CONTENTS

e-ECE 2021
23rd European Congress of Endocrinology

PRIZE LECTURES AND BIOLOGRAPHICAL NOTES

The Geoffrey Harris Prize Lecture AP1.1–AP1.2
The *European Journal of Endocrinology* Prize Lecture AP2
European Hormone Medal Lecture AP3
Clinical Endocrinology Trust Lecture AP4
Jens Sandahl Christiansen Award JSC1

PLENARY LECTURES

Plenary 1: The hard road to new therapies against diabetes and obesity PL1
Plenary 2: Light, body clocks and sleep: Biology to new therapeutics PL2
Plenary 3: 1 Year in Pituitary PL3.1–PL3.2
Plenary 4: Neuroendocrine stress response at single cell resolution PL4
Plenary 5: 1 Year in Bone PL5.1–PL5.2
Plenary 6: New advances in novel targets for thyroid cancer and thyroid cancer theragnostics PL6
Plenary 7: Central and Eastern European heritage in genetics of hypopituitarism - how the prevalent ancestral PROP 1 gene variants spread overseas PL7

SYMPOSIA

Symposium 1: The new technology in the clinical management of thyroid nodules S1.1–S1.3
Symposium 2: Adrenal incidentalomas S2.1–S2.3
Symposium 3: Expanding the benefits of GLP-1R agonists S3.1–S3.3
Symposium 4: Peripheral neuroendocrinology S4.1–S4.3
Symposium 5: Human foetal exposure to environmental endocrine disruptors S5.1–S5.3
Symposium 6: COVID: The sequelae of the virus S6.1–S6.3
Symposium 7: Inheritable metabolism S7.1–S7.3
Symposium 8: Lessons from MDT in MEN1 patients S8.1–S8.3
Symposium 9: Large ambitious and inspiring European prevention programs S9.1–S9.3
Symposium 10: New approaches in pituitary pathologies from a multidisciplinary team S10.1–S10.3
Symposium 11: Thyroid hormones, regulation of metabolism and energy balance S11.1–S11.3
Symposium 12: What's new in cardiovascular protection and function S12.1–S12.3
Symposium 13: TGF-β signalling in ovaries in women with PCOS S13.1–S13.3
Symposium 14: Complex clinical cases S14.1–S14.3
Symposium 15: Nutrition intervention: Not just to lose weight S15.1–S15.3
Symposium 16: Splicing in endocrine-related cancers S16.1–S16.3
Symposium 17: New advances in the managements of hypophosphatemia S17.1–S17.3
Symposium 18: The future of endocrinology Artificial Intelligence (AI) and big data! S18.1–S18.3
Symposium 19: Emerging concerns in reproduction S19.1–S19.3
Symposium 20: Diabetes and bone S20.1–S20.3
Symposium 21: Hot topics in neuroendocrine tumours S21.1–S21.3
Symposium 22: From adrenal stem cells to ACC S22.1–S22.3
Symposium 23: Novel targets in diabesity S23.1–S23.3
Symposium 24: Intermediate thyroid cancer soft or aggressive approach S24.1–S24.4
Symposium 25: Parathyroid disorders S25.1–S25.3

JOINT SESSIONS

ESE/EASD Joint Session: Diabetes and growth hormone JS1.1–JS1.3
ESE/ESPE Joint Session: Transition – A step into the unknown JS2.1–JS2.3
ESE/Endocrine Society Joint Session: Emerging endocrine abnormalities and COVID-19 outcomes JS3.1–JS3.5
ESE/SBEM, FASEN and SMNE Joint Session: Pituitary conditions and COVID-19 ..... JS4.1–JS4.3
ESE/KES Joint Session: COVID-19 and endocrine disorders JS5.1–JS5.3
ESE/EndoERN Joint Session: Rare endocrine disorders. Improving diagnosis, management and awareness by strengthening patients and physician collaboration JS6.1–JS6.4
ESE/EASO Joint Session: Endocrine lab findings in people with obesity and their therapeutic consequences JS7.1–JS7.4
ESE/Clinical Guidelines of the European Academy of Andrology: Male specific endocrine conditions JS8.1–JS8.3

NEW SCIENTIFIC APPROACHES

New Scientific Approaches 1: 3D adrenal models for the study of adrenal tumors NSA1
New Scientific Approaches 2: Regeneration or replacement of beta cells NSA2
New Scientific Approaches 3: Cutting-edge scientific advances NSA3
New Scientific Approaches 4: Multiplex analysis platform for endocrine disruption prediction using zebrafish NSA4
New Scientific Approaches 5: Whole genome sequencing in cancer care, lessons from the 100,000 Genomes Project and opportunities for NEN NSA5

DEBATE SESSIONS

Debate 1: Should the biochemical spectrum primary aldosteronism be expanded? D1.1–D1.2
Debate 2: CGM for all people with diabetes? D2.1–D2.2
Debate 3: Selenium for autoimmune thyroid disorders: necessary or unnecessary? D3.1–D3.2
Debate 4: Endocrine disruptors harmonisation in EU: The new EU Chemicals Strategy will speed up efficient reduction of EDC exposure for EU citizens! D4.1–D4.2
Debate 5: Treatment breaks should be mandatory in the majority of people taking oral bisphosphonates D5.1–D5.2
Debate 6: What levels of prolactin to aim for... The lower the better? D6.1–D6.2

MEET THE EXPERT BASIC SCIENTIST SESSIONS

Meet The Expert Basic Scientist 1: Histopathology of human obese adipose organ: New insights MTEBS1
Meet The Expert Basic Scientist 2: When and how to employ molecular genetic testing in thyroid pathology? MTEBS2
Meet The Expert Basic Scientist 3: Interference of EDC with thyroid hormone binding and transport impacts on neural stem cell fate: from development to ageing MTEBS3
Meet The Expert Basic Scientist 4: GWAS and mendelian randomisation studies in osteoporosis diagnosis MTEBS4

MEET THE EXPERT SESSIONS

Meet The Expert 1: New therapies in the treatment of thyroid ophthalmopathy MTE1
Meet The Expert 2: Non-contraceptive therapeutic use of combined oral contraceptives in PCOS MTE2
Meet The Expert 3: Long-term effects of testosterone replacement therapy MTE3
Meet The Expert 4: What one should know on PRRT-lessons from clinical practice MTE4
Meet The Expert 5: Craniopharyngeoma management MTE5
Meet The Expert 6: Difficult phaeochromocytoma cases MTE6
Meet The Expert 7: Do you know how to define sarcopenic obesity? MTE7
Meet The Expert 8: GH replacement in adults MTE8
Meet The Expert 9: Sequential osteoporosis treatments MTE9
Meet The Expert 10: Outlook for male fertility preservation MTE10
Meet The Expert 11: Cardiovascular risk reduction in endocrine patients MTE11
Meet The Expert 12: Pituitary surgery bites MTE12
Meet The Expert 13: Marrow adiposity and bone MTE13
Meet The Expert 14: For the use of AMH as a diagnostic tool in female reproduction MTE14
Meet The Expert 15: Challenges in genetic counseling for hereditary endocrine neoplasia syndromes MTE15

ORAL COMMUNICATIONS

Oral Communications 1: Adrenal and Cardiovascular Endocrinology OC1.1–OC1.6
Oral Communications 2: Diabetes, Obesity, Metabolism and Nutrition OC2.1–OC2.6
Oral Communications 3: Pituitary and Neuroendocrinology OC3.1–OC3.6
Oral Communications 4: Reproductive and Developmental Endocrinology OC4.1–OC4.6
Oral Communications 5: Thyroid OC5.1–OC5.6
Oral Communications 6: Calcium and Bone OC6.1–OC2.6
Oral Communications 7: Diabetes, Obesity, Metabolism and Nutrition OC7.1–OC7.6
Oral Communications 8: Pituitary and Neuroendocrinology OC8.1–OC8.6
Oral Communications 9: Endocrine-Related Cancer OC9.1–OC9.6
Oral Communications 10: Thyroid OC10.1–OC10.6
Oral Communications 11: Adrenal and Cardiovascular Endocrinology OC11.1–OC11.6
Oral Communications 12: Diabetes, Obesity, Metabolism and Nutrition OC12.1–OC12.6
Oral Communications 13: Pituitary and Neuroendocrinology OC13.1–OC13.6
Oral Communications 14: Across Endocrinology OC14.1–OC14.6
Oral Communications 15: Late Breaking OC15.1–OC15.6
Young Investigator Awards YI1–YI12

PRESENTED EPOSTERS

Presented ePosters 1: Adrenal and Cardiovascular Endocrinology PEP1.1–PEP1.8
Presented ePosters 2: Diabetes, Obesity, Metabolism and Nutrition PEP2.1–PEP2.8
Presented ePosters 3: Pituitary and Neuroendocrinology PEP3.1–PEP3.8
Presented ePosters 4: Reproductive and Developmental Endocrinology PEP4.1–PEP4.8
Presented ePosters 5: Thyroid PEP5.1–PEP5.8
Presented ePosters 6: Calcium and Bone PEP6.1–PEP6.8
Presented ePosters 7: Diabetes, Obesity, Metabolism and Nutrition PEP7.1–PEP7.8

Late Breaking EP231–EP240

AUTHOR INDEX

Prize Lectures and Biographical Notes

The Geoffrey Harris Prize Lecture
AP1.1

Complex problems often have simple solution - let's move on from Hippocrates!

John Wass
University of Oxford, Oxford, United Kingdom

The philosophy of my research over the years has been to ask clinically relevant questions which will enhance the practice of decision making in endocrinology, based on scientific assessment of reasonable cohorts. In hitherto unpublished data, we have done work on the assessment of somatostatin responsive headaches in acromegaly and show that they persist over many years, may respond to radiotherapy and may also remain problematic even if acromegaly is cured. We have also looked at a cohort of giants to see whether they present differently and have different complications. Lastly in as yet unpublished data, we have looked at disparate growth hormone and IGF-I in a cohort of patients taken from the UK Acromegaly Database to see whether this group has increased mortality and morbidity. In other work, we have shown the importance of pituitary surgical experience in improving outcome, the importance of debulking growth hormone secreting macroadenomas to improve long-term control with medical therapy, the natural history of non-operated non-functioning pituitary tumours and the indications for further treatment based upon post-operative scans in non-functioning tumours. In prolactinoma we have looked at pituitary functional recovery after treatment. We have done work on apoplexy showing the predictive factors for recovery and lastly shown the importance of various degrees of removal and likelihood of recurrence long-term. Research is accomplished with energy and enthusiasm. Good results are helped, as above, as well with warmth and lack of enmity.

AP1.2

Complex problems often have simple solution - let's move on from Hippocrates!

Vera Popovic-Brkic
Professor of Medicine, University of Belgrade, Belgrade, Serbia

Why should we be suspicious of simple explanations in complex problems? The past decades have seen critical advances in understanding the regulation of growth hormone (GH) secretion. I spent many fruitful years studying the actions of synthetic GH secretagogue , the GH releasing peptide-6 (GHRP-6), on human GH secretion. GHRP-6 mimicked GH releasing hormone (GHRH) but did not bind to GHRH receptor. Powerful joint action (synergism) of GHS/ GHRH was blocked in patients with hypothalamic-pituitary disorders. Amongst our many findings was a safe and reliable test for diagnosing adult GH deficiency. Our special interest was in testing with GHRH/GHS in patients with traumatic brain injury and after cranial irradiation in whom the primary damage is in the hypothalamus causing GH deficiency. Identification of ghrelin , the natural ligand for GH secretagogue receptor, with abundant literature which accumulated over 20 years, showed the complexity of ghrelin's actions: from GH releasing peptide to hunger hormone to glucose regulation. It was a long route to clinical utility of highly selective oral ghrelin mimetic (macimorelin) recently approved of its use in diagnosing GH deficiency in adults. Remarkable progress in collaboration with clinician investigators (investigating medical genetics) have borne fruit. We found families with genes associated with predisposition to early- onset pituitary tumors. We also hypothesized that shared genetic susceptibility may predispose a patient with a strong family history of malignancy to an early-onset pituitary tumor (in a clinical observational study). We better understood the intriguing clinical presentation of polycythaemia/ duodenal somatostatinoma with multiple paragangliomas, by discovering a mutation of the HIF-2A gene (the Pacak–Zhuang syndrome).Science is embedded in case stories.

Communication between the hypothalamus and peripheral organs in energy balance

Rubén Nogueiras
University of Santiago de Compostela, Spain

Obesity pandemic has a tremendous impact on economic and healthcare systems. Our group investigates molecular mechanisms involved in obesity and its associated diseases such as type 2 diabetes and non-alcoholic fatty liver disease. We are particularly interested in studying the actions and mechanisms by which the central nervous system, and more precisely the hypothalamus, controls energy homeostasis. We have provided evidence that different gastrointestinal hormones such as GLP-1, ghrelin or uroguanylin, acts through the hypothalamus to modulate not only food intake, but also peripheral metabolism. Furthermore, we have also shown that neuropeptides like melanin concentrating hormone and neurotransmitters like dopamine can differentially modulate systemic metabolism by acting on specific neuronal subsets. The effects of peripheral and central signals are tightly controlled through the autonomic nervous system. The appropriate crosstalk between peripheral organs and the brain is essential to maintain a fine-tune regulation of energy balance and understanding the complex and redundant metabolic networks are critical to find new targets to fight against metabolic syndrome.

European Hormone Medal Lecture
AP3

Is human reproductive health sustainable in the 21st century?

Niels E. Skakkebaek
Department of Growth and Reproduction, Rigshospitalet, University of Copenhagen, Denmark

Human birth rates are decreasing in industrial countries and are now far below levels, where our populations can be sustained. Although some socio-economic analyses suggest that the trends are due to behavioral changes, adverse health factors may also be at play. In Europe, we have epidemics of infertility resulting in increasing need for assisted reproduction. In Denmark, 9 – 10 % of all children are now born after medical assistance. Female infertility due to delays in pregnancy planning causing 'oocyte aging' combined with partner's poor semen quality may often be among the etiological factors. We have been focusing on possible links between increasing trends in testicular germ cell cancer and decreasing semen quality. Our work has provided evidence of a testicular dysgenesis syndrome (TDS) of fetal origin. The symptomatology of TDS includes cryptorchidism, decreased spermatogenesis, low sperm counts and risk of testicular germ cell cancer. In patients with TDS we detected a cell pattern which gives rise to testicular cancer (seminomas and non-seminomas). These precursor cells*, germ cell neoplasia in situ (GCNIS)*, are similar to primordial germ cells of testis in first trimester (gonocytes) and express several embryonic genes, including OCT-4, in line with the theory of fetal origin of testicular cancer occurring in young adults. We hypothesize that endocrine disrupters originating from fossil fuels may play a role in the increasing trends in reproductive health problems. Perinatal exposures may be particularly harmful for normal differentiation of the embryonic gonocytes into spermatogonia in the fetal testis and thereby cause TDS, including testicular cancer in young adulthood. If the hypothesis of links between trends in male reproductive disorders and non-sustainable birth rates is confirmed, unconventional and interdisciplinary research collaborations, followed by regulatory actions, will be needed to reverse the trends.

Clinical Endocrinology Trust Lecture
AP4

Advances on complications and therapy of cushing's syndrome

Rosario Pivonello
Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, University Federico II, Naples, Italy

In the last decade, new evidence on Cushing's syndrome (CS) complications and therapies have gradually emerged. CS is associated with well known systemic complications, mainly including metabolic syndrome,

cardiovascular disease, immune and infectious disorders, skeletal diseases, neuropsychiatric disorders, as well as impairment of gonadal function with impact on reproduction and sexuality. However, more recently several studies specifically focused on muscle and brain structure and function, as well as on the role of cortisol rhythm loss as key determing factor in development, and of glucocrticoid receptor sensitivity in the clincial manifestations of cortisol excess-related complications, offering new perspectives in the clinical management of CS and its complications. Undoubtedly, the main advance in CS management, classically based on surgical tumor removal or irradiation, is represented by medical therapy, which was historically conceived as a marginal treatment, but recently acquired an emerging role in both preoperative and postoperative settings, and as an alternative to surgery. The first advance was the introduction of pituitary-directed drugs, specifically targeting the cause of pituitary CS, namely Cushing's disease (CD), represented by cabergoline, a dopamine agonist, and pasireotide, a daily multi-ligand receptor somatostatin analogue, that showed a good efficacy on hormonal and tumour growth control, as well as an improvement in clinical picture. Although hyperglycemia was frequently reported during pasireotide treatment, european guidelines were provided for its safety management. More recently, a long-acting release pasireotide formulation showed similar efficacy and safety as compared to the daily formulation, with a potential better compliance. New advances appeared also on adrenal-directed drugs, with the introduction of osilodrostat and levoketoconazole, which showed a good efficacy on hormonal control and improvement in clinical picture, with a good safety profile. Compared to the classic steroidogenesis inhibitors metyrapone, also acting on 11β-hydroxylase, osilodrostat may allow higher efficacy at lower doses, due to its higher potency, and a twice-daily administration, due to its higher half-life. Similarly, compared to the classical ketoconazole, levoketoconazole, its 2S,4R enantiomer, might allow higher efficacy at lower doses, due to its higher potency, and decreased hepatotoxicity, due to its diminished CYP7A activity. However, comparative studies are needed to confirm this hypothesis. Lastly, in recent years, new advances appeared on glucocorticoid receptor (GR)-antagonists, with the introduction of relacorilant, a selective GR-antagonist, able to improve glucose metabolism and blood pressure in patients with impairment of glucose metabolism and hypertension, respectively. Compared to the classic GR-antagonist mifepristone, relacorilant was not associated with endometrial thickening and vaginal bleeding, due to its lack of affinity for the progesteron receptor. Although these new medical therapies may offer promising therapeutic options for CS management, further researches and advances are required to allow a more personalized and tailored approach.

Cardiovascular disease – menopause

Panagiostis Anagnostis
Unit of Reproductive Endocrinology First Department of Obstetrics and Gynecology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece

Transition to menopause is associated with increased cardiovascular disease (CVD) risk, mainly attributed to acquisition of a more atherogenic lipid profile, including an increase in total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), triglycerides (TG) and apolipoprotein B concentrations, and a decrease in high-density lipoprotein cholesterol (HDL-C) concentrations, mostly due to the HDL_2-C subfraction. Derangement in glucose metabolism, visceral adiposity and development of metabolic syndrome also contribute to the menopause-related CVD risk. Inconsistent data exist with regard to blood pressure and lipoprotein (a) [Lp(a)]. Whether the aforementioned changes are translated into an increased risk of CVD events and mortality, irrespective of age, remains to be established. However, this association is evident in cases with early age at menopause (i.e. < 45 years) or premature ovarian insufficiency (POI), which demonstrate a 1.5-2-fold increased CVD risk, compared with women of normal age at menopause. Oestrogen administration ameliorates most of the CVD risk factors to a various extent depending on the regimen, dose, duration and route of administration. In particular, it decreases TC, LDL-C and Lp(a), whereas it increases HDL-C concentrations. The effect on TG depends on the route of administration (i.e. increase with oral and decrease or neutral effect with transdermal oestrogen). Oestrogen also improves insulin resistance and reduces the risk of type 2 diabetes. These effects are dissipated after withdrawal. Menopausal hormone therapy (MHT) is recommended in cases with early menopause or POI, irrespective of the presence of menopausal symptoms. It may be also considered in symptomatic postmenopausal women <60 years old or <10 years since menopause, starting at the lowest effective dose. CVD and breast cancer risk should be assessed prior to MHT. Transdermal oestrogen and micronized progesterone or dydrogesterone are the preferred regimen. In any case, tailoring the MHT regimen according to women's risk profile and preference, constitute the wisest strategy.

Light, body clocks and sleep: Biology to new therapeutics

Eve Van Cauter
Department of Medicine, University of Chicago, United States

Circadian rhythms are a ubiquitous feature in living organisms. They are not just a passive response to daily cyclic fluctuations in the environment, but are instead driven by endogenous and self-sustained clocks. More than 40 years ago, the suprachiasmatic nucleus (SCN) of the hypothalamus was identified as the location of an endogenous circadian clock driving internal rhythmicity and this SCN oscillator was long thought to be the only mammalian clock, functioning as a master pacemaker. It is now well recognized that peripheral circadian oscillators are present in virtually every organ and cell of the body and that optimal functioning of the circadian system is dependent on the tight synchronization of the central and peripheral pacemakers. The tempo between central and peripheral clocks is transmitted by multiple pathways, including the hard-wired autonomous nervous system, the release of hormonal signals in the peripheral circulation (notably glucocorticoids and melatonin) and behaviors such as sleeping and eating. Circadian misalignment refers to abnormal timing between SCN rhythms, peripheral rhythms and behavior (e.g. sleeping during the biological day, eating during the biological night) and the environment (e.g. exposure to light during the biological night). Conditions of circadian misalignment abound in modern society and are invariably associated with metabolic and sleep disturbances. In the present talk, we will review the impact of impaired light perception (as occurs in diabetic retinopathy) and abnormal rhythmicity of circulating corticosteroids (as occurs in adrenal insufficiency) on endocrine and metabolic function. Novel therapeutic approaches, including timed melatonin administration and chronophysiological delivery of exogenous glucocorticoids will be discussed.

Plenary 3: 1 Year in Pituitary

PL3.1

1 Year in Pituitary

Clara V Alvarez

Neoplasia and Endocrine Differentiation Research Group. Center for Research in Molecular Medicine and Chronic Diseases (CIMUS). University of Santiago de Compostela. Santiago de Compostela, Spain. This has been an extraordinary year, where scientists have not been able to get close to the laboratory in many months. However, in the pituitary/hypothalamus we have outstanding contributions. Being at home does not mean stopping thinking, as highlighted by interesting reviews on the novelties in therapeutic peptides targeting GPCRs, new causes of hypopituitarism, DNA damage or pituitary stem cells. In pituitary tumours, use of several omics (mutations, genome alterations, mRNA expression, miRNA clustering, and methylation patterns) in a pangenomic study is a superb contribution, followed by other confirmatory studies allowing understanding of their cellular origin and pre-selection of patients responding better to analogs. At a functional level, we will highlight how the continued activation of the cAMP pathway increases the probability of DNA damage, how hypoxia activates PKA after repressing its regulatory subunits, and what is the molecular protein surface when GHRH activates its GHRHR receptor, obtained through cryo-EM studies. The GPR101 receptor mouse model explaining human pathology but also raising intriguing questions has been one of the milestones of this year. Single-cell RNA sequencing in normal tissue identifies the most abundant genes expressed in an individualized cell; collecting a sufficient number of unique cells it is possible to characterize the different populations of an organ. We have contributions in the changing populations during embryonic development of human pituitary, and several in populations of the mice hypothalamus. At a functional level, we have the role of histone H3 methyl-transferase in the development of GHRH neurons, a new relationship between lysosomes and primary cilium in the early stages of life with consequences in adiposity, or precocious puberty induction by protein signals or ceramides in animal models relevant to the human situation. New and surprising hypothalamic neural circuits in mice controlling metabolism, open exciting possibilities about its existence in humans.

Plenary 5: 1 Year in Bone

PL5.1

One year in osteoporosis

Cyrus Cooper
Professor of Rheumatology and Director, MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton, UK

Osteoporosis constitutes a major public health problem through its association with age-related fractures. These fractures typically occur at the hip, spine and wrist. Our research into osteoporosis at the MRC Lifecourse Epidemiology Unit over three decades has characterised the epidemiology of these fractures, and contributed to the generation of preventive strategies against them throughout the lifecourse. Around 1 in 2 women and 1 in 5 men in the UK will sustain an osteoporotic fracture from age 50 years onwards. Incidence rates rise with age, and rates in women are around double those in men above age 50 years (in large part due to the accelerated bone loss after the menopause among women). Rates are generally higher in Caucasian than in Asian and Afro-Caribbean populations. Life expectancy is increasing around the globe and the number of elderly individuals is rising in every geographic region. Assuming constant age-specific incidence rates for fracture, the number of hip fractures occurring worldwide among people aged 65 years and over will rise from 1.7 million in 1990 to 6.3 million in 2050. In this review of major research findings in the last twelve months, we shall review: (a) key developments in risk assessment of future fracture risk, including approaches to estimating "very high" or "imminent" fracture risk; (b) risks and benefits of currently available antiresorptive and formation stimulating osteoporosis therapies; (c) effectiveness of primary and secondary preventive strategies against fracture; (d) developmental contributors to fracture risk and the role of interventions during intrauterine and early postnatal life; and (e) characterisation of the osteoporosis treatment gap, and measures to try and close this.

PL5.2

1 year of basic research in bone

Wim Van Hul
Department of Medical Genetics, University of Antwerp, Belgium

The last year has definitely not been the most easy one for research in general as the COVID-19 pandemic resulted in limitations on how basic research could be performed. Despite this, it is definitely worthwhile to look back on the data that has been published over the last year. During this presentation, I will highlight some publications that, for one or another reason, can be considered of major importance for or impact on the bone field. This selection was made by searching high impact journals with terms including bone, osteoblast, osteoclast and osteocyte. Obviously this resulted in a large number of publications. Making a balanced selection on what can be considered as most breaking is difficult and clearly personal. Without doubt, the selection made can be debated and, also because of time restraints, unfortunately a lot of papers of high value will not make it to the presentation.

Plenary 6: New advances in novel targets for thyroid cancer and thyroid cancer theragnostics

PL6

New advances in novel targets for thyroid cancer and thyroid cancer theragnostics

Pilar Santisteban
Biomedical Research Institute, Spanish Council of Research and Autonomous University (CSIC-UAM), Madrid, Spain.

Thyroid cancer derived from follicular cells is the most frequently endocrine malignancy with an increasing rate of incidence. The identification of new molecules involved in the pathogenesis of these tumors is necessary in order to use it as a novel targets for a better diagnostic and therapy. Recently, the RNA networks emerge as fundamental in the control of gene expression, achieving a strong interest the microRNAs (miRNAs). Our RNA-Seq study together with the analysis of The Cancer Genome Atlas (TCGA) identified novel RNA regulatory mechanism in papillary thyroid carcinomas. We show that miRNA dysregulation involves not only individual changes in the expression of miRNAs, but also disruption of the biogenesis machinery and/or modifications of miRNA sequences by RNA editing. We explored the role of the oncogenic miR-146b, the most upregulated miRNA in thyroid cancer, identifying novel targets that help explain miR-146b-induced cell aggressiveness. Among them, DICER1, the enzyme involved in miRNA biogenesis, is downregulated in thyroid tumor cells overexpressing miR-146b. The decrease in DICER1 levels was associated with a worse clinical outcome of thyroid tumors. Restoration of DICER1 by different treatment reduced tumor aggressiveness both *in vitro* and *in vivo*. Currently, RNA editing is getting great relevance in cancer biology. Thus, we investigated the role of adenosine-to-inosine (A-to-I) RNA editing, a process governed by the enzyme ADAR1. We demonstrate that ADAR1 induces thyroid tumorigenesis by a mechanism dependent on the over-editing of the tumor-suppressor miR-200b, impairing its ability to inhibit the epithelial mesenchymal transition factor ZEB1. Altogether our results highlight potential therapeutic approaches based on miRNA inhibition, restoring global miRNA levels *via* the DICER1 pathway, and suppressing RNA editing, providing a basis for new thyroid cancer treatments.

Plenary 7: Central and Eastern European heritage in genetics of hypopituitarism - how the prevalent ancestral PROP 1 gene variants spread overseas

PL7

Central and Eastern European heritage in genetics of hypopituitarism – how the prevalent ancestral *PROP1* gene variants spread overseas

Jan Lebl
Department of Pediatrics, 2nd Faculty of Medicine, Charles University and University Hospital Motol Prague, Czech Republic

Pituitary development is governed by activation of a cascade of transcription factors that orchestrate both pituitary morphogenesis and differentiation. Among them, loss of function of PROP1 is the most common genetic cause of combined pituitary hormone deficiency (CPHD) with two *PROP1* gene variants (c.[301_302delAG];[301_302delAG] and c.[150delA];[150delA]) being most prevalent. We identified the homozygous c.[301_302delAG] variant in 70% out of 67 Lithuanian subjects with CPHD, suggesting a founder effect and precised their auxological and hormonal phenotype - normal birth lengths/weights, testicular retention in 31% of boys, and a progressive decline of median height SDS over years 1 – 5: –1.56, –2.34, –3.43, –3.52 and –3.70. Deficiencies of GH, TSH, ACTH and FSH/LH were diagnosed in 44/44, 44/44, 19/44 and 22/44 subjects at median age 5.5, 5.6, 13.1 and 15.0 years, respectively. In addition, we aimed to elucidate the origin of the two prevalent *PROP1* variants. We studied 237 patients originating from 21 different countries worldwide. We genotyped 21 single-nucleotide variant markers flanking the 9.6-Mb region around the *PROP1* gene. Haplotypes were reconstructed by Phase and Haploview software. We demonstrated the ancestral origin of both variants – c.[301_302delAG] originated in Lithuania ~ 101 generations ago (confidence interval 90.1 – 116.4). Patients from the Iberian Peninsula displayed a different haplotype, which was estimated to have emerged 23.3 (20.1 – 29.1) generations ago. Subsequently, the data indicated that both the haplotypes were transmitted to Latin American patients ~ 13.8 (12.2 – 17.0) and 16.4 (14.4 – 20.1) generations ago, respectively. The c.[150delA] variant that was carried on a haplotype spanning about 0.3 Mb was estimated to appear 43.7 (38.4 – 52.7) generations ago at the territory of current Byelorussia. We confirmed that the most frequent variants in the *PROP1* gene are founder variants that spread from Eastern/Central Europe overseas. That explains their unequal distribution among various populations.

Symposia

Symposium 1: The new technology in the clinical management of thyroid nodules

S1.1

Novel approaches beyond cytology

Pablo Valderrabano
Hospital Universitario Ramón y Cajal, Spain

Background
The traditional cytology-based management of thyroid nodules often leads those with indeterminate cytology to unnecessary resection for diagnostic purposes. In an attempt to improve presurgical diagnosis, several molecular marker tests have been developed in the last decade.
Methods
The benefits and limitations of prospectively validated molecular marker tests in cytologically indeterminate thyroid nodules; and other risk stratification strategies that allow the individualization of management will be discussed.
Results
A selective use of molecular marker tests could be useful in the identification of low-risk nodules; but long-term follow-up of molecularly-benign/negative nodules is currently necessary. Furthermore, their predictive values need to be validated in specific clinical scenarios. Meanwhile, the sonographic pattern and some cytological features enable risk-stratification and can be used to individualize management in cytologically indeterminate thyroid nodules.
Conclusion
An individualized approach for cytologically indeterminate thyroid nodules is not only desirable but also possible through the integration of clinical, sonographic, and cytological features. Current molecular marker tests could be of use selectively; but their role in the evaluation of cytologically indeterminate thyroid nodules needs to be better defined.

Can sonoelastography and artificial intelligence improve the diagnostics of thyroid nodules?

