilbao, Spain.

sTg is universally accepted as the best marker of disease status in DTC. Its presurgical serum level may suggest the presence of distant metastasis in case of very high level, but the correlation between its level and the characteristics of the tumour is yet to be defined.
Objective
To evaluate preoperative thyroglobulin as predictor of DCT features.
Methods
Preoperative sTg was measured in patients operated for DTC between 2011–2017. Patients with positive anti-Tg Ab, treated hypothyroidism, not controlled hyperthyroidism or controlled autoinmune hyperthyroidism were excluded. We evaluated the influence of extrathyroidal extension (ETE), positive lymph node (LN), cytological variant (CV), BRAF mutation, ATA 2015 risk and multifocality on sTg levels. sTg divided (adjusted) by thyroid weight (sTg/weight in grams) after thyroidectomy was also considered in order to reduce the effect of Tg secretion by non-neoplastic tissue, as well as its value corrected by TSH concentration and tumour size (main focus or global size).
Results
130 CDT (4 FTC, 126 PTC) were included. Median presurgical sTg was significantly lower in DTC with ETE (59.2 vs 106 ng/ml; $P<0.04$), and the

difference persisted when corrected by preoperative TSH (27.1 vs 50.5), glandular weight (2.3 vs 4.5), both parameters (1.2 vs 2.6) as when divided by bigger size (sTg/BS) (5.3 vs 8.5) or global size (sTg/GS) of DTC (2.3 vs 3.5). The differences persisted when preoperative TSH adjusted sTg/BS and sTg/GS. Total and corrected sTg also showed significant differences when DCT were grouped by LN (lower when positive), CV (lesser in classical in opposite to follicular variant), BRAF V600E (lower if present) and ATA2015 risk (lower in intermediate risk versus low risk). Multifocal neoplasm showed no difference in sTg levels when compared with DCT with a single lesion. There were 8 high risk DTC (ATA2015): 2 FTC (one with pulmonar metastasis and other with extensive vascular invasion), and 6 PTC:, one metastatic, 4 with lymph nodes larger than 30 mm and one with gross extrathyroidal invasion, all diagnosed before surgery. These patients collected the highest level of sTg. C - DTC aggressiveness defined by ETE, BRAF V600E positive, pN1 and ATA risk, associates less efficient thyroglobulin secretion, both gross value and TSH corrected levels. This parameter may be a helpful tool for surgical planning, demanding a thorough approach in DCT with low levels of sTg.

Coexistence of papillary thyroid carcinoma and autoimmune thyroid disease

Imen Sakka, Ibtissem Oueslati, Melika Chihaoui, Fatma Chaker, Meriem Yazidi, Ons Rejeb & Hedia Slimane
Department of Endocrinology, La Rabta Hospital, Tunis, Tunisia.

Introduction
Papillary thyroid carcinomas (PTC) represent up to 87% of all thyroid cancers with an incidence that has doubled over the past 30 years. Hashimoto's thyroiditis (HT) and Graves' disease are two autoimmune thyroid diseases representing the most common causes of hypothyroidism and hyperthyroidism, respectively. Although PTC with coexisting HT has been reported in literature, its association with GD is not a common condition. Herein, we report three cases of coexisting papillary thyroid carcinoma and autoimmune thyroid disease: HT in one case and GD in two cases.
Observations
The first case reported a 30-year-old-woman, who has been followed during three years for HT. Her thyroid ultrasound examination revealed a multinodular goiter with a suspicious nodule. Fine needle aspiration cytology showed features of PTC. Total thyroidectomy with lymph node dissection was performed to the patient and postoperative histopathological examination showed the PTC. The second case was a 69-year-old woman who was initially followed for GD with Graves'ophtalmopathy. Her thyroid ultrasound examination showed heterogeneous hypoechoic nodule in the right lobe. After medical preparation, the patient had a total thyroidectomy and the histopathological examination revealed a follicular variant of PTC. The third case reported a 34-year-old man, who presented with symptoms of thyrotoxicosis. On physical examination, he had an asymmetrical goiter with a right nodule measuring 2 cm $\times$ 1 cm. Thyroid scintigraphy image was consistent with the diagnosis of GD. Fine needle aspiration biopsy of the right nodule revealed features of PTC. After medical preparation, a total thyroidectomy with lymph node dissection was performed. Histopathological examination confirmed PTC.
Discussion
The pathogenic linkage between autoimmune thyroid diseases and PTC remains unclear. In the case of GD, studies have suggested that thyrotropin receptor antibodies may possibly play a role in the initiation and progression of thyroid cancer. Conversely, many hypotheses have been suggested to explain the relationship between HT and PTC, one of which is the concept of chronic inflammation leading to a neoplastic condition. In patients with autoimmune thyroid disease, thyroid ultrasound should be performed in order to detect suspicious thyroid nodules warranting cytologic analysis.

Analysis of the prognostic factors during I-131 therapy for differentiated thyroid cancer patients using BIOMAT ENDO data base

Mariana Purice[1], Iulia Andreea Chiriac[1], Monica Radulescu[2], Monica Livia Gheorghiu[1,3] & Andrei-Liviu Goldstein[1]
[1]"C.I.Parhon" National Institute of Endocrinology, Bucharest, Romania; [2]SOFTWIN, Bucharest, Romania; [3]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania.

BIOMAT-ENDO software is a *Windows Forms* application that stores all the main data regarding the patients with thyroid cancer (TC) hospitalized in the *Nuclear Medicine Department* of the National Institute of Endocrinology *in Bucharest,* starting with the first hospitalization, continuing with the periods of radioiodine therapy (RIT) and the follow up. Patient-monitoring MODULE contains clinical parameters, surgery details, in Vivo and in Vitro investigations, therapy information. Correlations can be done between any input data. Until now 2000 cases hospitalized during the last 50 years were digitalized in this data base.
Materials and methods
We selected 300 patients who had undergone a total thyroidectomy and subsequent I-131 therapy. Including criteria: at least two I-131 therapies, whole body scan result (WBS), serum TGL and AntiTGL values. Analysis also includes parameters associated with the curative effect: gender, age at diagnostic, risk factors (endemic/non-endemic area), environmental origin, surgical procedure, histopathologic diagnosis. We used Q15L to verify the correctness of existing data and for some statistical results.
Results
In the studied group there is a prevalence of DTC among women (84%) over 45 year, most of them from the urban area (70%). Endemic zones are the main area risk factor (70%). *Preablative* distribution of stimulated TGL values was: $<$ 2–10 ng/ml (35%), 10–100 ng/ml (39%) and $>$ 100 ng/ml (26%) with mean value $=$ 107.93 $\pm$ 278.25 ng/ml. Positive Anti TGL at the first RIT are present in 21% of patients. 96% of patients were with positive WBS. *After the RIT* (therapies number: 5.4 $\pm$ 3.6, cumulative dose: 382.6 $\pm$ 280 mCi) a significant decrease of TGL was found (mean 0.672 ng/ml, $P<$ 0.01) at 82% of the cases. WBS results were negative for 81% of patients. Not responding cases, with high TGL values and positive WBS after RIT, represented 18%.
Conclusion
Our study indicates that most DTC patients can obtain partial or complete remission after I-131 therapy. I-131 imaging and TGL levels at diagnosis are both important indicators to evaluate the curative effect. The analysis of efficacy and prognostic factors of RIT have the benefit to establish individualized treatment strategy, predict curative effect and assess the prognosis for those DTC patients. The clinical data reviewed revealed which biological features are predominant for a good overall prognosis of thyroid cancer, which patients are still with persistent/recurrent disease according to the measured serum thyroglobulin (TGL) levels and imagistic findings.

Treatment strategies in medullary thyroid carcinoma – outcome following initial surgery with a curative, debulking or prophylactic intent

Vasiliki-Ioanna Mitravela[1], Nigel Glynn[1], Mona Waterhouse[1], Scott Akker[1], Marta Korbonits[1], William Drake[1], Daniel Berney[2], Nick Plowman[3], Robert Carpenter[4], Laila Parvanta[4] & Maralyn Druce[1]
[1]Department of Endocrinology, St Bartholomew's Hospital, London, UK; [2]Department of Pathology, St Bartholomew's Hospital, London, UK; [3]Department of Oncology, St Bartholomew's Hospital, London, UK; [4]Department of Surgery, St Bartholomew's Hospital, London, UK.

Medullary thyroid carcinoma (MTC) is a rare malignancy which has often metastasised at time of diagnosis. Surgical resection represents the only prospect for cure. However, debulking neck surgery may be beneficial in advanced cases. Prophylactic surgery is increasingly undertaken in asymptomatic patients with known mutations in the *RET* oncogene. The aim was to describe the outcome following initial surgical treatment for MTC at our institution. We performed a retrospective analysis of medical records of patients diagnosed with MTC and followed up at our centre. Study period extended from 1976 to 2016. Data recorded included demographic, clinical, biochemical and radiological variables. Sixty five patients (27 men) were identified - 36 (55%) sporadic and 29 hereditary cases. Median age at diagnosis was 37 years. Sixty one patients underwent neck surgery, 14 (22%) received adjuvant neck radiotherapy and 4 (6%) received palliative care only. Median overall follow-up 9.3 years. Nine patients (15%) were deemed to have incurable disease but underwent debulking neck surgery – all had stage IV disease. Three patients died of MTC – median survival 23 months. Six (67%) were alive at last follow-up – two had progressive and four stable disease. Thirty six patients (59%) had neck surgery with a curative intent. Seventeen (47%) were in remission post-operatively – subsequently, two patients experienced recurrence. Nineteen patients (53%) did not achieve biochemical remission (normal basal serum calcitonin) post-operatively – disease progression was later detected in 7 patients. Three patients in the "curative intent" group died of MTC – median survival 171 months. Sixteen asymptomatic patients (26%) with germline mutations in the *RET* oncogene underwent thyroidectomy – so

called "prophylactic thyroidectomy". Median age 24 years; median follow-up 21.5 years. Post-operative biochemical remission was achieved in 10 patients (63%) – one experienced recurrence. All patients in this group were alive at last follow up except one who died of renal carcinoma. In conclusion, neck surgery may induce long-term remission in half of patients with MTC who have potentially resectable disease. However, in advanced or incurable disease, debulking surgery may be useful in selected patients.

Thyroid cancer prevalence and pathological features in thyroidectomy patients – five years experience

Oana-Stefana Enache[1], Sorina Martin[1,2], Oana Ion[3], Andreea Grigore[4], Irina Bojoga[1,2], Ovidiu Parfeni[1], Anca Sirbu[1,2], Carmen Barbu[1,2], Cosmin Giulea[5,6], Adrian Miron[5,6], Florin Andrei[7] & Simona Fica[1,2]
[1]Elias Hospital, Endocrinology Department, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology Department, Bucharest, Romania; [3]Fundeni Clinical Institute, Nephrology Department, Bucharest, Romania; [4]Fundeni Clinical Institute, Gastroenterology Department, Bucharest, Romania; [5]Elias Hospital, Surgery Department, Bucharest, Romania; [6]Carol Davila University of Medicine and Pharmacy, Surgery Department, Bucharest, Romania; [7]Elias Hospital, Pathology Department, Bucharest, Romania.

Objectives
In the last decades, thyroid cancer incidence has increased all over the world. This may be due to heightened medical surveillance and more addressability to surgery, as many cancers are diagnosed while under 1 cm. The aim of our study was to obtain data about the prevalence and histological subtypes of primary thyroid carcinoma in patients undergoing thyroidectomy.
Materials and methods
We retrospectively analysed the files of 953 patients who underwent thyroidectomy in our surgery department between January 2012- December 2017. Anthropometric, biologic and imagistic data, indication of thyroid surgery, surgical procedures and pathology results were recorded.
Results
222 (23 .29%) patients had a diagnosis of primary thyroid carcinoma. The primary indications for thyroid surgery included: 5 (2.3%) Graves' disease and nodular goiter, 181 (81.5%) multinodular goiter, 23 (10.4%) uninodular goiter and 13 (5.9%) thyroid cancer. The mean age at diagnosis was 52.49 ± 13.79, range 20-83 years, but 61 (27.47%) were diagnosed before the age of 45 years. The female to male ratio was $180{:}42 = 4.28$. The surgical procedure was lobectomy in 3 and total thyroidectomy in the remaining 219 patients. 207 (93.24%) suffered from differentiated thyroid carcinoma [194 (87.38%) papillary, 13 (5.85%) follicular], 7 (3.15%) from medullary thyroid carcinoma, 4 (1.8%) from poorly differentiated and 4 (1.8%) from anaplastic thyroid carcinoma. Multifocality was present in 62 (27.9%) patients. Pathological tumor stage was: T1 in 99 (44.6%), T2 in 38 (17.1%), T3 in 76 (34.2%) and T4 in 9 (4.1%) patients. 78 (35.1%) patients had tumors of 1 cm or less in diameter. 79 (35.6%) patients associated histopathologic chronic autoimmune thyroiditis.
Conclusions
One in five patients who underwent thyroidectomy had a thyroid cancer. This might be due to a real increased incidence of thyroid cancer or just a result of better selection of patients for surgery and diagnose of microcarcinomas that otherwise would have gone unnoticed. Papillary thyroid carcinomas constituted the vast majority of these neoplasms, this being usually associated with an iodide-sufficient area.

P1162

A case of familial follicular thyroid carcinoma

Amira Bouchenna, Brahim Ghennam, Sarah Kaci, Assya Chikh, Lila Brakni, Moussa Nacer Khodja, El Mehdi Heffaf & Samia Ould Kablia
Hopital Central De L'armée, Alger, Algeria.

Introduction
Familial follicular cell-derived tumors may account 5–15% of thyroid carcinoma cases. Defined as the attainment of two or more first-degree relatives by thyroid cancer in the absence of a known familial syndrome. When three or more family members are affected, the probability that the disease has a familial origin is 99.9%. We report the case of a family of 4 siblings affected.
Observation
- Patient aged 43 years, without a personal or family history particular, had a total thyroidectomy for a left lobe nodule classified Tirads IVb of 25 mm, anatomo-pathological study: papillary micro carcinoma of 4 mm vesicular variant and constituted of 80% of oncocytic cells.
- His sister 46 years had a total thyroidectomy for a suspected nodule Tirads V, anatomo-pathological study: 4 cm nodule with a well-differentiated vesicular carcinoma with vascular invasion of the capsule.
- Another sister 40 years operated as a part of screening with anatomo-pathological study: papillary carcinoma in its vesicular variant, encapsulated and bifocal.
- A brother 33 years, had a total thyroidectomy for a Tirads VIb nodule, anatomo-pathological study: papillary carcinoma in its solid variant.

Discussion
It is now widely recognized that familial cancers are more aggressive than sporadic ones. Characterized by, tumor multifocality, local invasion with lymph node metastasis, and local or regional recurrence. At present, the specific genetic basis is not clear. Studies suggest that familial cancers has an autosomal dominant behavior with incomplete penetrance and variable expression. Early diagnosis and treatment are very important to improve the quality of life and survival of patients.

Co-incidence of medullary and papillary thyroid carcinoma

Zelal Sahin Tirnova[1], Pinar Sisman[2], Ozen Oz Gul[3], Soner Cander[3], Canan Ersoy[3] & Erdinc Erturk[3]
[1]Uludag University Medical School, Department of Internal Medicine, Bursa, Turkey; [2]Medicana Hospital, Endocrinology and Metabolism Clinic, Bursa, Turkey; [3]Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey.

Introduction
Papillary thyroid carcinoma (PTC) is the most common thyroid carcinoma and is derived from thyroid follicular cells which originate from the endodermal origin. In contrast, medullary thyroid carcinoma (MTC) is rare and originates from the parafollicular C-cells, which are commonly thought to be derived from the ectodermal neural crest. Co-incidence of the two condition on the same patient is so rare. We describe a case of concurrent MTC and PTC occurring in the same thyroid lobe.
Case report
A 63-year-old woman was referred to our hospital for further evaluation of thyroid nodules. Ultrasound assessment revealed two nodules in the right lobe, 10.3 mm and 14.4 mm in size with accompanying calcifications. Her serum levels of calcium, parathormone, carcinoembryonic antigen, thyroid stimulating hormone and free thyroxine were normal. The baseline serum calcitonin level was 139 pg/ml (normal range [NR] <11.5 pg/ml). There were no antithyroid autoantibodies. A single fine-needle aspiration biopsy (FNAB) was applied, the result was suspicious for malignancy. Abdominal US was negative for adrenal nodules as well as urinary catecholamines and metanephrine levels were within normal limits. Total thyroidectomy was performed. The pathological examination revealed the presence of a tall cell type papillary carcinoma of the right lobe (1.5 cm) with an adjacent medullary microcarcinoma (0.6 cm). The tumour cells were positive for calcitonin. The postoperative TSH level was 40 mIU/ml (NR 0.3–4.9) and calcitonin level was <2 pg/ml. The patient was discharged without any complications. An ablative dose of iodine 131 treatment is planned.
Discussion
The synchronous occurrence of multiple thyroid carcinomas of different origin in the same patient is extremely rare, representing less than 1% of all thyroid malignancies. Interestingly, the incidence of PTC in patients with MTC is greater than that of PTC in patients undergoing thyroidectomy for non-malignant conditions, suggesting the presence of a common pathogenic etiologies. Even if it can be coincidental, possible hypotheses for the synchronous occurrence include involvement of the RET proto-oncogene in both PTC and MTC and an unidentified common mother cell with a capacity for differentiating parafollicular C cells and epithelial follicular cells which can be the origin of the cancer. Beacuse there is a lack of marked differences in the ultrasonografic features between MCT and PTC, the possibility of the coexistence must be taken into account. Since there is no evidence of a certain cause of this condition more data is needed from additional geographic areas and populations.

The prevalence of concomitent non-medullary thyroid carcinoma and primary hyperparathyroidism

Laura Teodoriu[1], Raluca Balaceanu[1], Maria-Christina Ungureanu[1,2], Letitia Leustean[1,2], Alexandru Grigorovici[1,2], Radu Danila[1,2], Gabriela-Delia Ciobanu[1,2], Cipriana Stefanescu[1,2] & Cristina Preda[1,2]
[1]Emergency Hospital "St. Spiridon", Iasi, Romania; [2]University of Medicine and Pharmacy "Grigore T. Popa", Iasi, Romania.

Introduction
Synchronous medullary thyroid cancer and pHPT is common in MEN-2A (Sipple syndrome). In contrast, concomitant nonmedullary thyroid cancer and primary hyperparathyroidism (PHPT) is very rare even if the pathological relationship between parathyroid and thyroid diseases is common.
Aim
Was to determine the prevalence of non-medullary thyroid carcinoma in patient who underwent neck exploration for PHPT.
Patients and method
Retrospective study of 259 patients who suffered surgery interventions for hyperparathyroidism at the University Emergency Hospital "St. Spiridon", Iasi, Romania. Data regarding parathyroid affections, surgical procedures and histological results were recorded.
Results
A total of 259 (198 women and 61 men) parathyroidectomies were performed between 2010-2016 at our hospital (parathyroidectomy only for 136 cases and concomitant thyroidectomy for 123 patients). Among 192 patients with PHPT, 103 also underwent thyroidectomy. The concomitance of HPTP and non-medullary thyroid carcinoma was found in 33 cases (29 women and 4 men). The occult papillary carcinoma was present in 25 (75%) cases, papillary carcinoma in 7 (21, 2%) cases and follicular carcinoma in 1(3%) case. The final prevalence of PHPT and non- medullary carcinoma was 32%.
Conclusion
Our results are in accordance with the main caracteristics of the association between PHPT and non-medullary thyroid carcinoma: more frequent in women, most cases are classical variant of occult papillary carcinoma, bilateral thyroid involvement and lymph node metastasis are very rare. However the high prevalence rise the question if the association between thyroid non-medullary carcinoma and PHPT may be coincidental or is something more to research?

Visualization of Hepatic Metastases of Medullary Thyroid Carcinoma on Tc-99 Bone Scintigraphy

Mouna Mezoued[1,2], Amine Habouchi[3] & Djamila Meskine[1,2]
[1]Laboratoire D'endocrinologie et Métabolisme Alger 1, Algiers, Algeria; [2]EPH Bologhine, Algiers, Algeria; [3]CHU BAB EL Oued, Algiers, Algeria.

Medullary carcinoma of the thyroid (MCT) is a tumor developed at the expense of the thyroid parafollicular cells, and secretes the polypeptide hormone calcitonin. It is known as an aggressive tumor that metastasizes early. Case Report: We describe a case of a 57 year-old women, who presented a neck mass, for which she underwent a total thyroidectomy associated to a bilateral neck dissection and was diagnose as MCT. Post operatively calcitonin remained elevated (19000 pg/ml). Computed tomography reveled multiples calcified masses in the liver, consisting in hepatic metastases. In the other hand bone scintigraphy with technitium-99m demonstrated not only multiples metastatic lesions in lumber spine but also extensive areas of uptake of Tc99 m in the liver. Liver uptake of technetium-99m MDP in hepatic MTC metastasis has rarely been reported in previous publications. Possible mechanisms of uptake might include adsorption of amorphous calcium due to the fact that these tumors do calcify. Other possibilities include calcitonin– calcium metabolism, active sequestration, or secretion of one of the tumor hormones.

Descriptive analysis of papillary thyroid microcarcinomas in a single-center

Elena Fernández González[1], Isabel Huguet Moreno[1], Jose Luis Muñoz[1], Nerea Aguirre Moreno[1], Begoña Pla Peris[1], Clara Marijuán Sánchez[1], Marta Araujo Castro[1], Ana Ramos-Leví[1], Mónica Marazuela Azpiroz[1], Manuel Luque Ramírez[2] & Marcos Lahera Vargas[1]
[1]Hospital Universitario de la Princesa, Madrid, Spain; [2]Hospital Ramón y Cajal, Madrid, Spain.

Introduction
The incidence of papillary thyroid microcarcinomas (MPT, max diameter ≤ 10 mm) has increased in recent years. Most have a very good prognosis but some have growth during follow-up, lymph node and / or distant metastases.
Material and methods
We performed a single-center, retrospective cohort study, n = 114 patients (86% women, average age 48.3 years), diagnosed with MPT between 1998 and 2012. Risk stratification system (ATA 2015): 10 high, 34 intermediate and 70 low risk at the diagnosis. Therefore, 38,6% had extrathyroid disease. The prevalence of certain clinical and histological characteristics that could predict a worse evolution was studied. We also analyzed excellence response (RE), indeterminate (RIN), biochemical incomplete (BIN) and structural incomplete (EIN) in the different ATA groups after 2 and 5 years. In low risk group, we differentiated those who had not received iodine. Statistical analysis SPSSv.15.0.
Results
Univariate and descriptive analysis according to ATA groups 1, 2 and 3: age (53.2 ± 14.4, 41.7 ± 12.2, 33 ± 18 years; $P = 0.004$), male sex (4.3, 26.5, 40%; $P < 0.001$), incidental diagnosis (51.4, 17.6, 0%; $P < 0.001$), isthmus location (7.1, 14.7, 0%; $P = 0.01$), capsular invasion (4.3, 44, 40%; $P < 0.001$), vascular invasion (0,2, 4.5%; $P = 0.07$), tumor size (5.9 ± 0.4, 6.1 ± 0.3, 6.5 ± 0.3 mm; $P = 0.015$), previous TSH (1.8 ± 1.4, 2.0 ± 0.6, 2.1 ± 1.2; $P = 0.09$). Isthmus location was associated with N1 ($P = 0.005$). Initial treatment: hemithyroidectomy (8.5,0,0%), central lymphadenectomy (8.6, 26.5, 40%), lateral (1.4, 50, 80%), radioiodine (32.8, 100, 100%). Retreatment after 2 years in ATA 2/3 group: 2 relymphadenectomy, 13 new radioiodine dose, 1 ethanol injection. Retreatment between 2 and 5 years in ATA 2/3: 3 surgical reintervention, 5 another radioiodine dose. Thus, 18,4% required at least one more treatment in the follow-up.

	2 years response				5 years response			
	RE	IND	BIN	EIN	RE	IND	BIN	EIN
ATA1 (Iodine yes/no)	82.61/ 66.7%	17.4%/ 33.3%	0%/2.3%	0%/0%	86.36%/ 72.3%	13.64%/ 22.26%	0%/0.04%	0%/0%
ATA2	64.52%	12.90%	12.90%	9.67%	70.83%	8.33%	12.5%	4.16%
ATA3	33%	22%	11%	33%	28.6%	42.86%	14.29%	

Conclusions
In our cohort: younger age, male sex, capsular and vascular invasion, larger tumor size and higher TSH, were more prevalent in MPTs with higher initial risk of recurrence. Only three patients presented distant metastases, and all from the diagnosis. Tumors that did not present lymph node metastases at diagnosis did not show it in the evolution either. Extrathyroidal involvement in our series was very frequent. Nevertheless, this did not translate into an increased mortality but in the need for more treatments during the follow-up.

TSH level and risk of malignancy in patients with thyroid nodules with Bethesda IV Cytopathology System

Carolina Fernández-Trujillo Moujir, Carlos Antonio Rodríguez Perez, Dunia Marrero Arencibia, Yaiza López Plasencia, Julio Pérez Zaballo, José Cabrera Galván, Francisco Javier Nóvoa Mogollon & Mauro Boronat Cortés
Hospital Universitario Insular de Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain.

Introduction
Fine needle aspiration biopsy (FNAB) is the mainstay diagnostic procedure for evaluation of thyroid nodules, but it doesn't permit to distinguish between benign and malignant follicular lesions (category IV in the Bethesda Cytopathology System). Some reports have suggested an association between increased serum levels of TSH and thyroid cancer. However, the specific relationship between TSH and malignancy has been scarcely studied in follicular thyroid nodules.

Objectives
To investigate the association between preoperative TSH levels and malignancy in patients with follicular thyroid nodules.
Methods
Retrospective study of all subjects who underwent surgical treatment for Bethesda IV thyroid nodules since the adoption of the Bethesda System for reporting thyroid cytopathology in a single centre from Spain (2012–2017), and for whom a preoperative measure of TSH was available. Cytopathologic diagnosis was established by ultrasound-guided FNAB. Clinical data and ultrasound characteristics of the nodules were recorded.
Results
A total of 125 subjects were identified (mean age 52.8 ± 14.0 years, 87.2% women). Forty-nine of them (39.2%) showed malignancy upon definitive histopathological examination (21 follicular variant of papillary carcinoma, 19 follicular thyroid carcinoma, 8 other types of papillary carcinoma and 1 medullary carcinoma). Subjects with thyroid cancer were older than those with benign conditions (57.0 ± 13.7 vs 50.1 ± 13.7 years; $P = 0.007$). The presence of ultrasonographic traits of malignancy (hypoechogenicity, irregular margins, microcalcifications, taller than wide shape and central vascularization), the maximum diameter of the nodule and its calculated volume didn't differ among malignant and benign lesions. Median (range) levels of TSH were 2.35 mU/l (0.34–37.0) among subjects with thyroid cancer and 2.04 mU/l (0.09–10.94) among those with benign diseases ($P = 0.35$). The ROC analysis showed a TSH cut off point of 2.14 mU/l to differentiate benign from malignant disease (sensitivity 65.3%, specificity 56.6%, positive predictive value 50.8%, negative predictive value 71.7% and area under the curve 0.55). The proportion of subjects with TSH ≥ 2.14 mU/l was greater among subjects with cancer ($P = 0.018$). A logistic regression model including age and TSH ≥ 2.14 mU/l as independent variables showed that both of them retained independent association with malignancy (OR [95% CI] for TSH ≥ 2.14 mU/l: 2.53 [1.17–5.44]; $P = 0.018$).
Conclusions
The present study supports an association between serum concentrations of TSH and risk of malignancy among subjects with Bethesda IV thyroid nodules. In this particular group of patients TSH levels could provide greater diagnostic yield than ultrasonographic examination.

A review of prevalence, reporting, and criteria for further investigation of incidental thyroid nodules reported on computed tomography scanning in an Irish general hospital

John Brazil & Jayant Sharma
Midland Regional Hospital Portlaoise, Portlaoise, Ireland.

The purpose of this study was to identify the prevalence of Incidental Thyroid Nodules (ITN's) on Computed Tomography (CT) scans of the chest, assess variation in reporting by radiologists and to apply recent guidance to assess which nodules may require further investigation. We performed a retrospective review of 742 CT scans which included the chest performed in a regional hospital. Thyroid abnormalities were reported in 9.8% ($n = 76$) of CT scans. There was considerable variation in reporting of nodules with the size of the nodule reported in 45% of scans with nodules present ($n = 14/31$), with five of these meeting American College of Radiology Criteria for further investigation. In the remaining 17 patients where a nodule was identified its size and shape were not further clarified. General descriptions such as 'Multiple nodules', 'Multinodular Goitre' and 'Bilateral nodularity' were given in 43% of scans with thyroid abnormality ($n = 33/76$). In these instances no discrete size of the largest nodule was given. Calcifications were reported in 10 cases. Our study highlights the heterogeneity of reporting of ITN's and the need for consistent reporting criteria in keeping with available evidence to identify nodules which may require further evaluation. Clarification and standardisation in this area can have the dual effect of reducing the need for unnecessary investigations and highlighting nodules in need of further workup.

A review of histology reports of 675 thyroid cancer cases in a single centre over ten years

Niall McVeigh[1,2], Aftab Khattak[1], Mary Toner[1], Esther O'Regan[1] & Marie-Louise Healy[1]
[1]St James's Hospital, Dublin, Ireland; [2]Galway University Hospital, Galway, Ireland.

The recently (2015) revised American Thyroid Association guidelines for the management of differentiated thyroid cancer recognise the importance of histological subtype in risk stratification. The prevalence of thyroid cancer subtypes in an Irish population is unknown. We reviewed all histology reports of thyroid carcinoma from a quaternary referral centre over a 10 year period, 2005 to 2015. 675 reports were reviewed. Of these, 87% were reported as papillary thyroid cancer (PTC), 7% follicular, 2.5% medullary, 2.5% anaplastic, 1% mixed. Absolute case numbers of thyroid carcinoma reports increased from 32 in 2005 to 111 in 2014. We then examined the annual incidence of each histological subtype (follicular variant, papillary, mixed, tall cell, insular and diffuse sclerosing) of PTC. Follicular variant PTC increased from 7/23 (30%) in 2006 to 36/90 (40%) in 2014, while other variants remained unchanged. The histological subtypes associated with higher risk, tall cell, insular and diffuse sclerosing variants all remained uncommon ($< 5\%$). The apparent increase in follicular variant PTC might reflect a change in reporting methods but also raises the possibility of a changing disease pattern over time. Re-analysis of the original histology specimens is required to answer this question. This data examination is the first review of characteristics of thyroid cancer in an Irish population. It can be used in informing future planning of services and ensure that treatment outcomes are as good as internationally predicted outcomes based on initial risk stratification.

Evolution of tumor markers after external beam radiotherapy in the non-undifferentiated thyroid cancer

Raquel Miralles Moragrega[1], María María Currás Freixes[2], Carolina Perdomo Zelaya[2], Javier Gargallo Vaamonde[2], María Llavero Valero[2], Marta Moreno Jiménez[3] & Juan C Galofré[2]
[1]Departamento de Endocrinología y Nutrición. Hospital General Universitario de Alicante., Alicante, Spain; [2]Departamento de Endocrinología y Nutrición. Clínica Universidad de Navarra., Pamplona, Spain; [3]Departamento de Oncología Radioterápica. Clínica Universidad de Navarra, Pamplona, Spain.

Introduction
The role of external beam radiotherapy (EBRT) as primary or as adjuvant therapy in the non-undifferentiated thyroid cancer (NUTC) is controversial. Most published data refer to retrospective case series. Therefore, little is known about the correlation between tumor markers and radiologic measurements of tumor response.
Objectives
The study aimed to analyze the kinetics of tumor markers and radiologic measurement of tumor response after EBRT in NUTC.
Material and methods
A retrospective analysis of a series of 11 patients diagnosed of NUTC, and consecutively treated with EBRT in the Clínica Universidad de Navarra (CUN) between 2010 and 2016 was performed.
Results
Clinical characteristics: gender: women (7) and men (4); age at diagnosis: 66 years (49–68); histological subtype: follicular (7), papillary (3), and medullary (1). EBRT techniques: intensity modulation radiotherapy (IMRT) (7), three-dimensional conformal radiotherapy (3D-RTC) (3) and radiosurgery (1). The median dose of EBRT was between 21 Gy and 76 Gy, and 18 Gy for radiosurgery. Localization of EBRT: bone (7), cervical (2), cervical-mediastinal (1) and cerebral (1) region. The most frequent adverse effects were dysphagia (three patients) and dermatitis (two patients). The toxicity grade according to the criteria of the Radiation Therapy Oncology Group (RTOG) was: 1–2 (4 patients) and 3 (1 patient). The twelve-month radiological response related to the area of EBRT administration, but not with other concomitant metastasis was: stability in 5 (3 follicular, 2 papillary), regression in 2 (both follicular), and progression in 4 patients (2 follicular, 1 papillary, and 1 medullary). In the 4 patients with follicular cancer showing stability or regression, a parallel reduction in thyroglobulin levels was observed at 6 and 12 months. In the patient with medullary cancer, we observed correlation between the radiological progression and calcitonin increase at 5 years.
Conclusions
In our series, we observed a correlation between the response to EBRT regarding the tumor burden and the corresponding thyroid marker: decreasing thyroglobulin levels in follicular thyroid cancers showing stability and regression, and increasing calcitonin levels in the medullary cancer showing progression.

P1171

Natural course of thyroid cancer nodules compared with benign thyroid nodules

Ki-Hyun Baek, Moo-Il Kang & Kyung-Jin Yoon
Division of Endocrinology and Metabolism, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea.

Purpose
The primary aim of this study was to evaluate changes in the diameter and volume of thyroid cancer nodules identified using fine-needle aspiration biopsy (FNAB) or surgery, and to compare the changes in size between thyroid cancer nodules and benign nodules. The secondary aim was to analyze the risk factors associated with thyroid cancer nodule growth.
Methods
A total of 96 patients with 102 nodules were enrolled in the cancer group, and 98 patients with 101 nodules were included in the benign group. All patients underwent thyroid ultrasonography at least twice at $\geq$1-year intervals.
Results
The initial mean age, gender, thyroid-stimulating hormone (TSH) levels, thyroid autoantibody levels, number of FNABs, initial maximum diameter, and initial volume did not differ between the two groups. The mean follow up durations in the cancer group and benign group were 29.5 ± 18.8 and 31.9 ± 15.8 months ($P = 0.32$), respectively. The maximum diameter change in nodule length per year was 0.40 ± 1.00 mm in the cancer group and -0.07 ± 0.77 mm in the benign group ($P = < 0.01$). The volume change (in mL and percent) per year was increased significantly in the cancer group compared with the benign group (0.06 ± 0.14 ml vs. 0.003 ± 0.05 ml, respectively, $P < 0.01$; $26.9 \pm 57.9\%$ vs. $1.72 \pm 26.0\%$ $P = < 0.01$). The initial maximum diameter and initial volume were independent risk factors for thyroid cancer nodule growth in multiple regression analysis.
Conclusion
In conclusion, the present study suggested that thyroid cancer nodules progress rapidly compared with benign nodules, as exhibited by the $\sim$30% volume increase per year. Initial nodule size was an independent risk factor for cancer nodule growth.

Risk of thyroid malignancy in large thyroid nodules greater than 4 cm

Jee Hee Yoon, Hee Kyung Kim & Ho-Cheol Kang
Chonnam National University Medical School, Gwangju, Republic of Korea.

Background
The risk of thyroid cancer in large thyroid nodules greater than 4 cm has been reported to be increased. Some authors insist that diagnostic lobectomy should be performed in patients with large thyroid nodules, irrespective of fine needle aspiration cytology (FNA) results. However, consensus on that matter has not been met. We wanted to investigate the risk of thyroid malignancy according to the size of the thyroid nodules, based on FNA results.
Methods
FNA results of 836 patients with thyroid nodules larger than 2 cm who visited Chonnam National University Hwasun Hospital from April 2004 to March 2009 were evaluated according to size category. The nodules were categorized to three groups by maximal diameter of the nodule on ultrasonography (Group A: 2–2.9 cm, Group B: 3–3.9 cm, Group C: $\geq$4 cm).
Results
Number of patients in group A, B and C were 476, 206 and 154 and the mean sizes of the nodules in each group were 2.4 ± 0.3 cm, 3.4 ± 0.3 cm, and 4.9 ± 1.0 cm, respectively. Based on ATA ultrasonographic category, high suspicion nodules were 51(10.7%), 13 (6.3%), and 9 (5.8%, $P = 0.073$). After FNA, the Bethesda system 6 category were reported in 32 (6.7%), 14 (6.8%) and 8 (5.2%), in each group and there was no increased risk of malignancy in larger thyroid nodules ($P = 0.887$).
Conclusions
Large thyroid nodules ($\geq$4 cm) are not at higher risk for malignancy. Surgical decision should be guided by FNA result of the nodule, not by the size the nodule.

Relationship between microRNA expression levels and tumor size in patients with papillary thyroid carcinoma

Daina Pamedytyte[1], Vaida Simanaviciene[1], Aurelija Zvirbliene[1], Mintaute Kazokaite[2], Valdas Sarauskas[3], Dalia Dauksiene[2], Arbertas Dauksa[4] & Birute Zilaitiene[2]
[1]Institute of Biotechnology, Vilnius University, Vilnius, Lithuania; [2]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Department of Pathology, Lithuanian University of Health Sciences, Kaunas, Lithuania; [4]Institute of Digestive Research, Medical Academy, Faculty of Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction
Despite low mortality rates of patients with papillary thyroid carcinoma (PTC), disease progression in PTC occurs in up to 20% of patients. Currently, recurrence risk stratification is accomplished by using clinicopathologic factors, despite their limited prognostic value. Some data suggest that patient age at disease onset and primary tumor size may predict the risk of disease progression. Identification of possible associations of traditional clinicopathological parameters of disease recurrence with molecular biomarkers of PTC may help better understanding the carcinogenesis and improving the clinical management of patients with PTC
Objectives
The aim of this study was to evaluate miRNA expression profiles in different age groups of patients with PTC and to compare the expression levels of miRNA in differently sized PTC tumors.
Methods
We selected 3 miRNA (miRNA-146b, -222 and -21) and measured the expression levels of these miRNAs in three patients groups according to age at disease onset (60 years and older, 40–60 years, and less than 40 years) and in patients with different PTC tumor size (2 cm or less and greater than 2 cm).
Results
The levels of miRNA (miRNR-146b, miRNR-222, miRNR-21) expression significantly differed between PTC patients with tumor size 2 cm or less ($n = 99$) and greater than 2 cm ($n = 84$). Higher expression levels of miRNAs (miRNR-146b $P < 0.001$; miRNR-222 $P < 0.001$; miRNR-21 $P < 0.001$) were observed in patients with tumor size greater than 2 cm. The expression levels of all three miRNA did not significantly differ in patients of different age groups ($P > 0{,}05$).
Conclusion
The levels of miRNA-146b, -222 and -21 expression in PTC were strongly associated with tumour size. Such difference in the expression levels could be due to the fact that in larger thyroid tumors there is a higher percentage of altered tumor cells in which the miRNA expression is severely disturbed. Selected miRNAs did not show age-related differences in expression, suggesting that mechanisms other than age may influence the expression of these miRNA.

Correlation of preablative thyroglobulin to the new response to therapy system in differentiated thyroid cancer

Athanasios Siolos, Paraskevi Exadaktylou, Nikitas Papadopoulos, Irini Poimenidou, Pantelitsa Rakitzi, Konstantınos Tziomalos, Vasiliki Chatzipavlidou & Kalliopi Pazaitou-Panayiotou
Division of Endocrinology and Department of Nuclear Medicine, Theagenio Cancer Hospital, Thessaloniki, Greece.

Introduction
Evidence supports the prognostic value of preablative stimulated thyroglobulin (ps-Tg) for recurrent and persistent disease in patients with differentiated thyroid cancer (DTC). The correlation of ps-Tg with therapeutic response however has been less studied.
Objective
To study the correlation of ps-Tg and the trend of serial preablative thyroglobulin measurements(DTg) with the response to treatment restaging system proposed in 2015 American Thyroid Association guidelines.
Methods
We conducted a retrospective study on patients with DTC who underwent total thyroidectomy and radioactive iodine (RAI) ablation in a tertiary referral hospital in 2009 and 2010. Patients with missing data or positive anti-Tg Abs were excluded from the study and the rest were divided in three groups in terms of ps-Tg levels: group 1, ps-Tg < 1 ng/ml ($n = 48$), group 2, $1 \geq$ ps-Tg ≤ 10 ng/ml ($n = 48$), group 3, ps-Tg > 10 ng/ml ($n = 19$). Responses to therapy were divided

in excellent (ER), biochemical incomplete (BIR), indeterminate (IR) and structural incomplete response (SIR) according to the new response to treatment system.
Results
115 patients were followed for a median of 60 months. SIR was detected in 3.4% in group 1, 8% in group 2, 20% in group 3. However, results were not statistically significant in the studied series ($\chi^2=3.435$, $P=0.179$).
Conclusion
Preablative thyroglobulin may be correlated to therapeutic response.

May hemocytometer parameters be a biomarker in medullary thyroid carcinomas?

Pinar Sisman[1], Buket Bicer[2], Hikmet Oztop[2], Soner Cander[3], Ozen Oz Gul[3], Canan Ersoy[3] & Erdinc Erturk[3]
[1]Endocrinology and Metabolism Clinic, Medicana Hospital, Bursa, Turkey; [2]Department of Internal Medicine, Uludag University Medical School, Bursa, Turkey; [3]Department of Endocrinology and Metabolism, Uludag University Medical School, Bursa, Turkey.

Aims
Medullary thyroid carcinoma (MTC) is a rare endocrine cancer that accounts for approximately 5% of all thyroid cancers. Both the diagnosis and management of MTC could be difficult. Surgery is a main therapy in MTC, chemotherapy and external radiotherapy have limited efficacy. Recently, the relationship between some of the hemocytometer parameters and cancer has been investigated. In this study we aimed to determine the relationship between MTC and hemocytometer parameters and also evaluate whether they would be useful parameters for MTC prognosis.
Methods
Thirty six MTC who underwent total thyroidectomy in our center between 2000–2017 were included to the study. Patients' data such as neutrophil/lymphocyte ratio (NLR), platelet lymphocyte ratio (PLR), red blood cell distribution width (RDW), platelet distribution width (PDW) collected from their electronic files. Also, recurrence and metastasis ratio of MCT were evaluated by using patients' data.
Results
Twenty (55.5%) female and 16 (44.5%) male patients were included in the study. The mean age was 53.38 ± 12.87 years. The mean follow-up period was 80.30 ± 76.12 months. In the follow-up of the patients, 13 (36.1%) patients developed recurrence and/or metastasis. NLR, PLR, RDW and PDW were 3.34 ± 3.57, 163.16 ± 78.94, 15.88 ± 2.12 and 15.38 ± 7.05, respectively in patients with recurrent and / or metastasis. NLR, PLR, RDW and MPV levels were 4.51 ± 5.66, 128.97 ± 77.33, 15.23 ± 1.59 and 16.76 ± 2.36, respectively in patients without recurrence and/or metastasis. When recurrent and/or metastatic patients were compared with non-developed ones in terms of hemocytometer parameters, there was no statistically significant difference between NLR, PLR, RDW and PDW between recurrent and/or metastases positive patients and negative ones ($P>0.05$).
Conclusion
It is known that inflammation is critical for cancer development and prognosis. There are many reports in the literature that increased neutrophil and platelet levels, indicative of systemic inflammatory response, are associated with tumor growth, invasion, angiogenesis and metastasis. Platelet increment has been shown to be associated with poor prognosis and poor survival in many types of cancer. As a result of our study, it was concluded that NLR, PLR, RDW and PDW levels of hemocytometer parameters do not have prognostic value in MTC.

^{131}I-MIBG as a treatment in medullary thyroid carcinoma with distant metastases.

Nerea Utrilla Uriarte, Pedro González Fernández, Alba Esteban Figueruelo, Marina Nevares Herrero & Javier Santamaría Sandi
Cruces University Hospital, Baracaldo, Spain.

Introduction and objectives
The strategies for therapy of metastatic medullary thyroid carcinoma (MTC) are limited. Although Tyrosine kinase inhibitors (TKI) seem to be the first-line treatment, we want to explore other possibilities. Metaiodobenzylguanidine (MIBG) is a guanethidine derivative, structurally similar to norepinephrine. It was developed as an imaging agent with ^{123}I radiolabeling. MIBG localizes neuroendocrine tumors including MTC. We are investigating the use of high doses of ^{131}I-MIBG as therapy for metastatic MTC. We present two case reports in which we used this therapeutic option.
Case reports
1) A 40-year-old woman, diagnosed at 26 of MCT with lymph node metastasis. She was surgically treated up to three times (due to lymph node recurrence). In 2015, there was an increase of calcitonin and CEA levels (1859 pg/dl, 27.1 ng/ml), showing metastases at lung, bone and breast. A ^{123}I-MIBG scan was performed, revealing an uptake of the radiotracer by bone lesions. One therapeutic dose of 200mCi ^{131}I-MIBG was administered, with uptake being appreciated by bone lesions but not by pulmonary lesions. After 6 months, the levels of calcitonin and CEA further raised (3353 pg/dl, 33.5 ng/ml). In the imaging study, an increase in the size of the pulmonary nodules was observed. TKI therapy was started.
2) A 39-year-old woman, diagnosed at 18 with endocrine neoplasia type 2B with CMT and bilateral pheochromocytoma, who underwent total thyroidectomy and bilateral adrenalectomy. In 2016, metastatic dissemination was observed with bone, liver and interaortocaval adenopathy lesions (calcitonin 10 279 pg/ml, CEA 64.7 ng/ml). It was treated with a high fractional dose of ^{131}I-MIBG (300 mCi, 360 mCi), with radiological progression of the disease in the hepatic parenchyma after 1 year. However, biochemical markers remained stable (calcitonin 9253 pg/ml, 85.6 ng/ml).
Conclusion
In our experience, the benefits of ^{131}I-MIBG therapy in metastatic medullary thyroid carcinoma are poor.

Role of the fine-needle aspiration biopsy of cervical lymph nodes with thyreoglobulin washing tests in management patients with differentiate thyroid cancer.

Jacek Galczynski[1], Elwira Bakula-Zalewska[2] & Marek Dedecjus[1]
[1]Department of Oncological Endocrinology and Nucelar Medicine, The Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland; [2]Department of Pathology, The Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland.

The aim of this study was the assessment of diagnostic utility of fine-needle aspiration biopsy needle washout fluids (FNAB-Tg) in the cases of thyroid carcinoma recurrence and analysis of false-positive and false-negative results.
Methods
Two hundred and fifteen FNAB-Tg samples from 201 patients with a history of differentiated thyroid carcinoma with suspicious lymph nodes were included in analysis. The wash-out of needle rinsed with 0.5ml of normal saline solution, using electrochemiluminescence method -ECLIA were performed.
Results
In 64 patients elevated FNAB-Tg levels correlated with positive cytology result. In 13 patients there were no correlation between elevated FNAB-Tg level and cytology result. Four of these patients had cystic metastasis of papillary carcinoma. Nine patients with metastases had not elevated FNAB-Tg levels. In four of them, FNAB revealed carcinoma cells from other malignancies. Three of patients had metastases of dedifferentiated thyroid carcinoma and two had differentiated thyroid carcinoma.
Conclusion
FNAB-Tg of the lymph nodes increases accuracy in the diagnosis of thyroid carcinoma recurrence, especially in detecting of cystic variants and micro-metastases or in coexisting malignances of other origin. False-negative FNAB-Tg results may occur in the cases of dedifferentiated thyroid carcinomas or with high serum anti-Tg antibodies.

DOI: 10.1530/endoabs.56.P1177

P1178

Malignancy risk stratification of thyroid nodules with cytological diagnosis of folicular neoplasm (Bethesda IV), according to the ultrasound sonographic patterns proposed by the American Thyroid Association (ATA)

José Javier Pineda[1,2], Ander Ernaga[1,2], Emma Anda[1,2], Marta Toni[1,2], Juan Pablo Martinez[1], Patricia Munarriz[1], Jorge Rojo[1], Dolores Ollero[1,2] & María Diaz[1]
[1]Thyroid Pathology Unit of Complejo Hospitalario de Navarra, Pamplona, Spain; [2]IdiSNA: Instituto de investigación sanitaria de Navarra, Pamplona, Spain.

Background
The main limitation of fine-needle aspiration (FNA) is represented by indeterminate category (Bethesda III and IV) in which the risk of malignancy is between 5-30%. Given this result, surgical treatment is necessary in many cases. The aim of our study is to assess whether the ultrasound patterns proposed by the ATA, help us to stratify the risk of malignancy in nodules with Bethesda IV cytology result.
Methods
From January 2011 to June 2017 we selected all thyroid nodules referred to our Thyroid Unit, with cytological diagnosis of follicular neoplasia (Bethesda IV). All patients underwent surgical treatment. We retrospectively analyzed the clinical data (computerized clinical history) and ultrasound images. (All images were reviewed and classified in different ultrasound patterns by two endocrinologists with at least 5 years of experience in thyroid ultrasound.).
Results
A total of 263 nodules were selected with the following characteristics: Mean age ±S.D.: 52.1±15.1 years; sex: F/M (4/1); mean size of nodules 30.6±13.3 mm; TSH: 2.5 mU/L±8.6; thyroid autoimmunity 27.8%. The malignancy risk of the following ultrasound patterns is: Very low suspicion (0%), Low suspicion (16.7%), Intermediate Suspicion (27.9%) and High Suspicion (63.4%). 15 Nodules (5.7%) could not be classified within a specific pattern, presenting a risk of malignancy of 26.7%. Of the 263 nodules 68 were malignant (25.9%). 44 malignant nodules (64.7%) were papillary carcinomas, being the follicular variant the most frequent histologic type.
Conclusions
Ultrasound patterns proposed by the ATA, allow an adequate stratification of the malignancy risk, in nodules with Bethesda IV cytological results. This information may have clinical utility to decide the most appropriate surgical approach. However, 5.7% of the nodules could not be classified properly, presenting a risk of malignancy similar to those of Intermediate Suspicion.

A rare case of mixed medullary and papillary thyroid carcinoma related with heterozygous VAL804MET mutationa rare case of mixed medullary and papillary thyroid carcinoma related with heterozygous VAL804MET mutation

Bağdagül Yüksel Güler[1], Sevgül Fakı[2], Cevdet Aydın[2], Abdussamed Yalçın[3], Huban Sibel Orhun Yavuz[4], Reyhan Ersoy[2] & Bekir Çakır[2]
[1]Atatürk Education and Research Hospital Internal Medicine Clinic, Ankara, Turkey; [2]Yıldırım Beyazıt Univercity Medical School Endocrinology and Metobolism Department, Ankara, Turkey; [3]Yıldırım Beyazıt Univercity Medical School General Surgery Department, Ankara, Turkey; [4]Atatürk Education and Research Hospital Medical Pathology Clinic, Ankara, Turkey.

Introduction
Papillary thyroid carcinoma(PTC) and medullary thyroid carcinoma(MTC) have always been considered different tumors. Concomitant presence of MTC and PTC in the same patient is a rare clinical event.
Case report
A 43 year-old woman admitted with fatigue, a serum thyrotropin of 4.6 uIU/ml and a 15×11 mm thyroid nodule in right lobe detected in another center. Fine needle aspiration(FNA) of the nodule was consistent with MTC. In family history, her mother had thyroid cancer but the type was unknown. Repeat thyroid ultrasonography revealed a 14×11.8×18.4 mm solitary thyroid nodule in right lobe. There were also suspicious lymph nodes in right level VI and IV and left level IV. FNA along with tyroglobuline and calcitonin wash-out was performed to lymph nodes and thyroglobulin levels were 8423, 373.3 and 0.3 ng/ml respectively while calcitonin wash-out results were >2000 pg/ml in all lymph nodes. FNA cytologies were atypia of undetermined significance for the right and nondiagnostic for the left lymph nodes. Serum calcitonin was 655 pg/ml (<5 pg/ml) and carcinoembryonic antigen(CEA) was 45.1 ng/ml (0–3.4 ng/ml) . Evaluation for concomitant primary hyperparathyroidism and pheochromocytoma revealed no pathology. Total thyroidectomy with right lateral, left lateral and bilateral central lymph node dissection was performed. Pathology of the nodule was reported as 17×14 mm mixed medullary and papillary thyroid carcinoma'. Immunhistochemistry was positive for TTF-1 and calcitonin, and in focal areas thyroglobuline, CK-19 and HMBE-1 stainings were positive. One right lateral and three right central lymph node were tumour positive. The patient received 150 mCi radioactive iodine ablation therapy. Stimulated thyroglobuline was 4.2 ng/ml and a focal activity uptake in thyroid location was seen in postablative whole body scanning. Serum calcitonin and CEA regressed to 20.0 pg/ml and 2.7 ng/ml, respectively. The patient was heterozygote for C2410G>A (VAL804MET) mutation in RET protooncogene analysis. 26-year old daughter of the patient was also heterozygote for C2410G>A (VAL804MET) while other daughter had no mutation. Mutation carrier daughter of patient preferred active surveillance rather than prophylactic thyroidectomy.
Conclusion
Our patient is one of the rare cases of mixed medullary and papillary thyroid carcinoma that was evaluated completely both clinically and genetically. Mixed medullary and papillary thyroid carcinoma is a rare clinical entity but merits consideration in differential diagnosis of thyroid nodules particularly in patients with a family history of thyroid malignancy.

Validity of sonographic pattern risk in thyroid nodules by the American Thyroid Association (ATA) and citological malignancy diagnosis

Emma Anda, Javier Pineda, Nerea Eguilaz, Ana Irigaray, Ander Ernaga, Marta Toni, Juan Pablo Martínez, Dolores Ollero & Elena Almudévar
Unidad Patología tiroidea, Complejo Hospitalario de Navarra, Pamplona, Spain.

Objetive
The aim of our study is to asses the validity of ultrasound patterns proposed by the ATA and malignancy risk in the cytological diagnosis classified by the Bethesda System.
Methods
Prospective study including all thyroid nodules (with no previous cytological results), assessed in our center from July/2016 to June/2017. We classified nodules in ATA sonographic risk patterns and follow-up its fine needle aspiration (FNA) recommendations. The statistical study has been carried out with the statistical package SPSS 20.0
Results
We evaluated 402 thyroid nodules. 160 were selected by ATA criteria to citologycal diagnosis. These correspond to 144 patients (80.2% women, mean age 52.8 years). Mean TSH was 1.82 (0.37–6.96) and 28.8% patients presented positive autoinmunity (antitiroglobulin and/or antiperoxidase antibodies). The mean size nodules was 2.8±1.2 cm, with those with lower ultrasound risk of malignancy being higher (3.2 vs 2.1 cm, P 0.02). The frequency distribution in the different sonographic risk categories were: High risk 16.3%, Intermediate risk 10.6%, Low risk 50%, and Very low risk 18.1%. The 5% of the nodules could not be classified in any of the previous patterns. The malignancy rates (according to Bethesda System Classification as malignant o suspicious for malignancy) in each sonographic group was: High risk 61.5%, Intermediate risk 5.9%, Low risk 0% and Very low risk 0%. Thyroidectomy was performed in 42 patients, 27 of them (64%) were thyroid carcinomas. The overall malignancy, including the histology in those patients surgically removed, correlates with the ultrasound data (P>0,001): 80.7% in High risk, 11% in Intermediate risk, 3.75% in Low risk and 0% in those with Very low risk. In non-classifiable nodules, malignancy was observed in 12.5%.
Conclusions
Our prospective results supports sonographic risk patterns of thyroid nodules and FNA recommendation proposed by ATA 2015 guidelines. We have found a highly correlation between each sonographic pattern and likelihood of malignancy, both in cytology and surgical histology.

The role of thyroid imaging, reporting and data system scores – ACR TI-RADS in thyroid nodular disease – our expirience

Tijana Icin[1,2], Jovana Prodanović[2], Ivana Bajkin[1,2], Sonja Slankamenac[2], Jovanka Novaković-Paro[1,2], Dušan Tomić[2], Đore Popović[1,2], Slaana Pejaković[1,2], Dragan Tešić[1,2], Edita Stokić[1,2] & Milena Mitrović[1,2]
[1]Medical Faculty, University of Novi Sad, Novi Sad, Serbia; [2]Clinic for endocrinology, diabetes and metabolic diseases, Clinical Center of Vojvodina, Novi Sad, Serbia.

Introduction
The American College of Radiology proposed in 2017. ACR-TIRADS scoring system for the ultrasound findings of the thyroid gland. It now represents a standardized system of scoring pathological changes determined from five categories registered with ultrasound. High cumulative result leads to higher TR level and the higher probability of malignancy, which provides recommendations for eather FNA (fine needle aspiration) or further ultrasound monitoring of nodules assessed as most likely benign. The aim of the paper is to examine the relationship between ACR TI-RADS scoring system and the cytological findings obtained after the FNA which is represented by the Bethesda system.
Material and methods
Prior to each FNA, TI-RADS was calculated based on the ACR TI-RADS calculator, whereas the type of vascularization of the nodus and the perinodal tissue was determined. The study included 65 patients with the average age of 59 years and average TI-RADS of 3.43. From a total of 65 patients, 72% showed benign cytological finding, whereas 9% were in the AUS or AUS/FLUS category (atypia of undetermined significance/follicular lesion of undetermined significance). The remaining 19% of smears was non-diagnostic. None of the findings obtained had a suspect of malignancy. The average age of patients with benign finding was 58 years, and with AUS was 63 years. It was observed that for patients with AUS the average TI-RADS was 4, and that nodules were positioned in the right lobe, except in one case, where the position was in the area of isthmus. Average TI-RADS in nodules with benign pathohistological findings was 3.3, while 55% were positioned in the left lobe region.Only 6% of patients with benign findings had TI-RADS 1, 15% with TI-RADS 2, TI-RADS 3 had 28% and TI-RADS 4 had 40%, while TI-RADS 5 had 11% of patients. The group of patients with AUS was evenly allocated to results TI-RADS 3, TI-RADS 4, TI-RADS 5 each respresented with 33.3%. Vascularization of nodus type 2 had 34% and 8% had type 4 patient with benign findings,while with AUS findings, 50% of patients had type 2 and 0% type 4. By measuring the volume of nodules, and comparing them, it was found that the average nodus size was greater for patients with the AUS.
Conclusion
There are indications that the higher ACR TI-RADS was obtained in AUS cytological findings. Benign cytological findings were obtained in all TI-RADS 1 and 2.

May cinacalcet improve psychiatric symptoms by decreasing calcium levels in lithium-associated hyperparathyroidism?

Sevgül Faki, Cevdet Aydin, Sefika Burcak Polat, Didem Özdemir, Muhammet Cüneyt Bilginer, Reyhan Ersoy & Bekir Çakir
Department of Endocrinology and Metabolism, Yıldırım Beyazıt University Faculty of Medicine, Ankara, Turkey.

Introduction
Lithium is the preferred and most efficacious therapy for acute and maintenance therapy of bipolar depressive disorder. Lithium use is associated with an increased incidence of hyperparathyroidism (4.3–6.3%) and have a female preponderance. Bilateral neck exploration was the most common surgical approach while a few patients were managed medically. The initial management of Lithium-associated hyperparathyroidism (LAH) is medical intervention which includes discontinuation of lithium or use of an alternative treatment such as atypical antipsychotics and calcimimetics. Here we demonstrate improved psychiatric symptoms after cessation of lithium and successful treatment of hypercalcemia by cinacalcet in a geriatric patient with LAH.
Case
81-year-old woman with a history of bipolar disorder treated with lithium carbonate for more than 10 years presented with nocturia and polyuria. Her serum calcium was 11.58 mg/dl (Normal – 9–10.5 mg/dl), alkaline phosphatase 175 U/L (Normal – 30–120 U/l)), serum parathyroid hormone 380 pg/ml (Normal – 10–60 pg/ml) and phosphorus 2.1 mg/dl (normal 3–4.5 mg/dl). No definite parathyroid lesions were identified by neck ultrasonography and Sestamibi/SPECT scans. Lithium treatment was stopped after consultation with psychiatrist. More than 3 months later, she had persistent hypercalcemia and depressive symtomps recurred. Cinacalcet (30 mg once daily) was started. After 2 weeks of treatment serum calcium level decreased to 9.5 mg/dl and PTH level was 160 pg/ml.Cinacalcet was well tolerated and the patient's psychiatric symptoms improved without any need for lithium or other antidepressant drug.
Conclusion
Cinacalcet is known to be effective in primary hyperparathyroidism but our observations also support the use of this calcimimetic agent in lithium-induced hyperparathyroidism as a potential alternative to surgery in geriatric patients. Treatment of hypercalcemia might help to resolve depressive symptoms in these patients. Cinacalcet could represent an important pharmacological intervention in MEN1-associated primary hyperparathyroidism before surgery and in post-surgical recurrences.

Pediatric thyroid cancer is associated with more aggressive phenotype and more frequent RET/PTC rearrangements compared with the adult patients

Běla Bendlová[1], Vlasta Sýkorová[1], Šárka Dvoráková[1], Eliška Václavíková[1], Barbora Peková[1], Rami Katra[2], Daniela Kodetová[2], Petr Laštûvka[3], Jan Plzák[3], Petr Bavor[2], Jirí Hoch[2], Petr Vlček[2], Pavla Sýkorová[2] & Josef Včelák[1]
[1]Institute of Endocrinology, Praha, Czech Republic; [2]2nd Faculty of Medicine, Charles University, Prague, and Motol University Hospital, Praha, Czech Republic; [3]1st Faculty of Medicine, Charles University, Prague, and Motol University Hospital, Praha, Czech Republic.

Thyroid cancer in children and adolescents is a rare disease but with an increasing incidence. As in adults, the most prevalent type is papillary thyroid carcinoma (PTC). Our aim was to describe the clinical and genetic comparison between pediatric and adult PTC. We analyzed the cohorts of 73 pediatric PTC (5-18 years, female to male ratio 2.3:1, 10 patients <10 years) and 460 adult PTC patients. DNA and RNA were extracted from cancer tissue samples. DNA was used for sequencing of *TERT* promotor C228T and C250T mutations with CEQ8000 and *BRAF* and *RAS* mutations by Nextera XT kit with MiSeq. RNA was used for detection of *RET/PTC1* and *RET/PTC3* rearrangements using Real Time PCR. Clinical and pathological data were compared between both cohorts. In the pediatric cohort, more aggressive categories T3 and T4 in TNM classification (47% vs 26.7%, $P=0.001$), significantly more frequent lymph node metastasis (73% vs 42%, $P<0.001$), extrathyroidal invasion (48.3% vs 29.9%, $P=0.007$) and angioinvasion (26.2% vs 14.0%, $P=0.026$) were present in comparison with adult PTC. The frequency of distant metastasis did not significantly differ between pediatric and adult PTC (4 vs 8.4%, $P=0.304$). Mutation in *RAS* genes was detected only in one patient - mutation Q61K in *N-RAS* gene (1,5% vs. 8% in adults, $P=0.065$), *BRAF* V600E mutation in nine pediatric patients (12.8% vs 37% in adult, $P<0.001$). No *TERT* mutations were found in pediatric PTC in contrast to 12% in adults ($P=0.004$). *RET/PTC* rearrangements were found in 14 patients (20.9% vs 5% in adults, $P<0.001$) – nine RET/PTC1, five *RET/PTC3* and one *RET/PTC1ex9* were detected. *RET/PTC1ex9* in 8 years old boy with aggressive classical variant of PTC (T4N1M1) was created by fusion of exon 1 of CCDC6 with exon 9 of extracellular domain of *RET* followed by exon 12 of RET. One 17 years old patient with T3N1M0 had *BRAF* V600E mutation together with RET/PTC1. In our cohort, PTC in pediatric patients presented more aggressive features than in adults, mainly with more advanced T in TNM classification, more frequent lymph node metastasis, extrathyroidal extension and angioinvasion. The molecular genetic analysis revealed that the prevalence of the *RET/PTC* fused genes was significantly higher in pediatric PTC compared with adult PTC, in contrast to significantly lower prevalence of the *BRAF* V600E and *TERT* mutations.

Serum osteopontin levels in newly diagnosed thyroid cancers

Taha Ulutan Kars & Mustafa Kulaksizoglu
Necmettin Erbakan University, Meram Medical Faculty, Konya, Turkey.

Purpose
Thyroid cancer is the most common cancer of endocrine system. Osteopontin (OPN) is a secreted glycoprotein that has a role in osteoblast differentiation and bone formation. Osteopontin has other roles in cell migration and cell survival and its related to tumorigenesis and cell invasion. Osteopontin levels have been determined higher in some malignancies. The purpose of this study is to determine plasma osteopontin levels in patients with new onset diagnosed thyroid cancer and to compare them with plasma osteopontin levels in healthy people.
Method
In our study we planned to compare two groups. The first group was composed of patients with newly diagnosed differentiated thyroid cancer (40 patients) and the second group was composed of healthy individuals (40 patients). Blood samples (5 ml) for osteopontin were collected for both groups, centrifuged and frozen at −80 °C. Osteopontin levels were studied with ELISA method at once.
Findings
OPN levels were determined 10.21 ± 3.67 ng/ml in patients and 6.14 ± 2.29 ng/ml in control group. OPN was determined higher in patients and this difference was statistically significant ($P < 0.001$). There was no significant correlation between OPN level and prognosis and aggressiveness.
Results
OPN levels were higher in patients with thyroid cancer. This case was associated with pathophysiological role of OPN in tumorigenesis. OPN levels were not significant in predicting prognosis and aggressiveness. Further studies are needed to be understood the role and importance of OPN.

First report of c.1683A > G *FLT3* mutation found in the follicular thyroid cancer

Martyna Borowczyk, Ewelina Szczepanek-Parulska, Szymon Dębicki, Bartłomiej Budny, Małgorzata Janicka-Jedyńska, Elżbieta Wrotkowska, Blanka Majchrzycka, Katarzyna Ziemnicka & Marek Ruchała
Poznan University of Medical Sciences, Poznan, Poland.