Ewelina Szczepanek-Parulska
Department of Endocrinology, Metabolism and Internal Medicine, Poznań University of Medical Sciences, Poland

Thyroid nodules (TN) are the most common endocrine disorder present in 10 – 67% of adults, with a malignancy risk of 3 – 15%. Sonoelastography (SE) is a novel ultrasound technique providing information on elasticity of TN. Decreased elasticity proved to be a useful predictor of malignancy. SE cannot be regarded as a substitute for fine-needle aspiration biopsy (FNAB), but should rather be considered as a complementary tool facilitating estimation of TN malignancy risk and selection of the region for FNAB. SE is particularly useful as a rule-out technique, thanks to its high negative predictive value, thus might help to reduce the number of FNABs. However, certain limitations of SE must be considered during interpretation of the results (TN size and localization, follicular lesions, calcified or cystic TN, multinodular goiter, subacute/acute thyroiditis, obesity, acromegaly, operator-dependence, lack of standardized method for data reporting and clearly defined cut-off values). The use of semi-quantitative methods is recommended. The TIRADS classification system corrected by SE is more accurate in TN diagnosis. Recently computer-aided diagnosis (CAD) systems based on artificial intelligence algorithms allowing for an automated ultrasound image analysis have been developed to obtain accurate, reproducible and more objective diagnosis of TN. In clinical settings CAD performed similarly or worse than experienced sonographists, but still markedly better than a physician with basic ultrasound skills. It may assist in decision-making and has a potential to be used as a screening device for less-experienced physicians. Future improvements of the technique would increase its diagnostic efficiency. Our research demonstrated that CAD characterizes with high sensitivity and good specificity. The EU-TIRADS classification used by an experienced sonographist allows to identify suspected lesions with high sensitivity but rather low specificity. The best diagnostic performance in estimation of malignancy risk of TN was obtained for the combined model of CAD and EU-TIRADS scale.

Novel biological targets for GLP-1R agonists

Darleen Sandoval
Department of Pediatrics, University of Colorado

The preproglucagon gene (Gcg), expressed in the intestine, the pancreas, and a small cluster of neurons in the hindbrain, encodes multiple peptides in a tissue-specific manner. One of these peptides, glucagon like peptide-1 (GLP-1) increases following meals, functions to stimulate insulin secretion, and is essential for normal glucose tolerance. The dogma is that intestinally-derived GLP-1 acts as a hormone binding to pancreatic GLP-1 receptors (GLP-1r) to stimulate insulin secretion. However, limited by rapid intravascular metabolism, the plasma concentrations of GLP-1 are relatively low and are only modestly elevated during meal ingestion. We have developed several mouse models that all tissue-specific gain- or loss-of-function manipulation of the GLP-1 system. We used these models to advance our understanding of the physiology and pharmacology of the GLP-1 system. An alternative to the endocrine model of GLP-1 physiology in regulation of glucose homeostasis is a paracrine model within the islet. To explore this hypothesis we administered a GLP-1r antagonist to our gain-of-function mouse targeted to Gcg. This work suggests that it is pancreatic, and not intestinal-derived GLP-1 that mediates the physiological regulation of glucose homeostasis. Thus, we hypothesize that the acute insulinotropic effects of endogenous GLP-1 are paracrine rather than endocrine, derived from islet ńcells and acting on β-cell GLP-1r to stimulate insulin secretion. Pharmacologically, while pancreatic but not central nervous system GLP-1r are necessary to regulate improvements in glucose homeostasis by long-

acting GLP-1r agonists, central but not peripheral nervous system GLP-1r are necessary for these agonists to induce weight loss.

Serotonergic regulation of insulin release – Hormone secretion, beta cell mass and metabolic status.

Malin Fex
Lund University Diabetes Centre (LUDC), Unit for Molecular Metabolism, Clinical Research Centre, Malmö, Sweden

The neurotransmitter Serotonin (5-hydroxytrympatmine (5-HT), influences hormone secretion from human and rodent islets of Langerhans. Given its confirmed local production in the insulin producing beta (β)-cells, this monoamine has been shown to modulate insulin secretion by both intra- and extracellular mechanisms. However, the precise mechanisms by which 5-HT its effects on insulin release and whole-body glucose metabolism is yet to be fully understood. Fourteen different 5-HT receptors are present in human islets, localized in the different hormone-secreting cell types (e.g., α-and β-cells). The receptors activate a number of intracellular signaling pathways. In fact, both stimulatory and inhibitory actions on insulin release by 5-HT have been observed. Recent advances have pinpointed specific receptors as being crucial for regulation of β-cell mass and compensatory insulin release during pregnancy. Under such circumstances, changes in metabolic status appear to alter both the synthesis of β-cell 5-HT as well as expression of specific 5-HT receptors. Whether actions of 5-HT are implicated in β-cell dysfunction in Type 2 Diabetes is yet to be clarified, but cannot be excluded. Indeed, 5-HT may be an important modulator that fine tunes the release of insulin both and glucagon, the two main hormones that control glucose and lipid homoeostasis.

Nutritional programming of cardio-metabolic health: The role of maternal and fetal hyperinsulinaemia

Susan Ozanne
University of Cambridge Metabolic Research Laboratories and MRC Metabolic Diseases Unit, Cambridge, United Kingdom

Strong evidence from studies in humans and animal models suggests that the nutritional environment to which a developing fetus is exposed impacts on long-term cardio-metabolic health. This concept has been termed nutritional programming. Although initial focus was on the detrimental consequences of fetal under-nutrition, the growing prevalence of obesity across the globe has focussed attention towards fetal over-nutrition. Obesity prevalence is increasing in all age groups, including women of childbearing age. In many populations over half of women are now either overweight or obese during pregnancy and this is accompanied by an increased prevalence of gestational diabetes. This is of major concern as evidence suggests that developing *in utero* in an obesogenic/diabetic environment has both immediate and long-term impacts on the health of the mother and child. The strongest evidence from humans to suggest that development *in utero* in an obesogenic environment "programmes" increased risk of obesity and cardio-metabolic disease comes from the study of siblings born before and after maternal bariatric surgery. These revealed that the sibling born post-surgery had reduced adiposity, lower blood pressure and increased insulin sensitivity compared to their sibling born prior to maternal weight-reducing surgery. We have used a mouse model of maternal diet-induced obesity to define the mechanisms by which obesity/impaired glucose tolerance during pregnancy impacts on the long-term cardio-metabolic health of the offspring. These studies show that the offspring of obese dams develop insulin resistance, cardiac dysfunction, hypertension and fatty liver even when the offspring are lean. We have identified maternal hyperinsulinaemia as a key 'programming" factor and shown that insulin resistance in some tissues can occur *in utero*. These findings highlight maternal hyperinsulinaemia as an important target of intervention studies such as those involving increased maternal physical activity to reduce the transmission of poor cardio-metabolic health between mother and child.

Pubertal urinary phthalate metabolite concentrations and semen quality among young Russian men: exploring potential windows of susceptibility

Lidia Minguez-Alarcon
Harvard School of Public Health, United States

Aim
To prospectively investigate the associations of urinary phthalate metabolite concentrations measured during four peri-pubertal windows with semen parameters in Russian men.
Methods
516 boys were enrolled at ages 8 – 9 years (2003 – 2005). Urine samples were collected annually and pooled into four pubertal exposure windows based on physician assessed Tanner stages and testicular volume (prepuberty, early puberty, late puberty and sexual maturity). 15 phthalate metabolites were quantified using isotope dilution HPLC-MS/MS at Moscow State University. We calculated molar sums (∑) of di-2-ethylhexyl phthalate (DEHP), non-DEHP, di-isononyl phthalate (DiNP) and di-isodecyl phthalate (DiDP) metabolites. At sexual maturity (18 – 19 years), men provided 1 – 2 semen samples for analysis. We estimated the associations between quintiles of ∑phthalate metabolites and semen parameters for each pubertal window by fitting generalized linear mixed models with random intercepts to account for repeated semen samples, adjusting for abstinence time, body mass index, and specific gravity. We also modelled the probability of having a semen sample below any WHO cut-offs measured as < 15 mil/ml for concentration, < 39 mil for count, or < 32% progressive motility.
Results
Higher urinary concentrations of ∑DiNP in the late pubertal samples were associated with poorer semen quality; men with the highest versus lowest quintile of ∑DiNP had 32% lower sperm concentration, 34% lower count and 33% lower progressive motile count. Also, men with the highest versus lowest quintile of ∑DiNP had 15% higher probability of having a semen parameter below WHO cut-offs. ∑DiNP measured in the other three peri-pubertal windows was not associated with semen quality. No

associations of ∑DEHP, ∑non-DEHP and ∑DiDP with semen quality parameters were observed.
Conclusions
∑DiNP metabolites in late puberty was associated with poorer semen quality, highlighting the importance of considering specific windows of exposure when investigating chemical exposures in relation to fertility in men.

Transgenerational influences of AMH and the pathogenesis of PCOS
Paolo Giacobini
University of Lille, Inserm, CHU Lille, UMR- S 1172 – Lab Development and Plasticity of the Neuroendocrine Brain, Lille Neuroscience & Cognition Center, Lille, France

Polycystic ovary syndrome (PCOS) is the major reproductive and metabolic disorder affecting 10 – 15% of women in reproductive age. Up to 70 percent of daughters of women with PCOS also develop the disease, but genetic variation doesn't fully explain the high incidence within families and the mechanisms underpinning its transmission remain to be elucidated. We have previously shown that prenatal anti-Müllerian hormone (AMH) exposure leads to the manifestation of PCOS-like traits in the female offspring (PAMH mice). More recently we utilized this animal model to show that the transmission of reproductive and metabolic PCOS-like traits occurs across three generations. We next performed RNA sequencing and genome-wide DNA methylation profiling of ovarian tissue from control and third-generation PCOS-like mice. We found that DNA hypomethylation regulates key genes associated with inflammation and metabolic related pathways in PCOS and that several of the differentially methylated genes are also altered in blood samples from women with PCOS compared with healthy controls. We further explored the epigenomic basis for this transgenerational transmission of PCOS-like phenotypic expression by reversing many of its traits through supplementation with the universal methyl donor, S-adenosylmethione (SAM). These findings show that the transmission of PCOS reproductive and metabolic dysfunctions to multiple generations occurs via altered landscapes of DNA methylation and highlight a roadmap to new diagnostic and therapeutic avenues of the disease.

Prevention program for male health
Daniele Gianfrilli
Department of Experimental Medicine, Section of Medical Pathophysiology, Food Science and Endocrinology, Sapienza, University of Rome, Rome, Italy

Context
Although in the past andrological health has been a poorly addressed topic due to historical and cultural reasons, in recent times male reproductive and sexual health has emerged as a main healthcare issue. Young male subjects could suffer from various andrological problems, as cryptorchidism, varicocele, sexual dysfunctions, sexually transmitted infections, testicular

cancers. Early finding and treatment are fundamental, especially because if some conditions are not promptly recognized, they are managed later with greater complexity. The identification of early risk factors, including modifiable ones, involved in the development of andrological disorders is extremely important and adolescence is a key time. Despite all this, there is still a clear gender gap in research and prevention programs for reproductive health and sexuality.
Objective
It is essential to provide health programs aiming to: 1) inform and educate young people about andrological prevention; 2) early detection of andrological pathologies.
Methods
In Italy, some information campaigns and programs focusing on andrological prevention have been made. An example is the national andrological health surveillance project named "Amico-Andrologo (AA)", which is conducted by the Sapienza, University of Rome and the Italian Society of Andrology and Sexual Medicine in the final year of high school. During the onsite visit, all subjects are invited to complete an anonymous, self-administered questionnaire and, if willing, to undergo a voluntary andrological examination performed by trained clinicians, who also provide all students informative material about andrological prevention issues.
Results
During the AA survey, abnormal andrological clinical examination was found in one third of students, showing high percentage of varicocele (27.1%), testicular hypotrophy (14%) and phimosis (7.1%). Unprotected sex was quite common and heavy alcohol or drug use were associated with testicular hypotrophy.
Conclusions
Prevention program for sexual and reproductive male health are effective and needed.

Symposium 10: New approaches in pituitary pathologies from a multidisciplinary team

S10.1

Abstract unavailable

S10.2

Tumor or not tumor and what's new in pituitary pathology

Jacqueline Trouillas
Faculté de Médecine Lyon Est, Lyon, France

Pituitary adenohypophyseal tumors are considered benign and termed "adenomas" but can also be invasive, "aggressive" and malignant with metastases (carcinoma). Taking into account this variability in behavior and the oncological definition, pathologists have proposed changing the term adenoma to tumor. Indeed, "tumor designates a neoplasm which is benign or malignant". The invasion of the surrounding tissues is a criterion of malignancy. For this reason, the terms "invasive adenoma or aggressive adenoma" are inappropriate pathologically. Recently, a Workshop of Endocrinologists (PANOMEN) recommended that the term adenoma be retained, arguing that "tumor may have a sinister tone and may adversely affect patients". What is your opinion? These tumors are classified into seven morphofunctional types and three lineages identified by transcription factors: lactotroph, somatotroph and thyrotroph (PIT1 lineage), corticotroph (TPIT lineage) or gonadotroph (SF1 lineage), null cell or immunonegative tumors and plurihormonal tumors. The WHO 2017 classification suggested that subtypes, such as male lactotroph, silent and "Crooke cell" corticotroph, sparsely granulated somatotroph, and silent plurihormonal PIT1 tumors, should be considered as "high risk" tumors. However, the prognostic impact of these subtypes remains controversial. In contrast, the French five-tiered classification, taking into account invasion (MRI), the immunohistochemical type, and proliferative markers (Ki-67 index, mitotic count, p53 positivity), has prognostic value for recurrence/progression, that has been independently validated by statistical analysis on around 2000 patients. In the European Society of Endocrinology (ESE) cohort of "aggressive" tumors (125 APC) and carcinomas with metastases (40 PC), the clinical and pathological features were similar. This cohort (APT+PC) differed greatly from a reference surgical cohort, especially in the percentage of tumors with Ki67 $\geq$ 10%. We suggest that these clinically aggressive, invasive and highly proliferative tumors represent tumors with malignant potential. Pathological diagnosis may help clinicians to adapt post-operative management, including appropriate follow-up and early recognition and treatment of potentially malignant tumors.

The cross talk between thyroid hormones and the central nervous system in thermoregulation

Jens Mittag
Internal Medicine I, Molecular Endocrinology, Center of Brain, Behavior and Metabolism, University of Lübeck, Lübeck, Germany

Thyroid hormone is long known for its profound effect on body temperature regulation. Patients suffering from hyperthyroidism display elevated body temperature and are sensitive to heat, while hypothyroid patients are cold sensitive. The precise regulation of body temperature by thyroid hormone, however, has been incompletely understood. In our recent studies, we have studied the thermogenic effects of the hormone in a mouse model in detail. We observed that the body temperature increase induced by the hormone persisted independent of the environmental temperature, demonstrating that it constituted an upregulation of the central set point comparable to fever. However, there was a parallel increase in peripheral thermogenesis, which at room temperature even exceeded the elevated set point, causing a hyperthermia response. Using mice lacking the thermogenic uncoupling protein 1, we subsequently demonstrated that this hyperthermia was not caused by brown or beige fat thermogenesis, but likely originated in muscle. To test the central set point hypothesis further, we studied mice lacking the thyroid hormone transporters MCT8 and OATP1C1. Consequently, these animals display a severely hypothyroid brain in the presence of systemically elevated T3 levels. Interestingly, the double knockout mice did not present with an elevated body temperature, demonstrating that the central actions of the hormone are required for the fever phenotype observed in hyperthyroidism. Taken together, our work shows that thyroid hormone

simultaneously acts thermogenic in the periphery and pyrexic in the brain, which is of particular interest for the role this hormone may have played in the evolutionary development of endothermy.

Chronic glucocorticoid treatment causes metabolic abnormalities: The role of hypothalamic glucocorticoids and DIO2

Erika Harno
University of Manchester, School of Medical Sciences, Manchester, United Kingdom

Synthetic glucocorticoids (GCs) are widely used in clinical practise to treat various inflammatory disorders including rheumatoid arthritis, asthma and some malignancies. Although generally well tolerated, long-term, especially high dose use can lead to metabolic side effects. We have developed a mouse model of GC treatment in drinking water, using corticosterone (Cort, the endogenous GC in rodents), which recapitulates many of the side-effects in patients treated with GCs. After 24 h treatment we observe hyperphagia, leading to increased body weight from day 10 of treatment. There are changes in gene expression consistent with insulin resistance from day 2 of Cort treatment and hyperglycaemia develops by day 21. Although GCs signal peripherally, there is growing evidence that peripheral metabolic effects can be mediated by GCs acting on the neurons of the arcuate nucleus of the hypothalamus (ARC). To investigate these potential central effects, we treated with Cort for 2 days and then carried out global transcriptomic analysis of the ARC, to identify novel GC target genes. Genes which were altered included well known target genes, such as *Fkbp5* and *Agrp*. However, we also identified novel GC target genes and interestingly, GCs upregulated type II iodothyronine deiodinase (*Dio2*), suggesting that GCs might increase the conversion of T4 to T3. *Dio2* was of particular interest, due to its discreet localisation in the tanycytes and astrocytes of the ARC, and because elevated T3, like glucocorticoids, can influence hyperphagia and energy balance, potentially by activating AgRP neurons. Therefore, we knocked down *Dio2* by injecting AAV-CRISPR-Cas9 guide RNAs bilaterally into the ARC. In these knockdown mice, we found little effect on the GC-induced metabolic phenotype. However, we observed a reduction in GC-induced *Agrp* expression, indicating that GC effects in the hypothalamus may be mediated in part by their actions on *Dio2*.

Role of inflammation in the therapy of cardiometabolic diseases

Marc Y Donath
University Hospital Basel, Switzerland

Morphological and therapeutic interventions have uncovered an inflammatory process in patients with type 2 diabetes. This inflammation is due to a pathological activation of the innate immune system by metabolic stress and is largely governed by IL-1 signaling. Initially, the inflammatory response is probably deployed to promote adaptation and regeneration. Indeed, we identified a role for IL-1β and insulin in the regulation of both metabolism and immunity in response to feeding. Yet, as it becomes chronic, activation of auto-inflammatory processes may then become deleterious. It follows that modulation of inflammatory mediators may present as a possible causal therapy. This is supported by clinical studies showing that IL-1 antagonism decreases glycated hemoglobin. Furthermore, IL-1 antagonism prevents heart failure and cardiovascular diseases, the major complication of diabetes.

TGF-β signalling in ovaries in women with PCOS

S13.1

Interplay between androgens and TGF-β signalling in the ovary

Phil G Knight
School of Biological Sciences, University of Reading, Reading, United Kingdom

Theca cells are indispensable for female reproduction being the source of androgens required for follicular oestrogen synthesis and also for interacting with androgen receptors in the ovary and other somatic tissues. Differentiated theca interna cells acquire responsiveness to LH and other endocrine signals, including insulin, that upregulate the steroidogenic pathway leading to androgen biosynthesis. In addition, numerous intraovarian factors of thecal, granulosal and/or oocyte origin modulate thecal androgen production, mostly in an inhibitory manner; many of these are members of the TGF-β family. These ligands bind to different combinations of type-I and -II signalling receptors expressed by theca cells; ligand-receptor interaction is regulated by various extracellular binding proteins, co-receptors and likely by competition amongst cross-reactive ligands for common receptors. In vitro studies in the author's and other laboratories indicate functional redundancy amongst TGF-β family ligands in that activins and various BMPs (including BMP2,4,6,7) suppress thecal androgen production in an inhibin-reversible manner. Follistatins neutralize activin action while other binding proteins (e.g. noggin, gremlin) selectively neutralize different BMPs. Other ligands including TGF-$\beta_{1,2,3}$ also strongly inhibit thecal androgen production while AMH and GDF9 appear to have limited effect. Recent evidence indicates that myostatin (GDF8) is expressed within human and bovine follicles and suppresses thecal androgen production in a manner opposed by follistatin. It has also emerged that bovine theca cells express free inhibin-α subunit and that its knockdown suppresses androgen output although the significance of this finding requires further investigation. With regard to ovarian hyperandrogenaemia commonly associated with polycystic ovarian syndrome, it is hypothesised that this could be due to compromised intraovarian signalling by one or more TGF-β family ligands that tonically suppress thecal androgen synthesis. This could arise from altered expression or processing of ligands, antagonists (i.e. inhibins), extracellular binding proteins, signalling receptors, co-receptors and/or intracellular signal transduction components.

LH-receptor activity and interaction with TGF-β family members in women with PCOS

Lisa Owens[1], Stine Gry Kristensen[2], Avi Lerner[1], Aylin Hanyaloglu[1], Kate Hardy[1], Claus Yding Andersen[2], Stephen Franks[1]
[1]Institute of Reproductive & Developmental Biology, Imperial College London; [2]Laboratory of Reproductive Biology, The Juliane Marie Centre for Women, Children and Reproduction, Copenhagen University Hospital, University of Copenhagen

The luteinising hormone/chorionic gonadotropin receptor (LHCGR) plays an essential role in ovarian follicular function, mediating the action of LH on theca cell steroidogenesis and, in the preovulatory follicle, on granulosa cell (GC) steroid production and the ovulatory cascade. Following ovulation, LH (and CG) are responsible for maintenance and function of the corpus luteum. Arrested antral follicle development in PCOS is characterised by premature responsiveness of GCs to LH and recent studies in our laboratory have indicated that LHCGR mRNA is increased in GCs of small, human antral follicles (hSAFs). A similarly increased gene expression of LHCGR was observed in granulosa-lutein cells (GLCs) from PCOS women. Several previous studies point to the interaction of LH with members of the TGF-β

family. TGF-β's, activin, inhibins and AMH have all been implicated in modulating LH action in both theca and granulosa cells. In our recent study we found that aberrant expression of LHCGR in GCs of hSAFs in PCOS, was associated with increased expression of inhibin A, but not of inhibin B, AMH, AMH receptor 2 (AMHR2) or follistatin. Nevertheless, there are functional studies that implicate AMH in abnormalities of gonadotropin-induced steroidogenesis in women with PCOS and there remains considerable scope for further investigation in attempting to understand what role the interaction between gonadotropins and members of the TGF-β family has to play in the mechanism of anovulation in PCOS.

S13.3

Cell-specific expression of TGF-β family members in follicles of women with and without PCOS

Jane Alrø Bøtkjær
Laboratory of Reproductive Biology, The Juliane Marie Centre for Women, Children and Reproduction, University Hospital of Copenhagen, Denmark

Polycystic ovary syndrome (PCOS) is a common endocrine disorder, affecting 5 – 10% of women of reproductive age, and is the major cause of anovulatory infertility. The mechanisms of reproductive dysfunction in PCOS remain to be clarified. Members of the TGF-β and IGF signalling pathway have been suggested to be involved in aberrant follicle development in women with PCOS. This talk will focus on previous and ongoing research that we carried out in Denmark and the United Kingdom, which imply differences in follicular TGF-β and IGF signalling between women with and without polycystic ovaries (PCO). The results in this talk are based on materials obtained from follicle fluids (FFs), granulosa cells (GCs), and fixed human small antral follicles (hSAFs) collected from women with and without PCO undergoing ovarian tissue cryopreservation as well as granulosa lutein cells (GLCs) collected from women undergoing IVF. Protein levels of inhibin-A and inhibin-B were significantly lower in FFs from women with PCO (hSAFs < 8 mm). *AMH* and *AMHR2* gene expression and AMH FF-levels in hSAFs < 8 mm did not differ between the groups, however, FF-levels of AMH remained high in hSAFs > 8 mm from women with PCO. FF-levels of GDF9 were higher, whereas levels of BMP15 were reduced in PCO women (follicles > 6 mm). Gene expression levels of inhibitors (stanniocalcins) of the IGF signalling were downregulated in GLCs of women with PCOS. Further, FF-levels of PAPP-A (enhances IGF signalling) in hSAFs were reduced in women with PCO. AMH, PAPP-A, and stanniocalcin proteins were identified and localised by immunohistochemistry in ovaries of both PCO and non-PCO subjects. In conclusion, aberrant levels of TGF-β and IGF members in ovaries from women with PCO(S) highlight dysregulated growth factor signalling as a contributory mechanism in follicle arrest and anovulation in PCOS.

Symposium 14: Complex clinical cases

S14.1

GH: too much, too early

Giovanna Mantovani
Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Department of Clinical Sciences and Community Health, University of Milan; Milan, Italy

According to the WHO classification and to clinical practice most pituitary tumors are benign, although invasion and aggressive behavior, as well as resistance to somatostatin/dopamine (SS/DA) analogs, occur in 25 – 50% of cases. In particular, genetic forms of acrogigantism (X-linked acrogigantism - X-LAG) are characterized by a very precocious and resistant phenotype associated with microduplications in the Xq26.3 region involving the GPR101 gene. The GPR101 gene encodes an orphan G protein-coupled receptor strongly expressed in the human normal pituitary during fetal development as well as in adolescence but not in adult pituitary. The molecular mechanism of pituitary tumorigenesis involves cAMP pathway activation. Indeed, GPR101 is constitutively coupled with stimulatory G proteins, leading to intracellular cAMP accumulation, with direct effects on somatotroph cells proliferation and GH secretion. The pathogenic mechanism may also involve the ability of GPR101 to increase GHRH secretion by hypothalamus, accordingly to the elevated circulating GHRH levels described in some XLAG patients. A young woman, now 24 years-old, has been followed at our Institution since she was 2. At that time, gigantism due to an endo and suprasellar GH-secreting pituitary macroadenoma was diagnosed and she underwent a first trans-sfenoidal neurosurgery at the age of 3. Because of persistent disease, she was treated with first-generation somatostatin analogues associated with cabergoline and then with pegvisomant. At the age of 18 she was operated for the second time but pharmacological treatment was again necessary after surgery. Since then, she was treated with octreotide, cabergoline, pasireotide and pegvisomant. The diagnosis of acrogigantism due to a microduplication in the Xq26.3 region was finally made when she was 18. The talk will describe in detail her clinical history focusing on the multimodal approach. It will also summarize the current knowledge on the clinical presentation and evolution of this rare disease.

Alternative splicing in breast cancer

Manuel D Gahete
Department of Cell Biology, Physiology, and Immunology, University of Cordoba, Spain

The dysregulation of the splicing process has emerged as a novel hallmark of metabolic and tumor pathologies. Specifically, in breast cancer (BCa), which represents the most diagnosed cancer type among women worldwide, several oncogenic splicing variants have been reported to have a relevant pathophysiological role. This is the case of the splicing variants of HER2 gene, or the In1-ghrelin and SST5TMD4 isoforms, which exhibit oncogenic roles, increasing the malignancy, poor prognosis and resistance to treatment of BCa. However, the implication and putative dysregulation of the elements belonging to the macromolecular machinery that regulate the splicing process [spliceosome components (SCs) and the associated splicing factors (SFs)] have not been systematically explored in BCa. Similarly, the impact of the metabolic status (i.e. obesity) of the patients on the regulation of the splicing machinery in the context of BCa has not been explored. A recent study from our group has characterized the expression pattern of key SCs (n = 17) and associated SFs (n = 28) in the tissue of 69 patients with BCa and 50 non-tumoral controls, demonstrating a profound dysregulation of the splicing machinery in BCa samples (i.e. upregulation of ESRP1 or SRSF10 and downregulation of CELF4, NOVA1 or PTBP1). These alterations have been found in other external cohorts (TCGA, Curtis) and correlate with the expression of oncogenic splicing variants, poor prognosis and reduced survival of the patients. Interestingly, the obesity and post-menopausal status clearly influenced the expression levels of certain splicing machinery components (i.e. SRSF3 or SRSF9) under normal and/or tumoral (BCa) conditions. In addition, the experimental modulation of these altered factors impacted the aggressiveness and tumorigenic potential of different BCa cell lines. In conclusion, there are growing evidence indicating that splicing machinery is deeply dysregulated in BCa samples, finely influenced by obesity and menopausal status and implicated in the tumorigenic potential of BCa cells.

Symposium 17: New advances in the managements of hypophosphatemia

S17.1

Pathogenesis and pathophysiology of hypophosphatemia

Signe Beck-Nielsen
Centre for Rare Diseases, Aarhus University Hospital, Aarhus, Denmark

The maintenance of a phosphate level within the normal range in the body is essential for an optimal function of several vital processes. Phosphate is an important component of bone and teeth, cell membranes, phospholipids, nucleic acids, enzyme systems, the energy carrier adenosine triphosphate (ATP) among others. Thus, the state of hypophosphatemia potentially disturbs many processes in the body. Hypophosphatemia may be mild, moderate or severe and may develop in acute or chronic disease processes. Examples of diseases characterised by acute hypophosphatemia are refeeding syndrome, diabetic ketoacidosis, and respiratory alkalosis in severe, acute diseases. Most often, chronic hypophosphatemia arises due to increased renal phosphate excretion. X-linked hypophosphatemia (XLH) is an inborn disease where a mutation in *PHEX* leads to an increased level of fibroblast growth-factor 23 (FGF23), being the main regulatory hormone for the phosphate homeostasis. Increased levels of FGF23 leads to increased renal phosphate excretion in addition to inappropriately low levels of active vitamin D, 1,25-dihydroxyvitamin D. During periods of skeletal growth, hypophosphatemia causes rickets and osteomalacia, leading to dysproportionate short stature and often bowing of weight bearing long bones. In addition, dental abscesses may occur. Adults with XLH experience osteomalacia, arthrosis, muscle fatigue, and increasing number of dental abscesses by age. A rare achieved phosphate disorder is tumour induced osteomalacia, TIO. An often very little tumour with excess production of FGF23 may lead to invalidating symptoms due to severe hypophosphatemia. In addition, the state of i.v. iron induced, FGF23 mediated hypophosphatemic osteomalacia is a rare complication to medical treatment. These are important differential diagnoses as they are potentially curative.

Symposium 18: The future of endocrinology Artificial Intelligence (AI) and big data!

S18.1

AI in the clinical setting

Didac Mauricio
Hospital Germans Trias Pujol, Department of Endocrinology, Badalona, Spain

There are different activities related to health care that are currently generating a large amount of data. Real-world evidence studies are becoming an important source of information that complements the one produced through other sources of evidence. On top of this, current knowledge in the field of massive data analysis allows processing of these data to produce relevant information that will eventually help clinicians in many aspects of their daily practice, especially regarding decision making. The aim of this talk is to provide the non-expert view on the applicability of the information produced from big data and its innovative analytical methodology. Several examples on the applicability of this approach in the field of endocrine and metabolic diseases will be provided during this presentation: endocrine imaging, thyroid disease, diabetes mellitus, obesity, and other endocrine conditions. Examples will include the application of AI in key areas like prevention, diagnosis, monitoring, therapeutics, and prognosis. The use of information obtained from big data through newer analytical approaches (e.g., artificial intelligence) will the basis of a changing scenario in the clinical practice of endocrinologists in the forthcoming years. Further, improved data management and newer tools derived from more precise information will contribute a better implementation of individualized endocrinology.