Introduction
The number of thyroid cancer diagnosis has increased worldwide. However, its diagnosis, particularly in a case of follicular cancer (FTC), may be challenging. New markers of malignancy are intensively searched for.
Case description
A 29-year-old female was referred for subtotal thyroidectomy in 2006 due to a nodule in the right lobe. The histopathological examination revealed follicular adenoma (FA). During endocrinological follow-up, in 2008 a local recurrence in the thyroid bed and the presence of metastases to the lymph nodes and lungs were observed. Thus, the patient was referred for total thyroidectomy and lymphadenectomy. Histopathological examination of the resected specimen demonstrated the presence of FTC. Due to persistent disease, the patient required two subsequent lymphadenectomies followed by radioiodine therapy. However, the result of the therapy was unsatisfactory. Consultation of the material acquired from the first surgery resulted in conclusion that, taking into account the clinical course of the disease and morphological similarity of weaving in both histopathological specimen, the nodule in the right thyroid lobe operated in 2006 was presumably a FTC. Patient has been subsequently treated by lenvatinib from 2012 to 2015 acquiring total structural and partial biochemical remission. The drug was withdrawn due to the disease recurrence. Patient was reoperated in 2015 and has been treated with sorafenib since 2016. However, the remission of the disease has not been achieved until now. The histopathological specimen from the first surgery has been prepared for next-generation sequencing. DNA was acquired from histopathological slide. NGS sequencing was done on the *Ion PGM Sequencer (Thermo Fisher,* USA) employing *Ion AmpliSeq Comprehensive Cancer Panel*. The obtained data from genomic experiments were subjected for analysis using dedicated software. The analysis revealed the presence of fms-related tyrosine kinase 3 (*FLT3*) mutation on chromosome 13 – c.1683A > G (COSM19740), silent substitution present in coding region, position 561 L → L. The occurrence of the mutation has not been confirmed in the patient's leucocyte DNA through NGS, which confirms its somatic character.
Conclusions
Although *FLT3* has been previously reported in hematological malignancies, such as acute myeloid leukemia or myelodysplastic syndrome, to the best of our knowledge this is the first report of the presence of *FLT3* mutation in the thyroid tissue. Due to diagnostic problems in a case of our patient, finding a new marker of FTC and possible prognostic factor is crucial, what might be the basis for new targeted therapeutic options.

Thyroglossal duct cyst papillary carcinoma: case report and review of literature

M Delgado[1], J Paz[1], E Linares[1], J Gonzales[1], R López[1], A Ponce[1], F Cabrera[1], K Calderón[1], S Regalado[1], J Casusol[1], M Castro[1], C Reaño[1], I Giles[1], J Corrales[1], S Sáenz[1], Marialejandra Delgado Rojas[2], Edgardo Linares Reyes[3] & Jose Luis Paz Ibarra[4]
[1]Endocrinology Service-Hospital Almanzor Aguinaga- Es salud-. Lambayeque-Perú; [2]Hospital Almanzor Aguinaga Asenjo, Chiclayo, Peru; [3]Hospital Belen, Trujillo, Peru; [4]Hospital Edgardo Rebagliatti, LIma, Peru.

Objective
To report a rare case of papillary thyroid carcinoma (PTC) in a thyroglossal duct cyst (TGDC).
Case report
A 34-year-old peruvian male came to our hospital with a complaint of a swelling cervical mass in the anterior central side of the neck, which was growing since 6 months earlier. The patient had no significant past medical, surgical history and was completely asymptomatic. He denied any family history of thyroid disease or history of head and neck irradiation. Physical exam reveal a nontender, not much mobile and semi-solid neck mass measuring 5 cm in the suprahyoid median line, with some phlogosis signs. Laboratory examinations include: TSH 3.21 uIU/ml, T4L 1.0 ng/dl and Anti-TPO/AbTg (-). Cervical ultrasonography revealed homogenous thyroid gland with normal dimensions. RTL: hypoechogenic nodule with defined edges of 9×7 mm soft consistency to elastography. In the anterior central side of the neck, suprahyoid cystic image with sediment and thick calcifications was observed, measuring $48 \times 39 \times 59$ mm, with a volumen of 58.5 cc. CT: encapsulated, lobulated and bilobed cystic lesion with small internal calcifications measuring $33 \times 30 \times 15$ mm, located in the midline cervical, as well as multiple cervical lymph nodes enlargement, the largest in the right carotid side. FNAB of cervical tumor: malignant neoplasm of papillary aspect of probable thyroid origin. Sistrunk procedure was performed, during which we found a 7 cm mass, with necrosis of the anterior side and thinning of the skin, as well as a superficial pre-laryngeal lymph node. Histopathology of the mass demostrated a PTC papillary and follicular variant in TGDC, with infiltrative borders and capsular and bone invasion, measuring in greatest dimension 1 cm, excision margins free of neoplasia. Presence of neoplasic invasion of lymphatic vessels. Lymph node and submental region free of neoplasia. Patient underwent a total thyroidectomy that reported absence of malignant lesion. Patient is waiting for ablative radioiodine.
Conclusion
The clinical presentation of PTC in the TGDC in the early phase; It presents an anterior cervical mass of rapid grow, fixed, indurated, irregular, accompanied by lymphadenopathies in the upper jugular group. The role of total thyroidectomy is still controversial, as is postoperative adjuvant treatment. The prognosis of PTC of the TGDC is good.

Thyroid imaging reporting and data system: how useful is it in distinguishing follicular adenomas from follicular carcinomas?

Francisco Sousa Santos[1], Catarina Saraiva[1], Ricardo Capitão[1], Cátia Ferrinho[1], Clotilde Limbert[1], Martinha Chorão[2], Sância Ramos[2] & Carlos Vasconcelos[1]
[1]Endocrinology Department, Hospital Egas Moniz, Lisbon, Portugal; [2]Pathology Department, Hospital Egas Moniz, Lisbon, Portugal.

Introduction
Various thyroid imaging reporting and data systems (TIRADS) have been proposed in recent years, such as the EU-TIRADS proposed by the European Thyroid Association (ETA). These classification systems intend to estimate the malignancy risk of thyroid nodules, however they are very much based on suspicious ultrasound (US) features typical of papillary thyroid cancer. As such, follicular carcinomas may be reported as low suspicion nodules. Our work aims to evaluate the performance of the EU-TIRADS in follicular neoplasms and how

accurate are their ultrasound high suspicion features in distinguishing follicular and Hürthle cell adenomas from carcinomas.
Methods
Retrospective study including patients followed-up in a Portuguese central hospital for the past 10 years who underwent to thyroid surgery and received subsequent histological diagnosis of follicular carcinoma, follicular adenoma, Hürthle cell carcinoma or Hürthle cell adenoma – 151 patients. We identified every patient who had US imagological records from before surgery available for review. The US features were retrospectively evaluated and the nodules were classified according to their EU-TIRADS score.
Results
We included 39 patients with histological diagnosis of follicular neoplasm (18 malignant) – seven follicular carcinomas, 16 follicular adenomas, 11 Hürthle cell carcinomas and five Hürthle cell adenomas. The mean age at surgery was 55 ± 14 years and 74% of patients were female. The mean nodule diameter was 31 mm (adenomas: 29 mm and carcinomas: 34 mm, $P = 0.260$). The presence of a hypoechoic halo was associated ($P = 0.034$) with increased odds of benign nodule etiology. No statistically significant differences were identified regarding nodular composition, shape, margins or existence of microcalcifications between carcinomas and adenomas. Both adenomas and carcinomas had EU-TIRADS score of 3 (benign: 8, malignant: 4), 4 (benign: 6, malignant: 8) or 5 (benign: 7, malignant: 6) and this distribution did not reach a statistically significant difference ($P = 0.479$). EU-TIRADS category four had the highest sensitivity for detecting malignant lesions – 44.4%. Most malignant ($n = 12$) and benign ($n = 14$) nodules did not present any EU-TIRADS high suspicion US features and the number of features was not statistically significantly different between carcinomas and adenomas ($P = 0.208$). Only 1 malignant nodule did not have an EU-TIRADS score and diameter that would imply fine-needle aspiration (FNA) according to ETA EU-TIRADS guidelines.
Conclusion
EU-TIRADS based high suspicion US features do not seem valuable in distinguishing follicular adenomas from carcinomas. Nevertheless, the majority of carcinomas scored as EU-TIRADS category 4 and 5 – intermediate and high-risk categories which should warrant FNA in most cases.

P1188

Descriptive study about clinical and surgical characteristics of patients with differentiated thyroid cancer in our health area

Javier González, Dulce María Calderon, David Martón, Mubarak Al-Ramadan & Jose Pérez
Hospital Virgen de la Luz, Cuenca, Spain.

Introduction, material and methods
Differentiated thyroid cancer is a pretty common reason for consulting in our specialty. In general terms, the prognosis is good in the main histological type but there are many others that can worsen the prognosis. It can determine the kind of surgery from hemithyroidectomy (e.g. microcarcinoma) to no intervention because of its extension at the moment of diagnosis. We have collected the data of our patients with differentiated thyroid cancer during the period from 2000 to 2015 and we have described the epidemiological, pathological and surgical aspects of them and compared with the rest of the main series published. Statistical analysis was made with Stata.
Results
A total amount of 87 valid cases of thyroid cancer were diagnosed during the period from 2000 to 2015. The average age was 46.16 (95% CI, 42.76–49.55). From these cases, 72 were female (83.0%) and 15 were male (17.24%). Diagnosis with FNA before surgery showed: 30 (34.88%) were Bethesda 2, 29 (33.72%) were Bethesda 5, 13(15.12%) were Bethesda 3 or 4, 6 (6.98%) were Bethesda 1 and in 8 (9.3%), FNA was not made. About surgery, they underwent to: 65 (74.71%) total thyroidectomy, 1 (1.15%) near-total thyroidectomy, 3 (3.45%) hemithyroidectomy, 17(19.54%) total thyroidectomy in two periods and 1 (1.15%) did not have thyroid surgery; 47(54.02%) were underwent lymphadenectomy and 40(45.98%) were not. About histological type, 80 (91.55%) were papillary thyroid cancer and 8 (8.05%) were follicular thyroid cancer. About histological subtype: 28 (36.44%) were classical forms, 14 (18.42%) were microcarcinoma subtype, 25 (32.89%) were follicular subtype, 3 (3.95%) were encapsulated subtype, 2 (2.63%) were tall cell variant, 1 (1.32%) was diffuse sclerosing variant, 1 (1.32%) was Hürthle papillary carcinoma, 1 (1.32%) was minimally invasive follicular carcinoma and 1 (1.32%) was invasive follicular carcinoma.
Conclusions
We can confirm that thyroid cancer is presented predominantly in women at a young age. Also, we can appreciate the low sensitivity of the FNA in our centre. Total thyroidectomy (in 1 or 2 periods) is the most usual technique for the thyroid surgery, leaving hemithyroidectomy for micropapillary thyroid cancer and conservative treatment for unresectable cases. The most frequent histological type is papillary thyroid cancer and within this, the classical form. Based on our data, we can say that our results are similar to the main series published (except in some fields as the FNA results).

P1189

Thyroid ultrasonography and fine needle aspiration: a center experience

Diana Catarino[1], Cristina Ribeiro[1], Diana Oliveira[1], Diana Martins[1], Adriana Lages[1], Mara Ventura[1], Nelson Cunha[1], Lúcia Fadiga[1], Bernardo Marques[2], Miguel Melo[1], Sandra Paiva[1] & Francisco Carrilho[1]
[1]Endocrinology Department, Coimbra Hospital and University Center, Coimbra, Portugal; [2]Portuguese Oncology Institute, Coimbra, Portugal.

Introduction
Thyroid ultrasonography and fine needle aspiration (FNA) are the most useful techniques in the evaluation of thyroid nodules. They are cheap, fast, minimally invasive and high precision methods. The FNA can be performed by palpation or ultrasound guidance. The use of ultrasound reduces the nondiagnostic results rate. However, the cytologic diagnostic accuracy depends on the technique and pathologist experience. Ultrasonography confirms the presence of a thyroid nodule, its precise location and the presence of other nodules not yet known; allows to characterize thyroid nodules, detect lymph nodes and screen high risk patients for thyroid malignancy. In Portugal, thyroid ultrasonography and ultrasound guided-FNA (US-FNA) were performed by radiologists but now are performed by endocrinologists too. The Endocrinology department of Coimbra Hospital was one of the pioneers, with experience since 2005.
Objective
The objective of this study is to show the experience of a center, that performs thyroid ultrasonography and US-FNA.
Material and methods
Review and statistical analysis of all thyroid ultrasonographies, US-FNA and histologic results, performed in the Endocrinology department of Coimbra Hospital, between January 1, 2017 and October 31, 2017.
Results and conclusion
Between January 1, 2017 and October 31, 2017: 381 ultrasonographies (without FNAB) and 1452 US-FNA.Total number of patient: 1517. Average age: 58.4 years (s.d.: 14.9 years). Younger patient: 10 years. Older patient: 91 years. Total number of women: 1250 (82%) and men: 266 (18%). Nondiagnostic/unsatisfactory results rate low (1.,8%). The most of histologic results was *benign* – class II of Bethesda Classification (80.8%). Other results*:* FLUS – a*typia* of undetermined significance or follicular lesion of undetermined significance (Bethesda III): 10.5%; follicular neoplasm or suspicious for a follicular neoplasm (Bethesda IV): 4.7%; Suspicious for papillary carcinoma (Bethesda V): 1.1%. Papillary thyroid carcinoma (Bethesda VI)*:* 1.3%. The complication rate was null. Thyroid ultrasonography and US-FNA are useful tools in the evaluation and management of thyroid disorders. It should be performed in all endocrinology departments. The benefit of this practice depends on the clinical endocrinologist experience and continuous training helps decision-making. Molecular studies will be helpful in elucidating indeterminate results – FLUS and follicular tumour.

Brain metastases from papillary thyroid carcinoma, 31 years later

Diana Catarino[1], Joana Saraiva[1], Cristina Ribeiro[1], Diana Oliveira[1], Diana Martins[1], Adriana Lages[1], Mara Ventura[1], Nelson Cunha[1], Lúcia Fadiga[1], Bernardo Marques[2], Sara Donato[3], Miguel Melo[1], Maria Corbal[4], Inácio Reis[5] & Francisco Carrilho[1]
[1]Department of Endocrinology, Coimbra Hospital and University Center, Coimbra, Portugal; [2]Portuguese Oncology Institute, Coimbra, Coimbra, Portugal; [3]Portuguese Oncology Institute, Lisbon, Lisboa, Portugal; [4]Radioterapy Department, Coimbra Hospital and University Center, Coimbra, Portugal; [5]Neurocirurgy Department, Coimbra Hospital and University Center, Coimbra, Portugal.

Introduction
Papillary thyroid carcinoma (PTC) is a differentiated thyroid carcinoma and is the most common variant. It is more frequent in women and the median age at diagnosis is 45 years. Most PTC are clinically indolent, have a good prognosis and

low incidence of distant metastases. The more frequent locals of distant metastases are bone and lung. Brain metastases are very rare and associated with a poor prognosis.
Case report
We present a case of a 74-years-old woman, without history of radiation and no family history of thyroid disease. In 1984, she underwent a total thyroidectomy with cervical lymphadenectomy. The histologic result was a *papillary thyroid carcinoma,* with cervical *lymph node and pulmonary metastases* (T4bN1M1). Between 1984 and 1999, she realized multiple doses of therapeutic radioiodine – I^{131} (cumulative dose $>$1Ci). After the last treatment (1999) she realized a post-therapeutic scan that showed no significant uptake (although she maintains pulmonary metastases – clinically indolent). At 2009 she underwent a thoracotomy (nodule with 12 mm). The histologic result was a papillary carcinoma metastase. In 2012 the 18FDG-PET showed bilateral pulmonary metastases with some dedifferentiated lesions. The follow-up showed stable values of thyroglobulin (Tg: 32–57 ng/ml, TgAb: negatives). In November, 2015, she developed a behavior change and realized a cranial CT: frontal lesion with 55$\times$26 mm. December, 2015: she underwent a total excision of the brain lesion; histology: brain metastases from papillary thyroid carcinoma. 18FDG-PET (February, 2016): no hypermetabolic lesions suggestive of dedifferentiated lesions. July, 2016: recurrence of the frontal/temporal brain metastase (50 mm). She realized a second surgery; histology: brain metastase. She underwent holocranian radiotherapy (30Gy) and started Sorafenib (October, 2016). Despite this, there was progression of brain lesions and she developed adverse effects. It was decided stop sorafenib. The patient maintains oncology and neurosurgery visits.
Discussion and conclusion
The present case show that brain metastases, although rare, can occur decades after the diagnosis of papillary thyroid carcinoma. Surgery and radiotherapy are the main therapeutics approach. Tyrosine kinase inhibitors was approved by FDA for the treatment of patients with radioiodine-refractory metastatic thyroid cancer, but the experience is limited. Patients with brain metastases have a poor prognosis.

Ectopic thyroid tissue challenge: clinical case report

David Veríssimo, Catarina Ivo, Vitória Duarte, Dolores Passos, Filipa Serra, João Silva, Luis Lopes, João Jácome de Castro & Mafalda Marcelino
Endocrinology Department, Portuguese Armed Forces Hospital, Lisbon, Portugal.

Introduction
Ectopic thyroid tissue is a rare embryonic developmental defect that occurs during the thyroid transition from its initial position in the floor of the primitive bowel to a pre-tracheal location. This defect has a prevalence in the general population of 0.3–1/100,000 inhabitants, increasing to 0.5–1/4,000 patients with thyroid pathology. It is more common in women and can be diagnosed at any age, with diagnosis being more common in young individuals.
Clinical case
A 78-year-old woman, referred to our department in September 2017 had complaints of hoarseness and choking with 2 months of evolution. The patient had history of nodular thyroid disease, with total thyroidectomy when she was 18 years old. At age 73, after diagnosis of ectopic thyroid, she underwent partial excision of thyroid tissue from the base of the tongue and anterior cervical region, which revealed Papillary Microcarcinoma. On physical examination it was observed a recurrence of the lesion at the base of the tongue with a nodule of 21$\times$18$\times$17 mm, for which subtotal removal of this region was performed. Histology of the surgical specimen revealed unchanged ectopic thyroid tissue.
Discussion/conclusion
The base of the tongue is the most frequent location of ectopic thyroid tissue, with a prevalence of 90% of all cases reported. The most frequent clinical presentation includes complaints of dysphagia and dysphonia, foreign body sensation, cough and airway compression symptoms that occur with a mean age of 40.5 years. Primary carcinomas of ectopic thyroid tissue are uncommon, with diagnosis of lingual thyroid tissue, thyroglossal ductal cyst, mediastinum, and ovary. They are usually diagnosed only after excision of the lesion, with a more frequently papillary pattern. However, follicular, mixed, Hurtle and medullary patterns are also reported. The approach of these malignant lesions is similar to those of thyroid origin, although the presence of ectopic thyroid tissue may be a therapeutic challenge, both in the surgical approach and in the adjustment of levothyroxine doses.

Tyrosine kinase inhibitors in iodine-refractory thyroid cancer. Clinical experience

Clara Marijuán, Begoña Pla, Nerea Aguirre, Elena Fernandez, Iñigo Hernando, Sara Jimenez, Mónica Marazuela & Marcos Lahera
Hospital Universitario de la Princesa, Madrid, Spain.

Introduction
Tyrosine kinase inhibitors (TKIs) are used for treatment of iodine-refractory differentiated thyroid cancer (DTC) in patients with progressive advanced disease.Sorafenib and lenvatinib are the TKIs currently approved for this indication.
Objective
To describe the clinical experience in patients with iodine-refractory DTC treated with TKIs in our Institution.
Materials and methods
Restrospective cohort study of patients with iodine-refractory DTC who received TKIs from 2010 to 2017 in Hospital Universitario La Princesa.We included patients with available clinical data and at least one radiographic control after starting treatment with TKIs.Patients with anaplastic or medullary thyroid carcinoma were excluded.Baseline clinical characteristics, evolution, objective response to treatment, tolerability and adverse events(AE) were collected.Data were analyzed by descriptive statistics with G-Stat 2.0.1.
Results
Twelve patients were included. Mean age at diagnosis was 54(SD13.7) years, (83.3% women). Histhologic diagnosis: 7 papillary thyroid cancer, 4 poorly differentiated follicular thyroid cancinoma and 1 Hürtlhe cell cancer. Distant metastasis at diagnosis were present in 25% of patients. In the other 75% median time to metastasis diagnosis was 24(IQR12) months. Seven patients had more than one metastatatic lesion site. Median time from diagnosis of distant metastasis to TKIs initiation was 24(IQR78) months. Sorafenib, lenvatinib and sunitinib were used as first-line treatment in 8, 2 and 2 patients respectively. First radiographic control was performed at 5.33 (SD2.7) months after start of treatment and showed partial response(PR), stable disease(SD), complete response(CR) and progressive disease(PD) in 5(41.67%), 1 (8.33%), 1(8.33%) and 5(41.67%) patients respectively, with an objective response rate of 58.3%. The only CR was seen on first-line lenvatinib. Before radiographic control 2 patients required a second-line treatment with sorafenib and sunitinib each, due to intolerability. AE occurred in all patients. The most common were fatigue/hyporexia (83.3%) followed by cutaneous AE (58.3%), diarrhea (41.6%), hypertension (16.6%) and mucositis (16.6%). Cutaneous AE ocurred only with sorafenib. The rest of AE were collected for all TKIs (including one case of grade 3 mucositis with Lenvatinib). All patients eventually required dose reductions due to toxicity. Definitive withdrawal was necessary in 83.33% of patients, 50% due to toxicity and 33.33% due to progressive disease. Mortality related to cancer occurred in 8 patients, with a median time of 18 (IQR36) months after start of TKIs.
Conclusion
In our study, use of TKIs showed a similar clinical response to reported in literature with sorafenib. AE are common, being necessary a multidisciplinary management of this treatment in specialized centers.

Correlation between TSH level and benignity and malignancy of thyroid nodules (about 250 cases)

Fatima Zahra Iftahy[1,2,3], Siham El Aziz[1,2,3] & Asma Chadli[1,2,3]
[1]Endocrinology, Diabetology and Metabolic Diseases Department Ibn Rochd University Hospital, Casablanca, Morocco; [2]Neurosciences and Mental Health Laboratory, Casablanca, Morocco; [3]Faculty of Medicine and Pharmacy, University Hassan II, Casablanca, Morocco.

Background
Plasma TSH is a fundamental marker of thyroid function. The TSH level might be different depending on nodule's type. Recent studies have shown a relationship between plasma TSH levels and thyroid nodules malignancy. The aim of this study was to compare the TSH level between two groups of subjects who had undergone total thyroidectomy, one group whose final histology was benign and one group who had a malignant histology.
Materials and methods
It was a retrospective study including 250 patients followed in Endocrinology department of bn Rochd University Hospital of Casablanca between 2012 and 2017, for nodule or multinodular goitre, having undergone surgery. Two groups of patients were compared according to the level of TSH: 1/3 higher, 1/3 medium

and 1/3 lower. Different variables were studied such as age, gender, family history of thyroid disease. Statistical analysis performed by the software SPSS.16.
Results
Mean age of the patients was 41 years (18-71 years), with a female predominance (92%). Familial thyropathy was present in 32% of cases. Surgical indicated was in front of the nodule size in 46% of the cases, the toxic character (23%) and the suspicion of malignancy in 25% of the cases. All patients were preoperatively on euthyroidism. Histology was benign in 68% of cases and malignant in 32% of cases. There was no significant difference between the two groups in terms of age, gender, family history of thyroid disease, or thyroid autoimmunity. Subjects whose final histology was malignant had a mean level of TSH significantly higher than subjects with benign disease (2.98 mU/l versus 0.96mU/l, $P=0.003$). Cancer risk was significantly greater when TSH was in the upper tertile of normal range ($P<0.001$)
Conclusion
These data confirm a higher level of TSH values in subjects with thyroid cancer. However, it seems difficult to define a threshold that would allow to know preoperatively if the nodule is benign or malignant.

P1194

Efficacy and toxicity of lenvatinib treatment for radioiodine refractory thyroid cancer in daily clinical practice: a single centre experience

Lucía Prieto[1], Rui Ferreira Carvalho[1], Virginia Osés[1], Concepción Blanco[2], Nuria Palacios[1] & Javier Aller[1]
[1]Endocrinology Department, Hospital Universitario Puerta de Hierro, Majadahonda, Spain; [2]Endocrinology Department, Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain.

Introduction
Lenvatinib is a multitarget tyrosine kinase inhibitor that has shown substantial efficacy in patients with progressive radioiodine refractory thyroid cancer (RAIRDTC) (progression free survival (PFS) 19.4 months and objective response rate 64.8%; SELECT trial) despite common adverse events (AEs).
Objective
To evaluate efficacy and toxicity of lenvatinib treatment for RAIRDTC in daily clinical practice.
Methods
Retrospective clinical record review of 12 RAIRDTC patients treated with lenvatinib from April 2015 to December 2017 in our hospital.
Results
Twelve patients were analyzed (4 females, median age 62 years (range, 47-82)). Every patient had distant metastasis (83% lung, 67% bone, 58% lymph nodes, 25% liver) and 11 out of 12 had evidence of progressive disease (PD) within 6 months prior to lenvatinib start. Only 4 patients received lenvatinib as first line treatment (range, $1^{st}-6^{th}$ line). Initial dose was 24 mg in 11 out of 12 patients and 10 mg in 1 patient (82 years, ECOG 3, several comorbidities). Median follow-up (duration of treatment) was 14.9 months [0.3-33.5]. Median PFS was 24.3 months (CI 14.7 - 33.8) although data are immature since only 4 patients had progressed at the time of analysis. In 2 patients lenvatinib was not stopped despite PD; both show stable disease at last follow up (6.1 and 3.1 months after first progression). 4 of the 8 patients (50%) in which evaluation of tumour response was available achieved a partial response; 4 (50%) stable disease. No complete responses were observed. All patients presented grade 3 (G3) or superior AEs. The most frequent AEs related to treatment were fatigue (100%; 16% G3), hypertension (83%; 83% G3), nausea (75%; 8% G3), weight loss (67%; 8% G3), diarrhea (50%; 0% G3), arthralgia (50%, 0% G3), mucositis (33%; 0% G3), hand-foot syndrome (25%; 0% G3) and proteinuria (17%, 0% G3). Seven (58%) and ten (83%) patients had dose reductions or interruption of lenvatinib due to AEs. Median time to dose reduction or interruption was 1.9 months. Most dose interruptions were very brief (median duration 2 days). Median dose at last follow-up was 14.9 mg/d (range 7.1 – 24 mg/d). Two deaths occurred, one considered to be drug related (bleeding during cervical abscess surgery).
Conclusion
Remarkable benefit of lenvatinib treatment for RAIRDTC is achieved in daily clinical practice. Our results, in heavily pretreated patients, are in agreement with those of the SELECT trial. AEs are frequent and require close management and dose titration.

Comparative study about clinical characteristics at the moment of surgery and follow-up depending of histological type in patients with differentiated thyroid cancer in our health area

Javier González, Dulce María Calderón, Mubarak Alramadan, David Martín & Dulce María Calderón
Hospital Virgen de la Luz, Cuenca, Spain.

Introduction, material and methods
Papillary thyroid cancer is well known to be a tumour with a good prognosis; in spite of that, it usually presents many recurrences that increases its morbidity. Follicular thyroid cancer is less frequent but has a higher rate of hematogenous dissemination and higher mortality than papillary thyroid cancer. We have collected the data of our patients with differentiated thyroid cancer during the period from 2000 to 2015. In this study, we have described the clinical and follow-up aspects of these patients and compared them depending if the patient was affected of papillary or follicular thyroid cancer. Clinical differences were measured trough odds ratio (OR) when possible. Statistical differences were measured through OR's confidence interval when possible, and Fisher's exact proof when OR was not possible. Papillary thyroid cancer was considered the category of reference. Statistical analysis of the data was made with Stata IC 14.2.
Results
A total amount of 87 valid cases of thyroid cancer were diagnosed during the period from 2000 to 2015. From the total amount of the cases, 80(91,95%) were papillary thyroid cancer and 7(8,05%) were follicular thyroid cancer. Comparing the follicular cases with the papillary, there were clinical and statistically significant differences in distant metastasis at the moment of diagnosis [OR 18.5 (CI 95% 1.74-176.8). There were also statistically significant differences in AJC7 classification (Fisher's exact $=0.002$), ATA risk classification (Fisher's exact $=0.006$), number of radioiodine sessions (Fisher's exact $=0.031$) and death because of thyroid cancer (Fisher's exact $=0.006$). There were no statistically significant differences in the rest of categories analysed: age, sex; multifocality, lymphadenopathies or extrathyroidal involvement in the moment of diagnosis; treatment with radioiodine and presence of antithyroglobulin antibodies.
Conclusions
We can confirm that patients affected of follicular thyroid cancer are more aggressive in the moment of diagnosis and have worse prognosis during the follow up with higher risk of death. We recognize two main limitations in this study: the first would be the few cases of follicular thyroid cancer in our data that can subtract power from the study; the second one would be that our study is a raw analysis and there may be confounding factors that interfere with the results of our study.

Insular carcinoma of the thyroid diagnostic and prognostic evaluation

Fatima Zahra Iftahy[1,2,3], Siham El Aziz[1,2,4] & Asma Chadli[1,2,4]
[1]Endocrinology, Diabetology and Metabolic Diseases Department Ibn Rochd University Hospital of Casablanca, Morocco, Casablanca, Morocco; [2]Neurosciences and Mental Health Laboratory, Casablanca, Morocco; [3]Faculty of Medicine and Pharmacy, University Hassan II, Casablanca, Morocco; [4]Faculty of Medicine and Pharmacy, University Hassan II, Casablanca, Morocco.

Background
Insular carcinoma of the thyroid is an extremely rare tumor (4% of cases) with a poor prognosis and an intermediate malignancy between differentiated and anaplastic cancers. The aim of this study was to define the particular points of this cancer by studying its diagnostic and prognostic aspects.
Materiel et methods
Retrospective study was conducted in Endocrinology and diabetology department of Ibn Rochd University Hospital of Casablanca, including 14patients followed for insular thyroid carcinoma between 1986 and 2017 among all thyroid carcinomas (614 patients)
Results
Insular carcinoma prevalence was 2%. Mean age was 56 (18-71)years. Reason for consultation was goiter in 9 patients and an isolated nodule in 5 patients. All patients had undergone total thyroidectomy with lymphnode dissection. Iratherapy (100 mci) was performed in all patients. Insular carcinoma represented the total tumor in 3 cases, or was associated with a well-differentiated follicular (3 cases) or papillary (8 cases) contingent. The mean size tumor was 4 cm (2–8 cm). Histological stages (pTNM) wereT2 (9 cases) T3 (3 cases) T4 (2 cases)

N0 (10 cases) N1 (4 cases). A recurrence was found in 2 patients (locoregional recurrence and bone metastasis) with a delay of 28 months. Predictors of poor prognosis were age, large size, multifocality, and capsule invasion ($P<0.01$).
Conclusion
Our results highlight the rarity of insular carcinoma with a potential severity (pTNM stage, frequency of recurrence).

Amiodarone – thyrotoxicosis and thyroid cancer

Georgiana Cristina Taujan[1], Adina Simona Dragomir[2], Alina Maria Dumitru[2] & Maria Olaru[2]
[1]Lotus Med, Bucharest, Romania; [2]National Institute of Endocrinology C. I. Parhon, Bucharest, Romania.

Introduction
Although thyrotoxicosis is considered to be a very rare finding in a patient with thyroid cancer, there are several reports regarding this unexpected association in specialty literature. A frequent cause of thyrotoxicosis in patients with cardiac disease is amiodarone-induced thyroid dysfunction. The mechanism underlying this adverse reaction can be attributed to high iodine content and the direct toxic effect of the drug on thyroid cells.
Case report
We present the case of a male patient, age 69, treated with amiodarone for paroxistic atrial fibrillation, which addressed our service for a large anterior cervical mass which was observed by the patient two months before presentation. Initial laboratory evaluation revealed thyrotoxicosis and the neck ultrasound revealed a very large anterior cervical hypoechoic mass which appeared of thyroid origin and which extended to the submandibular region and retrosternal. The contrast CT scan of the neck, thorax and abdomen revealed large non-homogenous thyroid mass extended cervical and thoraco-mediastinal with sternal invasion and bilateral pulmonary nodules. The fine needle aspiration and the immunohistochemistry results where consistent with undifferentiated thyroid carcinoma. The I131 scintigraphy of the thyroid revealed non-homogeneous distribution of I131 with areas with no captation in both thyroid lobes. The patient underwent external radiation therapy and chemotherapy. Since 09.2017, he was started on sorafenib and now is on substitutive treatment with levothyroxine.
Conclusions
There are few cases reported in specialty literature of undifferentiated thyroid cancer in patient with amiodarone therapy, but the question whether this rare finding is influenced by high iodine content in the antiarrhythmic drug is still unanswered.

DOI: 10.1530/endoabs.56.P1197

Thyroid carcinoma in adolescents and young adults (about 120 cases)

Fatima Zahra Iftahy[1,2,3], Siham El Aziz[1,2,3] & Asma Chadli[1,2,3]
[1]Endocrinology, Diabetology and Metabolic Diseases Department Ibn Rochd University Hospital of Casablanca, Morocco, Casablanca, Morocco; [2]Neurosciences and Mental Health Laboratory, Casablanca, Morocco; [3]Faculty of Medicine and Pharmacy, University Hassan II, Casablanca, Morocco.

Background
Differentiated adolescent and young adult thyroid cancers are under diagnosed. They would be characterized by their aggressiveness and the presence of particular histological forms. The aim of the study was to define the particular points of thyroid carcinoma in this population by analyzing the clinical, histological and therapeutic characteristics.
Materials and methods
A case-control study was conducted in the endocrinology and diabetology department of Ibn Rochd University Hospital of Casablanca between 1986-2017, including 120 cases of thyroid cancer in young adults < 25 years old. The control group included 290 patients followed for thyroid carcinoma and aged between 25 and 60 years. Statistical analysis performed by the software SPSS.16
Results
Mean age of our patients was 19.3 years (15-25 years).Family history of thyroid carcinoma was found in 10 patients. The predominant mode of discovery was an isolated nodule in 67% of cases. All patients underwent total thyroidectomy with lymphnode dissection in 25% of cases. Papillary carcinoma was the histological type in all cases of young adults. Recurrences were found in 7% of cases, (locoregional recurrence (5%) and pulmonary metastases (2%) with a mean delay of 18 months. Analytical study showed that the prognostic factors as multifocality, capsular invasion and extra-thyroid extension, were significantly higher in the young group compared to the control group and that the metastasis were earlier.
Conclusion
Differentiated cancers of the young subject are more frequent and invasive. Precocity and frequency of local and distant metastases are an evidence of particularly aggressive forms as reported in the literature.

Anaplastic thyroid cancer: a diagnostic and therapeutic challenge

Alexandra Mirica[1], Rodica Petris[1], Radu Mirica[2], Sorin Paun[3], Corin Badiu[1] & Diana Paun[1]
[1]C.I.Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Saint John Emergency Hospital, Bucharest, Romania; [3]Clinical Emergency Hospital, Bucharest, Romania.

Introduction
Thyroid cancer incidence has registered an important increase in the last years. Anaplastic thyroid cancer represent a rare malignancy with an aggressive biological behavior and a high mortality rate.
Case presentation
We present the case of a 69-years-old woman who addressed our department for endocrine evaluation in the context of a right latero-cervical lymph nodes, complaining of mixed dysphagia and dyspnea, that developed progressively over the last month. The patient associates essential hypertension and mixed dyslipidemia under treatment. Thyroid functional hormone profile indicated subclinical hyperthyroidism with suppressed TSH = 0.09 mUI/L (N = 0.5-4.5 mUI/L) and normal values for free thyroxine (FT4) and triiodothyronine (T3) of 21 pmol/l and 160ng/dl. In addition, normal calcitonin and carcinoembryonic antigen values were registered. The thyroid ultrasound performed showed a right thyroid lobe completely occupied by a hypoecogenic macronodule, apparently non-vascularized, of 6.3/5.5 cm, and a left thyroid lobe with a hypoecogenic macronodule of 2.5/1.6 cm. In the right supraclavicular region there were described multiple adenopathies, the largest with internal Doppler signal of 3.97/2.8 cm and superior to it other suspicious adenopathies of 1.31/1.04, 0.7/0.65 cm and 0.8/0.6 cm. The computer tomography scan of the cervical, thoracic, and abdominal regions with contrast enhancement have identified a large thyroid process with micro and macro-calcifications in the interior, extending in the posterior, moving laterally the esophagus and the trachea with dimensions of 4.28/6 cm. Also, a right adenopathic laterocervical process of 3.9/3 cm in the right supraclavicular fossa, multiple bilateral pulmonary nodules with a maximum diameter of 3 cm and multiple right pleural nodules with a maximum diameter of 2 cm (metastatic determinations). The patient was referred to surgery department, where surgical resection was attempted and a tracheotomy was performed. The histopathologic examination confirmed the anaplastic thyroid cancer. Subsequently, the patient was addressed to the oncology service where she started loco-regional radiation therapy, taking into account the association of chemotherapy with doxorubicin and cisplatin regimens.
Conclusions
Case of a patient diagnosed with metastatic anaplastic thyroid cancer (stage IV c) for whom prognosis is reserved.

DOI: 10.1530/endoabs.56.P1199

RET exon 11 genotype in medullary thyroid cancer

Andrei Muresan[1], Serban Radian[1,2], Cristina Ghervan[3], Monica Gheorghiu[1], Diana Paun[1], Ionela Baciu[1,2], Dumitru Ioachim[1], Adriana Padure[1], Ruxandra Dobrescu[1], Dana Manda[1] & Corin Badiu[1]
[1]C. I. Parhon' National Institute of Endocrinology, Bucharest, Romania; [2]Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania; [3]Iuliu Hatieganu' University of Medicine and Pharmacy, Bucharest, Romania.

Introduction
RET mutation is a well-known pathogenic event in medullary thyroid cancer. However, less than 25% of MTC cases present a germline mutation. First grade relatives of the patients with germline RET mutations may undergo genetic counselling and prophylactic appropriate therapeutic intervention.

Objective
The aim of the study was to evaluate the most frequent pathogenic RET exon 11 mutations and SNP in medullary thyroid cancer (MTC).
Patients and methods
A consecutive case series of 41 patients (30F, 11M) with confirmed MTC was submitted to genomic DNA sequencing for RET mutation. A number of 12 cases were included in familial syndromes (5 families), mostly MEN2A. Six of them were screened due to their affected relatives. Genomic DNA was isolated from EDTA-treated blood, using Promega Wizard Genomic DNA Purification Kit. Exon 11 of RET gene was amplified in a fragment of 419 bp, by polymerase chain reaction (PCR)using forward (ATACGCAGCCTGTACCCAGT) and reverse (CACAGGATGGCCTCTGTCTC) primers. Cycling conditions: 95° C for 7', 35 cycles of 95° C for 10"/ 60° C for 20" and72° C for 6'. Purified amplicons were amplified again using only the forward primer (0.25 μM) and DTCS dye mix (40%) in a final volume of 10 μL, in 30 cycles of 96° C for 20"/58° C for 20" / 60° C for 3'. Purified sequencing extension products were analyzed on a CEQ-8000 Beckman Coulter genetic analyzer. Sequences were compared with the reference sequence NM_020975.4 and chromatograms were visuallyexamined for mutations using Sequence Investigator software.
Results
The 634 codon mutation was found in 7 patients (17.07%), all of them with MEN2A phenotype. The most frequent was Cys634Arg mutation (5 patients); other variants were Cys634Phe and Cys634Tyr. In one patient with sporadic MTC we found a SNP in codon 649 TCG634TTG with unknown significance. Another SNP, rs1799939 (2071 G/A) was present in 8 MTC cases and 4 healthy screened relatives (without 634 codon mutation).
Conclusion
In our study group RET exon 11 genotyping showed pathogenic mutation of codon 634 in 17.07% patients with MTC, all having MEN2A syndrome. None of sporadic MTC cases presented any pathogenic mutation in exon 11 of RET gene.

Serum TSH levels as a predictor of thyroid cancer

Sophia Novosad[1] & Narine Martirosyan[2]
[1]Clinica of Administration of the President of the RF, Moscow, Russian Federation; [2]Sechenov Universsity, Moscow, Russian Federation.

Background
The aim of our study is to show the evaluate relationship between cytological feature of thyroid nodule and TSH level.
Objective
To retrospectively evaluate the usefulness of serum TSH levels as a predictor of thyroid cancer.
Methods
Patients with thyroid nodule(s) who underwent fine-needle aspiration biopsy under ultrasonographic guidance in a Clinica of Administration of the President of the RF were consecutively evaluated.
Results
Eighty patients underwent thyroidectomy and the final diagnoses were malignant in 32(40%) patients, 15 (19%) nodules was follicular adenoma, 33 (41%) was benign nodules. TSH level was significantly higher in patient with thyroid cancer compare with follicular adenoma and other benign nodules.. 30% patients with thyroid cancer had TSH > 2.5 μU/ml and only 18% with follicular adenoma, 12% with other benign nodules had TSH level > 2.5 μU/ml.
Conclusions
Our study showed that patients with thyroid cancer had significantly higher TSH. TSH level is an independent predictor for thyroid malignancy.

Impact of pregnancy on follow-up of thyroid papillary carcinoma:- About 30 cases

Yasmine Driouich, Siham El Aziz & Asma Chadli
Endocrinology, Diabetology and Metabolic Diseases, Department Ibn Rochd University Hospital, Casablanca, Morocco.

Introduction
Thyroid carcinoma is more frequent in women of childbearing age. It can alter both fertility and pregnancy's course.
Objective
The aim of this study was to evaluate pregnancy's influence on thyroid carcinoma's prognosis as a factor of recurrence or progression.
Patients and Methods
We conducted a descriptive cross-sectional study concerning 30 pregnant patients followed for thyroid papillary carcinoma with anterior thyroidectomy at the IBN ROCHD University Hospital of Casablanca's endocrinology department since January 2010. Statistical analysis was univariate for all the variables using SPSS version 22.0.0.
Results
The patients' average age was 35 ± 6.5 years old. Mean duration between first pregnancy and completion of treatment was 4.4 ± 3.1 years. Over an average follow-up period of 2.8 years postpartum, 22 patients were in remission (Thyroglobulin (Tg) < 1 μg /l and absence of morphological abnormality), eight in persistent disease (detectable Tg and / or morphological anomaly). The TSH average rate during pregnancy was 0.83 mIU/l. Cancer progression was correlated with persistence of thyroid cancer before pregnancy ($P = 0.02$) and delayed administration of I-131 therapy ($P = 0.01$). Time between diagnosis and pregnancy, TSH rate during pregnancy, or pre-conception thyroglobulin level did not have a statistically significant impact.
Discussion
Pregnancy's influence on thyroid cancer is controversial. In line with the literature, our study confirms that it has no impact on recurrence or progression of thyroid cancer in patients declared in remission prior to conception.
Conclusion
Only a delay in thyroid cancer's management, in particular, I131-therapy could affect the patients' prognosis undeclared healed during preconception period.

P1203

Comparative study about differences in staging and prognosis in patients affected or not of BRAF V600E mutation

Javier González[1], Dulce María Calderón[1], Mubarak Alramadan[1], José Pérez[1], David Martín[1], Raquel Acedo[1], Fulgencio Jiménez[1] & Yolanda Campos[2]
[1]Hospital Virgen de la Luz, Cuenca, Spain; [2]Hospital Virgen de la Salud, Toledo, Spain.

Introduction, material and methods
The BRAF isoform of RAF has been implicated in the pathogenesis of papillary thyroid cancer, but not of benign or follicular neoplasms. Also, *BRAF* mutations may confer a worse clinical prognosis than for papillary thyroid cancer without the *BRAF* mutation. Recurrence occurs more frequently when *BRAF* mutations are present. In addition, *BRAF* mutations are associated with extrathyroidal invasion, lymph node metastases, and advanced tumour stage at initial surgery. We have collected the data of our patients with differentiated thyroid cancer during the period from 2000 to 2015. In this study we have mainly compared the frequency of extrathyroidal invasion and lymph node metastases at initial surgery, and recurrences during the follow-up; depending if the patient is affected or not with BRAF V600E mutation. Clinical relevancies have been indicated through prevalence ratio(PR), and statistical differences have been indicated through confidence interval at 95%. Statistical analysis was made with Stata14.
Results
A total amount of 41 valid cases of papillary thyroid cancer were diagnosed during the period from 2000 to 2015. 22 (53.66%) patients were carriers of the BRAF V600E mutation and 19 (46.34%) were not. We compared the patients affected of the mutation with the non-carriers and these were the results: in the case of lymphadenopathies, we have not seen clinically relevant differences (PR 0.87) nor statistically significant (95% CI 0.43 – 1.77). About extrathyroidal invasion, we have not seen clinically relevant differences (PR 0.77) or statistically significant (95% CI 0.27 – 2.24) either. We have not seen either clinically relevant differences (PR 1.22) or statistically significant (95% CI 0.41 – 3.69) in the case of the recurrences. There were not clinically relevant or statistically significant differences in other variables such as multifocality (PR 0.95 (95% CI 0.44 – 2.04)) or the size of the tumour (6.57 mm (95% CI - 0.77 – 13.91)).
Conclusions
In our patients affected by papillary thyroid carcinoma, we have not seen poorer clinical outcomes such as tumour size, lymphadenopathies, extrathyroidal invasion, distant metastasis or mortality. However, the little size of the sample can subtract statistical power from the study. Also, the fact that it is a raw analysis does not allow the adjustment of potential confounding factors that could mitigate the effect.

Synchronous thyroid disease in patients with primary hyperparathyroidism

Najla Bchir, Ibtissem Oueslati, Melika Chihaoui, Meriem Yazidi, Fatma Chaker, Ons Rejeb & Hedia Slimane
Department of Endocrinology, La Rabta Hospital, Tunis, Tunisia.

Introduction
Retrospective analysis has shown that approximately 17–84% of patients suffering from primary hyperparathyroidism have a concomitant thyroid disease. However, it still remains controversial whether these two pathologies happen coincidental or are caused by specific risk factors or genetic changes. In this study we aimed to evaluate concurrently detected thyroid pathologies in patients who underwent surgery for primary hyperparathyroidism.
Methods
We conducted a retrospective study in 75 patients who underwent surgery for primary hyperparathyroidism between 2011 and 2017. Laboratory examination results were recorded and patients underwent preoperative 99 m-technetium sesta-MIBI scan (MIBI) and neck ultrasound (US).
Results
The mean age of participants was 56 ± 12.52 years (Extremes: 28–72) and the sex ratio (Women/Men) was 4.1. Laboratory investigation revealed primary hypothyroidism in 15 patients and hyperthyroidism in three patients. Preoperative thyroid US revealed thyroiditis in four patients (10%), a solitary nodule in 18 patients (24%), multinodular goiter in 18 (24%), and normal findings in 35 cases (47%). Collectively, the prevalence of thyroid disease was 53%. Of 75 parathyroidectomy procedures, 14 patients (18%) underwent simultaneous total or partial thyroidectomy. Indications were suspicious nodule in 11 patients and hyperthyroidism in three patients. Postoperative histopathological examination confirmed the diagnosis of papillary thyroid carcinoma in three patients.
Conclusion
Co-occurrence of thyroid diseases and primary hyperparathyroidism is common. Moreover, coexisting thyroid carcinoma has been reported in patients with PHPT. Although the probability of concomitant thyroid cancer is low, screening for thyroid lesions in patients with primary hyperparathyroidism is recommended. This identification is important prior to parathyroid operation in order to minimize surgical complications, patient discomfort, and costs. Therefore, TSH measurement and preoperative thyroid ultrasound should be performed to patients with primary hyperparathyroidism.

Association of thyroid papillary carcinomaand an ectopic parathyroid adenoma

Ikram Khalil[1,2], Siham El Aziz[1,2] & Asmaa Chadli[1,2]
[1]Endocrinology, Diabetology and Metabolic Diseases Department Ibn Rochd University Hospital of Casablanca, Morocco; [2]Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy- University Hassan II- Casablanca-Morocco, Casablanca, Morocco.

Introduction
Association between primary hyperparathyroidism and nodular thyroid disease is well recognized, this is mainly due to the high prevalence of this disease. However, association between thyroid carcinoma and primary hyperparathyroidism is less common.
Observation
Fifty-two years old patient with a history of renal colic and upper limb spontaneous fracture was followed for multinodular goiter evolving for 20 years. The patient had clinically diffused bone pain, fatigue and weight loss. Hypercalcemia at 132 mg/l was discovered during pre-anesthetic assessment. The assessment had objectified goiter multinodular classified TIRADS 3, high parathyroid hormone to 256 pg / ml (3 x normal), a right lobar parathyroid adenoma in supraclavicular with thyroid focal area capturing the MIBI scintigraphy. The cervical scan with additional angioscan showed a multi-hetero nodular goiter associated with a nodule above right clavicle inter-aorto-caval measuring 2 cm. The patient had undergone, after medical preparation a total thyroidectomy with resection of the ectopic parathyroid adenoma. Histopathological examination objective a papillary carcinoma with vesicular and insular differentiation and parathyroid adenoma. Evolution was favorable after surgery. The patient presented hypocalcemia needing calcium supplementation orally. Our patient received additional *radioactive iodine* therapy one month after surgery.
Conclusion
The observation of this case emphasizes the importance of a thorough thyroid gland and parathyroid glands evaluation in patients with primary hyperparathyroidism or thyroid disease to reveal or exclude simultaneous presence of a parathyroid adenoma and a thyroid carcinoma.

Is pheochromocytoma a diagnostics chameleon indeed? Series of cases

Marta Juszczyszyn[1], Lucyna Papierska[1], Jaroslaw Cwikla[2] & Wojciech Zgliczynski[1]
[1]Department of Endocrinology, Centre of Postgraduate Medical Education, Warsaw, Poland; [2]Department of Radiology, The Faculty of Medical Sciences, University of Warmia and Mazury, Olsztyn, Poland.

Presence of clinical symptoms and signs specific for suspected illness is, in general, a condition *sine qua non* to start diagnostics procedures. However, some diseases may proceed with various and disparate symptoms, which often suggests completely different diagnosis. One of them is pheochromocytoma – rare, usually benign neoplasm derived from chromaffin cells of adrenal medulla. It is very important to diagnose the disease while it is curable by surgery like many tumors but the appropriate premedication is necessary to carry out a successful operation. Unfortunately, the rarity, unspecific symptoms and extremely variable imaging phenotype render the investigation for these tumors very hard. The diagnose of pheochromocytoma is often made too late, and that may be very dangerous for patients. To prove this, we present several patients with completely different course of the disease.
Case 1
'Classic' clinical features (hypertensive paroxysms with tachycardia and sweating) in 48-yr old women with big, high density tumour in left adrenal gland.
Case 2
Paroxysms of sweating and worsening of circulatory insufficiency, without hypertension in 71-yr old women with heterogenic left adrenal mass with signs of bleeding inside.
Case 3
Acute back pain in 50-yr old man with nephrolithiasis and normal blood pressure.
Case 4
Postural hypotension in 62-yr old man with incidentaloma of the right adrenal gland.
Case 5
Panic attacks in 35-yr old woman with 5-cm tumour in right adrenal gland. We analyse clinical sings and symptoms, imaging features (CT, MRI, MIBG), results of biochemical and hormonal investigations of such cases.

Gastric NET due to atrophic gastritic combined with multiglandular syndrom type 3

Dimitra Tampouratzi[1], Konstantinos Papatheodorou[2], Olga Tzaida[3], Aggeliki Sapera[1], Styliani Kalaitzidou[1], Aspasia Drosou[1], Fotini Kanouta[1], Eleni Triantafillou[1], Michalis Kotis[1], Taxiarchis Kyrimis[1], Georgios Papapdakis[4], Anna Drakopoulou[1], Victoria Kaltzidou[1], Eirini Veniou[1], Chrysa Karavasili[1], Ginno Vecchini[3], Athanasia Tertipi[1] & Dimitrios Nikolakis[2]
[1]Endocrinology Department, Metaxa Anticancer Hospital, Piraeus, Greece; [2]Gastroenterology Department, Metaxa Anticancer Hospital, Piraeus, Greece; [3]Pathology Department, Metaxa Anticancer Hospital, Piraeus, Greece; [4]STEPS Stoffwechselzentrum, Biel/Bienne, Switzerland.

Introduction
Neuroendocrine tumors (NETs) are neoplasms that arise from cells of the endocrine and nervous systems. They most commonly occur in the intestine and are graded histologically according to markers of cellular proliferation. G1 and G2 neuroendocrine neoplasms are called neuroendocrine tumors (NETs) – formerly called carcinoid tumors. G3 neoplasms are called neuroendocrine carcinomas (NECs).
Objectives
We present a case of a patient with NET G1, type 1 with atrophic gastritis and multiple autoimmune diseases.
Methods
A 75-year-old woman underwent colonoscopy for anemia evaluation. The endoscopic biopsy revealed a low-grade gastric NET G1, 0.9 cm in the body of the stomach, with positive immunohistochemical staining for chromogranin (Cg). Serum gastrin was elevated up to 385 μU/ml (Ref. 28–185) and serum chromoganin-A was 6.1 nmol/l (Ref < 3). The tumor was endoscopically removed.
Results
The patient was also suffering from Hashimoto thyroiditis and hypothyroidism, atrophic gastritis, megaloblastic anemia, vitiligo and rheumatoid arthritis. The biochemical and radiologic evaluation for MEN-1 syndrome was negative. The patient had positive Islet Cell Autoantibodies (ICA) and Glutamic Acid Decarboxylase Autoantibodies (GAD65) and negative antiadrenal antibodies, and she was diagnosed with polyglandular syndrome Type 3 with gastric NET. Three months later the patient underwent a white light endoscopy. The gastric biopsies revealed: atrophic gastritis with intestinal metaplasia and possible microcarcinoids in the body of the stomach. Pathology report revealed linear and nodular hyperplasia of neuroendocrine cells, positive for chromogranin and synaptophysin staining, but not NET. The further follow-up of the patients included regular gastroscopy control and clinical and laboratory evaluation for possible appearance of autoimmune diabetes or adrenal insufficiency.
Conclusions
Patients with atrophic gastritis can develop gastric NET due to hypergastrinemia. Further diagnostic control for autoimmune diseases should be performed for the early detection of a possible multiglandular syndrome, as well as possible autoimmune diabetes and adrenal insufficiency.

Neuroendocrine carcinoma of the ampulla of Vater diagnosed preoperatively by endoscopic biopsy

Hodaka Amano[1], Yuichi Akama[1], Ryotaro Takano[1], Yohei Watanabe[1], Shuji Asahi[1], Kimiyoshi Shimanuki[1], Kei Niida[1], Toshiyasu Iwao[1] & Katsuya Hirose[2]
[1]Aizu Chuo Hospital, Aizu Wakamatsu, Japan; [2]Tohoku University of Medicine, Sendai, Japan.

Background
Neuroendocrine tumors (NETs) of the ampulla of Vater are rare and sometimes difficult to diagnose preoperatively. We report a case of neuroendocrine carcinoma (NEC) of the ampulla of Vater diagnosed by endoscopic biopsy.
Case presentation
The patient was a 83-year-old male complaining of jaundice. Endoscopic retrograde cholangiopancreatography (ERCP) was performed. It revealed a protruding tumor in the major papilla with a diameter of 18mm, and a obstruction of lower bile duct. Endoscopic biopsies from the ulcerative region, and endoscopic retrograde biliary drainege (ERBD) was performed. Pathological findings of the endoscopic biopsies revealed a poorly-differentiated tumor. Immunohistochemically, the biopsied specimens stained positive for chromogranin A, CD56, synaptophysin, and AE1/AE3. The Ki-67-labeling index was 80%. The final preoperative diagnosis was NEC G3. Enhanced abdominal computed tomography (CT) scan revealed a 17 mm slightly enhanced tumor at the ampulla of Vater and some regional lymph node swelling. Pre-operative diagnosis based on CT was difficult since it presented with a similar clinical picture to the adenocarcinomas of this region. Pancreaticoduodenectomy with regional lymph node dissection was performed. Pathological examination revealed a poorly differentiated carcinoma in the region of the major papilla, with a diameter of 20×18 mm. Lymph node on the posterior surface of the pancreatic head (#13) was positive. TNM staging was T2 N1 M0, StageIIb. The immunohistochemical study showed positive for chromogranin A, CD56, Neuron specific enolase (NSE), and synaptophysin. The mitotic index was seven mitoses in ten HPF and Ki-67 was 50%. First-line chemothepapy for the patient might be platinum-based regimens. Because the patient was 83-year-old, postoperative chemotherapy has not performed. Post operative course was uneventful and the patient discharged 24 days after the operation.

Diazoxide induced acute renal failure in patient with insulinoma

Özlem Tarçin, Eren İmre & Dilek Yavuz
Marmara University Medical School, İstanbul, Turkey.

A 76-year-old female patient has been admitted to various hospitals with complaints of low blood sugar especially in the morning, sweating, fainting, loss of consciousness, have been suspected of insulinoma with the results of the latest examinations made in 2012, but no focus has been detected. With the same complaints, the patient who applied to our out-patient clinic in December 2017 was subjected to an extended hunger test and invested for further research. Previously, the patient who has HT and COPD diagnoses had a BMI of 39.5 kg/m^2 and no significant physical examination. On the 3rd hour of the prolonged fasting test started at 0800 h in the morning, the blood sugar was 30 mg/dl while the C-peptide was 11.14 ng/ml and insulin was 58.83 μU/ml. Six

millimeter uniformly limited lesion was detected at the head of the pancreas in the withdrawn MRI. The patient was diagnosed insulinoma and EUS was planned, whereas due to technical problems it could not been performed. Triphasic CT was performed instead to clarify the location of the mass and surgical planning. Diazoxide therapy started at the dose of 3×100 mg in the patient who was followed up with Dextroz infusion during this period. After 2 days, the patient's creatine level rose from 1.33 to 2.45, with hypotension, hyponatremia, pretibial +++/+++ edema, and shortness of breath. The patient was evaluated with nephrology and the drug was discontinued due to the development of acute renal insufficiency secondary to diazoxide. The patient was hemodialized for 2 occasional days. Within 3 days, the patient's blood pressure and serum sodium level returned to normal levels. The patient who was followed up with Dextroz infusion was considered to be at high risk for surgery although the biochemical parameters returned to normal. The DOTA-PET was scheduled and until that time 2×1 dose of octreotide 0.1 mg SC short effective treatment was started. The patient recovered from hypoglycemia with this treatment, but sudden increase in creatinine level and atrial fibrillation was observed. We decreased dose of Octreotide to 1×0.1 mg in the patient who started cordarone infusion for arrhythmia. The final creatinine level of the patient was 1.5 and blood sugars were maintained in the normal ranges. The patient was discharged with current treatment to be implemented Radiofrequency occlusion therapy for pancreatic mass. Diazoxide is usually well tolerated whereas could be dangerous simetimes.

Isolated pheochromocytoma associated with mutation in the SDHAF2 (SDH5) gene: rare and challenging clinical case

Sofia Castro Oliveira[1,2], Ana Paula Santos[3], Lígia Gonçalves[4], Gonçalo Ferreira[5], Jorge Lima[6,7], Manuel Teixeira[8] & Isabel Torres[3]
[1]Department of Endocrinology, Diabetes and Metabolism of São João Hospital Center, Porto, Portugal; [2]Faculty of Medicine, University of Porto, Porto, Portugal; [3]Department of Endocrinology of Instituto Português de Oncologia do Porto FG, EPE, Porto, Portugal; [4]Department of Radiology of Instituto Português de Oncologia do Porto FG, EPE, Porto, Portugal; [5]Department of Nuclear Medicine of Instituto Português de Oncologia do Porto FG, EPE, Porto, Portugal; [6]Instituto de Patologia e Imunologia Molecular da Universidade do Porto (IPATIMUP), Porto, Portugal. [7]Instituto de Investigação e Inovação em Saúde, University of Porto, Portugal (i3S), Porto, Portugal; [8]Department of Genetics of Instituto Português de Oncologia do Porto FG, EPE, Porto, Portugal.

Introduction
Pheochromocytomas/paragangliomas are rare neuroendocrine tumors. Although mostly sporadic, about 1/3 of the cases correspond to inherited autosomal dominant syndromes, often associated with germline mutations of the SDHD, SDHC and SDHB genes. The association with the SDHAF2(SDH5) gene has been recently discovered, with only few cases published worldwide, and it presents as a paraganglioma of the head and neck, without previous known description of other locations. Its natural history is still unclear, making clinical follow-up truly challenging.
Case report
Forty seven year-old woman, referred to the Endocrinology Department in 2003 by right adrenal nodule of 3 cm, an incidental CT finding. MRI confirmed right suprarenal nodule, well delimited, hypercaptant, with hyperintense signal on T2-weighted-images, that could represent pheochromocytoma. Hormonal study was compatible with non-secretory nodule: metanephrine 96.5 µg/24 h (52–341), normetanephrine 273.1 µg/24 h (88–444), dopamine 234.6 µg/24 h (65–400), adrenaline 2.7 ug/24 h (5–20), noradrenaline 31.7 ug/24 h(15–80), vanillylmandelic acid (VMA) 5.2 mg/24 h (1.4–6.5) and homovanillic acid(HVA) 4.2 mg/24 h(<8.3) in 24-h-urine. The scintigraphy with I131-norcholesterol documented nonfunctioning lesion, aspiration biopsy was suggestive of pheochromocytoma and scintigraphy with I123-MIBG was negative. The patient was proposed to right adrenalectomy, which she declined. She remained under clinical, analytical and imaging surveillance. In the 14-year follow-up with annual CT and MRI, a nodule reduction of 3 cm to 1.7 cm of greater-axis was observed. A PET-FDG and a PET-68Ga-DOTA-NOC were performed in 2012 and were both negative. Analytic control remained without changes. In 2014, the molecular genetics analysis revealed an heterozygotic mutation in the SDHAF2 gene (c.97C>T, p.Arg33Cys), also confirmed in another Genetics Department. At that time, the patient mentioned a cousin living in France probably affected. In 2017, a second review of histological slides maintained the diagnosis of pheochromocytoma. The patient is under surveillance, asymptomatic and without directed therapy.
Conclusion
The authors describe a rare case of isolated pheochromocytoma associated with mutation in the SDHAF2 gene, in a patient who chose not to undergo surgery and represents a true therapeutic and follow-up challenge, given the absence in the literature of case reports with similar clinical presentation and limited knowledge of its long-term evolution. Recent studies suggest that mutation analysis of the SDHAF2 gene is warranted in very young patients with isolated head and neck paraganglioma without mutations in SDHD, SDHC or SDHB genes, and in individuals with family history that are negative for mutations in all other risk genes.

Co-existence of malign insulinoma and diabetes mellitus

Isilay Taskaldiran[1], Serife Mehlika Kuskonmaz[1], Tahsin Ozenmis[1], Gonul Koc[1], Nuriye Ozlem Kucuk[2] & Cavit Culha[1]
[1]Department of Endocrinology and Metabolizm, Ankara Reserch and Education Hospital, Ankara, Turkey; [2]Department of Nuclear Medicine, Ankara University Faculty of Medicine, Ankara, Turkey.

Insulinomas are rare neuroendocrine tumors (NETs) of the pancreas with an incidence of four per 1 million persons per year. The co-existence of diabetes mellitus (DM) and insulinoma is very rare. We report a case of 73 year old women with malignant insulinoma and type 2 DM. A 73 year old woman with type 2 diabetes was referred to our clinic for recurrent and severe hypoglycemia especially in the early morning hours. The patient had a history of type 2 DM for 10 years. Although oral antidiabetic drugs are stopped, hypoglycemic episodes persistenly recurred. The patient was hospitalized to investigate the cause of hypoglycemia. At the second day in hospital, the patient experienced a symptomatic hypoglycemic episode. Blood samples taken at that time revealed a low plasma glucose (23 mg/dl) accompanied with elevated insulin and c-peptide levels (17.4 mIU/l, 3,73 ng/l). Cortisol level was 26 µg/dl. Chromoranin A was >500 ng/ml (referange range <94). Calcitonin, parathormon, anterior pituitary hormones and anti insulin antibody test were also in normal range. Abdominal computed tomography (CT) scan showed thickening in the pancreas (14 mm), and multiple hepatic metastatic lesions. Ga-68 DOTATATE PET/CT was performed, which showed positive lesions in liver, pancreas and peripancreatic lymh nodes and also left temporal cortex in brain. Brain CT showed a 15×11 cm nodular lesion in the left temporal lobe with contrast enhancement. The patient refused liver biopsy. The patient was diagnosed as malignant insulinoma.She was discharged on diazoxide 100 mg twice a day and prednisolone 4 mg/day to prevent hypoglycemia. On follow up, diazoxide was stopped due to volume retention and edema. Prednsiolone is stopped due to hyperglycemia and insulin glargine is started together with octreotide LAR 20 mg/month. Three months after the initiation of octreotide LAR injecitons the patient is doing well without hypoglycemia. Diagnosis of malignant insulinoma depends on the presence of metastases.The localization of insulinoma may be difficult.Ga-68 DOTATATE PET/CT is shown to be successfull in localizing insulinomas in clinical studies. The main treatment of insulinoma is surgery if possible. In the present case surgery was not possible due to patients diaspproval. Diazoxide and glucocorticoids are options to prevent hypoglycemia. Somatostatin analogues are effective in controlling hypoglycemia and also have antineoplastic and antiproliferative effects in malignant insulinomas. Insulinoma should be considered in the presence of atypical and recurrent hypoglycemia in patients with diabetes mellitus.

DOI: 10.1530/endoabs.56.EP6

EP7

An atypical pheochromocytoma presenting with clinical sign and symptoms of non-mechanical bowel obstruction

Elif Gunes, Zelal Şirin Şahin Tırnova, Soner Cander, Ozen Oz Gul & Canan Ersoy
Uludag University, Bursa, Turkey.

Introduction
Pheochromocytomas are rare catecolamin-secreting neoplasms. The classic triad of symptoms in patients with a pheochromocytoma consists of episodic headache, sweating and tachycardia. Gastrointestinal spectrums have been reported such as chronic constipation, intestinal pseudo-obstruction or even intestinal perforation. We describe patient who presented with non-mechanical bowel obstruction and

interestingly hydronephrosis and acute kidney injury as a consequence of an underlying, undiagnosed phaeochromocytoma.
Case report
A-58-year-old man was admitted to the emergency unit with complaints of generalized abdominal pain, constipation and vomiting. The patient had a medical history of hypertension. On initial examination, he had a blood pressure of 180/120 mmHg. He was clinically dehydrated. Abdominal examination confirmed a distended abdomen with reduced bowel sounds. The laboratory investigation results were as follows: creatinine 3.4 mg/dl (0.7–1.1), BUN 127 mg/dl (8.4–25.7). Abdominal radiography showed distended large bowel loops. A CT was arranged and this revealed a unilateral 5 cm right adrenal tumor with bilateral moderate hydroureteronephrosis but no structural cause for the bowel obstruction or hydronephrosis. He required haemodialysis several times because of severe uremia and progressive kidney disease. The patient's serum and 24-hour urine catecholamine levels were high, confirming the diagnosis of phaeochromocytoma. Alpha blockade with doxazosin was administered to control his blood pressure and other symptoms. The hydronephrosis and intestinal pseudo obstruction findings were improved with adequate preoperative alpha blockade. He subsequently underwent uneventful surgical excision of the adrenal tumor. He remained well on follow-up after surgery and the antihypertensive drugs were stopped before discharge.
Discussion
Phaeochromocytoma may clinically manifest as a wide spectrum of gastrointestinal symptoms. The net effect of sympathetic over activity on the α and β-adrenergic receptors is a depressed peristaltic state and constriction of the sphincter, leading to ileus and constipation, as seen in this case. Another interesting feature observed in this patient was the presence of bilateral non-obstructive hydronephrosis. Because of the relaxation effect of the sympathetic system on the bladder and the construction of the internal uretral sphincher, excessive sympathetic stimulation can cause urinary retention and hydroureteronephrosis. This case report draws attention to the patients presenting with adrenal mass and unexplained ileus, constipation and non-obstructive hydroutereronephrosis the diagnosis of a pheochromocytoma should be considered. Our case demonstrates the successful outcome that can be achieved with appropriate medical and surgical intervention, as a delayed diagnosis can cause unfortunate consequences.

Malignant and multifocal metastatic pheochromocytoma: a case report

Diana Simoniene & Agne Kadusauskiene
The Hospital of Lithuanian University of Health Sciences Kauno klinikos, Kaunas, Lithuania.

Pheochromocytoma (PCC) is a rare neuroendocrine tumor, mainly sporadic, many cases are discovered incidentally by computed tomography or magnetic resonance imaging of the abdomen. Malignancy in pheochromocytoma is difficult to diagnose microscopically. Therefore, only the presence of distant metastases, derived from pleomorphic chromaffin cells, is widely accepted as a criterion of malignancy (1)
Case presentation
In March 2016, a 43 year old women presented with an episodic hypertension. Abdomen CT scan showed a mass in adrenal gland measuring 4.2×3.8 cm in the right. Preoperatively blood test confirmed PCC and a right adrenalectomy was performed. After histological evaluation pheochromocytoma was also certified. Patient had remission of symptoms for almost half a year until hypertension episodes appeared again. In September 2017, abdomen CT scan showed a contrast accumulation in the right adrenal place Hormonal test showed a significant increase in chromogranin A level (2594.2 ng/ml), immeasurable plasma normetanephrine level, normal metanephrin (0.2 nmol/l, n. 0–0.456). Other tests (morning cortisol, aldosterone, renin, DHEA-S, 17OHP, PTH levels) were also normal. For further evaluation an I-123 MIBG scan was performed and it showed intensive activity in right adrenal gland projection, moderate uptake of I-123 MIBG in sternum, ileum and low uptake in lowest right costal bone. There were two suspicious activity nodules in the right liver lobe margin, which were confirmed as metastasis during computed tomography imaging of the abdomen and pelvis. During chest CT scan, multiple metastasis in both lungs with pathological mediastinal, parathracheal and axillary lymph nodes were diagnosed. Laparoscopy with adrenal mass and partial liver resection was done. In January, 2018, patient was operated again. Unfortunately, during laparotomy multiple metastases in peritoneum cavity, liver surface, liver gate, ligaments of both small and large intestines were found. Samples from masses in liver gates were taken and malignant PCC was confirmed. At this moment, treatment by chemotherapy is being planned.
Comments
After PCC diagnosis and surgical extirpation, proper, intensive follow-up is very important in case to exlude malignant PCC.

Case report: management of a patient with malignant insulinoma

Oya Topaloglu[1], Mehmet Ali Sendur[2], Gurkan Dumlu[3], Fatma Yildirim[4], Isilay Taskaldiran[5], Cıgdem Soydal[6], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Yildirim Beyazit University School of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Yildirim Beyazit University Faculty of Medicine, Department of Medical Oncology, Ankara, Turkey; [3]Yildirim Beyazit University Faculty of Medicine, Department of General Surgery, Ankara, Turkey; [4]Ataturk Education and Research Hospital, Department of Pathology, Ankara, Turkey; [5]Ankara Education and Research Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [6]Ankara University Faculty of Medicine, Department of Nuclear Medicine, Ankara, Turkey.

Introduction
Malignant insulinoma is a rare functional endocrine tumor of the pancreas. Therefore, there are few data regarding their optimal therapy and long term prognosis. Malignancy is defined by the presence of metastases, mostly in lymph nodes or the liver. Generally these patients present with severe hypoglycemia and require multiple therapies. Here, we described the management of a patient with malignant insulinoma.
Case
A 41-year-old woman with symptomatic and proven hypoglycemia, presented with a 11×10 mm hypodense cystic lesion and a 16×14 mm hyperdense lesion in the tail of the pancreas, and multiple liver metastases following a computerized tomography (CT) scan. Distal pancreatectomy, splenectomy and biopsy from the metastatic liver lesions were performed. Pancreatic resection showed evidence of tumor infiltration into the peripancreatic adipose tissue and extense perineural and lymphovascular invasions. 4 of the 15 resected lymph nodes were evaluated as metastatic. The ki-67 proliferation index of the insulinoma was 7.8%. After surgery, the patient was treated with 120 mg lanreotide autogel/28 days, and with 100 mg of diazoxide two times a day. Dexamethasone therapy was started with 4 mg daily and progressively increased to 16 mg daily. Selective internal radiation therapy with yttrium-90 (Y-90) was administered to treat liver metastases. But the patient did not have benefit from radiation therapy. The patient was evaluated for the liver transplantation because Ga68 scintigraphy showed metastases only in the liver. Although dexthamethasone, lanreotide and diazoxide therapies, hypoglycemic episodes reappeared and she was rehospitalised for persisted hypoglycemia and diuretic resistant edema. Diazoxide was stopped after 6 weeks. Intravenous glucose (10–20% dextrose) infusion and subcutaneous glucagon average 1–2 ampules/day administration were performed. Oral everolimus at a dose of 10 mg/day was also started. Hypoglycemia did not resolve and then parenteral nitrution was performed. Chemotherapy was planned but general status of the patient was deteriorated and patient had respiratory distress due to probably infection or drug associated pneumonitis. Brochoscopy was planned but general status of the patients did not permit the procedure. She died from acute respiratory distress syndrome(ARDS) 3 months after the initial diagnosis.
Conclusion
Refractory hypoglycemia in patients with metastatic insulinoma is an important cause of morbidity and mortality. Surgery is the only curative treatment but does not mostly solve the hypoglycemia caused by malignant insulinomas. For our patient, although hypoglycemic episodes were controlled with aggressive medical treatment, she died due to respiratory distress.

A case of oncocytic adrenocortical neoplasm of borderline malignant potencial

Lourdes Garcia-Garcia-Doncel, Gloria Baena-Nieto & Rosa Marquez-Pardo
Jerez Hospital, Jerez de la Frontera, Spain.

Introduction
Oncocytic adrenocortical neoplasms (OAN) are very rare tumors and they are usually nonfunctional and benign. Approximately 17% of the adrenal

oncocytomas are functional. Their clinical and pathological characteristics are unique. The estimated overall median survival for malignant OANs is more favorable than that of conventional adrenocortical carcinomas.
Case report
We present the case of a 79-year-old male who attended consultations for severe pain in the right side. Among his medical background highlighted high blood pressure and heart failure. Abdominal ultrasound was performed and a solid polylobulated mass was detected in direct contact with the upper pole of the right kidney. Abdominal CT revealed a 9.5×13×12 cm hetegoneous adrenal mass. Overnight low-dose dexamethasone supression test revealed a 0800 h serum cortisol of 0.9 μg/dl. Urinary catecholamines and fractionated metanephrines, plasma testosterone, androstendione and dehydroepiandrosterone levels were within the normal range. Aldosterone and renin levels were compatible with essential hypertension. Adrenalectomy was performed. Histophatological examination described an oncocytic adrenal adenoma. A follow-up thoraco-abdominal scan was performed 6 months after the initial diagnosis and showed a 7 mm lung nodule. Conservative treatment was decided and the TC scan was repeated at 6 months. A 14 mm lung nodule and other smaller pulmonary metastases were discovered. A conservative attitude was decided by the multidisciplinary team due to patient's refusal to receive treatment together with a non-elevated tumor burden and high cardiac toxicity expected from the chemotherapy. OAN are clasified regarding their biological behavior by their histological features according to the Lin-Weiss-Bisceglia system (LBW). The existence of at least one major criterion defines a malignant oncocytoma (>5 mitotic figures per 50 hp fields, atypical mitoses or invasion pf venous structures), the presence of at least one minor criterion defines a borderline oncocytoma, and the absence of all criteria indicates benignancy. In our case, a lesser criterion was met since it was a tumor larger tnah 10 cm.
Conclusions
Commonly OAN of borderline malignant potential seems to have a relatively benign clinical behavior. However, the major clinical problem is to differentiate benign lesions from malignant ones. Further studies are warranted to determine predictors of malignancy and the length, frecuency and parameters needed to follow-up on patients with oncocytic neoplasms of borderline malignant potencial.

About a case of an association of two neuroendocrine tumors

Mourad Miloudi, Amina Bouchenna, Mouna Benfiala, Meriem Bensalah & Asma Ould Kablia
Central Hospital of Army, Algiers, Algeria.

Introduction
Pancreatic neuroendocrine tumors (PNET) are a heterogeneous group with various clinical presentations and lineage. They have an incidence of one per 100 000 individuals per year and represent about 1–2% of all pancreatic tumors. Non functional PNET (NF-PNET) are incidentally discovered in most cases. Pulmonary neuroendocrine tumors constitue a distinct category of tumors with morphologic and biologic neuroendocrine features, they present 20–30% of all NETs and 11–14% of all lung cancers. The association of the two tumors has never been reported.
Case report
We report a case of 46-year old men without particular pathological history admitted to our unit in October 2017 for impairment of general condition and abdominal pain. Clinical examination found a weakened (BMI: 17 kg/m^2) anorexic patient emaciated and jaundice. No carcinoid syndrome or clinical signs of tumor hypersecretion. The thoraco-abdomino-pelvic CT scan objectified a left mediastino-pulmonary mass measuring 162*91 mm with a necrotic pancreatic cephalic mass measuring 34*32 mm. Transthoracic pulmonary biopsy was realized; the pathological study concluded to a large cell lung primitive neuroendocrine carcinoma with positive immuno-histo-chemical study to chromogranin; synaptophysin; TTF1; and a Ki67 very high at 80%. We completed our investigation with a echoendoscopic biopsy of the pancreatic mass. The pathological and immunohistochimical study concluded to a primitive low differentiated pancreatic neuroendocrine carcinoma grade 3 (chromogranine −; synaptophysine +; CD56+; Ki67: 60%). Brain scan has found multiple cerebral secondary locations. Chemotherapy has been proposed to our patient, unfortunately he died before starting this treatment.
Conclusion
The combination of two primitive neuroendocrine tumors at the same time is very rare, the case of our patient is probably the first case reported in the literature.

The changing of clinical scenario in three consecutive generations of a Brazilian Family with Von Hippel-Lindau disease

Alice Violante[1], Jorge Lima[2], Paula Soares[2], Ana Macedo[2], Silvio Cunha Neto[3], Erika Naliato[4], João Migowski[5], Amanda Alecrim[5], Vinicius Lima[6], Denise Carvalho[6] & Delmar Lourenço Jr[7]
[1]Endocrine Unit, Medical School, Hospital Universitario Clementino Fraga Filho, Universidade Federal do Rio de Janeiro – UFRJ, Rio de Janeiro, Brazil; [2]Instituto de Patologia e Imunologia Molecular da Universidade do Porto-IPATIMUP, Porto, Portugal; [3]Surgery Unit, Medical School, Hospital Universitario Clementino Fraga Filho -UFRJ, Rio de Janeiro, Bouvet Island; [4]Centro de Estudos Ricardo A T Castilho da Associação Medica de Teresopolis, Teresopolis, Brazil; [5]Medical School – UFRJ, Rio de Janeiro, Brazil; [6]Fisiologia Endocrina -Instituto de Biofisica Medica Carlos Chagas Filho – UFRJ, Rio de Janeiro, Brazil; [7]Hospital das Clinicas, Medical School, Universidade de São Paulo, São Paulo, Brazil.

Background
Von Hippel Lindau Disease (VHL) is an autosomal dominant inherited syndrome characterized by high susceptibility to the development of a wide spectrum of benign and malignant, endocrine and non-endocrine neoplasias in diverse organs of patients harboring a germline mutation in *VHL* tumor suppressor gene. The major clinical manifestations of VHL are brain, cerebellar and spinal cord hemangioblastoma, retinal angioma, pheochromocytoma, renal cell carcinoma and/or cysts and pancreatic neuroendocrine tumor and/or cysts.
Results
From a parental generation whose clinical data are unavailable, two sisters from the 2nd generation (Sibling 1 and Sibling 2) died from brain tumors without pathologic or molecular diagnosis. The first (S1-2ndG) had five children (females =4) and the second (S2-2ndG) had two daughters. From S1-2ndG, 4 siblings were clinically and genetically investigated (3 females; 1 male): two sisters had multifocal pancreatic neuroendocrine tumor and cysts with one of them (S1-3rdG) presenting bilateral pheochromocytoma, while the other (S2-3rdG) had brain hemangioblastoma, endolymphatic sac tumor and retinal angioma. Their brother (S3-3rdG) was diagnosed with retinal angioma and renal cysts, while the 3rd sister (S4-3rdG) was asymptomatic, and negative for the VHL p.Asn78Ser (c.233A>G; exon 1) mutation that was found in all the affected members of this family. From S2-2ndG, one of the two sisters (S5-3rdG) who married with her affected cousin (S3-3rdG) harbored the same mutation found in their cousins and her husband. Exams directed to VHL-related tumors were performed after positive genetic testing, but two at-risk members (S5-3rdG and S6-3rdG) refused molecular diagnosis. From the 4th generation, five at-risk members with ages between 5 and 16 y-old were genetically investigated and all of them were non-*VHL* mutation carriers.
Conclusions
The combined molecular and clinical diagnosis has the potential of reducing VHL-related morbidity/mortality by offering an extensive periodic screening schedule directed to early detection and treatment of tumors in affected VHL patients and asymptomatic *VHL*-positive carriers. In addition, negative-*VHL* carriers are excluded of this preventive program after genetic counseling. Indeed, in these three generations from one VHL family, we could document the natural history of the syndrome in deceased members from the second generation, the impact of clinical diagnosis in the third-generation members and, finally, the benefits of genetic counseling to *VHL*-negative mutation children from the 4th generation.

Hypothyroidism occurrence during treatment of neuro endocrine tumor

Abderahmen Youssouf Belazzouz, Malha Azzouz & Aissa Boudiba
Mustapha Pacha Hospital Diabetologia Departement, Algiers, Algeria.

Introduction
Several treatments may be proposed against neuroendocrine tumors such as targeted therapies (Tyrosine kinase inhibitors: TKI) and somatostatin agonist. Since the first use of TKI in the oncological field, several studies have shown endocrine side effects type dysthyroidie. Several complex pathophysiological mechanisms and variable from one patient to another have been evoked ranging from a simple thyroiditis to complex autoimmune phenomena (cases of Basedow revealed have been reported as well as hashimoto.
Case
This is a 68-year-old patient cholecystectomized with arterial hypertension and type 2 diabetes who have been on glucophage for 10 years, followed for a

pancreatic neuroendocrine tumor of incidental discovery measuring 54×32 mm, with hepatic metastases. Biological check up reveals chromogranin A < 100 ng/ml. Puted on tyrosine kinase inhibitor 50 miligramms per day, after 3 therapeutic cycles (4weeks ON 2 weeks OFF), acute renal insufficiency appeared (clearance creatinine: 24 ml/min) and hypothyroidism TSH: 40 Uui/ml (0.46–4.6)/ FT4: 9 pmol/l (9.6–31). Treatment with Sinutinib was discontinued due to digestive side effects (grade 4) in addition to hematotoxic effect (Hemoglobin: 8 g/deciliter). Exploration of the cause of hypothyroidism concluded to a destructive cause. Thyroglobulin < 0.2 ng/ml undetectable. Antibodies (Ab) anti tyroperoxidase and Ab Tyroglobulin are normals. Cervical Ultra sound find a normal overall volume of 10 cm^3 with thyroiditis features. The results of histopathological examination of an hepatic metastasis biopsy show proliferation marker Ki67 <3% as well as the digestive intolerance stage 4 have made that Sinutinib is arrested definitively with switch to somatostatin agonists. Hypothyroidism was transient and reversible after 1month stop TKI.

Conclusion

Several studies have appreciated the beneficial effect of hypothyroidism in the survival of renal cancer as well as small-cell lung cancer which is not yet the case To our knowledge for neuroendocrine tumors of the pancreas which will be desirable in the to come up. In the event of confirmation of this latter effect, the treatment of subclinical hypothyroidism (defined by high TSH compared to normal FT4) will depend in this context in the absence of pre-existing cardiovascular pathologies rather than the existence of the symptoms of hypothyroidism. Even somatostatin agonist may have an inhibitory effect on thyroid function which requires regular monitoring of both TSH, FT4 and despite the fact that the mechanism is often central because of the past of destructive thyroiditis in our patient case.

Patient harboring RET D631Y mutation with long history of pheochromocytoma without evident medullary thyroid carcinoma

Liana Khatsimova[1], Uliana Tsoy[1], Lubov Yanevskaya[2], Anna Kostareva[1], Anna Dalmatova[1], Tatyana Karonova[1] & Elena Grineva[1]
[1]Almazov National Medical Research Centre, St Petersburg, Russian Federation; [2]Pavlov First Saint Petersburg State Medical University, St Petersburg, Russian Federation.

Purpose

D631Y is a rare mutation associated with MEN2a in which there is an aspartic acid to tyrosine amino acid substitution at codon 631 in exon 11. Common clinical features of this variant of RET mutation are pheochromocytoma in 50%, medullary carcinoma in 30%, primary hyperparathyroidism is very rare. We present the patient harboring RET D631Y mutation.

Clinical case

In April 2017 40-year-old woman was admitted to endocrine department of the Almazov Centre, she presented with paroxysmal hypertension and headaches. She had history of paroxysmal hypertension since age 29. At the age 31 left adrenal pheochromocytoma was revealed and operated on. The diagnosis was confirmed by the pathology. After surgery the blood pressure (BP) normalized. At the age 39 hypertensive crises resumed. In 2017 her blood metanephrine and normetanephrine were elevated: 192.7 pg/ml (0–65), 479.3 pg/ml (0–196) respectively, Chromogranin A level was slightly elevated 127.27 μg/l (0–100), 24-h urinary metanephrines were high: 0.167 μg/day (0–0.04). Abdominal CT demonstrated two right adrenal lesions 1.6×1.5×2.4 sm and 2.7×1.5×2.2 sm. 123I-MIBG scanning showed increased uptake in the right adrenal. Patient's calcitonin level was normal 4.59 pg/ml (0–5), as well as total calcium (2.53 mmol/l (2.15–2.65)), parathyroid hormone (65.21 pg/ml (15–65)). No thyroid nodules were found with the ultrasound examination (US). Right adrenalectomy was done in May 2017. Pathology examination confirmed the pheochromocytoma, immunnohistochemistry staining revealed the STTR2 expression. After surgery BP became normal. In April 2017 genetic testing was recommended, NGS was performed and RET D631Y mutation was found. These results were obtained in December 2017. At that time blood metanephrine was 11.2 pg/ml (0–65), blood normetanephrine was 207.4 pg/ml (0–196), chromogranin A was normal, calcitonin was 8.6 pg/ml (3–19). In January 2018 patient was re-examined: 24-h urine metanephrine level was 0.003 mg/l (0–0.04), total calcium and parathyroid hormone were at normal range. Slight calcitonin elevation was identified: 8.25 pg/ml (<5). Thyroid US revealed a small nodule 0.46×0.37 sm. Pentagastrine was not available, but considering the results of genetic testing total thyroidectomy was recommended to the patient.

Conclusion

Present report supports the relevance of RET testing in patients with pheochromocytoma even if the basal calcitonin over long period of time since the detection of adrenal tumor is normal. Prompt RET mutation diagnosis allows to choose the correct treatment strategy and timely conduct the thyroidectomy.

IGF-2-oma: a diagnosis to be considered in a patient with a leiomyosarcoma and recurrent hypoglycemia

Liliana Fonseca, Lia Ferreira, Teresa Alves Pereira, Ana Lopes, Raquel Almeida, Joana Vilaverde, Maria Teresa Pereira & Helena Cardoso
Centro Hospitalar e Universitário do Porto, Porto, Portugal.

Introduction

Non-islet cell tumor induced hypoglycemia (NICTH) is a paraneoplastic phenomenon involving many types of tumors. It is associated with the secretion of incompletely processed precursors of IGF-2 resulting in a persistent insulin-like activity and hypoglycemia. Most commonly, IGF-2–linked hypoglycemia has been observed in patients with solid mesenchymal or epithelial tumors. Typically, elevated IGF-2 levels are associated with suppressed plasma levels of insulin, IGF-1, and GH. Although the true incidence is unknown, the more recent epidemiologic data suggest that IGF-2-oma tumors are more frequent than previously thought.

Clinical case

A 60-year-old man was admitted in the emergency room with severe asthenia, weigh loss and abdominal pain. Over the last three years he had lost 20 kg in weight. His past medical history was irrelevant. On admission, the physical examination revealed an emaciated patient with a palpable and bulky abdominal mass. Abdominal CT scan showed a very large retroperitoneal tumor, measuring 29.9 cm of greater diameter, with necrotic areas and calcifications of the matrix, occupying virtually the entire abdominal cavity, which histologically proved to be a leiomyosarcoma. Fasting recurrent hypoglycemias associated with neuroglycopenic symptoms were recorded during hospitalization, despite intravenous dextrose. Biochemical investigations revealed: plasma glucose 48 mg/dl with suppressed serum insulin (0.5 μU/ml, normal 2.6–24.9 μU/ml) and C-peptide (0.86 ng/ml, normal 1.1–4.4 ng/ml). Spontaneous hypokalemia was documented (3.2 mmol/l, normal 3.5–5.00 mmol/L). The patient had normal renal and hepatic tests. Thyroid function and serum morning cortisol levels were normal. IGF-1 and IGFBP3 were below normal (8 ng/ml [normal 97–292] and 0.602 mg/dl [normal 3.40–6.90], respectively). β-hydroxybutyrate and IGF-2 levels were not evaluated. The hypothesis of IGF-2-oma was placed and prednisolone 40 mg/day was started with an improvement on glycemic levels. Unfortunately, few days later, the patient suffered from coronary heart failure and died.

Discussion

IGF-2-oma should be considered in unwell patients with very large mesenchymal or epithelial tumors suffering from hypoglycaemic episodes, when insulin and C-peptide levels are suppressed. In our patient, despite the unavailability of high IGF-2 confirmatory levels, GH-dependent proteins IGF-1 and IGFBP-3 reduced levels represent useful additional markers as well as the occurrence of hypokalemia, that is often present and associated with the insulin-like activity of IGF-2.

Patient experiences with continouous subcutaneous hydrocortisone infusion (CSHI)

Phillip Yeoh, Bernard Khoo, Paul Carroll & Simon Aylwin
The London Clinic, London, UK.

We recently reported the impact of continous s.c. hydrocortisone infusion (CSHI) on weight, patient AddiQoL scores and healthcare cost savings on five patients. This poster is to follow up on all our patients experiences since started on the CSHI as well as qualitative feedback on the impact on their lives.

This poster also gathered key points on how these patients managed their adrenal crisis.

Adrenal ganglioneurosis

Habra Bahia, Elmghari Ghizlane & El Ansari Nawal
Department of Endocrinology Diabetology and Metabolic Diseases, Laboratory FIPM, FMPM, Cadi Ayad University, CHU Mohamed VI, Marrakesh, Morocco.

Introduction
Ganglioneuromes are benign tumors from neural crest cells, most often located in the posterior mediastinum and retroperitoneum, and are rarely localized in the adrenal gland. We report the case of a patient.Ho was referred to the incidental alert service
Observation
We report the case of a 45-year-old patient followed by a benign colic sigmoid polypeptide with epigastralgia for which a pelvic abdomino CT scan was requested, demonstrating a left 56 mm adrenal mass. The patient was referred to the incidental alert service. At the anamnesis, it does not report a paroxysmal acute attack, nor weight gain, nor signs of hypercatabolism. A physical examination did not reveal arterial hypertension or signs of hypercorticism, with no milk-spot stain. The hormonal balance had shown normal results, including urinary methoxylates and urinary free cortisol. The patient performed adrenal CT, specifying adrenal mass characteristics, which was hypodense in spontaneous contrast (26UH) moderately elevated after injection of the contrast medium (45UH) with a Wash out at 89%. The patient was operated with left adrenalectomy, with anatomo-pathological study a mature benign ganglioneurome.
Discussion
The diagnostic approach to an adrenal incidentaloma is well codified, determining a precise etiologic orientation, since thorough endocrine exploration and radiological characteristics confirm the accurate diagnosis of certain tumors. Although in certain cases confirmation of diagnosis can only be made by histological examination, as is the case with this patient.

Independent ACTH Cushing's syndrome due to unilateral adrenocortical hyperplasia: two cases report

Yousra Aouinati[1,2], Siham El Aziz[1,2], Amal Mjaber[1,2] & Asmaa Chadli[1,2]
[1]Ibn Rochd University Hospital, Endocrinology Department, Casablanca, Morocco; [2]Hassan II University of Neuroscience Laboratory and Mental Health, Casablanca, Morocco.

Introduction
Cushing's syndrome adrenal's origin coul'd be an adenoma, an unilateral carcinoma and rarely a micronodular or macronodular hyperplasia. We report the cases of two patients followed for macronodular adrenal hyperplasia hospitalized in the Ibn Rochd University Hospital, endocrinology department in Casablanca.
Case 1
A 60-year-old patient with independent ACTH Cushing Syndrome with clinical and biological signs of hypercorticism with collapsed ACTH and unilateral adrenal mass at CT. Treatment consisted of an adrenalectomy with a good evolution. The anatomopathological examination objectified a macro-nodular adrenal hyperplasia.
Case 2
A 48-year-old female presented an independent ACTH Cushing Syndrome, discovered with clinical and biological signs, with normal ACTH, and a right adrenal nodule on CT. Patient underwent right-sided adrenalectomy with good progression. Histopathological examination showed macro-nodular adrenal hyperplasia.
Discussion and conclusion
Unilateral adrenal hyperplasia is a rare etiology of ACTH-independent Cushing's syndrome, often taken for adrenal adenoma on CT. This hence the value of histopathological examination for diagnosis confirmation.

Adrenal ganglioneuroma: a case report

Emna Elfaleh, Ibtissem Oueslati, Radhouane Gharbi, Meriem Yazidi, Melika Chihaoui & Hedia Slimane
Department of Endocrinology, La Rabta Hospital, Tunis, Tunisia.

Introduction
Ganglioneuromas (GN) are rare benign tumors arising from the neural crest tissue and are most commonly located in the posterior mediastinum and retroperitoneum; they are rarely found in the adrenal gland. We report a case of a female patient with adrenal ganglioneuroma.
Observation
A 51-year-old female patient with no previous comorbidities was admitted to our hospital. She had no significant past medical or surgical history. She had symptoms of hot flush and palpitations since the age of 18. At the age of 34, the patient developed abdominal pain. A physical examination revealed no signs and the results of routine laboratory tests were all found to be within the normal ranges. Our patient underwent computed tomography of his abdomen, which showed a right adrenal tumor. An endocrine workup, including urine catecholamine and a 1mg overnight dexaméthasone suppression test, was normal. The lesion was completely extirpated through laparoscopic resection. The histopathological examination confirmed the lesion as adrenal ganglioneuroma, which contains mature ganglion cells admixed with schwann cells.
Discussion
Adrenal ganglioneuroma is an extremely rare and benign entity comprising schwann cells and ganglion cells. They usually occur in older children and young adults and are the most common sympathetic nervous system tumor in adults. Most GNs are located in the posterior mediastinum and retroperitoneum. TheGN occurs only rarely in the adrenal gland. The clinical presentation of the most patients with adrenal GN is asymptomatic, and most of these tumors are hormone silent as in the present case. Although GNs are generally considered to be non-secretory, some GNs are endocrinologically active. The prognosis for an adrenal GN following surgical resection is good without the need for additional treatment.

Malignant sympathetic paraganglioma – case report

Ioannis Svilias[1], Tomáš Zelinka[2,3], Eva Krčálová[4] & Jan Čáp[1]
[1]4th Department of Internal Medicine – Hematology and Endocrinology Charles University Hospital and Faculty of Medicine in Hradec Králové, Hradec Králové, Czech Republic; [2]Third Internal Clinic – Clinic of Endocrinology and Metabolism, General University Hospital in Prague, Prague, Czech Republic; [3]Charles University in Prague, Prague, Czech Republic; [4]Department of Nuclear Medicine, Charles University Hospital and Faculty of Medicine in Hradec Králové, Hradec Králové, Czech Republic.

Introduction
Paragangliomas are rare neuroendocrine tumors that arise from the extraadrenal paraganglia. Sympathetic paragangliomas usually secrete catecholamines and are located in the sympathetic paravertebral ganglia of thorax, abdomen and pelvis.
Case report
We present a 66 year old patient with an incidentally found retroperitoneal mass on spine MRI. An open biopsy was performed (9/15) with the histological finding of benign paraganglioma (according to histopathology report from the local pathology). No further controls were provided. In 2017 during MR of the spine (after a sport trauma) progression of the tumor size was found and hormonal evaluation showed significantly increased norepinephrine, normetanephrine and chromogranin levels. Patient presented with paroxysmal hypertension, episodic sweating and tachycardia. ^{18}F-FDG PET/CT showed numerous bone metastatic lesions of spine and ribs. No tumor lesion took up ^{123}I-MIBG and somatostatin receptor scintigraphy is planned to decide if the patient is suitable for peptide receptor radiotherapy or systemic chemotherapy. Due to bone involvement, bisphosphonate therapy was initiated. Results of genetic examination are still pending.
Conclusion
Paragangliomas are rare neuroendocrine tumors. In this particular case, misleading pathological report led to incorrect therapeutic strategy since this tumor type can never be regarded as benign.

Bilateral pheochromocytoma in Von Hippel-Lindau syndrome: a case report

Egle Kvedaraviciute[1,2], Egle Kreivaitiene[1] & Lina Barsiene[1]
[1]Hospital of Lithuanian University of Health Sciences Kaunas Clinics, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction
Von Hippel–Lindau (VHL) disease is a rare disorder, characterized by the development of a variety of benign and malignant tumors. It is autosomal dominantly inherited disease that causes retinal or central nervous system hemangioblastomas, endolymphatic sac tumors, renal cell carcinomas, pancreatic cysts and tumors, pheochromocytoma and epididymal cystadenomas. The condition is associated with inactivation of a tumor suppression gene.
Case
The 31-year-old Caucasian male patient was consulted in the Hospital of Lithuanian University of Health Sciences, Kaunas clinics ophthalmology department because of the gradually decreasing vision with a right eye. Proliferative retinopathy and retinal hemangioma were diagnosed. VHL syndrome was suspected and abdominal computed tomography (CT) was performed. CT revealed masses in both adrenal glands and MIBG scintigraphy confirmed bilateral pheochromocytoma (PCC). Another diagnostic VHL sign - cysts in pancreas and kidney were also seen in CT. The patient had no clinical symptoms of PCC at that time. To confirm pheochromocytoma, the catecholamine blood test was done and five times elevated normetanephrine 5.65 pmol/l (0–1.037) and chromogranin A 177 μg/l (0–100) were detected. To exclude MEN 2 syndrome genetic test was done and no RET mutations were found. Diagnose of VHL was made based on clinical findings. The multidisciplinary team decided to remove left adrenal gland because the size of the left adrenal tumor was four times larger and in SPECT/CT it had more intensive radionuclide uptake. Histopathological examination revealed pheochromocytoma in 2.4×4×4.3 cm and 3.5×4×2.3 cm size masses with necrotic areas and on immunohistochemistry positive expression of chromogranin A. Catecholamine and chromogranin A levels decreased in one-year follow-up after the operation. Patient lost vision with a right eye because the hemangioblastoma of the retinae was inoperable and complicated in retinal detachment. His family history was unremarkable. Patient was scheduled for follow-up to monitor possible VHL complications.
Conclusion
VHL syndrome is a complex and rare disease, therefore, the diagnosis can be challenging. VHL requires systemic multidisciplinary management to achieve adequate control of these locally aggressive tumors to prevent avoidable morbidity and mortality.

Composite pheochromocytoma with neuroblastoma: a case report

Maria Mavromati, Jaafar Jaafar, Benedicte De Kalbermatten, Sophie Maitre, Karim Gariani, Giacomo Gastaldi & Jacques Philippe
University Hospital of Geneva, Geneva, Switzerland.

A 24-year old female patient was referred to the endocrinology department after discovery of a left adrenal tumor measuring 4×5 cm, on a CT-scan performed for recurrent back pain. She had a history of lower extremity lymph-oedema since the age of 13 years and juvenile xanthogranulomas operated at the age of 2 years. The tumor had a high density in native CT sequences (48 Hounsfield Units). MRI showed T1 iso-intensity and T2 hyper-intensity, as well as lymph nodes of the celiac trunk. 24-h urine metanephrines were 5 times higher than the upper limit of normal range. I^{123}-MIBG-scan was negative. The patient also fulfilled clinical criteria for type 1 neurofibromatosis (NF-1, Von Recklinghausen disease). After preparation with alpha-adrenergic blockers, a laparoscopic left adrenalectomy was performed. Histology showed composite pheochromocytoma with 30-40% differentiated neuroblastoma, exhibiting a Mib-1 proliferation index of 10-20%. Postoperative plasma-fractionated metanephrines were negative and I^{123}-MIBG-scan as well as PET-CT were normal. Genetic testing did not confirm NF-1 or any other genetic cause of pheochromocytoma. The patient had total thyroidectomy 3 years after initial presentation, for bilateral thyroid nodules with FNA having shown oncocytic follicular neoplasia. Calcitonin levels were negative. Histology only found oncocytic hyperplasia with no proof of malignancy. No tumor recurrence was found at follow-up (7 years). Composite pheochromocytomas are rare tumors consisting of pheochromocytoma and neurogenic tumors (most frequently ganglioneuroma but also ganglioneuroblastoma, neuroblastoma, or peripheral nerve sheath tumor), with only a few series of cases cited in literature. There is uncertainty concerning natural history of these tumors, which often seem to be associated with NF-1. Only a few cases of composite pheochromocytoma with neuroblastoma have been published, and prognosis seems to be related to this latter component. MYC-N gene amplification (negative in our patient) has been found to predict aggressive behavior.

Intestinal pseudo-obstruction as a fatal complication of a malignant hereditary paraganglioma: A case report

Joana Maciel, Sara Donato, Helder Simões & Valeriano Leite
Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal.

Background
Familial paraganglioma type 1 syndrome is a hereditary form of paraganglioma due to an autosomal dominant, paternally inherited, germinal mutation in the SDHD subunit. Intestinal pseudo-obstruction is a rare complication of secretory PGL. We present a case of a patient with a malignant PGL syndrome type 1 who developed intestinal pseudo-obstruction.
Clinical case
The patient was a Dutch male, aged 39 years, carrier of a germinal mutation in exon 3 of the SDHD gene, with multiple malignant and functioning PGLs, with bone, liver and abdominal metastases. In 2007 he was diagnosed with a palpable right cervical paraganglioma that was surgically removed. Noradrenaline was the main secretion product. As disease progressed, multimodality treatment was required: alfa end beta adrenergic receptor blockers, alfa-methyl-p-tirosine, surgically excision of an abdominal PGL, hepatic metastases resection and chemoembolization, radiotherapy for several bone metastases, three Lu177 treatments (total activity $=530$ mCi), decompressive surgery for an orbital bone metastasis, bisphosphonate therapy, and six cycles of cyclophosphamide, vincristine and dacarbazine chemotherapy. Disease progression was evident clinically and biochemically with serum chromogranin A (normal range <100 ng/ml) and urinary metanephrines (normal range <1 ng/ml) reaching 78870 ng/ml and 77 mg/24 h, respectively). By the end of 2017, he developed recurrent vomiting, food intolerance, severe constipation and abdominal bloating. The abdominal CT scan showed massive right colon dilatation without evidence of structural obstruction. Medical therapy with enemas, laxatives, intravenous fluids, erythromycin and neostigmine was started, and phenoxybenzamine dose was increased. However, his condition worsened and a right hemicolectomy with ileostomy was performed, which proved to be ineffective as well. Intravenous phentolamine perfusion and labetalol were then initiated. Unfortunately, due to limited availability of phentolamine and the high dose of continuous intravenous administration that was required, this treatment was unsustainable. Finally, the patient developed gastrointestinal bleeding, dying a few days later.
Conclusion
Intestinal pseudo-obstruction is a severe, rare and often unrecognized consequence of excessive catecholamine production by paraganglioma/pheochromocytoma. Catecholamines activate alfa-1, alfa-2 and beta-2 adrenoreceptors of the intestinal smooth muscle cells, reducing gastrointestinal motility and increasing vasoconstriction. This was a rare case of malignant and secretory PGL with a fatal intestinal pseudo-obstruction complication. Early use of alfa-blockers, in particular intravenous phentolamine, and eventually methyltyrosine, may be useful in relieving this complication which can have a poor outcome.

Thyroid nodule and flush syndrome: it's not always a medullary thyroid carcinoma

Fatima Zahra Zaher, Ghizlane Elmghari & Nawal Elansari
Department of Endocrinology, Diabetes, Metabolic diseases and Nutrition, Mohammed VI university hospital, Marrakech, Morocco.

Introduction
Neuroendocrine tumors are rare tumors with increasing incidence. They are characterized by the expression of proteins and hormonal products common to neurons and endocrine cells, and are often diagnosed at an advanced stage due to the delayed onset of nonspecific symptoms. We report the case of a patient who presented with a flush syndrome associated with a thyroid nodule and who was subsequently diagnosed with a digestive neuroendocrine tumor

Observation
A 60-year-old patient, chronic smoker, was admitted for a flush syndrome. The interrogation found liquid diarrhea at the rate of 5 stools per day, with palpitations and sweating for 1 year, dysphagia, without dysphonia, or dyspnea, slimming quantified at 14 kg over 15 days, asthenia and anorexia. The examination found a conscious patient, a BMI at 20 kg/m^2, bilateral malar erythema, slightly increased thyroid volume with palpation of a left nodule of 1 cm, slightly sensitive, hard, mobile, without vascular trill, a distended abdomen with hard epigastric mass, hard hepatomegaly, bilateral inguinal lymphadenopathy and edema of the lower limbs. Investigations showed hyperthyroidism with at the cervical ultrasound a multihetero nodular goiter classified TIRADS 3 and a negative calcitonin, thoraco-abdomino-pelvic CT showed duodenal lesion associated with ganglion masses, retractile mesenteritis, hepatic metastases and peritoneal carcinomatosis suggestive of a neuroendocrine tumor. Octreoscan showed a mass of D2 moderately fixing the product with liver metastases.
Discussion
NETs are rare tumors but must be evoked especially in the presence of symptoms indicating paraneoplastic endocrine secretions such as flush syndrome. The most frequent localizations are hailic, then bronchial, colic and gastric. Biologically, the diagnosis is based on the elevation of chromogranin A, blood serotonin and urinary 5-hydroxy-indol-acetic acid (5HIAA). Octreoscan may be useful for the diagnosis and tumor extension assessment. Certain factors favoring the triggering of a carcinoid syndrome are sometimes reported: diet, emotion, anesthesia, alcohol consumption, pentagastrin or catecholamine administration. The factors limiting or suppressing seizures are somatostatin, interferon alpha, antihistamines, alpha blockers, serotonin inhibitors and of course tumor resection.

Chemodectoma of carotid glomus coexisting with severe hypercalcemia masking parathyroid gland adenoma – diagnostic difficulties

Agnieszka Żyłka[1], Joanna Długosińska[1], Elwira Bakuła-Zalewska[2] & Marek Dedecjus[1]
[1]Department of Oncological Endocrinology and Nuclear Medicine, Maria Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology, Warsaw, Poland; [2]Department of Pathology, Maria Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology, Warsaw, Poland.

Introduction
Chemodectomas of carotid glomus secret mainly catecholamines and/or ACTH. These tumours are very rare cause of ectopic secretion of parathormone (PTH), althought this possibility should be taken into consideration. Therefore, diagnosis of primary hyperparathyroidism (PHPT) as a cause of hypercalcemia in patients with chemodectoma tumours is problematic and may lead to inappropriate diagnosis and treatment. Presented patient is a 64-years old female with non-operative chemodectomas of carotid glomus diagnosed in 1999 with confirmed SDHD mutation. The patient was treated with external beam radiation, and followed-up because of chronic hypercalcemia coexisting with the tumours. In 2010 the patient was hospitalized because of hypercalcemic crisis with serum calcium (Ca) reaching 3.5 mmol/l and PTH values up to 900 pg/ml. The patient required intravenous bisphosphonates administration, which was ineffective. Magnetic resonance (MRI), ultrasound and tomography did not reveal the occurrence of parathyroid adenoma, therefore the diagnosis of ectopic PTH excretion by chemodectoma was formulated. Difficulties in imaging lesions on the neck by ultrasound and MRI may be partially explained by the fact that the patient underwent subtotal thyroidectomy due to nodular goiter in 1987. In 2015 ultrasound examination showed hypoechogenic focal leasion with increased vascularization measuring 18×28×35 mm in the right thyroid bed. Fine needle aspiration suggested presence of parathyroid cells and concentration of PTH in wash-outs of the needle after Fine Needle Aspiration Biopsy (FNAB-PTH washouts) confirmed this suspicion. Patient was qualified to surgery and operated on in December 2015. Histopathological examination confirmed diagnosis of parathyroid adenoma (diameter of 40 mm) and PTH-positive immunohistochemical staining. Chemodectoma tumours are followed-up and show no progression (MRI imaging) and catecholamine/ACTH activity is stable.
Conclusions
Present case is an example of difficulties of PHPT diagnosis masked by coexisting paragangliomas. Suspicion of paraneoplastic syndrome mislead diagnostic process, and as a result imaging concentrated mainly on the radiological follow-up of the chemodectomas.

Neuroblastoma in 55-year-old patient - the role of MIBG scintigraphy

Dubravka Brdar, Gordana Soso, Sanda Sladic, Tina Majstorovic & Ante Punda
Department of Nuclear Medicine, University Hospital Split and Split University School of Medicine, Split, Croatia.

Neuroblastoma is a tumor that originates from immature nerve cells. It is the most common extracranial solid tumor in children, but is extremely rare in adults.
Aim
The role of MIBG scintigraphy in diagnosis and follow-up of patient with neuroblastoma.
Case report
A 55-year-old woman underwent for regular abdomen ultrasound examination. Sonography revealed inhomogeneous, predominantly isoehogenic tumor mass above the upper lobe of the right kidney, measuring 34×45×42 mm. She has been without simptoms. MSCT of abdomen revealed tumor mass in the right adrenal gland that measured 35×45×44 mm. The cathecholamine levels were normal. Laparoscopic right adrenalectomy was done. Pathohistological diagnosis was neuroblastoma. Immunohistochemical profile showed positive chromogranin A, neuron-specific enolase, synaptophysin. Proliferative activity (Ki-67) was 25%. After post-operative recovery scintigraphy with I-131-MIBG and FDG-PET for staging performed and it was negative. MR of abdomen was performed four months and ten months after operation and was negative. Because of neuron-specific enolase elevation, whole body MIBG scintigraphy with SPECT/CT was done. Thyroid blocade with Na-perchlorate had been srarted 30 min before injection of I-131-MIBG and continued during next five days. I-131-MIBG was intravenously applyed in dose of 37 MBq (1 mCi).
Results
Whole body planar scintigrams were performed 24 and 48 hours postinjection and showed intensive focal radiotracer accumulation in the right hemiabdomen. SPECT/CT confirmed accumulation of I-131-MIBG probably in lymph node in the right hemiabdomen, in front of the right crus of diaphragm, at the level of the upper mesenteric artery. The patient underwent extirpation of tumor mass and pathohistology confirmed metastatic neuroblastoma in lymp node.
Conclusion
MIBG scintigraphy with SPECT/CT is very important modality in diagnosis, staging and follow-up of patients with neuroblastoma because it is relatively simple method, with high sensitivity and specificity.

Optic neuritis and ectopic Cushing Syndrome: a case report

Tânia Matos, Cristiana Costa, Ana Filipa Martins & Sónia Vale
Endocrinology department, Centro Hospitalar Lisboa Norte, Lisboa, Portugal.

Introduction
Ectopic Cushing syndrome caused by a neuroendocrine tumor is uncommon and it's diagnosis is often delayed. Optic neuritis is another rare disease, with some cases also associated to neuroendocrine tumors.
Case-report
A 43-year-old female was referred to the endocrinology outpatient's department due to obesity. She had a past history of bilateral optic neuritis of unknown etiology. She complained of weight gain, hair loss, acne, hirsutism, proximal muscle weakness and visual hallucinations. Physical examination revealed facial plethora, moon facies, supraclavicular fat pads, acne, central obesity, purple striae, ecchymosis, edemas and moderate hypertension. Laboratory evalution showed an elevated ACTH (80–100 pg/ml) and cortisol (20–30 mcg/dL), the latter without a circadian rhythm. Dexamethasone prolonged low and high doses suppression tests showed absent cortisol suppression and the CRH stimulation test did not show an increase in ACTH levels. Pituitary MRI did not reveal any lesion and the inferior petrosal venous sinus catheterization suggested an ectopic origin of the ACTH. A Cushing's syndrome due to an ectopic production of ACTH was admitted, but the imaging study, including chest, abdominal and pelvic CT and MRI scans and an octreotide scintigraphy did not reveal the primitive tumor. The patient was treated with metirapone with non-sustained reduction of cortisol levels nor clinical improvement. Therefore she was submitted to bilateral adrenalectomy, with clinical resolution of Cushing's symptoms and signs, while maintaining raising ACTH levels (189 pg/ml). 14 months after adrenalectomy a new octreotide scintigraphy revealed a right perihilar mediastinic nodular lesion, with a PET scan showing a hypercaptant image at the same location. Nevertheless, the lesion did not appear on the respective CT nor on MRI scans. Tumor marker chromogranin A, started to rise (263 nmol/L), despite a normal

value of 5-Hydroxyindoleacetic acid. A right paramedian pretracheal mass was finally documented on the PET-CT 4 years later. The tumor was removed and the histology revealed a neuroendocrine tumor of lung origin. No recurrence was detected until the present date (55 year-old).
Discussion
Optic neuritis and Cushing syndrome have both been described as paraneoplastic syndromes. However, we haven't found any case described in the literature, combining both syndromes as a result of a neuroendocrine tumor. This case also highlights the long delay that can occur between the paraneoplastic syndromes diagnosis and the neuroendocrine tumor localization.

The infradiagnosis of primary aldosteronism as a public health problem

Francisco Javier Martinez-Martin[1], Paula Gonzalez-Diaz[2], Alba Lucia Tocino-Hernandez[2], Esperanza Perdomo-Herrera[3], Marta Martin-Perez[4], Ana Delia Santana-Suarez[5], Manuel Esteban Niyelo-Rivadeneira[5], Agnieszka Kuzior[5], Paula Fernandez-Trujillo-Comenge[5] & Carmen Acosta Calero[5]
[1]Outpatient Hypertension Clinic, University Hospital of Gran Canaria Doctor Negrin, Las Palmas de Gran Canaria, Spain; [2]Arucas Primary Care Center, Las Palmas de Gran Canaria, Spain; [3]Escaleritas Primary Care Center, Las Palmas de Gran Canaria, Spain; [4]Guia Primary Care Center, Las Palmas de Gran Canaria, Spain; [5]Endocrinology & Nutrition Department, University Hospital of Gran Canaria Doctor Negrin, Las Palmas de Gran Canaria, Spain.

Objectives
Understanding and propagating the knowledge of the burden caused by the massive infradiagnosis of Primary Aldosteronism (PA), partly due to unawareness of its high prevalence and partly to the complexity of its screening in Primary Care and workup in Specialized Care.
Methods
Review of the relevant literature and personal reflections.
Results
PA is the first cause of secondary hypertension and a highly prevalent disease (2–4%). Of the 16,500,000 Spanish hypertensives, at least 1,000,000 have PA. Norwithstanding, it is still widely considered as a rare disease, with $<1\%$ diagnosed cases; the rest are managed as essential hypertensives. However, PA:
- Is a potentially curable disease, while essential hypertension rarely is.
- Elicits a burden of cardiovascular complications estimated as fivefold that of essential hypertension with comparable blood pressure.
- It has a more severe impact on mental health and quality of life of the patients than essential hypertension, and higher association with metabolic syndrome and sleep-apnea.
- Blood pressure control in PA is not only more difficult (as it typically drives resistant hypertension), but also the risk of cardiovascular events is not reverted unless the aldosteronism is controlled (with normalization of PRA).

The present guidelines recommend screening for PA in multiple situations that may include 50% of the hypertensive patients. Pharmacologic interferences notoriously hinder the interpretation of the aldosterone/renin ratio. Confirmation test are complex, hazardous and may require hospital admission. Subtyping requires in most cases adrenal venous sampling (AVS) which is highly specialized, invasive, costly and poorly standardized. According to the guidelines we should screen about 8,000,000 patients, perform confirmation tests in $>1{,}000{,}000$ and AVS in about 500,000 in order to proceed to resolutive treatment in most of our patients with PA.
Conclusions
PA is not a rare disease, but it is overwhelmingly infradiagnosed, partly because of ignorance and partly because the screening and diagnostic procedures are exceedingly complex and costly. General implementation of the present guidelines is patently inviable, hence it is unsurprising that $<1\%$ of the cases are diagnosed and treated (in Spain as in the rest of the world). Early diagnosis and treatment of PA could potentially reduce very significantly the burden of cardiovascular events (stroke especially) with obvious implications for public health, besides improving the mental health and quality of life of a sizable segment of the population. However, in order to achieve these goals, the PA screening and diagnosis procedures need to be simplified, and their cognizance widened.

Patient with post-surgical hypoparathyreoidism and long QT interval

Zlata Kovacevic & Olivera Boskovic
Clinical Center of Montenegro, Podgorica, Montenegro.

Post-surgical hypoparathyroidism is most common cause of hypoparathyroidism develops after accidental damage to or removal of the parathyroid glands during surgery. Heart arrhythmias and fainting, even heart failure is reversible complications of hypoparathyroidism, due to low calcium levels. Long QT (LQT) interval may lead to syncope, cardiac arrest, or sudden death. The goal of hypoparathyrodisms treatment is to relieve symptoms and to normalize levels of calcium and phosphorus. A treatment regimen includes: oral calcium carbonate tablets, vitamin D and human parathyroid hormone, recombinant. A treatment of LQT interval with Implantable cardioverter-defibrillator (ICD) is prevention and termination of arrhythmias. Goal is to show a patient with post-surgical hypoparathyroidism, severe hypocalcemia, hyperphosphatemia, hypothyroidism, tetany, syncope and LQT interval.
Materials and methods
A case report of 60 years old woman who has developed post-surgical hypoparathyroidism and hypothyreoidism with the consequence hypocalcemia and prolonged QT interval. Preserved renal function.
Conclusion
Hypoparathyroidism is most commonly caused by surgery. Consequences are hypocalcemia,hyperphosphatemia. In our case is 60 years old patient who is not well-controlled on calcium supplements and active forms of vitamin D (ionized Calcium 0.67 mmol/l, phosphorus 1.59 mmol/l, magnesium 0.79 mmol/l, PTH 0.37 pmol/l) with tetany, syncope, arrhythmia with prolonged QT interval. We perform implantation of cardioverter defibrillator to prevent sudden death. In our country is not available Human parathyroid hormone, recombinant.

Evaluation of causes of high parathyroid hormone levels in elderly

Pelin Tutuncuoglu[1] & Fulden Sarac[2]
[1]Atatürk Training and Research Hospital, Department of Endocrinology and Metabolism, Izmir, Turkey; [2]Ege University Medical Faculty, Department of Geriatric Medicine, Izmir, Turkey.

Primary hyperparathyroidism (PHPT) predominantly affects the elderly, with a peak incidence between ages 55 and 70. Parathyroid adenoma is the principal cause, representing 80–85% of all cases. The aim of the study to determine the frequency of parathyroid adenoma in elderly with high parathyroid hormone levels.
Subjects and methods
We performed a retrospective analysis of 31 (30 female, 1 male) elderly wih high parathyroid hormone levels. The demographic caracteristics, biochemical tests and imaging features such as neck ultrasound and parathyroid scintigraphy were evaluated, retrospectively.
Results
The patients had a mean age of 67 ± 8.1 years, serum Ca of 10.9 ± 0.5 mg/dl, serum PTH of 110.6 ± 15.2 pg/ml, serum 25-hydroxy-vitamin D (25- OH D) of 22.9 ± 1.1 nmol/l. Two female patients 2/31) had a parathyroid adenoma shown on a sestamibi scan and neck ultrasound. The frequency of parathyroid adenoma was found to be 6.4%. These patients were underwent *parathyroidectomy* for *primary hyperparathyroidism*. 1 patient presented with severe abdominal pain diagnosed as parathyroid adenoma. Surgery was successful in all patients with no postoperative mortality. 12 patients had low serum 25- OH D (17.3 ± 3.9 nmol/l). Frequency of deficiency of vitamin D was 38.7%. And also, they treated with D vitamin and decreased their PTH levels. No cause was found related hyperparathyroidism with normal 25- OH D using imaging in the rest of them.
Conclusion
High PTH levels due to deficiency of D vitamin levels were higher than parathyroid adenoma in elderly.

Interventional study to compare two regimens of vitamin D suplementation

Inmaculada Gonzalez Molero, Monserrat Gonzalo Marin, Viyei Doulatram, Jose Abuin & Gabriel Olveira
CArlos Haya Hospital, Malaga, Spain.

Introduction
Vitamin D deficiency is very common in our population.It is not clear which is the most effective vitamin D dosing regimen in patients with deficiency.
Objective
To compare two vitamin D supplementation regimen in patients with vitamin D deficiency.
Material and methods
This is an interventional study: Patients atended in our clinic during May and June 2017 with 25-Hydroxyvitamin D below 30 ng/ml were consecutively selected and supplemented with two types of régimen.*Regimen 1*:one weekly calcifediol capsules during a month and then 1 capsule monthly for 2 more months (total 3 months) and *Regimen 2*: 1 weekly hydroferol capsule for one month and then monthly for 5 more months (total 6 months). Each capsule contains 0.266 mg of calcifediol(15.960 IU of vitamin D). In addition, everyone was given dietary advice to increase their vitamin D intake.Half of the patients with levels between 10 and 30 ng/ml were supplemented with regimen 1 and the other half with regimen 2. All patients with levels below 10 ng/ml were given the régimen 2. Vitamin D levels were checked after 6 months.
Results
Data were obtained from 40 patients, mean age 60.7+/−14.5 years(28–86), Mean diagnosis were:47.5% Diabetes/Obesity/dyslipidemia, 35%Thyroid/Pituitary disease,17.5%Malnutrition. Baseline mean 25-Hydroxyvitamin D levels were:15.4+/−4.9(3–23.8) ng/ml and after treatment:33.5+/−13.8 ng/ml(13.4–65,1) ($P<0.05$),with a mean rise of 12.9 ng/ml for patients supplemented with regimen 1 and 21.49 ng/ml for regimen 2($P<0,05$). Baseline deficiency percentage: levels lower than 10 ng/ml, 10–20 and 20–30 ng/ml: 20.5%, 61.5% and 17.9% respectively. After treatment: 10–20, 20–30 and above 30 ng/ml:21.4%,25% and 53.6%. After 6 months 25% of those treated with regimen 1 achieved levels above 30 ng/ml vs the group with regimen 2, which 75% achieved levels higher than 30 ng/ml ($P<0.05$). With régimen 2, only 40% of patients with baseline levels lower than 10 ng/ml achieved 30 ng/ml vs 100% of patients with baseline levels 10–30 ng/ml ($P<0.05$).
Conclusions
In patients with non-severe vitamin D deficiency or insufficiency (10–30 ng/ml) supplementation régimen with 16,000 IU of calcifediol weekly during 1 month and then monthly during 5 months achieve 100% of vitamin D sufficiency (25-Hydroxyvitamin D >30 ng/ml). Patients with severe vitamin D deficiency need other regimens with more doses.

Atypical parathyroid adenoma – a rare case of primary hyperparathyroidism

Theodor Oprea[1] & Carmen Barbu[1,2]
[1]Elias University Hospital, Bucharest, Romania. [2]Carol Davila University of Medicin, Bucharest, Romania.

Introduction
Parathyroid carcinoma and atypical parathyroid adenoma are among rarely encountered causes of primary hyperparathyroidism. Patients with parathyroid carcinoma often differ from those with atypical parathyroid adenoma or parathyromatosis at the time of presentation because patients with parathyroid carcinoma have more profound hypercalcemia as well as invasive tumors. However, at times, it is difficult to distinguish between these conditions both clinically and by final histologic examination.We report the case of a 59 year old woman, who adressed the endocrinology department for assement of macropolinodular goiter with chronic Levothyroxin treatment, polyuria and lombar pain.
Clinical examination
High blood pressure, lombar pain, normal BMD, macronodular goiter, polyuria and polydipsia (about 5l per day).
Lab tests results
Normal CBC, normal fasting plasma gloucose, normal renal function, mild hypercalcemia (12 mg/dl), hyperphosphatemia, normal TSH, high PTH (172 pg/ml), supressed calcitonin; 24h urine sample revealed high urinary calcium, suggesting primary hyperparathyroidism.
Cervical region ultrasound
Macropolinodular goiter, posterior and caudal of the right thyroid lobe a hypoechoic mass lesion (17/9 mm) which seemed to communicate with a blood vessel, resembling a parathyroid adenoma. Lombar spine X-ray: cuneiform compression of L1, narrowing of the intervertebral T12-L1 space. DXA revealed osteoprosis with a increased mineral lost on the distal third radius. Scintigraphy scan of the cervical region was performed with no conclusive findings. The patient was refered to the surgery department for near-total thyroidectomy due to macronodular goiter and to examin and excise what seemed to be a parathyroid adenoma. The histologic examination of the tumor has established the atypical parathyroid adenoma diagnosis. The patient was refered back to us, after three weeks, for the postoperative assessment and she had normal calcemia.
Conclusions
Atypical parathyroid adenoma is a rare cause of primary hyperparathyroidism, no clincal or biological finding can distinguish between the etiological pathways of primary hyperparathyroidism, blood calcium levels do not seem to follow a specific pattern, although, in literature, is mentioned that a higher calcemia is most frequently related with parathyroid carcinoma or parathyroid atypical adenoma. Utlimately the histological exam is the one that clarifies the diagnosis and sets the subsequent therapeutic conduct, so the surgical excision of the suspected tumor is imperative, serving also as therapeutic diagnostic tool.

EP33

Correlation levels of parathyroid hormone (PTH) and vitamin D (25(OH)D) in different age groups

Elena Kataeva, Guzel Rynova, Vasily Voinov & Valentin Fadeev
Sechenov University, Moscow, Russian Federation.

Introduction
The general function of vitamin D is to regulate phosphorus-calcium metabolism. Vitamin D takes part in other metabolic processes and it has an impact on body mass and on carbohydrate metabolism. Vitamin D also has an influence on nervous system' functioning and on immune processes. Vitamin D deficiency increases risk of hyperplasia of the parathyroid glands, primary and secondary hyperparathyroidism and osteoporosis.
Objectives
To investigate the reference values of PTH, considering response normalization of vitamin D levels in different age groups.
Methods
The study included 423 patients of both sexes between the age of 18 and 90. The patients were included between September 2017 and November 2017. All patients with endocrine pathology were observed in Moscow outpatient clinics no 5 and no 210. All patients were examined for level 25 (OH) D, PTH, total calcium and creatinine in the blood.
Results
390 patients in the selected age groups had a vitamin D deficiency, which was lower than the reference values. Some of the patients had increased level of PTH. Decreased level of PTH was revealed in all age groups, due to the process of taking saturating doses of the 25(OH)D. Herewith, increased level of PTH was revealed in the age group 60–74 and 75–90.
Conclusion
The results have shown that majority of patients have a pronounced vitamin D deficiency associated with insufficient insolation and malnutrition. PTH level reduction was noticed, due to the process of taking native vitamin D. Respectively, it can be assumed that the reference values for PTH are overestimated in the territory of the Russian Federation, because previous measurements were done without regard to saturation with 25(OH)D.

Bone mineral density and polymorphisms of the estrogen receptor gene,vitamin D receptor gene and collagen typei alpha 1 gene

Sonsoles Botella Martinez[1], Patricia Restituto[2], Monreal Ignacio[2], Amparo Calleja[2], Nerea Varo[2] & Macarena Rodriguez[2]
[1]Complejo Hospitalario De Navarra, Pamplona, Spain; [2]Clinica Universidad De Navarra, Pamplona, Spain.

Objectives
The aim of this study was to analyze the prevalence of some polymorphisms of the CTR-AluI, VDR-FokI, Col1A1y ER-α genes, (involved in bone metabolism),

in our population. And evaluate the association of these polymorphisms with bone mineral density and fracture.
Design, Patients, and Setting
We performed an observational prospective study in pre- and postmenopausal ambulatory women ($n=72$ and $n=152$, respectively).
Intervention
Blood samples were collected at baseline to the measurement of polymorphisms. Women filled out a questionnaire and underwent bone mineral density measurement using dual-energy x-ray absorptiometry at the time of enrollment. We evaluate the incidence of fragility fracture after 1 year of follow-up
Results
The prevalence of the polymorphisms in our population was: *Gen COL1A1SP1*:59% SS, 20% Ss, 21% ss; *Gen CTRALUI*: 5% AA, 41% Aa, 54% aa; *Gen ESR1PPVUII*: 36%PP, 35% Pp, 29% pp; *Gen ESR1XXBAI*: 10%XX, 48% Xx, 42% xx; *Gen VDRBBSMI*: 11% BB 44% Bb, 45% bb; *Gen VDRFFOKI*: 40%FF, 45% Ff, 15% ff. No polymorphisms were associated with low bone mineral density ($P>0.05$). Only an association was found in the postmenopausal group between the polymorphism of the PolESRXX gene and the presence of osteoporotic fracture after menopause ($P=0.02$).
Conclusions
The osteoporosis is a complex and multifactorial disease. Our data don't find any significant association between polymorphisms and bone mineral density. The prevalence of genotyped polymorphisms in our study is consistent with others described in the European population (except for the polymorphism of the COL1A1gene)

Diabetes, Obesity and Metabolism

EP35

Do our diabetic patients really manage to recognize hypoglycaemia and to act properly in front of it?

Chaima Jemai, Nadia Bn Amor, Amal Smida, Nadia Khessairi, Mariem Zarrouk, Aroua Temessek, Tertek Hajer & Faika Ben Mami
Institut National D Nutrition De Tunis, Tunis, Tunisia.

Introduction
Therapeutic education is very important in any patient with a chronic disease such as diabetes. The objective of our study is to evaluate the knowledge of diabetic patients already educated about hypoglycemia.
Materials and methods
This is a prospective study conducted on 50 diabetic patients hospitalized for equilibration of their diabetes in the "C" service of the Tunis National Institute of Nutrition and who were educated beforehand on hypoglycaemia. These patients' knowledge of the defining value of hypoglycaemia and severe hypoglycaemia, signs of hypoglycemia, and their behavior were assessed if they experience hypoglycaemic discomfort.
Results
The mean age of the patients was $68.6+/-11.2$ years. The average body mass index (BMI) was $37.9+/-3.3$ kg/m^2. Diabetes was insulin-dependent in 100% of cases that had been on the move for $16.8+/-8.3$ years on average. Diabetes was poorly balanced in all patients with mean HbA1C of $9.2\%+/-1.1$. Only 30% of patients had a glucometer and regularly monitored their blood glucose. Hypoglycemia was defined by the majority of patients (78%) as having a blood glucose level below 1 g/l. severe hypoglycaemia was defined as glucose lower than 0.5g/L by 86% of patients. The signs of hypoglycemia mentioned by patients are in order of frequency: hunger (100%), palpitations (100%), cold sweats (100%), tremors (96%), neuropsychic disorders (86%) and coma and death (52%) 86% of patients say that clinical signs are a function of the severity of hypoglycaemia.38% only know that if hypoglycaemia recurs, they may not be felt anymore.84% do not know that severe or repeated hypoglycaemia can cause neurologic sequelae. 80% reshape at the slightest malaise without confirming that it is hypoglycemia, even those with a glucometer. They ate bread (37.5%), fruit (30%), a dairy product (25%), chocolate (22.5%) and only 10% re-vegetated properly after confirmation of hypoglycaemia.
Conclusion
The fact of transmitting only information to diabetic patients is not enough to educate them. Therapeutic education must be well structured and patient centered to benefit it.