AI in endocrine learning

Miguel Sampedro-Núñez
Department of Endocrinology and Nutrition, Hospital Universitario de la Princesa, Instituto de Investigación Princesa, Universidad Autónoma de Madrid, Madrid, Spain

Artificial intelligence (A.I.) impacts patient care but it is also evolving our educational system. Several experts have pointed out the benefits and limitations associated with its use in medicine, however the applications of A.I. in an educational context requires further discussion. The rising popularity of A.I. for medical solutions is evident from the increasing amount of research conducted on this subject, and Endocrine Education should not be an exception. Researchers have proposed that A.I. could be used to analyze data to identify struggling students, similarly it can be used to assist teachers in creating personalized methods for said students increasing the chances of success. On the other hand, future endocrinologists should be able to utilize the expansive databases and other appropriate tools, resulting in a massive volume of information that can overwhelm students. In this context mentorship on data management should be provided by main endocrine societies. Furthermore, electronic health records highlight the impact of natural language processing and affect medical education. Endocrinologists in the future could learn about the natural history of chronic diseases and better identify endocrine pathologies, greatly reducing the diagnosis timeframe. There is also an opportunity to develop Endocrine Healthcare Leaders with expertise in Big Data and A.I., this newly trained professional could be the bridge between clinicians and data specialists to develop A.I. Projects. Therefore, A.I. and its applications should be taught within Endocrine Societies and needs to be formalized to train the next generations of endocrinologists with a new set of skills that will directly impact not only our education system but patient care as well.

Symposium 19: Emerging concerns in reproduction

S19.1

Influence of the pre- and post-natal environment upon metabolic physiology of the offspring

Julie A. Chowen
Department of Endocrinology, Hospital Infantil Universitario Niño Jesús. Instituto de Investigación la Princesa, CIBERobn and IMDEA de Alimentación. Madrid Spain

Our health and wellbeing are influenced by numerous factors, including our early developmental hormonal and nutritional environments. Indeed, modifications of hormones and nutrition during specific developmental periods can have long-lasting effects on fundamental functions such as metabolism and reproduction, with these long-term changes often being sex dependent. Moreover, modifications in one neuroendocrine system can have an important impact on other neuroendocrine axes, as well as on the propensity to suffer specific diseases later in life. Understanding how these processes interact throughout life is of great importance to improve health and wellbeing. We have employed various experimental models in attempt to understand how modifications in the fetal and neonatal environments can affect pubertal onset and metabolism in adulthood. For example, maternal separation can dramatically modify levels of hormones (e.g., leptin) implicated in the development of metabolic circuits, resulting in changes in the response to later dietary challenges and in the onset of puberty. Neonatal overnutrition also impacts on pubertal development and metabolic health in adulthood, with these effects being different between males and females. Likewise, maternal diet has been shown to modify metabolic wellbeing in adult offspring, and we have recently found that maternal intake of the polyphenol, resveratrol, impacts on the offspring's metabolic health in a sex specific manner, and more surprisingly, the response depends on whether the maternal diet is high fat or low fat. This talk will summarize the findings of the different models employed to support the hypothesis that our early developmental experiences have long-lasting effects on puberty and metabolism, as well as on our susceptibility to other diseases.

Epigenetics in NENs – lessons from MEN1-NENs models

Kate Lines
University of Oxford, Oxford, United Kingdom

Epigenetic mechanisms are gaining increasing interest in oncology, both as drivers of tumourigenesis and as potential novel therapeutic targets. This is particularly relevant in neuroendocrine neoplasms (NENs), as a key tumour suppressor gene involved in NEN development, multiple endocrine neoplasia type 1 (*MEN1*), plays a critical role in epigenetic regulation of gene expression through micro RNA (miRNA) and histone modification pathways. *MEN1* mutations can give rise to sporadic NENs, or those occurring as part of the MEN1 syndrome in which patients predominately develop parathyroid adenomas, and NENs of the pancreas, and pituitary. Investigation of these tumours in MEN1 models has revealed insights in to the utility of epigenetics in NENs for modulating cell proliferation. For example, menin (encoded by *MEN1*) knockout results in reduced expression of the miRNA's miR-15a and miR-16-1 with a concomitant increase in the

cell cycle regulator cyclin D1 expression, which promotes cell proliferation. In addition, menin is an essential component of histone methyltransferase and deacetylation complexes, interacting with proteins including mixed lineage leukaemia 1 (MLL1), MLL2 and protein arginine methyltransferase 5 (PRMT5). Current medical treatments for NENs have limited efficacy, therefore epigenetic inhibitors targeting these specific histone modification complexes offer a promising new class of drugs for NENs. Thus, JQ1, an inhibitor of the bromo and extra-terminal (BET) protein family that bind acetylated histones, can reduce proliferation and increase apoptosis of both pancreatic NEN cell lines and pancreatic NENs occurring in a conditional *MEN1* knockout mouse model. Furthermore, JQ1 can decrease proliferation and increase apoptosis of the pituitary tumour cell line AtT20, as well as downregulate expression of the *Pomc* gene, and subsequently reduce adrenocorticotropic hormone (ACTH) secretion. Therefore, advancing our knowledge of epigenetic mechanisms may provide a novel therapeutic approach for the control of NEN growth, and hormone secretion.

Symposium 22: From adrenal stem cells to ACC

S22.1

Adrenal cortex ageing and cancer

Katie Basham
Hammer Lab, University of Michigan Comprehensive Cancer Center, United States

The adrenal cortex functions to produce steroid hormones that are essential for life and regulate key biological processes, such as control of blood pressure, metabolism, reproduction, stress, and the immune response. In order to achieve both a rapid and precise response, the adrenal cortex employs hormonal feedforward-feedback systems that function in the context of histologically distinct adrenocortical zones. These layers, the outer zona glomerulosa (zG), intermediate zona fasciculata (zF), and inner zona reticularis (zR), produce mineralocorticoids, glucocorticoids, and androgens, respectively. Functional zonation within the adrenal cortex is established by centripetal differentiation, where multipotent progenitor cells in the mesenchymal capsule and outer zG give rise to concentric layers of differentiated cortex. Previous studies have shown that the Wnt/b-catenin signaling pathway is essential for maintaining adrenal progenitor cells and allowing for proper homeostatic renewal. This presentation will focus on more recent studies examining (1) how varying levels of Wnt/b-catenin signaling are regulated during adrenal homeostasis, (2) premature ageing and cellular senescence that result from Wnt-driven hyperproliferation, and (3) the potential role of cellular senescence in adrenal cancer and its therapeutic implications.

Clinical Case: Papillary thyroid cancer: A surgical disease

Antonio Sitges-Serra
Endocrine Surgery Unit, Hospital del Mar, Universitat Autònoma de Barcelona, Barcelona, Spain

Case history
A 27 year-old woman presents with a right 3 cm. papillary thyroid cancer (PTC) with lateral cervical lymph node metastasis. Her past history is irrelevant. Treatment consists of total thyroidectomy plus lymphadenectomy of compartments II-III-IV-VI. iPTH and s-Ca concentrations at 24 h were 6 pg/ml and 7 mg/dl respectively. Replacement therapy (calcium + calcitriol) was required for three months (protracted hypoparathyroidism). Pathology reveals a 27 mm. non-encapsulated PTC of follicular variant, with 0N+/6N in the central neck and 6N+/24N in the lateral neck (T2N1bM0, skip metastasis). One ipsilateral parathyroid gland was found in the specimen (PGRIS 3). At three months postop her stimulated Tg was undetectable and iPTH 39 pg/ml. Suppressive T4 was administered for three years. No radioidine ablation was performed. The patient has been followed wit basal Tg determinations and neck ultrasound once a year for ten years and then every two years up to 20 years. She is currently disease-free.
Comment
There is no such thing as “differentiated thyroid cancer”. PTC and follicular thyroid cancer have different clinical presentation, biological behaviour and require different therapeutic approaches and risk assessment. RAI ablation is losing momentum in the treatment of PTC because specialized surgical treatment can render patients biochemically cured. Survival and recurrence rates of classical PTC completely resected and with no distant metastasis, are not influenced by RAI ablation. Thorough surgery including total thyroidectomy, routine central neck dissection plus elective lateral dissection based on preoperative ultrasound, and a bland follow-up is all

that is needed for most patients with PTC. Permanent hypoparathyroidism remains the main postoperative complication, but it can be minimized (< 5%) by avoiding accidental parathyroidectomy and autotransplantation, and referring patients to high-volume centres. Routine postoperative scans, repeated thyroglobulin stimulations and aggressive imaging techniques to investigate minimally elevated thyroglobulin concentrations are obsolete.

How to discriminate between PHPT and FHH

Ghada El-Hajj Fuleihan
American University of Beirut Medical Center, Beirut, Lebanon

Primary hyperparathyroidism (PHPT) is a common and for the most part an asymptomatic endocrine disorder, usually discovered by routine biochemical screening, in western populations; and increasingly now in other parts of the word. It is characterized by abnormal calcium-PTH dynamics, manifesting with mild hypercalcemia, with increased or inappropriately normal plasma parathyroid hormone (PTH) levels. PHPT is most commonly seen in older post-menopausal women. In countries where routine biochemical testing is lacking, patients present with symptoms of bony pain, fractures, and nephrolithiasis. Cardiovascular and neuropsychiatric abnormalities have been described, mortality is increased, and quality of life may be decreased. Parathyroidectomy is the treatment of choice in symptomatic patients, with improvement in bone density, and a decrease in stone risk. Reversibility of other above-mentioned associated conditions is less clear. PHPT may occur in the setting of heritable disorders in 10% of all cases, some syndromic (MENs) and other non-syndromic such as familial hypocalciuric hypercalcemia(FHH), presentations. The pathophysiology of non-hereditary PHPT is not totally clear. *The calcium-sensing receptor (CaSR)* is the major regulator of PTH release and plays a central role in keeping serum ionized calcium (Ca_i) within a very narrow physiologic range. Clonal somatic mutations and allelilc loss of the CaSR do not play a role in most cases of sporadic PHPT. Recent data suggest that certain SNPs of *CASR* gene may increase the risk of PHPT. Alterations in CaSR expression due to hypermethylation of the *CaSR* promoter or increased formation of heteromeric receptor complexes of the CaSR and $GABA_{B1}R$ may contribute to pathophysiology of PHPT. *FHH:* is an autosomal dominant benign condition characterized by loss of function mutations of CaSR, or distal to it. FHH is characterized by mild hypercalcemia, with inappropriately normal or slightly elevated serum PTH levels, and low urinary calcium excretion. A heterozygous germline inactivating mutation of the CASR on 3q21.1 accounts for 2/3 of cases (FHH1), while the remaining result from mutations downstream of the CaSR; in GNA11 located on 19p13.3 (FHH2), in AP2S1 on 19q13.2-q13.3 (FHH3), or from other unknown mutations. Presentation at a young age, before age 30 years, a family history of failed PTX, and the absence of end organ damage (low BMD, stones nephrolithiasis), are strong indicators of FHH. However, it has become increasingly clear that there may be overlap in the clinical presentation and biochemical phenotype of PHPT and FHH. DNA testing may be instrumental in differentiating the two entities.

ESE/ESPE Joint Session: Transition – A step into the unknown

JS2.1

Transition of the patient with GHD

Mohamad Maghnie
IRCCS, Istituto Giannina Gaslini, University of Genova, Genova, Italy

GH plays a crucial role not only for growth, but also for the acquisition of bone mass and muscle strength. This process is completed after the achievement of adult height in the phase of transition from adolescence to adulthood. Therefore, continuation of GH replacement therapy in the transition age is essential in patients with a childhood-onset diagnosis of GHD. Higher likelihood of persistence is ovserved in patients with an early age at diagnosis, anatomical, organic, or genetic causes, and MPHD. Repeating a GH stimulation test is not necessary for patients with MPHD (≥ 3 PHD) and low-serum IGF-1 concentrations (<–2.0 SDS), in patients with documented genetic defects affecting pituitary function, and in patients with hypothalamic-pituitary structural brain defects. In these cases, rhGH therapy can be continued without interruption, although the dose should be reduced to the adult age dose. Indeed, patients with idiopathic IGHD and an IGF-1 ≥ 0 SDS are not likely to have persistent GHD, and hence transition therapy may not be necessary. There is still controversy about which limit for a normal GH response should be considered for the transition age group, and the lack of strong evidence leads to variable clinical practice. According to the last Consensus of 2019, the ITT remains the gold-standard test for establishing the diagnosis of young adult GHD using a peak GH cut-point of ≤ 5.0 µg/l, while according to others the optimal GH cut-off value after adult height achievement is 6 µg/l. While recent data have suggested that combined GHRH and arginine is unreliable and may fail to recognize patients with permanent GHD of different etiologies, it should be emphasized that the validated normative data of glucagon-stimulation test and macimorelin in transition age are still lacking.

Fractures

Luigi di Filippo
Department of Endocrinology, Vita-Salute San Raffaele University and IRCCS San Raffaele Scientific Institute, Milan, Italy

Osteoporotic fractures are the main clinical manifestations of skeletal fragility and are associated with decreased survival and impaired quality of life in the general population. At the beginning of COVID-19 spread in Europe, despite several studies investigated COVID-19 clinical characteristics, no data were reported on the prevalence of vertebral fractures (VFs) in patients affected and disease impact on osteoporotic patients. We performed a retrospective study at San Raffaele Hospital, a tertiary health care hospital in Italy, to assess VFs prevalence including COVID-19 patients for whom lateral chest x-rays at emergency department were available. VFs were detected using a semi-quantitative evaluation of vertebral shape. A total of 114 patients were included and thoracic VFs were detected in 41 patients (36%). Patients with VFs were older and more frequently affected by hypertension and cardiovascular disease ($P < 0.001$, $P = 0.007$, $P = 0.034$). Thirty-six (88%) patients in VFs+ group and 54 (74%) in VFs- group were hospitalized ($P = 0.08$). Patients with VFs more frequently required noninvasive mechanical ventilation compared with those without VFs ($P = 0.02$). Mortality was 22% in VFs+ group and 10% in VFs- group ($P = 0.07$). In particular, mortality was higher in patients with severe VFs compared with those with moderate and mild VFs ($P = 0.04$). Furthermore, a recent review reported COVID-19 likely an additional mortality risk factor in patients with hip fractures exceeding the previously reported mortality rate in fractured patients or COVID-19 alone. The COVID-19 hyperinflammatory response may amplify the "first-hit" inflammatory state of fracture trauma and thereby predispose to a severe thromboembolic "second-hit", whether the patient is symptomatic or not. VFs may integrate the cardiorespiratory risk of COVID-19 patients, being a useful clinical marker of fragility particularly in osteoporotic patients that are themselves at high risk of COVID-19 poor prognosis.

Acromegaly and Covid-19

Marcello D. Bronstein
Division of Endocrinology and Metabolism, Hospital das Clinicas, University of São Paulo, São Paulo, Brazil.

Acromegaly is a chronic disease caused almost invariably by a pituitary GH-secreting adenoma leading to overproduction of insulin-like growth factor I (IGF-I). The long-term hypersecretion leads to many comorbidities, as diabetes mellitus, arterial hypertension, and cardiovascular and/or pulmonary disease (including sleep apnea), which are related to an increased mortality rate. In fact, uncontrolled acromegaly is associated with a three times mortality rate as compared with normal population. Treatment of acromegaly can restore mortality rate to that of normal population. Transsphenoidal pituitary surgery is considered the first treatment option for most cases, being first generation somatostatin receptor ligands (SRL-octreotide LAR or lanreotide Autogel) and second generation SRL (pasireotide LAR), among other drugs, reserved for uncontrolled patients after surgery and for those to whom surgical procedure is not indicated. Therefore, it is of note that patients with uncontrolled acromegaly harbor the same comorbitities associated with poor prognosis for COVID-19 pandemics caused by SAR-COV-2 virus. Therefore, is crucial that acromegaly should be controlled, especially regarding the COVID-19 pandemics. Concerning medical treatment, an increase of QTc interval is a possible side effect of SRL´s, the main class of drugs used to treat acromegaly. Also drugs that have been proven to be inefficacious for COVID-19 prevention/treatment but still used as chloroquine and azithromycin and its association may prolong QTc intervals. Considering that acromegaly itself can increase QTc interval and risk of arrhythmias, the use of the above mentioned drugs should be avoided or strictly monitored. Also the hyperglycemic effect of SRL´s, especially pasireotide, should be considered. The impact of COVID-19 pandemics in acromegaly care is of relevance. Pituitary surgery has been frequently postponed, either due to risk of virus transmission or to lack of hospital availability. Also the monthly visit to medical facilities to get SRL´s injections shot has been severely compromised. Therefore, patients and health care staff need to be adapted to these changes in order to keep the disease and comorbidities controlled and to prevent acute illnesses such COVID-19 by vaccination and safety measures as masks and social isolation.

Hypopituitarism & Covid-19

Karina Danilowicz
Hospital de Clinicas, Jose de San Martin, UBA, Argentina

In December 2019, the outbreak of coronavirus disease (COVID-19) started in Wuhan, China[1], resulting in a global pandemic. A novel coronavirus (SARS-CoV-2) was identified. The virus enters the pneumocyte through the angiotensin-converting enzyme 2 (ACE2) as a receptor[2]. The enzyme is widely expressed. A relationship between COVID-19 and the endocrine system occurs at multiple levels. On autopsies, infarct, edema, and neuronal degeneration with SARS-CoV genoma have been identified in the hypothalamus. Low normal TSH and thyroid hormone levels have been described suggesting a central mechanism related to cytokines. Mortality rate is increased in hipopituitarism mainly due to cardiovascular and cerebrovascular disease, and these are risk factors for COVID-19 disease severity. Hypopituitarism impacts the course and management of COVID-19, specially in the context of adrenal insufficiency. Among the causes of hypopituitarism, pituitary apoplexy should be particularly considered. Adrenal insufficient patients seem not to be at paticular risk of COVID-19; however, they are susceptible to infections, and worse outcomes may be expected. The diagnostic approach does not differ from usual clinical practices. However, face-to-face contact with medical staff and other healthcare professionals should be limited to extremely necessary situations. Central diabetes insipidus may be at risk of more severe dysnatraemia when developing respiratory complications of COVID-19. Dose adjustment of pituitary hormone replacement can be performed by clinical assessment. And if supplies are not available, GH and gonadal replacement can be discontinued for a short time[3]. In the context of severe COVID illness, hydrocortisone should be adjusted to stress doses and desmopressin should be given parenterally. Education for AI patients is the basis for a better evolution, reminding about sick day management, and adequate supply.

Living with androgen insensitivity syndrome - Multidisciplinary care team and research

Martine Cools
Ghent University Hospital and Ghent University

Men and women who have AIS face a number of challenges. Based on research insights from the past two decades, management of this pleiotropic condition during childhood has totally changed. In this presentation, we will update endocrinologists who provide care for adults living with AIS about these changes, as they will, after transition, need to further counsel their patients and coordinate multidisciplinary care and surveillance of retained gonads in adulthood. Girls with complete AIS are fully informed about the condition in all its aspects already in early childhood. Research has demonstrated that their testes can be safely retained at least until the end of puberty, and possibly beyond, provided that optimal surveillance of tumour risk can be offered. Vaginal self-dilation has become a first choice therapy for vaginal hypoplasia but requires a supporting and experienced team. Remaining uncertainties with regard to long-term outcomes of these new approaches will need to be addressed in future research. Partial AIS in many cases remains a diagnostic odyssey. Non-coding and even epigenetic changes may underlie the condition, and with the advent of cutting-edge genomic strategies and innovative functional studies, re-testing can be considered in individuals who have remained for years without a molecular genetic diagnosis. As genital surgery in childhood becomes increasingly controversial, a new generation of children with partial AIS grows up with atypical genitalia. There is an urgent need to understand how this influences psychosocial and psychosexual development and gender well-being throughout life. In addition, individuals who have partial AIS more often grow up as boys nowadays, requiring novel strategies to address short penile length and breast development, as well as surveillance of retained gonads, and sometimes fertility. As for other DSD conditions, full transparency, adequate psychosocial support and peer contacts have been associated with positive outcomes and will in this presentation be placed ad the heart of multidisciplinary care.

Diagnostics and treatment of post - bariatric surgery hypoglycaemia

Loek de Heide
Department of Bariatric and Metabolic surgery, CON, Medical Center Leeuwarden, The Netherlands

Stimulation of insulin release by increased gut hormone levels after gastric bypass surgery, especially glucagonlike polypeptide-1(GLP-1), is considered to be the most important mechanism of action in diabetes remission. However, these beneficial effects can come at a price, namely the development of postprandial hyperinsulinaemic hypoglycaemia, more often called post bariatric hypoglycaemie (PBH). The exact pathophysiology of PBH is not known but GLP-1 plays an important role as blocking the receptor with exendin 9-39 can abolish the occurrence of hypoglycaemia. Altered betacel response, insulin sensitivity, FGF-19, bile acids and the gut microbioma probably also play a role. There is no established definition of PBH as it is probably part of a sliding scale of postprandial glucose values. Consequently, none of the diagnostic tools, self-measured blood glucose, provoking tests like OGTT and MMT, or CGM have established cut-off values. Most authors agree with the diagnosis of PBH in the combination of neuroglycopenic symptoms, a blood glucose level < 2.8 mmol/l with resolution of symptoms with correction of the hypoglycaemia (Whipple's triad). Treatment of PBH is not supported by well designed studies but relies mainly on clinical experience and case reports. A diet low in carbohydrates is the first step, lowering glucose excursions and thereby diminishing insulin release. Off-label medical treatment is a matter of trial and error and consists of acarbose, reducing postprandial glucose rise, somatostatin analogues, reducing GLP-1 and insulin release, diazoxide, inhibiting insulin secretion or liraglutide, a GLP-1 agonist, the mechanism of action is currently not known. Avexitide, exendin 9-39, a GLP-1r antagonist and colesevelam are promising new medications. Surgical options for PBH, resistant to medication are banding the pouch, placing a feeding tube in the native stomache, an undo operation or even pancreatectomy, all with limited success.

Investigation, treatment and monitoring of functional hypogonadism in males

Dirk Vanderschueren
Endocrinology, KU Leuven, Belgium

The focus of the new guidelines of the European academy of andrology is on functional hypogonadism since the diagnosis and treatment is more controversial than for organic hypogonadism. It is important to consider functional hypogonadism, only following formal exclusion of organic hypogonadism. Diagnosis should be made on basis of both clinical symptoms as well as the biochemical confirmation of serum repeatedly low morning fasting testosterone. Most specific symptoms are sexual complaints such as low libido and erectile dysfunction. Functional hypogonadism is commonly associated with overweight, metabolic syndrome and /or type 2 diabetes.

Lifestyle changes as well as weight reduction should be the first approach in obese men since functional hypogonadism may be reversible. Several drugs may also induce functional hypogonadism and withdrawal should be considered if possible in first instance. Testosterone replacement therapy (TRT) (preferably in first line via transdermal route) can be considered in order to improve sexual symptoms after exclusion of a number of absolute and relative exclusions of contraindications in shared decision with the patient. Positive effects of TRT on endpoints other than sexual symptoms are less well established. Not only improvement of sexual symptoms but also monitoring of serum hematocrit, testosterone and PSA is needed. More data, especially with respect to cardiovascular safety for long term TRT, are needed but may become available in the near future.

Regeneration or replacement of beta cells

Lorenzo Piemonti
Diabetes Research Institute, IRCCS San Raffaele Scientific Institute, Milan, Italy

In patients with type 1 diabetes (T1D), pancreatic β cells are destroyed by a selective autoimmune attack and their replacement with functional insulin-producing cells is the only possible cure for this disease. The field of islet transplantation has evolved significantly from the breakthrough of the Edmonton Protocol in 2000, since significant advances in islet isolation and engraftment, together with improved immunosuppressive strategies, have been reported. The main limitations, however, remain the insufficient supply of human tissue and the need for lifelong immunosuppression therapy. Great effort is then invested in finding innovative sources of insulin-producing β cells. One old alternative with new recent perspectives is the use of non-human donor cells, in particular porcine β cells. Also the field of preexisting β cell expansion has advanced, with the development of new human β cell lines. Yet, large-scale production of human insulin-producing cells from stem cells is the most recent and promising alternative. In particular, the optimization of in vitro strategies to differentiate human embryonic stem cells into mature insulin-secreting β cells has made considerable progress and recently led to the first clinical trial of stem cell treatment for T1D. Finally, the discovery that it is possible to derive human induced pluripotent stem cells from somatic cells has raised the possibility that a sufficient amount of patient-specific β cells can be derived from patients through cell reprogramming and differentiation, suggesting that in the future there might be a cell therapy without immunosuppression.

Multiplex analysis platform for endocrine disruption prediction using zebrafish

Sergio Jarque, Jone Ibarra, Maria Rubio-Brotons, Jessica García-Fernández, Javier Terriente
Zeclinics SL, Badalona, Spain

Small fish are excellent experimental models to screen endocrine-disrupting compounds, but current fish-based assays to detect endocrine disruption have not been standardized yet, meaning that there is not consensus on endpoints and biomarkers to be measured. Moreover, exposure conditions may vary depending on the species used as the experimental model or the endocrine pathway evaluated. Another drawback is the fact that most methods to detect endocrine disruption rely on the use of adults, falling therefore in the category of animal experimentation. If not, a battery of a wide range of assays is needed for the complete assessment of endocrine activities. With the aim of providing a simple, robust, and fast assay to assess endocrine-disrupting potencies for the three major endocrine axes, i.e., estrogens, androgens, and thyroid, we propose the use of a panel of eight gene expression biomarkers in zebrafish embryos. This includes brain aromatase (cyp19a1b) and vitellogenin 1 (vtg1) for estrogens, cytosolic sulfotransferase 2 family 2 (sult2st3) and cytochrome P450 2k22 (cyp2k22) for androgens, and thyroid peroxidase (tpo), transthyretin (ttr), thyroid receptor α (trα), and iodothyronine deiodinase 2 (dio2) for thyroid metabolism. All of them were selected according to their responses after exposure to the natural ligands 17β-estradiol, testosterone, and 3,3′,5-triiodo-L-thyronine (T3), respectively, and subsequently validated using compounds reported as endocrine disruptors in previous studies. Cross-talk effects were also evaluated. Importantly, EC50s observed in zebrafish larvae, although higher in terms of efficiency, showed strong correlation with those obtained in adults, pointing out the model as suitable alternative for animal testing.

AGAINST: CGM for all people with diabetes?

Luigi Laviola
Department of Emergency and Organ Transplantation, Section on Internal Medicine, Endocrinology, Andrology and Metabolic Diseases, University of Bari Aldo Moro, Bari, Italy

In people with diabetes, optimizing glucose control is critical to reduce the risk of both acute and chronic complications. Technologies measuring interstitial glucose concentrations provide professional teams and patients with glucose data and interpretation tools which can improve metabolic control and optimize therapy management. There is strong evidence supporting both rtCGM and FGM use in people with type 1 diabetes (T1DM), with benefits of reduced HbA1c and hypoglycaemia, and increased time in range. Similar benefits have been demonstrated in insulin-treated type 2 diabetic patients (T2DM). By contrast, evidence in non-insulin treated T2DM is less robust, with scarce RCTs and some observational studies showing limited or no impact on HbA1c and hypoglycemia. Notably, in most trials comparing CGM with SMBG in T2DM, the control arm was not on structured SMBG, which has been shown *per se* to significantly reduce HbA1c. Thus, the overall cost-benefit evaluation does not support continuous glucose monitoring in most T2DM. Thus, it seems reasonable to follow a personalized, patient-centered approach in taking advantage of the available CGM devices: T1DM and T2DM on MDI should be offered the opportunity to wear glucose sensors to improve metabolic control and glucose metrics. On the other hand, most DMT2 should be encouraged to exploit the benefits of adequately structured SMBG. Retrospective or intermittent CGM may be proposed in these patients, aiming at optimizing therapy and lifestyle management and increasing awareness of glucose patterns. As technology provides more and more accurate and reliable tools, more clinical research projects and a wider use of these devices will increase the expertise of diabetes teams and ultimately improve everyday life in people with diabetes.

Debate 3: Selenium for autoimmune thyroid disorders: necessary or unnecessary?

D3.1

AGAINST: Selenium for autoimmune thyroid disorders: necessary or unnecessary?

Steen J. Bonnema
Department of Endocrinology and Metabolism, Odense University Hospital, Odense, Denmark

Selenium is an essential element for humans. Important dietary sources of selenium include meat, seafood, and grains. Selenium is incorporated into a range of selenoenzymes with antioxidant properties. Being crucial for the activity of the deiodinase enzymes, selenium is especially important for the synthesis and metabolism of thyroid hormones. Selenium in relation to thyroid diseases has been widely explored. Epidemiological studies have shown that a low selenium status is associated with an increased risk of autoimmune thyroid diseases. This linkage may be causal as selenium supplementation seems to reduce the titer of thyroid autoantibodies in patients with autoimmune thyroiditis, probably by reducing proinflammatory cytokines. However, it is unsettled whether selenium supplementation affects the clinical course of autoimmune thyroiditis or improves quality of life in patients with this disease. In patients with mild Graves' orbitopathy, selenium supplementation reduces the orbital inflammation, while it remains to be shown that it also leads to faster remission of the hyperthyroidism. Two ongoing randomized clinical trials, one in Graves' disease and one in autoimmune thyroiditis, will help clarify the role of selenium supplementation in these disorders. Although current evidence does not support routine selenium supplementation as adjuvant treatment in patients with autoimmune thyroiditis or Graves' disease, such an approach is widely used by clinicians. While selenium deficiency should be corrected, a too high intake of selenium may result in adverse health effects. Therefore, the inclusion of selenium in the therapeutic armamentarium should be based on data from large and well-designed clinical trials.

Meet The Expert Basic Scientist 1: Histopathology of human obese adipose organ: New insights
MTEBS1

Histopathology of human obese adipose organ: New insights
Saverio Cinti
Marche Polytechnic University, Piazza Roma, Italy

Since 2003 there is a large consensus on the fact that obese adipose tissues of mice and humans are inflammed. This low-grade chronic inflammation is linked to insulin resistance inducing to type2 diabetes (T2D). In 2005 we showed that inflammation is due to death of obese adipocytes whose debris require macrophages infiltration of the tissue and consequent formation of crown like structures (CLS) as the basic histopathology aspect of inflammation. In 2008 we showed that visceral adipocytes have a critical death size smaller that that of subcutaneous adipocytes and, accordingly, inflammation of visceral fat is more severe. This offer an explanation to the well known clinical data claiming visceral obesity as the condition more frequently linked to the usual obesity related disorders and mainly to the T2D. In 2013 we showed that obese adipocytes die for pyroptosis. Here we show data suggesting that in adipose tissues of obese humans (66 fat biopsies from 33 bariatric patients) a large proportion (about 13%) of hypertrophic adipocytes die for self-choking due to fibrosis. Histochemistry, immunohistochemistry, electron microscopy and gene expression data showed that single or groups of obese adipocytes are surrounded by thick bands of fibrous collagen with evidence of hypoxia and correlation with signs of death (loss of perilipin1 immunoreactivity). Inflammation was mainly sustained by macrophages, but only a minority of them formed CLS. While the increased fibrous collagen is widely accepted the amount of collagen VI in obese fat is debated. Our data showed a reduction in gene expression and the analysis of tissue from a patient with the rare mutation inducing a reduction of active collagen VI production showed fibrosis comparable with that in obese fat suggesting a causative role for this gene.