Primary mitochondrial disorders and diabetes mellitus – two case reports

Lúcia Fadiga[1], Joana Saraiva[1,2], Diana Oliveira[1], Adriana Lages[1], Mara Ventura[1], Nelson Cunha[1], Diana Catarino[1], Joana Guiomar[1], Diana Silva[1], Carolina Moreno[1,2] & Francisco Carrilho[1]
[1]Endocrinology Department, Coimbra Hospital and Universitary Centre, Coimbra, Portugal; [2]Faculty of Medicine of the University of Coimbra, Coimbra, Portugal.

Introduction
Primary mitochondrial disease is a heterogeneous group of disorders of mitochondrial energy metabolism. Neuromuscular symptoms are the main features, but diabetes mellitus (DM) is present in many patients. DM is related to a deficient energy production, which leads to decreased insulin secretion and ultimately to β-cell apoptosis. In most cases, DM has an insidious onset with requirement of insulin 2-4 years after diagnosis. About 20% of cases present with acute symptoms. We present two cases of patients with mitochondrial disorders, who developed DM.
Case 1
36-year-old male, with mitochondrial encephalomyopathy, lactic acidosis, and stroke like episodes syndrome (MELAS) diagnosed at the age of 29, carrier of mtDNA mutation A3243G, with grade 4 tetraparesis, bilateral ptosis, cognitive impairment and epilepsy. He was under carbamazepine, valproic acid, idebenone, mirtazapine, riboflavin and a multivitamin supplement. He was admitted at the emergency department with symptoms of polyuria, polydipsia, dizziness and prostration. Blood tests revealed hyperosmolar hyperglycaemic syndrome, with venous glycaemia 989 mg/dL, plasma osmolality 325 mOsm/Kg, sodium 153 mmol/L, creatinine 1.1 mg/dL, normal pH and negative ketones. He started intravenous insulin and was admitted to the ward. He weighed 40Kg, with BMI 14.8Kg/m^2. Complementary investigation showed A1C 14.9%, C-peptide 0.1 ng/mL (1.0–7.6) and negative islet autoantibodies. He had improvement of clinical status and was discharged home with intensive insulin therapy, with total daily dose of 32U.
Case 2
52-year-old female, with mitochondrial myopathy with Kearns-Sayre phenotype, with grade 4 tetraparesis, bilateral ptosis, external ophthalmoplegia, atrioventricular block (with pacemaker) and chronic respiratory failure. She had past history of papillary thyroid carcinoma (total thyroidectomy at the age of 46), DM diagnosed at the age of 48, hypertension, dyslipidaemia and depression. She was under metformin plus sitagliptin, levothyroxine, telmisartan plus hydrochlorothiazide, bisoprolol, omeprazole, fenofibrate, fluoxetine and valproic acid. She was admitted at Endocrinology department due to uncontrolled diabetes, to start insulin. She weighed 51Kg, with BMI 21.8Kg/m^2. Complementary investigation revealed A1C 10.7%, C-peptide 1.4ng/mL (1.0–7.6) and negative islet autoantibodies. Metformin was suspended due to hyperlactacidaemia and insulin glargine was started. She was discharged home with glargine 18U and sitagliptin 100 mg.
Conclusion
These cases show the heterogeneity of DM in mitochondrial disorders. Differential diagnosis with other forms of DM is challenging, because mitochondrial disorders are rare and present with very different phenotypes. DM treatment at initial stages, before insulin deficiency, is controversial.

Features of distribution of fat component in patients with type 2 diabetes mellitus giving insulin

Yuliya Dydyshka[1], Alla Shepelkevich[1] & Lobashova Veronica[2]
[1]Belarusian State Medical University, Minsk, Belarus; [2]Republic Center of Medical Rehabilitation, Minsk, Belarus.

Background
The central distribution of body fat has been identified as a significant risk factor for development of macrovascular complications in type 2 diabetes mellitus (T2D) in particular. The aim of the study was the features of fat mass distribution in T2D patients using insulin.

Materials and methods
We studied 138 T2D patients with insulin in therapy (31 men and 107 women; mean age 51.43 + 8.41 yrs; disease duration 6.40 + 2.01 yrs; BMI 31.15 ± 1.99 kg/m^2; HbA1c was 8.05 + 0.95%; total daily dose (TDD) of insulin – 0.74 + 0.12 U; duration of insulin using - 3.86 + 0.87 yrs) and 32 matched for age and body mass index controls. The research involved anthropometry, general clinic examination, dual energy X-ray absorptiometry performed on "PRODIGY LUNAR" using program "Total body" and "Body composition".
Results
There were no significant differences in fat component in general group of T2D patients and controls: Total Body 39.10 ± 7.70% vs 36.88 ± 7.84%, $P = 0.057$; Android: 45.35 ± 8.06% vs 44.34 ± 7.15%, $P = 0.393$; A/G Ratio: 1.12 ± 0.19 vs 1.16 ± 0.25, $P < 0.05$; Trunk/Total: 0.58 ± 0.07 vs 0.56 ± 0.07, $P = 0.070$. But in the subgroups of women (T2D vs controls) the following features were established: Total Body 40.75 ± 6.63% vs 41.81 ± 5.34%, $P = 0.384$; Android: 46.38 ± 7.71% vs 46.56 ± 7.28%, $P = 0.898$; Gynoid,%: 43.14 ± 6.95% vs 46.10 ± 5.32%, $P = 0.021$; A/G Ratio: 1.08 ± 0.15 vs 1.02 ± 0.16, $P = 0.033$; Trunk/Total: 0.57 ± 0.07 vs 0.53 ± 0.06, $P = 0.001$; (Arms + Legs)/Total 0.72 ± 0.23 vs 0.87 ± 0.24, $P = 0.001$; Legs/Total: 0.29 ± 0.07 vs 0.33 ± 0.07, $P = 0.001$. Increasing A/G Ratio, Trunk/Total and decreasing (Arms + Legs)/Total, Legs/Total in diabetic patients evidence of fat redistribution in the trunk towards the extremities. Android (central) fat distribution was positively correlated with the age of T2DM women ($r = 0.18$; $P = 0.023$), however no correlation was found with the duration of the disease, level HbA1c, the TDD insulin dose. Similar differences were not found in the subgroups of men (T2D vs controls) in the following parameters: Total Body ($P = 0.271$), Android, % ($P = 0.906$), Gynoid, % ($P = 0.280$), A/GRatio ($P = 0.146$), Trunk/Total ($P = 0.974$), (Arms + Legs)/Total ($P = 0.095$); Legs/Total ($P = 0.976$).
Conclusions
There are differences in the distribution of fat in men of women with type 2 diabetes getting insulin. Women are characterized by a redistribution of fats with an increase in sediment in the trunk region.

Hyperglycemia and thyroid disorders in chronic hepatitis C virus infected patients in Fayoum, Egypt

Mohamed Mashahit & Tarek Ibrahim
Department of internal medicine, faculty of medicine, Fayoum University.

Background
Hepatitis C virus is common in Egypt and its prevalence varies from 10 to 17%. Beside its harmful effect on the liver, it can lead to variable other effects on various organs and tissues known as the extrahepatic manifestations of HCV. hepatitis C virus induced thyroid diseases in the form of thyroiditis resulting in hypofunction or even hyperfunction of the gland. thyroid disease was found to be of immune nature. Also diabetes which is often termed hepatogenous diabetes was common in patients with chronic HCV and this form of diabetes differs from the classic type 2 diabetes as the patient are usually non obese but have insulin resistance and also the absence of family history of diabetes. interestingly and GAD and anti islet cell antibodies were found in some chronic HCV diabetic patients. The aim of this work is to study the prevalence of hyperglycemia and thyroid disorders in chronic HCV patients.
Patients and methods
This observational cross sectional study included 1400 chronic HCV patients referred to Fayom University hospital, Fayoum general hospital as well as Fayoum insurance hospital for HCV treatment according to the national Egyptian HCV treatment program.
Results
In this study it was found that 90% of the patients had insulin resistance measured by HOMA-IR , 24% had hyperglycemia (16% T2DM, 8% IGT) and 21% had thyroid diseases (hypothyroidism in 13%, hyperthyroidism in 6% and goiter only with normal function in 2% of the studied population)
Conclusion
Hyperglycemia and thyroid diseases are very common in chronic HCV patients and are linked to the extra-hepatic manifestations of HCV

Keywords: HCV, Hyperglycemia, Diabetes, Thyroid, Insulin Resistance

The prevalence of risk factors for type 2 diabetes among workers of the industrial enterprisein Minsk with FINDRISK questionnaire

Svetlana Sehen', Natalia Karlovich, Tatyana Mokhort & Olga Shishko
Belarusian State Medical University, Minsk, Belarus.

Introduction
Type 2 diabetes (T2D) and obesity are currently among the most common non-communicable diseases in the world. According to IDF experts in 2015, 415 million people suffered from diabetes, more than 90% of them are in T2D, and half of the disease is hidden and not timely diagnosed.
Aim
To determine risk factors and ten-year T2D risk with FINDRISK questionnare.
Materials and methods
We included 566 people who were proposed to write in FINDRISK questionnaire. We measured height, weight, waist circumference (WC), body mass index (BMI) and blood glucose which was measured by rapid test method. Patients with history of diabetes were excluded. Results are presented as M ± SE, differences were statistically significant at $P < 0.05$.
Results
The study included 310 men aged 48.11 ± 16.35 years, and 256 women aged 48.91 ± 14.53 years. The average age of participants in the action was 44.26 ± 12.62 years, BMI 25.09 ± 3.16 kg/m^2 and blood glucose 5.02 ± 0.42 mmol/l. 46.9% of participants were at low risk for T2D, men (63.7%) were twice as much as women (35.2%) ($P < 0.05$). A low risk of developing CD2 is characteristic of young and middle-aged patients (44.26 ± 12.62 years), height 171.65 ± 8.07 cm, weight 74.19 ± 10.73 kg, with normal or overweight (BMI 25.09 ± 3.16 kg/m^2), WC 83.35 ± 7.89 cm and normal blood glucose 5.02 ± 0.42 mmol/l. 6.2% were registered as patients with high risk, men (44.4%) were a slightly less than women (55.6%). The average age was 55.94 ± 5.61 years, BMI 31,66 ± 2,55 kg/m^2, WC 100,72 ± 8,39 cm, blood glucose 5.43 ± 0.46 mmol/l. According to the results of the study very high risk group of the patients was not identified. In the older age group (over 45 years) the proportion of patients at high risk is significantly more prevalent over the proportion of patients under the age of 45 years with the same risk ($R < 0.001$). Hyperglycemia was detected in 43 participants (7.6%) that was mostly in respondents with increased risk for T2D. During the course of correlation analysis it was found that the age of the respondent ($R = 0.25$), WC ($R = 0.24$), BMI ($R = 0.22$), hyperglycemia anamnesis ($R = 0.21$), arterial hypertension ($R = 0.20$) have the greatest impact on the detection of hyperglycemia.

Vitamin D status in a population of type 1 diabetics

Fatima Zahra Zaher, Ghizlane Elmghari & Nawal Elansari
Department of Endocrinology, Diabetes, Metabolic Diseases and Nutrition, Mohammed VI University Hospital, Marrakech, Morocco.

Introduction
Vitamin D deficiency is a health problem related to cardiovascular diseases, autoimmune diseases and cancers. Several studies have shown a significant prevalence of vitamin D deficiency in T1D with positive impact of supplementation on glycemic control. The objective of our work is to evaluate vitamin D status in our T1D patients
Patients and methods
Our study has included 35 patients followed for T1D, vitamin D status was ordered in all patients.
Results
The mean age of patients was 22.5 years, the sex ratio was 1.35 with female predominance. The average duration of diabetes progression was 8.8 years with extremes ranging from 0 to 26 years. The average insulin requirement was 0.85 IU/ kg/day. HbA1C was performed in 54% of our patients and showed poor glycemic control in 88% of cases. Vitamin D levels were within the normal range in 10%, insufficient in 15% and deficient in 75%.
Discussion
Vitamin D deficiency is widely prevalent in T1D, it's able to induce pancreatic islets inflammation inducing an alteration of insulin secretion as well as insulin sensitivity and associated with poor glycemic control. Moreover, it appears that vitamin D has an effect on carbohydrate homeostasis, directly on cell B, and indirectly by regulating calcium levels since insulin secretion is calcium-dependent

Diabetic ketosis profile during the month of Ramadan what are the specificities?

Loubna Oukit, Ghizlane El Mghari & Nawal El Ansari
CHU Mohamed VI, Arrazi's Hospital, Marrakech, Morocco.

Introduction
Sick or tired subject, just like the diabetic patient, is exempted from fasting during Ramadan, when it can jeopardize health or well being. Nonetheless, many people want to keep holding onto this practice. However, diabetes can be revealed in this context. The aim of the study is to evaluate the characteristics of the diabetic ketosis during this month by comparing them to data far from this period.
Patients et methods
Descriptive, retrospective study about patients hospitalized for diabetic ketosis in endocrinology department of University Hospital, during the holy month of Ramadan 1437 (July 2017), the month before and the one after it. The study concerned 64 patients.
Results
20 diabetic patients hospitalized for ketosis during the month of Ramadan, 21 patients the month before and 23 the one after. The average age of the patients was 43.1 years, with a masculine predominance. The average duration of the diabetes was 5.67 years and 35% of these ketosis were inaugural. Our patients fasted during Ramadan in 76% of the cases. The precipitating factor of the ketosis was infection in 45% of the cases, heart disease in 17%, and an interruption of treatment in 38% of the cases, the insulin deficiency was retained in 12% of the cases. Outside of this holy month, the number of cases of ketosis was not significantly different and the commonest precipitating factor stayed infectious in 40% of the cases.
Discussion
The ketosis during Ramadan is thought to be more frequent. The reasons explaining that are the risk of dehydration, a miss dosing the antidiabetic treatment, and due also to insulin and glucagon alteration. The exempted patients that insist on fasting can put themselves in situations of dangerously severe complications. This severe unbalance concerns, as well, the diabetic patients that are not fasting, because their food habits and lifestyle change during this month.

Evaluation of microcirculation in patients with diabetes mellitus by laser doppler fluorometry

Anna Stepanova
First Pavlov State Medical University, Saint Petersburg, Russian Federation.

Laser Doppler fluorometry (LDF) is not an invasive method for diagnosing microcirculation in patients with diabetes mellitus, but the method needs to be improved. Evaluation of the LDF method in patients with diabetic neuropathy (DN) before and after the appointment of vitamin D (VD). Included patients with DM and VD deficiency, DM duration more then 5 years, HbA1c up to 9.0%, non-smokers, signed IC. LAKK-M was used. The value of perfusion was measured-M, σ- average modulation of blood flow and CV –coefficient of variation, two functional tests (postural and occlusive). Patients without changing hypoglycemic treatments were randomized into three groups: 5000 IU (group I) and 40 000 IU (group II) per week cholecalciferol treatment and control group (group III). The duration of observation is 24 weeks. Group I included 12 patients (6F) at the age of 56.1 ($\pm$5.4) with an average HbA1c of 8.17$\pm$0.36% and vitamin 25 (OH) D of 21.4$\pm$3.4 nmol/l. Group II included 12 patients (6F), the mean age was 51.3 ($\pm$5.9), HbA1c 8.35$\pm$0.63%, 25 (OH) D 20.9$\pm$4.1 nmol/l. Group III included 14 patients (7F) HbA1c 7.32$\pm$0.19% and 25 (OH) D 27.1$\pm$1.9 nmol/l. The initial parameters of microcirculation did not differ in the three groups (data given in I-II- III groups): M = 10.63$\pm$1.37, 12.36 ($\pm$2.51), 12.36 ($\pm$1.92), σ = 5.32$\pm$0.79, 4.44$\pm$1, 05, 7.1$\pm$0.38, Kv = 11.36$\pm$1.59, 10.64$\pm$2.93, 15.44$\pm$2.49. After 24 weeks HD we found no changes in group I-HbA1c 8.06$\pm$0.39%, 25 (OH) D 24.68 (P = 0.07), M = 10.30$\pm$1.14 (P = 0.08), σ = 4, 98$\pm$0, 56 (P = 0.05) and Kv = 11.82$\pm$2.38 (P = 0.87). Significant differences were found in group II: HbA1c decreased to 7.42$\pm$0.73% (P = 0.023), 25 (OH) D increased to 60.88 (P = 0.003); All parameters were improved microcirculation M = 19.69$\pm$2.52 (P = 0.003), σ = 6.05$\pm$0.93 (P = 0.005), Kv = 13.36$\pm$3.15 (P = 0.017). The indices of group III did not change statistically significant (P = 0.46). The LDF method for the diagnosis of changes in microcirculation DN was informative in conjunction with functional tests. diabetes mellitus; laser dopplerography; Vitamin D

Serum levels of vitamin B12 in cobalamin deficient subjects with or without diabetes mellitus

Duygu Nurdan Avcı[1], Canan Ersoy[1], Soner Cander[1], Özen Öz Gül[1], Pınar Şişman[1] & Alparslan Ersoy[2]
[1]Uludağ University Medical Faculty, Department of Endocrinology and Metabolism, Bursa, Turkey; [2]Uludağ University Medical Faculty, Department of Nephrology, Bursa, Turkey.

Vitamin B12 or cobalamin is mainly found in animal origin food products. The frequency of vitamin B12 deficiency varies between 3 and 40% in different populations. Metformin is the first-choice therapy for type 2 diabetics having some side effects, one of them being vitamin B12 malabsorption. The study aimed to evaluate serum levels of vitamin B12 in diabetic and non-diabetic patients with cobalamin deficiency.
Methods
Medical records of subjects having a vitamin B12 level $<$180 pg/ml were screened, consecutive 98 subjects (75 females and 23 males with a mean age of 51.3$\pm$15.9 years) were included in the retrospective study. 34 had the diagnosis of type 2 diabetes mellitus. Mean fasting blood glucose level of the diabetics was 128.1$\pm$8.3 mg/dl and mean HbA1c was 6.3$\pm$0.2%. Thirty DM patients were using metformin treatment in a dosage of 2 g/day.
Results
The mean age was 59.0$\pm$10.8 years in diabetics and 47.2$\pm$16.8 years in nondiabetics. Mean BMI was 27.8$\pm$6.2 kg/m^2 and mean vitamin B12 level was 139.3$\pm$29.2 pg/ml for whole population. Mean vitamin B12 level was found to be low in diabetics compared to nondiabetics (131.2$\pm$30.6 and 143.5$\pm$27.7 pg/ml, respectively, P = 0.05). There were accompanying illnesses other than DM in whole group. Thyroid abnormalities without autoimmunity including multinodular goiter were present in 22 patients, dyslipidemia in 16, Hashimoto thyroiditis in 16, hypertension in 10, hirsutism in 5, hyperprolactinemia in 5, gastric problems in four, chronic kidney disease in three, panhypopituitarism in three, osteoporosis in two, heart failure in two, parathyroid adenoma in two, stomach cancer in one and lung cancer in one patient. Among comorbidities, as being autoimmune, Hashimoto thyroiditis can be together with insufficient absorbtion of vitamin B12. In the group with DM only three had accompanying Hashimoto thyroiditis. Vitamin B12 levels of subjects with Hashimoto thyroiditis did not differ those of subjects without Hashimoto thyroiditis (142.6$\pm$32.5 vs. 138.6$\pm$28.7 pg/ml, respectively).
Conclusion
Our results demonstrated that vitamin B12 levels were similar in diabetic and non-diabetic subjects with cobalamin deficiency. All patients with or without the diagnosis of diabetes should be encouraged for sufficient vitamin B12 intake and all possible factors that lead to deficiency should be eliminated.

Are plasmathyrotropin levels associated with degree of obesity and metabolic syndrome in euthyroid obese patients?

Okan Sefa Bakiner[1], Emre Bozkirli[1], Gulhan Cavlak[1], Kursad Ozsahin[2] & Melek Eda Ertorer[1]
[1]Baskent University, School of Medicine, Endocrinology and metabolism disorders, Adana, Turkey; [2]Baskent University, School of Medicine, Familiy Physicians, Adana, Turkey.

We aimed to observe the association between degree of obesity and metabolic syndrome and plasma thyrotropin levels in obese, euthyroid patients. 947 obese and overweight patients who admitted to our outpatient clinic were assessed retrospectively. 150 healthy euthyroid cases were also recruited as the control group. Cases with metabolic syndrome were determined. Patients were divided into various subgroups as overweight, obese, morbid obese, men, and women. No statistical significance was determined when all the patients' and subgroups' plasma thyrotropin levels were compared to normal weight control group. No association was shown between the presence of metabolic syndrome and plasma thyrotropin levels for both all patients and subgroups. Also there was not any association between each component of metabolic syndrome and plasma thyrotropin levels. In conclusion, we did not found any significant association between plasma thyrotropin levels and obesity and metabolic syndrome in our euthyroid-obese cohort.

The efficacy of glp-1 analogue therapy in patient with hypotalamic obesity

Bojana Carić[1,2] & Jelena Malinović Pančić[1,2]
[1]University Clinical Center of Republic of Srpska, Banja Luka, Bosnia and Herzegovina; [2]Faculty of Medicine, University of Banja Luka, Banja Luka, Bosnia and Herzegovina.

Craniopharyngiomas are rare tumors that in a high percentage of patients leads to damage of periventricular nucleus and suprachiasmatic nucleus, what leads to the development of hypothalamic obesity. Hypotalamic obesity is associated with numerous metabolic disorders. Regardless of the numerous studies of new therapeutic approaches, there is still no official approved effective (phramacological or bariatric) treatment for hypotalamic obesity. Liraglutide is an GLP-1 analogue that stimulates insulin released from beta cells of pancreas after eating, suppresses glucagon secretion and induce the weight loss. It is proposed that liraglutide has the peripheral and central effects in the maintenance of weight loss, but the clear mechanism of liraglutide action in CNS is still lacking. We present the case of patient who was diagnosed with craniopharyngioma as a 31 year old after sudden headache attack, followed by vomiting and unconsciousness. CT scan showed an expansive, suprasellar cystic tumor of dimension 25×27X21 mm with pituitary compression. Three years before diagnose of head tumor, the patient had a markedly enhanced appetite, causing the significant weight gain (>20 kg), and consequently the diagnose of arterial hypertension, hyperlipoproteinemia and type 2 diabetes. After the operation of the tumor was performed (PH: Craniopharyngeoma papillare, WHO grade I), endocrinological testing showed panhypopyuitarism and uncontroled diabetes (HbA1c 10.3%) with obesity (BMI 31.9 kg/m^2). Replacement therapy with hydrorortisone, levothyroxine and testosterone were induced, but also the liraglutide as an antidiabetic drug. Three months later, the patient was well hormone substituted and has the better glycemic control (HbA1c 8.2%). Also, he lost 5 kilograms. Continuous loss of the weigt was obsserved 6 months. The plato was achieved on BMI 26.8 kg/m^2 by maximally tolerable dose of 1.2 mg/day of liraglutide, with well-control diabetes (HbA1c 7.3%). Further researches and results of randomized studies are needed in order to prove the efficacy of GLP-1 analogues as therapy for hypothalamic obesity.

Relation between eating behaviors, exercise and weight loss in post bariatric period

Claudine CIta[1], Manelle Benbouaziz[1], Marinos Fysekidis[2], Jean-Marc Catheline[1] & Régis Cohen[1]
[1]Hôpital Delafontaine, Saint-Denis, France; [2]Hôpital Avicenne, Bobigny, France.

We analyzed the eating behavior and physical activity in patients operated in our obesity surgery center and their relation to weight loss. We mailed to patients a simple self-questionnaire to assess the use of eating or physical activity advices given from our stuff during the preoperative period. Patients had a bariatric surgery from September 1, 2013 to August 2016 Questionnaires were collected during their follow-up (September 2017). One hundred forty four out of 750 patients answered this questionnaire. The mean age was 45 ± 10.48 years, 81% were women, the average BMI before intervention was 45.03 ± 7.1 kg/m^2 and 133 had longitudinal sleeve gastrectomy. The mean BMI loss was 13.92 kg/m^2 and the average follow-up 2.07 years. Analysis of the questionnaires revealed that 64% of patients had physical activity that lasted less than 30 min/day Among patients 46% declared abnormal hungriness, 60% completed their meal in less than 20 min, 18.7% had regular chewing gum consumption, 32% had more than three snacks a week in, 66% had sugar consumption more than twice a week in, and 18% had less than three meals a day Female sex and a meal duration <20 min and meal duration <20 min were significantly related to lower BMI loss (13.4 vs 15.8 kg/m^2, $P=0.0049$; 13.6 vs 14.4 kg/m^2, $P=0.0002$; 12.2 vs 14.3 kg/m^2, $P=0.0307$; respectively). Fast eating was related to a lower weight loss in bariatric surgery patients.

Weight loss 6 months after sleeve gastrectomy

Marwa Omri, Faten Mahjoub, Nadia Ben Amor, Sabeh Bhouri, Awatef Kacem & Henda Jamoussi
National Institute of Nutrition of Tunis, Tunis, Tunisia.

Aim
The aim of our study was to evaluate the impact of sleeve gastectomy on weight loss 6 months after surgery.
Methodology
This was a prospective study including 30 obese patients undergoing sleeve gastrectomy. Their weight,height, BMI, fat mass index and waist circumfernce, were measured at baseline and 6 months after surgery.
Results
Mean patient age was 36.77 ± 7.82 .80% of the study patients were women. There were significant changes in all anthropometric measurments before and after surgery. Average excess weight and average excess BMI lost at 6 months were respectively 43.53 and 50.37%.There was a significant association between excess weight lost and respectively age,preoperative BMI,preoperative fat mass index and preopeartive waist circumfence.
Conclusion
Our data suggest that sleeve gastrectomy is an effective procedure in morbidly obese patients that leads to an important weight loss.

Diabetes during paraneoplastic cushing: about two cases

Marwa Khiari, Ibtissem Ben Nacef, Nadia Mechrigui, Youssef Lakhoua, Karima Khiari & Nejib Ben Abdallah
Department of Internal Medicine 'A', Endocrinology Unit, Charles Nicolle Hospital, Tunis, Tunisia.

Diabetes in paraneoplastic Cushing is often severe with a risk of acute metabolic complications.
Observation n° 1
A 36-year-old patient, with no medical history, was hospitalized for inaugural diabetic ketoacidosis with no intercurrent infection. The physical examination found facio-truncal obesity, amyotrophy of extremities, melanoderma, arterial hypertension and severe psychiatric disorders. The blood tests showed an hypokalemia at 1.9 mmol/l. High doses of insulin were required to control the diabetes. The diagnosis of an ACTH-dependent Cushing Syndrome was retained in the presence of high cortisol levels (2000 nmol/l), non-suppressed after dexamethasone suppression test (DST), and high ACTH levels at 466 pg/l. Conventional localization techniques (Hypothalamic-pituitary MRI, cervico-thoraco-abdominopelvic CT, bronchial fibroscopy, octreoscan scintigraphy) failed to show any tumor. Bilateral adrenalectomy (in two phases) was performed because of the severity of the patient's condition with no obvious etiology. The clinical course was marked by an improvement of the clinical signs and even a diabetes remission (we stopped all antidiabetic drugs). Two years later, Cushing syndrome recurred with the reappearance of diabetes requiring an insulin therapy. Cervicothoracic CT showed a right anterior mediastinal nodule and it was octreoscan-positive. The patient had a total thymectomy. Histology confirmed an atypical carcinoid stage III thymos tumor. The patient underwent radiotheray. The Cushing syndrome disappeared and the diabetes was well balanced under low metformin dose.
Observation n°2:
A 35-year-old patient with no medical history, smoking 35 pack-year, was hospitalized for inaugural diabetic ketoacidosis requiring intensive insulin therapy. The physical examination found a patient with debilitating medical conditions, facio-truncal obesity and melanoderma. The blood tests showed an hypokalemia. The diagnosis of ACTH-dependent Cushing was retained in the presence of hypercorticism (cortisol = 2900 nmol/l), non-suppressed after DST, and high ACTH levels (980 µg/l). This was a paraneoplastic cushing due to pulmonary neoplasia identified on chest X-ray and thoracic CT. The diabetes remained very unbalanced (Glycemia at 30 mmol/l) despite high doses of insulin (>0.5 IU/kg per day). The evolution was quickly fatal. The patient died of acute respiratory failure during bronchial fibroscopy.
Conclusion
These two cases clearly show that secondary diabetes can be very severe and difficult to balance based on the severity of the underlying endocrinopathy.

Diabetes profile during cyclic Cushing syndrome: about one case

Marwa Khiari, Imen Rojbi, Nadia Mechergui, Youssef Lakhoua, Karima Khiari & Nejib Ben Abdallah
Internal Medicine Department 'A', Endocrinology Unit, Charles Nicolle Hospital, Tunis, Tunisia.

Endogenous Cushing's syndrome comes generally with permanent hypercorticism often complicated by diabetes which can be difficult to control. However, the cortisol's excessive production may be cyclic or intermittent, and, therefore, complications may have a specific course which leads to diagnostic and therapeutic delay.
Observation
We report the case of a 28-year-old woman with no previous medical history who was hospitalized for a Cushing's syndrome. The clinical picture was marked by severe hypertension requiring triple therapy and poorly-controlled diabetes under intensified insulin therapy (0.7 IU/kg per day). Cushing disease was diagnosed in the presence of high cortisol levels (800 nmol/l), not suppressed after dexamethasone suppression test, and high ACTH levels (106 μg/ml). Surgery was not indicated since the pituitary MRI was normal but the evolution was spontaneously favorable. The clinical signs of Cushing syndrome regressed, blood pressure levels got back to normal and diabetes was cured (we stopped all diabetes medications) for eight years, then Cushing syndrome recurred. The diabetes reappeared requiring once again high doses of insulin (0.9 IU/kg per day). The hormonal assessment was in favor of Cushing disease and the pituitary MRI did not show any abnormalities. Once again, the patient went spontaneously into remission. Blood glucose levels were well-controlled only by metformin. Four years later, Cushing's syndrome recurred a second time. Diabetes reappeared requiring intensive insulin therapy (0.6 IU/kg per day). Pituitary MRI showed a microadenoma. The patient underwent surgery with complete remission of the Cushing' syndrome and was cured from her Diabetes.
Conclusion
This case highlights the hyperglycemic hormones role in the genesis of diabetes through its cyclic evolution during a cyclic Cushing.

Diabetes mellitus development secondary to chronic pancreatitis in a kidney transplant recipient

Alparslan Ersoy[1], Nimet Aktaş[2], Ayşegül Oruç[1], Abdülmecit Yıldız[1] & Canan Ersoy[3]
[1]Uludag University Medical Faculty, Department of Nephrology, Bursa, Turkey; [2]University of Health Sciences, Bursa Yuksek Ihtisas Training and Research Hospital, Bursa, Turkey; [3]Uludağ University Medical Faculty, Department of Endocrinology and Metabolism, Bursa, Turkey.

Acute pancreatitis in kidney transplant recipients is an infrequent complication with complex etiology. However, there was no enough data about chronic pancreatitis after kidney transplantation. Glucose intolerance occurs with some frequency in chronic pancreatitis, but overt diabetes mellitus usually occurs late in the course of the disease. We presented long-term course of a kidney transplant recipient who developed recurrent acute pancreatitis.
Case report
A 43-year-old female patient underwent cholecystectomy due to pancreatitis attack secondary to cholelithiasis on January 2008. She had no history of obesity, dyslipidemia, diabetes and alcohol abuse. She received a successful kidney transplant from a deceased donor in our center on March 2008 because of end-stage kidney disease. Post-transplant immunosuppressive treatment consisted of prednisolone, mycophenolate sodium and everolimus. Gemfibrozil was started 600 mg daily due to her high serum triglyceride level (592 mg/dl) on May 2008. After a week, she was admitted to the emergency service because of abdominal pain, nausea, vomiting, mild dehydration and upper abdominal tenderness. Her tests revealed a serum glucose of 120 mg/dl, total cholesterol 306 mg/dl, triglyceride 323 mg/dl and amylase 746 IU/l. Acute pancreatitis complicated by a pseudocyst was diagnosed and treated. Hyperglycemia that developed during this period was treated with insulin administration. Fenofibrate and pravastatin were started. After sphincterotomy to pancreatic duct and a biliary stent insertion by ERCP, her complaints resolved. Then, the pancreatic biliary stent was removed. In 2009 and 2016, acute pancreatitis recurred due to stones. The head and corpus of pancreas were atrophic. Pancreatic duct was enlarged. In 2013, a 2-h oral glucose tolerance test was performed due to hyperglycemia (fasting glucose 129 mg/dL and 2nd hour glucose 178 mg/dl, HbA1c 6.5%). The patient was started insulin glargin treatment (10 U/d) with a diagnosis of secondary diabetes mellitus. Then, metformin (2×500 mg) was added to the treatment. She went on her follow-ups with a serum creatinine of 0.8 mg/dl (glucose; fasting: 89 mg/dl, postprandial: 108 mg/dl, HbA1c 6.2%, total cholesterol 211 mg/dl, HDL cholesterol 65 mg/dl, LDL cholesterol 110 mg/dl and triglyceride 176 mg/dl) with medical treatment.
Conclusion
Chronic pancreatitis is an inflammatory condition. The clinical manifestations of this disorder include chronic abdominal pain and pancreatic exocrine and endocrine dysfunction leading to secondary diabetes. When needed, these patients should be treated with insulin and oral hypoglycaemic agents.

Familial chylomicronemia with multiple complications

Sebai Imen, Amrouche Chiraz, Mahjoub Faten, Berriche Olfa & Jamoussi Henda
National Institute of Nutrition, Tunis, Tunisia.

Background
Familial chylomicronemia is a rare disorder of lipoprotein metabolism characterized by severe fasting hypertriglyceridemia. We present here a case of severe familial chylomicronemia with multiple complications.
Case presentation
A 35-year-old Tunisian woman was suffering from chylomicronemia (Fredrickson type I hyperlipoproteinemia) since the age of 10 years old. Her dyslipidemia was caused by a lipoprotein lipase deficiency. Since her childhood, she was instructed to adhere to a low fat diet with prescription of omega-3-fatty acids. Her diet was sometimes enriched with medium chain triglycerides (MCT). However, her adherence was unsatisfying. Her last laboratory examination revealed a milky blood sample, marked elevation of Triglyceride (41.29 mmol/l), of cholesterol (91 mmol/l) and of gamma-glutamyl transferase (11*normal) whereas hemoglobin was remained low at 8 g/dl. Her liver transaminases, alkaline phosphatase, lactate dehydrogenase and amylase were normal. Her past medical history revealed recurrent bouts of pancreatitis since she was 25 years old. All the episodes of acute pancreatitis were associated with major hypertriglyceridemia. There was a history of eight episodes of acute pancreatitis with the development of severe local complications. Two pancreatic pseudocycts were formed. The patient had undergone a gastro-entero-anastomosis for the biliary-digestive compressive syndrome caused by pancreatic pseudocycts. Further hospital admissions occurred because of gastro-esophageal variceal bleeding. Indeed, pancreatic pseudocycts were complicated by regional portal hypertension that gave rise to gastric and oesophageal varices. The patient was kept under beta-blocker (propranolol) treatment. Endoscopic injection of biological glue was performed. For her, it required 17 sessions. Her first pregnancy was interrupted because of the occurrence of acute pancreatitis at the 24th week of pregnancy. Fortunately, thanks to good adherence to low fat diet, her chylomicronemia was successfully managed during her second pregnancy and a healthy preterm infant was born at 35 weeks of gestation.
Conclusion
In conclusion, this case shows the large number of complications that may cause familial chylomicronemia. The ffective management of hypertriglyceridemia would potentially decrease the occurerence of complications. Hence, health providers in should underscore the benefits of continuing and adhering to the low fat diet.

EP52

Association of hyperlipidemia with cancer colon

Aasem Seif, Hemmat El Haddad, Maha Hussein & Heba Baz
Cairo University, Cairo, Egypt.

A 46-year old male patient, living in Giza, father of 4, used to work as a baker. He is an ex-smoker. He has diabetes on insulin for 4 years, not hypertensive.He was diagnosed to have colonic carcinoma upon which surgical intervention was done in the form of right hemicolectomy with splenectomy and cholecystectomy. Postoperative pathology report revealed invasive moderately differentiated adenocarcinoma. He received postoperative chemotherapy, twelve sessions over the past one and half years. During the treatment he developed recurrent attacks of pancreatitis and was discovered to have hyperlipidaemia upon which four sessions of plasmapharesis were done and the patient was discharged on statins and fibrates. One of his brothers has diabetes and cancer colon, the other brother has colonic polyps. His uncle and two of his cousins died from cancer

colon. There is positive consanguinity. There is a family history of ischemic heart disease.
Examination
The patient is cachectic, BMI: 19.5 kg/m^2, Blood Pressure: 110/70. Pulse: 100 BPM regular, Temp: 37.2–37.6 °C, RR: 16/min. Head and neck examination showed wasted masseter & temporalis with prominent zygoma. Fundus examination was normal. Abdominal examination showed mid line scar 25 cm healed by secondary intension, appendectomy scar healed by secondary intension, no organomegaly. Chest, cardiac and neurological examination were free.
Investigations
CBC, kidney and liver functions, serum amylase and lipase were in the normal range. HbA1c: 13.74%, (4–5%), total cholesterol: 870 (200 mg/dl),triglycerides: 9527(150 mg/dl),HDL: 227 (60 mg/dl),LDL: 57 (160 mg/dl). Echocardiography showed grade I diastolic function. Contrast CT abdomen and pelvis showed no focal lesions or dilated IHBRs, normal CT appearance of the pancreas, spleen, aorta, IVC and both kidneys. No areas of abnormal pelvic enhancement or collections. No pathalogical enlarged LNs, no ascites.
Conclusion
Our patient had familial adenomatous polyposis (FAP) which is characterized by the development of hundreds to thousands of colonic adenoma, it usually leads to inevitable colorectal carcinoma in untreated individuals. FAP are caused by germline mutations in Adenomatous Polyposis Coli (*APC*), which encodes a tumor suppressor that is part of the WNT signaling pathway. The link between germline mutations and APC FAB & hyperlipidemia that it was found experimentally, that mice with mutation of APC gene show decreased adipogenesis but paradoxically elevated serum lipid level. It is caused by downregulated expression of FFA use genes in white adipose tissue (WAT) of old mice.

Vascular surgeons: do they ask enough?

Maria Molina Vega[1], Pilar Losada Mora[2], Alfonso Garrido Castro[3] & Juan L Carrillo Linares[3]
[1]Endocrinology, Hospital Virgen de la Victoria, Malaga, Spain;
[2]Cardiology, Hospital Virgen de la Victoria, Malaga, Spain;
[3]Internal Medicine, Hospital Virgen de la Victoria, Malaga, Spain.

Introduction
Consultations are a common practice among different units of a hospital. In particular, those from the Vascular Surgery Service (VS) to the medical units are some of the most frequent.
Objectives
Analyze the total number of consultations performed from the Vascular Surgery Service (VS) service to a medical team (T) specifically assigned to the control of decompensated medical conditions in surgical areas, in relation to the number of total admissions in that area.
Material and methods
Descriptive analysis on the total number of consultations sent quarterly from VS to T. It is compared to the total number of VS admissions.
Results
From January 2011 to November 2014 173 consultations were sent from VS to T. The total number of consultations progressively increased in time. There was a very significant decrease in the 3rd quarter of 2013, due to the assignment of VS admitted patients to a new professional who was not informed of the existence of T, sending 2 consultations during the trimester. These figures were compared with the total number of VS admissions during the same period. The number of admissions remained approximately constant throughout the period, with the lowest numbers declining in the third quarter of each year, coinciding with the summer holiday period. In the first year of T activity, the% of patients consulted is slightly higher than 6%. Subsequently stabilizes around 10% (except for the aforementioned 3rd trimester of 2013) of hospitalized patients. In 2014 the percentage decreases to 7.36%.
Conclusions
There is an increased demand for the assessment of patients admitted by VS to Internal Medicine, Nephrology, Penumology, Endocrinology and Cardiology in the first year of T. Although this demand tends to stabilize later around 10%, in the last year it decreases, probably due to the interest shown by VS professionals in improving the control of the medical decompensations of their patients. This did not correspond to a higher or lower number of VS admissions. Taking into account the great comorbidity and vascular risk factors of VS patients, the data suggest a good control of the medical decompensations by VS professionals.

EP54

Diabetes and other frequent clinical problems in patients admitted in vascular surgery

Maria Molina Vega[1], Pilar Losada Mora[2], Alfonso Garrido Castro[3] & Juan L Carrillo Linares[3]
[1]Endocrinology, Hospital Virgen de la Victoria, Malaga, Spain;
[2]Cardiology, Hospital Virgen de la Victoria, Malaga, Spain;
[3]Internal Medicine, Hospital Virgen de la Victoria, Malaga, Spain.

Objectives
To analyze the most frequent consultations on patients admitted to VS sent to a medical team (T).
Material and methods
Descriptive analysis of consultations on patients admitted to the VS who suffered any medical decompensation that needed to be notified to Internal Medicine, Cardiology, Endocrinology, Nephrology or Pneumology.
Results
From February 2011 to November 2014, 173 consultations were sent from the VS Service to T. The most common consultation was 'dyspnea' in 62 (35.8%), followed by "pluripathology control" in 18 (10.4%), "decreased level of consciousness" in 13 (7.5%), 'fever' in 13 (7.5%), 'renal failure' in 7 (4%) and "blood pressure control" in 7 (4%) patients. The reason for the consultation was 'poorly controlled DM' in 8 patients (4.6%) of whom had hyperglycemia 4 (50%) and hypoglycemia, 4 (50%) as well as "control of vascular risk factors" in 18 (10.4%). However, after analysis of all patients, only 22 (12.7%) were diagnosed as decompensated DM in the discharge report.This implies a real decompensation of 23.4% of patients with known DM.
Conclusions
More than one third of the consultations for medical decompensations in the patients admitted to the VS unit correspond to dyspnea. DM is a single cause of medical decompensation in 4.6% of patients admitted to VS. However, associated with decompensation of other vascular risk factors, one out of four known diabetics had abnormal blood glucose levels. We suggest that an early evaluation of all these processes that could induce to heart failure, blood glucose and blood pressure performed by Cardiology, Endocrinology or Internal Medicine could be beneficial in terms of morbidity and hospital stay, since previous studies associate the diabetic uncontrolled in patients admitted to Vascular Surgery to an average stay 9 days superior compared to non-diabetics.

The risk of symptomatic hypoglycemia over 4 years of intensive insulin treatment and combined therapy in type 2 diabetes patients

Said Ismailov & Alexandra Vodovskaya
Tashkent Paediatric Medical Institute, Tashkent, Uzbekistan.

The aim
To evaluate the risk factors for symptomatic hypoglycemia (SG) over 4 years of intensive insulin treatment (IIT) and combined therapy (CT) in type 2 diabetes.
Material and methods
Under our supervision in the departments of the Center of Endocrinology of PH Ministry of RUz in the period from September 2016 for December, to 2017, 20 patients were observed with DM 2, men – 9, women – 11; 54.5 ± 1.5 m/61.6 ± 1.8 w years old. The remoteness of disease hesitated in limits from 7 to 9 years. All patients were observed by standard rules.
Results
Patients were distributed on two groups: 1 gr – 10 patients (5/5), which received IIT, 2 gr – 10 patients (4/6) on CT (insulin + Metformin, SM, etc). In 1st gr BMI 28.5 ± 1.5/27.14 ± 1.8, in 2 gr – BMI 36.6 ± 1.4/31.6 ± 1.2. For patients with DM 2 on IIT we found the duration of IIT – more than 3.6 years for men and 5 years for women. In second group the start of IIT – more than 3.75 years for men and 5.1 years for women. The middle range of HbA1C in 1st gr: 7.3 ± 0.2 for men and 7.9 ± 0.4 for women. The middle range of HbA1C in 2nd gr: 8.4 ± 0.4 for men and 8.02 ± 0.5 for women. Among comprehensive diseases we found in 1st gr: ischemic heart disease (IHD) 1/3, arterial hypertension (AH) 5/5, dislipidemiya (D) 0/1, liver cirrhosis 1/0, diabetic nephropathy (DN) II-III 5/2. In 2nd gr: IHD 0/4, AH 4/4, D 1/0, DN II-III 3/4.All patients have diabetic encephalopathy I-II
Conclusions
1) For patients with DM 2 on IIT among risk factors of symptomatic hypoglycemia we found the AH and DN, for DM 2 on CT – AH, DN, BMI – 36.6 ± 1.4/31.6 ± 1.2 for men and women. 2) For patients with DM2 on ITT and CT among risk factors of symptomatic hypoglycemia we found diabetic encephalopathy I-II.

DOI: 10.1530/endoabs.56.EP55

An uncommon case of diabetic mastopathy

Rujuta Katkar, Manasi Shah & Antoine Makdissi
University at Buffalo, Buffalo, NY, USA.

Objective
Diabetic mastopathy (DMP) is an uncommon fibrous disease of the breast, most commonly found in premenopausal women with type 1 diabetes exposed to long-standing insulin therapy. Often mimicking breast cancer clinically and on imaging, this condition poses a diagnostic challenge requiring pathological confirmation.
Case presentation
A 68-year-old woman with type 1 DM and a family history of breast cancer in paternal aunt had an abnormal screening mammogram showing a lobular nodular density in the subareolar region deep to the nipple measuring atleast 2.5 cm in the left breast. Ultra Sound (US) showed a hypoechoic, heterogenous mass 2 cm from the nipple, measuring $41\times13\times46$ mm with relatively circumscribed margins, demonstrating some internal blood flow on Doppler. Lymph nodes were normal. Patient underwent US-guided biopsy. Pathology showed hyalinized stromal fibrosis and chronic mastitis. Within a short period of time, patient presented with a painless palpable area in the right breast. Mammography and US of right breast showed a very dense tissue in the palpable area of concern, corresponding to heterogeneous, slightly hypoechoic mass with relatively circumscribed margins measuring $38\times18\times65$ mm with internal vascularity. It had a very similar appearance to the area that was biopsied on the left breast. Given the bilaterality and history of diabetes, a preliminary diagnosis of bilateral diabetic mastopathy (DMP) was made. A decision was made to follow up annually with regular mammography. Later, patient developed retraction in the skin and nipple areolar complex in both breasts. Mammogram and US of both breasts revealed large densities that were relatively stable, however the skin changes prompted repeat biopsies. Thickened tissue on both breasts was excised and sent for pathology revealing features consistent with DMP.
Discussion
Patients with DMP clinically present with painless, irregular, hard, unilateral or bilateral breast masses. It is rare as it represents 0.6% to 13% of benign lesions observed in woman with type 1 diabetes. The pathogenesis is not fully understood but many theories involving the effects of sustained hyperglycemia and glycosylated end products on the connective tissues of the breast have been proposed. Malignant transformation has not been described.
Conclusion
This case underlines the importance of considering diabetic mastopathy in the differential diagnoses when evaluating breast lesions in women with diabetes. Recognizing the presentation of this rare condition can help avoid unnecessary surgical intervention.

Dermatologic manifestations ofdiabetes mellitus-diabetic thick syndrome

Anca E Chiriac[1], Tudor Pinteala[1], Anca Chiriac[2,3] & Doina Azoicai[4]
[1]University of Medicine and Pharmacy 'Grigore T Popa', Iasi, Romania; [2]Nicolina Medical Center, Iasi, Romania; [3]Apollonia University, Iasi, Romania; [4]University of Medicine and pharmacy 'Grigore T Popa', Iasi, Romania.

A broad spectrum of cutaneous disorders may be diagnosed in patients with type 1 and type 2 diabetes mellitus. Some of dermatologic lesions may precede any clinical or biochemical evidence for diabetes, while others are considered well known complications of the metabolic disorder. We highlight typical, rare dermatological manifestations of diabetes, excluding infectious, disorders related to complications of diabetes mellitus and skin conditions induced by treatment of diabetes. Cutaneous marker for diabetes are important to be recognized rom early stages, although they are rare or misdiagnosed.
We present case series of diabetic thick syndrome classified as follows:
1) clinical asymptomatic
2) hand skin thickening presenting as
- 'waxy skin'
- finger pebbles
- 'velvety' skin over the small joints of the digits
- knuckle pads

3) scleredema adultorum

EP58

Influence of vitamin D therapy on albuminuria in patients with type 2 Diabetes mellitus

Hanna Fadieieva
Sumy State University, Sumy, Ukraine.

Background
Vitamin D deficiency has been shown to be a risk factor related to diabetes mellitus (DM). Some studies suggest an association between diabetic kidney disease (DKD) and vitamin D (VD).
Aim
To evaluate the effect of the vitamin D therapy on albuminuria in type 2 DM patients.
Methods
There was a 4-month study (January – April 2017) of 48 participants on stable antihyperglycemic (metformin and/or sulfonylurea) and antihypertensive treatment (including angiotensin II receptor blocker). Patients were randomized into two groups: 24 patients of the Ist group received 2000 IU/day of cholecalciferol for 16 weeks, the IInd group of 24 patients continued antihyperglycemic and antihypertensive treatment. BMI, glomerular filtration rates (GFR), hemoglobin A1c (HbA1c) were estimated. Inclusion criteria: type2 DM patients with HbA1c $\geq$7%; GFR $>$90 ml/min/1.73 m^2, duration of DM no more than 10 years, controlled arterial hypertension. Exclusion criteria were bone metabolism and liver diseases. Serum 25(OH)vitaminD, low-density lipoprotein cholesterol (LDL-C), HOMA-index, urinary albumin excretion rate (UAER) obtained before and after 4-month period of treatment. Quantitative data are expressed as the mean$\pm$S.D. The Student's *t*-test was used to compare data before and after VD supplementation. The correlation between variables was assessed using the Pearson correlation coefficient. All information was processed with SPSS 21.0.
Results
The mean age of the participants was (54 ± 6.8) years, BMI – (30.9 ± 2.41) kg/m^2, HOMA – (6.3 ± 2.30), HbA1c – (7.8 ± 0.85)%, the baseline UAER – (69.8 ± 37.62) mg/24 h, the mean 25(OH)vitamin D – (28.5 ± 5.80) ng/ml, LDL-C – (3.1 ± 0.74) mmol/l. 25 (OH) vitamin D levels were inversely associated with BMI ($r=-0.4$; $P=0.05$), HOMA ($r=-0.7$; $P=0.005$), UAER ($r=-0.7$; $P=0.005$), LDL-C ($r=-0.4$; $P=0.02$). Compared with the IInd group, vitamin D therapy had no significant effect on HOMA, plasma LDL-C concentration and UAER ($P>0.5$). UAER was reduced but only four patients of 24 had their DKD stage improved.
Conclusion
Strong inverse correlation between 25(OH)vitamin D levels and albuminuria can indicate on benefits of vitamin D supplementation for prevention of DKD in diabetic patients. Although cholecalciferol therapy did not decrease urinary albumin excretion rate and LDL-C concentration significantly in patients with diabetic nephropathy the sample size of our study needs to be enlarged to reinforce data.

Gender differences in patients with coronary heart disease and diabetes. A retrospective study

Mariana Tomé Fernández-Ladreda[1], Ana Isabel Jimenez[2] & Lourdes Garcia Garcia-Doncel[3]
[1]Hospital Punta De Europa, Algeciras, Spain; [2]Hospital Puerto Real, Puerto Real, Spain; [3]Hospital De Jerez, Jerez, Spain.

Introduction
There are known biological differences between men and women in coronary heart disease. It is important to know these differences in order to avoid inequalities in prevention, diagnosis and treatment of this pathology.
Methods
We designed a retrospective, descriptive study in which we included all diabetic patients admitted to the hospital with acute coronary syndrome in 2016. Demographic data and degree of control of risk factors were registered.
Results
We studied 132 patients (60.6% men; mean age 68.7 years), 47.7% had a prior acute coronary event. We observed that our female population was older (72.15 vs 68.08 years, $P<0.05$), had more prevalence of high blood pressure (92.3% vs 72.5%, $P<0.05$) and less smoking habit (44.7% vs 55.3%, $P>0.05$). Degree of control of risk factors was slightly better in men group although we did not observe a significant difference (HbA1c $<$7% in 51.3% of men and 46.2% of women; LDL$<$100 mg/dl in 62.5% of men and 53.8% of women). We found a significant difference in lethality between both groups (15.38% of women vs 1.25% of men, $P<0.05$).

Conclusions
As it is described in literature we observed a later development of coronary heart disease in women of our sample and more lethality. The degree of control in our group was unsatisfactory and it was slightly poorer in women. A greater awareness of the differences in presentation of acute coronary syndrome between men and women, with gender-based interpretation of diagnostic tests, is mandatory for health care professionals to improve therapeutic strategies and outcomes in women.

Diabetic foot ulcers (DFU) in eastern India: an observational

Edward Jude[1,2], Ghanshyam Goyal[3], Rashmi Sahay[4], Resmi Gupta[4], S Banka[3], Rekha Srivastava[3], Shammi Kapoor[3] & Jaydeep Mazumder[3]
[1]University of Manchester, Manchester, UK; [2]Tameside Hospital NHS Foundation Trust, Ashton under Lyne, UK; [3]ILS Hospital, Kolkata, India; [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, USA.

Foot ulceration in diabetes is known to represent a major cause of morbidity and mortality, and carry considerable financial implications for healthcare organisations. Little research has studied the outcomes for patients with foot ulcer in Eastern India. We identified 717 patients aged 18 years and over with Type 2 diabetes mellitus (T2DM) who presented for management of their diabetic foot ulcers from February 2013-February 2016 with mean follow up of 2 years. Methods: Of the 717 patients (574 male (71.4%), mean age 56 (range 49–63) years); 645 (89.9%) healed during follow up. We compared risk factors between healed and non-healed ulcers. All patients received standard of care including off loading where appropriate.
Results
There was no difference in age, gender, duration of diabetes and HbA1c and site or number of ulcers on the feet or amputation between healed and non-healed groups; but patients were heavier in the latter group. There was however increased vascular calcification in the non healed group and also higher Wagner grade but more use of total contact casting (TCC). In a multivariable logistic regression analysis the odds ratios for non-healing were: weight (1.02), duration of ulcer (1.27), higher Wagner classification (1.52), vascular calcification (yes/no) (2.21) and use of TCC (2.24).
Conclusion
Calcification of foot arteries, higher grade ulcers, longer duration of ulcer and patient's weight play a role in non-healing. Having a better understanding about the risk factors involved in the non-healing of DFU and treatment strategies provided will help in reducing the prevalence of foot ulcers. Further studies are required to see if these modifiable risk factors need to be looked at to improve wound healing.

What is the knowledge of a population of Tunisian diabetic women on the diabetic foot?

Chaima Jemai, Nadia Ben Amor, Amal Smida, Senda Sellami, Mariem Zarrouk, Hajer Tertek, Aroua Temessek & Faika Ben Mami
Institut National De Nutrition De Tunis, Tunis, Tunisia.

Introduction
The diabetic foot is a public health problem in Tunisia. The objective of our study is to evaluate the knowledge of diabetic patients on this entity.
Material and method
This is a prospective study involving 60 diabetic patients hospitalized at C service of diabetology and nutritional diseases at the National Institute of Nutrition of Tunis. The knowledge of these diabetics was assessed using a pre-established questionnaire.
Results
The mean age was 57.35 years $\pm$ 11.22. The average BMI was 29.45 kg/m^2 $\pm$ 4.55. Diabetes was type 2 in most cases, poorly balanced in all patients with an average HbA1C of 10.23% $\pm$ 1.55. The cardiovascular risk factors associated with diabetes in our patients were: sedentary lifestyle (90%), obesity (76.6%), menopause (61.6%), hypertension (46.6%), dyslipidemia (41%), 6%) and smoking (15%). Only 26.6% of patients received a prior education in foot hygiene. 58.3% associate this foot injury with arterial disease (43.3%) and neuropathy (15%). All patients report foot infection as a triggering factor. The clinical signs according to our patients are: mycotic infections, trolling bacterial infections, amputations, gangrenes and plantar perforators. The mistakes made by our patients were: the lack of daily inspection of the feet (100%),
Conclusion
Regular diabetic foot education sessions are extremely important in teaching patients simple and practical actions that limit potentially serious complications.

Predictive factors of hyperuricemia in diabetics Type 2: About 168 cases

Halima Fennoun, Siham El Aziz, Salma Bensbaa & Asma Chadli
The Endocrinology Department of IBN Rochd University Hospital, Casablanca, Morocco.

Introduction
Hyperuricemia is common in type 2 diabetics particularly in patients with very high cardiovascular risk.
Objective
To evaluate the relationship between hyperuricemia and type 2 diabetes, and to determine its predictive factors in this population.
Patients and methods
A retrospective cross-sectional study including168 patients with type 2 diabetes who were hospitalized in the endocrinology department of Ibn Rochd University Hospital, Casablanca from January 2015 to January 2017. Hyperuricemia was defined by a serum uric acid concentration $>$70 mg/l (men) and $>$60 mg/l (women). Variables studied were anthropometric measurements), cardiovascular factors (tabagism, hypertension, dyslipidemia) and degenerative complications (retinopathy, neuropathy, renal insufficiency, ischemic heart disease). Analyziswas performed by the SPSS software.
Results
Average age of our patients was 53.8 years (27–81).Hyperuricemia was found in 28% of patients with a clear predominance of women (78.9%, $P<0.30$), an average age of 56.5 years, and a mean diabetes duration of 12.3 years. Glycemic imbalance was found in 84.6% of the cases with a glycated hemoglobin average of 8.4% ($P<0.30$). Predictive factors prevalence for hyperuricemia were smoking objectified in 7.6% of patients ($P<0.90$), obesity in 62.1% ($P<0.10$), which was moderate in 22.5% ($P<0.20$) and morbid in 20.3% (p <0.30). 85% of patients were hypertensive ($P<0.05$), 80.3% were dyslipidemic ($P<0.001$) with hypertriglyceridemia in 58.3% of cases ($P<0.02$), and hypoHDLemia in 38% ($P<0.001$). The search for degenerative complications related to hyperuricemia showed retinopathy in 52.8% of patients ($P<0.10$), neuropathy in 28.6% ($P<0.9$), renal failure (GFR between 15 and 60 ml/min) in 53% ($P<0.001$), which was moderate in 42.8% ($P<0.01$) and severe in 11.1% ($P<0.02$). Ischemic heart disease was found in 45.8% of cases ($P<0.01$).
Discussion
In our study, hyperuricemia in type 2 diabetic patients is common in female patients, particularly with hypertension, dyslipidemia and renal failure. Other factors such as age, obesity, smoking are not related to hyperuricemia in type 2 diabetics.

Sympathetic hyperactivity and sleep disorders: is Type 2 diabetes the link between these two situations?

Carolina López-Cano[1,2], Liliana P Gutierrez-Carrasquilla[1], Enric Sánchez[2], Anna M Gaeta[3], Raquel Marti[2], Marta Hernández[1], Gonzalo Cao[4], Merce Ribelles[4], Xavier Gómez[5], Marta Sánchez[1], Chadia Mizab[1], Ferran Barbe[2,3] & Albert Lecube[1,2]
[1]Endocrinology Service, Hospital Universitari Arnau Vilanova, Lleida, Spain; [2]Institut de Recerca Biomedica, Lleida, Spain; [3]Pneumology Service, Hospital Universitari Arnau Vilanova, Lleida, Spain; [4]Hospital Universitari Arnau Vilanova, Lleida, Spain; [5]Medicine Department, Universitat de Lleida, Lleida, Spain.

Results
Main clinical, analytical and polygraphic data: 58.1 $\pm$ 6.4 years, body mass index 32.4 $\pm$ 5.4 kg/m^2, 70.4% female, HbA1c 8.0 $\pm$ 1.9%, AIH 27.4 events/hour (in the range of severe sleep apnea and hypoapnea index), and CT90% 32.9%. Nocturnal concentration of urine total metanephrines were higher than diurnal levels (226 $\pm$ 12 vs 98 $\pm$ 13 µg/l; $P=0.085$). In addition, its nocturnal concentration was significantly associated, in a positive way, with both the AIH and the CT90;

however, this association disappeared when the diurnal concentration was evaluated. Furthermore, nocturnal concentration was also associated with a decrease in resting parasympathetic tone. In the multivariate analysis, the concentration of urine metanephrines at night independently predicted CT90 ($P=0.016$).

Conclusion

We suggest that the increased sympathetic activity previously described in patients with T2D is mediated through the deleterious effect of diabetes in nocturnal breathing. In addition, sympathetic activity is associated with disorders of autonomic tone at resting, suggesting a new pathological pathway between T2D and cardiovascular risk.

Awareness of gestational diabetes, its risk factors and its consequences among tunisian pregnant women

Sebai Imen, Abdessalem Haifa, Stambouli Islem, Ounaissa Kamilia, Ben Brahim Asma, Yahiaoui Rym & Amrouche Chiraz
National Institute of Nutrition, Tunis, Tunisia.

Introduction

The prevalence of Gestational diabetes mellitus (GDM) has been increasing recently. Educating women of childbearing age about GDM, its risk factors and complications may help its prevention and improve its outcomes. Hence, the aim of this study was to assess the level of knowledge of Tunisian pregnant women about gestational diabetes, its risk factors and its consequences.

Methods

We conducted a cross-sectional study among pregnant women who were referred to the National Institute of Nutrition for management of GDM. Women without prior diabetes mellitus were included. Qualitative semi-structured interviews were conducted to collect their socio-demographic characteristics and to assess their knowledge about gestational diabetes, its risk factors and its consequences. Data of biological examinations were collected from medical files of patients.

Results

The study included 30 pregnant women of average age 33.6 ± 5.3 years. Approximately 37% of women were primiparous. Overweight (body mass index ≥ 25 kg/m^2), diabetes mellitus in first-degree family members and advanced age (≥ 35 years) were prevalent risk factors in our population (73%, 60% and 57% respectively). Quarter of women had a past medical history of GDM and only 3% reported a previous history of macrosomia. More than 75% had completed at least secondary school education. Less than half of women (47%) didn't have an idea about GDM. However, 43% of the population knew that GDM is a transitory hyperglycemia which occurs in pregnancy. Other definitions as transitory pancreatic dysfunction or as feeling of hungry or as asthenia were reported. The most commonly reported risk factors of GDM were high carbohydrate intake (80%) and psychological stress (40%). Only 6% of women knew that overweight and family history of diabetes can be predictive factors of GDM. Consequences of GDM weren't well known for the majority of our patients. Macrosomia and malformations were identified as GDM consequences by 33% and 27% respectively. Sixty percent were worried about causing diabetes to the fetus. Also, many women (43%) didn't know the increased risk for development of Type2 diabetes in future.

Conclusion

In this study, the majority of women had limited knowledge of gestational diabetes, its risk factors and its consequences. Furthermore, it was interesting to report that Tunisian pregnant women thought that stress increased the risk of developing gestational diabetes. The improvement of awareness of GDM since the preconception period can be useful to reduce the prevalence of this type of diabetes and to incite pregnant women to better take care during all their pregnancy.

Characteristics of insulin-requiring diabetes among elderly patients in hospitals

Sebai Imen, Oueslati Insaf, Rezgani Imen, Ben Cheikh Marwa, Temessek Aroua & Ben Mami Faika
National Institute of Nutrition, Tunis, Tunisia.

Introduction

Diabetes in the elderly is a major public health problem in Tunisia. Its prevalence increases with aging population. The aim of this study was to determine the particularities of insulin-requiring diabetes in elderly patients in hospitals.

Methods

This was a retrospective cross study about insulin-treated diabetics admitted in our institute between August and October 2016 for uncontrolled diabetes. Was considered as elderly diabetic any patient of 60 years and older. Data about medical history, comorbidities and clinical examination were collected from medical file of patients.

Results

This study included 132 patients with insulin-requiring diabetes. Patients aged 60 and older accounted for 37.8% of cases ($n=50$). The mean age was 69 years (raging 60–84 years). Sex ratio(F/H) was 0.56. The mean number of years since diagnosis of diabetes was 17.6 years with extremes ranging from 3 months to 42 years. Insulin therapy was initiated for an average of 8 years. The incomplete basal bolus regimen was the most prescribed (40%). Only 16% of patients were on insulin analogues and half of them were over 75 years old. One third of the patients reported hypoglycaemia. None of them were under analogues. The significantly more frequent complications in elderly patients than in younger ones were: retinopathy (69% vs 45%, $P=0.01$), neuropathy (62% vs 44%, $P=0.005$) and nephropathy (58% vs 28%, $P=0.01$). One third of patients was treated for a coronary artery disease and 10% had cataracts. Dyslipidemia, arterial hypertension and obesity were observed in 80, 68 and 50% of elderly diabetics, respectively.

Conclusion

The typical profile of our elderly population was that an obese type 2 diabetic woman at high cardiovascular risk. The frequency of hypoglycaemia and the high prevalence of degenerative complications in our diabetic elderly population can lead to a loss of autonomy.

Alterations in intestinal microbiota and arginase activity in leukocytes of type 1 diabetes patients

Yelena Aghajanova[1], Arthur Melkonyan[1], Nina Alchujyan[2], Margarita Hovhannisyan[2], Gayane Bayburdyan[1], Lusine Navasardyan[1] & Renata Markosyan[1]
[1]Yerevan State Medical University after Mkhitar Heratsi. Department of Endocrinology, Yerevan, Armenia; [2]H. Bunyatyan Institute of Biochemistry NAS RA, Yerevan, Armenia.

Type 1 diabetes mellitus (T1DM) is one of the most frequent autoimmune disorders in childhood, adolescence and youth, developing due to autoimmune destruction of pancreatic β-cells, which leads to an absolute insulin deficiency. Gut microbiota (GM) is associated with the functions of the body's immune system, and immune-mediated diseases, including T1DM. However, the exact mechanisms by which GM is involved in the T1DM are still unknown. Accumulating data suggest that GM may contribute to the pathogenesis of diabetes influencing the immune response, in which arginine-metabolizing enzymes are involved, particularly arginase. Here, we examined the connection between gut microbiota and cytoplasmic and mitochondrial arginase isoforms (AI and AII respectively) in the leukocytes of patients with T1DM. The A1 activity is necessary to protect M2 macrophages from inflammation, it is constitutively expressed in human neutrophils and exhibits fungicidal activity, whereas A2 is involved in the production of reactive oxygen species implicating in the oxidative stress and inflammatory processes involved in the T1DM pathophysiology. This offers that arginases can be therapeutic targets in T1DM, and this issue is studied in the presented work. Arginase assay was based on the accumulation of L-ornithine produced by arginase in the reaction mixture during 1-hour incubation and determined by means ninhydrin. Measurement of the nitric oxide stable metabolites in protein-free samples was performed using Griess-Ilosvay reagent. Number of *E. coli* and Clostridium spp were drastically decreased with a concomitant increase in that of *Candida albicans*, and a manifestation of *Staphilococcus aureus* was also observed in T1DM, which may compete with the gut beneficial bacteria. Of note, *E. coli* and Clostridium *spp* play a protector role for GM, whereas clinical cultures of *C. albicans* has detrimental effects causing desquamation of small fragments peptidoglycan layers of cell wall and total destruction of the cytoplasm in lactobacilli. The arginase activity was increased by 2 and 1.6 times in the cytoplasm and mitochondria of leukocytes from T1DM patients as compared respectively to control. Arginase is known contribute to decreased availability of L-Arginine in the organism, and particularly to nitric oxide synthase that may cause a subsequent reduction of NOS/NO production attributed to the pathological processes associated with diabetes. Based on this, the nitrite levels in the leukocyte cytoplasm, mitochondria and blood plasma were examined and in line with other findings it was dropped by 1.9, 2.3 and 1.6 times respectively.

DOI: 10.1530/endoabs.56.EP66

EP67

Reduction of glycemic variability in a patient with type 1 diabetes with hipoglycemia

Daria Fomina[1], Margarita Dudina[1,2] & Sergey Dogadin[1,2]
[1]Krasnoyarsk State Medical University named after Prof. V.F. Voino-Yasenetsky, Krasnoyarsk, Russian Federation; [2]Krasnoyarsk state regional clinical hospital, Krasnoyarsk, Russian Federation.

The routine approach to evaluating the effectiveness of diabetes treatment based on the level of glycated hemoglobin (HbA1c) accounts for the average glucose level but does not consider its fluctuations. However, recent data indicate that the development of late complications of diabetes is associated with the degree of variability in glycemia. (GV).

Clinical case

Patient F. is 54-year-old woman with a 33-year history of type 1 diabetes with multiple chronic complications: Diabetic autonomic neuropathy (unrecognized hypoglycemia). Diabetic sensorimotor polyneuropathy. Non-proliferative diabetic retinopathy. Diabetic nephropathy, CKD C2A1. There were frequent hypoglycemic episodes in the night and morning hours, including two unrecognized episodes requiring hospitalization. She tests her glycemia rarely, according to glucose meter from 1.7 to 14.0 mmol/l. But, the level of HbA1c from December 2017 is 7.3%. She received insulin therapy: insulin lispro 12 IU at 0800 h, 8 IU at 1800 h, insulin glargine 10 IU at 1000 h, 12 IU at 2200 h. Continuous glucose monitoring with the iPro-2 Medtronik (USA) system was carried out for a detailed study of glucose curves for 6 days. The increase in glycemia in the morning was recorded more than 22.2 mmol/l. Also episodes of lowering to 4.5–3.2 mmol/l, both clinically recognized and not recognized. Data analysis was carried out using the Easy GV calculator (v.9.0), proposed by N.Hill et al. We found a deviation in the parameters of GV: standard deviation SD 4.25 mmol/l (3,0), mean amplitude of glycemic excursions MAGE up to 5 mmol/l (2.8), lability index LI 5.85 $(mmol/l)^2/h$ (4.7), the continuous overlapping net glycemic action CONGA 11.39 mmol/l (5.5), the M-value index 31.21, which characterizes the "quality" of glycemic control. Therapy with long-acting insulin was started – glargin-300. The drug is chosen taking into account its longer period of action, gradual release from the subcutaneous fat, less variability of the action. The total dose of glargin-300 was 14 units (decreased by 8 units), GV during the day – from 6.5 to 13.0 mmol/l. Hypoglycemic episodes were not observed.

Conclusion

The choice of therapy taking into account the characteristics of GV allowed to achieve a decrease in the amplitude of fluctuation in glycemia, thus improving the long-term prognosis. Insulin glargin-300 may be the preferred drug in patients with type 1 diabetes and high GV, regardless of the level of HbA1c.

Diabetic ketoacidosis and dapagliflozin: a case report

Diana Catarino[1], Cristina Ribeiro[1], Diana Oliveira[1], Diana Martins[1], Adriana Lages[1], Mara Ventura[1], Nelson Cunha[1], Lúcia Fadiga[1], Bernardo Marques[2] & Francisco Carrilho[1]
[1]Endocrinology Department, Coimbra Hospital and University Center, Coimbra, Portugal; [2]Portuguese Oncology Institute, Coimbra, Portugal.

Introduction

Dapagliflozin is an oral antidiabetic drug, recently approved for type 2 diabetes and is a sodium-glucose cotransporter type 2 inhibitor (iSGLT2). Its mechanism of action is glycosuria induction, associated with lowering glycemia. The effects of SGLT2 inhibition are insulin-independent, and efficacy is not affected by declining β-cell function or insulin resistance. Additional benefits: weight loss, reduction in blood pressure, lower incidence of hypoglycaemias. Secondary effects: diabetic ketoacidosis risk (in some cases, euglycemic ketosis), in type 2 diabetes and type 1 diabetes (in the last case, when used off-label).

Objective

To show the risk of diabetic ketoacidosis in patients treated with iSGLT2, particularly in type 1 diabetes.

Case report

A 82 years-old woman**,** with more than 50 years diabetes diagnosis, associated with microvascular and macrovascular complications (coronary disease, diabetic neuropathy and retinopathy); treated with insulin at the diagnosis. Classified always on type 2 diabetes. She presented at the emergency service with two days of headache, anorexia, nausea, abdominal pain. Previously, the patient had been evaluated and treated with analgesia and proton pump inhibitor. Physical examination at the emergency service: dehydration, tachycardia and abdominal pain. Laboratory findings: hyperglycaemia (556 mg/dl), acidosis (pH – 7.21, HCO3 – 9.8 mEq/l), positive ketone test (5.7 mmol/l), acute renal failure (creatinine: 1.86 mg/dl, basal creatinine 0.5 mg/dl), leucocytosis (19.3 G/L) and negative C-reactive protein. It was diagnosed a diabetic ketoacidosis and the patient was hospitalized with continuous insulin infusion and fluids. Further investigation showed recent onset of dapagliflozin (10 mg/day). Other medication: Abasaglar ® id, metformin (1000 mg 3id) and sitagliptin (50 mg 2id). Laboratory findings: haemoglobin A1c – 11.1%, c-peptide 0.2 ng/ml (1.0–7.6 ng/ml), ICA – positive, GADA – 79.81 U/ml (<1.0) and IA-2 – 0.16 U/ml (<1.0). After clinical stabilization, the patient was discharge with insulin (NovoMix 30®, 3id). Dapagliflozin and others oral antidiabetic drugs were stopped.

Discussion and conclusion

The present case pretends to show the risk of diabetic ketoacidosis in both type 1 and type 2 diabetes, particularly in type 1 diabetes. So, when hyperglycaemia and/or ketosis symptoms are present, it is essential to perform ketone test and gasometry. It is important to know that patients treated with iSGLT2, may have mild hyperglycaemia, even in diabetic ketoacidosis. This case is also intended to show that a considerable rate of patients, classified with type 2 diabetes, have effectively an autoimmune diabetes.

When is it possible to withdraw insulin in patients with type 2 diabetes and multiple cardiovascular risk factors? Can the new drugs be of help?

Isabel Ramos-Gomez[1], Maria Dolores Perez-Ramada[1], Ana Delia Santana-Suarez[2], Manuel Esteban Nivelo-Rivadeneira[2], Agnieszka Kuzior[3], Paula Fernandez-Trujillo-Comenge[2], Carmen Acosta-Calero[2], Sara Quintana-Arroyo[2], Claudia Arnas-Leon[2] & Francisco Javier Martinez-Martin[4]
[1]Internal Medicine Dpt, University Hospital of Gran Canaria Dr. Negrin, Las Palmas de Gran Canaria, Spain; [2]Endocrinology & Nutrition Department, University Hospital of Gran Canaria Doctor Negrin, Las Palmas de Gran Canaria, Spain; [3]Endocrinology & Nutrition Department, University Hospital of Gran Canaria Dr. Negrin, Las Palmas de Gran Canaria, Spain; [4]Outpatient Hypertension Clinic, University Hospital of Gran Canaria Doctor Negrin, Las Palmas de Gran Canaria, Spain.

Introduction

Insulin is not an optimal treatment in obese type 2 diabetic patients with insulin resistance. We often introduce it as a last resort hoping to improve the metabolic control of our patients. However it is not always effective, and tends to increase body weight, worsen the global cardiovascular risk and cause hypoglycemias. New drugs such as the GLP-1 agonist receptors can be a better alternative and sometimes allow withdrawal of insulin.

Clinical case

A 59 year old female patient had morbid obesity (BMI 41 kg/m^2) and type 2 diabetes mellitus diagnosed 17 years ago, chronically poorly controlled (HbA_{1C} > 8% in the last 10 years) with metformin 850 mg TID and insulin in escalating doses up to 36 units of 75NPH/25R premix TID. She also had hypertension, chronic coronariopathy with anterior AMI diagnosed five years ago and successive heart failure with preserved ejection fraction and paroxystic atrial fibrillation. Her treatment included Atenolol 50 mg BID, Olmesartan 40 mg, Amlodipine 10 mg, Hydrochlorothiazide 25 mg, Doxazosine 4 mg and acenocumarol. She was admitted in Internal Medicine because of decompensated heart failure in the context of a respiratory infection. Her HbA1c was 8.6% and eGFr CKD-EPI 82.2 ml/min, with LDL-cholesterol 72 mg/dl. On discharge she was offered treatment with Liraglutide but chose Dulaglutide 1.5 mg/week. Metformin was maintained and the insulin dose was reduced to 20-20-14 units. Four months later she had reduced the dose to 19-19-13 because of mild hypoglycemias and her HbA1c was 6.1%. She had lost 9 kg of body weight. After three months her dose was 12-12-6 with HbA_{1C} 5.8% and LDL-cholesterol 56 mg/dl. Sixteen months after discharge she maintains a body weight loss of 10 kg, insulin was withdrawn while maintaining adequate glycemic control, her HbA_{1C} was 6.8%, and her antihypertensive treatment was reduced (Olmesartan 20 mg, Bisoprolol 2.5 mg substituted for Atenolol 50 bid, and Hydrochlorothiazide withdrawn). Moreover, the patient was quite satisfied with her evolution.

Conclusions

The new therapeutic arsenal for type 2 diabetes mellitus, particularly the SGLT2 inhibitors and the GLP-1 receptor agonists, have improved our ability to achieve

metabolic control in obese patients with marked insulin resistance, and in many cases may avoid the introduction of insulin and even allow its withdrawal in patients such as ours. We must also consider the positive results of trials like EMPA-REG OUTCOME, CANVAS and LEADER in secondary cardiovascular prevention.

Controversies of endocrine treatment in Prader-Willi syndrome: a case report of two monozygotic twins

Vânia Gomes, Florbela Ferreira & Maria João Bugalho
Endocrinology Department, Hospital de Santa Maria, Centro Hospitalar Lisboa Norte EPE, Lisboa, Portugal.

Introduction
Prader-Willi syndrome (PWS) is a neurobehavioral imprinting disorder, which arises due to an absence of paternally expressed genes within the 15q11.2-q13 region. It is the most common syndromic form of obesity, with an estimated prevalence of about 1 in 25,000 individuals.
Case report
we report the case of two monozygotic twins, 20-year-old, naturally conceived, both affected by PWS. They were born by eutocic delivery at 34 weeks of gestation and somatometry was appropriate for gestational age. Both presented neonatal hypotony, feeding difficulties, psychomotor delay, characteristic facies and cryptorchidism. Genetic test confirmed maternal uniparental disomy of chromosome 15. From 4 years of age they presented progressive increasing weight (percentile > 95) associated with binge-eating but delayed height growth (percentile 10-25). Orchidopexy was performed at 5 years of age. Puberty started at 12 years but did not progress. At 16-year-old, treatment with testosterone enanthate monthly injections and recombinant human growth hormone (rhGH) was started. Despite dietetic measures, both twins developed insulin resistance and morbid obesity (body mass index: 49.8 and 44 kg/m^2) due to marked hyperphagia. Furthermore, they had obstructive sleep apnea, cognitive delay and behavioral problems (temper tantrums, stubbornness, impulsivity, aggressiveness), which ultimately led to the cessation of treatment with testosterone. Worsening of obesity and sleep apnea at the age of 19 dictated the stop of rhGH.
Conclusion
To our knowledge, very few cases of naturally conceived twins affected with PWS were reported. Endocrine treatments can be controversial in these patients, because of a possible exacerbation of behavioral problems and other comorbid conditions.

Evaluation of diabetes and cardiovascular risk factors in a population of diabetic patients in a rural area

Loubna Oukit, Ghizlane El Mghari & Nawal El Ansari
CHU Mohamed VI, Arrazi's Hospital, Marrakesh, Morocco.

Introduction
Diabetes is a real problem of public health. One of the main preoccupations that arises from it are the cardiovascular complications that are associated to it. In our context, the socioeconomic conditions and the isolation of certain regions constitute a brake that cannot be neglected in the diagnosis, the observance of the treatments and the regular supervision. The aim of this study is to raise the particularities related to the cardiovascular risk factors in the population of a rural region.
Patients and method
Transversal descriptive study, realized on a health campaign day in the rural region of Imessouane (82km far from Agadir) and concerning diabetic patients of the region. The anthropometric parameters, the glycemic balance and the cardiovascular risk, using the NHAES score, have been evaluated.
Results
The average age was 52.2 years with a feminine predominance. Type 2 diabetes has been found in 98.4% of the cases, the average duration of the diabetes was 5.1 years. Also, 72.9% of the diabetic patients were under oral treatment and 72.9% consulted a doctor regularly for their diabetes. The average glycated hemoglobin was 7.9%. The hypertension and the dyslipidemia were found in 29% of the cases. The patients had a regular physical activity in 68% of the cases. The cardiovascular risk was above 30% in 31.4%.
Discussion
The access to healthcare keeps being a real problem, especially in the remote areas. The progress of this day enabled as well to evaluate the epidemiological and clinical characteristics of these patients, having access to unique socio-demographic and epidemiologic data as there are almost no studies done in remote areas. The glycemic balance stays precarious as the follow-ups are non-sufficient. In our rural population, very active by their agricultural activities, the cardiovascular risk is lower than some similar studies done in the same conditions but to a more sedentary population.

Type 2 diabetes: an unexpected journey

Yasmin Nikookam[1], Caoimhe Bonner[1], Bonnie Grant[1], Anthony Pittathankal[1,2], Dhafir Al-Okati[1,2], Imran Syed[2], Edel Casey[1] & Khash Nikookam[1,2]
[1]Barking Havering and Redbridge University Hospitals NHS Trust, Greater London, UK; [2]Spire Roding Hospital, Greater London, UK.

We report a case of a well 40 year old gentleman who self-referred for confirmation of diagnosis of diabetes. On further history he had been informed by other healthcare professionals the possibility of diabetes based on his elevated fasting serum glucose of 13.8 mmol/L and HbA1c of 81mmol/mol with no osmotic symptoms. His triglyceride was also elevated at 12.26 with rather variable compliance to statin. Examination of all systems were unremarkable, however on neck examination both thyroid lobes were palpable. Right lobe felt irregular and nodular, and left lobe smooth. It was rather difficult to palpate the lower pole of the thyroid lobes. No thyroid or carotid bruits audible; no lymphadenopathy felt. The patient was clinically euthyroid. Ultrasound of neck and thyroid was arranged and showed pathological level III lymph nodes and an indeterminate hypoechoic left thyroid nodule with possible areas of micro-calcification; U3 thyroid nodule. Subsequently, an MRI of the neck confirmed a single morphologically abnormal lymph node at level IV on the right. FNA of the left thyroid nodule was suspicious of papillary neoplasia and FNA of the right cervical node was suggestive of metastatic carcinoma. The patient underwent a total thyroidectomy with an uneventful recovery. He was commenced on thyroxine and calcichew D3. He is awaiting I131 therapy. This case emphasises thorough history and examination is crucial for patients wellbeing which may well improve comorbidities and prolong one's life.

Clinical case of late diagnosed diabetes in ketoacidotic coma III in teenager: lessons to be learned

Anna Alieva[1], Kamil Rakhmankulov[1] & Saydiganikhodja Ismailov[2]
[1]Republican Specialized Scientific-Practical Medical Centre of Endocrinology, Tashkent, Uzbekistan; [2]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan.

Patient Z., 13 years old, transferres to the ICU with diagnosis: Diabetes mellitus newly diagnosed. Diabetic ketoacidotic coma II. Concomitant: Left-sided pneumonia.
Objective
Cussmaul's breath, 36/minute. Pulse 128/min. BP 100/60 mm Hg. Glycemia 30.4 mmol/l, ketones in urine: $++++$. CBC, urine, biochemical analysis of blood had not any special features. In the dynamics of the phenomenon of increasing respiratory failure and falling hemodynamics, the patient was intubated, pulmonary ventilation was started in the SIMV mode, inotropic support started. Lungs: left-sided upper-lobe large-focal pneumonia, Pseudomonas Aeruginosae was found in the sputum. The patient was admitted with extremely severe dehydration, disturbed microcirculation, including violation of renal blood flow, which was reflected in diuresis inadequate to glycemia. Infusion therapy was carried out under strict control of CVP and diuresis, however, CVP was negative during the first two days. The speed of infusion therapy was 15 ml/kg/h for the first 24 h, 11.4 ml/kg/h during the following 24 h, followed by a decrease to 7–8 ml/kg/h at the 3rd and 4th days, 6 ml/kg/h at the day 5. On the fourth day the introduction of fluids through the nasogastric tube, and on the 5th day feeding was started. The decrease in glycemia during the first day was down to 13 mmol/l, on day 2 - to 7.8 mmol/l. Ketonuria was eliminated by the 2nd day.

Insulin infusion rate during the first day was 0.2 units/kg/h during the first 6 h, but as this dose was insufficient, it has been raised to 0.38 U/kg/hr during the 2nd day, 0.1 unit/kg/h for the first 12 h of the 3rd day, with gradual decrease during the next day to 0.07–0.06–0.04 units/kg/h. Long acting insulin was added on the 6th day of treatment. At the time of discharge, the daily dose of insulin was 13 units. Potassium solutions were administered according to international recommendations. The reasons for the development of a critical life-threatening condition in this patient are: late admission; late diagnostics; the presence of severe competing diseases - left-sided large-focal pneumonia, bilateral acute purulent otitis media; excessively high insulin requirements associated with puberty. Patient was checked out in 1 month for reabilitation and diabetes education.

Role of the dentist in managing obese patients and patients with diabetes mellitus – why oral health matters?

Anja Jankovic-Pejicic
University of Vienna, Vienna, Austria.

Physicians and dentists have long known that the health of an individual's mouth can have significant effects on the health of the rest of the body. Researchers are finding more medical reasons to maintain good oral hygiene. Numerous recent scientific studies indicate association between oral health and a variety of general health conditions including diabetes and obesity. Studies have suggested a bidirectional relationship between periodontitis and diabetes and periodontitis and obesity. Diabetes and obesity promote the occurence, the progression and the severity of periodontitis. Conversely, periodontitis was shown to be a risk factors for poor glycemic control in patients with diabetes due to bacteria and their byproducts in the inflammed periodontal tissue constituting a chronic source of systemic chalenge to the host, increases the risk of diabetes-associated complications and possibly even of ist onset. Some studies suggest mechanisms by which oral bacteria may contibute to development of obesity by increasing apetite and changing of diet habits and redirecting energy metabolism by facilitating insulin resistance through increasing levels of TNF-α or reducing levels of adiponectin. Tooth loss due to periodontitis seriously decreases chewing abillity which is related to quality of life and general health, possibly reflecting the impact on chewing food choice and enjoyment of meals and diet and also indicated the importance of oral health to general well-beeing. It is still not sufficienty communicated within the medical community, because the periodontal disease is stil considered as the concern of only dentists. Physicians and dentists need to be aware of the relationship between periodontitis and diabetes and take adaquate steps to minimaze negative outcomes in patient with diabetes mellitus or obese patients.Periodontal therapy which decreases the intraoral bacterial bioburden and reduces periodontal inflammation can have a significant impact on systemic inflammatory status and improves glycemic control in many patients with diabetes and periodontitis. Recognition of the bilateral relationship between oral and systemic helath will chalenge physicians and dentists to work together closely in the future when managing patients with diabetes and periodontal disease. The entire dental team, working together with medical colleagues, must become increasingly involved in the management of patients with diabetes and perform periodontal screening as a matter of routine of all patients diagnosed with diabetes mellitus and periodontitis.

Mucormycosis in a patient with diabetes and orbital trauma

Şeyma Üneşi[1], Aşkin Güngüneş[2], Şenay Durmaz Arikan [2], Ela Cömert[3] & Melike Tekşut[1]
[1]Department of Internal Medicine of School of Medcine, Kirikkale, Turkey; [2]Department of Endocrinology of School of Medcine, Kirikkale, Turkey; [3]Department of Otorhinolaryngology of School of Medcine, Kirikkale, Turkey.

Introduction
Mucormycosis is a serious fungal infection, It is frequently observed in immunocompromised patients such as diabetes mellitus. The most common clinical presentation of mucormycosis is rhino-orbita- cerebral infection.

Case presentation
A seventy three-years- old man with diabetes mellitus who was operated due to orbital trauma a mounth ago. Periorbital cellulitis and diabetic ketosis developed during post-operative period and the patient was transferred to the endocrine clinic. Orbital and paranasal computed tomography were performed, and then necrosis areas were observed in the nasal cavity, middle and lower concha. Mucormycosis was considered with present findings. Surgical debridement and AmphotericinB treatment were started. Pathologic examination confirmed mucormycosis. Despite surgical debridement and amphotericin B treatment infection could not be controlled and he was referred to the upper center for hyperbaric oxygen therapy.
Conclusion
The evaluation in terms of mucormycosis may be important in a patient with diabetes mellitus and orbital trauma for early treatment approaches. However, treatment response may not always be good despite early diagnosis.

From severe metformin-associated lactic acidosis to colorectal cancer diagnosis, case-report

Iva Jakubíková[1,2] & Terezie Pelikánová[1]
[1]Diabetes Centre, Institute for Clinical and Experimental Medicine, Prague, Czech Republic; [2]Charles University, Faculty of Medicine in Hradec Králové, Hradec Králové, Czech Republic.

Introduction
Metformin is recommended as the first-line pharmacological agent for patients with diabetes mellitus type 2. Its most feared adverse effect is the metformin-associated lactic acidosis (MALA), which appears rarely, but the mortality risk reaches almost 50 percent. This case report describes a story of a severely metformin intoxicated patient with several rare complications and uneven outcome.
Case-report
A 74-year-old man was found at home, unconscious, spontaneously breathing, hypotensive and hypoglycemic. He was admitted to ICU on vasopressor treatment. Major laboratory findings were severe metabolic acidosis including severe hyperkalemia, hyperlactatemia (maximal level of 12 mmol/l), severe renal impairment (eGFR 5 ml/min/1.73m^2), troponin T (84 ng/l), CRP (31 mg/l), leukocytosis (22×10^9), anemia (80g/l), metformin level (34.2 ug/ml). Initially acute coronary syndrome, pulmonary embolism, acute sonographic pathology of the urological tract were excluded and renal replacement therapy (RRT) was necessary for suspect metformin intoxication. After stabilization, he was transferred to a standard internal ward. According to prior patients history, his regular medication was metformin 2 g/day and glimepiride 4mg/day. His last documented laboratory results were normal renal functions, normal blood count one year ago. After 14 days on RRT was the patient still anuric, so the postrenal obstruction was suspected. Ultrasound-guided percutaneous bilateral nephrostomies were inserted with a prompt effect and restoration of diuresis and reparation of renal functions. An X-ray pyelouretrography showed bilateral ureteral obstruction without concrement involvement. An abdominal contrast CT scan revealed a tumor suspect formation in colon ascendens. Via colonoscopy, a diagnosis of colorectal cancer was established and it explained the initial anemia, despite its laboratory findings typical for anemia of chronic diseases. A rare complication appeared, a late onset of heparin-induced thrombocytopenia (HIT), 16th day after initiation of heparin administration, for which the patient had to be anticoagulated with therapeutic doses of Fondaparinux for a HIT-associated deep vein thrombosis of the left leg and mild pulmonary subsegmental embolism. Even though there was no suspect liver metastasis on the CT scan, during the surgery a peritoneal carcinosis was found and so palliative ileotransversoanastomosis was done, concomitant oncological treatment was not planned. A bilateral postrenal extraluminal obstruction due to disseminated colorectal carcinoma was settled.
Conclusion
A case of quickly silently growing colorectal cancer of colon ascendens was described, which in one year resulted in bilateral postrenal obstruction, which led to chronic metformin overdose and sudden severe lactic acidosis.

Diabetic ketoacidosis and myocardial 'pseudoinfarction'

Rahat Ali Tauni, Anna Stears & Mark Evans
Cambridge University Hospitals, Cambridge, UK.

A 68-year-old lady was admitted with constipation, epigastric pain, vomiting, occasional coffee ground emesis and melena. She had no chest pain, osmotic symptoms or weight changes. Past medical history was significant for peptic ulcer disease and she was not taking any medications apart from over the counter cod liver oil. She did not have diabetes or cardiovascular risk factors. Her sister had type 1 diabetes. Examination was remarkable for dehydration, mild tachycardia and melena on rectal examination. Blood tests including haemoglobin, clotting, renal function, electrolytes were normal. Glucose was 37 mmol/l, ketones were 4.3 mmol/l and there was mild acidosis. She was treated with intravenous fluids, intravenous insulin, proton pump inhibitors and anti-emetics. Electrocardiogram (ECG) showed deep T wave inversions in infero-lateral leads. Cardiac enzymes repeated many times were normal, chest X-ray was normal and echocardiogram revealed normal left ventricular function. ECG changes resolved in 24 h. She was diagnosed to have diabetes with high glycated haemoglobin, negative diabetes auto-antibodies and raised C-peptide level, and was commenced on subcutaneous insulin and metformin. Oesophago-gastro-doudenoscopy suggested mild gastritis. ECG changes in diabetic ketoacidosis (DKA) usually signify cardiac ischaemia or electrolyte abnormalities. Abnormal ECG in absence of the above causes in patients with DKA is reported in literature and has been termed as 'pseudoinfarction'. The ECG changes may include ST-segment elevation or depression, T-wave changes and can be non-specific. It is postulated that the acidosis causes change in myocyte cell membrane permeability leading to electrolyte shifts across the membrane with resultant abnormalities in electrocardiogram. The abnormalities tend to resolve with the resolution of acidosis. All patients with DKA and chest pain or ECG changes should have standard assessment with cardiac biomarkers, electrocardiographic monitoring, if appropriate, echocardiogram and coronary angiogram. Cardiology consult should be obtained in suspicious cases but clinicians should be mindful that ECG abnormalities in DKA are not always sinister.

Childhood granuloma annulareas first sign of diabetes mellitus: case series

Anca E Chiriac[1], Tudor Pinteala[2], Liliana Foia[3] & Anca Chiriac[4,5]
[1]University, Iasi, Romania; [2]University of Medicine and Pharmacy 'Grigore T Popa', Iasi, Romania; [3]University of Medicine ad Pharmacy 'Grigore T Popa', Iasi, Romania; [4]Nicolina Medical Center, Iasi, Romania; [5]Apollonia University, Iasi, Romania.

Ganuloma annulare (GA) is a self-limited inflammatory dermatosis, clinically characterized by the presence of papules arranged in annular or circinate pattern, mostly on the extremities. GA has rarely been reported in childhood, although is a not a rare condition seen in adulthood. Aetiology and pathogenesis of GA are still unknown, although variable associations have been reported, during last decades, with diabetes mellitus, thyroid disorders, HIV infection, malignancies, tuberculosis, Epstein Barr and hepatitis C virus infection or drug administration. Controversial statistically correlation between GA and diabetes mellitus has been published in the literature. We present cases of GA diagnosed in children (based on clinical and histological features) with diabetes mellitus at the moment of diagnosis or diagnosed later and similar cases in children without diabetes mellitus. GA was in a few children a "cutaneous marker" for a newly detected diabetes mellitus. GA patients should be assessed for diabetes mellitus even in children. More studies and reports are needed for establishing the real link between GA and diabetes mellitus.

Parapharyngeal abscesses of dental origin in diabetics

Halwani Chiraz, Zoghlami Imène, Zgolli Cyrine, Akkari Khmaeis & Ben Mhamed Rania
ENT Department, Military Hospital, Tunis, Tunisia.

Introduction
Parapharyngeal abscesses develop at the pharyngeal lateral wall. It is a rare infectious complication. The starting point is most often a pharyngeal infection that extends through the fibers of the upper constrictor muscles of the pharynx. The dental origin is more rare. It raises the problem of therapeutic management. The aim of this presentation was to detail the clinical diagnostic aspects of parapharyngeal abscesses in diabetics and to detail the therapeutic modalities.
Methods
We report a series of 10 patients treated in our ENT department over a period of 8 years (from 2009 to 2017).
Results
They are 8 men and 2 women, aged from 23 to 65 years old. One patient was diabetic type 1 and the other was type 2 insulin-requiring in 5 cases. The reason for consultation was painful dysphagia associated with limitation of mouth opening. Outpatient treatment with antibiotics and anti-inflammatories was given in 3 cases. The examination noted in all cases a trismus, a bad dental state and a parapharyngeal bulge. In the CT scan, parapharyngeal abscesses of varying size and extent were present. The puncture returned serosities and the bacteriological examination was negative in 2 cases. The etiological investigation had concluded to a dental origin. The treatment was medical (intravenous antibiotic therapy, optimal equilibration of diabetes), surgical (flattening of abscess by the oropharyngeal route in all cases) and treatment of the causal tooth.
Conclusion
The treatment of parapharyngeal suppurations is medico-surgical and necessarily involves the treatment of the infectious center in question. Untreated, they provide serious complications including vascular thromboses and extensive cellulite that can be life-threatening.

Mental health and diabetes – are we doing enough for our patients?

Gideon Mlawa[1,2], Yuvanaa Subramaniam[1] & Kaenat Mulla[2]
[1]Queen's Hospital, London, UK; [2]King George Hospital, London, UK.

Background
Managing mental health patients with Diabetes Mellitus can be challenging. Patients with mental health problems are poorly compliant with both antipsychotic and diabetes treatment. Literature has suggested that some psychiatric illnesses can be independent risk factors for diabetes. Furthermore, diabetic patients have a higher incidence of psychiatric disorders. There is a causal relationship between newer antipsychotic medications and metabolic abnormalities.
Cases from two hospitals
1. 72 year old lady was admitted after being found on the floor in the psychiatric unit. On admission, her glucose was 56 mmol/l with ketonuria. She was treated as Diabetic Keto-Acidosis (DKA). She was on olanzapine.
2. 43 yearold lady was admitted with glucose of 38 mmol/L. Her HbA1C was 160 mmol/mol. She was treated as hyperosmolar hyperglycaemic state (HHS). She was on amisulpride.
3. 38 year old lady admitted with increased confusion, her glucose was 76mmol/L. Complicated by an acute kidney injury, sepsis and acidosis; she was treated as DKA. She was on olanzapine
4. 36 year old lady was admitted after general decline in health. She had a glucose of 73.3 mmol/L and was acidotic. She was treated as DKA. She was on olanzpine and amisulpiride.

Discussion
Olanzapine, clozapine and amisulpride are known as novel antipsychotics. The British National Formulary states diabetes and hyperglycaemia are side effects of antipsychotics. Olanzapine and clozapine have the highest propensity to induce hyperglycaemia. The time taken for clinical manifestations of hyperglycaemia varies from days to years. Poor compliance leads to recurrent hospital admission especially in patients with both conditions. The recent introduction of Abbot's Freestyle Libre has transformed glucose monitoring. Its simplicity may play a vital role in patients with psychiatric disorders. The use of insulin pumps in patients with mental health remains debatable.
Conclusion
- Patients on antipsychotics should be monitored for hyperglycaemia.
- We recommend if one is commencing an antipsychotic in a patient then the assessment for diabetes should take place at initiation, at 3–4 months and annually.
- Physicians must be made aware of the growing association between atypical antipsychotics, diabetes and hyperglycaemic crises.
- Managing diabetes in patients with psychiatric disorders requires an integrated multidisciplinary approach involving both primary and secondary care teams.

- We suggest that clinicians encourage the use of technology such as flash glucose monitoring together with support from family or carers to improve compliance and diabetes care in this special group of patients.

Calculation of the risk of non-compliance with antihypertensive treatments in diabetic patients

Rym Bourguiba, Fatma Boukhayatia, Aroua Temessek, Senda Sallemi, Khadija Ben Naceur & Faika Ben Mami
Nutrition and Metabolic Diseases Department C. National Institute of Nutrition of Tunis, Tunis, Tunisia.

Introduction
High blood pressure (HBP) is a public health problem because it is a major cause of global morbidity and mortality. Antihypertensive therapy has evolved significantly in recent years to reduce the number of tablets to improve adherence therapy.
Purpose of our work
The purpose of our work was to estimate the risk of non-compliance with antihypertensive treatments for a population of hypertensive and diabetic patients, by using a validated calculator.
Patients and methods
This is a retrospective study that collects all hypertensive patients hospitalized in our department from December 2017 to January 2018. For the calculation of the risk of nonobservance, we used a validated calculator available online at http://www.comitehta.org/flahs-observance-hta/.
Results
We included 60 hospitalized hypertensive diabetic patients. The average age was 64.87 years with a s.d. of 9.99 years. The sex ratio was 2.1. All patients were diabetic treated with insulin. 43 patients were on both insulin and oral antidiabetic drugs. Hypercholesterolemia was noted in 80% of our patients (48). Coronary heart disease was noted in 20% of our patients (12). 37 patients were suffering from vision disorder: 10 patients are followed for cataract and 17 others are followed for diabetic retinopathy. The average number of tablets taken for HBP was 2.6 with a standard deviation of 0.93. Angiotensin converting enzyme inhibitors and calcium channel blockers are prescribed in respectively 80% and 43.3% of cases. The calculation of the risk of non-compliance concluded that 48.3% of our patients (29) had a high risk of non-compliance, 35% had an intermediate risk and only 17.7% had a low risk of non-compliance. The risk of high nonobservance was noted in 17 women and in 12 men with a significant difference ($P=0.05$). A number of tablets >3 alone is not correlated with a higher risk of non-compliance (Kappa$=0.29$). However, its association with retinopathy increases the risk of non-compliance ($P=0.01$).
Discussion and conclusion
The risk of nonobservance calculator is an easy, accessible and available tool, allowing the optimization of antihypertensive treatment according to the profile of the patients. Its use must be wider in order to better control the High blood pressure.

Deep abscess in the diabetic patient

Lygie Kibhat[1,2], Siham El Aziz[1,2] & Asma Chadli[1,2]
[1]Endocrinology, Diabetology and Metabolic Diseases Department Ibn Rochd University Hospital of Casablanca, Morocco; [2]Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy, University Hassan II, Casablanca, Morocco.

Introduction
Deep abscess represent infectious emergencies. The aim of our study was to evaluate the clinical, biological, radiological and evolutionary of deep abscess in diabetic patients.
Patients and methods
A prospective descriptive study was conducted over a period of 12 months in 2017, including 52 diabetic patients hospitalized in the University Hospital with a our patients deep abscess.
Results
The average age of 52.4 years, a sex ratio of 2.06 M/F, type 2 diabetes predominant (84.6%), an average age of 7 years, a lack monitoring (53.8%), an average HbA1c of 10.5% and degenerative complications (69.2%). Clinical signs found in our patients were fever (34%), pain in the right upper quadrant (28%), earache (8%), localized pain (10%) and proptosis (14%). We noted that 40% were asymptomatic. Biological assessment achieved found a high CRP (88%) with an average of 47.4 mg/l, leukocytosis (50%), multiple abscesses on ultrasound (85%) with an average size of 7 cm, and infiltration/or collection at tomography (60%).We noted the following locations: liver (19), ocular (12), ORL (5), lung (4), psoas (2), breast (2), one conus medullaris, a tuboovarian, renal (2), mediastinal (2), parietal (1) and brain (1). A bacteriological analysis was performed in 90% of patients, blood culture (35%) and removal of pus (70%). Gram negative bacilli were predominant: *E. coli* (30%), Klebsiella (60%) for hepatic abscesses, pseudomonas aeruginosa (16.6%) of corneal abscess and specificity of *Aspergillus fumigatus* in the case of a complicated pansunisitis of orbital cellulitis. Combination therapy with surgical drainage (59.6%), an injectable antibiotic therapy alone (30.8%), bi or triple therapy (69.2%) with an average duration of 14 days and intensified insulin therapy. The outcome was favorable in 95% of patients. One patient who died in post-operative following a pulmonary embolism.
Conclusion
Our study highlighted the interest to seek a deep abscess before any imbalance with a clinical picture which is sometimes little noisy, to improve patients prognosis, which is overshadowed by the lesions severity and delayed diagnosis.

Abscess in the diabetic patient

Lygie Kibhat[1,2], Siham EL Aziz[1,2], Asmaa Mjebbar[1,2] & Asma Chadli[1,2]
[1]Endocrinology, Diabetology and Metabolic Diseases Department Ibn Rochd University Hospital of Casablanca, Morocco; [2]Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy, University Hassan II, Casablanca, Morocco.

Introduction
Hypoglycemia in diabetic patient is susceptible to infection incidence (abscesses). The aim of our study was to evaluate the clinical, biological, radiological and bacteriological abscesses in diabetic patients.
Patients and methods
We conducted a study prospective, including 74 diabetic patients with a confirmed abscess admitted our hospital, from January to December, 2017. Variables studied were epidemiological, clinical, paraclinical and therapeutic. Analysis was done by excel.
Results
Average age our patients were 51 years, a sex ratio of 1.64 M/F. We found average HbA1c of 8.3% and a kenotic decompensation (60.8%). Localizations were: Brain (1), ORL (9), eye (12), lung (4), mediastinal (1), liver (19), psoas (2), breast (2), conus medullaris (1), genitourinary (6) and skin (15). Clinical presentation was polymorphic and insidious on set but corresponded to the site of the abscess for soft tissue infections. Biological assessment found a high CRP (78.2%) and leukocytosis (60%). Identification was based on bacterial blood cultures (40%) and drained fluid analysis (70%). Germs found were: Klebsiella (42.16%), *E.coli* (20.3%), pseudomonas aeruginosa (10.8%), staphylococci and/or streptococci (39%), a specificity of Aspergillus fumigates and of Candida tropicalis. Treatment was medical and surgical, antibiotic susceptibility testing with suitable average duration of 2 weeks and a strict glycemic control. Outcome was favorable in 95% of cases.
Conclusion
The poorly controlled diabetes is a field of immunosuppression favoring infection in various locations. Abscess diabetic patients are often localized in the liver and the eye, with a hight prevalence of Klebsella pneumonia.

A case report of MODY 2 treated as type 2 diabetes mellitus in pregnancy

Adnan Batman, Emre Sedar Saygili, Seda Eren Basmaz, Sezin Dogan Cakir, Duygu Yildiz, Feyza Yener Ozturk, Esra Cil Sen, Rumeysa Selvinaz Erol, Muhammed Masum Canat & Yuksel Altuntas
University of Health Sciences, Sisli Hamidiye Etfal Training and Research Hospital, Endocrinology and Metabolism Department, Istanbul, Turkey.

Introduction
Maturity-onset diabetes of young (MODY) type 2 is caused by mutation of the glucokinase gene. It is characterized by mild fasting hyperglicemia and absence

of vascular complications. It is estimated that the incidence of gestational diabetes is 3%. We aimed to present a pregestational diabetic case with MODY-type 2 in pregnancy.
Case report
A 38-year-old pregnant woman was referred to our clinic for glycemic regulation at 22th week of gestation. She had diagnosis of diabetes mellitus 2 years ago and she was on metformin therapy before pregnancy. Her body mass index was 23.8 kg/m^2 and physical examination findings were normal. Laboratory test results were HbA1c: 7%, fasting serum glucose: 114 mg/dl, C-peptide: 1.85 ng/ml, total cholesterol: 262 mg/dl, triglyceride:138 mg/dl, LDL-cholesterol: 169 mg/dl, Creatinine: 0.76 mg/dl. Her mother and cousin of her mother had diabetes mellitus also. She had two daughters with 23 and 12 years of age. 12-years-old one was being followed in the pediatric polyclinic due to impaired fasting glucose. Because of her family history and BMI $<$ 25 kg/m^2, genetic analysis for MODY was performed. Insulin therapy was started as her glycemic regulation could not be provided with medical nutrition therapy alone. The insulin requirement for glycemic regulation was up to 72 units/day (1.24 U/kg) towards to the end of the pregnancy. No complications were observed in obstetric follow-ups of the patient. At 38th week of gestation, she gave birth to a 3700 g baby by C/S. Genetic analysis demonstrated heterozygous mutation of p.G81S (c.241G>A) compatible with MODY 2 and polymorphism of IVS9c.1253 + 8T $>$ C (rs2908274) associated with 'Type 2 diabetes'. These genetic findings were also determined for newborn baby and 12-years old daughter.

Impact of magnesium deficiency on chronic complications of type 2 diabetes

Marwa Chiboub[1], Faten Hadjkacem[1], Dorra Ghorbel[1], Rim Marrekchi[2], Mohamed Mallek[2], Kamel Jamoussi[2] & Mohamed Abid[1]
[1]Endocrinology-Diabetology Department, CHU Hédi Chaker, Sfax, Tunisia; [2]Biochemistry laboratory CHU Hédi Chaker, Sfax, Tunisia.

Introduction
The magnesium deficiency is frequently associated with diabetes mellitus, it is also incriminated in the occurrence of diabetic complications (micro and macrovascular). Our objective was to study the correlation between magnesium deficiency (Mg) and the presence of chronic diabetic complications.
Material and methods
Prospective study that concerned type 2 diabetics (T2D). Our patients were subdivided into 2 groups G1 and G2: G1 including 17 patients with Mg deficiency, G2 including 13 patients with normal Mg status.
Results
G1 and G2 patients had a mean age of 60.4 $\pm$ 7.5 years and 53.1 $\pm$ 11.6 years, respectively. The sex ratio (H/F) was 0.54 in G1 and 1.6 in G2. G1 patients had a more unbalanced T2D than G2 patients. Diabetic retinopathy, diabetic nephropathy and autonomic neuropathy were observed in 37, 30 and 10% of cases, respectively. These complications were more common in G1 subjects, but without a statistically significant difference between the two groups. The prevalence of microalbuminuria was higher in G2 patients compared to G1 (15.3% vs. 6%). Lower extremity arterial disease was found only in G1 with a frequency of 6%. Coronary and cerebrovascular disease were noted more frequently in G1.
Conclusion
Several mechanisms could explain the role of Mg deficiency in the development of chronic complications of T2DM including the increase in oxidative stress resulting from Mg depletion.

Severe hypertriglyceridemia in type 1 diabetes accompanied by acute pancreatitis and organomegaly

Ibrahim Elebrashy, Hemmat El Haddad, Ahmed Rabie, Mona Yousry, Maha Rakha & Randa Salam
Faculty of Medicine Cairo university, Cairo, Egypt.

Case report
21-year-old female patient visited the emergency department with repeated attacks of vomiting accompanied with continuous non radiating epigastric pain diagnosed as acute pancreatitis. She had three plasmapheresis sessions. She gave history of recurrent similar attacks for the last 5 years with frequent hospitalization she is known diabetic since the age of 15.Hypertensive for 1 year. Menarche at age of 14 with only one cycle. Upon admission, the patient was alert, Weight: 60 kg, height: 164 cm. BMI: 22 pulse: 90 beat/minute blood pressure: 130/70 respiratory rate: 14/min. Temperature: 37°C. Physical examination: eruptive xanthoma on the extensor surface of the forearms and back. Cardiac examination: apex localized in the left fifth space outside MCL, hyper dynamic. Hepatomegaly two fingers below RT costal, normal fundus, normal neurological examination Breast: Tanner 3, Pubic hair: Tanner 4 Laboratory investigations; RBS 375 mg/dl HBA1C: 14.7%, ABG (PH: 7.38 HCO3: 26 Mm/l SaO2 98.0%) CBC HB;11.6 g/dl, TLC: 5.800/ul PLT:245,000/ul/CRP: 132 mg/dl/Chol: 464 mg/dl, LDL: 257 mg/dl, HDL: 25 mg/dl, TG: 9068 mg/dl amylase: 1120 U/l, Lipase: 370 U/l/Na: 141 mEq/l, K: 3.8 mEq/l, Urea: 34 mg/dl Creatinine: 5 mg/dl, 24 h. Urinary PTN: 1.146 g. ALT: 17 IU/l, AST: 19IU/l,Bil T: 0.9 mg/dl, albumin: 4 g/dl FSH: 0.1, LH:0.5, Estradiol:5, TSH:1.7, FT4:1, ACTH:12, Cortisol AM:8, GH:0.1 ng/ml. Abdominopelvic sonar showed: Enlarged Bright hepatomegaly 16 cms, Mild splenomegaly. Diffuse enlarged pancreas of hypo echoic pattern, picture suggestive of acute pancreatitis. Enlarged swollen kidneys (RT kidney 154*48 mm, LT kidney 152*75 mm.) CT abdomen with contrast: diffusely enlarged pancreatic head. X-ray both arms: Bilateral distal humorous multiloculate bubbly lesion with sclerotic margin. Echocardiography: Concentric LT ventricular hypertrophy. MRI brain (Bulky pituitary gland showing a focal central bulge (0.4 $\times$ 1 $\times$ 0.7). Renal biopsy: Minimal change glomerulonephritis. After three plasmapheresis sessions, Intravenous insulin a marked reduction in triglyceride/total cholesterol levels was observed. CHOL 334 mg/dl, LDL 190 mg/dl, HDL 48 mg/dl, TG 880 mg/dl. She was discharged on dietary, lifestyle modifications and fenofibrates 4 month later she came for follow up Marked improvement of her xanthomata, regular cycles, TG 627mg/dl, HbA1c:8.9, normal pituitary imaging, no organomegaly.
Conclusion
Patients with severe hypertricylcerideamia require fast and effective lowering of TG levels in order to reverse the lipotoxic effect on different organs

Diabetic ketoacidosis and acute pancreatitis associated with antipsychotic drugs: report of a case

Maria Cristina Campopiano, Angela Dardano, Cosimo Rodia, Alessandra Bertolotto, Annamaria Ciccarone, Cristina Bianchi, Roberto Miccoli & Stefano Del Prato
Department of Clinical and Experimental Medicine, Section of Diabetes and Metabolic Disease, Azienda Ospedaliero-Universitaria Pisana, University of Pisa, Pisa, Italy.

Introduction
Diabetic ketoacidosis (DKA) is a feature of type 1 diabetes mellitus, but it can develop in people with type 2 diabetes (T2DM) in the presence of precipitating factors. Antipsychotics have been associated with pancreatitis without DKA or hyperglycemia or acidosis with no evidence of pancreatitis. To our knowledge, there are few reports of patients who developed pancreatitis and DKA during treatment with antipsychotis. We present a case of a patient who developed such life-threatening conditions while on antipsychotics.
Clinical case
A 53-years-old Caucasian woman (BMI 32.7 kg/m^2) was transferred to our Unit from the ED where she was admitted for dyspnea and abdominal pain. She had T2DM, managed with diet, and bipolar disorder treated with mood stabilizers and antipsychotics (valproic acid, haloperidol, quetiapine). Initial lab results revealed hyperglycemia (446 mg/dl; HbA1c 118 mmol/mol) and metabolic acidosis (pH 7.0; HCO3- 5.3 mmol/l; 3-beta-hydroxy-butyrate $>$ 3 mmol/l; BEE $-$25 mmol/l). Patient received i.v. fluid and insulin therapy until DKA resolution, but clinical course was complicated by acute pancreatitis (amylase 550 U/l; lipase 1574 U/l). Abdomen CT showed moderate edematous acute pancreatitis, with no evidence of stones or bile duct dilatation. On admission and during the early phase of acute pancreatitis, triglycerides were modestly increased (365 mg/dl). Supportive care with i.v. fluids, bowel rest and pain control were mainstays of therapy. The patient became medically stable after 15 days of hospitalization. Before withdrawal insulin, metformin was introduced with maintenance of satisfactory glycemia (fasting 122 mg/dl; post-prandial 124 mg/dl). Antipsychotic medications were reviewed after psychiatric consultation.
Discussion
We present a case of a T2DM patient who developed pancreatitis and life-threatening DKA while receiving antipsychotics, that may be the common denominator linking DKA and acute pancreatitis though the exact mechanisms responsible remain to be identified. As far as DKA is concerned, antipsychotics may have an isolated toxic effect on beta-cell resulting in relative

hypoinsulinemia and hyperglucagonemia. Marked hypertriglyceridemia can trigger acute pancreatitis, but triglyceridemia were only moderately increased in our case. This suggest that in our patient pancreatitis may be the result of drug-mediated acinar-cell damage or idiosyncratic drug reaction. In summary, physicians should be aware of the possibility of life-threatening adverse effects in T2DM patients on antipsychotic treatment especially when in combination with mood stabilizers. These subjects should undergo careful monitoring as they may have inappropriate assessment of signs and symptoms.

Diabetic ketoacidosis, hypertriglyceridemia and acute pancreatitis- a case report

Sanja Borozan, Snezana Vujosevic, Brigita Smolovic, Sreten Kavaric, Aleksandar Djogo & Djordjije Krnjevic
Clinical Centre of Montenegro, Podgorica, Montenegro.

Diabetic ketoacidosis (DKA) is a state of absolute or relative insulin deficiency characterized by hyperglycemia, metabolic acidosis and ketosis and occurs mainly in type 1 diabetes mellitus (DM). While enhanced lipolysis and inhibition of lipoprotein lipase in DKA lead to typically not severe elevation of triglyceride (TG) level, extreme hypertriglyceridemia (HTG) is rarely seen. If complicated with acute pancreatitis (AP), DKA and HTG form a scarcely reported triad, controversial regarding pathophysiology and possible sequence of events. We report a case of a 35-years-old obese male, non-smoker, admitted to the hospital through the emergency department because of a worsening, sharp pain in upper abdomen associated with high fever, anorexia, nausea and vomiting. His past medical history included dyslipidemia diagnozed 2 years ago (shortly on statins) and cholecystectomy 9 years ago. He denied any alcohol consumption. On physical examination, he was concious, dehydrated, dyspneic and normotensive, with mildly tender abdomen in epigastric region. Laboratory findings revealed blood glucose of 24.6 mmol/l with metabolic acidosis and positive ketones in urine. His serum was milky and turbid, which suggested severe HTG: measured TG level was 110 mmol/l. Serum amilase and lipase levels were 878 and 1862 IU/I respectively. A contrast-enhanced computed tomography of the abdomen confirmed the diagnosis of AP. Upon admission, DKA and AP were successfully treated by insulin infusion, intravenous hydratation, potassium supplementation and analgesics. Additional analysis showed normal level of C-peptide, glycated hemoglobin (HbA1c) of 13.4% and negative immunology for type 1 DM which supported the diagnosis of DKA as initial manifestation of type 2 DM (T2DM). The reported case of DKA in adult with previously undiagnosed T2DM accompanied with severe HTG and AP demonstrates a significance of multidisciplinary approach concerning a challenging prompt diagnosis, treatment modalities and consequent follow-up after hospital discharge.

Implications of dietary omega-3 fatty acid supplementationon oxidative damage and inflammatory response in type 2 diabetic depressive patients

Alina Crenguta Nicolae[1], Andreea Letitia Arsene[1], Maria Ladea[1,2], Mihnea Manea[2], Mihai Bran[1], Olivia Timnea[2], Daniela Elena Popa[1], George Traian Alexandru Burcea Dragomiroiu[1], Bruno Stefan Velescu[1], Cristina Manuela Drăgoi[1] & Ion-Bogdan Dumitrescu[1]
[1]University of Medicine and Pharmacy 'Carol Davila', Bucharest, Romania; [2]Ecological University, Bucharest, Romania.

The prevalence of depressive symptoms in patients suffering from type 2 diabetes is commonly acknowledged. Even mild depression is recognized as clinically relevant for the general health outcomes in this vulnerable patient group. Research in this area has been focused on biochemical markers reflecting common pathological processes of insulin resistance, inflammation and oxidative damage, all being assumed to be interconnected in both diabetes and depression. Most of the studies revealed the massive inference of oxidative stress in diabetes pathogenesis by the alteration in enzymatic systems (catalase, superoxide dismutase), lipid peroxidation, impaired glutathione metabolism and decreased vitamin C and lipoic acid levels. Reactive oxygen species cause damage to lipids, proteins and DNA when in excess, and can ultimately result in cell death, playing a role in the pathophysiology of diabetes mellitus, cardiovascular disease, cancer and a number of psychiatric disorders, including depression. Oxidative stress is a candidate pathway that may link depression to physiological changes. Also, a hypothesis on the involvement of inflammatory as well as oxidative stress pathways in the pathogenesis of depression has received much attention. Association between depression and oxidative damage due to both increased reactive oxygen species production and decreased antioxidant capacity has been clearly demonstrated, suggesting that oxidative stress might provide a plausible biochemical link between depression and unfavorable health outcomes. The most likely generator of oxidative stress in depression is considered to be a chronic, low-grade inflammation resulting from activation of cellular immunity able to induce an immune-mediated damage to the cells. In the present clinical study, we aimed to assess changes that occurred during a period of 6 months, consequent to the administration of polyunsaturated fatty acid supplements (300 mg of omega-3 fatty acids). Biomarkers of oxidative stress and inflammation were evaluated in three different groups of patients: non-diabetic but depressive patients; diabetic, but non-depressive patients; and finally, in diabetic-depressive patients. Results were corroborated with cortisol and serotonin levels, in order to provide a clear conclusion on the molecular homeostasis modulation effects of omega-3 fatty acids. The unequivocally obtained regulatory effect of omega-3 fatty acids can be explained by the fact that it stabilizes cell membranes, participates constitutively in their structure, normalizing membranes fluidity and improving cell membranes' ability to counteract oxidative stress.

Psychosis because of alcohol abstinence in a diabetic subject

Marjeta Kermaj[1], Edlira Hoxha[1], Ermira Muco[1], Thanas Fureraj[1], Violeta Hoxha[1], Ruden Cakoni[1], Enalda Demaj[2] & Agron Ylli[1]
[1]UHC 'Mother Tereza', Tirana, Albania; [2]Regional Hospital of Berat, Berat, Albania.

Introduction
Although psychiatric manifestations in the form of delirium, confusional states, and psychosis have been commonly reported in relation to hypoglycemia, association of hyperglycemia with psychiatric manifestations has been less commonly reported. Acute hyperglycemia is known to alter mood state and impairs cognitive performance in patients with diabetes mellitus. However, association of acute psychosis (in the absence of cognitive disturbances) with hyperglycemia has not been reported. It is generally accepted that alcohol-related psychosis remits with abstinence.
Case report
We report the case of a male 67 years old diagnosed with diabetes mellitus (DM) 3 years ago, treated with combined hypoglycemic oral medications, which has been discontinued for some days. He consumed high quantities of alcohol for many years, but he had stopped drinking for two days. He presented in emergency unit with these complaints: Vomiting, epigastric pain, Polyuric-polydipsic syndrome, fatigue, agitation. Familiar history negative. Objectiv examination: conscious, active position, low turgor skin, dry tongue, rhythmic heart rate, TA 110/60 mmHg, Fc 88/1 min. lungs normal, lower limbs neither edemas nor wounds. Blood biochemistry: glycemia 615 mg/dl, urea 82 mg/dl, creatinine 3.7 mg/dl, AST 49U/L(0–35), AlT 23 U/L(0–45), LDH 340 U/l (0.3–1.2),total protein 5.9 g/dl (6.2–8.3), troponin 0.283 ng/ml. WBC 5100, Granulocyte 80.2%, lymphocytes and monocytes normal. RBC 3.14 million/mm^3, HGB 10.9, PLT 187/mm^3, MCV micron/m^3 100 (80–97), urine analyses: negative acetone, albumin 2.64 g/leukocyte filled areas, 4–5 erythrocytes/field. Imagery examination:Abdominal ultrasonography, hepatosteatosis, liver with large dimension 158 mm, rough echo structure, portal vein 11 mm, pancreas normal.without peritoneal liquid. According to surgeon consultation, the patient was without acute surgical problems. He was treated with Insulin, fluids, electrolytes,thiamine, antibiotics.The next day: The general condition was better but he had visual hallucinations and he wanted to leave the hospital during the night. Psychiatrist Consultation: Psychotic Symptoms caused by alcohol abstinence. After starting of the psychiatrist treatment with Librium 10 mg 3x1 tb, haloperidol 2×10 drops, he was feeling better.
Conclusion
Psychosis in a diabetic person (alcohol user) with hyperglycemia, can be caused by stopping drinking for only some days. Every physician must be aware about this situation to diagnose it early, and to prevent sad results.

Selfie driven thyroid disease leads (SET): a study on a unique phenomenon from Surgical Endocrinology Department

Ramakanth Bhargav Panchangam[1], Chakrapani B[2], Ramesh B[3], Rajesh B[3], Venkateshwara Reddy M[3], Vignesh D[3], Vimala Devi N[1] & Gayathri G[3]
[1]Endocare Hospital, Vijayawada, India; [2]Neuro Hospital, Vijayawada, India; [3]VMC, Kurnool, India.

Introduction
Taking a photograph of self alone or with a group called Selfie, has become modern day rage with spurt in smart phone technology. It has catapulted from a hobby in to psychiatric ailment, especially amongst teens and young adults. Though, it is considered as a psychiatric aberration keeping them aloof from social interactions, we observed an inadvertent advantage in this habit. In this context, we present some intriguing findings through this study.
Material and methods
This retrospective study was based on compilation of 6 cases from endocrine surgery outpatient and inpatient database collected over 2 years period. The inclusion criteria are – the chief complaint (CC) was noted only after watching the selfie picture and not otherwise; the patient is obsessive of taking frequent selfie photographs and/ or uploads their pictures frequently in social media ($\geq$3 pictures/day); the CC lead them to consult physician; the picture was captured by oneself or other person who was part of that image; the CC lead to definitive diagnosis of thyroid disease requiring treatment. All other clinical, investigative and treatment (medical and surgical) were studied.
Results
In all we had 6/5520 (0.0011%) cases meeting the above criteria. CC and later confirmed in pictures were three cases of Grave's disease associated ophthalmopathic exophthalmos, two cases of goiter and one case of facial puffiness (myxoedema related). All these CC helped in diagnosing Graves' disease (3), Nodular goiter (2) and hypothyroidism confirmed by appropriate investigations. 4 cases underwent thyroidectomy, two cases took conservative medical treatment.
Conclusions
Though selfie is considered as a modern day life style induced psychiatric disease, sometimes it can help in picking up endocrine diseases in earlier stages.

FGF21 levels in patients with breast cancer

Zeynep Sahiner[1], Anara Karaca[2], Filiz Bakar[3], Gıray Akgul[4], Mehmet Ali Gulcelik[4] & Nese Ersoz Gulcelik[5]
[1]Department of Internal Medicine, Ankara Trainig Hospital, Ankara, Turkey; [2]Department of Endocrinology, Ankara Trainig Hospital, Ankara, Turkey; [3]Department of Biochemistry, School of Pharmacy, Ankara University, Ankara, Turkey; [4]Department of Surgical Oncology, Ankara Oncology Hospital, Ankara, Turkey; [5]Department of Endocrinology, Ankara Gulhane Medical School, Ankara, Turkey.

Aim
FGF-21, is a member of the FGF family that is involved in biological processes such as embryonic development, cellular growth, morphogenesis, tissue repair, tumor growth and invasion, with mitogenic and cellular vital activity activity in the cytogenetic localization of 19q13.33. Breast cancer is the fatal disease most commonly seen in women and increasing in frequency and the relationship between hormones secreted from adipose tissue and some cancers has been shown in recent studies. Our aim in this study is to measure FGF21 levels in breast cancer patients and show their association with breast cancer.
Method
39 patients with newly diagnosed breast cancer and 39 healthy subjects as control group were participated in the study. An extra tube blood sample was taken during the patient's routine blood test and FGF-21 was studied by ELISA method from serum samples.
Results
The demographic and laboratory data of the newly diagnosed breast cancer patient group and the control group were compared. The control group consisted of 39 participants with a mean age of 52.49 $\pm$ 7.02 years. In the patient group, 39 participants with a mean age of 52.15 $\pm$ 6.21 years were included in the study. In the control group, average FGF21 measurement was 121.35 $\pm$ 88.4 pg/ml, while FGF21 measurement in the patient group was 171 $\pm$ 117.45 pg/ml and a significant difference was detected (*P*: 0.036).
Conclusion
It has been thought that FGF21 has significant and positive effects on glucose, lipid and energy metabolism as well as slowing effects on growth in cancer cells and may be used later as a biological marker for breast cancer.

Pharmacological chaperones for rescue of the mutant AVPR2s

Beril Erdem, Dilara Sahin, Hatice Mergen & Emel Saglar
Department of Biology, Faculty of Science, Hacettepe University, Ankara, Turkey.

Using pharmacological chaperones is one of the most common area to rescue trapped proteins from Endoplasmic reticulum (ER) or Golgi apparatus as therapeutic targets in research of some endocrine disorders. Diabetes insipidus is one of these disorders and AVPR2 is seen mostly mutated in hereditary type of the disorder. As proteins go through a journey from ribosome till the place where they function at, AVPR2 also tracks the same way as a G-protein coupled receptor. A mutation in AVPR2 could effect three dimensional functionally active structure of the protein and it could be trapped in ER or Golgi apparatus. Consequently, its cell surface expression, which primarly locates at the basolateral membrane of principal cells in the collecting duct, could decrease which shows its affects on the syptoms. As a therapeutic agent, SR121463A and SR49059 are commonly used for research the rescue potential of mutant AVPR2s. We aimed to show the rescue potential of SR121463A and SR49059 as a pharmacological chaperones in treated AVPR2 mutants (G12E, R68W, ΔR67_G69/G107W, V88M, R106C, V162A, T273M). These mutants were previously described and functionally analysed by our group. After treatment with SR121463A and SR49059, cell surface expression analyses were done for mutants. This work was funded by The Scientific and Technological Research Council of Turkey (SBAG Project No: 216S304). As a result, these pharmacological chaperones showed that they has a rescue potential at different levels according to the mutation. Some mutations have severe symptoms and also they showed loss of function but we could show the rescue of these some mutants using with SR121463A and SR49059. In conclusion, as a therapeutic target, SR121463A and SR49059 could be used to rescue of some mutated AVPR2s *in vitro* and many of these kind of targets are mainly used. To get a more clear view, we will perform cAMP accumulations assay and cell imaging analysis for these mutants using with SR121463A and SR49059. In our opinion, these kind of *in vitro* studies will be helpful to use of these pharmacological chaperones *in vivo* and shed light to the future studies. Especially for the disorders which have severe symptoms, *in vitro* and *in vivo* studies have an importance to reduce the severeness of the symptoms.

Tolvaptan; OPC-41 061, Mozavaptan; OPC-31 260, OPC-21 268 as pharmacological chaperones to rescue of mutant AVPR2s

Dilara Sahin, Emel Saglar, Beril Erdem & Hatice Mergen
Department of Biology, Faculty of Science, Hacettepe University, ANKARA/Çankaya, Turkey.

Nefrojenic Diabetes insipidus is one of the typical conformational disorders result from protein misfolding and degredation or aggregation due to the mutations in AVPR2. The patients of nephrogenic Diabetes insipidus have difficulty in concentrate of urine and because of this, they have polyuria, hypoosmolar urine and hypernatremia in variable levels. To make them relieved, many treatment strategies have been studying and using dDAVP nasally is one of these strategies. Another treatment approach on this type of conformational disease is *in vitro* treatment of mutant AVPR2s with pharmacological chaperones (PCs). PCs are small molecules that bind to misfolded proteins and stabilize them and rescue these mutated proteins from quality control system of Endoplasmic reticulum. In this study, Tolvaptan; OPC-41 061, Mozavaptan; OPC-31 260 and OPC-21 268

were selected as pharmacological chaperones for treatment of previously identified and functionally analyzed mutations (R68W, DR67_G69/G107W and T273M) by our group. As a functional analysis, we performed cell surface ELISA after the treatment of mutant AVPR2s with OPC-41 061, OPC-31 260 and OPC-21 268. Our study was supported by The Scientific and Technological Research Council of Turkey (SBAG Project number 216S304). According to the ELISA results, some mutant AVPR2s could be rescued after the treatment with OPC-41 061, OPC-31 260 and OPC-21 268, separately. In conclusion, we think that using pharmacological chaperones *in vitro* has an importance on developing treatment strategies for these kind of conformational disorders. In the future, we will perform more functional analysis experiments on these mutants after the treatment with OPC-41 061, OPC-31 260 and OPC-21 268, separately. Consequently, all these analysis will make us to understand the precise affect of OPC-41 061, OPC-31 260 and OPC-21 268 *in vitro*.

A case with autoimmune polyglanduler syndrome type 3A

Adnan Batman, Rumeysa Selvinaz Erol, Feyza Yener Ozturk, Esra Cil Sen, Muhammed Masum Canat, Emre Sedar Saygili, Sezin Dogan Cakir, Seda Eren Basmaz, Duygu Yildiz & Yuksel Altuntas
University of Health Sciences, Sisli Hamidiye Etfal Training and Research Hospital, Endocrinology and Metabolism Department, Istanbul, Turkey.