Meet The Expert Basic Scientist 2: When and how to employ molecular genetic testing in thyroid pathology?
MTEBS2

Meet The Expert Basic Scientist 2: When and how to employ molecular genetic testing in thyroid pathology?
Ralf Paschke
University of Calgary, Calgary, Canada

There are three main applications for molecular genetic testing in thyroid pathology:
1. As part of an integrated approach of careful clinical, ultrasound and FNBC assessment with local outcome data molecular analysis of fine needle biopsy cytology is able able to improve diagnostic outcomes for thyroid nodules by identifying patients with an indeterminate FNBC as most likely benign with < 5% false negatives and thus obviating diagnostic lobectomy or by identifying patients for upfront total thyroidectomy as definitive surgical treatment
2. 70% of high risk thyroid cancer patients develop a structural recurrence after total thyroidectomy and radioiodine treatment. Revision surgery and/or a second RAI treatment lead to remission in only 42 – 51% of these patients. Therefore, early prospective systematic detection of actionable driver mutations for thyroid cancer patients with local relapse or distant metastasis is needed to guide new targeted treatments such as NIS re-expression to re-enable RAI treatment or treatment with RET or NTRK inhibitors, ALK inhibitors, PAX8/PPARG agonists or emerging off label drugs. However, lack of systematic molecular analysis is the missing piece limiting access to emerging targeted and translational therapies for advanced thyroid cancer. All *BRAF* mutation-negative patients with progressive structural incomplete response to total thyroidectomy and RAI treatment, and ATA high/intermediate recurrence risk patients with progressive structural incomplete response, should be screened for *NTRK* and *RET* gene fusions to enable early intervention.
3. Several studies have reported large interobserver variability for the differential diagnosis between thyroid adenomas/adenomatous nodules and FTCs and other thyroid cancer histologies. Therefore, the current histology-based classification of thyroid tumors will ultimately most likely evolve into a blended histologic and molecular classification of thyroid tumours like for other endocrine tumors or other cancers.

Meet The Expert 1: New therapies in the treatment of thyroid ophthalmopathy
MTE1

New therapies in the treatment of thyroid ophthalmopathy
Mario Salvi
Graves' Orbitopathy Centre, Endocrinology Department, Fondazione IRCCS Ca' Granda, University of Milan, Italy

Introduction
Medical immunosuppressive treatment of Graves' orbitopathy (GO) is advised for patents with moderate-severe disease. Steroids represent the mainstay of therapy, as they possess anti-inflammatory activity, but about 20 – 30% of patients are unresponsive and up to 20% of patients may relapse. Immunosuppressive therapeutics alternative to corticosteroids are those targeting the different antigens involved in the pathogenic reactions of GO. Some of these have already been challenged in clinical studies for potential use, although the lack of randomized and controlled trials may at the moment limit their use in clinical practice.
Evidence from studies
Potential targets for therapy in GO are B and T cells, the TSH receptor and the IGF-1 receptor on the fibroblasts, inflammatory cytokines involved in the cascade of immune reactions in the early phase of disease. Consistent open study reports on the efficacy of rituximab have been confirmed by randomized controlled trials. A recent study has shown non inferiority of belimumab, an anti-BAFF monoclonal antibody, with methylprednisolone. Significant improvement of proptosis has been shown with the anti-IGF-1R monoclonal antibody teprotumumab. A recent controlled study has also shown that tocilizumab, an anti-sIL-6R antibody, inactivates GO, and another is underway.
Conclusions
Clinical practice is seeking disease modifying agents in GO as an alternative to steroids, currently standard treatment for GO. Novel therapeutics are currently indicated, especially in patients resistant to steroid or with contraindications to steroids. However, larger randomized controlled trials are needed before these drugs are shown to be more effective and can be approved for routine clinical use in GO.

What one should know on PRRT-lessons from clinical practice
David Taïeb
Aix-Marseille University

Personalized (precision) medicine has already made its mark and has the potential to enhance patient management. It consists in adapting healthcare strategies tailored to individual and disease characteristics. Nuclear medicine has a central role in personalized medicine via theranostics approaches. PRRT is now a well established treatment option for well-differentiated advanced neuroendocrine tumors (NETs). PRRT is based on the administration of somatostatin analogs (SSA) labeled with a therapeutic isotope (e.g. ^{177}Lu, ^{90}Yttrium (^{90}Y)). Before PRRT, assessment of *in vivo* SSTR expression is mandatory and is based on the use of a companion diagnostic agent corresponding to a SSA labeled with ^{68}Ga, which is now preferred for molecular imaging of NET. Beyond SSTR expression, several important factors need to be considered for determining whether an individual patient is likely to benefit from PRRT (e.g., age, general condition, tumor grade, SSTR expression profile...). In metastatic insulinomas, PRRT may be recommended as a second-line therapy after failure of diazoxide to control hypoglycemia. PRRT can also be considered in some grade 3 NETs. Overall, toxicity is limited, especially when using ^{177}Lu due to its lower tissue penetration range compared with ^{90}Y but needs to be monitor especially for hematological (bone marrow) toxicities.

Difficult Phaeochromocytoma cases
Tomáš Zelinka
Charles University, Prague, Czech Republic

Phaeochromocytoma and paraganglioma (PPGL) are rare neuroendocrine tumours arising from chromaffine cells either from adrenal medulla (phaeochromocytoma) or extra-adrenal paraganglia (paraganglioma). Phaeochromocytomas and sympathetic paragangliomas (arising from thoracic, abdominal, or pelvic sympathetic ganglia) may secrete catecholamines which are associated with the most clinical symptoms and signs whereas parasympathetic paragangliomas (arising from parasympathetic ganglia of the head and neck region) are secretory inactive. PPGL may develop metastases, in particular in those patients harbouring mutation in the *SDHB* gene. Around two thirds of phaeochromocytomas are diagnosed incidentally during morphological examinations from other reasons and only one third after targeted biochemical screening in symptomatic subjects. Symptomatology of PPGL varies from mild symptoms on one side such as headache, palpitations, and sweating (reported in around 50 – 60% of patients) to life-threatening complications such as circulatory shock, takotsubo cardiomyopathy, arrhythmias on the other side. Unique combination of signs in PPGL is the association of hypertension with orthostatic hypotension, in some cases seriously limiting quality of life. Once is PPGL diagnosed (nowadays using metanephrines either in plasma or in urine), patients are scheduled for tumour removal and prepared with ńadrenergic receptor blockers. Experienced surgeons and anaesthesiologist are required for successful tumour removal due to hemodynamic instability during and after operation. Due to the risk of recurrence or metastases (may be present also at initial presentation), patients with PPGL should be followed-up for at least 10 after the surgery.
Conclusion
Awareness of PPGL among different medical specialties such as anaesthesiology, cardiology or internal medicine may contribute to early diagnosis of PPGL which is the best prevention of potentially lethal cardiovascular complications or development of metastases.

DOI: 10.1530/endoabs.73.MTE6

Do you know how to define sarcopenic obesity?
MTE7

Do you know how to define sarcopenic obesity?
Irene Bretón
Endocrinology and Nutrition Unit. Hospital General Universitario Gregorio Marañón. Madrid, Spain

Sarcopenic obesity is a clinical condition characterized by the coexistence of excess fat mass and sarcopenia, i.e. a decrease in muscle mass or function. This coincidence leads to an increased risk of complications. Sarcopenia induces increased insulin resistance and worsens the metabolic status of obesity, while impairing functional capacity. Obesity itself can induce changes in muscle mass and function, as a consequence of changes in diet and physical activity and alterations in different hormonal axes (GH/IGF-1, hypogonadism, decreased adrenal androgens, etc.). Insulin resistance itself as well as the secretion of hormones and inflammatory mediators by adipose tissue may promote protein catabolism. There is no unanimous agreement on the diagnostic criteria for sarcopenic obesity or the most appropriate method of assessing body composition or muscle function. For this reason, the prevalence of this clinical condition is not well known, although it is more frequent in the elderly or in patients with a chronic disease that induce inflammation or increased catabolism (heart failure, pulmonary, renal or chronic liver disease). The clinical approach to the sarcopenic obese patient should be multifactorial, and treatment includes correction of predisposing factors, increased physical activity and adjustment of the dietary pattern. There is an urgent need to increase our knowledge of the factors influencing the genesis and progression of sarcopenic obesity and to define uniform diagnostic criteria accepted in the scientific community.

Meet The Expert 8: GH replacement in adults
MTE8

Growth hormone replacement therapy in adults

Maria Vorontsova
Endocrinology Research Centre, Moscow, Russia

Background
Growth hormone replacement therapy in adults is mostly used in case of adult growth hormone deficiency (AGHD). The condition is characterized by altered body composition, lower than average bone mineral density (BMD), elevated cardiovascular risks and, among other remaining factors, lower quality of life.
Main discussion topics
After over 30 years of recombinant growth hormone (rGH) usage substantial data has been accumulated to assess treatment efficacy and safety. Careful consideration should be given to the question who is eligible for rGH treatment. Transition patients warrant extra attention to determine the correct dose at a given period of time and to avoid losing the patient out of site. Body composition and increase of BMD seem to be the most prominent benefits with an increase in exercise capacity and quality of life following suit. The effects on cardiovascular risks are less certain. The ultimate end-point criteria – weather rGH therapy in adults decreases mortality – also remains unclear. With a growing interest toward endocrinology for anti-aging therapy and biohacking, physicians need to continue discussion as to what is safe and what is off-limits in situations outside of pathology. Therapy monitoring is very important during treatment to detect possible side effects and to make sure that treatment yields the expected benefits. These aspects find new importance with the development of long-lasting GH forms. Despite available data, optimal safety and efficacy biomarkers still pose a challenge. Combining rGH with other hormones warrants extra attention.
Conclusion
rGH therapy has proven positive effects on patients with GH deficiency. Some benefits, as in reduction of cardiovascular risks, remain to be determined. Finding optimal biomarkers to monitor treatment safety and efficacy remain somewhat elusive. Ever-growing interest of healthy individuals for GH treatment warrants and endocrinologist's attention.

Meet The Expert 9: Sequential osteoporosis treatments
MTE9

Sequential osteoporosis treatments

Polyzois Makras
Department of Endocrinology and Diabetes, 251 Hellenic Air Force General Hospital, Athens, Greece

Postmenopausal osteoporosis is a chronic condition requiring long-term treatment. Based on personalized patient care the physician should decide the optimal treatment strategy, namely the use of the available osteoanabolic and antiresorptive agents, sequentially or even in combination, in the most effective and safe way. Transitioning from one antiresorptive to another is probably the most common treatment sequence in clinical practice. In this context transition to a potent oral or intravenous bisphosphonate is mandatory to maintain bone mineral density (BMD) gains and avoid the rebound phenomenon and the increase in fracture risk in patients discontinuing Denosumab. Initiation with an osteoanabolic agent followed by an antiresorptive seems to be the optimal treatment sequence, at least in patients with severe osteoporosis and prevalent fractures. Treatment with an osteoanabolic following an antiresorptive agent seems to lead in more modest responses in BMD and bone turnover markers. Although switching to teriparatide is a quite common strategy among patients that either did not adequately respond to antiresorptives or have completed the maximum duration of antiresorptive treatment, this could lead to a transient loss of hip BMD and probably strength, and therefore it should be carefully followed especially in high-risk patients. Combination of teriparatide with denosumab or zoledronate has achieved higher BMD gains compared to each agent alone. On the contrary, the combination of teriparatide with alendronate results in smaller BMD increases than teriparatide monotherapy. However, due to the high cost, combination therapy is rarely reimbursed. In conclusion, it is a real challenge for the physician to set the optimal long- term osteoporosis treatment plan for each individual patient based on different needs, preferences, and peculiarities.

Meet The Expert 10: Outlook for male fertility preservation
MTE10

Outlook for male fertility preservation

Aleksander Giwercman
Department of Translational Medicine, Lund University. Malmö. Sweden

Cryopreservation of spermatozoa, has been utilized for decennia as an easily accessible tool in male fertility preservation, prior to treatment for cancer and autoimmune diseases. However, although this technique is well established, there is a number of questions regarding this procedure which still needs to be answered. Which patient groups should be offered semen cryopreservation? Are spermatozoa preserved prior to treatment safer to use for fertilization than fresh, ejaculated sperms produced after completion of cancer treatment including radiotherapy and/or medical treatment potentially hazardous to DNA? Should young cancer survivors with severe oligozoospermia be offered fertility preservation because they are at risk of azoospermia due to age related deterioration of spermatogenesis? Another emerging aspect is the question whether the indication for cryopreserving sperms should be widened: Increasing parental age is a global and well-known phenomenon. There is now an evidence showing that high paternal age is associated with increased risk of transmitting mutations and premature birth as well as higher infantile mortality. One could, therefore, consider offering freezing of spermatozoa to men wishing to postpone their fatherhood. Men with azoospermia as well as pre- and early pubertal boys represent a specific challenge due to lack of access to ejaculated sperms which can be used for cryobanking. Currently, several research groups are making attempts to develop techniques for *in vitro* and *in vivo* maturation and generation of germ cells suitable for assisted reproduction. Although we are still waiting for the final breakthrough in treatment of humans, the results of experimental studies give promises, that we in a near future will have access to one or more options for helping men for whom biological fatherhood, so far, is not possible. The development in the field of medical technology will provide new options for preserving male fertility. However, it will also lead to new ethical questions which need to be considered before the new methods become a clinical routine.

Meet The Expert 14: For the use of AMH as a diagnostic tool in female reproduction
MTE14

AMH as a diagnostic tool in female reproduction

Richard A Anderson
MRC Centre for Reproductive Health, University of Edinburgh, United Kingdom

AMH is produced by the granulosa cells of growing follicles in the ovary, with peak expression at the small antral stage, followed by a sharp decline, and it is not produced by the corpus luteum. It therefore provides an indirect index of the ovarian reserve, and will also be affected by factors that influence folliculogenesis, such as hormonal contraception. This provides the basis for understanding and developing its potential use as a diagnostic tool in assessing the ovary. The most established role for AMH is prior to ovarian stimulation for assisted reproduction, where is has become very widely used in conjunction with ultrasound assessment of the antral follicle count. This allows identification of women who are likely to over-respond and are at high risk of ovarian hyperstimulation, and conversely those with an unexpectedly low AMH for their age, who will respond poorly: stimulation protocols can be tailored, and expectations managed. Allied to this is a potential diagnostic value in PCOS, and while it is clear that women with this condition often have markedly elevated AMH levels, it has not yet become part of diagnosis. The menopause results from exhaustion of the follicle pool, thus AMH may be of value in its diagnosis and indeed prediction. Initial ELISAs were inadequately sensitive, with AMH becoming undetectable some 5 years before the menopause, but more sensitive assays have been developed, and a role in menopause diagnosis is also now established. Prediction is more challenging, especially with a longer time to menopause and younger age. Thus its value in predicting premature ovarian insufficiency is unclear, although as a diagnostic it has value. Special circumstances include following chemotherapy, where diagnosis of permanent loss of ovarian function would be of value.

Meet The Expert 15: Challenges in genetic counseling for hereditary endocrine neoplasia syndromes
MTE15

Challenges in genetic counseling for hereditary endocrine neoplasia syndromes

Auli Karhu
Department of Medical and Clinical Genetics, University of Helsinki, Helsinki, Finland

Genetic counseling has long been an integral component of the care of individuals and families with hereditary endocrine neoplasia syndromes. Molecular biology has made a great progress during the past years, and genetic testing and genetic counseling have received more and more public attention. The recent progress, especially in the next-generation sequencing (NGS) technology allows multiple genes or even the whole-genome to be sequenced with high resolution and speed. Nowadays, the NGS has found a firm place in carrier identification and genetic counseling of individuals affected by endocrine neoplasia syndromes. However, generation of a large amount of genomic data in a short time has led to challenges in variant identification and interpretation of the test results. The NGS technology together with other high-throughput molecular methods have greatly increased the number of variants of uncertain significance (VUSs) in clinical practice and research. Also NGS-associated unintentional incidental findings as a by-product of genetic testing have become more frequent. Because the great deal of genetic variation is rare and even unique to individuals, the VUS "issue" is likely here to stay. However, the long-term solution to the VUS interpretation difficulties is to gain more data. Functional studies of genes and variants, and additional population-level data with accurate phenotyping will in the future improve variant classification. Reduced prices and even more sensitive screening methods coupled with advanced bioinformatics capabilities will increase the uptake of genetic testing and counseling in endocrine neoplasia. While there are many challenges in the area, there are even more significant opportunities to use genome-wide technologies in multiple medical situations, including the molecular characterization of rare endocrine neoplasia, the individualization of treatments, and population screening for disease risk.

Risk of developing autonomous cortisol secretion and/or significant tumor growth in non-functioning adrenal incidentalomas during follow-up

Marta Araujo Castro[1], Cristina Robles Lázaro[2], Paola Parra Ramírez[3], Rogelio García Centeno[4], Paola Gracia Gimeno[5], Mariana Tome[6], Miguel Antonio Sampedro Núñez[7], Mónica Marazuela[7], Héctor F. Escobar-Morreale[1] & Pablo Valderrábano Herrero[1]

[1]Hospital Universitario Ramón y Cajal, Department of Endocrinology & Nutrition, Madrid, Spain; [2]Hospital Clínico Universitario de Salamanca., Department of Endocrinology & Nutrition, Salamanca, Spain; [3]Hospital Universitario de la Paz, Department of Endocrinology & Nutrition, Madrid, Spain; [4]Hospital Universitario Gregorio Marañón, Department of Endocrinology & Nutrition, Madrid, Spain; [5]Hospital Royo Villanova, Department of Endocrinology & Nutrition, Zaragoza, Spain; [6]Hospital Universitario Puerto del Real, Sevilla, Spain; [7]Hospital Universitario de la Princesa, Department of Endocrinology & Nutrition, Madrid, Spain

Purpose
To assess the risk of developing hypercortisolism and/or tumor growth in non-functioning adrenal incidentalomas (NFAIs) during follow-up.
Methods
Seven Spanish institutions participated in this retrospective study for patients with AIs. 1097 patients with one or more AIs ≥ 1 cm evaluated by participating physicians between 2013 and 2020 were subject to inclusion. Patients with missing values in the overnight 1 mg-dexamethasone suppression test (DST) (n = 63); with pheochromocytoma (n = 7); primary aldosteronism (n = 26); autonomous cortisol secretion (ACS) (n = 337) overt Cushing syndrome (CS)(n = 10); or adrenal carcinoma (n = 3), were excluded. ACS was defined as a value >1.8 μg/dl after DST without specific data of CS. Tumor growth was defined as an increase in tumor maximum diameter >20% from baseline; and of at least 5 mm.
Results
654 patients with NFAIs were included. Mean age was 62.1 ± 10.8; and 56% (n = 368) were women. At presentation, median tumor size was 19.3 ± 9.8 mm; 130 patients (20.1%) had bilateral tumours and the median cortisol post-DST level was 1.1 μg/dl (0.4 – 1.8). Of the 654 subjects, tumor diameter and DST were re-evaluated during follow-up in 410 and 364 patients, respectively. After a median follow-up of 26.4 [IQR 10.6 – 50.6] months, 40 out of 364 patients with NFAIs (11%) developed ACS; and none developed overt CS. The risk for developing ACS during follow-up was higher for patients with higher cortisol post-DST values (HR 4.1 for each μg/dl, 95% CI 1.4 – 11.7), older age (HR 1.04 for each year, 95% CI 1.01 – 1.08); and smaller tumor size (HR 0.92 for each mm, 95% CI 0.86 – 0.99), at presentation. The best cortisol post-DST threshold to predict ACS development in NFAI patients was 1.4 μg/dl (AUC 0.67, 95% CI 0.62 – 0.72, sensitivity 58% and specificity 72%). Significant tumor growth was observed in 23 out of 401 patients (5.6%). Median tumor growth in these patients was 11.0 ± 4.9 mm. Unilateral laparoscopic adrenalectomy was performed in 2 patients, and histology was benign in both. Tumour growth was more common in women (HR 3.7, 95% CI 1.4 – 9.3), but other predictive variables were not identified. Final tumor size was linearly correlated with initial (r = 0.12, P = 0.012) and last-visit cortisol post-DST (r = 0.14, P = 0.018). ACS was developed during follow-up in 18.8% of tumours that demonstrated significant growth; and in 8.7% of tumors that remained stable in size (P = 0.181).
Conclusions
11% of patients with NFAIs developed ACS; and 5.6% of tumors grew during follow-up. Cortisol post-DST levels at presentation are associated with the risk of ACS development and are linearly associated with the follow-up adrenal tumor size.

YAP/TAZ signaling is involved in the regulation of adrenocortical progenitors in stress

Ilona Berger[1], Alice Santambrogio[1,2], Stefan Bornstein[1,3], Cynthia L. Andoniadou[1,2] & Charlotte Steenblock[1]

[1]University Hospital Carl Gustav Carus Dresden, Department of Internal Medicine III, Dresden, Germany; [2]King's College London – Guy's Campus, Centre for Craniofacial and Regenerative Biology, London, United Kingdom; [3]King's College London – Guy's Campus, Diabetes and Nutritional Sciences Division, London, United Kingdom

A tightly regulated stress system is pivotal for health and the adrenal cortex is a master regulator of the endocrine stress response. The adrenal cortex is characterized by constant cell renewal in part mediated by differentiation and lineage conversion of undifferentiated cell types. To date, the contribution of stem cells to organ plasticity during stress has been implicated but is not fully understood. Recently, we were able to show that a prolonged stress exposure leads to differentiation of non-steroidogenic Nestin-GFP progenitors into specialized cell types in the adrenal cortex of mice. These cells reside in the stem cell niche during homeostasis. The niche in the outermost layer of the adrenal cortex, the capsule and zona glomerulosa, is tightly regulated by signaling pathways including SHH and WNT, which control maintenance and differentiation. However, recent research suggests that YAP/TAZ signaling may further regulate adrenocortical maintenance, since ablation of effector genes leads to degeneration of the organ. Our study explores a functional role for YAP/TAZ downstream signaling in the adrenal cortex during homeostasis and stress. We show that YAP/TAZ targets are normally expressed in different cell types throughout the adrenal cortex including in the stress-responsive Nestin-GFP(+) progenitor cells. We show that during stress, YAP/TAZ targets expressed in the stem cell niche are upregulated. This upregulation is accompanied by downregulation of WNT target genes in the zona Glomerulosa, suggesting differentiation of progenitor cells in this zone. In an in vitro cell differentiation model of adrenocortical progenitors, YAP/TAZ target upregulation accompanied by WNT target downregulation favors adrenocortical differentiation. We further show that YAP/TAZ signaling decreases in HPA-axis inhibiting conditions leading to quiescence of the cells. In summary, this study introduces the YAP/TAZ cascade as putative regulator of the adrenocortical stem cell niche which may be upregulated in stress conditions to mediate differentiation.

[1]Institute Cochin, INSERM U1016, CNRS UMR8104, Paris, France; [2]Cochin Hospital, Endocrinology, Paris, France; [3]National Institutes of Health, Department of Endocrinology and Genetics, Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, United States; [4]University Hospital Würzburg, Endocrinology and Diabetes, Würzburg, Germany; [5]Hospices Civils de Lyon, Endocrinology, Lyon, France; [6]Bicetre Hospital AP-HP, Endocrinology, Le Kremlin-Bicêtre, France; [7]Hopital Haut Leveque, Endocrinology, Pessac, France; [8]Chu De Lille, Endocrinology, Diabetology and Metabolism, Lille, France; [9]Instituto do Câncer do Estado de São Paulo, Endocrinology, Brazil

Introduction
Primary bilateral macronodular adrenal hyperplasia (PBMAH), the most common cause of adrenal Cushing's syndrome due to bilateral adrenal tumors, is an heterogenous disease with various clinical, hormonal and morphological characteristics. *ARMC5* inactivating mutations is the most frequent genetic cause of PBMAH and variants of *PDE11A4* have been associated with the disease. In order to better understand the heterogeneity of PBMAH, this study was undertaken to determine whether *PDE11A4* variants might be associated with a specific phenotype.
Methods
Leukocyte DNA of 354 index cases of PBMAH were sequenced for *ARMC5* and *PDE114A* by NGS (Ion Torrent). The frequency of variants was established in this cohort and the phenotypic characteristics were analysed in order to determine the genotype/phenotype correlations. Were considered pathogenic: *PDE11A4* variants with altered enzymatic function; *ARMC5* nonsense, frame shift and rare missense variants predicted deleterious *in silico*.
Results
ARMC5 mutations were present in 76 patients (21.5%) and pathogenic variants of *PDE11A4* in 65 patients (18.4%), with a similar frequency regardless of *ARMC5* status. Phenotype was more severe in *ARMC5* mutated patients compared to *ARMC5* wild type, with a higher 24-hour urinary

free cortisol, expressed as a multiple of the upper standard range (UFC) (2.04 vs 0.99, $P = 0.005$) and midnight plasma cortisol (MPC) (328.06 vs 187.24 nmol/l, $P = 0.003$), larger adrenals (122.7 vs 91.31 mm, $P = 4.87e – 05$) and higher number of nodules as determined on CT-scan (10.25 vs 3.44, $P = 8.62e – 07$). There were six *PDE11A4* pathogenic variants (p.R804H, p.R867G, p.M878V, p.D609N, p.Y727C, p.R307X). Patients with these variants had a less severe phenotype, with a lower MPC (162.17 vs 222.91 nmol/l, $P = 0.015$) and fewer adrenal nodules (3.45 vs 4.75, $P = 0.015$) in comparison with the *PDE11A4* wild type group. Regarding the initial management, 50% of patients with pathogenic variants of *PDE11A4* were abstaining from treatment, 37% were treated by adrenalectomy and 10.9% were treated medically. This phenotypic modulation of the *PDE11A4* was confirmed in *ARMC5* mutated patients: patients with pathogenic variants of *PDE11A4* ($n = 13$), had lower UFC (1.1 vs 2.25, $P = 0.014$), smaller adrenal glands (90 mm vs 127 mm, $P = 0.008$) and a lower number of nodules (6 vs 10.94, $P = 0.03$) compared to the *PDE11A4* wild type group.

Conclusion

This association of *PDE11A4* variants with a less severe PBMAH phenotype regardless of *ARMC5* status suggests that *PDE11A4* is a modulator of PBMAH development. The mechanisms of this modulation remain to be determined and will help to better describe the heterogeneity of PBMAH and to elucidate its pathophysiology.

The impact of targeted treatment on echocardiographic indices in patients with overt and mild primary aldosteronism, compared to patients with essential hypertension.

Christos Gravvanis[1], Labrini Papanastasiou[1], Andreas Kaoukis[2], Spyridoula Glikofridi[1], Nicoleta Monastirioti[1], Nikolaos Voulgaris[1], Ernestini Tyfoxylou[1], Athina Markou[1], George Piaditis[1]

[1]General Hospital of Athens G.Gennimatas, Unit of Endocrinology and Diabetes Centre, Athens, Greece; [2]General Hospital of Athens G.Gennimatas, Department of Cardiology, Athens, Greece

Introduction

Primary aldosteronism (PA) is associated with cardiovascular events and target organ damage, such as left ventricular (LV) hypertrophy and cardiac dysfunction. However the impact of subtle aldosterone secretion on cardiac function has not yet been evaluated.

Aim

To prospectively evaluate the cardiac function using echocardiographic indices in patients with biochemical overt, mild PA and essential hypertension (EH) and investigate the impact of targeted therapy.

Patients and methods

We included 72 (44 men) patients (mean age 55 ± 11 years) with hypertension. The diagnosis of PA was based on the combination of valsartan, captopril and dexamethasone suppression test (DCVT)[1]. The patients were divided in three groups: those with EH ($n = 30$) (negative DCVT), with biochemical overt ($n = 21$)(basal aldosterone/renin ratio (ARR) > 67 pmol/mU^2 and positive DCVT) and with mild PA ($n = 19$)(ARR < 67pmol/ mU and positive DCVT). Mean blood pressure, LV diastolic and systolic dimensions (LVEDD, LVEDDi, LVESD, LVESDi), left ventricular and atrial mass index (LVMI, LAVI), and total diastolic function were evaluated with cardiac ultrasound at presentation and after targeted treatment. The delta values of the abovementioned parameters were calculated to evaluate the magnitude of therapeutic impact among the three groups.

Results

At presentation, LVMI (88.19 17.44 vs 73.34 ± 11.85) ($P = 0.001$), LAVI (38.01 ± 14.5 vs 27.74 ± 5.12) ($P = 0.001$) and LVESDi (15.65 ± 2.36 vs 14.39 ± 2.01) ($P = 0.041$) were significant higher in overt PA vs EH patients. Mild PA have also higher LVMI(80.26 ± 19.99 vs 73.34 ± 11.85) ($P = 0.052$), LAVI(31.05 ± 5.6 vs 27.74 ± 5.12) ($P = 0.058$), and LVEDDi (22.82 ± 2.9 vs 22.41 ± 2.11) ($P = 0.015$) vs EH patients. When biochemical overt and mild PA patients were compared, ejection fraction (63.66 ± 6.25 vs 64.34 ± 11.83) was lower and LVMI (88.19 ± 17.44 vs 80.26 ± 19.99) was higher in biochemical overt PA patients, compared to mild PA.The mean follow up, during treatment (MRAs for PA and conventional therapy for EH) was 14 ± 2months. Delta values of LVEDD ($P < 0.001$) and LVEDDi ($P = 0.002$) were significant higher in overt and mild PA patients, showing a significant improvement of cardiac function from baseline in comparison with EH patients. Furthermore, biochemical overt PA patients exhibited a significant improvement of LVESD (-2.31 ± 3.5 vs -0.6 ± 2.32, $P = 0.015$), LVEDDi (-1.77 ± 1.8 vs -0.57 ± 1.15, $P = 0.013$) and LVESVi (-5.44 ± 3.93 vs 0.9 ± 7.76, $P = 0.002$) compared to mild PA patients.

Conclusion

The present study shows that milder forms of PA have a similar though more subtle effect on cardiac function, compared to biochemical overt forms. Furthermore, targeted treatment resulted in a significant greater improvement in patients with overt forms of PA.

Primary aldosteronism (PA) is considered the sole, often curable, cause of hypertension in 5–10% of patients. Yet there has been only one RCT, and practice has changed little since the advent of CT scanning. Adrenal vein sampling (AVS) and adrenalectomy remain the standard, invasive interventions, leading to a 50% reduction in pill count as the average clinical improvement.

Study Design

In MATCH (Is Metomidate PET-CT superior to Adrenal vein sampling in predicting ouTCome from adrenalectomy in patients with primary Hyperaldosteronism), 142 patients, mean age 52, 32% female, 32% of African ancestry, 46% hypokalemic, had both AVS and 11C-metomidate PET CT (MTO) in random order, and were referred for surgery if aldosterone/cortisol ratio differed >4-fold between adequately cannulated adrenal veins, and/or SUVmax on MTO was >1.25x higher, in a definite tumour, than the opposite adrenal. The primary outcome is the proportion of patients in whom adrenalectomy achieved complete or partial biochemical or clinical cure, analysed hierarchically using PASO criteria.[1] Anticipating ~50% incidence of unilateral PA, MATCH is powered to detect 25% superiority of MTO vs AVS, or non-inferiority at a lower-bound CI of -17%. Secondary outcomes include non-randomised comparison of outcomes between unilateral and bilateral PA; prediction of clinical outcome from home BP readings before and after starting spironolactone 100mg daily for 4 weeks; quality-of-life assessments; and analyses, by RNAseq, of genotype and transcriptomes of tumors, correlated with ethnicity and outcomes.