Introduction
Autoimmune polyendocrine syndromes (APS) are rare endocrinopathies characterized by the coexistence of at least two glandular autoimmune diseases. APS comprise a wide spectrum of autoimmune disorders and are divided into a very rare juvenile (APS type 1) and a more common adult type with (APS 2) or without adrenal failure (APS 3). We present a patient with polyglanduler syndrome type 3a.
Case report
A 39-years-old female patient was presented to our emergency department with the complaints of nausea, vomiting and urinary incontinence. She was consulted to our endocrinology clinic with the diagnosis of diabetic ketoacidosis. In her physical examination, webbed neck, shortness of height (145 cm), low hairline at the back of the neck, exophthalmos and genu valgum was determined. In her past medical history, she had received intermittent hormone replacement therapy because of primary amenorrhea and she had been diagnosed with diabetes mellitus 2 years ago and she was using oral antidiabetic drugs also added insulin treatment for the last 6 months. The patient was admitted to our clinic and underwent insülin infusion and fluid replacement therapy.Laboratory testresults as follows glucose: 114 mg/dl, HBA1C: 11,8%, TSH >0.005 uIU/ml, FT4: 0.98 ng/dl, FT3: 4.8 pg/ml, anti-TPO: 600 IU/ml, anti TG: 341.2 IU/ml (0–115), FSH: 36 mIU/ml, LH: 15 mIU/ml, E2: <5 pg/ml, Cortisol: 18.96 ug/dl. The patient's anti GAD and ICA antibodies were positive and the patient was diagnosed as Type 1 diabetes mellitus. The intensive insülin treatment was started after resolution of diabetic ketoacidosis. The thyroid stimulated antibody was positive and the scintigraphy and ultrasound was consistent with the graves. The genetic test for hypergonadotropic hypogonadism was consistent with Turner's syndrom(46X DEL (X) Q13). ANA, celiac antibody, anti-parietal antibody and the other autoimmun antibodies which screening were negatively determined.
Discussion
The third type has been described in adults that, contrary to types 1 and 2, does not involve the adrenal cortex. No clinical differences between types 2 and 3 have been described except the absence of adrenal failure. APS-3A includes autoimmune endocrine diseases autoimmune thyroid disease, type 1 diabetes mellitus, lymphocytic hypophysitis, premature ovarian failure, and Hirata's disease. It is concluded that patients with a single autoimmune component of polyendocrine syndrome should be screened to exclude other autoimmune endocrine disorders.

DOI: 10.1530/endoabs.56.EP95

Cardiotoxicity from glycyrrhizic acid inhibition of 11-beta steroid dehydrogenase

Christopher Philbey[1] & Arran Marriott[2]
[1]Hull Royal Infirmary, Hull, UK; [2]York Teaching Hospital, York, UK.

Ingestion of excessive amounts of liquorice may cause significant electrolyte imbalances due to a mimicking of mineralocorticoid excess. A 70-year-old female attended hospital with palpitations and was found to have hypokalaemia. She was documented to have multiple supraventricular ectopic beats coinciding with her feeling of palpitations, This was precipitated by toxic consumption of liquorice, more than 2 kg in 72 h, to celebrate her 70th birthday. All abnormalities resolved with abstinence from further birthday liquorice. Mineralocorticoids and corticosteroids are structurally similar and bind equally to the Minrealocorticoid Receptor (MR). It is the selective presence of isoform 2 of 11beta-hydroxysteroid dehydrogenase (11BHSD) that downregulates the effect of cortisol in the tissues mentioned above. This enzyme utilizes NAD to oxidize cortisol to the inactive cortisone to prevent MR activation. Isoform 1 of this enzyme is present in all metabolic tissues to conversely reduce cortisone to cortisol to activate Glucocorticoid Receptors. Therefore, the placement and function of 11BHSD is critical to preventing an apparent mineralocorticoid excess from the unopposed effect of cortisol on a non-selective MR. Liquorice root (Glycyrrhiza glabra) contains glycyrrhizic acid (GZA), this molecule directly inhibits type 2 11BHSD. Acceptable safe dosage is 0.2 mg/kg with toxic doses beginning at consumption greater than 2 mg/kg. Given that liquorice contains 0.2% GZA by mass, a 60 kg adult would therefore exceed safety at 6g and reach toxicity at 60 g of liquorice per day. Our patient's intake therefore exceeded this by a factor of 11. Hypokalaemia has long been associated with an increase in cardiac conduction abnormalities. The resultant hypokalaemia from upregulating the aforementioned pumps then has three major cardiotoxic effects in that it inhibits outward potassium currents in ventricular tissue, it inhibits the cardiac $Na+-K+$ pump, and the resting membrane potential is elevated with increased threshold for depolarization and hyperpolarized, this generally slows effective wave conduction. The combination of these three effects therefore facilitates re-entry rhythms with resultant tachyarrhythmias. Reports of these are not new, but they are usually in extremis. A case in Turkey linked the ingestion of liquorice to an episode of ventricular fibrillation in a patient with Brugada syndrome. Similarly, a patient from Oman developed recurrent polymorphic ventricular tachycardia episodes however, she was morbidly obese. Our patient was unique in having a structurally normal heart without cardiac risk factors and her rhythm returned to its baseline without intervention, thus, demonstrating the early stages of liquorice-induced cardiotoxicity.

Stein leventhal syndrome: a report of two cases

Amina Abdi
E.P.S.P Ghoualem Oran, Oran, Algeria.

Introduction
The polycystic ovary syndrome (PCOS) is the most common endocrine disorder of women. Its clinical manifestations are characterized by infertility, hirsutism and obesity. We report two cases of PCOS but with different signs revelations.
Observation 1
23 year old patient presenting with metabolic syndrome, with dysmenorrhea, after investigation, diagnosis of type two diabetes with PCOS.
Observation 2
Patient aged 35 years old who consults for infertility that lasts for 5 years with obesity and hirsutism, diagnosis PCOS was diagnosed according to different criteria clinico' radiologiques.
Results
For both our patients the care first focus was weight control, changes in eating habits, promote physical activity. Introduction of an oral antidiabetic (metformin) for both our patients and correction of cardiovascular risk factors.
Discussion
Most published studies confirm that metformin improves insulin sensitivity and reduces hyperinsulinemia in PCOS in a similar manner to what is known for patients with type 2 diabetes. In addition, the reduction of the insulin is associated to hormonal changes: increase of SHBG, decrease in circulating levels of LH and hyperandrogenism, often with improvement of ovulation.
Conclusion
The polycystic ovary syndrome is a common condition affecting nearly 12% of women of childbearing age. It is characterized by an increase in plasma testosterone and LH, and insulin resistance, mainly in anovulation, diet and lifestyle rules and metformin, can give satisfactory results.

Diabetes mellitus reveals malignant vaterian ampulloma

Amina Abdi
E.P.S.P Ghoualem Oran, Oran, Algeria.

Introduction
Diabetes is a risk factor for pancreatic cancer and recent studies confirm this relationship. We report the case of a patient in whom an inaugural diabetes mellitus revealed a malignant vaterian ampuloma.
Observation
A 56-year-old woman with a family history of type 2 diabetes consults for suspicion of type 2 diabetes, polydipsic syndrome, and all-day hyperglycaemia greater than 2 g/dl. During the interrogation, there is a loss of appetite, a significant weight loss without quantification, a cutaneous-mucous sub-jaundice, pruritus and clinical cholestasis syndrome. Presence of a biological cholestasis syndrome with vaterian ampulloma at bili-MRI, an adenocarcinoma was confirmed in the pathological study. Insulin therapy has been initiated for the treatment of diabetes mellitus and surgical treatment such as duodeno-pancreatectomy due to the invasive nature of the tumor, currently the patient is post-surgery stable but very unbalanced in terms of glycemic control.
Conclusion
The link between diabetes and pancreatic cancer is well known, but the mechanisms of this association remain to be clarified. Between type 2 diabetes associated with pancreatic neoplasia or paraneoplastic diabetes, hence the importance of monitoring newly diagnosed diabetics.

Where is the hitch in our interdisciplinary approach? Perceptions of health care providers towards the challenges at diabetes management clinics in Oman

Kamila Al-Alawi[1,2], Margareta Norberg[1], Ahmed Al Mandhari[3] & Helene Johansson[1]
[1]Umea University, Umea, Sweden; [2]Ministry of Health, Muscat, Oman; [3]Sultan Qaboos University Hospital, Muscat, Oman.

Background
The diabetes management clinics in primary health care centres in Oman aim to provide interdisciplinary diabetes management for their patients. The inter-disciplinary management is proved in the literature to have successful outcomes and help the patients to reach their glycemic control fast and safe. Therefore the diabetes management in Oman follows national guidelines, which are based on IDF and AACE guidelines and support the interdisciplinary approach. Despite the presence of guidelines and interdisciplinary team, the diabetic clinics still face several challenges that can affect the health care providers interdisciplinary approach and the diabetic patients' glycemic goal and cause serious implications.
Materials and methods
A study was conducted in five purposely-selected health care centres in Muscat the capital of Oman to explore the present challenges and their implications on the diabetic service provision. The methodology used was non-participant observations and interviews with members of the team that includes: physician, nurse, dietician, health educator, pharmacist, assistant pharmacist, psychologist and medical orderly.
Results
The results disclosed several challenges related to diabetes management clinic at public primary health care centres. The challenges were related to many factors including health care providers' shortage and communication, health providers' interests, knowledge and skills, interdisciplinary service provision, cultural believes and traditions in the community, in addition to diabetes and health awareness in the country.
Conclusion
The study disclosed perceptions of care providers towards challenges related to diabetes management clinics in three different settings in public primary care and within two contexts: health care centre and community. The study identified the findings in the frames of the providers' tasks and roles during service provision and addressed them at different levels with a lot of involvements, shared responsibilities and implications.

Characteristics of clinical and morphological features of functioning and nonfunctioning pituitary adenomasand disorders commonly associated with them

Kotryna Tulabaite[1], Anna Splitaite[1], Agne Abraitiene[2] & Gintare Zelnyte[2]
[1]Vilnius University, Vilnius, Lithuania; [2]Vilnius University Hospital Santaros Klinikos Centre of Endocrinology, Vilnius, Lithuania.

Background
The prevalence of pituitary adenomas (PAs) is increasing as the development of imaging techniques. The objective of this study is to assess the clinical and morphological features of non-functioning, prolactin, and grown-hormone secreting pituitary adenomas and to analyze the accompanying diseases of each condition.
Methods
A retrospective analysis of the clinical records of patients with non-functioning (NFPA), prolactin (PRL+) or grown hormone (GH+) secreting adenoma was performed. A total of 194 patients who attended Vilnius University Santaros Clinic's in the year of 2016 were analyzed.
Results
The distribution of each pituitary adenoma subtype was prolactin-secreting adenomas occupying 45.9% of the total subjects. The study founds that between all PAs, men have significantly larger tumors (average 23.46 mm) than women (average 11.84 mm). Most patients complain of one symptom related to their diagnosis, patients who complain of three and more symptoms tend to have bigger tumors (12.27 mm – average size in one symptom group, 16.87 mm – in three symptoms group), however, there is no significant correlation between the higher number of symptoms and tumor size. Headaches were the most common symptom among NFPA patients (36.5%), menstrual dysfunction in females was among PRL+ group (36.4%) while enlargement of hands and feets were in GH+ group (48.7%). Younger patients were more often diagnosed with prolactin-secreting adenomas (average 39 years old), nonfunctioning and GH secreting adenomas are usually diagnosed within 49–51 years old patients. Thyroid conditions (hypothyroidism, hyperthyroidism, goiter, thyroid nodules and cancer) accompanied 49% of all patients diagnosed with PA's. Statistically significant correlation was between those two disorders was found in GH secreting group, where 81% of patients had had thyroid conditions.
Conclusion
Male patients tend to have significantly larger pituitary tumors than female. Patients with prolactin-secreting pituitary adenomas are more likely to be diagnosed at a younger age compared with patients with nonfunctioning and GH secreting adenomas. There is a correlation between GH secreting adenomas and thyroid diseases.

Prolactinoma management: factors that might predict remission of the disease after 12 months of treatment

Anna Splitaite[1], Kotryna Tulabaite[1], Agne Abraitiene[2] & Gintare Zelnyte[2]
[1]Vilnius University, Vilnius, Lithuania; [2]Vilnius University Hospital Santaros klinikos Centre of Endocrinology, Vilnius, Lithuania.

Background
Dopamine agonists (DAs) are the primary treatment for both microprolactinomas and macroprolactinomas. Two medications are FDA approved for the medical treatment of prolactinomas: cabergoline and bromocriptine. Although bromocriptine is deemed a secondary option after cabergoline, its lower cost may be a consideration for some patients. The purpose of this study is to analyze patients treated with different DAs during 12 months period and to identify the unchangeable factors that might predict the remission.
Methods
We retrospectively evaluated 89 patients with the diagnosis of prolactinoma who had been treated with dopamine agonists at Vilnius University Santaros Clinics in the year of 2016. The patients were divided into two groups, according to whether biochemical remission was achieved after 12 months of treatment, or not, and the factors that might predict possible remission were analyzed. Patients, treated with both drugs: cabergoline and bromocriptine or with surgery during 12 months period were excluded.
Results
Sixty-six patients (52 women and 14 men) with a mean age of 19–76 years were studied. 44 patients (66.7%) were treated with bromocriptine, while 22 (33.3%) with cabergoline. 46 patients (69.7%) achieved remission after 12 months of treatment while 20 patients (30.3%) did not. 75% of patients used bromocriptine

in a group where remission was not achieved while in the remission group bromocriptine was used for 56.5% of patients. Patients who achieved remission were younger: on average 38.5 years old, while other 41.1 years old, also the initial prolactin level was 8.82 time lower in the remission group.
Conclusion
Although more patients who were treated with cabergoline achieved a positive outcome, it is not statistically significant that cabergoline increases the chance of remission. Possible unchangeable factors that might predict the positive outcomes like the age, a smaller size of the tumor or a lover prolactin level before starting the treatment are not statistically significant either.

A differentiated approach to the treatment of pituitary apoplexy

Maxim Kutin, Pavel Kalinin, Dmitriy Fomichev, Oleg Sharipov & Liudmila Astafyeva
N.N. Burdenko National Medical Research Center of Neurosurgery, Moscow, Russian Federation.

Introduction
The risk of pituitary apoplexy (PApopl) is up to 9.5%. In 80% of cases, it is the first manifestation of the disease.
Material and methods
The study included 94 PApopl from 1 day up to 9 years. Conservative treatment was performed in 37 cases, and 59 were operated on including 14 giant posthemorrhagic cysts. The probability of resorption – it is possible in 85%, instead of cysts (the probability of resorption of $\sim$ 15%). After 3 months, for PApopl, resorption of the tumor is sharply reduced. The use of Dexamethasone in the treatment shows an important role: slightly increases the probability of resorption and significantly increased the probability of visual oculomotor improvement. Regression hypopituitarism was shown in 87.5% of cases, and it was shown in 17.3% of cases without Dexamethasone. Most of the tumors did not show aggressive growth. Mutation p53 was not found. Only half of the observations identified receptors for epidermal growth factor (EGFR). In almost all cases revealed the expression of Cyclin D1, but the presence of mitosis in tumor cells revealed only a quarter of them. The level of Ki-67 did not exceed 5% in most cases. Quite a separate group of tumors should be considered a tumor with giant posthemorrhagic cysts. This is actually a separate disease. Treatment of such patients is associated with an extremely high risk of complications, and mortality reaches 30%. The most effective method of treatment was transsphenoidal endoscopic cyst evacuation followed by prolonged drainage into sphenoid sinus, in cases without intraoperative CSF-leak.
Conclusion
In contrast to the conventional view, when the most PApopl need for urgent removal, we offer a differentiated approach to the treatment choice depended on the size and radiological characteristics of the tumor and the dynamics of the patient condition during the conservative therapy.

Unusual association: turner syndrome and anterior pituitary insufficiency in 6 cases

Wajdi Safi[1], Faten Hadj Kacem[1], Mariem Moalla[2], Dorra Ghorbel[1], Fatma Mnif[1], Mouna Mnif Feki[1], Nabila Rekik[1], Neila Belghith[3], Fatma Abdelhedi[3], Hassen Hadj Kacem[2] & Mohamed Abid[1]
[1]Department of Endocrinology, Sfax, Tunisia; [2]Laboratory of Molecular and Cellular Screening Processes, Center of Biotechnology of Sfax, Sfax, Tunisia; [3]Human genetic laboratory, Hedi Chaker Hospital, Sfax, Tunisia.

Introduction
Turner syndrome (ST) affects 1/2500–1/4000 of female births, its association with congenital malformations is traditional, however the coexistence of hypopituitarism is exceptional. In this context, we report 6 patients; including 3 belonging to the same family and in whom the association of anterior pituitary insufficiency (IAH) to a ST was confirmed.
Results
The average age of our patients was 17.2 years (11–31). The ST was selected for dysmorphic syndrome with impuberism in sporadic cases ($n=3$) and familial cases ($n=3$), except for the fourth sister who presented spontaneous puberty with integrity of the pituitary axes with the presence of an X ring chromosome. Somatotropic deficiency (peak GH <10 ug/l) and corticotropic deficiency (cortisol: average 65 ng/ml and ACTH: average 4 pg/ml) were confirmed in all sporadic cases while the gonadotropic and thyrotropic axes were spared. On the contrary; in familial cases they were consistently affected (FSH: mean 1.1 mU/ml, LH: mean 2 mU/ml, E2 <9 pg/ml, FT4: average 4.2 pmol/l, TSH: average 1.3 mU/l) with integrity of the corticotropic axis. MRI showed pituitary hypoplasia in all familial cases and pituitary stalk interruption syndrome in only one sporadic case. The karyotype showed a monosomy in 3 cases and a mosaic ST in the 3 remaining cases, including one case with abnormal X chromosome structure. No correlation was found between the chromosome formula and the anterior pituitary involvement.
Discussion
We report the largest serie concerning the association between IAH and ST: 6 cases out of 11 in the literature. Co-segregation of congenital IAH with pituitary hypoplasia and X chromosome aberrations could imply a biomolecular anomaly of transcription factors responsible for the differentiation and development of pituitary cells such as: PROP1, POUF1, Hesx1, Lhx3, Lhx4, and Ptx2.
Conclusion
The aetiopathogenic link between X chromosome abnormalities and the occurrence of AHI remains unclear; the progress of molecular biology may clarify the interrelation between transcription factors and sex chromosome segregation abnormalities.

EP104

Evaluation of differential diagnosis and treatment stages of TSH-secreting pituitary microadenoma which responding to cabergoline therapy

Soner Cander, Ozen Oz Gul, Elif Gunes, Canan Ersoy & Erdinc Erturk
Uludag University, Bursa, Turkey.

Introduction
High thyroid hormone levels with unsupressed TSH (atypical hyperthyroxinemia) is one of the difficult endocrinologic conditions. When the conditions leading to euthyroid hyperthyoxinism are excluded, TSH secreting pituitary adenomas (TSHoma) and thyroid hormone resistance beta syndrome (THRB) lead to this picture as rare diseases. This report aims to evaluate the diagnostic and therapeutic stages in the case of TSH-secreting pituitary microadenoma which response to cabergoline treatment.
Case
A 49-year-old male patient was evaluated three years ago for palpitations and sweating. TSH, fT3 and fT4 were found 1.0 μIU/ml (0.350–4.940), 5.2 pg/ml (1.71–3.71) and 1.84 ng/dl (0.70–1.48) respectevely. Patient subsequently losted from the follow-up. Because of the increase in complaints has been reevaluated two months ago and similar findings were found in the tests. Pituitary MRI showed a pituitary adenoma on the left side and 7×4 mm in-size. Atrial fibrillation was present in the clinic, SHBG level was 62 nmol/l (10–57). In the TRH stimulation test, TSH levels were 1.598, 5.43, 6.702, 6.081, 5.521 (considered non-diagnostic). Alpha subunit level was 1.49 ng/ml ($\leq$ 0.5). Cabergoline treatment has been started to the patient because he has not tolerated short-acting sandostatin due to diarrhea. Genetic test result was negative for THRbeta. TSH levels were decreased from 1.39 to 0.86 and fT4 levels were decreased from 1.97 to 1.67. The patient's complaints improved and then after make sure diagnosis of TSHoma he was referred to the neurosurgery.
Conclusion
In patients with atypical hyperthyroxinemia, a very good clinical evaluation should be performed for differential diagnosis between TSHoma and THRB. Negative family history/screening, high alpha subunit level, 5-fold increase in TSH after TRH stimulation, adenoma on MRI are features of TSH-secreting adenoma. However, hypophyseal hyperplasia can be seen in THRB, heterogeneity in clinical findings, genetic testing can not always be done or result is negative in 10% of patients with THRB, makes the differential diagnosis problematic. In patients diagnosed with TSHoma, the pathologic condition is often macroadenoma, but occasionally also microadenoma may occur. Surgical treatment is the main treatment option and long-acting somatostatin analogues are used effectively in patients who can not undergo surgery or who are not cured and for pre-surgery in some patients. The effect of cabergoline is more limited. However, it can be seen that if there are microadenomas and the clinical findings are milder, such as in our case, cabergoline may be considered a suitable option.

EP105

Case presentation: Double non-functioning pituitary adenomas

Pinar Sisman[1], Ozen Oz Gul[2], Soner Cander[2], Canan Ersoy[2] & Erdinc Erturk[2]
[1]Medicana Hospital, Endocrinology and Metabolism Clinic, Bursa, Turkey; [2]Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey.

Background
Pituitary adenomas are usually benign epithelial tumors and they are the most common cause of sellar masses from the third decade on, accounting for up to 10% of all intracranial neoplasms. Pituitary adenomas typically present with neurologic symptoms, clinical findings of hormonal abnormalities or as an incidental finding on magnetic resonance imaging (MRI). Double pituitary adenomas are very rare, and they account for 1% of all pituitary adenomas in autopsy series and up to 2% in large surgical series. In this case report we planned to present a case of double pituitary adenoma that was rare.
Case
A 53-year-old female patient was admitted to another center 6 years ago because of menstrual irregularity. Due to the high prolactin levels and the presence of pituitary adenoma on sella MRI, treatment with cabergoline 1 mg/week was started. The patient applied to our polyclinic after using the drup for one year. Patient complained of frequent menstrual irregularity when she referred to our outpatient clinic. She had no galactorrhea. Anterior pituitary hormone examinations revealed that prolactin was 73.3 ng/ml, LH was 5.4 mIU/ml, FSH was 13 mIU/ml, estradiol was 200 pg/ml and progesterone was <0.1 ng/ml. Other anterior pituitary hormones were normal. The sella MRI revealed a 5 mm sized adenoma. The patient was not considered as prolactinoma. Considering that the patient was in the premenopausal state, monitoring without medication was planned. Prolactin levels were gradually decreased in follow-up. After 1 year FSH: 46.7 mIU/ml, LH: 16 mIU/ml and PRL: 35 ng/ml were detected as compatible with menopause. Control sella MRI revealed a 4 mm sized adenoma that caused a convexity to the suprasternal cistern in the left pituitary gland. At the same time, another adenoma with a diameter of approximately 4 mm was observed in the right pituitary gland, near the cavernous sinüs. Monitoring of the patient without medication is continued.
Conclusions
Multipl pituitary adenomas are defined as simultaneous, morphologically or immunocytologically, distinct tumors. These tumors usually are microadenomas and most of them are clinically silent. Double or multiple pituitary adenomas confirmed by preoperative imaging or intraoperative exploration in particular, are considerably rare. MRI are able to identify multiple adenomas in only a few cases. Detailed preoperative imaging will prevent surgery failure in patients whom operation planned.

Rare combination of Acromegaly and Klinefelter syndrome

Ivana Sagova[1,2], Dusan Pavai[1], Matej Stancik[2], Daniela Kantarova[2], Helena Urbankova[1], Juliana Gregova[1], Anton Vanuga[1,3] & Peter Vanuga[1]
[1]National Institute of Endocrinology and Diabetology, Lubochna, Slovakia; [2]Department of Internal MedicineI, University Hospital, Martin, Slovakia; [3]AlphaMedical, Lubochna, Slovakia.

Acromegaly is a rare disorder usually caused by a benign tumour of the pituitary gland. Long-term presence of elevated growth hormone (GH) and insulin like growth factor I (IGF-I) levels accompanying this disease is associated with complications such as heart failure, cerebrovascular disease, diabetes mellitus, sleep apnoea and arthropathy. Incidence of acromegaly is 3-5 patients per million ***per year. Klinefelter syndrome*** is the most common sex chromosome disorder occuring in about 1/500 live male births. Common physical features include tall stature, reduced muscle tone, small testes, delayed pubertal development, lack of secondary male sex characteristics and gynecomastia. We present a 31-year-old man suffering from both acromegaly and 47, XXY Klinefelter syndrome (KS). The patient was admitted to our Institute with typical acromegalic features. Laboratory tests revealed high level of GH which was not suppressed after glucose administration, high level of IGF-1, low testosterone concentration with high concentation of gonadotropines. A magnetic resonance imaging scan revealed a $25\times18\times18$ mm macroadenoma involving the pituitary gland. A diagnosis of acromegaly was established. After this examination trans-sphenoidal resection was performed. Histopathologic and immunohistochemical findings revealed growth hormoneproducing pituitary adenoma. The presence of infertility with clinical features such as small testes, lack of secondary male sex characteristics and laboratory findings revealed hypergonadotropic hypogonadism that could not be explained by the diagnosis of acromegaly. A chromosomal karyotyping revealed a 47, XXY, confirming the diagnosis of KS. Testosterone replacement therapy wasn't begun because of patient disagreement. The rare finding of the combination of Acromegaly and Klinefelter syndrome suggests the need for rigorous examination of each patient by a "clear" endocrinopathy.

EP107

Could it be recurrent immunoglobulin G4-associated inflammatory mass at the hypothalamic region?

Utku Erdem Soyaltin, Ilgin Yildirim Simsir, Banu Sarer Yurekli & Fusun Saygili
EGE University, Izmir, Turkey.

Case
Thirty seven years old patient whose complaint was head ache was seen in the out patient clinic for the follow up of her hormone replacement therapy. First time she was admitted to hospital with the complaint of confusion was in 2013. Her cranial MRI revelaed enlargement of optic chiasma with the possible diagnossis of optic chiasmatic glioma. Biopsy was taken out from this mass twice in July and November of 2013. In histological examinations, there were B and T lymphocytes, eosinophils and histiocytes. Lymphoid malignancies was rulled out by IHC staining. The patient has the diagnosis of panhypopituitarism since 2013. She was taking cortisol, l-thyroxine, desmopressin replacement therapies. Since she had pulmonary thromboembolism in her past medical history, estrogen replacement was given as transdermal estrogen. She has also been using insulin treatment for diabetes mellitus. Recently, her state of consciousness decreased and has been operated urgently, in another health institution. The preoperative pituitary MRI revealed that there was contrast enhancement around hypothalmic-chiasmatic region including pituitary stalk. Cranial MRI showed a lesion located at right caudate nucleus measured as 2.5×1.6 cm in diameters causing edema in white matter. Histopathology was consultated with the pathologist of our center and it was reported as infiltraiton of lymphocytes, plasma cells and histiocytes. It was stated that IgG4 positivity ($>$ 50%) of plasma cells could be taken as a sign of "IgG4 associated disease".
Conclusion
Recurrent mass lesions at the suprasellar region could be due to IgG4 associated disease. Immunosuppressive treatment should be discussed with this possible diagnosis.

Rheumatoid arthritis, acromegaly, primary hyperparathyroidism – what's next?

Irina Manuela Nistor[1], Raluca Cristina Pascu[1], Ioana Maria Lambrescu[1,2] & Simona Fica[1,2]
[1]"Elias" University and Emergency Hospital, Endocrinology, Diabetes and Nutrition Diseases, Bucharest, Romania; [2]"Carol Davila" University of Medicine and Pharmacy, Elias' Endocrinology Department, Bucharest, Romania.

Introduction
Rheumatoid arthritis is an inflammatory disease characterized by joint destruction, the erosion being caused by invasion of articular cartilage by the synovial pannus. This chronic systemic disease affects approximately 0.5–1% of the adult population, occurring more often in women than in men (3:1). The etiology is thought to be multifactorial, environmental factors or infectious agents being suggested to play a role, but their contribution is yet to be defined. Acromegaly is a chronic endocrinopathy characterized by hypersecretion of growth hormone (GH) and insulin-like growth factor-1 (IGF-1), most likely caused by a pituitary adenoma. Primary hyperparathyroidism is a disorder of one or more of the parathyroid glands, characterized by an elevated PTH that causes hypercalcemia.
Case report
A 57 year old female patient, Caucasian, with no significant family history, non-smoker, diagnosed in 2007 with rheumatoid arthritis (treated with sulfasalazine, methotrexate and leflunomide) and acromegaly (caused by a pituitary macroadenoma of 1.5/1.5/1.4 cm, treated with surgery, gamma-knife, lanreotide and octreotide – medical treatment interrupted 5 years ago), was admitted to our department with recent history of thoracocentesis (rheumatoid pleural effusion

with low glucose level and present rheumatoid factor). The medical history included hypertension, osteoporosis, total histerectomy, sleep apnea and multinodular goiter with hypothyroidism. Clinical examination showed acromegaloid facial appearance, bilateral ulnar deviation of fingers, morning stiffness, swollen and painful joints, swan neck finger deformity, absent breath sounds in the lower 1/3 left hemithorax and a small goiter. Blood tests depicted normal TSH, elevated PTH (80.15 pg/ml), slightly elevated calcium (10.0 mg/dl), insufficient 25-OH-Vitamin D levels (14.75 ng/ml) and a normal IGF-1 (167 ng/ml). Thyroid ultrasonography revealed multiple micronodules with calcification and a hypoechoic mass lesion of 0.7/0.5 cm at the posterior aspect of the right thyroid lobe, resembling a parathyroid adenoma. A small-medium left pleural effusion was noted on chest X-ray without drainage recommandation. Thus, we confirmed the current inactive status of the acromegaly and the absence of pituitary gonadotropin and thyrotropin insufficiency. Treatment was initiated with Zolendronic acid and Vitamin-D 2000 UI/day.

Conclusion

Although genetic testing for multiple endocrine neoplasia syndrome type 1 and type 4 could not be performed, the simultaneously diagnosis of acromegaly and rheumatoid arthritis, associated with the latter presence of primary hyperparathyroidism, arise questions about the occurence of both autoimmune and neuroendocrine pathogeny in the same patient.

DOI: 10.1530/endoabs.56.EP108

EP109

Ectopic clival prolactinoma with empty sella in a patient using antipsychotic

Ramazan Gen[1] & Anıl Özgür[2]
[1]Mersin University Endocrinology and Metabolism, Mersin, Turkey; [2]Mersin University Radiology, Mersin, Turkey.

Prolactinoma is the most common cause of chronic hyperprolactinemi and drugs that rise serum prolactin levels have been ruled out. Altough almost all of them arise within the sella turcica, there are some rare cases in which prolactinoma is located outside the intrasellar region, so it is defined as ectopic prolactinoma. Neuroleptics (e.g., haloperidol, chlorpromazine, risperidone.) can elevate serum PRL to levels that usually are detected with prolactinomas. We report a case ectopic prolactinoma within the clivus with empty sella in a patient using risperidone and paroxetine.

Case

A 46-year-old woman was referred to the endocrinology clinic for investigation of her clinical presentation of galactorrhea and amenorrhea. She had been taking risperidone two years for the treatment of psychosis. During the admission the physical and neurological examinations of the patient were normal. The complete blood count values and basic serum levels of the biochemical parameters were normal. The hormonal parameters were as follows: St4 12.9 pmol/l (normal referece;12.8–20.4), TSH 1.52 uIU/ml (0.4–3.77), IGF-1 92.9 ng/ml (74-196), and GH 0.014 ng/ml (0—5), FSH 0.7 IU/l (3.5–12.5), LH 0.9 IU/l (2.4–12.6), estradiol 14.6 pg/ml (5–54.7), PRL $>$470 ng/ml (6–29.9). Medication-induced hyperprolactinemia was suspected, and after psychiatric consultation, paroxetine and risperidone were stopped and aripiprazol was begun. After 30 days, her prolactin level was again $>$470 ng/ml and after withdrawing the medications, her symptoms not resolved. Pituitary MRI showed homogeneously enhancing mass within the clivus and basisphenoid associated with an empty sella (figure A,B,C). A mass at the level of the clivus with empty sella, combined with very high prolactin levels, suggested the diagnosis of an ectopic prolactinoma. Because of ammnorhea, possibly due to this tumour, the patient was treated with the longacting dopamine agonist, cabergoline, in a dose of 2×0.5 mg weekly. Prolactin levels dropped from $>$470 ng/ml to 405 ng/ml in four weeks and to 214 ng/ml in eight weeks and to 16 ng/ml in twelve weeks.The treatment was well tolerated by the patient and complaints of galactorrhea and amenorrhea subsided, with the normalisation of the prolactin levels. A control MRI after 6 months illustrated a minimal reduction in the volume of the adenoma (Figure D). The dose of cabergoline was reduced after six months to 0.5 mg weekly, with the continuation of normal prolactin levels.

Clinical profile of patients with hyperprolactinemia: a study based on nepalese population

Ansumali Joshi & Priyadarshini Yonzon
Kathmandu Diabetes and Thyroid Center, Kathmandu, Nepal.

Background

Hyperprolactinemia is a common endocrine disorder. Yet, data on clinical profile of Nepalese patients with hyperprolactinemia is missing. The aim of this study was to assess the clinical profile of Nepalese patients with hyperprolactinemia.

Methodology

Retrospective clinic based study conducted at the endocrine centre Kathmandu Diabetes and Thyroid Center, Lalitpur, Nepal, in which data was collected from the patient record files of the subjects diagnosed with hyperprolactinemia within the last one and a half year (March 2013 to October 2014). The data was calculated as mean and percentage frequency.

Results

A total of 30 patients diagnosed with hyperprolactinemia(mean prolactin 145.36 ± 145.53 ng/ml) were included in the study. Mean age of the patients was 27.3 ± 7.3 years. Menstrual irregularity was the most common presenting problem (48%), followed by galactorrhea (34%). 14% had infertility and 7% had visual disturbances.10% each had hypothyroidism and PCOS. Pituitary adenoma was demonstrated in 37% patients and idiopathic hyperprolactinemia was seen in 33%. Drug induced hyperprolactinemia accounted for 10% of the total cases. Cabergoline was used in 92% and Bromocriptine was used in 8% patients for treatment of hyperprolactinemia.

Conclusion

Menstrual irregularity and galactorrhea were the most common presenting problems seen in hyperprolactinemia patients. Pituitary adenoma was the most common cause of hyperprolactinemia in Nepalese patients. Cabergoline was the drug of choice for treatment of hyperprolactinemia.

EP111

GSP gene mutation in a sample of Iraqi acromegalic patients and their response to long-acting repeatable octerotide

Abbas Rahmah[1], Assel Sami[2] & Wathiq Abbas[2]
[1]National Diabetic Center, Baghdad, Iraq; [2]Genetic Engineering and Biotechnology Institute, Baghdad, Iraq.

Patients and methods

190 acromegalic patients are registered in the National Diabetes Center, 60 were enrolled in the study. They were randomly selected by simple sampling technique according to their scheduled visits monthly to receive - long acting repeatable octreotide injections (LAR).

Results

Table 1 Demographic data of the enrolled acromegalic patients.

	All subjects	Males	Females
Number	60	32	28
Age (mean ± SD) years	46.35±10.81	46.3±10.9	46.3±10.8
Duration (mean ± SD) years	10.44±6.5	10.5±6.7	10.4±6.5
Minimum duration years	1 month	6 month	1 month
Maximum years	30 years	30 years	20 years

Table 2 Those harboring micro or macroadenoma.

	Patients with mutation	Patients without mutation	*P*-Value
Number	28	32	
Males number (%)	14 (50%)	18 (56.25%)	0.7293
Females number (%)	14 (50%)	14 (43.75%)	0.7449
Macroadenoma	22 (78.5%)	25 (78.12%)	0.9751
Microadenoma	6 (21%)	7 (21.87%)	0.9708
Trans-sphenoidal hypohysectomy	8 (28.5%)	15 (46.87%)	0.4031
No hypophysectomy	20 (71.4%)	17 (53.12%)	0.2576

Response	Full responder	8 (40%)	6 (75%)	0.2094
	Partial responders	6 (30%)	1 (21.5%)	0.8722
	Non responders	6 (30%)	1 (21.5%)	0.8722

Table 5 Shows the variable data of those with type A and non A.

	Mutation A	Non A mutation	*P*-value
Number	20	8	
Males number (%)	10 (50%)	4 (50%)	1.0000
Females number (%)	10 (50%)	4 (50%)	1.0000
Macroadenoma	16 (80%)	6 (75%)	1.8034
Microadenoma	4 (20%)	2 (25%)	0.8982
Hypohysectomy	7 (35%)	1 (12.5%)	0.6735
No hypophysectomy	13 (65%)	7 (87%)	0.3046

Conclusion

The gold – standard therapy for acromegaly, there is a role for medical treatment by somatostatin analogues as long-acting octreotide (LAR). The response to LAR was found to be affected by *gsp* gene mutation on chromosome 20 in a sample of Iraqi acromegalic patients. *gsp* gene mutation was found to reduce the response to LAR versus those with no mutation, however deletion of cystine in codon 196 of exon 8 was found to be favorable by increasing the percentage of full respondents to LAR versus other types of mutation.

EP112

Quality of life of patients with active acromegaly which didn't underwent surgery

Olivera Boskovic[1], Zlata Kovacevic[1], Emir Muzurovic[1,2] & Snezana Vujosevic[1,2]
[1]Clinical Center of Montenegro, Podgorica, Montenegro; [2]Medical faculty, University of Montenegro, Podgorica, Montenegro.

Acromegaly is chronic disease caused by hypersecretion of growth hormone (GH), most common caused by adenoma of pituitary gland. Cardiovascular risk, respiratory complication and malignancy are more common in this patients. Most often onset is between 30 to 50 years old, equally between gender. Therapy is almost always surgery, it can be combined with radiotherapy and gamma knife. Medicament therapy with somatostatin analogues, dopamine agonists and GH receptor antagonist. Goal is to show quality of life of patient that didn't underwent surgery treatment, with active acromegaly, aged 84 on analogs of somatostatin therapy for 12 years. Materials and methods: A case report. We used AcroQol questionnaire form on the start of disease and 10 years after.

Conclusion

Acromegaly is rare disease. In active form it is associated with significant morbidity and mortality. In our case during the follow up we diagnosed diabetes mellitus, hypertension, diastolic heart dysfunction stage I and cholecystectomy was preformed because of calculus (probably side effect of octreotide). Based on AcroQol questionnaire in 84 years old patients we conclude that in the beginning of the disease quality of life was reduced because of psychological characteristic/appearance (score −12, 5 vs −3, 4). Over the years condition is changing and physical characteristics were more dominant (score −3, 6 v.s. 0), which can be explained with patients age. Somatostatin analogs therapy in our case is efficient even after 12 years. Glycoregulation is good, and diastolic dysfunction is stable.

Serum concentration of insulin-like growth factor I (IGF-I): reference values for adult Romanian population: Preliminary results

Dan Alexandru Niculescu[1], Ramona Dobre[2], Andra Caragheorgheopol[3], Nicoleta Popescu[4] & Catalina Poiana[1]
[1]Department of Endocrinology, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]Department of Pituitary and Neuroendocrine Disorders, C. I. Parhon National Institute of Endocrinology, Bucharest, Romania; [3]Research Laboratory, C. I. Parhon National Institute of Endocrinology, Bucharest, Romania; [4]Biochemistry Laboratory, C. I. Parhon National Institute of Endocrinology, Bucharest, Romania.

Background

Growth hormone, age, sex, genetics or nutrition status play an important role in insuline-like growth factor 1 (IGF-1) liver production and serum levels. Currently, there is no IGF-I reference range for Romanian population.

Aim

To define sex- and age-adjusted reference values for serum IGF-I measured by an automated chemiluminescence immunoassay in adult Romanian population of healthy subjects.

Methods

The study included 174 adult healthy subjects (148 females and 26 males) from the general population of an urban area in Romania. Exclusion criteria are a body mass index below 18 kg/m2 or over 30 kg/m2, fasting blood glucose over 125 mg/dL, chronic kidney disease stage III or more or liver function test over 2 times the upper limit of normal. IGF-I was measured using a Liaison XL IGF-I chemiluminescence assay (DiaSorin, Sallugia, Italy).

Results

For females median (5, 95 percentile) were 200 (172, 323) ng/mL, 197 (110, 297) ng/mL, 165 (104, 265) ng/mL, 154 (83, 234) ng/mL, 153 (83, 218) ng/mL, 156 (81, 228) ng/mL, 153 (61, 224) ng/mL, 139 (29, 241) ng/mL for 20–24, 25–29, 30–34, 35–39, 40–44, 45–49, 50–54 and 55–59 age groups respectively. Due to the small number of subjects median values for age groups in male population could not be calculated. For age-IGF-1 correlation Default (r, p) were $-2.1893x+251.85$ (-0.42, <0.001) and $-0.7321x+184.18$ (-0.17, 0.40) for females and males, respectively.

Conclusion

Reference values for age groups in female adult population of Romania were preliminary defined. Age dependency of IGF-1 was confirmed.

Hyponatremia as a first symptom of hypopituitarism due to pituitary metastasis of gastric cancer: Case study

Agnieszka Zwolak[1], Marcin Lewicki[2], Ewa Tywanek[3], Joanna Swirska[1], Marta Dudzinska[1] & Jerzy Tarach[3]
[1]Chair of Internal Medicine and Department of Internal Medicine in Nursing, Medical University of Lublin, Lublin, Poland; [2]Chair and Department of Epidemiology and Clinical Research Methodology, Medical University of Lublin, Lublin, Poland; [3]Chair and Department of Endocrinology, Medical Universisty of Lublin, Lublin, Poland.

Introduction

Hypopituitarism can be caused by a number of different etiologic factors including metastatic cancer. Metastasis to the pituitary gland is rare, accounting for only 1.8% of all metastases, and is often detected incidentally by symptoms associated with hormone dysfunction like hyponatremia. Breast and lung cancer are the primary neoplasms with well established properties of pituitary infiltration. Metastases from gastric cancer are unusual and constitute less than 2% of pituitary gland metastases.

Case study

37-year-old woman with 7-month history of gastric cancer (adenocarcinoma tubulare without HER2 amplification), treated with capecitabine, epirubicin, and oxaliplatin based chemotherapy formulation was admitted to the ER due to persistent headache and nausea. Laboratory results revealed hyponatremia (125 mmol/l) and pancytopenia presumably due to chemotherapy. During admission she complained of generalized fatigue and was hypotensive. She had a history of secondary amenorrhea. She was admitted to Endocrinology Department to conduct differential diagnosis of hyponatremia. Laboratory work-up revealed panhypopituitarism with low ACTH, cortisol, TSH and free thyroid hormone levels as well as decreased prolactin, gonadotrophin and IGF-1 concentrations. Diabetes insipidus was absent and the function of the posterior lobe of the pituitary gland was preserved. MR imaging confirmed the pituitary involvement showing a 35×15mm mass infiltrating sella turcica and suprasellar cistern. She

received hydrocortisone and L-thyroxine hormone replacement therapy with significant improvement of her clinical status (stabilization of blood pressure, correction of hyponatremia), and was referred to Oncology Department for further treatment.

Conclusions

Hypopituitarism due to pituitary metastasis is a rare complication of gastric cancer. The possibility of pituitary metastasis should always be considered in patients with malignant tumors, who present with hyponatremia or other symptoms suggestive for endocrine dysfunction. The early diagnosis and introduction of appropriate hormone replacement therapy treatment improves the quality of life and can possibly prolong survival.

Macroprolactinemia diagnosed in a patient evaluated for primary infertility

Claudia Nogueira[1], Filipe Cunha[1], Ivan Ferreira[1] & Joana Mesquita[2]
[1]Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, Portugal; [2]Centro Hospitalar de Entre o Douro e Vouga, Santa Maria da Feira, Portugal.

Introduction

Hyperprolactinemia is associated with suppression of the hypothalamic-pituitary-gonadal axis and it's a frequent cause of infertility, occurring in about 30–40% of infertile women. The bioactive fraction of prolactin is a 23-kDa monomer. However, there are other isoforms with reduced or absent bioactivity, such as macroprolactin, which can be detected by the precipitation reaction by polyethylene glycol. Macroprolactinemia should be suspected in the presence of asymptomatic hyperprolactinemia.

Clinical case

33-year-old woman referred to the Endocrinology appointment in April 2014 for hyperprolactinemia detected during the study of primary infertility with 7 years of evolution. Past medical history irrelevant. The age at menarche was 13, she had regular menstrual cycles, 0G 0P. She had been treated with bromocriptine from June 2011 to June 2013. Since then she took no pills. She had no galactorrhea or hirsutism. Biochemical study during follicular phase: normal renal and liver function, TSH 2.27 mIU/l (0.27–4.20), free T4 20.9 pmol/l (11.7–21.7), FSH 7.7 mUI/ml, LH 5.42 mUI/ml, estradiol 65.6 pg/ml, prolactin 1630 mU/l (127–637), total testosterone 0.17 ng/ml (0.06–0.82), delta 4-androstenedione 2.52 ng/ml (0.30–3.30), cortisol 606.2 nmol/l (171–536), ACTH 18.8, IGF-I 197 (109–324), 17-hydroxyprogesterone 0.7 ng/ml. Progesterone in luteal phase was 16.9 ng/ml (1.7–27.0). Prolactin levels remained high in subsequent measurements (1391, 1158 and 1133 mU/l). Pituitary MRI in 6/2013 and in 10/2014 were normal. Since she had asymptomatic hyperprolactinemia and normal pituitary MRI, we searched for macroprolactin that was positive (percentage of prolactin recovery - polyethylene glycol precipitation: 8%).

Discussion

This case reveals the difficulty of etiological diagnosis of hyperprolactinemia in a woman with a history of primary infertility. However, asymptomatic and slightly elevated levels of prolactin associated with normal pituitary MRI has raised the hypothesis of macroprolactinemia. The diagnosis of this entity was very important to avoid further inappropriate treatment with dopaminergic agonists and to refer the couple to medically assisted reproduction treatment.

Clinical characteristics and management of 4 patients with chordomas of the skull base attending Beaumont Hospital

Roxana Maria Tudor, Hannah Forde, Amar Agha, Clare Faul & Mohsen Javadpour
Beaumont Hospital, Dublin, Ireland.

Introduction

Chordomas are rare slowly growing locally aggressive neoplasms of the bone arising from embryonic remnants of notochord. These tumours typically occur in the axial skeleton and have a proclivity for the spheno-occipital region of the skull base. Parasellar/clivus chordomas account for one third of all chordomas.

Methods

We conducted a retrospective chart review of 4 patients with chordomas of the clivus treated in Beaumont Hospital between 2011 and 2017.

Results

Three of the four patients were male. The median age at presentation was 39 years and the median length of follow-up was 36.5 months. All patients presented with headaches, diplopia and cranial nerve palsies. 6th cranial nerve involvement was noted in all cases at the time of the presentation. Magnetic resonance imaging was employed to localise the tumours. 3 of the patients had evidence of local invasion. None of the patients had clinical evidence of tumour metastasis to distant sites. All patients underwent surgery followed by adjuvant high-dose proton radiotherapy. 3 patients had craniotomies, while one patient had EM guided endoscopic trans-nasal tumour excision. There was no post-operative mortality. However 3 of the 4 patients had evidence of post-operative pituitary dysfunction. Recurrence was noted in one patient. Six further surgical excisions were required prior to radiotherapy (time to first recurrence was 22 months). None of the 4 patients returned to their pre-morbid status, as they all have residual cranial nerve palsies.

Conclusion

Chordomas are aggressive invasive tumours. A multidisciplinary approach in a neurosurgical centre is necessary in the management of these rare tumours. The best results in the treatment of chordomas are reported when using surgery and adjuvant radiotherapy.

GH/TSH secreting adenoma: a clinical case report: GH/TSH secreting adenoma: a clinical case report

Tatiana Tarasova, Alexander Lutsenko, Elena Przhiyalkovskaya, Ekaterina Pigarova, Larisa Dzeranova, Anatoly Tiulpakov & Ivan Dedov
Endocrinology Research Centre, Moscow, Russian Federation.

Case description

A 26-year-old female visited an endocrinologist for the first time in 2014 with complaint of neck swelling. Lab results revealed increased blood level of TSH, initially the diagnosis of hypothyroidism was set and levothyroxine therapy was initiated with consequent addition of thiamazole due to increasing levels of free T4 and TSH. In 2015 the diagnosis of TSH-secreting adenoma was made on the basis of MRI findings (pituitary microadenoma 3.1 mm in size) and laboratory results (TSH 7.8 IU/l, free T4 26.9 pmol/l, free T3 6.6 pmol/l). The patient first visited Moscow Endocrinology Research Centre in 2017. In further clinical observation we revealed new clinical data: patient reported face and hand enlargement for the last two years. Family history: father had enlarged facial features, died at the age of 34 from obstructive sleep apnoea, grandfather also had enlarged facial features. Laboratory tests revealed the data consistent with mixed TSH/GH-secreting pituitary adenoma: free T4 29.6 pmol/l, free T3 10.4 pmol/l, TSH 6.3 mIU/l, IGF-1 327.1 ng/ml (less than 280.0), beta-crosslaps 0.71, SSBG 200.0 nmol/l (less 110.0). Short-acting octreotide treatment resulted in normalization TSH and IGF-1. Thyroid ultrasound revealed single 5 mm nodule, increased thyroid volume - 20,5 ml. DEXA revealed no BMD loss. Lab investigations revealed no evidence on hyperparathyroidism: PTH and calcium levels were within the reference range. Due to the young age of the patient we chose a transnasal transsphenoid pituitary surgery as the first-line treatment. Postoperative histological investigation: pituitary adenoma. In the postoperative period levels of free T4 and T3 normalized, but the level of TSH remained slightly elevated - 3.7 mIU/l. One month after surgery, laboratory data revealed recurrence of hyperthyroidism, somatostatin analogue treatment was initiated.

Genetic investigation

Due to the evidence of familial case, a NGS was performed using the gene panel (*MEN1, CDKN1B, PRKAR1A, GNAS, AIP, SDHA, SDHB, SDHC, SDHD, PRKCA, CDKN2C, CDKN2A, POU1F1, PTTG2*), which revealed following changes: SDHA: NM_004168: exon8:c.G1002A:p.A334A, rs144252500, MAF 0.002; DICER1:NM_177438:exon2:c.A20G:p.Q7R, rs117358479, MAF 0.0035, more likely to be non-pathogenic.

Conclusion

GH/TSH secreting pituitary adenoma is very rare and could be associated with hereditary cause.

Antiphospholipid syndrome and pituitary necrosis

Manel Jemel, Hanene Sayadi & Ines Khochtali
Fattouma Bourguiba University Hospital, Depatment of Endocrinology, MONASTIR, Tunisia.

Introduction
Antiphospholipid syndrome (APS) is an acquired thrombotic disorder. It mainly occurs with systemic disease or as a primary disorder. All organs may be involved by thrombosis. But endocrine disorders seen in antiphospholipid syndrome are rare. In the literature, rare cases of hypopituitarism with APS have been reported.
The observation
It is a 27 years old patient who consults for headache with diplopia. The interview underlines galactorrhea with amenorrhea lasting for 12 years. Physical examination revealed a visual field, a central facial paralysis and monoparesis right upper limb. In biology, it has a hyperprolactinemia to 40 times normal and central hypothyroidism. Anticardiolipin antibodies were positive. Synacthen test was normal. Pituitary MRI showed an expansive process parasellar right 3×2 cm, mainly cystic and hemorrhagic, with mass effect on the right cavernous sinus.
Conclusion
APS should be searched for whenever a history of adenoma with apoplexy is found associated with recurrent thrombosis.

A rare emergency case in endocrinology: pituitary apoplexy

Suheyla Gorar, Cezmi Cagrı Turk, Tolga Gediz & Gülsah İnal
Antalya Training and Research Hospital, Antalya, Turkey.

Introduction
Pituitary apoplexy is a relatively rare clinical emergency in endocrinology. It results from hemorrhage or infarction in the pituitary gland. This clinical state is characterized headache, vomiting, visual defects, and signs of meningeal irritability.
Case
22-years-old woman was referred to hospital because of predicted haemorrhagic or cystic pituitary adenom in magnetic resonance imaging (MRI). She was married but not a child. She had menstruel irregularity. Her clinical examination was normal except for slightly headache. Pituitary MRI was repeated. It was showed that T2-weighted images measured 12 mm in diameter reveal a nodular appearance with blood-forming blood products forming fluid levels, which was compressing the optic chiasm. Hormonal laboratory results: TSH: 1.36 mIU/ml (0.3–5.8), LH: 2.77 mIU/ml, FSH: 6.15 mIU/ml, prolactin: 45.6 ng/ml, kortizol: 8.98 mg/dl, ACTH: 16.4 pg/ml, GH: 0.05 ng/ml, IGF-1: 118.1 ng/ml. Serum glucose, creatinin, sodium, potassium, calcium, liver enzymes and hemogram were normal. The headache of the patient was getting worse during the clinical follow-up and added visual defects. Visual field test was consistent bitemporal hemianopsia. She was consultated with insistent headache and visual disturbance by neurosurgery and decided operation. During surgery, there was soft suckable grayish mass with evidence of altered blood. Histopathology revealed apoplexy-like pituitary fragments and 0.1 cm diameter predicted pituitary adenoma. Immunohistochemistry revealed positive reactivity for prolactin and negative reactivity for ACTH, TSH, GH, FSH hormones. She showed instantly headache and vision in both eyes improvement during postoperative period. Cabergolin therapy was started.
Conclusion
We present the case of a woman diagnosed pituitary apoplexy during clinical follow-up. Clinical evaluations and MRI findings was important for pituitary apoplexy diagnosis and management.

Macroprolactinoma found in obesity setting: case report

Ana Sofia Osório, Ana Filipa Martins, João Vieira, David Barbosa, Carolina Faria, Ema Nobre & Maria João Bugalho
Endocrinology Department, Hospital de Santa Maria, Centro Hospitalar Lisboa Norte EPE, Lisbon, Portugal.

Obesity is growing fast worldwide. Although environmental factors play a major role, endocrine dysfunction may contribute to the weight gain. We report an invasive macroprolactinoma diagnosed in obesity setting. A 35-year-old male was referred to our endocrine outpatient department due to grade 2 obesity (IMC 38.4 Kg/m2). His weight was increasing since the beginning of his professional activity at the age of 20 due to a sedentary lifestyle. On physical examination he had an hypogonadal facies, with sparse beard, pale skin with fine wrinkles on the corner of the mouth and eyes and bilateral gynecomastia without galactorrhea. Descending testis of 4×3 cm were found, but a micropenis (3 cm) was evident. Patient complained of decreased libido and erectile dysfunction. He denied headache or visual disturbances. When blood analysis were performed, hyperprolactinemia of 1121 ng/ml (Reference range: 4–23 ng/ml) and hypogonadotrophic hypogonadism were found. No other pituitary defects were established and serum calcium was within normal values. Selar magnetic resonance (sMRI) showed a macro adenoma of 26 mm in the highest diameter slightly invading the right cavernous sinus and growing downward to the sphenoidal bone. One month after starting of cabergoline 0.5 mg 3 times a week, serum prolactin markedly decreased to 34.8 ng/ml and the patient lost 5% of body weight. He is awaiting a sMRI re-evaluation. Although the relation between hyperprolactinemia and obesity is established, pathophysiologic mechanism is not clearly understood. This case highlights that even when facing an epidemic disease, careful examination is mandatory and clinical suspicion must be paid.

Emotional disorders in patients with tumors of diencephalic localization

Yuliya Sidneva, Liudmila Astafyeva, Oleg Zaitsev, Pavel Kalinin, Maxim Kutin & Irina Klochkova
N.N. Burdenko National Medical Research Center of Neurosurgery, Moscow, Russian Federation.

Among tumors of the diencephalic region there are: pituitary adenomas, craniopharyngiomas, gliomas, meningiomas and others. They differ in location, histology, clinic with corresponding hormonal disorders. Emotional disorders in the clinic of tumors of the diencephalic region are revealed in 2–67% by the literature. Emotional disturbances with hormone-active pituitary adenomas there are 30–60%, and with non-functioning pituitary adenomas there are ones less than 6%. Emotional disturbances are revealed in 67% of patients with craniopharyngiomas on the background of a decrease in hormonal secretion. Psychopathology can be caused by the localization of lesions/irritation of the brain, histology and, possibly, changes in the level of neurohormones. Pituitary adenomas has the leading place among tumors of the diencephalon localizations. This is 15% of all brain tumors, the 1st and 2nd places are detectable at the age of 15 to 54 years. Hormone-active pituitary adenomas differ by prolactinoma (PRL-secreting pituitary adenomas −35%), acromegaly (GH-secreting pituitary adenomas – 15%), cushing's syndrome (ACTH-secreting pituitary adenomas −10%), thyrotropinoma (TSH-secreting adenomas-1%) and non-functioning pituitary adenomas (40%).

1. Pituitary adenomas with excessive secretion of growth hormone (GH) - Emotional disorders are in 60% of patients, and nonspecific symptoms, mostly asthenia. It is often stable dysphoria - the predominance of "gloomy-spiteful" mood.
2. Pituitary adenomas gland with excessive secretion of adrenocorticotropic hormone (ACTH):

1) Cushing's disease - changeable mood, depression, apathy, sleep disturbance, with visceral symptoms (tachycardia, fluctuations in blood pressure) are in 50%.
2) Nelson's syndrome - a decrease in emotional reactions and motor activity. Patients are apathetic, monotonous, poor in mimic manifestations.

3. Pituitary adenomas with excessive secretion of prolactin (PRL) - emotional disorders, sleep disturbance are in 30%. Nonspecific symptoms of the asthenia in almost a quarter of patients.
4. Pituitary adenomas with excessive secretion of thyroid-stimulating hormone (TSH) - increased emotionality, excitability, changeable mood, with frequent "panic attacks" are in 40%.
5. Non-functioning pituitary adenomas:

a) With hormone-inactive tumors of the pituitary psychopathology is present in 6% patient. There are violations of sleep, changeable mood, weakness, decreased memory.
b) In craniopharyngiomas emotional and personality disorders was in 67%. This is combined with cognitive, motivational and other impairments.

Conclusion
Violations of emotions in the defeat of the diencephalic region are caused by the localization of the tumor with the involvement of the corresponding brain structures in the pathological process.

Clinical improvement of hyperglycemia after use of octreotide lar in a patient with acromegaly who presented with nonketotic hyperosmolar state

Umit Cavdar, Nilufer Ozdemir, Bercem Aycicek & Halit Diri
Gazi Yaşargil Training and Research Hospital, Diyarbakır, Turkey.

A 37-year-old patient with a history of transcranial pituitary surgery because of acromegaly was referred to our clinic with the glucose level 731 mg/dl. she was not using any medication. There was no ketone in the urine and HbA1c was 18.6%. She has 17×16×15 mm of residual macroadenoma on pituıtary MRI with level of GH 17.5 ng/ml and IGF-1 422 ng/ml. She was using 140 units of insulin glargin U300 and 100 units of insulin regular per a day before octreotide LAR injection. After the first week of injection her need for insulin decreased day by day. She was using aproximately 70 units of insulin in a day before the second injection of octreotide LAR. It remains controversial whether or not octreotide impairs the glucose levels in patients with acromegaly. We herein present the use of Octreotide LAR as an adjunctive option for the treatment of hyperglycemia in patient with acromegaly who needs to use insulin immediately.

Z. Yu. Khalimova, G.D. Narimova, Yu.M. Urmanova, G/O/ Alimukhamedova. Sh.M. Safarova

The aim
To study the characteristic of associated diseases in risk groups of Cushing syndrome (CS) in the Khorezm, Namangan and Kashkadarya regions of the Republic of Uzbekistan
Material and methods of investigation
In total in 2017 in the specified regions it was captured within the project of 21990 persons subject to screening of CS from whom 2185 people for further inspection were selected. From 2185 people of men was – 639 (29.2%), women-. 1546 (70.7%). The age of patients fluctuated from 15 to 45 years.
Results
During the screening research at 21 the subclinical Cushingoid was taped. All patients with subclinical Cushingoid are registered and dynamic observation is prescribed. In risk groups such diseases as a diabetes mellitus (3.9%), goiter (2.2%), arterial hypertension (2.2%), an obesity (2.6%), anemia, a syndrome of polycystic ovaries (2.1%), hypothalamus dysfunction (1.2%), disturbances of a menstrual cycle (1.4%) met.
Conclusions
The most frequent disease in risk groups of patients in the Khorezm, Namangan and Kashkadarya regions was the diabetes mellitus (3.9%).

G.D Narimova., Z.Yu. Khalimova, Yu.M. Urmanova, M.I. Narimova, Sh.M. Safarova, G.O. Alimukhamedova

The aim
To study the characteristic of the index of body weight in risk groups of a syndrome of Cushing in the Khorezm, Namangan and Kashkadarya regions of the Republic of Uzbekistan
Material and methods of investigation
In total in 2017 in the specified regions it was captured within the project of 21,990 persons subject to screening of SK from whom 2185 people for further inspection were selected. From 2185 people of men was - 639 (29,2%), women-. 1546 (70.7%). The age of patients fluctuated from 15 to 45 years.
Results
Patients complained of raising of the ABP – 347 (16,0%), headaches – 105 (4,8%), excess body weight – 721 (33,0%), etc. Thus, the most part of patients complained of excess body weight. Thus, patients in three regions the dominating complaint have obesity – 721 patients (33%). The research of the index of body weight (IBW) at patients showed the following characteristic of degree of an obesity at them. The first degree of an obesity (BMI from 18.5 to 24.9 kg/m^2) was taped at 570 patients (26.0%), from them the man – 188, women – 382. The second degree of an obesity (BMI from 25 to 29.9 kg/m^2) was taped at 130 patients (5.94%), from them the man – 31, women – 99. The third degree of an obesity was found in 43 patients (1,9%), from them the man – 16, women – 27. And, at last, the fourth degree of an obesity is defined at 31 patients (1.4%), from them the man-10, the woman – 21). Thus, 1 degree of an obesity (26.0%) generally met.
Conclusions
The most frequent complaint among risk groups of patients in the Khorezm, Namangan and Kashkadarya regions was the excess body weight (33%).

Republic of Uzbekistan, 100125, Tashkent, Mirzo Ulugbek str. 56
M.Yu. Shakirova, Yu.M. Urmanova

The aim
To study dynamics of indicators of the questionnaire of QoL AGHD at assessment of quality of life at patients in 3 months and 6 months after operation of transnasal pituitary adenomectomy by the replacement treatment growth hormone Djintropin.
Material and methods
The patients (men-10 and women-3, aged from 18 up to 45 years) who were on stationary and out-patient inspection in the Center of Endocrinology, were selected in group of patients with the diagnosed GH deficiency ($n=13$) and received treatment by growth hormone Djintropin.
Results
Against the background of replacement therapy of GR "DjINTROPIN" reliable increase in values of the IGF-1, GR levels in blood ($P<0.05$) in 3 months of treatment and respectively increase in values of the IGF-1, GR levels in blood (P <0.05) and also blood GR ($P < 0.05$) in 6 months has been recorded. Significant reliable increase in level of calcium ($P < 0.05$), phosphorus ($P < 0.001$) and also increase in activity of alkaline phosphatase is noted ($P < 0.01$) indicating acceleration of processes of bone metabolism against the background of the carried-out therapy. Decrease in levels of the general cholesterol and Lipids is recorded that demonstrates beneficial effect of GR "DJINTROPIN" on lipid exchange.
Conclusions
Assessment of change of anthropometrical indicators against the background of the carried-out therapy of GH "DJINTROPIN" has shown normalization of indicators of QoL according to the questionnaire of QoL AGHD: 10.2 ± 2.5 points (during 6 months). Against the background of replacement therapy of GR "DJINTROPIN" reliable increase in initially low values of the IGF-1, GH levels in blood ($P < 0.05$) in 3 months of treatment and also increase in STH ($P < 0.05$) in 6 months has been recorded.

Years of Misery: a final resolution 'panhypopituiatirsm'

Caoimhe Bonner[1], Bonnie Grant[2], Anna Hawkins[1], Yun-ni Lee[1], Augustine Williams[1], Sanjiv Chawda[1], Raj Tanday[1], Edel Casey[1] & Khash Nikookam[1]
[1]Barking Havering and Redbridge University Hospitals NHS Trust, Greater London, UK; [2]Barking Havering and Redbridge NHS Hospitals Trust, Greater London, UK.

We report a case of a 76 year old gentleman referred to the endocrine department by his general practitioner (GP) with a few years history of severe lethargy, low mood, and dizziness on changing posture. He is known to have hypothyroidism, hypertension, hypercholesterolaemia, benign prostatic hypertrophy, and benign colonic polyps. His medications included amlodipine, finasteride, lansoprazole, atorvastatin and levothyroxine. Examination of all systems were unremarkable, in particular neurological examination with no postural drop. A full pituitary profile was performed which showed low free T4, cortisol, testosterone, and IGF-1, indicative of panhypopituitarism. A short synacthen test showed a serum cortisol at 0 and 60 minutes of 57 and 480 nmol/l respectively. He subsequently underwent an insulin tolerance test showing a drop in glucose from 4.8 to 2.0 mmol/l after 50 min, at which point the patient developed symptoms of dizziness and blurred vision. His blood glucose of 2.0 mmol/l was corrected to 4.2 mmol/l with two doses of glucojuice and 100 ml of 20% glucose infusion. A second drop in glucose was observed to 2.9 mmol/l which was corrected to 4.9 mmol/l with two further doses of glucojuice. The insulin tolerance test confirmed cortisol and growth hormone deficiency with flat cortisol and undetectable growth hormone levels. A computed tomography (CT) head scan was arranged instead of a magnetic resonance imaging (MRI) scan as the patient was claustrophobic, and did not reveal any pituitary abnormality. Following commencement of hydrocortisone he has felt much better and awaiting assessment for growth hormone and testosterone therapy.