Results

The analysis set is 75 patients who, on 31st Dec 2020, had undergone adrenalectomy with >6 months follow-up. 67 patients (89%) had complete biochemical cure following PASO criteria,[1] and 63 (84%) had complete or partial clinical cure. In 39/75 surgical patients, only one of MTO or AVS was scored as high-probability using criteria above. This score was confirmed at the multi-centre, MDT meeting which reviewed all MTO scans without knowledge of AVS. The primary analysis compared accuracy of MTO and AVS by McNemar test. The 39 discordant results were allocated as a win to the positive investigation if the patient was cured, or to the negative investigation, if not cured. 50/56 CYP11B2-positive tumors had a known mutation; the frequency was *CACNA1D>KCNJ5>ATP1A1>ATP2B3>CTNNB1>GNAQ>CLCN2*, differing between patients whose hypertension was completely or partially cured. Two other tumors had novel gene mutations. Several RNAseq transcripts varied with genotype and outcome, including some encoding measurable, secreted proteins.

Full primary and secondary outcomes will be presented.

All-cause mortality in adrenal insufficiency patients using prednisolone or hydrocortisone replacement

Kanchana Ngaosuwan[1,2], Desmond Johnston[2], Ian Godsland[2], Jeremy Cox[3], Azeem Majeed[4], Jennifer Quint[5], Nick Oliver[2] & Stephen Robinson[3]
[1]Faculty of Medicine and Public Health, HRH Princess Chulabhorn College of Medical Science, Chulabhorn Royal Academy, Bangkok, Thailand; [2]Faculty of Medicine, Imperial College, Metabolism, Digestion and Reproduction, London, United Kingdom; [3]Imperial NHS Trust, London, United Kingdom; [4]School of Public Health, Imperial College, London, United Kingdom; [5]National Heart and Lung Institute, Imperial College, London, United Kingdom

Background
Whilst hydrocortisone is standard glucocorticoid replacement therapy in patients with adrenal insufficiency, some have considered prednisolone an alternative. Some data have shown diabetes and osteoporosis risk. Mortality of patients using prednisolone in relation with those using hydrocortisone is not known. We compared all-cause mortality risk compared to matched controls in patients with primary or secondary adrenal insufficiency using prednisolone or hydrocortisone.
Subjects
In hydrocortisone cohort, 4228 patients with adrenal insufficiency of any type (1,405 primary adrenal insufficiency, 2,461 secondary) were compared with 41,934 matched controls (13,965 primary, 24,401 secondary). In prednisolone cohort, 1,250 adrenal insufficiency patients (137 primary, 897 secondary) were compared with 12,380 matched controls (1,347 primary, 8909 secondary).
Methods
Participants were extracted from a UK general practitioner database (Clinical Practice Research Datalink; CPRD) from 1987 to 2017. Each study patient was matched with up to 10 controls who had the same sex, GP practice, 5-year strata of the year of birth, and 5-year strata of the start of follow-up. Follow-up began on the latest of the date at which patients were diagnosed, registered to GP, or the GP provided standard information. Follow-up finished on the earliest date of death, or de-registering from the GP. All-cause mortality risk relative to controls was analysed separately in hydrocortisone and prednisolone cohorts then compared between cohorts.
Results
In adrenal insufficiency of any type, the hazard ratio for mortality of prednisolone users was 1.67 (95% CI, 1.47–1.90) with a follow-up period of 6725 and 66430 person-years for cases and controls, respectively. The HR was not different from that of hydrocortisone users (HR, 1.73 [95% CI, 1.61–1.87]; p for HR difference = 0.69) with a follow-up period of 24574 and 256815 person-years for cases and controls, respectively. In primary adrenal insufficiency, the hazard ratio of prednisolone users was 2.45 (95% CI, 1.86–3.23) which was higher than hydrocortisone users (HR, 1.82 [95% CI, 1.60–2.08]; p for HR difference =0.043). In secondary adrenal insufficiency the hazard ratio of prednisolone users was similar to hydrocortisone users (HR, 1.42 [95% CI, 1.18–1.72] vs. 1.59 [1.44–1.75]; p for HR difference = 0.34).
Conclusion
All-cause mortality risk in patients using prednisolone appeared is higher than those using hydrocortisone in patients with primary adrenal insufficiency. The mechanisms of this difference may be patient and care mechanism related.

Monogenic variants in the Finnish Pediatric Diabetes Register

Minna Harsunen[1,2,3], Jarno Kettunen[2,3,4], Päivi J. Miettinen[1,5], Mikael Knip[1,3] & Tiinamaija Tuomi[2,3,4,6,7]
[1]New Children's Hospital, Pediatric Research Center, University of Helsinki and Helsinki University Hospital, Helsinki, Finland; [2]Folkhälsan Research Center, Biomedicum Helsinki, Helsinki, Finland; [3]Research Program for Clinical and Molecular Metabolism, University of Helsinki, Finland; [4]Finnish Institute for Molecular Medicine, University of Helsinki, Helsinki, Finland; [5]Translational Stem Cell Biology and Metabolism Research Program, Faculty of Medicine, University of Helsinki, Helsinki, Finland; [6]Abdominal Centre, Endocrinology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland; [7]Lund University Diabetes Centre, Department of Clinical Sciences, Lund University, Sweden

Background and aims
Monogenic forms of diabetes caused by a single gene defect include maturity onset diabetes of the young (MODY), neonatal diabetes mellitus and syndromic forms. They are estimated to account for 1–3% of all diabetes cases, but the prevalence is higher among pediatric patients without islet autoantibodies (AAB). Despite presenting with insulin deficiency, many patients can be treated with anti-hyperglycaemic agents to stimulate their insulin secretion. Our main objective was to assess the prevalence and clinical manifestations of monogenic diabetes in pediatric patients who were AAB-negative or positive only for low titer islet cell antibodies (ICAs) at diagnosis.
Materials and methods
At diagnosis, 6484 patients were tested for AAB through the Finnish Pediatric Diabetes Register, which covers approximately 90% of newly diagnosed diabetic patients aged < 16 years in Finland. Only 174 patients (3%) tested negative for all five AAB (ICAs, IAA, GADA, IA-2A and ZnT8A) and 58 patients (0,9%) had only low titer ICAs (< 10RU). DNA samples were available for 214 patients. A next generation sequencing (NGS) gene panel including 42 genes associated with monogenic diabetes (exons ± 50 nucleotides, and promoter regions harboring known pathogenic variants) was used for the detection of monogenic diabetes.
Results
We identified a monogenic cause for diabetes in 20 patients negative for all five AAB, accounting for 12% of the AAB-negative patients and 0,3% of all 6484 children in our cohort (n = 4 mutations in *GCK*, n = 6 mutations in transcription factors *HNF1A, HNF4A* or *HNF1B*, n = 4 mutations in *INS*, n = 6 rare monogenic forms caused by mutations in *KCNJ11, RFX6, LMNA* and *WFS1)*. At diagnosis, the median [IQR] age was 9.3 [6,6–13,8] years and the median ISO-BMI was 20.2 [17,7–25,2] kg/m^2. None of these 20 patients had presented with ketosis or ketoacidosis at diagnosis and none carried a high-risk HLA susceptibility genotype for type 1 diabetes. So far, two of these patients have been successfully transferred from insulin to oral treatment. The screening results of patients with low ICAs will be presented at e-ECE 2021.
Conclusion
A monogenic cause for diabetes was found in 12% of the AAB-negative patients screened by the NGS gene panel. As AAB-negative patients account for only approximately 3% of all diagnosed pediatric patients in Finland, screening of all AAB-negative pediatric patients for monogenic diabetes should be considered.

Autoantibodies in prediction of diabetes after gestational diabetes – A 23-year prospective cohort study

Kaisu Luiro[1], Anna-Maaria Auvinen[2,3], Juha Auvinen[4], Juha Jokelainen[4,5], Ilkka Järvelä[2], Knip Mikael[6,7,8] & Juha Tapanainen[1,2,3]
[1]Helsinki University Hospital and University of Helsinki, Obstetrics and Gynecology, Helsinki, Finland; [2]Oulu University Hospital and University of Oulu, Obstetrics and Gynecology, Oulu, Finland; [3]University of Oulu, Medical Research Center Oulu, Oulu, Finland; [4]University of Oulu, Center for Life Course Health Research, Oulu, Finland; [5]Oulu University Hospital, Primary Care, Oulu, Finland; [6]University of Helsinki and Helsinki University Hospital, Children's Hospital, Helsinki, Finland; [7]University of Helsinki, Research Program for Clinical and Molecular Metabolism, Helsinki, Finland; [8]Tampere University Hospital, Tampere Center for Child Health Research, Tampere, Finland

Objective
To study the predictive value of autoantibodies in progression to type 1 (T1DM) and type 2 (T2DM) diabetes after gestational diabetes (GDM) in a 23-year follow-up study.
Background
Women with GDM are at high risk for T2DM later in life, but also the risk of T1DM is increased. We have previously reported a prospective 6-year cohort study showing an association of islet cell and glutamic acid decarboxylase autoantibodies, GDM below the age of 30 years and the need for insulin treatment during pregnancy with a high risk of progression to T1DM. Recently, we reported the results of a 23-year follow-up showing that 5.7% of women with GDM developed T1DM and the disease progression was predictable with high OGTT 2-hour glucose levels during pregnancy. In addition, 50.4% of women developed T2DM after GDM with a linear incidence until the end of the study.

Study Design
This is a prospective cohort study including 391 women with GDM and 391 age-, parity−and delivery date-matched controls who delivered in 1984–1994. Four autoantibodies associated with T1DM were analysed from first trimester samples; islet cell (ICAs), glutamic acid decarboxylase (GADAs), insulin (IAAs) and insulinoma-associated antigen 2 autoantibodies (IA-2As). A follow-up questionnaire assessing later T1DM and T2DM morbidity was sent in 2012−2013. The mean follow-up time was 23.1 (18.7–28.8) years, which is to our knowledge, the longest follow-up to date.
Results
Single autoantibody positivity was detected in 12% (41/391) of the GDM cohort and in 2.3% (8/391) of the control cohort. In the GDM cohort, 2.6% (9/391) tested positive for two autoantibodies and 2.3% (8/391) for three autoantibodies, whereas only one subject in the control cohort had two autoantibodies detected. ICA positivity was found in 12.5% of the cases, followed by GADA (6.0%), IA2A (4.9%) and IAA (1.2%). In the control cohort, GADA positivity was found in 1.4%, IA2A in 0.8%, IAA in 0.6%, and ICA in 0.3% of the subjects. Detection of ICA, GADA and/or IA-2A autoantibodies decreased T1DM-free survival time and time to diagnosis. All subjects with three positive autoantibodies developed T1DM within seven years from the GDM pregnancy. Development of T2DM after GDM occurred independent of autoantibody positivity.
Conclusion
Development of T1DM can be reliably predicted with GADA and ICA autoantibodies during early pregnancy. We recommend that women with high glucose values in OGTT and insulin treatment be tested for autoantibodies to identify individuals with high risk of T1DM later in life.

Long-term testosterone therapy improves glycaemic control and weight control in men with type 2 diabetes: 12-year observational data from a controlled registry study in a urological setting

Farid Saad[1], Karim Sultan Haider[2] & Ahmad Haider[2]
[1]Bayer AG, Medical Affairs Andrology, Berlin, Germany; [2]Private Urology Practice, Urology and Andrology, Bremerhaven, Germany

Background
Prevalence of hypogonadism has been reported as high as 50% in men with T2DM and/or obesity. ADA and AACE Guidelines recommend assessment of hypogonadism in men with T2DM and obesity.
Material and methods
In a registry of 865 men with hypogonadism, 361 men (41.7%) had T2DM. 183 received TU 1000 mg/12 weeks (T-group), 178 opted against treatment (CTRL). Changes over time between groups were compared and adjusted for age, weight, waist circumference, fasting glucose, blood pressure, lipids and quality of life to account for baseline differences between the two groups. 12-year data are reported.
Results
Mean follow-up: 8.7 ± 3.1, baseline age: 60.7 ± 5.5 (T-group) and 63.0 ± 4.9 (CTRL) years. Glycaemic control at 12 years (mean values ± SE): HbA1c (%) progressively decreased by 3.7 ± 0.2 in the T-group and increased by 3.2 ± 0.2 in CTRL, estimated adjusted difference between groups: -6.9 [95% CI: -7.4;-6.4] (P < 0.0001 for all). Fasting glucose (mmol/l) decreased by 1.9 ± 0.1 (T-group) and increased by 1.8 ± 0.1 (CTRL), difference between groups: -3.6 [95% CI: -4.0;-3.3] (P < 0.0001 for all). HOMA-IR decreased by 8.0 ± 0.3 (T-group) and increased by 6.5 ± 0.4 (CTRL), difference between groups: -14.4 [95% CI: -15.5;-13.4] (P < 0.0001 for all). In CTRL, 22 patients were started on insulin during the observation period. Weight control at 12 years (mean values ± SE): 293 men (81.2%) were obese, 61 (16.9%) overweight and 7 (1.9%) had normal weight. Weight (kg) decreased by 22.5 ± 0.5 (T-group) and increased by 8.5 ± 0.5 (CTRL), difference between groups: -31.0 [95% CI: -32.7;-29.2] (P < 0.0001 for all). Weight loss (%) was 19.7 ± 0.4 in the T-group, weight gain 9.1 ± 0.4 in CTRL, difference between groups: -28.8 [95% CI: -30.2;-27.4] (P < 0.0001 for all). Waist circumference (cm) decreased by 13.6 ± 0.4 (T-group) and increased by 8.5 ± 0.4 (CTRL), difference between groups: -22.1 [95% CI: -23.4;-20.8] (P < 0.0001 for all). BMI (kg/m^2) decreased by 7.4 ± 0.2 (T-group) and increased by 2.8 ± 0.2 (CTRL), difference between groups: -10.2 [95% CI: -10.8;-9.5] (P < 0.0001 for all). Since injections were administered in the office and documented, there was a 100% adherence to testosterone therapy.
Conclusion
Long-term testosterone therapy with TU in men with hypogonadism and T2DM progressively improved glycaemic as well as weight control which deteriorated in untreated men.

OC2.4

Predicting optimal diabetes drug management using AI/ ML – Developing a prototype clinical decision support algorithm.

Rajiv Singla[1], Shivam Agarwal[2], Ankush Singla[2], Jatin Bindra[2] & Sweta Singla[3]
[1]Kalpavriksh Healthcare, Endocrinology, Diabetes and Metabolism, Delhi, India; [2]Kalpavriksh Healthcare, Health Informatics, Delhi, India; [3]Kalpavriksh Healthcare, Neurology, Delhi, India

Universal reach of diabetes care and assurance of minimum standard of care is a milestone yet to be achieved. Application of artificial intelligence/ machine learning (AI/ML) for diabetes care can help solve both these aspects of diabetes care.
Objective
Creating a clinical decision support system using AI/ML approach for predicting best anti-diabetes drug class to be introduced to help optimally manage glycaemic control in people living with diabetes mellitus type 2.
Methodology
Study was conducted at an Endocrinology clinic and data collected from electronic clinic management system. 15485 diabetes prescriptions of 4974 patients were accessed. A data subset of 1671 diabetes prescriptions with information on diabetes drugs, demographics (age, gender, body mass index), biochemical parameters (HbA1c, fasting blood glucose, creatinine) and patient clinical parameters (diabetes duration, compliance to diet/ exercise/medications, hypoglycemia, contraindication to any drug, summary of patient self monitoring of blood glucose data, diabetes complications) was used in analysis. The patients in this data set had mean HbA1c of 7.3% ±1.3% (median 7.05%, 25th percentile 6.5%, 75th percentile 7.89%). For analysis, 67% of the dataset was used as a training set and 33% as a testing set. An input of patient variables (current diabetes medications, demographics, biochemical parameters and patient clinical parameters) were used to predict all diabetes drug classes to be prescribed. Random forest algorithms were used to create decision trees for all diabetes drugs. Accuracy for predicting use of each individual drug class is depicted in Table 1 and varied from 85% to 99.4%. Multi-drug accuracy considering that all drug predictions in a prescription need to be correct stands at 72%. Multi drug class accuracy in clinical application may be higher than this result, as in a lot of clinical scenarios, two more diabetes drugs may be used interchangeably.

Table 1 Individual drug class prediction accuracy

Drug Class	Training Set Accuracy (%)	Testing Set Accuracy (%)
Metformin	100	97.8
Sulfonylureas	100	90
DPP-4 inhibitors	100	85
SGLT2-inhibitors	100	92.4
AGI	100	96.9
Pioglitazone	100	96.2
Meglitinides	100	99.3
Short acting insulin	100	99.4
Basal insulin	100	97.1
Premix Insulin	100	97.5

Clinical Impact
This report presents a first positive step in developing a robust clinical decision support system to transform access and quality of diabetes care. Multi-drug accuracy is likely to improve further with time as the depth of the dataset increases over time.

Genetic characterization of MODY patients in greece

Amalia Sertedaki, Eirini Fylaktou, Elizabeth Tatsi & Christina Kanaka-Gantenbein
National and Kapodistrian University of Athens, Division of Endocrinology, Diabetes and Metabolism, First Department of Pediatrics, Medical School, Athens, Greece

Background
Maturity Onset Diabetes of the Young (MODY) constitutes a genetically and clinically heterogeneous type of Monogenic Diabetes (MD), characterized by early onset of hyperglycemia, autosomal dominant inheritance and defect in β-cell insulin secretion. To date, various MODY subtypes have been reported, each one of a distinct genetic etiology.
Materials and methods
A total of 114 patients of Greek origin fulfilling MODY criteria are reported. Twenty-four patients with GCK-MODY phenotype were tested by Sanger sequencing. Ninety patients were tested employing a Next Generation Sequencing Targeted Gene Panel of seven MODY genes (*GCK, HNF1A, HNF4A, HNF1B, INS, ABCC8* and *KCNJ11*), 40 of which had been previously tested by Sanger sequencing for *GCK, HNF1A* and *HNF4A*, according to patients' phenotypes. Patients, with no pathogenic variant detected, were tested by Multiplex Ligation-dependent Probe Amplification (MLPA) for CNVs.
Results
GCK-MODY was found to be the most frequent MODY subtype (18.4%), followed by *ABCC8*-MODY (9.6%) and *HNF1A*-MODY (6.1%), whereas *HNF4A*-MODY is rare (0.8%). Two patients were identified with *HNF1B* variants and another 3 with whole *HNF1B* gene deletion, making a total of 4.4% of *HNF1B*-MODY. The *ABCC8* MODY patients (9.6%) presented with a wide spectrum of clinical and biochemical characteristics: fasting blood glucose ranging from 103 to 365 mg/dl (5.7–20.3 mmol/l), HbA1c 5.4% to 11.9% (35.5–107 mmol/mol), age of onset of diabetes from 9 yrs to 42 yrs, BMI from 17.2 to 27.7 kg/m^2 and birth weight from 2700 g to 4100 g.
Conclusions
Overall in our cohort a diagnostic rate of 45% was achieved. The majority of the patients were GCK-MODY (18.4%), followed by ABCC8-MODY 9.6%, indicating that *ABCC8* gene variants are frequently related to MD. The phenotypic characteristics of the patients carrying *ABCC8* variants, exhibit genetic heterogeneity, ranging from a mild phenotype, similar to the mild *GCK* phenotype, to a more severe phenotype, similar to that of *HNF1A* and *HNF4A* defects. Molecular genetic diagnosis of the MODY subtype is of outmost importance for clinical diagnosis, disease progression prognosis and family counseling. Furthermore, it specifies pharmacologic treatment, since different MODY subtypes require different therapeutic approaches, constituting an example of personalized medicine.

Insulin receptor isoforms in human adipogenesis: Possible role in the onset of adipose tissue expansion

Valentina Annamaria Genchi, Angelo Cignarelli, Sebastio Perrini, Cristina Caccioppoli, Rosella D'Oria, Annalisa Natalicchio, Luigi Laviola & Francesco Giorgino
University of Bari, Department of Emergency and Organ Transplantation, Bari, Italy

Insulin is a major endocrine hormone able to regulate whole-body energy disposal and lipid metabolism. Particularly, insulin stimulates the renewal of the adipose tissue (AT) via activation of insulin receptors (IR) consisting of two splicing variants: a short isoform (IRa) involved in cell proliferation, and a long isoform (IRb) mainly implicated in metabolic responses. The contribution of these isoforms to the AT expansion is still poorly understood. We investigated the expression of both isoforms in human adipose-derived stem cells (ASC), in vitro differentiated adipocytes (dASC), and whole AT obtained from subjects with different BMI. Gene expression analysis was performed in subcutaneous AT (S-AT), visceral AT (V-AT), and ASC before and after differentiation into adipocytes (dASC) by qPCR. Adipogenesis was evaluated according to protein levels of IR and Nile red (NR) staining by flow cytometry. mRNA levels of IRa were more expressed than IRb in both S-ASC and V-ASC. S-ASC showed higher mRNA levels of total IR, IRa and IRb than V-ASC, as well as greater activation of insulin signaling. IRa expression significantly correlated with BMI (r = 0.53) and waist circumference (r = 0.51) in S-ASC and with BMI (r = -0.36) in V-ASC. Increased mRNA levels of total IR, IRa and IRb was observed after adipocyte differentiation in both S-dASC and V-dASC, with higher expression levels in S-dASC than V-dASC. Accordingly, IRa was more expressed than IRb in both S-AT and V-AT. Flow cytometric analysis revealed a time-dependent and tissue-specific increase of differentiated adipocytes stained with NR (NR+: 60% S-dASC, 23% V-dASC) but only a fraction of NR+ cells expressed IR, particularly in S-dASC (day 16, NR+IR+: 64% of NR+; day 30, NR+IR+: 77% of NR+). Conversely, V-dASC showed a high proportion of IR+ cells in the early phases of adipogenesis (day 16, NR+IR+: 82% of NR+), while a consistent reduction of the percentage of triglyceride-filled cells expressing IR was observed in the late phases (day 30, NR+IR+: 61% of NR+). In conclusion, mRNA levels of IR, particularly IRa, increase with BMI and adipocyte maturation especially in S-ASC. S-ASC display greater activation of insulin signaling and adipogenic phenotype as compared to V-ASC. A greater percentage of V-dASC expressing IR was observed during early adipogenesis but not in the late phase. IRa expression levels are associated with AT expansion typically in S-AT. The role of IR in V-AT expansion, particularly in the early phase of adipocyte commitment, needs further elucidation.

Introduction
Osilodrostat, a potent, oral 11β-hydroxylase inhibitor, normalized mean urinary free cortisol (mUFC) in most patients with CD during a Phase III, randomized-withdrawal study. We now report findings from a Phase III study of osilodrostat in patients with CD that featured an initial double-blind, randomized, placebo-controlled period (LINC 4; NCT02697734).
Methods
Adults with CD (mUFC > 1.3 × ULN) were randomized 2:1 to osilodrostat 2 mg bid or matching placebo for a 12-week (W) double-blind period; dose adjustments (range 1–20 mg bid) were permitted based on efficacy at W2, W5, and W8 and tolerability. From W12 to W48, all patients received open-label osilodrostat, with dose adjustments permitted (range 1–30 mg bid). At W48, patients could enter an optional extension. Primary endpoint: proportion of randomized patients who received ≥1 treatment dose with mUFC ≤ ULN at W12.
Results
Seventy-three patients were randomized and received osilodrostat (n = 48) or placebo (n = 25; baseline median [range] mUFC 2.5 × ULN [0.7–12.5] vs 2.2 × ULN [0.2–18.9]). At W12, 77% of osilodrostat recipients achieved mUFC ≤ ULN vs 8% on placebo (OR 43.4; 95% CI 7.1–343.2; P < 0.0001). At W36, 81% (95% CI 69.9–89.1) of osilodrostat recipients achieved mUFC ≤ ULN (key secondary endpoint). Median time to first controlled mUFC response for osilodrostat patients was 35 days (95% CI 34–52). At data cut-off (25 February 2020), median osilodrostat exposure was 71.7 vs 62.3 weeks for patients initially randomized to osilodrostat vs placebo (median [IQR] osilodrostat dose: 4.7 [3.8–9.0] vs 6.0 mg/day [3.7–9.7]). Up to W12, three osilodrostat recipients discontinued, one because of an AE (arthralgia), vs 0 with placebo. Most commonly reported AEs by W12 were decreased appetite (38% osilodrostat vs 16% placebo), arthralgia (35%

vs 8%) and nausea (31% vs 12%). AEs related to hypocortisolism (15% osilodrostat vs 0% placebo) and adrenal hormone precursor accumulation (44% vs 36%) were mostly grade 1/2 and resolved with dose reduction/interruption and/or concomitant medication. Most common AEs occurring on osilodrostat treatment during the overall study period were arthralgia (45%), decreased appetite (45%), fatigue (38%), nausea (37%) and headache (33%). Improvements in clinical signs of hypercortisolism, including systolic/diastolic blood pressure and HbA_{1c}, were observed with osilodrostat at W12 and W48.

Conclusions

Osilodrostat was superior to placebo at normalizing mUFC at W12 (77% vs 8%). Improvements in mUFC were sustained at W36. Few patients discontinued treatment because of AEs; hypocortisolism-related AEs were infrequent and manageable. We conclude that osilodrostat is a highly effective and well-tolerated treatment for patients with CD.

Castaño[4], Renzhi Cai[5], Wei Sha[5], Antonio C. Fuentes-Fayos[4], Raùl M. Luque[4], Ezio Ghigo[1], Andrew V. Schally[5,6] & Riccarda Granata[1]

[1]University of Turin, Division of Endocrinology, Diabetes and Metabolism, Department of Medical Sciences, Turin, Italy; [2]University of Santiago de Compostela and Complexo Hospitalario Universitario of Santiago de Compostela, Centro de Investigaciones Medicas (CIMUS) e Instituto de Investigaciones Sanitarias and Department of Physiology, Santiago de Compostela, Spain; [3]University of Ferrara, Section of Endocrinology and Internal Medicine, Department of Medical Sciences, Ferrara, Italy; [4]Maimonides Institute for Biomedical Research of Córdoba (IMIBIC), Reina Sofia University Hospital and University of Cordoba, Cordoba, Spain; [5]University of Miami Miller School of Medicine, Division of Endocrinology, Department of Medicine, Miami, Florida, United States; [6]University of Miami Miller School of Medicine, Division of Medical Oncology, Department of Medicine, Miami, Florida, United States

Pituitary neuroendocrine tumors (PitNETs) are mostly benign lesions originating from the anterior pituitary and represent 10–15% of all the intracranial neoplasms. PitNETs can be classified in non-secretory, clinically non-functioning pituitary adenomas (NFPAs), and secretory, comprising prolactin (PRL), growth hormone (GH) and adrenocoticotropic hormone (ACTH). Surgical resection is the first line treatment for PitNETs, whereas chemotherapy and radiotherapy are preferred for resistant or metastatic tumors. Growth hormone-releasing hormone (GHRH), besides promoting pituitary GH secretion, exerts many extrapituitary functions, including stimulation of cell proliferation and survival. GHRH, GHRH receptor (GHRH-R) and its splice variant 1 (SV1), are expressed in different cancer cell types, where they promote cell proliferation and tumor progression. Conversely, GHRH antagonists inhibit the growth of different tumors *in vitro* and *in vivo*; moreover, it has been demonstrated that first generation GHRH antagonists reduce GH secretion in tumoral rat GH-secreting (GH3) cells. However, to date the role of GHRH antagonists in PitNETs remains largely unknown. Thus, we aimed to clarify the potential antitumor effects of last generation GHRH antagonists, MIA-602 and MIA-690 in ACTH-secreting PitNET cells (AtT-20/D16v-F2), rat PRL–and GH-secreting PitNET cells, transfected with human GHRH-R (GH3-hGHRHR), and in primary cells isolated from patients with PitNETs. Our results show that MIA-602 and MIA-690 dose-dependently reduced cell survival and promoted apoptosis in AtT-20 and GH3-hGHRHR; in addition, we observed an increase in expression of the proapoptotic protein BAX and the tumor suppressor protein P53, paralleled by a reduction of the antiapoptotic protein Bcl-2. MIA-602 and MIA-690 also reduced colony formation and expression of c-Myc oncoprotein, indicating inhibitory activity on migration and proliferation. Furthermore, the combination of MIA-602 or MIA-690 with the main chemotherapy drug temozolomide showed a synergistic effect on inhibition of AtT-20/D16v-F2 cell survival. In addition, both GHRH antagonists reduced the secretion of GH, but not PRL, in GH3-hGHRHR, but showed no activity on ACTH secretion in AtT20/D16v-F2. Finally, preliminary results show a potential antitumor role for MIA-602 and MIA-690, alone or in combination with the somatostatin analog octreotide, in human primary cells isolated from NFPAs and ACTH–or GH-secreting PitNETs. Overall, these results indicate that GHRH antagonists display antitumor activities in ACTH and GH tumor cells and suggest their potential use for the treatment of PitNETs, alone or in combination with standard therapies.

Background

Retrospective studies led to European approval of the steroidogenesis inhibitor Metyrapone for the treatment of endogenous Cushing's syndrome (CS). We prospectively showed good efficacy and safety of Metyrapone after 12 weeks (Wk12) treatment in the phase III/IV PROMPT study and now report results of an extension study (EXT) sponsored by HRA Pharma Rare Diseases.

Design

This was a single arm, open-label, 24Wk extension of PROMPT that enrolled patients whose mean of 3 UFC (mUFC) was normal or less than 2-fold the upper limit of normal (ULN, 165 nmol/d) at Wk12. The EXT measured UFC at Wk24 (for dose titration) and Wk36 by liquid chromatography tandem–mass spectrometry.

Results

At the end of PROMPT (Wk 12), mUFC was normal in 23 of 49 patients and < 2-fold ULN in 19. The EXT baseline median mUFC was 0.96-fold ULN (159, range 5 – 333 nmol/d, n = 41). At Wk36, median mUFC in 35 completers was 1.04-fold ULN: mUFC was normal in 17 patients, < 2 × ULN in 11 and ≥ 2× ULN in 7. mUFC at Wk36 was normal in 5/14 evaluable patients with mUFC 1–2× normal at Wk12. mUFC at Wk24 was normal in all 20 patients with normal Wk12 mUFC; at Wk36 12 maintained normal values, 4 had mUFC < 2 × ULN, and 4 had mUFC ≥ 2× ULN. PROMPT and EXT response rates were similar (80%, 95% CI 66–89 vs 71%, 95% CI 55–84). Wk36 metyrapone dose was higher in mUFC 2-fold ULN group than others (2357 vs 1618–1750 mg/d). Median late night salivary cortisol was 4.8-fold ULN at Wk0 and 1.7-fold ULN at Wk36; 27% were normal. Clinical improvement of physical symptoms, cardiovascular and metabolic parameters continued. Adverse events (n = 3: hirsutism, acute glaucoma or hypotension) or patient's or physician's decision (n = 3) prompted discontinuations. Compared to

first 12-week period, good tolerability profile was maintained: no patient was treated for adrenal insufficiency and fewer patients reported nausea, vomiting, dizziness, or fatigue. There were 3 new cases of female hirsutism and one new case of hypertension.
Conclusions
mUFC was normal in 47–49% of completers at Wk12 and Wk36, and good tolerability continued. Normalization of mUFC during EXT validates continued titration after Wk12 in some patients. Variability of intra-patient steroidogenesis, baseline UFC and titration algorithms should be considered to improve overall UFC normalization. Late night salivary cortisol improvement was maintained during the extension and the distribution of metyrapone over the day should be considered to improve this rate.

Introduction
Cushing's disease is the result of prolonged exposure to excess cortisol caused by a pituitary tumor, known as corticotropinoma, which hypersecretes adrenocorticotropin (ACTH). Treatment with somatostatin analogs (SSA) has been shown to reduce hormone secretion and, to a lower extent, tumor growth in some subtypes of pituitary tumors, such as growth hormone secreting tumors. However, SSA are commonly ineffective in corticotropinomas. Previous studies indicated that the presence of the truncated receptor variant SST_5TMD4 is associated with a lack of response to SSA in growth hormone secreting tumors. However, its presence and functional role in corticotropinomas is still poorly defined.
Aims
The aim of this study was to explore the molecular and functional role of somatostatin receptors (SSTs) in corticotropinoma cells, and in particular to assess the contribution of SST_5TMD4 to SSA response.
Methods
The expression levels of SSTs were evaluated in 28 corticotropinomas and 8 normal pituitary samples. Functional assays (free cytosolic calcium kinetics, ACTH secretion and cell viability) were assessed in response to SSA in primary corticotropinoma cultures. Moreover, cell viability was evaluated after transiently SST_5TMD4 overexpression.
Results
In general, a lower expression of the receptors SST_1/SST_2/SST_3 was observed in corticotropinomas compared to normal pituitary samples. A more detailed analysis revealed the existence of two subpopulations of corticotropinomas that differed in the presence of high (n = 7) or low levels (n = 17) of expression of SST_5TMD4. The named 'high' population expresses all SSTs, presenting a higher expression of SST_2/SST_3/SST_5TMD4 compared to the 'low' subpopulation, which predominantly expresses SST_5. Furthermore, SST_5TMD4 was significantly over-expressed in the 'high' population compared to normal samples. Pilot functional studies in cell cultures derived from corticotropinomas revealed that both 'high' and 'low' corticotropinomas differentially respond to in vitro treatment with SSA, octreotide and pasireotide. Finally, SST_5TMD4 overexpression increased cell viability.
Conclusions
Our data indicate that there might be two discinct subpopulations of corticotropic tumors, one expressing most SSTs and another that predominantly expresses SST_5, which could confer differential responsiveness to SSA. Furthermore, the trasfection assay revealed that the presence of SST_5TMD4 seems to be associated with a higher proliferative rate in corticotropinomas. Consequently, a detailed expression profile of all the SSTs in corticotropinomas, especially SST_5 variants, could assist the prediction of response to SSA in patients with Cushing's disease.

Pregnancies after childhood craniopharyngioma – Results of KRANIOPHARYNGEOM 2000/2007

Panjarat Sowithayasakul[1,2], Svenja Boekhoff[1], Brigitte Bison[3] & Hermann Müller[1]
[1]University Children's Hospital, Car von Ossietzky University Oldenburg, Department of Pediatrics and Pediatric Hematology/Oncology, Klinikum Oldenburg AöR, Oldenburg, Germany; [2]Srinakharinwirot University, Department of Pediatrics, Bangkok, Thailand; [3]Augsburg Hospital, Department of Neuroradiology, Augsburg, Germany

Background
Data on female fertility, pregnancy, and outcome of offspring after childhood-onset craniopharyngioma (CP) are rare.
Study design
Observational study on pregnancy rate and outcome of offspring after CP in postpubertal, female patients recruited in KRANIOPHARYNGEOM 2000/2007 since 2000.
Results
451 CP patients (223 female) have been recruited. 269 CP patients (133 female) were postpubertal at study. Six of 133 female CP patients (4.5%) with a median age of 14.9 years at CP diagnosis had 9 pregnancies, giving birth to 10 newborns. Three patients achieved complete surgical resections. No patient underwent postoperative irradiation. Five natural pregnancies occurred in 3 CP patients without pituitary deficiencies. Four pregnancies were achieved in 3 CP with hypopituitarism under assisted reproductive techniques (ART) (after median 4.5 cycles, range: 3–6 cycles). Median maternal age at pregnancy was 30 years (range: 22–41 years). Six babies (60%) were delivered by caesarean section. Median gestational age at delivery was 38 weeks (range: 34–43 weeks); median birth weight was 2,920 grams (range: 2,270–3,520 grams), the rate of preterm delivery was 33%. Enlargements of CP cysts occurred in 2 women during pregnancy. Other severe complications during pregnancy, delivery and postnatal period were not observed.
Conclusions
Pregnancies after CP are rare and achieved in 45% after ART. Close monitoring by an experienced reproductive physician is necessary. Due to a potentially increased risk for cystic enlargement, MRI of cystic CP is recommended during pregnancy. Severe perinatal complications, birth defects, and postnatal morbidity of mothers and offspring were not observed.

Expression and possible role of integrins in corticotroph tumours

Xiao Chen[1], Julia Simon[1], Luis Perez-Rivas[1], Jörg Flitsch[2], Jürgen Honegger[3], Walter Rachinger[4], Günter Stalla[1], Martin Reincke[1] & Marily Theodoropoulou[1]
[1]Klinikum der LMU München, Medizinische Klinik und Poliklinik IV, München, Germany; [2]Universitätskrankenhaus Hamburg-Eppendorf, Klinik für Neurochirurgie, Hamburg, Germany; [3]Department of Neurosurgery, University Hospital Tübingen, Tübingen, Germany; [4]Klinikum der LMU München, Neurochirurgische Klinik und Poliklinik, München, Germany

Introduction
Integrins are heterodimeric transmembrane proteins composed of alpha and beta subunits that mediate cell-cell and cell-extracellular matrix (ECM) interactions. Several integrins are overexpressed in human cancers and their ECM recognition motif, arginine-glycine-aspartate (RGD), is being utilized for tumour imaging and targeting.
Aim
To explore the expression and function of RGD-binding integrins in corticotroph tumours.
Methods
We determined the expression of RGD-binding integrins by qPCR in 18 corticotroph tumours and compared transcript levels with gonadotroph

tumours ($n = 16$) and normal pituitaries ($n = 2$). To study the role of integrins, we established their expression profile in murine corticotroph tumour AtT-20 cells by RT-PCR and investigated the effect of their inhibition with RNA interference on human POMC promoter activity and cell viability (WST1 colorimetric assay). We used fluorescence microscopy to assess RGD peptide binding in these cells.
Results
Corticotroph tumours express αv (*ITGAV*), β1 (*ITGB1*), β5 (*ITGB5*), β8 (*ITGB8*), and α8 (ITGA8). Integrins αv, β1, β5 are overexpressed in corticotroph compared to gonadotroph tumours, where expression was almost undetectable ($P < 0.0001$) and human normal pituitary ($P < 0.001$). The expression of β8 was higher in corticotroph only compared to gonadotroph tumours ($P = 0.04$), but not to the normal pituitary. We found that AtT-20 cells express all these four integrins. Knocking down each αv, β1, and β5, decreased human *POMC* promoter activity compared to scramble control (% suppression 63 ± 22, 54 ± 23, and 69 ± 28 respectively; $P < 0.05$), while β8 had little effect. Knocking down αv and β1 had a small but significant effect on AtT-20 cell viability (% suppression 15.92 ± 1.6 and 27.4 ± 1.4 respectively; $P < 0.05$). Using immunofluorescence, we observed that an RGD peptide conjugated with the near-infrared fluorophore cyanine-5.5 could bind to and label AtT20 cells, with no deleterious effects on AtT-20 cell viability (WST1 assay) and function (determined by *POMC* promoter activity).
Conclusions
This study shows that corticotroph tumours express the genes encoding the alpha and beta subunits of the RGD-binding integrins αvβ1, αvβ5, and αvβ8. We have preliminary evidence that these integrins may regulate *POMC* promoter activity. RGD peptide conjugates potential as corticotroph tumour imaging agents.

Background
Polycystic Ovary Syndrome (PCOS) is the most prevalent endocrine disorder in women of reproductive age. The main components are hyperandrogenemia and oligo-/amenorrhea. The pathophysiology of PCOS is not fully understood which is why no causal treatment options are available. A multitude of observational studies demonstrated elevated C-reactive protein (CRP) levels in patients with PCOS compared with weight-matched controls. CRP is a sensitive marker for the proinflammatory cytokine Interleukin-(IL)-1. IL1 stimulated ovarian androgen production and impaired gonadotropin signaling and fertility in experimental studies. In clinical studies, therapeutic IL1 blockade had beneficial effects on cardiometabolic health. The aim of this study was to investigate whether IL1 blockade ameliorates hyperandrogenemia in patients with PCOS.
Methods
This is a prospective, interventional, single-arm, proof-of-concept trial. Seventeen patients with PCOS and C-reactive protein (CRP) levels ≥1 mg/l were treated with 100 mg of the IL1 receptor antagonist anakinra daily for 28 days. The primary endpoint was change in serum androstenedione levels on day 7 of treatment, assessed with liquid chromatography-tandem mass spectrometry. Secondary endpoints included changes in serum androgen concentrations, pituitary-gonadal axis hormones, and clinical parameters on treatment days 7, 14, 21, 28, and one week after end of treatment.
Results
Treatment with anakinra reduced CRP levels on days 7, 21, and 28 ($P < 0.001$). It increased serum androstenedione levels by a median (IQR) of 0.6 (0.2, 1.7) nmol/l to day 7 ($P = 0.008$). Serum testosterone as well as dihydrotestosterone levels increased from baseline to day 7 (both: $P = 0.03$). Estradiol levels were increased during the first three weeks of treatment ($P = 0.02$), which was followed by a menstrual bleeding in five patients of which three were previously oligo-/amenorrheic. There was no overall change in gonadotropins or other clinical parameters.
Discussion
We conclude that chronic low-grade inflammation is regulated by IL1 in PCOS as evidenced by a reduction of circulating CRP levels upon anakinra. Short-term IL1 blockade increased steroidogenesis likely by enabling gonadotropin action. Additionally, this increase might reflect the onset of a new anakinra-induced ovulatory cycle, since androgens as well as estradiol levels rise during the transition from the early to late follicular/ovulatory phase. Three patients experienced an unexpected menstrual bleeding by the end of the study. This data is reassuring to conduct a next randomized placebo-controlled long-term trial with menstrual cyclicity as primary endpoint.

A molecular analysis of genes involved in disruption of hypothalamo-pituitary-gonadal axis causing delay in onset of male puberty

Maleeha Akram[1], David J. Handelsman[2], Marina Kennerson[3], Sania Rauf[1,4], Shahid Ahmed[5], Osama Ishtiaq[6], Muhammad Ismail[7], Qaiser Mansoor[7], Afzaal Ahmed Naseem[1,8], Mazhar Qayyum[1] & Syed Shakeel Raza Rizvi[1]
[1]Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Department of Zoology/Biology, Rawalpindi, Pakistan; [2]ANZAC Research Institute (ARI), University of Sydney, Andrology Department, Sydney, New South Wales (NSW), Australia; [3]ANZAC Research Institute (ARI), University of Sydney, Neurobiology Laboratory, Sydney, New South Wales (NSW), Australia; [4]University of Wah, Department of Zoology, Wah Cantt, Pakistan; [5]Military Hospital (MH), Department of Endocrinology, Rawalpindi, Pakistan; [6]Shifa International Hospital,, Department of Endocrinology, Islamabad, Pakistan; [7]Institute of Biomedical and Genetic Engineering, Islamabad, Pakistan; [8]University of Lahore, Islamabad Campus, Institute of Diet and Nutritional Sciences, Islamabad, Pakistan

Of 563 genes involved in multiple processes of development of hypothalamo-pituitary-gonadal (HPG) axis during embryogenesis, mutations in 62 genes cause delayed puberty. We selected 6 of 37 delayed puberty patients for whole exome sequencing (WES) based on advanced age (>18 years) and severity of disease symptoms. Genomic DNA extraction was done using Qiagen kit at Institute of Biomedical and Genetic Engineering, Islamabad, Pakistan. DNA samples were taken to ANZAC Research Institute (ARI), New South Wales (NSW), Australia for genetic analysis. Each sample was diluted to final concentration of 25 ng/µl DNA and was outsourced to Macrogen Inc., Seoul, South Korea for WES using Illumina HiSeq 2000 platform. Bioinformatics analysis was performed at ARI. Only missense, splice region, frameshift, exon lost, stop gained and stop lost variants expressed along HPG axis having minor allele frequency of < 1% were included. Manual evaluation of BAM files and In Silico analysis of missense variants were performed to assess functional consequences. Selected variants were confirmed by Sanger sequencing at Australian Cancer Research Foundation, Garvan Institute of Medical Research, NSW. We report mutations in 31 genes expressed along HPG axis, 7 already reported confirmed, 6 reported but unconfirmed and 18 novel mutations. Of 53 genes involved in hypothalamic regional territories development, mutation in one confirmed gene was identified. Of 60 genes for GnRH neuron differentiation, mutations in 2 confirmed, 1 reported unconfirmed and 2 new genes were identified. Among 101 genes for GnRH neuron migration, mutations in 4 confirmed, 1 reported unconfirmed and 6 new genes were identified. Of 60 genes for development of GnRH neural connections with supra-hypothalamic neurons, mutations in 3 confirmed, 1 reported unconfirmed and 6 novel genes were identified. Of 24 genes for neuron homeostasis, 2 novel mutations were observed. Among 46 genes coding for molecules regulating GnRH neuron activity, mutations were identified in 2 reported unconfirmed and 4 novel genes. Of 56 genes coding for receptors/proteins on GnRH neurons, mutations in 1 reported unconfirmed and 1 novel gene were observed. Among 21 genes coding for signaling molecules, mutations were identified in 1 reported unconfirmed and 3 novel genes. Of 95 genes for GnRH synthesis, mutations in 1 confirmed and 1 reported unconfirmed gene were observed. Of 31 genes for gonadotropins production/release, mutations in 1 confirmed, 1 reported unconfirmed and 1 novel gene were identified. Of 115 genes for steroid hormone action, mutations were identified in 1 confirmed and 1 new gene.

Gender difference in genetic and diagnosis of congenital hypogonadotropic hypogonadism (CHH) in a large cohort from an Endo-ERN referral center

Silvia Federici[1,2], Biagio Cangiano[1,2], Giovanni Goggi[1,2], Luca Persani[1,2] & Marco Bonomi[1,2]
[1]University of Milan, Dept. of Medical Biotechnology and Translational Medicine, Milan, Italy; [2]IRCCS Istituto Auxologico Italiano, Dept. of Endocrine and Metabolic Diseases and Lab. of Endocrine and Metabolic Research, Milan, Italy

Congenital hypogonadotropic hypogonadism (CHH) is a rare condition characterized by impairment of pubertal development, that can be associated with hypo/anosmia (Kallmann Syndrome, KS) or normosmia (nCHH). A genetic basis can be identified in nearly 50% of cases, with increasingly common detection of oligogenicity. CHH has a strong male predominance (MtoF ratio 5–3:1), although sex ratio for CHH in families with autosomal inheritance has been proven to be close to equal. The rationale for this epidemiologic difference is not clearly understood. Our study aims to evaluate gender differences in clinical and genetic diagnosis of CHH. 313 CHH patients with absent pubertal development, consecutively referred to our Center from 01/2016, were enrolled in this study. Data collection included clinical assessment at diagnosis and genetic analysis performed by next generation sequencing (NGS), employing a panel of 27 candidate genes (ANOS1, FGFR1, PROK2, PROK-R2, KISS1, KISS1R, GnRH, GnRHR, FGF8, TACR3, TAC3, HS6ST1, CHD7, DUSP6, FEZF1, FGF17, FLTR3, IL17RD, SEMA3A, SEMA3E, SEMA7A, SOX2, SOX10, SPRY4, WDR11, HESX1, NELF). Among 313 patients 87 were female (F) and 226 male (M) (FtoM ratio 1:2.6). 43.8% had a diagnosis of KS and 56.2% of nCHH (no significant gender difference). Rare genetic variants were found in 54.3% of patients (F 55.2% vs. M 54%). Monoallelic rare variants were found in 37.1% (F 33.3% vs. M 38.5%), biallelic monogenic rare variants in 4.2% (F 5.7 vs M 3.5%) and oligogenicity in 13.1% (16.1% vs. 11.9%), with no significant difference between sex, even after exclusion of X-linked ANOS1. Prevalence of rare variants in each candidate gene resulted in line with literature, showing no significant gender differences, except for IL17RD (F 5,7% vs. M 1,3%, *P* 0.040). Age at diagnosis was 17.2 ± 2.9 for F and 16.8 ± 3.5 for M (*P* 0.065). Presence of clinical "red flags" (family history, hypo/anosmia, micropenis, cryptorchidism, midline defects, bimanual synkinesis, renal abnormality, deafness) was significant higher in male (F 64.4% vs. M 79.2%, *P* 0.008), but not related to age at diagnosis or presence of rare variants. Nevertheless, these rates become similar after excluding micropenis and cryptorchidism, as only male manifestations. Our data confirm the male predominance in CHH but they do not allow to identify substantial differences in genetic or clinical presentation between gender, suggesting that gender gap in CHH prevalence do not depend upon variability of the underlying pathogenic mechanisms, but rather to gender specific characteristics of GnRH function or differences in diagnostic capability.

DOI: 10.1530/endoabs.73.OC4.3

OC4.4

Fertility outcomes in women with hypopituitarism compared to women with hypogonadotrophic hypogonadism in a single UK centre

Carol Cardona Attard, Oliver O'Donovan, Sasha Nair, Davina Puri, Vikram S Talaulikar, Melanie C Davies & Gerard S Conway
University College London Hospitals, Reproductive Medicine Unit, London, United Kingdom

Objective
Previous studies have documented poor fertility results in women with hypopituitarism (HP) both in terms of pregnancy rates and outcomes. We aimed to assess ovulation induction (OI) and pregnancy outcomes in women with HP compared to women with hypogonadotrophic hypogonadism (HH) treated at University College London Hospitals.
Design
A retrospective study.
Patients
39 women with HP and 57 women with HH underwent 143 and 266 cycles of OI respectively (median age at cycle 33.5 years [interquartile range (IQR) 31.4–37.0] vs 34.3 years [IQR 32.3–36.6] respectively, $P = 0.35$).
Methods
OI was carried out by using human menopausal gonadotropin (hMG) according to a standard protocol and a 10,000 IU human chorionic gonadotropin trigger. Baseline serum oestradiol, follicle stimulating hormone, luteinizing hormone, prolactin, thyroid functions tests and insulin-like growth factor-1 were measured together with a uterine scan. Ovulation was confirmed by a mid-luteal phase progesterone of >30 nmol/l or ultrasound evidence of corpus luteum. Clinical pregnancy was defined by the presence of at least one heartbeat on an ultrasound scan.
Results
Ovulation rates were similar between women with HP and HH. Although pregnancy and live birth rates per cycle were greater in women with HP compared to women with HH (28.7% vs 16.2%, $P = 0.003$ and 17.0% vs 9.4%, $P = 0.025$ respectively), pregnancy and live birth rates per patient were similar (66.7% vs 50.9%, $P = 0.125$ and 48.6% vs 37.5%, $P = 0.286$ respectively). Foetal loss per pregnancy was not different between women HP and HH (29.3% vs 39.5%, $P = 0.323$ respectively), with a similar proportion of multiple pregnancies per live births between the 2 groups of women (HP 8.3% vs HH 20.0%, $P = 0.243$). There were no major complications in most of the deliveries. Median number of cycles to pregnancy in women with HH was 9 (Standard Error [SE] 0.0) vs 6 cycles (SE 0.8) in women with HP (Log Rank: $P = 0.001$).
Conclusions
Encouraging ovulation and pregnancy rates can be obtained in women with HP using hMG. A smaller uterine size and lack of size normalisation following standard oestrogen replacement therapy may in part explain the greater miscarriage rate compared to the general population in these women. Management in a multidisciplinary team is advised.

Lower level of sexual maturation rating and reduced concentrations of reproductive hormones, luteinizing hormone, follicle stimulating hormone, testosterone and estradiol in short stature children with mutations in growth hormone secretagogue receptor 1a

Nighat Kausar[1], Maleeha Akram[1], Gulbin Shahid[2], Mazhar Qayyum[1], Afzaal Ahmed Naseem[1,3], Fahim Tahir[4], Sarwat Jahan[5], Kiran Afshan[5], Muhammad Rafi[6] & Syed Shakeel Raza Rizvi[1]
[1]Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Department of Zoology/Biology, Rawalpindi, Pakistan; [2]Pakistan Institute of Medical Sciences (PIMS), Islamabad, The Children's Hospital, Islamabad, Pakistan; [3]University of Lahore, Islamabad Campus, Islamabad, Institute of Diet and Nutritional Sciences, Islamabad, Pakistan; [4]National Institute of Health, Reproductive Physiology, Public Health Laboratories Division, Islamabad, Pakistan; [5]Quaid-i-Azam University, Department of Animal Sciences, Islamabad, Pakistan; [6]Pakistan Institute of Engineering and Applied Sciences (PIEAS), Islamabad, Pakistan, Islamabad, Pakistan

Puberty onset is sensitive to the energy reserves of the organism, especially in females where there is an association between obesity and early puberty. Studies have shown that in the presence of growth hormone secretagogue receptor 1a (GHSR1a) mutations, there is a decrease in ghrelin-mediated appetite, resulting in relatively low BMI, which contributes to the delayed onset of puberty. Furthermore, delayed puberty is observed in clinical conditions associated with low IGF1, suggesting that IGF1 also exerts stimulatory, synergistic, or permissive effects on the onset of puberty. Thus, low IGF1 levels due to a decrease in GH secretion caused by GHSR1a insufficiency may also negatively modulate the timing of puberty onset. The present study was designed to determine the level of sexual maturation rating (SMR) and the concentrations of reproductive hormones, luteinizing hormone (LH), follicle stimulating hormone (FSH), testosterone (T) and estradiol (E2) in normal and short stature children having GHSR1a mutations. SMR including penile length, testicular volume, pubic hair and facial hair stage for boys ($n = 21$) and breast development and pubic hair stage for girls ($n = 14$) having short stature between the ages of 2 and 14 years was measured and compared with age matched control subjects ($n = 50$). The stage of pubertal development was assessed by using the criteria described by Tanner and Whitehouse. ELISA was used for analysis of plasma LH and E2 and specific RIA systems were used for analysis of plasma FSH and T. Data were analyzed using Student's t test, ANOVA and Pearson correlation r. The results revealed a significant difference between mean penile length and testicular volume of normal boys and short stature boys at early and mid-pubertal stages. Similarly, breast development was significantly delayed in short stature girls than normal girls at early and mid-puberty. Pubic hair development in short stature girls and pubic and facial hair development in short stature boys were also significantly delayed as compared to normal girls and boys at early and mid-puberty. The levels of LH, FSH, T and E2 were higher in normal than short stature boys and girls and a significant difference was witnessed at early and mid-pubertal stages. In conclusion, SMR was higher in normal children as compared to short

stature children. Furthermore, the concentrations of gonadotropins LH and FSH and sex steroids, T and E2 were significantly higher in normal children as compared to short stature children.

The potential role of androgens as early determinants of body composition and metabolic health.

Thiberiu Banica[1], Charlotte Verroken[1], Hans-Georg Zmierczak[1], Stefan Goemaere[1], Guy T'Sjoen[1], Tom Fiers[2], Jean-Marc Kaufman[1] & Bruno Lapauw[1]
[1]Ghent University Hospital, Department of Endocrinology, Gent, Belgium; [2]Ghent University Hospital, Department of Clinical Chemistry, Gent, Belgium

Introduction
Even in healthy men, androgen levels start decreasing from early adulthood and these decreases are more pronounced in men with an increasing body mass index (BMI). It is, however, unclear to what extent changes in other indices of body composition and metabolic health are associated with changes in sex steroid exposure in healthy men over time.
Objective
Investigating longitudinal changes in body composition and metabolic health in relation to sex steroid levels in young adult men.
Methods
Longitudinal, population-based, observational study: 999 healthy men aged 24–46 years of whom 691 were re-evaluated after 12 ± 2 years. Serum sex hormone binding globulin (SHBG) and insulin levels were measured using immuno-assay, glucose by hexokinase method, testosterone (T) using LC-MS/MS, free T (cFT) and homeostasis model for insulin resistance (HOMA-IR) calculated. Body composition was determined using DXA (Hologic) at the whole body minus head. Fat (FM%) and lean mass (LM%) percentages were calculated. Mixed models were used for statistical analyses. All models were adjusted for baseline age.
Results
Baseline age was 34 ± 6 years. Mean BMI increased by 4.7% (25.1 kg/m^2 vs 26.3 kg/m^2). Mean T levels decreased by 14.2% (20.8 nmol/l vs 17.8 nmol/l), cFT by 19.1% (392 pmol/l vs 317 pmol/l) and SHBG increased by 3.0% (39.8 nmol/l vs 41.0 nmol/l) (all $P < 0.001$). FM% increased by 10.2% (19.6% vs 21.6%; $P < 0.001$), especially at the trunk (8.1 kg vs 9.6 kg; $P < 0.001$). LM% decreased by 1.8% (77.3% vs 75.4%; $P < 0.001$). HOMA-IR increased from 1.7 to 2.2 ($P < 0.001$). At baseline, total T, cFT and SHBG were inversely associated with truncal fat, FM% and HOMA-IR and positively associated with LM% (all $P < 0.001$). Longitudinally, changes in sex steroids were not associated with changes in either FM% and LM%. However, changes in total T, cFT and SHBG were inversely associated with changes in truncal fat and HOMA-IR (all $P < 0.018$).
Conclusion
In healthy young men, adiposity and insulin resistance increased while LM% decreased over a period of 12 years. We found that a stronger decline in both total and free T levels was associated with stronger increases in truncal adiposity and insulin resistance. Our findings suggest a direct role of sex steroids as determinants of metabolic state. Whether these findings result from residual confounding or are mediated by the intriguing relationship between SHBG levels and metabolic health remains to be established. Moreover, the possibility of a reverse causality between changes in androgen levels and metabolic state should be taken into account.

Identification of iodothyronine deiodinase 2 inhibitors among FDA-approved drug library using high throughput screening

Caroline Frädrich[1], Kostja Renko[2], Niklas Wiese[1], Anja Fischbach[1], Carola Seyffarth[3], Martin Neuenschwander[3], Jens Peter von Kries[3] & Josef Köhrle[1]
[1]Charité-Universitätsmedizin Berlin, Institute of Experimental Endocrinology, Berlin, Germany; [2]German Federal Institute for Risk Assessment, German Centre for the Protection of Laboratory Animals (Bf3R), Berlin, Germany; [3]Leibniz-Forschungsinstitut für Molekulare Pharmakologie, Screening Unit, Berlin, Germany

Background
Development and application of novel drugs frequently fail due to adverse changes of TH-levels or thyroid histology in animal experiments. Such effects potentially arise from interference with thyroid gland function or key regulators of local thyroid hormone (TH) transport, metabolism and action. Deiodinases are key enzymes in TH in-/activation, with impact on development, cell differentiation and energy metabolism among other physiological processes, and have therefore been identified as molecular initiating events (MIE) in the assessment of chemicals for endocrine disruption.
Method
A robust semi-automatic 384-well High Throughput Screening (HTS) platform was developed and now employed for screening substances interfering with DIO2 activity, utilizing the non-radioactive Sandell-Kolthoff (SK) reaction to determine DIO-depending iodide release. In an initial HTS using recombinantly expressed human DIO2, 1759 components from a FDA-approved drug library were tested at a single concentration of 20 μM.
Results
At the given concentration, 1.1% of the tested drugs showed DIO2 inhibition by >25% and 0.2 % an inhibition by >€50%. 11.5% of the screened drugs had characteristics of either potential DIO2 activators or SK interference. Among the inactive compounds were some well-known DIO1-selective inhibitors such as PTU or Genistein, a finding which supports the specific and predictive quality of this HTS approach.
Conclusion & outlook
In this pilot study, we were able to demonstrate that even a library of FDA-approved drugs does contain compounds that may exert adverse effects on TH metabolism by DIO2 inhibition. In perspective, such compound should be revised regarding potential side effects that might appear from such interference, e.g. abnormal patterning of TH metabolites in serum or defects that might appear from local suppression of DIO2 activity. While this screening setup is appropriate to detect endocrine disruptors (ED) affecting DIO2 activity, it does, on the other hand, also opens the perspective to identify highly potent drug candidates and reference compounds for ED research. In summary, this study represents a major success in the development of an in vitro strategy to identify endocrine disruptors, characterized by inhibition of deiodinases. The established 384-well assay protocol also provides the basis for further testing of large chemical libraries against DIO2, and can be adapted to other deiodinating enzymes modulating TH availability, e.g. DIO1 or dehalogenase (IYD). Furthermore, generated data pools provide the basis to select Quantitative Structure Activity Relationship training sets to develop predictive in silico tools for preselection and toxicological assessment.

Use of thyroid hormones in hypothyroid and euthyroid patients: A 2020 THESIS* questionnaire survey of members of the Danish Endocrine Society (*Treatment of hypothyroidism in europe by specialists: An international survey)

Kamilla Ryom Riis[1], Jacob Froelich[1], Laszlo Hegedüs[1], Roberto Negro[2], Roberto Attanasio[3], Endre Nagy[4], Enrico Papini[5], Petros Perros[6] & Steen J. Bonnema[1]
[1]Odense University Hospital, Endocrinology, Denmark; [2]Division of Endocrinology, V. Fazzi Hospital, Italy; [3]IRCCS Orthopedic Institute Galeazzi, Endocrinology Service; [4]Division of Endocrinology, Department of Medicine, Faculty of Medicine, University of Debrecen, Hungary; [5]Department of Endocrinology and Metabolism, Opsedale Regina Apostolorum, Italy; [6]Department of Endocrinology, Royal Victoria Infirmary, Newcastle upon Tyne, United Kingdom

Purpose
The standard treatment of hypothyroidism is levothyroxine (LT4), which is available as tablets or soft-gel capsules in Denmark. This study aimed to investigate Danish endocrinologists' use of thyroid hormones in hypothyroid and euthyroid patients.
Method
An e-mail with an invitation to participate in an online survey investigating practices about substitution with thyroid hormones was sent to all members of the Danish Endocrine Society (DES) on 27th February 2020. The initial e-mail was followed by three reminders between February and May 2020, and where after it was closed. Survey responses were collected and electronically stored by the Lime-Survey service.

Results
Out of 488 eligible DES members, a total of 152 (31.2%) respondents were included in the analysis. The majority (94.1%) of responding DES members use LT4 as the treatment of choice. Other treatment options for hypothyroidism are also used, as 58.6% prescribe combination therapy with liothyronine (LT3)+LT4 in their clinical practice. LT4+LT3 combination is preferred in patients with persistent symptoms of hypothyroidism despite biochemical euthyroidism on LT4 treatment. Over half of the respondents answered that thyroid hormone therapy is never indicated for euthyroid patients, but 42.1% will consider it for euthyroid infertile women with high antibody levels. In various conditions that could interfere with the absorption of LT4, most responding Danish endocrinologists prefer tablets to soft-gel capsules or liquid LT4 and do not expect a significant difference when switching from one type of tablet formulation to another. The Danish endocrinologists are nearly equally divided into two categories regarding supplementation; 57 (37.5%) answered that supplementation with selenium or iodine can be used if requested by the patient, while 62 (40.8%) stated that such supplementation should never be used.
Conclusion
The treatment of choice for hypothyroidism is LT4. Combination therapy with LT4+LT3 is considered for patients with persistent symptoms. Even in the presence of conditions affecting bioavailability, responding Danish endocrinologists prefer LT4 tablets rather than newer LT4 formulations, such as soft-gel capsules.