Conclusion

It is paramount to consider endocrine dysfunction in patients with multitude/non-specific symptoms despite unremarkable clinical examination and normal basic pathological investigations.

Prolactinoma and granulomatous mastitis

Maryam Soussou, Ghizlane EL Mghari & Nawal EL Ansari
Department of Endocrinology Diabetes and metabolic diseases. Laboratory PCIM FMPM, Cadi Ayad University, CHU Mohamed VI, Marrakech, Morocco.

Granulomatous mastitis (GM) is an inflammatory lesion of the breast relatively rare with multiple etiologies suggested. Although most cases of GM show an association with breastfeeding and pregnancy, a minority of cases were related to hyperprolactinemia caused either by drugs dopamine antagonists or intracranial lesions, including pituitary adenoma. We report a case of a patient who had GM associated with microprolactinoma. Surgical treatment of the adenoma was indicated because of gastrointestinal intolerance of drug treatment with the effects of hyperprolactinemia on the mammary gland. Indeed it is reported in the literature a complete resolution within the inflammatory lesions and normalization of prolactin response to medical or surgical treatment of brain injury causing hyperprolactinemia, suggesting that it would be the direct cause of GM. Therefore, the authors suggest to detect pituitary tumors and to evaluate the levels of prolactin in the assessment of patients with MG recent history without breastfeeding or pregnancy and in the absence of another identified etiology.

Epidermoid cyst of the sella turcica: about a case

Habra Bahia, Elmghari Ghizlane & El Ansari Nawal
Department of Endocrinology Diabetology Metabolic Diseases and Nutrition, Hospital Mohamed VI -Arrazi VI, Laboratory for pneumo-cardio-immunopathology and Meabolism research (PCIM), Faculty of Medecine and Pharmacy, Cadi Ayad University, Marrakesh, Morocco.

Introduction

Epidermoid cyst (EC) or cholesteatoma is a benign tumor, often of congenital origin. It accounts for 1% of intracranial tumors and is mainly located at the ponto-cerebellar angle and suprasellar, EC takes the aspect of a beaded tumor with nodular surface and white pearly color simulating candle wax. The treatment is surgical taking into account the substitution of endocrine pituitary deficits in this form of description.

Patient and observation

We report the case of the married patient EY, aged 38 and father of two but with no particular pathological history, particularly no cranial trauma. He showed left visual acuity decrease, left temporal headache and vomiting, with anterior pituitary deficiency symptoms of the corticotropic axis such as pallor, asthenia, fluid diarrhea, thyrotoxic such as depilation of the forearm, legs, armpits and pubic, slowing down; and gonadotropic such as libido decrease, 1 year ejaculations and morning erections. Cerebral MRI has revealed craniopharyngioma in the patient. Hormonal checkup revealed corticotropic deficit. Indeed, MRI revealed heterogeneous signal intra and supra-sellar process containing hypo and isointense tissue areas in T1, intermediate in T2, and hyperintense in Flair, with no calcifications; hyperintense multilocular zones in T1, measuring 18 * 15 * 27 mm of major axes, bridging the suprasellar cistern, elevating the optic chiasm and the anterior cerebral A1 segments and extending to the left hypothalamic region. The patient was operated using high temporal approach. Anatomopathological checkup showed a morphological aspect compatible with an epidermoid cyst. Post-operative follow up revealed the appearance of diabetes insipidus for which the patient was put under minirin; gonadotropic, thyreotropic and corticotropic deficiencies were substituted by hormonal treatment, Postoperative eye fundus was in favor of bilateral papillary palate which the patient used to have before, bilateral visual acuity improved to 10/10. Visual cham has remained altered, particularly to the right.

Conclusion

Epidermoid cyst is a benign tumor of slow but inevitable linear evolution and requires surgical treatment. The diagnosis becomes easier, especially with MRI scattering sequences' advent. Such observation argues in favor of the congenital origin and the slow evolution of this type of tumors.

Adult onset hypopituitarism – a surprising diagnosis in a postmenopausal women

Georgiana Cristina Taujan[1], Adina Simona Dragomir[2], Maria Olaru[2] & Alina Maria Dumitru[2]
[1]Lotus Med, Bucharest, Romania; [2]National Institute of Endocrinology C.I. Parhon, Bucharest, Romania.

Adult-onset hypopituitarism is a frequently delayed diagnosis because of the insidious debut and non-specific symptoms, frequently attributed to normal aging or many other pathologies - fatigue, malaise, cognitive impairment, decreased libido. Left untreated, it can have severe consequences with vital impact.

Case-report

We present the case of a female patient, aged 69, who was initially addressed for evaluation of hypercalcemia. She had had four live births, last one at 38 years and she entered menopause at 54 years old. At the initial evaluation, the patient presented with hypercalcemia and elevated parathyroid hormone, as well as low fT4 and low TSH levels, suggesting secondary hypothyroidism along with primary hyperparathyroidism. Subsequent evaluations revealed also hypogonadotropic hypogonadism. The patient did not associate polyuric-polydipsic syndrome nor secondary adrenal insufficiency. The visual field evaluation was inconclusive due to cognitive impairment and difficult collaboration. There were no pathological changes in the pituitary area on contrast CT scan. She was started on levothyroxine therapy, with mild improvement in cognition. She will undergo DXA evaluation, parathyroid scintigraphy and surgery for hyperparathyroidism. She will remain under surveillance for developing adrenal insufficiency.

Conclusions

What seemed to be a simple case of primary hyperparathyroidism, turned out to be a surprisingly association between two endocrine diseases and a challenging diagnosis because fatigue, malaise and cognitive impairment are non-specific symptoms and could have been all attributed to hyperparathyroidism. Therefore, clinical and laboratory evaluation for hypopituitarism would be recommended in patient presenting with those subtle complaints.

EP131

Gonadotropinoma without clinical function

Ozgen Celer[1] & Erhan Celikoglu[2]
[1]Division of Endocrinology, Fatih Sultan Mehmet Training and Educational Hospital, İstanbul, Turkey; [2]Department of Neurosurgery, Fatih Sultan Mehmet Training and Educational Hospital, İstanbul, Turkey.

Introduction
Pituitary adenomas are the most common cause of sellar masses. Several types of tumors may involve the sellar region, because of complex anatomy. They are classified according to size, function, immunohistochemical examination cell type of adenomas. Most of the pituitary adenomas without clinical function are gonadotropin-releasing adenomas on immunohistochemical examinations. They are usually seen as macroadenomas. They are often diagnosed with pituitary insufficiency due to adenomatous compression.
Case
A 68-year-old female patient presented with complaints of diplopia and narrowing of the visual field. There was no feature on her resume. No pathology was found on physical examination. A lesion consistent with a 39×30×25 mm adenoma was found on hypophysis MR. The adenomatous cavernous sinus lengthened and there was marked pressure on the optic chiasm. Bitemporal hemianopsy is present in the visual field examination. In laboratory tests panhypopituitarism was detected (Prolactine level is normal). Hormone replacement therapy started. The patient was operated under steroid replacement treatment. Visual function improved after the surgery. The histopathologic report showed an adenoma and immunohistochemical findings were consistent with gonodotropinoma.
Conclusion
In macroadenomas without clinical function, it is recommended to apply surgical treatment to visual field deficit or loss, ophthalmoplegia, optic chiasmal pressure, pituitary hormone deficiency and apoplexy. The aim of surgical treatment is to correct neurological deficits, hormone insufficiency and prevent recurrence.

EP132

Pitfalls in the management of inadequate TSH in the outpatient endocrine clinic: a case report

Snezana Marinkovic
Special Hospital for Thyroid Diseases, Cigota, Zlatibor, Serbia.

A 34-years old woman was referred to the outpatient clinic due to elevated TSH level during last three years. She was aware on the decreased thyroid function due to autoimmune thyroiditis since she was 24-years old. At that time L-thyroxine was introduced to the patient in a daily dose od 75 μg. Since elevated TSH up to 6.3 mU/l was noticed, she experienced frequent temporal headaches, noticed enlargement of hands, lips and nose, and increased shoes size. However, menstrual cycles remained regular. At the first visit, her hormone profile showed FT4 13.0 pmol/l and TSH 5.1 mU/l on the daily L-thyroxine of 150 μg. As the pituitary tumor was suspected, patient was send for contrast MR of the pituitary gland that showed an existence of macroadenoma of 17×12×11 mm in diameter. Additional analyses revealed IGF1 of 992 ng/ml, growth hormone of HR 5.0 mU/l with normal prolactin, cortisol and ACTH. No additional functional tests were performed. Echocardiography was normal while abdominal ultrasound showed slightly enlarged spleen (13×5.6 cm). The neurosurgeon has been consulted and the patient was sent for the surgical procedure. Transsfenoidal adenectomy was performed in the Departent for neurosurgery without post-operative complications. Pathohistological examination with immune-histochemical staining confirmed gowth hormone secreting pituitary adenoma. Post-surgical hormone profile showed TSH 0.88 mU/l, FT4 12.9 pmol/l, cortisol 443.8 nmol/l, IGF1 119.9 ng/ml and GH 0.14 mU/l. Patient continued with daily therapy with 100 μg of L-thyroxine, and was lost from further follow-up. In conclusion, prolonged inadequate TSH during high L-thyroxine therapy should be suspicious for TSH-secreting pituitary adenoma. This case was lacking in proper functional diagnosis before operation, adequate immune-histochemical staining on TSH and Ki-67 for the assessment of possible mixed forms and it's aggressiveness, and proper post-surgical follow including functional testing and MR of the pituitary.

Galactorrhoea, severe anxiety and an unexpected outcome

Caoimhe Bonner[1], Bonnie Grant[1], Anthony Pittathankal[1,2], Imran Syed[2], Edel Casey[1] & Khash Nikookam[1,2]
[1]Barking Havering and Redbridge University Hospitals NHS Trust, Greater London, UK; [2]Spire Roding Hospital, Greater London, UK.

We report a case of a 43 year old lady who was referred by her general practitioner (GP) to the endocrine team with an 8 month history of extreme fatigue, difficulty losing weight, galactorrhoea and mild breast enlargement. She has two children aged 16 and 14, all well. Her background medical history included depression, asthma and hysterectomy for fibroids 3 years ago. Examination of all systems were unremarkable including visual fields to confrontation, fundoscopy and full neurological exam, except for a drop of milky discharge on expressing nipples and a palpable right thyroid nodule. She was investigated by means of a pituitary profile which showed prolactin of 768 mainly monomeric (upper limit 496), E2 <44 with the remainder of her pituitary screen being normal. A subsequent magnetic resonance imaging (MRI) scan showed a bulky pituitary gland but no definite lesion/adenoma. Her galactorrhoea subsided on cabergoline which was stopped at 6 weeks. She then reported bilateral galactorrhoea after cessation of cabergoline. It was a joint decision to take a wait and see approach, with repeated blood tests earlier if need be. Her thyroid ultrasound showed a 5 mm U3 nodule with FNAC reported as THY4. In view of the high suspicion of malignancy she was referred to the endocrine surgeon following endocrine MDT meeting. As part of her pre-operative work up, a chest x-ray showed an incidental finding of a possible mass in the right atrium. She was further investigated with a computed tomography (CT) scan of the neck, chest, abdomen and pelvis to assess the atrial mass and for routine staging. This showed a 5 mm hypo enhancing nodule in the thyroid isthmus with no evidence of malignancy, an incidental finding of a 7 mm left adrenal nodule and a 2.5 cm×2 cm soft tissue mass attached to the atrial septum suggestive of an atrial myxoma. An echocardiogram showed a strong possibility of atrial myxoma, hence she was referred to the cardiothoracic surgeons for further assessment and surgical excision after confirmation of normal urinary metanephrines. She is awaiting total thyroidectomy in view of cytology findings (THY4).
Conclusion
The importance of a good thorough history and examination of all systems is paramount as it can reveal other incidental findings which may well then have an impact on future comorbidities, mortality and ones life.

A case of acromegaly and Cushing's syndrome

Faiza Bensmaine, Marie Laloie, Ines Barka, Tiphaine Vidal-Trecan, Clara Bouche, Florine Feron, Jean-Pierre Riveline & Jean-Francois Gautier
Laribosiere Hospital, Paris, France.

We herein describe a 55-year-old woman who showed a dramatic improvement in glucose control following treatment for co-existing acromegaly and Cushing's syndrome. The co-occurrence of acromegaly and Cushing's syndrome in one individual is extremely rare. This patient was diagnosed as having diabetes mellitus 7 years ago. Afterwards, in spite of insulin therapy, her hyperglycemia could not be well controlled. Endocrinological and radiological examinations revealed subclinical adrenal Cushing's syndrome. Successful treatment for these endocrinopathies resulted in greatly improved blood sugar control because of a reduction in insulin resistance. The insulin treatment was discontinued following the treatment of acromegaly. This report describes insulin resistance before and after treatment in a case of acromegaly accompanied by adrenal preclinical Cushing's syndrome.

Clinical and diagnostic features of prolactinomas

Khurshida Nasirova, Diyora Mukhammedaminova & Umida Mirzaeva
Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan.

Relevance
Prolactinoma is an adenoma of the pituitary gland with the production and secretion of prolactin (PRL) in varying degrees, almost always benign, but, nevertheless, often clinically significant and causing difficulties in treatment. Often prolactinomas are classified according to size as microadenomas (less than 10 mm in diameter) or macroadenomas (more than 10 mm in diameter). More than 90% of prolactinomas are small, intrasellar tumors that rarely increase in size. Sometimes, these adenomas can be aggressive or locally invasive and cause compression of vital structures. Malignant prolactinomas that are resistant to treatment and are dissiminated into I and out of the CNS are very rare. Approximately 40% of all pituitary adenomas are prolactinomas. The age of patients varies widely and there are publications about prolactinomas in patients between the ages of 2 and 80 years. Prolactinomas are common in women with a peak frequency in fertile age. Although often these tumors attract attention after discontinuation of oral contraceptives, there is no correlation between the use of oral contraceptives and the development of prolactinomas. Most prolactinomas in women are presented by microadenomas. About 90% of premenopausal women have oligo/amenorrhea, up to 80% also observe galactorrhea. Inovulatory infertility may also occur in some cases. Pathogenesis of prolactinomas is unknown, but the process may involve an early genomic mutation leading to a mutation in pituitary stem cells. Various contributing factors can stimulate the proliferation of mutated cells. Family forms of prolactinomas were also described, which indicate the possibility of a genetic component playing role in pathogenesis. Prolactinomas are the most common cause of persistent increase of serum prolactin levels, which is more common in women of reproductive age and may be the cause of infertility. The clinical manifestations of hyperprolactinemia vary widely, the symptoms mainly include reproductive, sexual, metabolic and emotional-personal impairments, and in macropolactinoma, signs and symptoms of a volumetric process in the hypothalamic-pituitary region. The method of choice in the treatment of most patients with prolactin secreting pituitary adenomas is drug therapy. Treatment of hyperprolactinemia in prolactinomas is aimed at achieving the restoration of normal prolactin concentration, restoring ovulatory menstrual cycles, restoring fertility in women and men and in improving impaired sexual function in men, and reduction in tumor size.

The clinical management and follow-up of adults with Turner's syndrome in University College Hospital Galway

Clarissa Ern Hui Fang, Mohammed Faraz Rafey, Mohamad Mustafa & Marcia Bell
Centre for Diabetes, Endocrinology and Metabolism, University College Hospital Galway, Galway, Ireland.

Background and Aim
Turner's syndrome (TS) or 45 XO is a condition in which a female is partly or completely missing an X chromosome. TS affects 0.025–0.05% of females and can involve multiple organs through all stages of life, necessitating a multidisciplinary approach to care. We aim to evaluate our practice compared to the clinical practice guidelines, which recommends the following: annual BMI, blood pressure, HbA1c, lipid profile, liver function, thyroid function, skin and teeth inspection; 3 yearly serum calcium, vitamin D, echocardiogram; 5 yearly audiometric evaluation and DEXA scan. As appropriate, renal ultrasound, ophthalmologic evaluation, ECG, liver ultrasound, fertility counselling, uterine ultrasound and coeliac screen.
Methods
Online Patient Correspondence System was used to identify patients with TS in University College Hospital Galway (UCHG). Charts were ordered, reviewed and data was collected and analysed on an encrypted excel sheet.
Results
16 patients with TS were identified. Two paediatric patients were excluded. Of the 14 included, three patients were not under endocrine service follow-up and 1 patient had follow up in another hospital. The following are the compliance to management guidelines; 86% echocardiogram, 36% cardiac MRI, 95% blood pressure measurement, 71% lipid profile, 36% DEXA scan, 86% serum calcium, 50% serum vitamin D, 93% liver function test, 79% HbA1c, 100% thyroid function test, 64% coeliac screen, 71% renal ultrasound, 29% audiology testing, 36% fertility discussion, 64% HRT, 14% uterine ultrasound, 14% dermatology review, 0% orthodontic, ophthalmology and psychiatric evaluation.
Conclusion
We are planning to use a standardised proforma and re-audit the patients, to improve the management of Turner Syndrome in University College Hospital Galway.

EP137

Etiological profile of premature ovarian failure: about 42 cases

Najoua Lassoued, Asma Ben Abdelkrim, Yosra Hasni, Maha Kacem, Molka Chaieb, Amel Maaroufi & Koussay El Ach
Endocrinology Department, Farhat Hached University Hospital, Sousse, Tunisia.

Introduction
Premature ovarian failure (POF) is defined as amenorrhea lasting more than four months before the age of 40 with a high level of gonadotropins in at least two separate samples. The aim of this work was to describe the etiological profile of a series of Tunisian women followed for POF.
Patients and methods
It is a descriptive study of 42 cases of POF collected in the endocrinology department of Sousse between 2000 and 2017.
Results
The average age of the patients was 23.85 years old. Thirty patients consulted for primary amenorrhea with an average age of 18.8 years and 12 patients consulted for secondary amenorrhea with an average age of 36.5 years. Eleven patients reported irregular periods before the installation of secondary amenorrhea while the beginning was brutal in the twelfth. A family history of primary sterility was found in two patients, a family autoimmunity field was found in two patients, whereas no history of early menopause was found in our patients. Nine patients were followed for type 1 diabetes, six patients for primary hypothyroidism and one patient for celiac disease. The hormonal profile showed an average FSH level of 90.7 mIU/ml, an average LH level of 49.82 mIU/ml and an average estradiol level of 21.42 pg/ml. The karyotype was requested in all patients who consulted for primary amenorrhea. It showed a mosaic Turner syndrome in two of our patients. In addition, the immunological survey showed positive anti-ovarian antibodies in one patient. At the end of this investigation, an autoimmun origin of POF was retained in 38% of patients and a genetic origin related to Turner syndrome in 4,76% of patients. The POF was idiopathic in 57,24% of our patients.
Discussion and conclusion
The POF is not an exceptional pathology. The most commun etiologies are at the present time sterilizing treatments such as chemotherapy or radiotherapy. Genetically, abnormalities of the X chromosome, in particular Turner syndrome, are identified. Most often, after a thorough clinical investigation, no etiology is found. Indeed, idiopathic POF still accounts for more than 75% of cases.

Evaluation of dynamic thiol-disulphide homeostasis in healthy postmenopausal women

Hakan Gozcu[1], Cemile Bicer[2], Mahmut Şenyurt[1], Salim Neselioglu[2] & Ayse Carlioglu[1]
[1]Erzurum Regional Training and Research Hospital, Erzurum, Turkey; [2]Yildirim Beyazit University Faculty of Medicine, Ankara, Turkey.

Introduction
The purpose of this study was to evaluate the relation between menopausal women and the thiol/disulphide balance, used as a marker of oxidative stress, by measuring that exchange using a novel technique.
Methods
Fourty five postmenopausal subject and 39 healthy participant were included in the study.
Results
We found that in postmenopausal group, disulphide ($P=0.04$), disulphide/native thiol ($P=0.004$), disulphide/total thiol ($P=0.004$) were higher than the control group, in postmenopausal group, albumin ($P=0.008$), native thiol ($P=0.007$), total thiol ($P=0.016$) and native thiol/total thiol ($P=0.004$) were lower than the control group with independent of age. Furthermore, a positive correlation was determined between albumin and native thiol ($r=0.425$, $P=0.000$), total thiol levels ($r=0.416$, $P=0.001$). We found negative correlations between native and total thiols and inflammatory parameters white blood cell (WBC) ($r=-0.371$,

$P=0.001$ – $r=-0.390$, $P=0.001$), neutrophil lymphocyte ratio (NLR) ($r=-0.306$, $P=0.008$ – $r=-0.293$, $P=0.011$).
Conclusion
This study showed that postmenopausal phase is associated with oxidative stress. Our study supports the hypothesis that decreased albumin and inflammation might be the major cause of oxidative imbalance.

EP139

Correlation of LH and FSH with serum TSH levels in polycystic ovarian syndrome

Anila Rrupulli[1], Lindita Vrushi[2] & Brunilda Gishto[3]
[1]Hospital of Elbasan, Elbasan, Albania; [2]Laboratory Lui Paster, Elbasan, Albania; [3]Hospital of Fier, Fier, Albania.

Background and objectives
PCOS is the most common endocrine disorders among women between the ages of 17 and 44. It affects approximately 5% to 10% of this age group. It is one of the leading causes of poor fertility. PCOS patients usually develop thyroid disorders which have an adverse effect on fertility and other hormones. Hence this study was done to estimate levels of LH, FSH, and TSH hormones and to find a correlation between LH,FSH and TSH levels.
Study population
A total of 50 patients of age group 17–44 years were studied for the six months. The patients were included if they satisfied the diagnostic criteria suggested by Androgen Excess PCOS Society. They were excluded if they were having DM II. Hypertension, liver disorders,renal disorders and other chronic diseases. After informed consent and brief clinical history, examination was done to rule out renal disorders, liver disorders or any other condition that would affect the parameters under study. LH.FSH and TSH was estimated. We study a group of patients who are diagnostic with PCOS. In this group we estimate LH, FSH, TSH. Normal levels of FSH is 3–20 mIU/ml, LH <7 mIU/ml, TSH .4–4 uIU/ml.
Interpretation and conclusion
The results of our study showed that levels of LH were high in patients with PCOS with ratio of LH/FST $>2:1$. Though there is a positive correlation between LH and TSH in both age group it is more significant in older group.TSH levels were high in cases which signifies the evaluation of thyroid function in PCOS patients Thus It was concluded that in PCOS diagnosed patients we should evaluate thyroid functions along with hormonal evaluation to prevent further infertility.

Ameliorating effect of Cuscuta japonica chois (CJC) extract on hind-limb ischemic mice

Hye Jin Kim, Dong Ho Jung, Hyun Yang & Byung Seob Ko
Korean Institute of Oriental Medicine, Daejon, Republic of Korea.

Cuscuta japonica chois (CJC) has been used traditionally to treat sexual disorder and skin problem such as pimples, freckles and melasma in Korea. The present study aimed to investigate the alleviating effect of CJC extract on surgical injury-induced ischemia in the hind-limb of mice. In this study, Female C57BL/6 mice were ovariectomized and excised the vessels of hind-limb after ligated by surgical silk (6-0). The mice were administered with CJC (150 or 450 mg/kg per day) for 3 weeks and blood blow rate was evaluated using a laser Doppler system at -7, 0, 7, 14, 21 days after hind-limb ischemia. The serum profiles of angiogenetic factors and inflammatory factors were measured by antibody array, and its transcript-level were evaluated by RT-PCR. The blood flow rate was normalized with non-ischemic lesion, and the rate was significantly elevated at 14 and 21 days after hind-limb ischemia compared with the vehicle group. The density of capillaries was also significantly increased by CJC treatment in a dose-dependent manner. In addition, CJC up-regulated the transcriptional expression of angiogenetic factors including ET-1, ANGPT-1 and IGFBP-3, whereas, the inflammatory cytokines, TNF-α, IL-6 and IL-1b were down-regulated in the hind-limb of mice. These results of present study assumed that CJC extract may have therapeutic potential in the treatment of hind-limb ischemia due to its peripheral angiogenesis and anti-inflammation in mice.

Differences in the use of contraception between Roma and non-Roma women in Hungary

Melinda Vanya[1,2,3], Lajos Juhasz[1] & László Párducz[1]
[1]Department of Obstetrics and Gynaecology, Kalman Pandy Munipicial Hospital, Gyula, Hungary; [2]Mediteam Corporation, Szeged, Hungary; [3]Teacher Training Faculty, Janos von Neumann University, Kecskemet, Hungary.

Objective
The purpose of this study was to investigate the contraceptive practice and sociodemographic determinants of employment of contraceptive methods among sexually active Roma and non-Roma women.
Design and methods
This research included 133 Roma and 687 non-Roma women aged 18–26 from secondary schools Szeged. Women completed self-report questionnaires on sociodemographic characteristics, contraceptive practice and sexual activity between 2015 and 2017. Oral contraceptives, intrauterine devices, male/female sterilization, vaginal ring, plaster, implant and injection were regarded as reliable methods, while barrier methods, periodic abstinence, withdrawal, spermicides, vaginal douche or no method were considered less reliable methods based upon the Pearl index. Multivariate logistic regression analyses were used to analyze socio-demographic factors associated with the use of contraception and unwanted pregnancy in both population groups.
Results
The mean age of the women was 25.4 years (± 8), and 77% reported urban residents. The rate of use of reliable methods (hormonal contraceptives, intrauterine devices or sterilization) was 43%, while no method was used by 4.7% of the participants. Most women were married or lived in a long-term relationship (74.9%). Roma women are less educated than non-Roma women ($P<0.001$) Roma women use any type of contraception more often than non-Roma women. However, Roma women rely more on traditional and unsafe methods such as withdrawal and lactational amenorrhea method, but significantly less on modern methods such as pill, condom and intrauterine device ($P<0.001$).
Conclusion
Promoting reliable contraception methods and to organise educational courses about the importance of the use reliable contraceptive methods should be in the focus of national health policies and strategies related to reproductive health to reduce these ethnic differences and inequalities.
Funding statement
The present study supported by the Research Grant of ESC.

Atypical presentation in a patient with 45,X/46,X,i (X) (q10) Isochromosome Xq in mosaic turner syndrome: a case report

Mark Ramon Victor Llanes & May Naranjo
Southern Philippines Medical Center, Davao City, Philippines.

Isochromosome Mosaic Turner Syndrome (IMTS) is a variant of Turner Syndrome (TS) characterized by cytogenetic profile of 1 or more additional cell lineages aside from 45,X, and the presence of a structurally abnormal X chromosome consisting of either two short or two long arms. IMTS is rare, with only 8–9% prevalence among women with TS based on international studies, and 15% of all TS in the Philippines. A 20 year old female came in due to amenorrhea and alopecia. Physical examination revealed short stature, cubitus valgus and Tanner Stage 1 pubic hair and breast development. Transrectal ultrasound revealed absent ovaries and infantile uterus. Hormonal evaluation revealed hypergonadotropic hypogonadism. Bone aging was that of a 13 year old for females with non fusion of epiphyseal plates. Cytogenetic study revealed 45,X [37]/46, X, i (X) (q10) [13]. This is consistent with a variant Isochromosome Mosaic Turner Syndrome. She was screened for medical complications. Audiogram and two-dimensional echocardiography were unremarkable. She has dyslipidemia and was given statins. She has subclinical hypothyroidism with positive test for anti-thyroglobulin antibody. Her intelligence quotient (IQ) was below average. She received incremental doses of conjugated estrogen and progesterone that patterned the hormonal changes in normal menstrual cycle. On the third week of hormonal therapy, she developed breast mound. On the fourth week, she had her first menstrual period. Her alopecia resolved spontaneously. The above case is a rare variant of Turner Syndrome, more so, a presentation of alopecia in IMTS makes it more atypical. This required optimal supportive, medical and psychological care.

Serum 25-Hydroxy vitamin D levels and insulin resistance in polycystic ovary syndrome

Özen Öz Gül[1], Firdevs Ulutaş[2], Soner Cander[1] & Canan Ersoy[1]
[1]Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey; [2]Uludag University Medical School, Department of Internal Medicine, Bursa, Turkey.

Background
The polycystic ovary syndrome (PCOS) is often seen in reproductive age women. Although the ratio of insulin resistance is not knowm definitely in PCOS patients it is thought to be between 50 to 65%. Several studies have shown that low serum 25-Hydroxy Vitamin D (25(OH) D) levels are associated with high body mass index (BMI), insulin resistance, and waist/hip circumference, but it has not yet been clearly determined. In this study, we aimed to determine the correlation between serum 25(OH) D status and metabolic or clinical profiles of the PCOS and non-PCOS groups.
Methods
A total of 40 premenopausal female patients with (mean(SD) age: 26.77 (7.54 years) who were diagnosed with PCOS based on clinical and biochemical evaluation in accordance with revised Rotterdam criteria upon their admission to our clinic with the complaints of excessive hair growth and menstrual irregularity and age matched healthy volunteers (mean(SD) age: 28.10 (4.48) years) were included in this study. Polycystic ovarian morphology was confirmed via in USG in patients. Hirsutism was evaluated using Ferriman–Gallwey score and menstrual disturbance (none, oligomenorrhea, amenorrhea) was evaluated based on medical history in all subjects. Following the physical examination and anthropometric measurements of the patients and healthy subjects, their hormone profiles, glycemic parameters, insulin resistance and 25(OH) D were evaluated. Insulin resistance was evaluated by homeostasis model assessment (HOMA-IR).
Results
PCOS patients are found to be obeser than our control group ($P<0.01$). Plasma glucose levels were significantly higher in women with PCOS than in control group. It is found that homeostatic model assesment (HOMA-IR) which is an indication of insulin resistance is statistically significantly higher in PCOS patients ($P<0.01$). In the hormonal evaluation of the subjects the level of dehydroepiandrosterone-sulphat (DHEA-S) and androstenedione were statistically significant higher in PCOS patients. Vitamin D levels were found to be lower in PCOS patients. When PCOS patients were evaluated as obese and non-obese, vitamin D levels were found to be lower in the obese group ($P<0.01$).
Conclusion
In this study we demonstrate lower levels of vitamin D in PCOS patients. In our study, the detection of lower vitamin D levels in PCOS patients suggested that this may be one of the causes of insulin resistance and metabolic complications in these patients.

Endocrine disruption and oxidative stress implications of imipenem therapy in the ovary of 'wistar' rats

Amal Tahri[1], Manel Naifar[2], Salima Daoud[3], Faten Haj Kacem[4], Tarek Rebai[3], Fatma Ayedi[2], Mohamed Abid[4] & Zouheir Sahnoun[1]
[1]Research Unit of Pharmacology and Toxicology of Xenobiotics (UR12 ES13) and Laboratory of Pharmacology – Sfax Medicine School, sfax, Tunisia; [2]Unit of Research 'Molecular Bases of Human Diseases',12ES17 Sfax Medicine College, Sfax 3029, Tunisia, Sfax, Tunisia; [3]Research Unit of Pharmacology and Toxicology of Xenobiotics (UR12 ES13) and Laboratory of Histo-embryology – Sfax Medicine School, Sfax, Tunisia; [4]Endocrinology Department, Sfaox, Tunisia.

Imipenem (IMP) is a carbapenem antibiotic mainly used to treat nosocomial infection diseases. We aimed to evaluate the oxidative stress of therapeutic doses of imipenem (IMP) on the ovary of 'wistar' rats. In this respect, female rats were divided into four groups: animals were intraperitoneally treated with physiological serum, 30, 50 and 80 mg/kg of IMP for one week. We found that therapeutic doses of this drug did not significantly affect the levels of ovarian malondialdehyde (MDA), superoxide dismutase (SOD) and catalase (CAT). On the other hand, levels of reduced glutathione (GSH) and glutathione peroxidase (GPx) activities in the IMP-treated groups were decreased following the increasing doses of IMP. In addition, oestradiol and progesterone levels were also significantly reduced by IMP therapy compared with the control group ($P<0.05$). The light microscopy evaluation revealed normal ovary parenchyma. These results suggested that IMP induced oxidative stress and disrupt hormonal balance in the rats'ovaries.

The combination of cardiovascular risk factors in PCOS and the risk for cardiovascular disease events

Georgios Papadakis[1], Eleni Kandaraki[2], Olga Papalou[3], Andromachi Vryonidou[2] & Evanthia Diamanti-Kandarakis[3]
[1]STEPS Stoffwechselzentrum, Biel/Bienne, Switzerland; [2]Department of Endocrinology, Red Cross Hospital, Athens, Greece; [3]Department of Endocrinology, Diabetes and Metabolic Diseases, Ygeia General Hospital, Athens, Greece.

Objectives
- PCOS is defined by the presence of hyperandrogenism (clinical and/or biochemical), ovarian dysfunction (oligo-anovulation and/or polycystic ovaries), and the exclusion of related disorders.
- Women are exposed to increased risk for cardiovascular disease, hypertension, type 2 diabetes mellitus and other metabolic complications
- Cardiovascular disease (CVD) is one of the most common cause of mortality worldwide
- Women with PCOS appear to have increased number of risks compared to healthy, age-matched women at any age. The question remains unanswered whether this increased cardiovascular risk in women with PCOS can be translated also to increased cardiovascular events.
- PCOS is not only one of the commonest causes of subfertility in women, but it has also many metabolic consequences. It is associated with insulin resistance and diabetes mellitus, obesity, dyslipidemia as well as alterations of the fibrinolytic system.
- All the above are independent, traditional cardiovascular risk factors that can predispose women with PCOS to early onset CVD.

Methods
- In the next Figure we present the combination and the interaction of the main cardiovascular risk factors in women with PCOS
- The CVD factors included and combined are insulin resistance, androgen levels, systolic blood pressure, body mass index (BMI) and androgen levels.
- This Figure illustrates that women who have many risk factors are, possibly, at increased risk for cardiovascular events
- The different CVD risks are depicted in different colors and the number of co-existing risks that are present in one woman is reflected with the intensity of the color

Discussion
- In this figure is a scheme which combines wellknown CVD risk factors with and without the presence of hyperandrogenemia, a specific dishormonal alteration for PCOS women, reflecting a unifying approach of CVD risk factors in women with PCOS
- This may provide a more individualized assessment of how real is the cardiovascular risk in these women
- It may be used as a tool of assessing the potentiality of multiple interconnections of CVD risk factors linked with cardiovascular events in women with PCOS

Conclusion
- This type of combined presentation of CVD risk factors may prove to be of clinical significance in PCOS, as it could help of real life CVD risk stratification and subsequently prevention or targeted therapeutic management of these patients

Endometrioid adenocarcinoma of abdominal wall in histerectomized patient 18 years before

Monica Zambrano[1], Richard Buendia[2], Nicolas Campo[3], Laura Lopez[3] & Maria Alejandra Ramirez De La Cruz[3]
[1]Hospital De La Samaritana, Bogota DC, Colombia; [2]Colsubsidio, Bogota DC, Colombia; [3]Universidad El Bosque, Bogota DC, Colombia.

A 69-year-old patient with a history of hysterectomy 18 years ago due to apparent uterine myomatosis, who presents with a clinical picture of 6 months of evolution

of a solid suprapubic mass without any other associated symptomatology. Normal vaginal cytology 3 years ago; Menarche at 16 years of age and obstetric history: G1P2V2(Twin).
Physical examination
Indurated mass in the suprapubic region, mobile, not painful External atrophic genitalia; Vaginal examination: mass in suprapubic region, solid, mobile, without clarity regarding intrapelvic location; vaulted vagina and uncovered dome. Abdominal-pelvic CT-SCAN: Solid mass that makes body with the abdominal wall located on the midline of suprapubic region reaching diameters of length 6.5 cmx6 cmx10 cm, richly vascularized, with adequate cleavage planes with the surrounding structures and located above of the vesical dome. Tranvaginal-Echography: Absence of uterus due to surgical history, free vaginal dome without masses or collections, right adnexal mass of 55×52×61 mm for a volume of 93 cc, left ovaryof 17×10×15 mm, volume of 1.5 cc, free sac fundus. Tumor markers: Alphaphetoprotein (AFP): 3.6 ng/ml (normal value(NV) < 10 ng/ml (−); CARCINEMBERIONAIRE ANTIGEN(CEA): 4.0 mcg/L(NV < 5 mcg/L) (−); CA-125:58.5(NV < 35 U/ml)(+) and human chorionic gonadotropin: Negative. 05/31/2017 the patient underwent an exploratory laparotomy and resection of mass: Surgical description Extensive abdominal wall fibrosis, preperitoneal midline mass of firm lobulated consistency of approximately 7×10 cm, adhered to muscle and posterior in relation to dome / anterior bladder wall. Free pelvic cavity. there are no masses, atrophic left ovary, right not visualized. no adenomegalies are evident. Anatomopathological study: Macroscopic: Nodular lesion of violaceous tissue that weighs 136 grams and measures 10×6×5 cm, smooth large surface; internal surface with hard consistency, and areas of necrosis. Microscopic: Fibroadiposous tissue committed by moderately differentiated endometrioid adenocarcinoma, figo2, nuclear degree 2 with focal squamous differentiation. Immunohistochemistry study: Positivity in tumor cells for CX7, PAX 8, RE, RP, VIMENTIN. Negative for CK20, CEA, AE1/AE3, TTF-1, THYLOGLOBULINE AND WT-1. Cell proliferation index measured by KI67 30%. Pathology conclusion: primary origin in endometrium. 08/17/2017. Chest CT: Nonspecific pulmonary nodule in the apicoposterior segment of the left upper lobe. The patient is taken to segmental lobectomy wedge resection of left lung lesion by thoracoscopy. Pathology report:confirms metastatic disease of gynecological origin, with edges of section and pleura compromised by tumor.
Conclusion
Sixty-nine-year-old patient with a history of Hysterectomy 18 years before with metastatic endometrial adenocarcinoma to abdominal wall and lung.

DOI: 10.1530/endoabs.56.EP146

From aneuploidy to eyploidy: a spontaneous, uncomplicated pregnancy in a patient with 45X0/47XXX mosaicism

Artemis Mavridi[1], Georgia Ntali[2], Marianna Theodora[1], Kimon Stamatelopoulos[3] & Lina Michala[1]
[1]1st Department of Obstetrics Gynecology, Alexandra Hospital, National and Kapodistrian University of Athens, Athens, Greece; [2]Department of Endocrinology – Diabetes, Evaggelismos Hospital, Athens, Greece; [3]Department of Clinical Therapeutics, Alexandra Hospital, National and Kapodistrian University of Athens, Athens, Greece.

Turner syndrome (TS) is a chromosomal abnormality, due to a total or partial loss of one of the X chromosomes and is mostly characterized clinically by short stature and primary ovarian insufficiency. Spontaneous pregnancies in TS are rare (5%) and of relatively high risk, due to cardiovascular complications. Therefore, close medical monitoring is required. We report a case of a 21-year old woman with TS that had a full term uncomplicated pregnancy after spontaneous conception, giving birth to a healthy female (46XX) infant. The factors leading to this favorable outcome are discussed.

Birth weight of children born to women with AITD compared with those born to women without AITD

Agnieszka Dubiel[1] & Tomasz Milewicz[2]
[1]Departament of EndocrinologyJagiellonian University Medical College, Cracow, Poland; [2]Departament of Gynecological Endocrinology Jagiellonian University Medical College, Cracow, Poland.

Aim
The aim of the study was to evaluate the birth weight of children born to women with AITD compared to with those born to women without AITD.
Material and methods
The study included 596 pregnant women and their children in 2007–2015. The patients were divided into two groups. The first (group A) consisted of 191 pregnant women with chronic autoimmune thyroiditis and their children, while the second (group B) consisted of 405 pregnant women without this disease and their children. In each woman, the serum levels of anti-TPO and anti-TG were measured during pregnancy. In newborns birth weight was assessed.
Results
In group A, 191 newborns of women with AITD the average birth weight was 3450 g. In group B, 405 newborns of women without AITD the average birth weight was 3300 g.
Conclusion
The occurrence of autoimmune thyroid disease in pregnant women increases birth weight of their children.

"Gym and anabolists"

Pilar Rodriguez, Catalina Diaz, Isabel Rebollo, Irene Gonzalez & Maria Jose Lopez
Hospital Juan Ramon Jimenez, Huelva, Spain.

This is a 38-year-old male, a regular user of a gym with the sole purpose of improving his physical performance and muscular strength and habitual consumer of hyperproteic dietary supplements. Among his PAs he denies toxic habits, and highlights the removal of the right testicle in childhood. Consultation for decreased desire and sexual potency, together with pain and turgor in the left breast; hair loss at the frontal level, in analytic carried out by the Primary Care Physician, the level of Testosterone decreased (0.21 ng/ml) is the normal units, reason for which it is derived to Endocrinology Consultations. In the history acknowledges that from 2005 to 2009 has been a consumer of anabolic (Decarbolin, Sustanol 5HT, Histrol) cyclically and by different routes of administration, with the sole purpose of increasing physical power to exercise, denies such consumption in the last year and a half. In the physical examination gynecomastia draws attention being the rest of the normal exploration. In the complementary study performed, testosterone levels 0.21 ng/dl, with rest of hormonal profile within normality (FSH 1.5 mU/ml, LH 0.7 mU/ml, PRL 17.9 ng/ml, ACTH 20 IU/ml, Basal cortisol 16.40, TSH 2.29 μUI/ml, HCG < 0.05 ng/ml, 17 beta-estradiol 21 pg/ml), high CPK levels. Abdominal, mammary and testicular ultrasound, normal except absence of right testis. Incidentaloma pituitary MRI scan (4 mm). Given the findings of complementary tests and history of consumption of anabolics, hypogonadotropic hypogonadism was diagnosed secondary to taking anabolic steroids, without consumption at present for a year and a half. Testosterone treatment is started, and reviewing literature, there are cases in which patients benefit from adjuvant treatment with human chorionic gonadotrophin (hCG) at doses 500 IU, after testosterone for three months. He has always shown a demanding attitude, questioning the diagnosis, so he asks for a second medical opinion. Anabolic androgenic steroids are synthetic androgens derived from testosterone, widely used in athletes, especially in bodybuilders and athletes of high competition, the administration of doses far superior to physiological induce the appearance of side effects, highlighting alterations in sexual function and reproductive.

Amenorrhea and benign intracranial hypertension as an effect of antipsychotic therapy in a patient with schizophrenia

Ifigenia Kostoglou-Athanassiou[1], Lambros Athanassiou[2], Athanasios Fortis[3], Ioannis Myriokefalitakis[4] & Thomais Kalogirou[3]
[1]Department of Endocrinology, Asclepeion Hospital, Voula, Athens, Greece; [2]1st Department of Medicine, Asclepeion Hospital, Voula, Athens, Greece; [3]2nd Department of Medicine, Asclepeion Hospital, Voula, Athens, Greece; [4]Department of Rheumatology, Asclepeion Hospital, Voula, Athens, Greece.

Introduction
The management of schizophrenia involves drugs which inhibit domapine receptors. The drugs control the disease. However, they increase prolactin secretion and induce amenorrhea. The drugs induce the development of metabolic syndrome and as a result of obesity they may cause benign intracranial hypertension.

Aim
The aim was to describe the case of a patient who developed schizophrenia and after therapy with antipsychotics benign intracranial hypertension and amenorrhea.
Case description
A patient, female, aged 21, developed schizophrenia. After diagnosis treatment with antipsychotic medication was initiated. Antipsychotic treatment induced obesity and subsequently benign intracranial hypertension. Benign intracranial hypertension reduced her visual acuity and induced hearing loss within a year. Acetazolamide was administered for the control of intracranial hypertension. The patient also developed amenorrhea. Prolactin was 150 ng/ml (normal range 2–29 ng/ml). Cabergoline was administered for the management of hyperprolactinemia.
Conclusion
Antipsychotic treatment for the management of schizophrenia may be accompanied by the development of obesity and in some cases benign intracranial hypertension. Benign intracranial hypertension, despite its name, may have severe consequences such as reduction of visual acuity and hearing loss, being, according to the literature "not so benign". Amenorrhea affects health and quality of life in a young female patient. The use of the new atypical antipsychotics may be a solution for the prevention of the serious adverse effects of antipsychotic treatment, such as benign intracranial hypertension and amenorrhea.

Hirsutism in patients with polycystic ovary syndrome

Emna Elfaleh, Ibtissem Oueslati, Ons Rejeb, Fatma Chaker, Melika Chihaoui, Meriem Yazidi & Hedia Slimane
Department of Endocrinology, La Rabta Hospital, Tunis, Tunisia.

Introduction
Polycystic ovary syndrome (PCOS) is a heterogeneous disorder, characterized by chronic anovulation and hyperandrogenism. Hirsutism, defined as excessive terminal hair that appears in a male pattern in a woman, is frequently present in patients with PCOS. We aimed to determine the clinical and biological characteristics of hirsute patients with PCOS.
Methods
It was a retrospective study included 30 women diagnosed with PCOS according to the Rotterdam consensus. Hirsutism was defined as a Ferriman–Gallwey score ≥ 8. The medical history, physical examination findings and hormonal profiles were documented and analyzed.
Results
The mean age of the study population was 27.7 ± 8.4 years. A family history of hypertension and diabetes was found in 73% of cases. Hirsutism occured in puberty in 80% of cases. It was severe in only one woman (3%) and mild to moderate in 29 women (97%). Menstrual abnormalities were present in 22 women (73%) and 4 women (13%) had a history of miscarriage. The remainder of the clinical examination revealed the presence of acne, acanthosis nigricans, android obesity and hypertension in 17%, 30%, 70% and 16% of cases, respectively. Hormonal assessment showed hyperandrogenism in 70% of patients with a mean level of testosterone of 0.9 ± 0.4 ng/ml and moderate hyperprolactinemia in 3 cases (10%). Metabolic exploration found a glucose intolerance, diabetes and hypertriglyceridemia in 10%, 13% and 13% of patients, respectively. The prevalence of metabolic syndrome was 36.7%.
Conclusion
In patients with PCOS, hirsutism is often mild to moderate with a progressive onset and without other signs of virilization. The association with metabolic disorders is frequent, highlighting the contribution of insulin resistance in the pathophysiology of PCOS.

EP152

Evolution of premature ovarian failure after 15 years of follow-up

Najoua Lassoued, Asma Ben Abdelkrim, Yosra Hasni, Maha Kacem, Molka Chaieb, Amel Maaroufi & Koussay El Ach
Endocrinology Department, Farhat Hached University Hospital, Sousse, Tunisia.

Introduction
The therapeutic management of premature ovarian failure (POF) consists of a hormone replacement therapy that must be regular to avoid cardiovascular and bone complications as well as psychological management. The objective of this work was to study complications at 15 years of evolution of 42 tunisian women followed for POF.
Patients and methods
It's a retrospective study of 42 patients followed in the endocrinology department of Sousse for POF between 2000 and 2017.
Results
The average age of the patients was 23.85 years old. All patients were treated with combined estrogen/progestin hormone replacement therapy with a sequential regimen in 11 patients to ensure withdrawal bleeding. After 15 years of follow-up on average, a final small height was found in 5 patients with an average height of 147.85 cm. The average body mass index was 24.51 kg/m^2. The average waist circumference was 90,5 cm. Three patients became diabetic, one patient was followed for hypertension and one patient was followed for dyslipidemia. Metabolic syndrome criteria were met in one third of patients. No patient had a cardiovascular event. Bone densitometry showed osteoporosis in 21.43% of patients and osteopenia in 35.71% of patients. Two patients had pathological fracture at the age of 28 and 39, respectively. Therapeutic non-compliance of hormone replacement therapy was observed in 20% of patients.
Conclusion
The two major risks of hypoestrogenism secondary to POF are cardiovascular risk and bone risk. If the patient is substituted, these risks should be avoided. However, few studies have prospectively evaluated the effects of estrogen therapy on cardiovascular risk in patients with POF.

EP153

Diagnostic difficulties in precocious puberty

Hamza El Fekih, Yosra Hasni, Bilel Ben Amor, Asma Ben Abdelkarim, Maha Kacem, Molka Chadli, Amel Maaroufi & Koussey Ach
Department of Endocrinology and Diabetology, Farhat-Hached University Hospital, Sousse, Tunisia.

Introduction
Precocious puberty (PP) is the development of secondary sexual characteristics before the age of 8 years in girls and beforethe age of 9 years in boys. Central PP has an idiopathic origin in upto 95% of girls while in up to 50% of males. The diagnostic and the management of PP can beparticularly complex. Here we describe cases of two sisters having central PP with different presentation and evolution.
Observations
First case: A 13-years-old female diagnosed at the age of 6 years and a half with central PP. She presented anaccelerated linear growth with an initial height equal to 126 cm/+3SD, Tanner stage 3 and advanced bone age by 3 years and a half. Basal LH level was high at 2.5 mIU/mL which was multiplied by 14 after GnRH administration, estradiol was 12 pg/mL. Brain Imaging was normal. She received GnRH agonist therapy during 3 years and a half with a final height of 155 cm. Second case: Her little sister aged of 10-years 3 months was followed-up from the age of 4 years and a half. Her initial height was 104 cm/-1SD,Tanner stage 2 and she had an advanced bone age by 1 year. Basal LH and FSH was respectively 1.2 and 2 mIU/mL and its peak concentrations after GnRH agonist stimulation was respectively 6.5 and 12 mIU/mL. Brainimaging was normal. The decision was to follow-up the patient. During her irregular follow-up, she experienced an accelerated growth rate of 16 cm between the age of 7-9 years followed by a gain of only 1 cmin the year after. Menarche occurred at the age of 10 years, her height was 137 cm VS target height of 147 cm.
Conclusion
The management of PP has several challenges especially distinguishing normal from pathologicalpubertal development, achieving normal adult height and avoiding its psychosocial consequences.

Mayer-Rokitansky-Kuster-Hauser syndrome type II

Hemmet EL Haddad, Mona Radwan, Naglaa Abdel El Kawi, Naglaa El Sayed, Rasha Sobh, Shaimaa Fathy & Randa Salam
Faculty of Medicine Cairo University, Cairo, Egypt.

The normal development of the female reproductive tract depends on the interaction between genetic, hormonal and environmental factors for the differentiation of the Müller and Wolff ducts, and the urogenital sinus
Case report
16-year-old female, single, school student presented to our endocrine department complaining of primary amenorrhea. No history of chronic diseases, excessive exercise,medications, anorexia, clinical hypothyroidism or hyperandrogenism. Family history revealed positive consanguinity. Mother menarche at age 11, her elder sister diagnosed as turner syndrome [45xo] with infantile uterus and both ovaries are not visualized. Physical examination: weight 61kg, height:170 cm BMI: 21.1. Female phenotype, Tanner classification: breasts (4) axillary hair (2), pubic hair (2). Genital examination rudimentary clitoris, unchanged inner and outer labia grooved urethra with elevated edges. Laboratory work up showed follicle-stimulating hormone: 5.35 mIU/ml (N: 0.7–11.1). Luteinizing hormone: 8.1 mIU/ml (N: 0.8–7.6). Pelvi abdominal ultrasonography showing midline solitary pelvic kidney, absent uterus,visible rt ovary measuring 23×15 mm,visible lt ovary measuring 23×22 mm. Genetic evaluation revealed karyotype 46,XX, thus determining the diagnosis of Mayer-Rokitansky-Kuster-Hauser syndrome. Type II
Conclusion
Mayer-Rokitansky syndrome generates anxiety and psychological distress with consequences on the patient's quality of life, thus requiring a multidisciplinary approach

EP156

Pituitary hyperplasia secondary to congenital primary hypothyroidism in adult patient

Nadia Khessairi, Ibtissem Oueslati, Fatma Chaker, Meriem Yazidi, Melika Chihaoui, Ons Rejeb & Hedia Slimane
Department of Endocrinology, La Rabta Hospital, Tunis, Tunisia.

Introduction
The reactive pituitary gland enlargement is a non-neoplastic growth of at least one pituitary lineage, which can often be essential or secondary to prolonged deficit of a gland target. It may be difficult to differentiate from functional pituitary adenomas. Herein we report a case of pituitary hyperplasia secondary to congenital primary hypothyroidism diagnosed at the age of 38 years.
Observation
A 38-year-old female patient presented with spaniomenorrhea, mental retardation and delayed stature. On physical examination,she had a height of 134 cm, a weight of 54 kg, adult pubertal status, galactorrhea, skin infiltration and non-palpable thyroid gland. Her hormonal profile showed raised thyrotropin stimulating hormone (TSH) (>100 mIU/L, range: 0.35-5), low FT4 (<0.40 ng/dL, range: 0.7-1.5) and hyperprolactinemia (142 µg/L). Further investigation showed negative antiperoxydase antibodies and the scintigraphy confirmed an ectopic sublingual thyroid gland. The patient was put on levothyroxine replacement therapy. Four months later, she presented with a normal TSH level but a persistent hyperprolactinemia (69 µg/L). A pituitary magnetic resonance imaging (MRI), requested in order to explore this hyperprolactinemia, showed diffuse pituitary enlargement with stalk deviation.
Conclusion
In our review of the literature, primary uncontrolled hypothyroidism has been described as a precursor to pituitary hyperplasia. It results from the loss of thyroxine feedback inhibition and the subsequent overproduction of thyrotropin-releasing hormone (TRH). L-thyroxine replacement therapy prevents enlargement of pituitary gland and may regress the change, but is not the only outcome of pituitary enlargement. Other coexisting disturbances must be considered when the treatment is not successful.

Thyroid disease in very elderly patients

Juan Marti, Lluis Jordana & Marisol Zurutuza
Hospital Zumarraga, Zumarraga, Guipuzcoa, Spain.

Objective
To know characteristics of patients older than 80 years with thyroid disease.
Patients and methods
Prospective 6-month study in which we analyze characteristics of patients that have been treated and followed for thyroid disease in endocrinology consult.
Results
Hundred and fifteen patients were analyzed of them, 23 men and 92 women, with 83.78±2.12 years-old. Comorbidities. Arterial hypertension 53%, previous neoplasms 18%, CHF15%, COPD 11%, cognitive impairment 11%, stroke 8%, ischemic heart disease 8%, chronic renal failure 6%. Thyroid pathologies were: hyperthyroidism 29% euthyroid goiters 28%, hypothyroidism 16%, subclinical hyperthyroidism 13%, thyroid cancer 6%, subclinical hypothyroidism 4%, amiodarone thyroiditis 4%. Study and treatment used was similar to patients under 80 year-old, multinodular goiter was the most frequently cause of hyperthyroidism. Metabolic pathologies associated: dyslipidemia 35%, type 2 diabetes mellitus 30%, osteoporosis 19%, hyperuricemia 10%, obesity 7%, hypoparathyroidism secondary to surgery 4%.
Discussion
The most common form of thyroid dysfunction in the elderly is subclinical hypothyroidism occurring up to 15%. In our study was hyperthyroidism, possibly due that subclinical hypothyroidism was controlled from primary care. Prevalence of hyperthyroidism in elderly ranges from 0.5 to 2.3%.The most frequents causes were toxic multinodular goiter, Graves' disease, toxic adenoma. Subclinical hyperthyroidism may be present in up to 2%.
Conclusions
The prevalence of thyroid disease in elderly is higher than the general population and is associated with significant morbidity. Usually in the elderly healthy population there is a high rate of thyroid dysfunctions that are not detected. Dyslipidemia and diabetes mellitus were the main associated endocrine pathologies.

EP157

Beyond conventional hyperthyroidism: a rare association of inflammatory bowel disease and inflammatory myopathy with Grave's disease

Ananda Mohan Chakraborty, Soumitra Ghosh, Srabani Ghosh, Debashish Mondal, Himadri Sanowal & Sukalpa Chowdhury
Institute of Post Graduate Medical Education and Research, Kolkata, India.

Introduction
Graves' disease being one of the common cause of hyperthyroidism and thyrotoxicosis at presentation, is actually caused by an antibody directed to TSH receptor which leads to hyper functioning of the gland. Being an autoimmuno disease, it may be associated with other autoimmuno diseases. Inflammatory myopathy like polymyositis is less frequently observed in patient with Graves and inflammatory bowel disease again is infrequent as per as the association is concern. Association of inflammatory myopathy and inflammatory bowel disease in a single patient of Grave's disease is rare and poses a significant diagnostic and therapeutic problem.
Case study
A 51 years menopausal woman presented to outpatient department of IPGMER with history of shortness of breath, palpitation, bilateral lower limb swelling for one month and Jaundice for last 15 days. She was also complaining of swelling of her neck for last six months and episodic large volume diarrhoea with occasional blood mixed stool for last eight months. She was apparently well until six months prior when she noticed gradually progressive neck swelling. Clinical and Biochemical evaluation imparted that she was having thyrotoxicosis with congestive cardiac failure and jaundice. Thyroid evaluation showed she was having diffuse goitre. She had Anti TPO and Anti TSH receptor antibody high positive. A diagnosis of graves presented with thyrotoxicosis was made. She was salvaged conservatively with thyroid suppression and beta blocker. On the day 4th of admission when she was recovering from the thyrotoxic crisis she developed severe proximal muscle weakness with power or 2/5 in both lower limbs and 3/5 in both upper limbs with preservation of jerks, normal tone and sensory and autonomic functions. EMG study showed myopathic pattern and biopsy proved

that as polymyositis. Diarrhoea was persisting and history of prolong episodic bloody stool lead us to go for a colonoscopy and guided biopsy. Lesion was consistent with Crohn's disease. We have made our final diagnosis as Grave's disease presented with thyrotoxicosis having an associated inflammatory myopathy with inflammatory bowel disease. Steroid was added with pre administered regime and patient symptomatically improved.
Discussion
This case illustrate a rare association of Grave's disease with polymyositis and Crohn's disease. Mimicar, thyroid myopthy may suppress inflammatory myopathy and diarrhoea itself can be a feature of thyrotoxicosis.There is scarcity of cases shown association among these three autoimmunidiseases. Recognition of this condition is essential as per as proper therapy is concern.

DOI: 10.1530/endoabs.56.EP157

What should be the cut-off level for antithyroperoxydase antibody? January 2018

Bogdan Oprisan[1], Mihaela Ratcu[2], Cosmina Ilie[2], Payman Gharibafshar[2], Dan Peretianu[2] & Mara Carsote[3]
[1]Department of Biophysics Univ.Med.Gr.T.Popa, Iassi, Romania; [2]Medical Center Povernei, Bucharest, Romania; [3]Institue of Endocrinology, Bucharest, Romania.

Aim
The biological diagnostic of Hashimoto thyroiditis (HT) is based on higher than normal levels of antithyroperoxydase antibodies (ATPO). Our goal was to establish the cut-off limit of normality (the upper limit) for ATPO in our thyroid normal patients. This limit, and not that of the laboratory, should be used as diagnosis of Hashimoto thyroiditis.
Material and method
1. ATPO was investigated in patients with normal level of thyroid hormones (euthyroidism) and normal ultrasound of thyroid (linear probe at 7.5–10 MHz). 2. ATPO was analyzed in several Bucharest laboratories, accredited for this investigation. The laboratory cut-off limit for normality was 34 ui/ml. 3. Conventionally, the normality is considered as the average (mean) plus/minus standard deviation multiply by 2.
Results
A. Patients: 404; women - 328 (77%), men – 76 (23%); age: average - 44.6, median - 42; average TSH: 1.84 mui/ml, FT4, 15 nmol/l. B. ATPO level was: average: 8.65 ui/ml, standard deviation: 6.88. Therefore, the upper limit should be 21.89 ui/ml.
Discussion
Based on 34 ui/ml cut-off limit, we registered 1750 patients with HT (higher ATPO), 205 patients with only high antithyroglobuline thyroiditis (ATG-T) (low ATPO), 126 patients with idiopathic myxedema (hypothyroidism, lower ATPO/ATG, and inflammatory ultrasound signs) and 1875 patients control, with other thyroid diseases (mostly thyroid nodules). Considering ATPO cut-off as 21.89 ui/ml, 29 patients with ATG-T (14.15%) and 12 patients with idiopathic myxedema (9.52%) should be considered, in fact, HT patients. Moreover, 135 control patients (7.19%) with ultrasound inflammatory signs should be considered HT patients, too.
Conclusions
1. Using the data from our patients, the cut-off limit for ATPO should be 21.89 ui/ml and not 34 ui/ml. 2. Based on 23 ui/ml cut-off limit, the number of patients with Hashimoto thyroiditis increased by 10.3%. 3. Every research group should establish its specific cut off for ATPO level.

DOI: 10.1530/endoabs.56.EP158

EP159

Total thyroidectomy can be a radical method of treatment of Grave's disease in alcohol addicted patient who has hepatitis B at the same time, because medical treatment can aggrivate liver disease and bring to recurrence of Grave's disease

Meri Hambardzumyan
Police Hospital of Armenia, Yerevan, Armenia.

34 years old male patient was admitted to Endocrine department with palpitation (130–140 beats/minute), weight loss(15 kg during 3 months), anxiety, nervousness, hand tremor, generalized nocturnal pruritus. Laboratory examination showed: decreased level of thyroid stimulating hormone (TSH) <0.005 (n 0.3–4.0 iu/ml), markedly increased level of free thyroxin (FT4) - 100(n 12–22 pmol/l), free triiodthryonine FT3-6,5 (n-0,8-2,0 ng/ml),anti-R-TSH 15-(n- $<$ 1,75T, Anti –TPO 1000,0 (n-$>$34). Glucose and other blood tests ALAT, ASAT,creatinine, ammonia were within normal range.Thyroid ultrasound showed bilaterally enlarged gland with volume of 50 ml, without nodules. Presence of $\ll$ thyroid inferno $\gg$. Patient was diagnosed Grave's thyrotoxicosis. Follow up after 3 weeks of treatment with Thyrazol 50 mg per day, Anaprilin 160 mg 4 times per day, Mirtazapine 7,5 mg showed:weight gain 5 kg, pulse 90–100 beats/minute, absence of nocturnal pruritus after Miratzapine. Laboratory follow up: FT4 40,0, (n-12–22 pmol/l)T3 4,5 ng/ml(n-0,8-2,0 ng/ml). Treatment continued with same daily dose of Thyrazol and Anaprilin 120 mg.Mirtazapine canceled. After 4 weeks patient had weight loss 2,5 kg, palpitation 110–120 beats/minute, abdominal pain, diarrhea, jaundice. Abdominal ultrasonography showed few small calcifications on the right lobe of liver. Laboratory follow up showed increased (AlAT)150 U/l, increased Total Bilirubin 2,5(n-0,2-1,2 mg/dl) and elevated FT4() -105 pmol/l. Hepatitis are checked: Hepatitis C and A were negative.HBsAg 1081,55 S/CO. HBV quantitative 108 IU/ml. It appeared patient had teeth removal one year ago. After consultation with infectionsit anti viral treatment didn't prescribed. Taiking in account presence of hepatitis B, alcoholism, hepatotoxicity of Thyrazol, heigh level of anti-R TSH, Thyrazol canceled and patient prepared for total thyroidectomy as Radioiodine therapy is unavailable in Armenia.Patient was given lyugol solution for 10 day 7 dropss per day and b –blocker.After 10 day FT4 became 24 pmol/l (n-12-22 pmol/l), Ft3 1,9-(n–0,8-2,0 ng/ml) L. Patient underwent total thyroidectomy than prescribed replacement therapy with L- Thyroxin. One month after FT4- 15 pmol/l, TSH 1,5 IU/ML, ALAT-35 U/I, Total Bilirubin 0,9 mg/dl. Hepatitis markers were within same ranges. Patient's condition has improved.
Conclusion
Medical treatment of Grave's disease with presence of Hepatitis B, high level of Anti R-TSH and alcohol addiction can not only aggravate liver disease but bring to recurrence of Grave's disease.Total thyroidectomy can be a method of chose in this case.

The complications of diseases of thyroid gland at children and teenagers according to data for 5 years

Shakhnoza Azimova[1], Yulduz Urmanova[1,2], Nazira Rikhsieva[2], Feruza Khodgaeva[2], Kim Min Dgi[2], Ortikali Tursunkulov[2] & Edvard Akhmadiev[2]
[1]Center of Endocrinology, Tashkent, Uzbekistan; [2]Tashkent Paediatric Medical Institute, Tashkent, Uzbekistan.

The aim
To study the complications of diseases of thyroid gland at children and teenagers according to data for 5 years.
Material and methods of investigation
Under supervision of the employees of the department of children's endocrinology the Center of Endocrinology of PH of RUz during from 2012 on 2016 years was hospitalized 213 children and teenagers with various diseases of thyroid gland, from them of the boys was - 67 (31,4%), girls -146 (68,5%). 20 sound children and the teenagers of the appropriate age made the group of the control.
Results
The most of patients were in teenager age, namely from 11 to 17 years - 147 patients (69,1%), were at the same time mostly sick girl - 100 from 147 (68,0%). At our patients the manifest hypothyroidism was marked, that is authentic increase in TSH against the background of authentic lowering of the free thyroxin of blood on a comparison with group of monitoring was watched. According to our data, children and teenagers had the following frequency of complications of the main diseases: delay of skeletal development – 17,8%, delay of physical, sexual, mental, speech development – 25,8%, delay of physical, mental development – 20,4%, delay of physical, sexual development – 15,6%, delay of physical development – 14,5%.
Conclusions
The researches conducted by us allowed to estimate gravity of the goiter endemiya and expressiveness of manifestations of violation of sexual and physical development. The results received by us confirm need of further long observation and treatment of patients.

A TSH pituitary adenoma due to Hashimoto Thyroiditis and L-tiriiodotironin treatment experience: Case report

Beray Selver Eklioğlu, Muhammed Burak Selver & Mehmet Emre Atabek
Necmettin Erbakan University Faculty of Medicine, Konya, Turkey.