Derivation of thyroid progenitors from human induced pluripotent stem cells

Alberto Posabella[1,2], Hendrik J. Undeutsch[3], Andrea Brigitta Alber[1], Anthony N. Hollenberg[3], Darrell N. Kotton[1,4]
[1]Center for Regenerative Medicine, Boston University and Boston Medical Center, Boston Massachusetts, United States; [2]University Center of Gastrointestinal and Liver Diseases–Clarunis, University of Basel, Basel, Switzerland; [3]Division of Endocrinology, Diabetes and Metabolism, Joan and Sanford I. Weill Department of Medicine, Weill Cornell Medicine, New York, United States; [4]The Pulmonary Center and Department of Medicine, Boston University School of Medicine, Boston, Massachusetts, United States

Despite the availability of synthetic thyroid hormone for therapeutic use, a significant number of patients with hypothyroidism do not feel well on replacement doses of thyroid hormones suggesting that better individualized therapy is needed. For this reason, hypothyroidism resulting from congenital lack of functional thyrocytes, surgical tissue removal, or gland ablation, represents a particularly attractive endocrine disease target that may be conceivably cured by transplantation of long-lived functional thyroid progenitors or mature follicular epithelial cells, provided a source of autologous cells can be generated and a variety of technical or biological challenges can be surmounted. To generate thyroid follicular progenitors from human induced pluripotent stem cells (hiPSCs), we sought to develop a directed differentiation approach by activating or inhibiting endogenous developmental signaling pathways previously identified in the mouse. To facilitate tracking and purification of candidate human thyroid progenitors, we engineered a hiPSC-line carrying a tdTomato reporter targeted to the PAX8 locus and a GFP reporter targeted to the NKX2–1 locus. We adapted our published in vitro differentiation protocol previously used to differentiate mouse PSCs into endoderm, foregut endoderm and then thyroid progenitors and observed tdTomato/GFP co-expressing cells first emerging from our hiPSC line by day 12 of culture and persisting for at least 2 months of further culture in thyroid maturation media, supplemented with TSH. We profiled all cells (regardless of fluorochrome expression) deriving from hiPSCs using this protocol by single cell RNA sequencing >6.000 cells captured on days 12 and 29 of *in vitro* differentiation. At day 12 of differentiation, tdTomato/GFP co-expression was observed in 17% of all cells and these cells appeared to be early thyroid follicular progenitors as they uniquely co-expressed the tetrad of thyroid lineage selective transcription factors, NKX2–1, PAX8, FOXE1, and HHEX, and already expressed thyroid maturation markers, TG or TPO. By day 29 tdTomato+/GFP+ cells represented 72.1% of all cells and had upregulated TG, TSHR, NIS and TPO expression in addition to the previously described four thyroid lineage markers, suggesting time dependent differentiation and maturation of thyroid follicular epithelial cells. Thus, we have employed a novel hiPSC line to optimize a protocol able to generate human thyroid progenitors and mature follicular epithelial cells, representing a purifiable source of human thyroid lineage cells whose functional and thyroid reconstituting potential can be tested in vivo in animal models of hypothyroidism.

The ablation of thyroid nodule's afferent arteries before radiofrequency ablation: preliminary data.

Chiara Offi[1], Sara Garberoglio[2], Giovanni Antonelli[1], Maria Grazia Esposito[1], Umberto Brancaccio[1], Claudia Misso[1], Edoardo D'Ambrosio[1], Daniela Pace[1] & Stefano Spiezia[1]

Induced radiofrequency thermal ablation is cytoreductive treatment of symptomatic benign thyroid nodules, metastatic and recurrent thyroid tumors and papillary thyroid microcarcinomas. It is a safe and effective alternative to surgery and it allows to obtain satisfactory results in terms of volumetric reduction of the nodule with significant improvement in the quality of life. The trans-isthmic approach and the moving shot technique are the two basic techniques; however, an advanced technique, as artery-first feeding radiofrequency ablation has been developed and validated. We have prospectively included 29 consecutive patients who have undergone radiofrequency ablation (Group A) or artery–first vRFA (Group B). All included patients had a diagnosis of benign nodular goiter and they were undergoing to a single session of radiofrequency ablation. All patients followed a follow-up program at 1 month, 3 months and 6 months. Continuous variables (age, TSH value, basal volume of nodule, used Joule, time in second of the procedure, nodules' volume at 1-, 3–and 6–months of follow-up and percentage of volume reduction at 1-, 3–and 6–months of follow-up) were described as mean, standard deviation and range, while categorical variables (gender, nodule structure and nodule vascularization) were described as number of cases and percentage. Independent samples t-test were performed to compare the continuous variables. A Test of Proportions was applied to the categorical variables. The Fisher's exact test was used to analyze the gender. Statistical significance was considered in case of P-value < 0.05. Solid structure and spongiform structure showed statistic differences with p-values of 0.022 and 0.023 respectively between two groups. The percentage of reduction at 1 month did not show a significant difference between two groups; instead, the percentage of volume reduction was decreased mostly in the Group B at 3 months and 6 months of follow-up with a p-value of 0.003 and 0.013, respectively. The Joules/energy used showed a statistically significant difference (P –value = 0.05), more energy must be used in vascular radiofrequency ablation. These data allow us to hypothesize that vRFA may improve the effectiveness of the procedure, allowing for a reduction in volume more quickly. They were preliminary but promising results, clearly a larger series of cases and prolonged follow-up are needed to clarify and confirm our observations.

Martino, Section of Pathological Anatomy, Department of Human Pathology "Gaetano Barresi", Messina, Italy; [6]Università di Catanzaro "Magna Graecia", Department of Health Sciences, Catanzaro, Italy

Radioiodide 131I (RAI) is the therapy of choice for radioiodine-avid differentiated thyroid cancer (DTC). However, 5–15% of DTC patients become RAI refractory (RAIR), and the 10-year survival rate for metastatic disease decreases to 10%. The failure of RAI response is mainly due to the loss of thyroid differentiation, that leads to the loss of expression/function of components of iodide metabolism, first of all the Na/I symporter (NIS). The

finding that the MAPK pathway is involved in this process suggested that the protein kinase inhibitors therapy may be effective for redifferentiation in the treatment of RAIR patients. However, nowadays, fully efficient treatments for advanced thyroid cancer patients are still missed. Different approaches aimed to re-activate radioiodine uptake in RAIR tumors have been trying, including the use of a miRNA-based strategy. Although MiRNAs have been shown to be useful predictive biomarkers and targets of therapeutic options in thyroid cancers, only few studies investigated their role in response to RAI therapy. We investigated the miRNA signature associated with RAI refractory DTC in order to identify novel biomarkers that will be potential target for a redifferentiation therapy. Using the real-time PCR we analysed the expression of 734 miRNA in 26 DTC tissues, 13 responsive (R) and 13 not-responsive (NR) to RAI therapy. By comparing both groups we found a statistically significant dysregulation of 15 miRNAs analysed: 14 miRNAs were upregulated and only one (miR-139–5p), was down-regulated in RAI refractory tumors. Then, we performed in-vitro experiments to investigate the role of miR-139–5p in the iodine uptake metabolism. Using two primary cell lines and five immortalized cell lines, we overexpressed miR-139–5p, and we analysed the transcript and protein levels of NIS. Moreover, we investigate the NIS activation status through the iodine uptake assay and the subcellular protein localization. The findings of a higher intracellular iodine level and of an increase in cells' membrane protein localization in miR-139–5p overexpressing cells, supported the effect of such miRNA in increasing NIS function. Although the downregulation of miR-139–5p expression has already been found to correlate with the thyroid cancer's aggressiveness, this is the first study aimed to investigate its role in the iodine uptake metabolism. However further studies are necessary to confirm the possible role of miR-139–5p as therapeutic target for RAI refractory DTCs.

Comparison of Simultaneous calcitonin washout and cytology procedure success in recurrent medullary thyroid cancer

Asena Gökçay Canpolat[1], Mustafa Sahin[1], Koray Ceyhan[2] & Demet Çorapçıoğlu[1]

[1]Ankara University, Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara University, Faculty of Medicine, Department of Pathology, Ankara, Turkey

Background

Medullary thyroid carcinoma (MTC) accounts for 3–5% of thyroid cancers, but recurrent MTC, manifested by elevated calcitonin levels, is a common problem. We aimed to perform a calcitonin washout procedure simultaneously with cytological evaluation and compare their effectiveness to diagnose metastatic lymph nodes.

Methods

94 patients diagnosed with MTC were recruited from our institutional database from 2010–2021. The analysis of calcitonin washout procedure (CTW) and fine-needle aspiration (FNA) cytology for metastatic lymph nodes were recorded for recurrent MTC. Only one cytologist performed the cytological examination. The cut-off level above ≥100 pg/ml was determined as a pathologic lymph node. The demographic features, mean age at diagnosis, laboratory analysis of preoperative and postoperative calcitonin and Carcinoembryonic antigen (CEA), cytopathological data were all collected.

Results

The median age at diagnosis was 40.7 ± 17 years; the mean CTW level was 1800 (142–9000) pg/ml, the mean preoperative CT level was 620 (54–9000) pg/ml, and the mean CEA level was 9.4 (0.5–1958). Out of 94 patients, 32 were recurrent cases. CTW and FNA procedures were applied for 44 suspicious lymph nodes. 43 cytological examination were done for these lymph nodes. The FNA results' distribution was 4.6% reactive lymph node(n:2), 11.6% non-diagnostic(n:5), 81.3% (n:35) MTC and 2.32% (n:1) suspicious for malignancy. The two reactive lymph node cytology had CTW levels of 800 pg/ml and 2942 pg/ml, so they were operated on and diagnosed as MTC. 44 positive CTW procedures were applied, and 42 of them were compatible with MTC. The false positive lymph nodes were; a reactive lymph node with a CTW result of 221 pg/ml and a cytologically non-diagnostic lymph node with a CTW result of 800 pg/ml.

Conclusion

Recurrent MTC is a progressive disease in half of the cases, but it can be handled with correct diagnostic methods and surgery. CTW procedure is an easy and quick laboratory test as compared with cytological evaluation. According to our results, CTW measurements were also more accurate than cytological examination when defining pathological lymph nodes. CTW evaluation was mainly evaluated for either thyroid nodules alone or combined with neck lymph nodes. This is the first and largest study evaluating the metastatic lymph nodes of MTC with CTW and cytology together.

Parathyroid glands regulate bone metabolism through PTH, while bone modulates parathyroid function through calcium and FGF23. We tested the hypothesis that the matrix protein osteocalcin (OC), secreted by osteoblasts, may modulate parathyroid function. In human parathyroid cells derived from adenomas (PAds), incubation with g-carboxylated OC (GlaOC) or undercarboxylated OC (GluOC) modulated the intracellular signaling pathways: both GlaOC and GluOC inhibited the basal phosphorylated ERK/total ERK ratio (pERK/ERK) and increased the basal phosphorylated AKT/total AKT ratio (pAKT/AKT) and active b-catenin levels. Moreover, GlaOC and GluOC modulated the expression of parathyroid genes: GlaOC increased the expression levels of the *PTH* gene, modulated the expression of genes involved in cell cycle, increasing *CCND1* and reducing *CDKN1B*/*p27* and *TP73*, and increased the expression of *CASR*. GluOC also stimulated the transcription of *PTH*, while it did not exert any effect on the other genes, except by inhibiting *MEN1* expression. Of note, GlaOC and GluOC treatments reduced the proportion of apoptotic cells induced by incubation with staurosporin. OC acts through the putative membrane receptor GPRC6A, whose transcripts and proteins were variably detected in human PAds and did not correlate with the expression of CASR. Immunohistochemistry showed specific GPRC6A cytoplasmic staining in some cells and membrane staining in other cells scattered throughout the parenchyma, both in normal and tumor parathyroids. As GPRC6A and CASR share high homology, OC may activate both the receptors. Reducing the CASR expression by treating PAds-derived cells with *CASR* siRNA, we observed that GlaOC and GluOC modulated the ERK pathway mainly through GPRC6A activation, while CASR activation was involved in the modulation of the AKT and b-catenin pathways. Using HEK293A cells transfected with GPRC6A and with CASR, we further dissected the effects of GlaOC and GluOC on the signalling pathways in presence of different extracellular calcium concentrations ($[Ca^{2+}]_o$), finding that GlaOC and GluOC can activate CASR, that $[Ca^{2+}]_o$ is needed to activate CASR by GlaOC and GluOC, and that GlaOC activates GPRC6A also in calcium-free medium as well as in presence of 5.0 mM $[Ca^{2+}]_o$ but exerting opposite effects with respect that observed in presence of 1.5 mM $[Ca^{2+}]_o$.

Conclusion

OC can be added to the bone-parathyroid cross-talk; it may modulate the CASR sensitivity to $[Ca^{2+}]_o$ of the parathyroid cells, representing a target for potential medical treatment of parathyroid disorders.

Adeno-associated virus (AAV) gene therapy reached the maturity and a liver-targeting approach is currently used as a replacement treatment for rare hepatic and muscular diseases. X-linked hypophosphatemia (XLH) is a rare disease associated with hyperfunction of fibroblast growth factor 23 (FGF23) in bone and characterized by severe skeletal deformities and short stature. The current medical therapies for XLH requires life-long repeated treatment presenting major limitations as an inadequate treatment compliance due to i) multiple doses per day and severe long-term side effects for the conventional treatment (based on phosphate supplementation and active vitamin D analogs) or ii) an extremely expensive cost for the health care system for the monoclonal anti-FGF23 antibody therapeutic. Here we studied the hypothesis whether the liver-targeting approach could be used as a therapeutic modality for rare diseases associated with hyperfunction of growth factors as XLH, treating this bone pathology with a single injection. We elaborated a novel therapeutic approach for XLH based on a single injection of AAV gene therapy aiming to stimulate the production of a FGF23 neutralizing factor (cFGF23) in the liver in a murine model of XLH, the Hyp-Duk mouse. We demonstrated that one single injection of AAV-cFGF23 treatment led to restoration of impaired skeletal phenotype, and to significant reduction of osteomalacia, bone and joint alterations in Hyp-Duk mice. This provides a proof-of-concept that the liver-targeting approach represents an adequate modality to rescue the growth factor's hyperfunction, thus opening the new perspectives on the treatment of skeletal diseases by gene therapy.

Bone material strength index is altered in patients with Cushing's syndrome even after long-term remission

Manuela Schoeb[1], Paula J.C. Sintenie[1], Femke van Haalen[2], Michiel Nijhoff[2], Friso de Vries[2], Nienke Biermasz[2], Elizabeth M. Winter[1,2], Alberto M Pereira[2] & Natasha Appelman-Dijkstra[1,2]
[1]Leiden University Medical Center, Center for Bone Quality, Department of Medicine, Division of Endocrinology, Leiden, Netherlands; [2]Leiden University Medical Center, Center for Endocrine Tumors Leiden, Department of Medicine, Division of Endocrinology, Leiden, Netherlands

Background
Endogenous Cushing's syndrome (CS) is detrimental to bone. The skeletal complications are characterized by decreased bone formation and increased bone resorption, resulting in decreased bone mineral density (BMD) and an increased risk of fractures at time of diagnosis. After remission of the disease, BMD improves towards normal values but fracture rate remains elevated. Therefore, components of bone quality other than BMD, such as bone material properties, must be affected in CS, even after remission. Bone material properties can be assessed by Impact Microindentation (IMI) in a minimally-invasive way.
Aim
To evaluate bone material properties using IMI in patients with CS in remission.
Methods
In this cross-sectional study, 57 consecutive patients (45 women), 16 with prevalent fragility fractures, and 57 controls matched for age, sex, and BMD (45 women), 25 with fragility fractures, were included. Bone material strength index (BMSi) was measured by IMI using the OsteoProbe device at the midshaft of the tibia after applying local anesthetic. In addition, laboratory investigation, BMD, and vertebral fracture assessment were performed. Remission was defined according to the Endocrine Society Clinical Practice guidelines.
Results
Mean age of the patients was 54.5 ± 12.5 years and 55.2 ± 12.4 years in controls, (P = 0.70). The main origin of hypercortisolism was pituitary in 47 patients, followed by adrenal (n = 8) and ectopic origin (n = 2). Median time of remission was 6 years (IQR 3 to 15 years). BMD was comparable in patients and controls at the lumbar spine (0.98 ± 0.16 g/cm^2 vs 0.95 ± 0.11 g/cm^2, P = 0.49) and the femoral neck (0.75 ± 0.12 g/cm^2 vs 0.74 ± 0.12 g/cm^2, P = 0.73). However, BMSi was significantly lower in patients compared to controls (76.5 ± 6.9 vs 81.4 ± 5.1, P < 0.001). In patients, BMSi was negatively correlated with BMI (r = -0.51, P < 0.001), but not related to the presence of fragility fractures, dependence, duration and dosage of hydrocortisone suppletion, or other pituitary failure. In controls, BMSi was not related to BMI, but significantly lower in those with fragility fractures compared to those without fragility fractures (78.1 ± 4.5 vs 84.0 ± 4.1, P < 0.001).
Conclusion
BMSi was significantly lower in CS patients in remission than in matched controls, independently of BMD. Our findings indicate that bone material properties are permanently altered in patients with endogenous Cushing's syndrome even after long-term remission, which may contribute for their persisting increased fracture risk. The IMI technique might be a valuable additional tool in the evaluation of bone fragility in these patients.

Bisphosphonates after Denosumab withdrawal reduce the vertebral fractures incidence

Giorgia Grassi[1], Iacopo Chiodini[2], Serena Palmieri[2], Elisa Cairoli[2], Maura Arosio[2] & Cristina Eller Vainicher[1]
[1]IRCCS Fondazione CA Granda, Endocrinologia, Milano, Italy; [2]University of Milan, Milano, Italy

Objective
Several studies showed that patients discontinuing denosumab (Dmab) may experience bone loss and incident vertebral fractures (VFx) due to a rebound bone turnover increase, suggesting the need of anti-resorptive (i.e. bisphosphonate BPs) therapy to mitigate this occurrence. However, the morphometric VFx (morphoVFx) incidence after Dmab discontinuation is unknown and scarce data are available about the BPs effect on BMD changes and Fx risk in this setting.
Methods
In this monocentric retrospective study, 120 patients (111 females) discontinuing Dmab (mean injections n. 6.2 ± 2.7) were included. After Dmab discontinuation, 19 patients have not been treated with BPs (Not-treated Group, 16 females, age 63.5 ± 15.0 years) and 101 patients have been treated (Treated Group, 95 females, age 70.0 ± 10.6 years) with BPs (28 alendronate, 73 zoledronate single infusion). We evaluated the BMD variation (Δ) and the incidence of both clinical VFx and morphoVFx in Treated Group and Non-treated Group.
Results
After Dmab discontinuation the mean ΔBMD at lumbar spine (LS), femoral neck (FN) and total hip (TH) were not different between the Treated Group (-2.7 ± 6.5%, -3.0 ± 7.3% and 2.3 ± 0.8%, respectively) and Not-Treated Group (-0.8 ± 5.8%, -5.1 ± 6.7% and -0.2 ± 7.7%, respectively, P = ns for all comparisons). The number of patients with BMD at TH lower than prior to Dmab administration was lower in Treated Group (8.9%) than in Not Treated Group (35.7%, P = 0.046), while no differences were found between the two groups at LS (12.9% and 26.3%, respectively) and FN (17.8% and 21.1%, respectively, P = ns for all comparisons). Patients in Treated Group had a lower VFx incidence (n = 6, 5.9%, 3 clinical, 3 morphoVFx) than patients in Not-treated Group (n = 4, 21.1%, 4 clinical, 3 multiple), respectively, in spite of a comparable fracture risk profile at the time of Dmab initiation. The VFx incidence was independently associated with the lack of BPs treatment (odds ratio 16.7, 95% confidence interval 1.8–142.8, P = 0.013) but not with number of Dmab injections, age, discontinuation of BPs administration at least 12 months before Dmab initiation, BMD at Dmab withdrawal and multiple VFx prevalence at Dmab initiation.
Conclusions
The Dmab withdrawal is associated with an increased risk of clinical VFx. The treatment with oral BPs or with a single zoledronate infusion reduces but not abolishes the increased VFx risk after Dmab withdrawal.

Safety, tolerability and pharmacodynamics of AZP-3601, a novel long-acting PTH analog, in healthy adults: Data from a randomized, double-blind, placebo-controlled phase 1 study

Soraya Allas[1], Michel Ovize[1], Michael D. Culler[2], Clarisse Geraul[1], Jeroen van de Wetering[3] & Michael Mannstadt[4,5]
[1]Amolyt Pharma, Ecully, France; [2]Amolyt Pharma, Cambridge, United States; [3]PRA Health Sciences, Groningen, Netherlands; [4]Massachusetts General Hospital, Endocine Unit, Boston, United States; [5]Harvard Medical School, Boston, United States

Hypoparathyroidism is a rare disease characterized by a deficiency in parathyroid hormone (PTH) that results in hypocalcemia and hyperphosphatemia. Current treatment approaches, including high dose oral calcium and active vitamin D, as well as recombinant human PTH (1–84), do not provide adequate or consistent control of either serum calcium or clinical symptoms over a full 24-hour period. AZP-3601 is a novel 36 amino-acid PTH analog that has been designed to potently bind to the R^0 conformation of the PTH1 receptor, which results in prolonged signaling responses in vitro and prolonged calcemic responses in animals despite having a short circulating half-life. A Phase 1 double-blind, placebo-controlled, single and multiple ascending dose study is being conducted to evaluate the safety, tolerability and pharmacodynamics of AZP-3601 in healthy adults. Here we report data from the first cohorts of the single ascending dose portion of the study. Sequential cohorts of 4 (cohort 1) to 8 (cohort 2 to 4) healthy male subjects aged 18–60 years, with a body mass index of 19–28 kg/m^2, were assigned to receive 5, 10, 20 or 40 μg of AZP-3601 or placebo at a ratio of 3:1. The study drug was administered in the morning by subcutaneous injection in the abdominal wall and was well tolerated with no remarkable adverse events. As compared with placebo controls, AZP-3601 treatment produced a clear, dose-dependent increase in mean albumin-adjusted serum calcium values from baseline. The normal physiological diurnal variation of albumin-adjusted serum calcium was gradually attenuated with 5 and 10 μg AZP-3601, and was completely eliminated with 20 μg. With the dose of 40 μg AZP-3601, mean albumin-adjusted serum calcium values were significantly increased but stayed within normal laboratory range and remained elevated through at least 24 hours post-administration. We observed a dose-dependent decrease in mean endogenous serum PTH that was significantly correlated with the concomitant increase in mean serum calcium. Data from these 4 cohorts of subjects provide initial evidence of the pharmacodynamic effect of AZP-3601 in healthy humans characterized by a sustained calcemic response for at least 24 hours following a single administration. The study is ongoing and updates will be reported.

TransCon PTH as a potential hormone replacement therapy for patients with hypoparathyroidism: PaTH forward open-label extension trial week 26 results

Peter Schwarz[1], Lars Rejnmark[2], Mishaela Rubin[3], Tamara J. Vokes[4], Bart L. Clarke[5], Intekhab Ahmed[6], Andrea Palermo[7], Claudio Marcocci[8], Uberto Pagotto[9], Erik Eriksen[10], Sanchita Mourya[11], Denka Markova[11], Susanne Pihl[12], Aimee Shu[11], Michael Beckert[12] & Aliya Khan[13]
[1]Rigshospitalet, Copenhagen, Denmark; [2]Aarhus University Hospital, Aarhus, Denmark; [3]Columbia University, New York, United States; [4]University of Chicago, Chicago, United States; [5]Mayo Clinic, Rochester, United States; [6]Thomas Jefferson University, Philadelphia, United States; [7]Universita Campus Bio-Medico, Rome, Italy; [8]University of Pisa, Pisa, Italy; [9]University of Bologna, Bologna, Italy; [10]Oslo University Hospital, Oslo, Norway; [11]Ascendis Pharma, Inc., Palo Alto, United States; [12]Ascendis Pharma A/S, Hellerup, Denmark; [13]Bone Research & Education Centre, Oakville, Canada

Background
Hypoparathyroidism is characterized by insufficient levels of parathyroid hormone (PTH), resulting in hypocalcemia, hyperphosphatemia, hypercalciuria, and a reduced quality of life (QoL). PTH replacement therapy should restore physiologic levels of PTH and restore downstream physiologic levels of calcitriol, promoting independence from Ca and active vitamin D supplements and normalization of QoL. TransCon PTH is an investigational long-acting prodrug of PTH(1–34) for the treatment of hypoparathyroidism. Week 26 results from the PaTH Forward open-label extension (OLE) Trial in adult patients with hypoparathyroidism are reported.
Methods
Subjects received fixed doses of TransCon PTH 15, 18, or 21 μg PTH(1–34)/day or placebo for 4 weeks, followed by an OLE period during which TransCon PTH dose was titrated (6–30 μg PTH[1–34]/day) with the goal to maintain normocalcemia. Safety and efficacy endpoints were evaluated at predefined timepoints over the OLE. Efficacy end points evaluated at Week 26 included intake of active vitamin D and calcium supplements, 24-hour uCa, sCa, sP, and CaxP. QoL was assessed by the SF-36 and the Hypoparathyroidism Patient Experience Scales (HPES).
Results
All 59 subjects completed the initial 4-week period and continued in the OLE; 58 subjects continue in the OLE beyond 6 months (1 withdrew unrelated to safety or efficacy). By Week 26, TransCon PTH enabled 91% of subjects to achieve independence from SoC (active vitamin D = 0 mg/day and calcium ≤ 500 mg/day) and 76% of subjects to achieve complete independence from SoC (active vitamin D = 0 mg/day and calcium = 0 mg/day). Mean 24-hour uCa decreased from a baseline mean of 415 mg/24 h to 178 mg/24 h by Week 26 (n = 44) while maintaining sCa and reducing sP and CaxP to fall within the normal range. By Week 26, the mean scores for all SF-36 summary and domains increased from below normal at baseline to within the normal range. The HPES Symptom and Impact scores decreased through 26 weeks for TransCon PTH and placebo subjects switching to TransCon PTH (lower scores are associated with less symptoms/impact). TransCon PTH continued to be well-tolerated with no treatment-related serious or severe adverse events.
Conclusions
Through Week 26 of the PaTH Forward OLE Trial, TransCon PTH enabled independence from active vitamin D and calcium supplements for most subjects while maintaining normal sCa, sP, uCa, CaxP, and demonstrating enhanced QoL. These results support TransCon PTH as a potential hormone replacement therapy for adults with hypoparathyroidism.

Circulating concentrations of TMAO is associated with all-cause mortality in subjects with Non-alcoholic fatty liver disease. Results from a dutch prospective cohort

Jose L. Flores-Guerrero[1], Peter R. van Dijk[2], Margery A. Connelly[3], Erwin Garcia[3], Gerjan Navis[1], Stephan J.L. Bakker[1] & Robin P.F. Dullaart[2]
[1]University Medical Center Groningen, Internal Medicine, Division of Nephrology, Groningen, Netherlands; [2]University Medical Center Groningen, Internal Medicine, Division of Endocrinology, Groningen, Netherlands; [3]Laboratory Corporation of America Holdings (LabCorp). Groningen, Netherlands

Objective
Due to the increasing prevalence of Non-Alcoholic Fatty Liver Disease (NAFLD), it has become a global health challenge by being the most common cause of chronic liver disease. Recently, the microbiota has been linked to NAFLD, via altered bile acid and lipid metabolism. Whether serum Trimethylamine-N-oxide (TMAO), a gut microbiota-dependent metabolite, is associated with NAFLD and NAFLD health outcomes remains unclear. The aim was to investigate the association of TMAO with NAFLD and to assess the extent to which the association of TMAO with all-cause mortality is dependent on the presence of NAFLD in the general population.
Methods
We included 6415 participants enrolled in the PREVEND (Prevention of Renal and Vascular End-stage Disease) general population-based cohort study. TMAO was measured by Nuclear Magnetic Resonance Spectroscopy. Cox proportional-hazards regression analyses, adjusted for traditional risk factors, were performed to study the association of TMAO with all-cause mortality in subjects with and without NAFLD, determined by Fatty Liver Index (FLI) ≥ 60.
Results
A total of 3694 had a FLI score < 60, and 1598 ≥ 60. During a median follow-up of 8.2 years, 307 participants died, of whom 133 were classified with NAFLD. TMAO concentrations were positively associated with FLI at baseline (Std β 0.08, 95% CI 0.05; 0.11, P < 0.001). Cox regression analyses revealed that TMAO was associated with increased risk of all-cause mortality in crude analysis (Hazard Ratio (HR), 2.55, 95% CI 1.60, 4.05, P < 0.001) and after full adjustment for age, sex, blood pressure, smoking status, alcohol consumption, cancer history, type 2 diabetes, use of lipid lowering medication, total cholesterol, HDL-cholesterol, glucose, albuminuria and eGFR ($_{adj}$HR 1.90, 95% CI 1.18, 3.04, P = 0.008), in subjects with NAFLD.

Such an association was not present in subjects without NAFLD, neither in the crude model (HR 1.14, 95% CI 0.81,1.71, $P = 0.39$), nor in the fully adjusted model ($_{adj}$HR 0.95, 95% CI 0.65, 1.39, $P = 0.78$).
Conclusion
This prospective study revealed that plasma concentrations of TMAO were associated with all-cause mortality in subjects with NAFLD independently of traditional risk factors.

Hepatocyte GH signaling regulates carbohydrate processing in a STAT5b-independent manner

Mari C. Vázquez-Borrego[1,2], Mercedes Del Rio-Moreno[1,2], André Sarmento-Cabral[1,2], Mariyah Mahmood[1,2], Jose Cordoba-Chacon[1,2], Michelle Puchowicz[3] & Rhonda Kineman[1,2]
[1]University of Illinois at Chicago, Department of Medicine, Section of Endocrinology, Diabetes, and Metabolism, Chicago, United States; [2]Jesse Brown Veterans Affairs Medical Center, Research and Development Division, Chicago, United States; [3]University of Tennessee Health Science Center, Department of Pediatrics, Memphis, United States

In the healthy liver, GH signals through multiple pathways to modulate hepatic function, with JAK2/STAT5b required to maintain circulating IGF1 levels. It has been previously reported that mice with developmental knockout of hepatocyte GHR, JAK2 or STAT5 develop steatosis associated with glucose intolerance, systemic insulin resistance and white adipose tissue (WAT) lipolysis. These changes are thought to be secondary to increased circulating GH, due to loss of IGF1 negative feedback. However, we have previously reported that mice with adult-onset hepatocyte-specific GHR knockdown (aHepGHRkd), that present with reduced IGF1 and elevated GH in the circulation, develop steatosis associated with enhanced *de novo* lipogenesis (DNL), without major alterations in systemic metabolic function. Importantly, steatosis and enhanced DNL are still evident in aHepGHRkd mice after normalization of GH by IGF1 treatment, indicating GH acts directly on the hepatocyte to control fat accumulation. We have extended our investigations to determine if loss of GHR-mediated STAT5b is the primary cause of sustained steatosis/DNL in the aHepGHRkd model. Specifically, male aHepGHRkd mice were treated with a hepatocyte-specific vector expressing constitutively active mouse STAT5b (AAV8-TBGp-STAT5b^{CA}) and compared to GHR-intact mice [treated with control vector (Null)] 0010 h after 0700 h food withdrawal (post-absorptive state). STAT5b normalized IGF1 and GH levels in aHepGHRkd mice to that observed in GHR-intact controls and reduced, but did not completely normalize hepatic lipid content and DNL. Hepatic protein levels of glucokinase (GCK), fructokinase (KHK) and carbohydrate response element binding protein (ChREBP) were increased in aHepGHRkd mice with or without STAT5b reconstitution, suggesting the GHR signals independent of STAT5b, to control early events in hepatocyte carbohydrate processing. RNAseq analysis revealed 1278 hepatic genes were altered by aHepGHRkd. Of those genes, 942 were STAT5b-independent and included *Gck* and *Khk*, as well as liver pyruvate kinase (*Pklr*) and the glycogen branching enzyme (*Gbe1*). Taken together, these suggest GH acts directly on the hepatocyte, in a STAT5b-independent manner, to suppress carbohydrate processing. These actions may limit substrates for DNL and prevent steatosis. Additional studies in fed conditions are underway to test this hypothesis.