Aim
We report a child with reactive pituitary enlargement and microadenoma due to Hashimoto thyroiditis.We want to emphasize the importance of good endocrine evaluation in pediatric cases of pituitary adenomas
Case report
A 7 year 7 month old boy presented with mild symptoms of hypothyroidism. There was no feature in his past medical story.He had normal cognitive and neurological development. At physical examination his weight was 24 kg (0.06 SDS) and height was 122.5 cm (−0.20 SDS). His systemic evaluation was normal. In hormonal workup low free thyroxine (0.75 ng/dl) (0.82–1.62),low tiriiodotironin (0.99 pg/ml) (2.73–4.92) and high TSH (>150 mIU/ml)(0.8–5.4) levels, and hyperprolactinemia (prolactin level at 36.33 mIU/l), TSH reseptor antibody was 0.49, TGAb (>3000 mIU/ml), TMAb (>1000 mIU/ml) were obtained.. In ultrasonography thyroid gland was larger and heterogeneous images were seen. Hashimoto thyroiditis were diagnosed and Levotiroksin treatment (3 mcg/kg/g) was started and gradually increased.In follow up TSH was not suprese despite free t4 rise. Macro TSH was negative.Pituitary imaging was performed. The height of the pituitary was measured as 11.5 mm. It creates a slight pressure on the optical chiasm. Within the pituitary, there is a region of 6×9 mm in diameter with low contrast.It was reported as microadenoma. Then treatment was planned as L-tiriiodotironin (12.5 mcg/day) and dose adjustment done according to hormone levels.After 1 month in pituitary imaging, the height of the pituitary was measured as 6.6 mm,staining was homogeneous and no mass was seen. TSH level was depressed. (TSH: 47.64 mIU/ml, FT4: 1.15 ng/dl). The patient's treatment and follow-up continues
Conclusion
Based on the clinical and laboratory data a diagnosis of pituitary microadenoma secondary to chronic autoimmune thyroiditis was made. Primary hypothyroidism should be considered in the differential diagnosis of pituitary masses

Expectant management in patients with multinodular goiter: expected development options

Yuri Aleksandrov[1], Artem Dyakiv[1] & Vasilyi Semikov[2]
[1]Yaroslavl State Medical University (YSMU), Russian Federation, Yaroslavl, Russia; [2]First MSMU n. a. I. M. Sechenov Of Ministry Of Healthcare (Sechenovskiy University), Russian Federation, Moscow, Russia.

Today dynamic observation are given preference in most cases multinodular goiter. Small nodes without disruption of thyroid function do not affect the quality of life of patients. Wait-and-see tactic with multinodular goiter has previously been submitted due to the lack of adequate replacement therapy. Wait-and-see tactic previously criticized because of its passivity and predictable negative effect on growth nodes. The result of passive observation is the occurrence of goiters of large size that patients are treated as a minor inconvenience. A retrospective investigation of multinodular goiter large size was made. Over 8 years of experience in the operational treatment were 2519 patients with various thyroid disease (women, 2194, men - 325). Of the total number of patients, we selected 34 cases (1.35%) multinodular goiters. The inclusion criteria in the study were: i) the presence of multiple nodes in thyroid, ii) the mass of the removed thyroid tissue 200 g or more, iii) pathological confirmation of focal lesions of thyroid (macro-microfollicular colloid goiter, thyroid adenoma, thyroid cancer). Assessed clinical and instrumental diagnostic methods in the evaluation of the severity of the changes in the thyroid gland in this disease. Describes the features of performing operations in patients with large multinodular goiters. Presents a clinical case illustrating features of the development, diagnosis, surgical treatment and postoperative rehabilitation of patients with thyroid cancer arising in the background of a giant multinodular goiter. Today there is no clear clinical criteria of the syndrome of compression that would allow to set the indications for surgery. The subjective assessment of well-being, fear of surgery prevent patients adequately assess the effects of high thyroid in human health. The necessary precise regulation of the stages of the monitoring, a must for doctors and patients, as well as an emphasis on instrumental methods in the evaluation of thyroid growing. It is proved that dynamic monitoring in multinodular goiter effective only when adequate monitoring of patients, and with pronounced negative dynamics must be indications for surgery. Among instrumental diagnostic methods the most informative has the x-ray computed tomography.

The effects of vitamin D supplementation on insulin resistance in patients with hypothyroidism

Ivan Pankiv
Higher State Educational Establishment of Ukraine «Bukovinian State Medical University», Chernivtsi, Ukraine.

Background
Over the past decade, numerous non-skeletal diseases have been reported to be associated with vitamin D deficiency including autoimmune thyroid pathology.
Aim
The aim of the study is to evaluate the effects of vitamin D supplementation on insulin resistance in hypothyroidism.
Materials and methods
Forty-seven participants, 32–74 years old, including 39 women (82.9%) and 8 men (17.1%) took part in the study. Serum TSH, insulin and 25(OH)D concentration were measured, and HOMA-IR was calculated. All measurements were performed at the beginning and the end of the study. Patients with hypothyroidism received 21,000 unit of cholecalciferol orally per week for 12 weeks. The results were analyzed by descriptive tests, and a comparison between variables were made using paired *T*-tests or Wilcoxon tests, as a appropriate.
Results
All of the participants were vitamin D deficient. Mean serum 25(OH)D concentration was 21.72±6.14 ng/ml. The results at baseline and at the end were for insulin 19.36±2.39 and 9.92±2.38 mIU/l ($P<0.05$) and for HOMA-IR, 3.91±0.32 and 2.38±0.17 ($P<0.05$) respectively.
Conclusions
Our data showed significant improvement in serum insulin and in HOMA-IR after treatment with cholecalciferol, suggested that vitamin D supplementation could reduce insulin resistance in hypothyroidism.

Clinical and morphological characteristics of the first time nodular goiter

Eldar Nadyrov, Irina Savasteeva, Elena Makhlina, Inna Kolyada, Tamara Evdochkova & Tamara Moskvicheva
Republican Scientific Center for Radiation Medicine and Human Ecology, Gomel, Belarus.

We analyzed the results of a survey of 51 patients aged 18 to 25 years who were not exposed to ^{131}**I**. Patients included in the study had a the first time nodular goiter. The median age of the patient at the time of the diagnosis of nodular goiter was 22.00 (20.32; 23.21) years. Male/female ratio was 1/16. In 23.5% of patients the site was formed against the background of autoimmune thyroiditis, in 76.5% the true nodal formations were revealed against the background of the normal ultrasound structure of the thyroid gland. The sizes of the revealed nodes were in the range of 0.7–1.5 cm. One-half of those surveyed in the thyroid gland were lysed with isoechoic nodes, about 10% of which had ultrasound signs of cystic degeneration. The median free T_4 level was 14.72 (13.25, 16.83) nmol/l, TSH - 1.56 (1.01, 2.23) MmE/l and corresponded to the range of reference values. More than 50% of those surveyed had indications for a fine needle aspiration biopsy. Based on the results of the cytological examination, benign changes were detected in the nodal formations with different degrees of proliferation of the thyroid epithelium. About 10% of those surveyed had cytological signs of degenerative node changes. In 7 (13.7%) of the patients examined, there was a suspicion of papillary cancer. The cytological conclusion was confirmed in all cases after the histological examination. In young adults, benign forms of nodular goiter prevail against the background of a normal thyroid status. However, sporadic cases of thyroid cancer are recorded.

Thyrotoxic vomiting: an unusual presentation

Tahir Omer, Manu Shrivastava & Ian Seetho
Cambridge University Hospital, Cambridge, UK.

Introduction
Thyrotoxicosis classically presents with tremor, goitre, sweating and diarrhoea. It is increasingly appreciated, however, that presentations can be complex and non-specific. Gastrointestinal symptoms in thyrotoxicosis are thought to derive from increased motility. Thyroid overactivity may be a cause for unexplained repeated vomiting and abdominal pain.
Case
A case of 41-year-old man presented with a three-year history of intractable vomiting, intermittent abdominal pain, sweating, hiccups, and 20 kg weight loss. He previously had surgical laparotomy to correct malrotation that had been found on CT scan at his local hospital. The malrotation was thought to be the cause of his symptoms. However, surgery did not lead to symptomatic relief, and caused complications in the form of poor wound healing and infection. He was then commenced on Sertraline for anxiety that was attributed to multiple hospital admissions and invasive investigations over three years. He was referred over to our unit for further investigations. A repeat CT showed that the malrotation had not been fully corrected, but that there was no sign of obstruction. It was agreed that the malrotation was probably an incidental finding. A marked tachycardia and hypertension were noted at this point, but attributed, along with pyrexia, to infection with Clostridium difficile. Other differential diagnoses were considered and more tests ordered, including: a porphyria screen, C4 levels, serum lead, faecal calprotectin, C1 esterase and a specific test for Familial Mediterranean Fever. Moreover, imaging was scheduled: MRCP, a gastric emptying study, endoscopic ultrasound and, CT head. Towards the latter part of his admission, he noticed a swelling in his neck. One month later, thyroid function blood tests were ordered; these showed a TSH $<$0.03 mU/l (0.35–5.5) and T4 55.9 pmol (10–19.8). TRAB antibody was positive. He was diagnosed with Grave's disease. The vomiting and epigastric pain remarkably improved following treatment with Carbimazole.
Discussion
Whilst uncommon, thyrotoxicosis should be considered in patients with persistent, unexplained vomiting. Thyroid function tests should be checked so as to avoid delays in diagnosis and potentially obviate the need for invasive and non invasive tests and procedures, allowing the initiation of treatment as early as possible.

EP166

Thyrotoxic periodic paralysis: a rare complication of hyperthyroidism for 21-year-old male.

Modesta Petravičiūtė[1,2], Gintarė Naskauskienė[1,2], Vigantas Dunauskas[1,2] & Žydrūnė Visockienė[1,2]
[1]Vilnius University Faculty of Medicine, Vilnius, Lithuania; [2]Vilnius University Hospital Santaros Klinikos, Centre of Endocrinology, Vilnius, Lithuania.

Introduction
Thyrotoxic periodic paralysis (TPP) is very rare (prevalence in non-Asian populations 0.1–0.2%, more frequent in men) and potentially life-threatening complication of hyperthyroidism. TPP develops when thyroid hormones cause sodium-potassium-adenosine triphosphatase (Na/K-ATPase) pump overactivity, leading to rapid potassium shift into the cells resulting in hypokalaemia. This causes transient episode of muscular weakness usually involving lower limbs and hypokalaemia, sometimes - respiratory weakness and severe, even fatal arrhythmias. TPP usually presents early in the morning, after heavy unusual exercise, stress or a high carbohydrate intake. Diagnosis is difficult because of the rarity and subtlety of symptoms.
Case presentation
A 21-year-old male was admitted to the emergency room with tetraplegia, which gradually developed for about 24 hours and was provoked by unusually vigorous physical activity. First it was hard to climb the stairs and in 12 hours – he woke up in the morning and couldn't move. On physical examination: BMI–28.7 kg/m^2, HR 93beats/minute, BP 125/60 mmHg. Thyroid non-palpable. Weakness of all limbs with power 1-2/5. No other neurological changes were found. Laboratory analyses: chemistry panel and complete blood count was all normal, except of serum potassium of 1.8 mmol/l. Instrumental analyses: Head CT scan – no acute pathology was found. ECG-sinus tachycardia- HR 97beats/minute and U waves. After acute treatment with intravenous potassium supplements (KCl 10%60 ml per 12 h), muscle weakness disappeared, serum K raised to 5.8 mmol/l and patient was moved to endocrinology department. Revised medical history: excessive sweating, heat intolerance for about 1 month. Physical examination showed normal power of all limbs (5/5). Laboratory analyses: K– 4.5 mmol/l. 24 hour urine: K–58.5 mmol/24 h (*n*.38–125 mmol/24 h). Prolactin–248.0 mU/l (*n*.72.6–407.4), Aldosterone–211.92 ng/l (*n*.13.3–231.4), ACTH–22.7 ng/l (*n*. $<$46). TTH–0.001 mU/l (*n*.0.4–4.0), FT4–31.14 pmol/l (*n*.9.0–19.0), FT3–16.53 pmol/l (*n*.2.61–7.70). Thyroid ultrasound – diffuse nodular goiter. Clinical diagnosis: Diffuse nodular goiter, hyperthyroidism. Thyrotoxic periodical paralysis. Hypokalaemia. Treatment: Thiamazoli 30mg daily, with down-titration, after 10days. After 1 month of recommended treatment, muscle weakness episodes didn't recur, excessive sweating, heat intolerance diminished, potassium concentration and thyroid hormones were normal K-4.7 mmol/l, FT4 – 15.07 pmol/l, FT3 – 6.35 pmol/l.
Conclusion
TTP is potentially lethal condition, which is difficult to diagnose, thus for all patients with unclear ethology of paralysis, thyroid hormones should be tested. All efforts should be used to achieve euthyroidism as early as possible, because it's the only way to avoid TPP.

EP167

Graves disease, pericarditis and thymus hyperplasia: the improbable triad!

Catarina Ivo, David Veríssimo, Vitória Pires, Filipa Serra, Dolores Passos, Luis Lopes, João Jácome de Castro & Mafalda Marcelino
Endocrinology Department, Armed Forces Hospital, Lisboa, Portugal.

Introduction
Ophthalmopathy and dermatopathy are the most frequent manifestations of Graves Disease (GD). It is also known the relation between GD and other autoimmune diseases like myasthenia gravis. Thymus hyperplasia in GD is already documented on literature but it's mechanism is not well understood. There are two possible explanations, one related to thyrotrophin receptors stimulation present on thymus, and other related to tissue stimulation due to generalized hyperplasia from lymphoid system. On the other hand, the association between hyperthyroidism and pericarditis, although rare, has been described before. However, aetiology remains unknown. There is only one case reported, describing the association between GD, pericarditis and thymus hyperplasia.
Clinical Case
22 years old, healthy man attended endocrinology department at February 2017 with symptoms of hyperthyroidism. Laboratory evaluation revealed TSH $<$ 0.1 mUI/l (0.45–4.5mUI/l), FT4 3.87 ng/dl (0.79–1.76 ng/dl), anti-thyroid peroxidase antibodies 663 UI/l and anti-thyrotropin receptor antibodies (TRABs) 15.6 UI/l (both positive), and anti-acethylcholine antibodies were negative. After diagnosis of hyperthyroidism, he started therapy with methimazole and propanolol. Five months later, he was admitted at the ER, complaining from fever and pre-cordial pain. The electrocardiogram showed acute pericarditis, although without effusion or suggestive image on the echocardiogram, reason why he performed a TC scan. TC revealed an anterior homogeneous mediastinum mass with 39$\times$20 mm, compatible with thymus hyperplasia. After observation by a cardio-thoracic surgeon, he had indication to maintain GD therapy and imaging re-evaluation in 3 months.
Discussion
This case reveals a coexistence of pericarditis and thymus hyperplasia in a patient with GD. In the presence of mediastinum mass with benign features (homogeneous mass, defined outlines, without calcifications and without invasion of fat or pleura nor cystic component) and if concomitant GD, the hypothesis of thymus hyperplasia should prevail. It is also known the regression of thymus volume during hyperthyroidism treatment. Therefore, in the presence of a benign criteria mediastinum mass, invasive diagnostic exams should be delayed while hyperthyroidism treatment is under way, however, imaging control of the mass should be maintained. Rare cases exist reporting pericarditis as a severe hyperthyroidism complication and therefore, its aetiology remains unexplained. The relation between pericarditis and thymus hyperplasia, also described, may be due to, proximity of the hyperplasic thymus tissue to the moving pericardium, resulting in inflammation. The nature and the comprehension of the coexistence of these three entities described, remains unknown, lacking more similar clinical cases for their understanding.

EP168

Familial dysalbuminaemic hyperthyroxinaemia, a thyroid conundrum

Yuvanaa Subramaniam & Gideon Mlawa
Queen's Hospital, Romford, London, UK.

Background
Familial dysalbuminaemic hyperthyroxinaemia (FDH) is an interesting autosomal dominant condition that is associated with euthyroid hyperthyroxinaemia, whereby patients remain euthyroid but laboratory value will show high free thyroxine (fT_4) level. It is caused by mutations in *ALB* (albumin) gene that increase affinity of albumin for thyroxine (T_4). The usual thyroid assay will show a spuriously high level of thyroxine. This interference could be excluded when the free hormone is extracted from serum and analysed separately. We present a case of a Caucasian lady who was referred to endocrinology team for deranged thyroid function test.
Case
A 50-year-old lady with polycystic ovarian syndrome presents with elevated fT_4, 30.4 pmol/l and triiodothyronine (T_3) level of 5.5 pmol/l with a normal thyroid stimulating hormone (TSH), 4.47 mU/l. Symptoms on presentation include one month history of hot flushes, palpitations and lethargy. Examination findings revealed normal thyroid gland. US thyroid and thyroid uptake scan were unremarkable. Her TSH receptor and thyroid peroxidase antibodies were negative. Her maternal aunt has suffered from thyroid disorders. She was commenced on carbimazole 15 mg once a day. TSH level went up to 6.69 with a T_4 level of 23 and T_3 level of 5.5. She continued to have palpitations and anxiety. Her carbimazole was further increased to 20 mg. Her repeat blood test then showed a TSH and fT_4 of 9.42 and 22. Her case was discussed with Cambridge team who suggested TRH stimulation tests and MR pituitary which were normal. In the meanwhile patient was advised to take alternating dose of carbimazole 20 and 25 mg. Her symptoms remained the same throughout. We sent her blood sample to Cambridge for FDH testing. DELFIA assay in Cambridge showed TSH 3.85 and T_4 19.3. Genetic testing at Cambridge showed a positive mutation in the albumin gene, R242H in keeping with FDH. We stopped carbimazole and commenced propranolol for anxiety. Her repeat results show TSH 3.28 and T_4 26.8 with our laboratory values but normal values with DALFIA analyser.
Conclusion
Euthyroid hyperthyroxinemia is a common condition with several causes. Although rare, FDH should always be one of the differentials. When there is mismatch between the clinical picture and biochemical results, we should establish possible differentials and resist the temptation to treat high free thyroxine as this could potentially lead to unpleasant consequences. It is also important to screen the immediate family members of FDH to avoid unnecessary treatment in similar individuals.

EP169

Two cases of Graves dermopathy: A rare and pathognomonic symptom

Muhammet Cuneyt Bilginer[1], Burcak Polat[1], Berna Ogmen[2], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Department of Endocrinology and Metabolism, Ankara Yildirim Beyazit University School of Medicine, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Ankara Atatürk Education and Research Hospital, Ankara, Turkey.

Introduction
Pretibial myxedema is a rare manifestation of Graves' disease caused by local autoimmune attack of the connective tissue probably mediated by anti TSH receptor autoantibodies (TRab). Its prevalence changes between 0.4 and 5% in Graves 'patients and usually is accompanied by opthalmopathy. The diagnosis requires physical examination and clinical suspicion and in doubtful cases biopsy may be performed.
Case 1
Sixty four years old female patient who has been taking methimazole treatment with the diagnosis of Graves' disease for eight months came to the endocrinology clinic with the complaint of a lesion on the anterior face of lower third of right leg. At the dermatological examination, a plaque with a shiny surface, measuring five centimeters, looking like an orange peel was observed. Upon palpation, it presented a firm and non-depressible consistency. Patient had a history of active moderate orbitopathy and received iv steroid therapy (4.5 gr prednisolone in divided doses). The patient was euthyroid at the time of evaluation with methimazole 2 tb/day and Trab was 1.3 IU/l (at the time of diagnosis it was 135 IU/l). Histopathological incisional biopsy was performed and histopathology revealed accumulation of mucin in reticular dermis leading to separation of collagen bundles. Dermopathy was successfully treated topical corticosteroids.
Case 2
Thirty seven years old female patient admitted to the clinics with symptoms of palpitations, excessive sweating and weight loss. She was diagnosed to have Graves' disease. Radioactive iodine uptake of the thyroid was increased and TRab was three times higher than the upper limit of normal range. She had reddish edema on the distal tibia and was referred to the dermatology clinics. Pretibial myxedema diagnosis was made clinically and the lesion disappeared completely with topical steroids.
Conclusion
Graves' dermopathy is typically asymptomatic, they are rarely pruritic or painful. In severe cases, associated with acropathy, bone pain may result from an underlying periosteal reaction. In patients with high TRab levels and orbitopathy, we should make a proper physical examination and refer the patient to a dermatologist if the patients has a lesion and the diagnosis is equivocal.

BsmI, TaqI, ApaI and FokI VDR polymorphism in women wit and without goiter

Roman Kołodziejczak[1], Alicja Łuczyńska-Kołodziejczak[2], Anhelli Syrenicz[3] & Monika Koziołek[3]
[1]Regional Hospital Gorzow Wielkopolski, Internal Medicine and Endocrinology, Gorzów Wielkopolski, Poland; [2]Regional Hospital Gorzów Wielkopolski, Internal Medicine and Endocrinology, Gorzów Wielkopolski, Poland; [3]Pomeranian Medical University, Szczecin, Poland.

Objective
Vitamin D deficiency is common in polish population and seem to play role in pathogenesis of some diseases. We looked for correlation between polymorphisms BsmI, TaqI, ApaI and FokI of vitamin D receptor and vitamin D influence on goiter development.
Methods
One hundred and fifty two women-96 with and 56 without nontoxic goiter were examined in 2014. In US examination we calculated the volume of the thyroid gland and volume of nodules. Blood samples for 25-(OH) D total and genetic research were taken. We made statistical analysis of correlation between volume of the thyroid gland, volume of the nodules and levels of vitamin D in groups of various polymorphisms.
Results
Ninety-six women with goiter size from 5.67 to 68.85 ml– mean 19.7 ml, median 15.6 ml, the total nodules volume varied from 0.1 to 39 ml mean 4.59 ml, median 0.94 ml and the control group of 50 women with thyroid volume in normal range from 5.1 to 19.9 mean 11.2, median 11.2 ml. The 25(OH)total levels varied in control group from 5.3 to 31.8 ng/ml, mean – 14.4, median 12.95, and in goiter group from 4.7 to 39.8 ng/ml, mean 15.00, median 13.3 ng/ml. Only 14% in control and 22% in goiter group had vitamin level over 20 ng/ml. We found no correlation between vitamin D level and volume of thyroid gland in goiter group and no correlation between vitamin D level and summary volume of the thyroid nodules. We analyzed all alleles variants of VDR polymorphisms in groups with and without goiter in correlation with vitamin D level. We did not found statistical correlation between VDR polymorphisms BsmI, TaqI, ApaI and FokI using x^2 test with goiter size or nodules size.
Discussion
VDR polymorphism may have role on impact of vitamin D deficiency on osteoporosis, osteomalacia development but we did not find change of action of vitamin D on goiter development in any type of studied polymorphism - BsmI, TaqI, ApaI and FokI. Common Vitamin D deficiency in polish population have no significant influence on goiter development independent from VDR BsmI, TaqI, ApaI and FokI polymorphism

An unusual presentation of Graves' Ophtalmopathy: About 3 cases

Zineb Boulbaroud[1,2], Siham El Aziz[1,2] & Asma Chadli[1,2]
[1]Endocrinology, Diabetology and Metabolic Diseases, Department Ibn Rochd, University Hospital of Casablanca, Casablanca, Morocco; [2]Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy; University Hassan II- Casablanca-Morocco, Casablanca, Morocco.

Introduction
Dysthyroid ophthalmopathy corresponds to eye damage encountered in various thyroid diseases. It is seen mainly in Graves' disease, and may develop any time in the course of the disease evolution. Clinical presentations of Gravesâ€™

ophtalmopathy (GO) are extremely heterogeneous. GO may be sight threatening in 3–5% of cases, and then represent an emergency requiring immediate treatment. We report three cases illustrating a particularÂ Â Â presentation of these orbitopathies.
Observation 1
A 61 years old man, followed for 1 year for Graves' disease (GD) with Carbimazole 10 mg / day, presents for 4 months bilateral exophtalmopathy with lid retraction predominant at the left eye, associated with retroorbital pain. Clinical examination found a homogeneous goiter grade 1. Visual acuity was to hand movements on the right and light perception on the left. He had an important chemosis, Mourits score at 7/10 for left and 5/10 right. The patient had corneal abscess having evolved under intravenous antibiotics. For orbitopathy, our patient received three consecutive boluses of methylprednisolone 1 gÂ daily , then 6 weekly bolus of 500 mgÂ Â then 250 mgÂ Â for 6 more weeks with a good evolution.
Observation 2
A 41 years old man, who had a total thyroidectomy 1 month ago for GD, with hormonal replacement. He presents since 5 months an exophthalmopathy with inocclusion of the left eye. He had an opaque cornea with significant chemosis, quoted 7/10 according to Mourits score. Patient wasÂ receivedÂ intravenous corticosteroids: 3 daily bolus of methylprednisoloneÂ 1 g / day, then 500 mg / week for 6 weeks and 250 mg /week for 6 weeks. The outcome was favorable, with persistent corneal opacity.
Observation 3
A 70 years old woman, followed for 3 years for multinodular goiter which progress like GD. She was treated by Carbimazole. She presented for 1 month a bilateral exophthalmopathy with eyelid and conjunctival edema. She had a grade 2 goiter with two nodules, respectively measuring 1 to 2 cm. Visual acuity was reduced with chemosis and conjunctival hyperemia. Our patient received 12 bolus ofÂ injectable steroids: 500 mg /week for 6 weeksÂ Â then 250 mg/ week with good evolution.
Conclusion
GO is a complex inflammatory disorder that is better managed by a multi-disciplinary team.Â Â An appropriate assessment of both severity and activity of the disease warrants an adequate treatment. Intravenous glucocorticoids remain the treatment of choice for active moderate to severe disease.

BRCA1 mutations and polyporphisms in women with and without goiter

Roman Kołodziejczak[1], Alicja Łuczyńska-Kołodziejczak[1], Anhelli Syrenicz[2] & Monika Koziołek[2]
[1]Regional Hospital Gorzow Wielkopolski, Internal Medicine and Endocrinology, Gorzów Wielkopolski, Poland; [2]Pomeranian Medical University, Szczecin, Poland.

Objective
There are many suggestions of predispositions to goiter in women with benign and malignant masthopaty, we looked for BRCA1 mutations in women wit and without goiter
Methods
One hundred and fifty two women-96 with and 56 without nontoxic goiter were examined in 2014. In US examination we calculated the volume of the thyroid gland and volume of nodules. Blood samples for BRCA1 were taken, ex05 - p.Cys61Gly; ex 11 polymorphisms K1183R, mutations: c.3819del5, c.3875del4, c.3986delT, c.4154delA; ex20 mutations: 5382insC, 5370C>T
Results
Ninety-six women with goiter size from 5.67 to 68.85 ml– mean 19.7 ml, median 15.6 ml, the total nodules volume varied from 0.1 to 39 ml mean 4.59 ml, median 0.94 ml and the control group of 50 women with thyroid volume in normal range from 5.1 to 19.9 mean 11.2, median 11.2 ml. The 25(OH)total levels varied in control group from 5.3 to 31.8 ng/ml, mean – 14.4, median 12.95, and in goiter group from 4.7 to 39.8 ng/ml, mean 15.00, median 13.3 ng/ml. Only 14% in control and 22% in goiter group had vitamin level over 20 ng/ml. We found no one pathogenic mutation in any group, and polymophisms on ex 11 were represented in similar number in goiter and non goiter group.
Discussion
Goiter is very common condition in polish female population over 40, rare BRCA1 mutation were not found in the research group and common polymorphisms do nod differ groups with and without goiter.
Conclusion
We need probably bigger group do make final conclusion, but on the basis if our research there is no increased incidence of BRCA1 mutations and polymorphism in goiter women.

EP173

Simultaneous occurrence of papillary and medullar thyroid carcinoma report of a case

Bouizammarne Ilham, El Mghari Ghizlane & El Ansari Nawal
Department of Endocrinology, Diabetes and Metabolic Diseases, Marrakesh, Morocco.

Introduction
Mixed thyroid carcinoma is an entity that corresponds to tumors with a double component: one of the vesicular type (Tg +) and the other of the medullary type (CT +). We report the occurrence of papillary and medullary thyroid carcinoma in a 44-year-old patient. This coexistence is considered rare.
Case
A 44-year-old patient underwent a thyroidectomy due to a goiter, histopathological examination identified multifocal papillary carcinoma, multiple colloidal nodules, with metastases in supra isthmic and left supraclavicular lymph nodes. A complement by iratherapy was performed, with bilateral cervical lymph node dissection, which revealed: bilateral *jugular* chain metastases, three metastases in the recurrent chain with capsule invasion. The *mediastinal lymph node dissection showed* seven metastases with capsule invasion, immunohistochemistry confirmed the presence of calcitonin. For the extension assessment: Postoperative calcitonin = 228 ng / l. CT scan revealed: *empty thyroid* bed, bilateral submandibular nodes, intraparenchymal and subpleural lung nodules, *bilateral axillary lymphadenopathy*, *Hepatic steatosis* and an osteocondensation lesion at the inferior angle of the left scapula. Bone scintigraphy: no sign of secondary bone localization.
Discussion
The Simultaneous occurrence of medullary carcinoma with a differentiated carcinoma of the thyroid, although exceptional, should always be considered as it could change the therapeutic approach and the prognostic evaluation.

EP174

Graves' ophthalmopathy presenting with hypothyroidism

Panagiotis Athanassiou[1], Eleni Pantazi[2], Lambros Athanassiou[3], Eleni Xanthakou[4], Panagiotis Spyropoulos[5] & Ifigenia Kostoglou-Athanassiou[6]
[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece; [2]Department of Endocrinology, Alexandra Hospital, Athens, Greece; [3]1st Department of Medicine, Asclepeion Hospital, Voula, Athens, Greece; [4]Endocrinologist, Sparta, Greece; [5]Endocrinologist, Athens, Greece; [6]Department of Endocrinology, Asclepeion Hospital, Voula, Athens, Greece.

Introduction
Graves' disease is a multi-system autoimmune disease characterized by hyperthyroidism, ophthalmopathy and pretibial myxedema. The disease presents with hyperthyroidism or more rarely with ophthalmopathy. It runs a various course and many times during its natural course permanent hypothyroidism may ensue.
Aim
The aim was to describe the case of a patient with Graves' disease presenting with ophthalmopathy and subclinical hypothyroidism.
Case description
A patient, female, aged 59 years, presented with proptosis of the right eye and other symptoms such as a sense of foreign body within the eyes. A CT scan of the orbits was performed which showed increased volume of the extraocular muscles of both eyes, which was prominent in the right eye. A laboratory evaluation showed TSH receptor antibodies marginally positive 1.7 IU/l (normal values <1.5 IU/l), positive microsomal and antithyroglobulin antibodies, TSH 4.9 mIU/l and FT_4 normal. Methylprednisolone was administered 500 mg/wk iv for a period of 6 weeks followed by tapering of prednisolone orally. The proptosis of the right eye improved. A new laboratory evaluation showed TSH 5.7 mIU/l. Thyroxine was administered at a dose of 75 μg daily. The patient is stable and euthyroid, TSH being 2.1 mIU/l on thyroxine and low dose prednisolone.
Conclusions
The case of a patient with Graves' disease is described which presented with ophthalmopathy and subclinical hypothyroidism. In Graves' disease permanent hypothyroidism may develop over the course of the disease. However, presentation of the disease with subclinical hypothyroidism is very rare and underlines the relationship, as far as pathogenesis and pathophysiology is concerned, between autoimmune Hashimoto thyroiditis which causes hypothyroidism and Graves' disease, a multi-system autoimmune disease characterized by multiple organ system involvement and hyperthyroidism.

Cretinism and language delay are rare manifestations of central hypothyroidism: 2 cases report

Vinicius Beldi, Tomás Marson, Aiana Araújo, Thais Siena, Mariana de Paula, Patrícia Atique, Rodrigo Custódio, Lea Maciel, Ivan Ferraz, Luiz Del Ciampo & Carlos Martinelli Jr
Ribeirão Preto Medical School, Ribeirão Preto, Brazil.

Cretinism and neurological impairment are related to primary hypothyroidism (PHT) while children with central hypothyroidism (CHT) are usually diagnosed during the investigation process for short stature.
Objective
To describe two children with unusual presentation of CHT.
Case 1
Baby girl, born after 38 weeks of gestation, weighing 3000 g, and measuring 49.5 cm long was admitted when 3 months old. The parents reported stunted neurological development and difficulty in gaining weight. Neonatal screening: TSH < 0.1 mU/ml. A typical cretinism face was observed, with depressed nasal base, pig nose and infiltrated eyelids associated with umbilical hernia, reduced muscle tone, short length (< P10) and low weight (< P10). Biochemical analysis: Free T_4 < 0.1 ng/ml, Total T_4 = 0.9 ng/ml, TSH < 0.1 mU/ml and IGF-I: undetectable. Following thyroxin replacement, there was an improvement in the neurological development, height velocity and weight gain. IGF-I concentration increased to 70 ng/ml(P50). At the age 4.5 years, she was readmitted to the clinic after the treatment had been discontinued for 1.5 year. Her features were typical of severe cretinism with slow movements, difficulty in walking and height velocity close to 0 cm/yr and serum IGF-I level: undetectable. A low thyroxin treatment (1.5 ug/Kg per day) was initiated with full recovery of the cretinism features and neurological impairment.
Case 2
Baby girl, born after 38 weeks of twin pregnancy, weighing 2680 g and measuring 47 cm long. Neonatal screening: TSH = 0.4 mIU/ml. She was admitted to the clinic when 1.7 years referring language delay. Initial investigation: TSH = 1.3 mIU/ml and total T_4 = 5.4 mg/dl. Significant improvement in language development occurred after thyroxin replacement. Serum TSH and total T_4 during treatment were 0.6 mIU/ml and 7.6 mg/dl and change to 1.5 mUI/ml and 5.7 mg/dl, respectively thyroxin was discontinued for investigation purposes. Molecular analysis of the deceased twin brother revealed c.826G > A p.G276R mutation of *MCT8* in the X chromosome (Xq13.2), in heterozygosis. *MCT8* encodes the monocarboxylate transporter-8 (MCT8), responsible for the transmembrane transport of T_3 into the neuron.
Conclusion
Although rare, neurological and developmental related symptoms can be the leading finding to the diagnosis of CHT. Depending on its aetiology, CHT can be associated with cretinism and extremely low TSH and thyroxin levels. Thyroxin determination should be considered in cases of undetectable/extremely low TSH in order to prevent adverse outcomes. Regarding the *MCT8* mutation, the severity of clinical findings is variable and changes in neurodevelopment and mental retardation are more frequently observed in male patients.

EP176

Strumectomy in nodular goiter - does it make sense? Reflections after 22 years of observation of one patient

Krzysztof Marczewski[1,2], Marta Węgrzyn-Bęk[1], Dorota Boniek-Poprawa[1] & Marek Maciejewski[1]
[1]Pope John Paul II Regional Hospital, Zamość, Poland; [2]Faculty of Medical Sciences WSEI Lublin University of Economics, Lublin, Poland.

Introduction
Although the thyroidectomy is one of the most frequently performed operations in endocrine surgery, indications for this procedure as well as recommendations for further observation are still controversial. Therefore we would like to present what is happen with our patient during 22 years after thyroid surgery.
Case report
In 1995, at the 46-year-old woman at that time, a subtotal strumectomy was performed due to the nodular goiter. Postoperative histopathological examination revealed *struma colloides macro et microfollicularis* and *adenoma folliculare.* During the next 12 years, a thin-needle aspiration biopsy aimed at focal lesions with mixed echogenicity of the thyroid gland was performed 4 times. The last one in January 2012, without malignant features. But in 2010, the Sjoegren syndrome was diagnosed, treated with prednisone and methotrexate, and nodular changes in both lungs. 2012 she suffer under heart attack. 2014 in view of the enlargement of nodules in the lungs, upper right lobectomy was performed. The histopatological result: metastases from well-differentiated thyroid cancer, maybe follicular TTF-1 (+) TGB (+). Unfortunately preparations from 1994 were no longer available. The total strumectomy was performed but in the histopathological examination only sings of struma nodosa colloides were found. Further treatment with J131 was complicated by anemia, leukopania and thrombocytopenia.
Discussion
We do not know where thyroid cancer cells came from in the lungs. Probably from an outbreak existing in the removed thyroid, and not detected during the post-operative examination. If so, we do not know why the symptoms appeared only after 11 years, or whether the treatment of Sjoegren's syndrome accelerated the growth of cancer.
Conclusion
The lack of malignant traits in the histopathological material originating from the strumectomy does not give confidence and it certainly does not give a guarantee of successful long-term results.

EP177

Simultaneous medullary and papillary thyroid cancer in Graves-Basedow disease. Two case reports

Roxana Dumitriu, Eugenia Petrova, Andra Buruiana, Mircea Ghemigian & Adina Ghemigian
National Institute of Endocrinology 'C. I. Parhon', Bucharest, Romania.

Introduction
The occurence of simultaneous medullary and papillary thyroid cancer is very rare. There were only 17 case reports in the literature, and fewer with Graves-Basedow disease associated. A retrospective study conducted at the National Institute of Endocrinology 'C. I. Parhon' showed that 7,6%of the patients who underwent total thyroidectomy for Graves-Basedow disease had thyroid cancer. Recent studies show that specific cellular pathways are determined by the binding of anti-TSH receptor antibodies stimulating cellular growth and invasion and angiogenesis.
Case reports
We present two cases diagnosed with Graves-Basedow disease with total thyroidectomy and a histopathological report that showed the simultaneous presence of a papillary and medullary thyroid cancer.
Conclusions
Graves-Basedow disease can be associated with differentiated thyroid cancer and medullary cancer in the same patient.

DOI: 10.1530/endoabs.56.EP177

EP178

A rare case of hurthle cell adenoma and parathyroid adenoma

Fulden Sarac[1], Sumru Savas[1] & Pelin Tutuncuoglu[2]
[1]Department of Geriatric Medicine, Ege University Medical Faculty, İzmir, Turkey; [2]Department of Endocrinology and Metabolism, Atatürk Training and Research Hospital, İzmir, Turkey.

Introduction
Hurthle cell of adenoma (HCA)of thyroid gland is rare neoplasms of the thyroid. They have been found in association with various benign thyroid conditions like Hashimoto's thyroiditis, hyperthyroidism, nodular goiter, and thyroid neoplasms; where they often represent oncocytic metaplasia. Oncocytic cells are also present in normal parathyroid tissue. Oncocytic parathyroid adenomas, predominantly (more than 70%) or exclusively composed of oncocytic cells are rare (4.4 to 8.4%). We report a patient with an extremely unusual clinical presentation of Hürthle cell adenoma in thyroid and parathyroid adenoma.
Case presentation
We presented a case that of a 50-year-old woman with neck swelling. There were no associated pain or pressure symptoms. Ultrasonography showed a nodule 2 cm diameter in left and showed a nodule 2.5 cm in right thyroid lobewith central and peripheral blood supply. Fine-needle aspiration revealed cellular smears containing monotonous oncocytic cells arranged in monolayered sheets and pseudopapillary structures. No abnormality was detected on the laboratory. Thyroidectomy was done and microscopic examination revealed a HCA of the left thyroidnodule and oncocytic parathyroid adenoma in right thyroid lobe. The patient was discharged on thyroid replacement therapy and has remained healthy after more than 36 months of follow-up.

DOI: 10.1530/endoabs.56.EP178

EP179

Prognostic factors affecting neck lymphnode recurrence and distant metastasis in papillary thyroid cancer: results of a study in 40 patients

Georgios Papadakis[1], Eleni Triantafillou[2], Fotini Kanouta[2], Aspasia Drosou[2], Styliani Kalaitzidou[2], Aggeliki Sapera[2], Dimitra Tampouratzi[2], Michalis Kotis[2], Taxiarchis Kyrimis[2], Aggeliki Aravantinou[2], Chrysa Karavasili[2], Anna Drakopoulou[2], Eirini Veniou[2], Victoria Kaltzidou[2] & Athanasia Tertipi[2]
[1]STEPS Stoffwechselzentrum, Biel/Bienne, Switzerland; [2]Endocrinology Department, Metaxa Anticancer Hospital, Piraeus, Greece.

Objectives
Overall, papillary and follicular carcinoma is associated with a 30-year cancer-related death rate of 6 and 15%, respectively. Poorer outcomes have been associated with older age, male gender, tumor size, grade and extrathyroidal extension. We investigated the clinical and laboratory characteristics of 40 patients who presented recurrence of thyroid disease.
Patients data
- 40 Patients (21 Females and 19 males) with papillary thyroid cancer and recurrence of the disease.
- Mean age ± s.d. of last follow-up: 54.68 ± 16.24 years.
- Mean age ± s.d. of surgery 47.57 ± 15.57 years.
- Mean years ± s.d. after surgery of lymph nodes meta: 1.55 ± 2.52 years.
- All with papillary thyroid carcinoma, 15 (62.5%) with aggressive type and 25 (37.5%) with no aggressive type.

Results
TG and ANTI-TG measurement in different time points (Mean value ± s.d.):
- TG in first postoperative control with stimulation: 20.54 ± 26.65 ng/ml and 20% of patients had positive anti-TG.
- TG measure at diagnosis of lymph nodes metastasis: 52.95 ± 137.40 ng/ml and 17.5% of patients had positive anti-TG.
- TG measured at last follow-up control: under suppression therapy: 3.59 ± 12.20 ng/ml. And Tg under stimulation: 6.57 ± 14.36 ng/ml. 17.5% of patients had positive anti-TG in the last follow-up control.

Total I-131 Dosis: 252.75 ± 169.44 mCi. At the first post-therapy WBS all the patients had uptake only in the neck, whereas at the last WBS (post-therapy or diagnostic) 11 patients (27.5%) had negative uptake. When examining the lymph nodes with U/S, nine patients (22.5%) had reduction of the maximal diameter, 23 patients (57.5%) had no change in the maximal diameter and eight patients (20%) had an increase in the maximal diameter of the suspicious lymph node. Two patients (5%) presented with a distant metastasis. Over the time of follow-up, six patients (15%) increased, and 26 patients (65%) reduced the TG levels. Furthermore, over the time of follow-up three patients (7.5%) increased, and three patients (15%) decreased the anti-TG levels.
Conclusions
The recurrence of the disease can be presented clinically with symptoms like dysphagia, dyspnea, voice changement or with a palpable mass in the neck. The biochemical recurrence concerns the increase in Tg of anti-Tg levels and the anatomical recurrence refers to disease detected in Ultrasound, Whole Body Scan, CT, MRI or PET/CT. With all these tests the recurrence can be detected before it is clinically evident.

The association of breast cancer and thyroid cancer: what relationship? (Preliminary results)

Fatima Zahra Iftahy[1,2,3], Siham El Aziz[1,2,3] & Asma Chadli[1,2,3]
[1]Endocrinology, Diabetology and Metabolic Diseases, Department Ibn Rochd, University Hospital of Casablanca, Casablanca, Morocco; [2]Neurosciences and Mental Health Laboratory, Casablanca, Morocco; [3]Faculty of Medicine and Pharmacy, University Hassan II, Casablanca, Morocco.

Background
Several studies have demonstrated the relationship between breast cancer and thyroid cancer by the presence of common genetic determinants as well as hormonal factors. The aim of the study was to define the prevalence of breast cancer among patients followed for thyroid carcinoma and to determine the factors that favor this association.
Materials and methods
A Cross-sectional study was conducted in Endocrinology and Diabetology department of IBN Rochd University Hospital of Casablanca, including 50 patients followed for thyroid carcinoma between 1986 and 2017 among all the differentiated carcinomas of the thyroid (614 patients) and presenting breast cancer. Statistical analysis performed by the software SPSS.16
Results
Prevalence of patients presenting breast cancer and thyroid cancer was 8.1% with female predominance. The mean age was 56 (35–72) years. Family history of neoplasia was found in 60% of cases. Breast cancer preceded the discovery of thyroid cancer in half of the cases with a delay of 5.8 years (6 months and 20 years). Iratherapy was performed in all patients. External radiotherapy was realized in 47% of cases for the treatment of breast cancer. Papillary carcinoma was the predominant histological type (93%). Predictor factors of this association were female patients who had the first neoplasia at a young age (<45 years), family history of neoplasia and prior external radiotherapy.
Conclusion
While waiting for confirmation of these preliminary results, several authors recommend greater vigilance regarding early detection of thyroid cancer in patients treated for breast cancer.

EP181

Association thyroid carcinoma and lung adenocarcinoma

Lygie Kibhat[1,2], Siham El aziz[1,2], Asmaa Mjebbar[1,2] & Asma Chadli[1,2]
[1]Department of Endocrinology, Diabetology and Metabolic Diseases, Ibn Rochd, University Hospital of Casablanca, Casablanca, Morocco; [2]Neurosciences and Mental Health, Laboratory Faculty of Medicine and Pharmacy, University Hassan II-, Casablanca, Morocco.

Introduction
Pulmonary adenocarcinoma is an epithelial tumor with differentiation glandular whose frequency increases sharply. The association with cancer thyroid is rare. In this context, we report a medical observation.
Observation
A 58-year-old patient with no history of smoking was admitted to one of our departments. Thyroidectomy 4 years ago, the pathological study a poorly differentiated carcinoma of 4.5 cm, class PT2 TNM. Our patient had benefited from an iodine 131 therapy course with a complete CT scan of body showing a white isotopic map. Thyroid suppressing the dose with bad adherence. She experienced exercise dyspnea and pain thoracic for 3 years, aggravated by a respiratory distress. A scanner showed a left lower lobe of 28 mm and a mass nodular of the same lobe of 20! 32 mm.
Objective bronchoscopy bronchitis chronic without suspicious cells identifiable on the biopsy. A lobectomy left was found, which revealed a primary pulmonary glandular (positivity TTF1 and CK7).
Conclusion
This observation shows the coexistence of multiple malignancies in a patient, whose diagnosis and treatment may be delayed, which aggravates the prognosis.

DOI: 10.1530/endoabs.56.EP181

EP182

The concept of idiopathic myxedema: The relationships between hypothyroidism and ATPO evolutive level

Bogdan Oprisan[1], Dan Peretianu[2], Mihaela Ratcu[2], Payman Gharibafshar[2], Dana Cristina Staicu[2] & Mara Carsote[3]
[1]Department of Biophysics, University of Medicine and Pharmacy 'Gr.T.Popa', Iassi, Romania; [2]Medical Center Povernei, Bucharest, Romania; [3]Institue of Endocrinology, Bucharest, Romania.

Background
Hashimoto thyroiditis (HT) is defined as thyroid chronic inflammation due to high level antithyroperoxydase antoantibodies (ATPO) and/or antithyroglobuline autoantibodies (ATG) and their destructive process on thyroid cell. The diagnostic uses specific and very characteristic ultrasound features. What diagnosis has to have those patients with ultrasound features of HT, who are hypothyroid, but with normal levels of ATPOs *and* normal levels of ATGs ?
Method
i) ATPO and ATG levels were analyzed in accreditated Bucharest laboratories. ii) We considered HT those patients with high ATPO/ATG levels, cut off over 34 ui/ml. iii) FT_4 and TSH were considered for functional diagnostic. iv) Thyroid ultrasound was done with a 7.5–10 MHz probe. v) Idiopathic means: I do not know what it is, after eliminating all I know !
Results
A. Patients: 3962. **B.** Based on ATPO/ATG level we considered: i) HT: 1753; ii) thyroiditis with only high ATG (ATPO normal): 205; iii) Other thyroid diseases

(mostly nodules): 1878 - ATPO/ATG normal, 1729 euthyroid, 113 hyperthyroid, no TRAB, 38 identified cause of induced hypothyroidism. iv) *Special patients with hypothyroidism with normal ATPO and normal ATG, without any intervention on thyroid (thyroidectomy, 131-I) or neck area (radiation for lymphomas) and ultrasound features indicating inflammation*: 205.
Discussion
ATPO evolution in HT is mostly undulatorious (Ratcu, this congress). In some patient, ATPO decreased under the cut off limit, if they had no thyroid, through thyroid interventions, and thyroid atrophy. These patients were hypothyroid. It is possible in evolution when the antigen (thyroid) disappeared, the autoantibodies disappeared, too ! Like in special patients described in point 4 ?
Conclusions
1. Those patients who are hypothyroid, without a known and identifiable causes of hypothyroidism, who present obvious ultrasound sign of HT, but in who ATPO and ATG is in normal limits, have to be considered as idiopathic myxedema.

EP183

The frequency, specification of diseases of thyroid gland at children and teenagers according to data for 5 years and the kinds of surgical treatment"

Yulduz Urmanova[1,2], Shakhnoza Azimova[2], Nazira Rokhsieva[1], Firuza Khodjaeva[1], Khurshida Nasirova[1], Kim Min Dji[1], Ortikali Tursunkulov[1] & Edvard Akhmadiev[1]
[1]Tashkent Paediatric Medical Institute, Tashkent, Uzbekistan; [2]Center of Endocrinology, Tashkent, Uzbekistan.

The aim
To study the frequency, specification of diseases of thyroid gland at children and teenagers according to data for 5 years and the kinds of surgical treatment
Material and methods of investigation
Under supervision of the employees of the department of children's endocrinology the Center of Endocrinology of PH of RUz during from 2012 to 2016 years was hospitalized 213 children and teenagers with various diseases of thyroid gland, from them of the boys was - 67 (31.4%), girls -146 (68.5%). 20 sound children and the teenagers of the appropriate age made the group of the control.
Results
The most of patients were in teenager age, namely from 11 to 17 years - 147 patients (69.1%), were at the same time mostly sick girl - 100 from 147 (68.0%). Greater part of patients on turned was made by patients with congenital hypothyroidism- are 94 cases (44.1%), on the second place - the mixed goiter is 35 supervisions (16.4%), on the third - a diffusely-toxic goiter is 30 patients (14.0%), and also diffuse goiter of 1-2 degree - 19 (8.9%), autoimmune thyroiditis - 14 (6.5%), multinodular goiter - 15 (7.0%), sharp festering strumitis - 2 (0.9%), papilliferous adenocarcinoma - 2 (1.0%). To the patients the different spectrum of surgical help was executed, a total thyroidectomy - 14 (34%) supervisions, hemistrumectomy was most often executed here - 10 (24%) cases, large resection of lobuli - 6 (14.5%), etc.
Conclusions
The results received by us confirm need of further long observation and treatment of patients.

DOI: 10.1530/endoabs.56.EP183

EP184

Role of thyroid dysfunction in patients with menstrual disorders

Khurshida Nasirova & Aziza Amilova
Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan.

Menstrual disorders pose a huge burden on gynecology OPD, accounting for approximately 20% of attendance Thyroid hormones play an important role in reproductive function by direct effects on ovaries and indirectly influencing on sex hormone-binding globulin. Thyroid impairment can cause menstrual irregularities and infertility. In India, thyroid disorders are most common endocrine diseases. Thyroid disorders manifestation increases with age, and approximately 26% of premenopausal and menopausal women have thyroid pathology. Thyroid disorders are more common in women than in men and older people suffer more often than younger age groups. Hypothyroidism is linked to a large range of reproductive disorders: abnormal sexual development, menstrual irregularities, and infertility. The impact of hypothyroidism on the menstrual cycle has been identified since the 1950s and it leads to changes in cycle length and blood flow. Subclinical hypothyroidism has been associated with occult menorrhagia (mild disturbances in menstrual volume and duration) before becoming symptomatic. Subclinical hypothyroidism occurs in 9.5% of women. Hyperthyroidism manifesting before puberty delays the menarche. In women of fertile age, oligomenorrhea and amenorrhea are the commonest abnormalities associated with hyperthyroidism. These irregularities sometimes precede thyroid dysfunction. Nowadays subclinical hyper- and hypothyroidism can be diagnosed very early, while a few decades ago they would have passed undiagnosed. Timely detection of thyroid pathology in patients with menstrual disorders and management can prevent surgeries like curettage and hysterectomy. Thyroid autoimmunity is reported to be associated with various kinds of thyroid dysfunction. Number of foreign studies show association of thyroid dysfunction and menstrual disorders, but there are not many Indian studies in this regard.
Conclusions
There is a strong correlation between thyroid dysfunction and menstrual disorders. Timely diagnosis and treatment of thyroid pathology in patients with menstrual dysfunction leads to settlement of the menstrual irregularities, and avoidance of unnecessary interventions such as hormonal therapy and surgery. Menorrhagia followed by hypo/oligomenorrhea and polymenorrhea are the most commonly observed menstrual abnormalities. Since thyroid dysfunction is an important treatable cause of menstrual disorder, thyroid status examination should be done in patients with menstrual disorders. Prevalence of subclinical hypothyroidism in patients with menstrual dysfunctions emphasizes the need to detecting the hypothyroidism at this stage, so that treatment can be initiated on time. Anti-TPO antibody test is an expensive routine test recommended to patients with menstrual disorders. However, prospective studies are required to analyze the cost effectiveness of anti-TPO antibody testing and its possible benefits to treatment.

It is a link between gallstone disease and pathology of thyroid gland

Marta Węgrzyn-Bąk[1], Krzysztof Marczewski[1,2] & Marek Maciejewski[1]
[1]Pope John Paul II Regional Hospital, Zamość, Poland; [2]Faculty of Medical Science, University of Economy and Innovations, Lublin, Poland.

Introduction
Gallstone disease is one of most common in the Europe with prevalence till 15%. The basic mechanism of stone formation is precipitation of cholesterol crystals in the supersaturated bile. The relationship between thyroid function and the content of cholesterol has been known for quite a long time, as well as the work confirming the relationship between hypothyroidism and cholelithiasis. Recently, in mice it has been shown that both hypothyroidism and hyperthyroidism promote the formation of gallstones, although in other mechanisms. Cholecystectomy, despite the changing range of indications for its implementation remains an important method of treatment of the consequences of cholelithiasis. That is why we would like to present our observation in which the starting point was cholecystectomy.
Aim
The aim of our study was the prospective observation of patient after cholecystectomy where the place of observation was an endocrinology out-patients clinic
Results
In years 2002–2008 in our hospital 1125 cholecystectomy was performed (1025 laparoscopic). In the same years, 127 (11%) of these patients were treated our endocrine outpatients clinics due to thyroid diseases. Among the patients treated for thyroid diseases, the most numerous were diagnosed as nontoxic goiter (E04 = 49%), followed by hyperthyroidism (E05 = 19%) and hypothyroidism (E03 = 17%)
Conclusion
Of course, our observation from one hospital has many limitations. It cannot be ruled out that the effect on the frequency of visits to the outpatients clinic had already existing contact with the health service and / or the requirements for the assessment of the thyroid status before the procedure set by surgeons.However, a fairly high incidence of thyroid problems in patients undergoing cholecystectomies prior to surgery and in the following years would speak for a link between thyroid diseases and cholelithiasis.

Graves' disease in a patient with myasthenia gravis: a case report

Imen Sakka, Ibtissem Oueslati, Melika Chihaoui, Meriem Yazidi, Fatma Chaker, Ons Rejeb & Hedia Slimane
Department of Endocrinology, La Rabta Hospital, Tunis, Tunisia.

Introduction
Myasthenia gravis is an autoimmune neuromuscular disease characterized by the presence of anti-acetylcholine receptor antibodies. It can be isolated or associated with other auto-immune conditions. Graves' disease is an autoimmune disorder typically characterized by the presence of circulating autoantibodies that tie to and stimulate the thyroid hormone receptor. Coexisting myasthenia gravis and Graves' disease is a rare but well recognized condition. The physiopathology of this association has not been clearly established. We report the case of a woman with known generalized myasthenia gravis who developed Graves' disease 15 years after.
Observation
A 43-year-old woman was referred to our department for thyrotoxicosis. Her past medical history was remarkable for generalized myasthenia gravis. In fact, at the age of 28 years, the patient presented with a fluctuating muscle weakness, difficulty swallowing, double vision and fluctuating ptosis. The diagnosis of myasthenia gravis was established. Then, the patient had a total thymectomy and treated with pyridostigmine. On physical examination, she had homogenous goiter and bilateral exophthalmos. Thyroid laboratory investigation revealed overt hyperthyroidism. The diagnosis of Graves' disease was established and the patient was initially treated with antithyroid drugs. Then, she was referred to the department of Nuclear Medicine for a radioactive iodine therapy.
Conclusion
The occurrence of Graves' disease and myasthenia gravis in the same patient indicates a genetic predisposition to autoimmune diseases. Muscle weakness may be the first symptom of thyrotoxicosis as well as myasthenia gravis, so a distinction between the two autoimmune diseases can be difficult in some situations. The myasthenic syndrome may precede hyperthyroidism as was the case of our patient or may appear sometimes during the treatment of hyperthyroidism. Propranolol treatment is contraindicated and radical treatment of hyperthyroidism is required.

Case report and literature review. surgical management of hyperthyroidism in pregnancy

Alin Abreu Lomba[1], Melanie Santrich[2], Claudia Bastidas[3], Gustavo Perdomo[3], rodrigo cifuentes[3] & Diana Milena Martinez[3]
[1]Centro Medico Imbanaco, Cali, Colombia; [2]Universidad Javeriana, Cali, Colombia; [3]Universidad Libre, Cali, Colombia.

Hyperthyroidism during pregnancy is determined by decreased thyroid stimulating hormone (TSH), and high levels of thyroid hormones: thyroxine (T_4), triiodothyronine (T_3), being a complication in 1–2 women per 1,000 pregnancies, and occurs first as Graves' disease in 0.1–1% of pregnancies. There are specific reference ranges of THS and free T_4 for each population and each trimester. For the medical management in the first trimester it is recommended propylthiouracil, and for second and third trimester is methimazole. The surgical management is recommended in the second trimester in cases of intolerance to the medication, such as allergies or agranulocytosis. Next, we describe three cases of pregnant patients who undergo surgical management with total thyroidectomy, because of intolerance to medication during second trimester, previous management with lugol. The three patients received levothyroxine post-surgical. Literature review is made.
Case 1
Age 28, gestational age = 16.2 weeks. Diagnosis before pregnancy. TSH = 0.00 uiu/ml, free T_4 = 7.77 ng/dl. At physical examination with tachycardia, hypertension, trembling limbs and aortic heart murmur. Thyroid US with heterogeneous echogenicity, echocardiogram with mild pulmonary hypertension. Initial medical treatment with methimazole 30 mg/day, lugol 6 drops every 8 hours for 10 days. Total thyroidectomy carried out without any complications. TSH = 0.007, free T_4 = 2.95 ng/dl (post-surgical). Pregnancy termination; weight 3.100 grams and size 48 cm.
Case 2
Age 26 years, gestational age = 16.3 weeks. Diagnosis before pregnancy. TSH = 0.005 uiu/ml, free T_4 = 5,7 ng/dl. At physical examination with tachycardia, hypertension, trembling limbs. Thyroid US with diffuse goiter. Initial medical treatment with Methimazole 40 mg/day, lugol 6 drops every 8 hours for 10 days and corticosteroids. Total thyroidectomy carried out without any complications. TSH = 2,4 uiu/ml, free T_4 = 1.23 ng/dl (post-surgical). Pregnancy termination at 38.5 gestational weeks; weight 2.946 grams and size 48 cm. TSH = 3.1 uiu/ml and free T_4 = 1.09 after pregnancy.
Case 3
Age 21 years, gestational age = 17 weeks. Diagnosis before pregnancy. TSH = 0.003 uiu/ml, free T_4 = 6.5 ng/dl. At physical examination with tachycardia, hypertension, trembling limbs and auricular fibrillation. Thyroid ultrasonography with multinodular goiter Trads 3. Medical treatment before surgery with Methimazole 50 mg/day with intolerance, lugol 6 drops every 8 hours for 10 days and corticosteroids. Total thyroidectomy carried out without any complications. TSH = 2.7 uiu/ml, free T_4 = 0.98 ng/dl (post-surgical). Pregnancy termination at 39.1 gestational weeks; weight 3.129 grams and size 49 cm. TSH = 1.76 uiu/ml and free T_4 = 1.2 after pregnancy.

Comparison of results of cytological and hystological research of thyroid gland nodes

Saodat Issaeva[1], Zamira Khalimova[1], Said Ismailov[1], Akram Yuldashev[2], Feruza Yuldasheva[1], Nilufar Ubaydullaeva[1], Gulnara Allayarova[1], Mijgona Safarova[1], Aliya Gumarova[1] & Saida Khodjaeva[1]
[1]Republican Specialized Scientific and Practical Medical Center of Endocrinology Uzbekistan, Tashkent, Uzbekistan; [2]Tashkent Medical Academy, Tashkent, Uzbekistan.

Purpose
To assess the sensitivity and specificity of the cytomorphological method in the diagnosis of the nosological variant of nodal goiter.
Materials and methods
A comparison of the results of cytological and histological studies of thyroid nodules in 36 patients (15 women and 11 men, average age 54.2 ± 9 years), operated for nodular goiter. Cytological findings were divided into 4 categories: 'non-informative material', 'benign lesion', 'follicular neoplasia', 'malignant formation'.
Results
The analysis of the results of cytological research showed that 17 (47.2%) cases were given the conclusions 'non-informative material', 14 (38.9%) 'benign lesion', in 5 (13.9%) - 'follicular neoplasia', and not a single conclusion 'malignant formation'. According to the results of histological examination, in 10 (58.8%) cases, colloidal proliferating nodes were diagnosed in different categories, in 6 (35.3%) - follicular adenoma, in 1 (5.9%) - papillary cancer. Among the conclusions of the category 'benign lesion' in 9 (64.3%) cases, according to the results of histological examination, colloidal proliferative nodes in different degrees were diagnosed, in 5 (35.7%) - follicular adenoma. Among the conclusions of the category 'follicular neoplasia' in 3 (60%) cases - follicular adenoma, in 1 (20%) - colloidal proliferative nodes in different degrees, in 1 (20%) - papillary cancer. The sensitivity of the cytomorphological method of diagnosis of 'nodular colloid goiter' was 44%, specificity-69%, 'follicular neoplasia' 20 and 91%.
Conclusions
The results of the study showed a high percentage of the conclusions of the category 'non-informative material' and identified malignant formations in this category, which significantly reduces the sensitivity of the cytomorphological diagnostic method at the preoperative stage with nodular goiter and requires unification and optimization of both FNA and cytological classification.

Incidence of thyroid cancer among patients with thyroid nodules

Aoife Gilmartin[1] & Mary Ryan[2]
[1]Graduate Entry Medical School, Univeristy of Limerick, Limerick, Ireland; [2]Barringtons Hospital, Limerick, Ireland.

Introduction
Thyroid nodules are observed in 8% of the entire population and have a 5–15% prevalence of malignancy. Thyroid cancer is the most common endocrine neoplasia. Advancements in diagnostic tools such as fine needle aspiration (FNA) are linked to an increasing incidence of thyroid cancer worldwide. The objective of this audit was to evaluate thyroid nodules and to determine the incidence of malignant and benign tumours.

Methods
This retrospective cohort study collected data from eight patients who presented with thyroid nodules. Ultrasound/FNA results of thyroid nodules were used to measure the incidence of thyroid cancer.
Results
The number of thyroid nodules diagnosed as malignant was significantly greater than benign nodules (P-value <0.0001, 95% confidence interval (-1.168 to -0.5459)). This data indicates that females are more likely to develop thyroid cancer than males.
Conclusion
The incidence of thyroid cancer is growing at a rapid pace. This is largely due to the development of radiological tools. In particular, the utilisation of these tools in diagnosing small impalpable thyroid nodules. Papillary carcinoma is the most common thyroid cancer associated, as well as having the highest mortality rates. Notably, it is also the most likely diagnoses in impalpable sub-centimetre thyroid nodules. Analysis of gender data shows females are more likely to develop thyroid cancer than males.

Insights from large-scale mHealth data: the impact of Levothyroxine dosage on intensities of symptoms experienced by Hashimoto's patients

Vedrana Högqvist Tabor[1], Mikael Högqvist Tabor[1] & Pelle Almquist[2]
[1]VLM Health UG, Berlin, Germany; [2]Time Well Spent AB, Stockholm, Sweden.

Hashimoto's thyroiditis is the most common autoimmune condition, with increasing number of people being diagnosed and experiencing varying ranges of symptomes and intensities. This makes the diagnosis as well as treatment challenging. The benefit of preventive health management strategies has been successfully working for diabetes type 2, where condition is managed through implementation of healthy lifestyle and patient-doctor shared decision making. Health care today is increasingly digital, with millions of patients using health apps to track their symptoms and report to doctor. Health apps can serve as research tools to understand behavioural patterns influencing health outcomes. We have investigated a correlation between the medication type, dosage and adherence to commonly experienced symptoms such as fatigue, focus and weight in different cohorts of people diagnosed with Hashimoto's. We observed that the increasing doses of levothyroxine do not scale in relieving symptoms experienced by Hashimoto's patients. Further management might be necessary to relieve from the most common symptoms, such as focus, muscle pain and digestion issues. This is specifically true for patients experiencing digestive problems, which seem to be independent of medication, but can impact and intensify other thyroid-related symptoms. Next, we have investigated whether using medication reminders (alarms) and making peer-reviewed information available to patients via the mHealth app will result in symptom improvement as well as normalizing BMI and will report our findings in detail at the meeting.

Autoimmune thyroid disease (Hashimoto thyroiditis) disscussions as possible predicting of thyroid papillary microcarcinoma (MPTC)

Liana Gogiashvili, Tamuna Gvianishvili & Zurab Tsagareli
Iv. Javakhishvili Tbilisi State University, A. Natishvili Institute of Morphology, Tbilisi, Georgia.

It's have been reported, that an evidence a mixture of immune cells frequently found inside, or surrounding primary thyroid microcarcinoma. In this point of view, we support the concept, that the immune system, such autoimmune thyroid disease, may interfere or predict in thyroid carcinoma or microcarcinoma development and progression. Arising in nonneoplastic tissues, local immune response under autoimmune chronic thyroiditis would be associated with Hashimoto parenchyme atypia converts in classical papillary carcinoma or its precursors (gray zone lesions). Most of this tumors are diagnosed incidentally. Based of the our data, we conclude, that Hashimoto thyroiditis have some distinct histo- and immunopathological features involving in thyrocytes and extra-follicular domens differences. Our data ($n=155$), collecting and clasifical according to TBSRTC, were shown, that in Hashimoto parenchyme comprised most of immature follicular cells (solid nest cells) estimating as thyroid stem/progenitor cells with some atypia, high mitotic and invasive potentialities. Results obtained by Cyclin-depending Kinase activities detection, indicate on the high prevance of Cyclin D1/E and Galectin-3 expression in Hashimoto thyroiditis and support the current concept about the asossiation of 'carcinoma - type' immature follicular cells with gene amplification in micro papillary thyroid carcinoma and autoimmune thyroiditis.