Long-term glucocorticoids are associated with increased odds of metabolic syndrome after an intensive combined lifestyle intervention

Mostafa Mohseni[1], Eline S. Van der Valk[1], Robin Lengton[1], Mesut Savas[1], Yolanda De Rijke[2], Sjoerd A.A. Van den Berg[2], Bibian Van der Voorn[1] & Liesbeth F.C Van Rossum[1]
[1]Erasmus MC, University Medical Center Rotterdam, Obesity Center CGG, Department of Internal Medicine, Division of Endocrinology, Rotterdam, Netherlands; [2]Erasmus MC, University Medical Center Rotterdam, Department of Clinical Chemistry, Rotterdam, Netherlands

Background
Long-term glucocorticoids, as measured in scalp hair (HairGC), are associated with obesity and the metabolic syndrome (MetS). It is not known whether this represents a state of obesity or whether chronic hypercortisolism may influence the course or reversibility of obesity. In this study we longitudinally examine the relation between HairGC concentrations and metabolic syndrome parameters in patients with obesity who participate in a 1.5 year intensive combined lifestyle intervention (CLI).
Methods
A total of 99 adults with a body-mass index (BMI) ≥30 kg/m^2 (mean age 42, 75% females) were enrolled in the CLI at our academic obesity center. They received guidance on a healthy eating pattern, exercise and psychoeducation. Anthropometric measures, metabolic parameters (blood) and HairGC were assessed at baseline and at the end of the program (75 weeks). A hair sample of 3 cm closest to the scalp was cut and analyzed for cortisol (HairF) and cortisone (HairE) concentrations using liquid chromatography-mass spectrometry (LC/MS). Covariates for regression analyses were age, sex, ethnicity, smoking, alcohol intake, use of antidepressant and glucocorticoid drugs.
Results
Mean weight, BMI and waist circumference decreased from 117 kg, 39.9 kg/m^2, and 114 cm at baseline to 111 kg, 37.8 kg/m^2, and 107 cm after 75 weeks (all $P < 0.001$). Median HairF and HairE decreased from 3.60 pg/mg and 11.46 pg/mg at baseline to 2.37 and 9.36 pg/mg($P = 0.004$ and $P = 0.604$ respectively). Median insulin levels and HOMA-IR significantly decreased from 140 pmol/l and 5.03 at baseline to 118 pmol/l and 4.31 after 75 weeks ($P = 0.004$, and $P = 0.002$ respectively). Baseline HairGC were not related to anthropometrics or the presence of MetS at baseline. However, baseline HairF was a significant predictor for the presence of MetS at 75 weeks (OR per quartile increase in baseline HairF was 1.78 (95% CI: 0.97–3.27), OR for the highest HairF quartile vs HairF in quartile 1–3 was 8.05 (95% CI: 1.64–39.55)). Baseline HairE was not associated with higher odds of MetS at 75 weeks.
Discussion/Conclusion
High baseline hair cortisol concentrations are associated with higher odds for no remission of the metabolic syndrome after an intensive combined lifestyle intervention. This may indicate that high baseline hair cortisol concentration may impair cardiometabolic improvement by a lifestyle intervention, although causality is yet to be proven. Further studies should assess whether such cases require an accelerated intensification of obesity treatment, e.g. by adding anti-obesity medicine to the lifestyle intervention.

Liver GPR55 regulates NAFLD progression from steatosis to fibrosis

Uxía Fernández[1], Marcos Fernández Fondevila[1], María Jesús González Rellán[1], Natalia Da Silva Lima[1], Xabier Buque[2], Agueda González Rodríguez[3], Teresa Delgado[4], Marta Varela Rey[1], Eva Novoa[1], Marta Tojo[1], Miguel López[1], Carlos Diéguez[1], Miguel Marcos[5], María Luísa Martínez-Chantar4, Marco Arrese[6], Carmelo García-Monzón[3], Jose Mato[4], Patricia Aspichueta[2] & Rubén Nogueiras[1]
[1]CIMUS, University of Santiago de Compostela, Spain; [2] Biocruces Bizkaia Health Research Institute, Spain; [3] Instituto de Investigación Sanitaria Princesa, Spain; [4] CICBiogune, Spain; [5] University Hospital of Salamanca-Institute of Biomedical Research of Salamanca, Spain; [6] Pontificia Universidad Católica de Chile, Chile

Background and aims
G protein-coupled receptor 55 (GPR55) is a putative cannabinoid receptor, and l-α-lysophosphatidylinositol (LPI) is its only known endogenous ligand. Although GPR55 has been linked to energy homeostasis in different organs, its specific role in lipid metabolism in the liver and its contribution to the pathophysiology of non-alcoholic fatty liver disease (NAFLD) remains unknown.
Method
We measured (1) GPR55 expression in the liver of patients with NAFLD compared with individuals without obesity and without liver disease, as well as animal models with steatosis and non-alcoholic steatohepatitis (NASH), and (2) the effects of LPI and genetic disruption of GPR55 in mice, human hepatocytes, and human hepatic stellate cells.
Results
Notably, we found that circulating LPI and liver expression of GPR55 were up-regulated in patients with NASH. LPI induced adenosine monophosphate-activated protein kinase activation of acetyl-coenzyme A carboxylase (ACC) and increased lipid content in human hepatocytes and in the liver of treated mice by inducing *de novo* lipogenesis and decreasing β-oxidation. The inhibition of GPR55 and ACCα blocked the effects of LPI,

and the *in vivo* knockdown of GPR55 was enough to improve liver damage in mice fed a high-fat diet and in mice fed a methionine-choline-deficient diet. Finally, LPI promoted the initiation of hepatic stellate cell activation by stimulating GPR55 and activation of ACC.
Conclusion
The LPI/GPR55 system plays a role in the development of NAFLD and NASH by activating ACC.

[1]CIMUS, Physiology, Santiago de Compostela, Spain; [2]Clínica Universidad de Navarra, Metabolic Research Laboratory, Pamplona, Spain; [3]CIC Biogune, Bilbao, Spain; [4]University of Geneva, Department of cell physiology and metabolim, Geneva, Switzerland; [5]Helmholtz Zentrum München, München, Germany

Background and aims
Glucose homeostasis is essential for life. The liver is among the key tissues for maintaining an adequate metabolic homeostasis and its alterations are at the root of the pathogenesis of many disease states. A perfect balance between glucose production, mainly at the liver, and glucose consumption in different tissues, is provided by the action of insulin and counterregulatory hormones as glucagon, cortisol or catecholamines. There is nowadays growing evidence demonstrating that cell cycle regulators have important actions in the metabolic control. In cancer cells, p53 regulates glucose metabolism, opposing the Warburg effect. Nevertheless, the relevance of endogenous hepatic p53 in the physiological fluctuation of gluconeogenesis, as well as the molecular pathways mediating these effects, remains totally unknown.
Method
Either *wild type* (WT) mice or hepatic p53-deficient littermates were subjected to different nutritional conditions to evaluate p53 expression and function. These experiments were also performed *in vitro*, in both THLE-2 cells and HEP3B cells (a hepatic KOp53 cell line). PTT, Gly, GTT and ITT were performed to study glucose homeostasis in WT mice and p53-deficient mice, as well as a clamp to further test their gluconeogenic capacity. Gain-of-function experiments were also performed, over-expressing p53 in the liver. *In vitro* and *in vivo* models were treated with gluconeogenic hormones and insulin, to study the role and function of p53 mediating their hepatic actions. Mutagenesis experiments were also performed to evaluate the relevance of *O*-GlcNAcylation on p53 gluconeogenic actions.
Results
We show that upon starvation hepatic p53 is stabilized by O-GlcNAcylation, and plays an essential role in the physiological regulation of glucose homeostasis. p53 binds to PCK1 promoter and regulates its transcriptional activation, thereby controlling hepatic glucose production. Mutant p53 that cannot be O-GlcNAcylated is unable to promote PCK1 activity gluconeogenesis. Mice lacking p53 in the liver show a reduced gluconeogenic response during calorie restriction. Glucagon, adrenaline and glucocorticoids augmented protein levels of p53, and administration of these hormones to human hepatocytes and to liver-specific p53 deficient mice fails to increase glucose levels. Moreover, insulin decreases p53 levels, and over-expression of p53 impairs insulin sensitivity. Finally, protein levels of p53, as well as genes responsible of O-GlcNAcylation are elevated in the liver of T2D patients, and positively correlate with glucose and HOMA-IR.
Conclusion
Our results indicate that O-GlcNAcylation of p53 plays an unsuspected key role regulating *in vivo* glucose homeostasis, with a potential therapeutic target interest.

NTCP is a new promising target for treatment of metabolic diseases: A proof of mechanism from double-blind phase I clinical trials of Hepalatide

Zhenzhen Zhu[1], Xiaolu Tang[2], Shanwei Zhu[1], Lizhen Wang[1], Xian Gao[2], Fei Cai[2], Li Zhang[1], Hongli Liu[2] & Zhenman Wei[1]
[1]No. 5 Medical Center, Chinese PLA General Hospital, Phase I unite, Peking, China; [2]HEP Pharmaceutical Co. Ltd, R&D Department, Shanghai, China

Bile acids (BAs) are potent signaling molecules that regulate glucose, lipid and energy homeostasis predominantly via farnesoid X receptor (FXR) and transmembrane G protein-coupled receptor 5 (TGR5). Modulation of bile acid profiles might affect the treatment of metabolic diseases, indicating new possible therapeutic avenues. The sodium taurocholate co-transporting polypeptide (NTCP) plays a pivotal role in the enterohepatic circulation of bile salts as the main uptake transporter of conjugated BAs from the (portal) blood into the liver. The inhibition on NTCP will lead to a temporary increase in systemic bile acid levels in humans. However, either the direct quantitative relation between NTCP and BAs in systemic circulation or the metabolic effect by inhibiting NTCP has not been studied previously in human. Hepalatide is a NTCP inhibitor with 47aa synthetic peptide. In our current randomized placebo-controlled double-blind phase I clinical trials, 80 healthy subjects were administrated with s.c. single dose or multiple dose (once/day for 7 days). The BA profiles were analyzed. The conjugated BAs (GCDCA, GCA, TCDCA, GDCA, TCA, TDCA, GUDCA, TUDCA, TLCA, and GLCA) and unconjugated BAs (CA, UDCA, CDCA, DCA, and LCA) in peripheral plasma sampled before injection (bi) and at 1 h, 2 h, 4 h, 6 h, 8 h, 12 h, and 24 h post injection (pi) were measured by HPLC-mass method. Among 17 healthy subjects with placebo, just as physiological state, circulating conjugated BAs peak at day, while unconjugated BAs peak late at night. Hepalatide dramatically amplified conjugated BAs diurnal rhythm in a dose dependent manner but not affected unconjugated BAs. The mean AUC0–24 h of total conjugated BAs in cohort with single hepalatide adminstration at 10.5 mg was 20.64 times of that in placebo-controlled subjects. BAs are synthesized in hepatocytes from cholesterol and feedback represses BAs synthesis. Hepalatide is expected to uncouple BA synthesis from negative feedback leading more cholesterol to break down. At the end of the 7-day treatment, serum total cholesterol (TC) was reduced in a dose-dependent manner, and it was significantly lower in 8.4 mg cohort than in placebo cohort (P = 0.0029). The LDL-c also decreased with an average of 20% in the 6.3 mg and 8.4 mg cohorts vs the placebo cohort, with a maximum decrease of 39% in one healthy subject. In conclusion, NTCP is a surprising molecule to redistribute BAs between liver and peripheral tissues, which make it a promising target to modulate BAs signal with therapeutic effects on metabolic diseases.

Introduction
Somatic USP8 mutations are found in around 50% of Cushing's disease tumours and are located in a single mutational hotspot that contains the recognition site for 14–3-3. These proteins bind to phosphoserine recognition motifs to alter the function and location of their target proteins, and are deregulated in several cancers.
Aim
To explore the expression and function of 14–3-3 proteins in corticotroph tumours.

Methods
We analysed the expression of 14–3-3 epsilon (*YWHAE*), gamma (*YWHAG*), sigma (*SFN*) and zeta (*YWHAZ*) on 16 fresh frozen human corticotroph (8 USP8 wild type, 6 USP8 mutant, 2 unknown) and 3 normal pituitaries by qPCR. We determined 14–3-3 epsilon immunoreactivity on 54 FFPE human corticotroph tumours (23 USP8wt, 31 USP8mut) by immunohistochemistry (H-score). To investigate the possible role of 14–3-3 epsilon on corticotroph physiology, we overexpressed human 14–3-3 epsilon in AtT-20 corticotroph tumour cells and examined its action on human *POMC* promoter activity. A ligand-binding defective 14–3-3 epsilon mutant (14–3-3 epsilon K49E) that cannot interact with client proteins was used as control.
Results
Transcripts for 14–3-3 epsilon and zeta were 3× and 7× higher in corticotroph tumours compared to normal pituitary ($P = 0.04$ and $P = 0.009$ respectively). In contrast we did not detect differences in the expression levels of 14–3-3 gamma and sigma ($P = 0.875$ and $P = 0.21$ respectively). 14–3-3 epsilon is the most abundant transcript in corticotroph tumours and its levels are 2.2× higher in *USP8mut* corticotroph tumours compared to *USP8wt* ($P = 0.006$). Cytoplasmic 14–3-3 epsilon immunoreactivity was detected in all but two FFPE corticotroph tumours. Overexpressing human 14–3-3 epsilon in AtT-20 cells significantly increased *POMC* promoter activity (% increase 234 ± 68, $P < 0.05$), while the binding defective K49E mutant had no effect.
Conclusions
Corticotroph tumours overexpress 14–3-3 epsilon compared to the normal pituitary, and this expression is higher in *USP8mut* tumours. 14–3-3 epsilon triggers *POMC* promoter activity in a yet to be delineated mechanism with potential role to corticotroph pathophysiology.

Introduction
Osilodrostat, a potent oral 11β-hydroxylase inhibitor, normalized mean urinary free cortisol (mUFC) in most patients with CD during the 48-week (W) core phase of a Phase III study (LINC3: NCT02180217). We present efficacy and safety results following an extension to LINC3.
Methods
CD patients with mUFC > 1.5× upper limit of normal (ULN) received osilodrostat during the core. Patients benefiting from osilodrostat at W48 could enter an extension. Dose adjustments were permitted (maximum dose 30mg bid). LINC3 ended when all ongoing patients had received ≥72 weeks' treatment and could enter a separate safety study (results of which are not presented here). Efficacy/safety are reported for all enrolled patients unless otherwise stated. Mean change is calculated for patients with evaluable assessments at core baseline and W72.
Results
106 of 137 enrolled patients entered the extension. Median osilodrostat exposure from core baseline to study end for all enrolled patients was 130 weeks (range, 7–245), with a median dose of 7.4mg/day. 98 patients completed W72 and 52 received ≥3 years of treatment. At W72, 81% (86/106) of patients who entered the extension had mUFC ≤ ULN. Mean mUFC and serum and late-night salivary cortisol levels remained ≤ULN during the extension. Improvements in cardiovascular-related parameters were maintained during the extension; mean (SD) change from core baseline to W72: systolic BP, –10.1 (18.1) mmHg; diastolic BP, –5.8 (11.3) mmHg; HbA_{1c}, –0.4% (0.6); BMI, –1.8 (2.5) kg/m^2. AEs related to hypocortisolism and adrenal hormone precursor accumulation, respectively, occurred in 54% (74/137) and 58% (80/137) of patients during the study. Most hypocortisolism-related AEs emerged during the first 26 weeks of treatment. AEs related to adrenal hormone precursor accumulation were less frequent in the extension than the core (occurring in 46%, 19%, 15% and 15% of patients with a safety assessment during the following intervals: baseline–W26, W26–48, W48–72 and W72–study end). Overall, 32% (34/106) of patients who entered the extension discontinued, most commonly because of AEs or patient/guardian decision ($n = 12$ each). Median change in tumour volume from core baseline to W72 was 1.0 mm^3 (range: –74.7 to 1268.5). Mean (SD) 11-deoxycortisol level was stable during the extension (7.4 [6.7] ×ULN at W72). Mean (SD) testosterone level tended to decrease in females during the extension (0.8 [0.7] ×ULN at W72).
Conclusions
Osilodrostat provided long-term control of mUFC in CD patients and improved clinical signs of hypercortisolism and QoL. Osilodrostat was well tolerated, with no new safety signals reported during long-term treatment.

GFRα2 as a GPS marker: Role of GFRα2 in pituitary gland

Alberto Pradilla Dieste[1,2], Montserrat García Lavandeira[1,2], Sihara Pérez-Romero[1,2], Jesuina Arcángela Graça Fonseca[1,2], Jussi Kupari[3], Miguel Japón[4,5], Matti S. Airaksinen[3] & Clara V. Álvarez[1,2]
[1]CiMUS–Centro Singular de Investigación en Medicina Molecular y Enfermedades Crónicas, Santiago de Compostela, Spain [2]Health Research Institute of Santiago de Compostela (IDIS), Santiago de Compostela, Spain; [3]University of Helsinki, Helsinki, Finland; [4]Ibis–Biomedicine Institute of Sevilla, Sevilla, Spain; [5]Virgen del Rocío University Hospital, Sevilla, Spain

The pituitary gland is the master gland of the endocrine system, controlling important physiological steps like growth, puberty or reproduction. There are different endocrine cell types within the adenopituitary, each one producing a specific hormone. Adaptation to different life stages and moments requires a plastic capacity based in proliferation and differentiation of pituitary stem cells. We ans others discovered the existence of a stem cell niche in the pituitary. Parenchymal stem cells from this niche are called GPS, as they co-express especific markers such as GFRa2, Prop1, Sox2 and Sox9 together with Cytokeratins and b-catenin, which are not co-expressed in any other pituitary cell. The objective of this study is to investigate about the role of GFRa2 in pituitary stem cells. To do so, we have used the GFRa2 knockout (KO) mouse strain compared to wild-type (WT) littermates. Characterization and validation for pituitary stem cell study was performed by postnatal growth assessment, serum hormone assays, qRT-PCR for gene expression and also Western Blot and image techniques for protein expression. Pituitary Gfra2 knockout was validated as we found absence of gene expression at mRNA and protein levels in comparison with littermate WT mice. Adult KO mice present a significant and marked difference in weight and size; those differences appear postnatally and increases during childhood to puberty. Gfra2 KO have decreased pituitary volume with significant less cells per section in the adenopituitary. Molecular analysis consisted on PCR and Western Blot to study gene and protein expression of RET pathway members and also different markers related to stem cells. Further research involving image techniques was also performed, demonstrating different distribution of stem cells in adenopituitary from KO mice in comparison to WT. Our data suggest an increased in proportion of Sox2 positive cells within the adenopituitary in KO mice. Moreover, Sox2+ cells in adenopituitary from KO mice are grouped. However, there is no difference in Sox+2 positive cells in the stem cell niche. Finally, we studied cell proliferation using the EdU click chemistry technique, suggesting that proliferation rates in KO mice are increased when compared to WT. In conclusion, absence of Gfra2 produces pituitary phenotype in mice, however, further investigation about the biology and cellular mechanisms is needed.

Novel insight into ACTH-secreting pituitary tumors biological behavior: hormone secretion and cell proliferation modulation by Ubiquitin Specific Peptidase 8 inhibitor RA-9

Genesio Di Muro[1], Donatella Treppiedi[1], Giusy Marra[1], Federica Mangili[1], Rosa Catalano[1], Anna Maria Barbieri[1], Marco Locatelli[2,3], Anna Spada[1], Maura Arosio[1,4], Giovanna Mantovani[1,4] & Erika Peverelli[1]
[1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Neurosurgery Unit, Milan, Italy; [3]University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy; [4]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit,, Milan, Italy

Cushing's Disease (CD) is a rare condition mostly caused by an ACTH-secreting pituitary tumor resulting in excess of cortisol release by the adrenal glands. Although pasireotide is the only pituitary-targeted drug approved to treat adult patients, many side effects are encountered during the clinical practice and a curative therapy for CD is still challenging. Recently, the discover of somatic mutations in the deubiquitinase *USP8* gene in a subset of patients has shed new light on the crucial role played by the ubiquitin system in the modulation of corticotroph cells growth and hormone secretion. However, the anticancer potential of USP8 inhibition in the corticotrophs has been poor explored so far. Aim of this study was to characterize the *in vitro* responses induced by the USP8 inhibitor RA-9, in murine corticotroph AtT-20 cells and primary cultures from ACTHomas, and to compare them with those triggered by pasireotide. First, AtT-20 cells and ACTHomas were screened for USP8 mutations, all samples resulting wild type. Then, 48 h of incubation with RA-9 caused cell proliferation decrease (-24.3 ± 5.2%, $P < 0.01$ vs basal) and cell apoptosis increase (207.4 ± 75.3%, $P < 0.05$ vs basal) in AtT-20 cells, as observed with pasireotide. Interestingly, RA-9 significantly reduced ACTH secretion in AtT-20 cells (-34.1 ± 19.5%, $P < 0.01$ vs basal), as well as in 1 out of 2 primary cultures *in vitro* responsive to pasireotide (-40.3 ± 6% reduction at RA-9). Western blot experiments revealed that, similarly to pasireotide, RA-9 lowered phospho-ERK1/2 levels in AtT-20 cells (-52.3 ± 13.4%, $P < 0.001$ vs basal) and in all primary cultures regardless of their *in vitro* responsiveness to pasireotide (-32.9 ± 19.8% vs basal in the sensitive group, $P < 0.001$; -33.1 ± 11.8% vs basal in the resistant group, $P < 0.05$). On the contrary, upregulation of $p27^{kip1}$ was observed at 48 h of treatment with RA-9 only, both in AtT-20 cells (167.1 ± 36.7%, $P < 0.05$ vs basal) and one primary culture tested (168.4% vs basal), whilst phospho-CREB expression level was similarly halved in AtT-20 cells by both RA-9 and pasireotide. No synergic effect was observed in any experiments when RA-9 and pasireotide were co-administrated. Altogether, our data demonstrate that RA-9 is able to exert cytotoxic effects and inhibitory actions on cell proliferation and hormone secretion in tumor corticotrophs by modulating the expression of phospho-ERK1/2, phospho-CREB and $p27^{kip1}$. Moreover, although acting on different targets, RA-9 and pasireotide elicit a comparable spectrum of biological responses *in vitro,* therefore inhibition of USP8 might represent a novel mean to pharmacologically target ACTHomas in patients with CD.

The clinical effects of miR-26a, miR-16, let-7,miR-128a and miR-223 in acromegaly patients

Islam Cagrı Bosna[1], Nese Cinar[2], Tuba Edgunlu[3], Gulhan Akbaba[2], Guzin Yaylali[4], Sevim Karakas Celik[5], Ebru Onalan Etem[6], Aycan Celik[5] & Murside Gizem Bircan[6]
[1]Mugla Sitki Kocman University Faculty of Medicine, Department of Internal Medicine, Turkey; [2]Mugla Sitki Kocman University Faculty of Medicine, Department of Endocrinology and Metabolism, Turkey; [3]Mugla Sitki Kocman University Faculty of Medicine, Department of Medical Biology, Turkey; [4]Pamukkale University Faculty of Medicine, Department of Endocrinology and Metabolism, Turkey; [5]Zonguldak Bulent Ecevit University Faculty of Medicine, Department of Medical Biology, Turkey; [6]Fırat University Faculty of Medicine, Department of Medical Biology, Turkey

Background and aim
MicroRNAs (miRNA) are small nucleotide sequences that affect gene expression in cells at the posttranscriptional level. Some miRNAs behave like oncogenes, while others behave like tumor suppressors. In this study, it was aimed to investigate the role of miRNAs in tumor development and its effects on clinical and metabolic parameters of the patients with acromegaly.
Methods
39 patients diagnosed with acromegaly (20 F / 19 M, mean age 51.6 ± 10.1 years) and 39 age–and gender-matched healthy controls (27 F/ 12 M, mean age 52.1 ± 12 years) were included in the study. The levels of miR-16, miR-26a, let-7, miR-128a and miR-223 were measured in peripheral blood by real-time PCR methods. Demographic features of the patients, radiological features of the adenoma, treatment modalities and comorbidities of the patients were evaluated. The relationship between these parameters and miRNAs was evaluated.
Results
While there was no significant difference in miR-16, miR-26a and miR-128a levels between acromegalic patients and the control group, let-7 levels were found to be lower in acromegalics compared to the control group [0.945 (0.29–5.77) vs1.261 (0.25–3.1); $P = 0.053$]. Moreover, acromegalic patients had significantly higher miR-223 levels compared to controls [2.101 (0.004–7.56) vs1.52 (0.36–10.22); $P = 0.021$]. There was no effect of miRNAs on adenoma size, optic chiasm compression and cavernous sinus invasion of the adenoma. Regarding the effects of miRNAs on need of medical treatment, miR-26a expression is demonstrated to be increased in patients who use medical treatment (N: 26, 66.6%) [1.22 (0.63–5.98) vs 0.74 (0.51–2.62); $P = 0.004$] whereas miR-16, let-7, miR-128a and miR-223 levels were found to be similar in both groups. When the patients were evaluated according to the presence of of coronary artery disease, hypertension, hyperlipidemia, Type 2 diabetes mellitus, malignancy and colonic polyps, no statistically significant difference was found between the groups in all miRNA levels.
Conclusion
Decreased expression of tumor suppressor gene let-7 miRNA levels and increased expression of oncogene miR-223 levels suggest that these two microRNAs may have a role in tumor development in acromegaly. While these was no effect of these miRNAs on the development of clinical features and comorbidities of acromegalic patients, increased miR-26a expression in patients receiving medical therapy supports the potential role of miR-26a in determining the long-term prognosis of acromegalic patients.

Increased PCSK1N in silent corticotroph pituitary adenomas may explain their "silence"

Kjersti Ringvoll Normann[1,2,3], Kristin Astrid Berland Øystese[1,2], Linn Guro Olsen[2], Tove Lekva[3], Daniel Dahlberg[4], Jens Bollerslev[1,2], Jens Petter Berg[1,5] & Nicoleta Cristina Olarescu[1,2,3]
[1]Institute of Clinical Medicine, Faculty of Medicine, Oslo, Norway; [2]Division of Medicine, Department of Endocrinology, Oslo, Norway; [3]Research Institute for Internal Medicine, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo, Norway; [4]Institute for clinical medicine, Department of Neurosurgery, Oslo, Norway; [5]Institute for clinical medicine, Avdeling for medisinsk biokjemi, Oslo, Norway

Background
Corticotroph pituitary adenomas present different degrees of functionality, from silent to whispering and finally to functioning adenomas leading to Cushing's disease. Compared to their functioning (FCA) counterpart, the silent corticotroph adenomas (SCA) express lower levels of the corticotroph cell lineage marker–TBX19 (TPIT), proopiomelanocortin (POMC), and prohormone converting enzyme 1/3 (PC1/3, PCSK1)–the main enzyme involved in the cleavage of POMC towards a functional ACTH molecule. Our recent data (Eieland, Normann et al. 2020) suggests that SCA may express higher levels of PCSK1N, a specific inhibitor of PC1/3. In vitro studies with AtT-20 cells demonstrated that overproduction of PCSK1N, coding for the protein called Pro-SAAS, reduced the processing of POMC leading to diminished ACTH production.
Aim
To study key molecules involved in the processing of POMC including the regulator proteins PCSK1N/Pro-SAAS and PC1/3 and characterize possible differences between FCA and SCA.
Material and methods
Clinical and imaging characteristics were recorded in a cohort of 30 FCA (18 women, 15 microadenomas) and 18 SCA (7 women, all macroadenomas). Measurement of gene expression by RT-qPCR of POMC, TBX19, PCSK1 and PCSK1N was performed in adenoma tissue from the patients. Data was analyzed with IBM SPPS version 27.0.0.0.

Results
Morning plasma ACTH and cortisol levels, measured preoperatively, were significantly lower ($P = 0.032$ and $P = 0.01$) in SCA compared with FCA patients: ACTH median (IQR): SCA 5.6 (1.8–13.2) pmol/l, vs FCA 14.1 (11.6–30.1) pmol/l, $P = 0.032$; cortisol: mean (SD) SCA 314 (154.6) nmol/l vs FCA 577.6 (230.9) nmol/l, $P = 0.01$. Tumor size (mm) was significantly larger in SCA ($P < 0.001$). In SCA as compared to FCA, gene expression of TBX19 ($P < 0.001$), POMC ($P < 0.001$) and PCSK1 ($P = 0.008$) was significantly lower and PCSK1N was higher ($P < 0.001$). For FCA and SCA combined, POMC gene expression was associated with PCSK1 ($r = 0.339$, $P = 0.018$) and PCSK1N ($r = -0.678$ $P < 0.001$). TBX19 gene expression likewise correlated strongly with PCSK1 ($r = 0.421$, $P = 0.003$) and PCSK1N ($r = -0.531$, $P < 0.001$). Plasma cortisol correlated with gene expression of POMC ($r = 0.401$, $P = 0.017$) and PCSK1 ($r = 0.448$, $P = 0.007$). Tumor size correlated with gene expression of POMC (r=-0.618, $P < 0.001$), TBX19 ($r = -0.385$, $P = 0.014$), PCSK1 ($r = -0.340$, $P = 0.032$), PCSK1N ($r = 0.739$, $P = 0.000$) and plasma cortisol ($r = -0.496$, $P = 0.003$).
Conclusion
We present a strong negative correlation between gene expression of POMC and PCSK1N in human corticotroph pituitary adenomas. In addition to being a new potential differentiation marker distinguishing between SCA and FCA and possibly a marker of tumor growth of corticotroph adenomas, the higher PCSK1N expression in the SCA might explain their diminished ACTH production.

[1]Vall d'Hebron Universitary Hospital, Endocrinology, Barcelona, Spain; [2]Hospital of Cabueñes, Endocrinology, Gijón, Spain; [3]Hospital General Universitario de Albacete, Endocrinology, Albacete, Spain; [4]Hospital Universitario Cruces, Endocrinology, Barakaldo, Spain; [5]Basurto University Hospital, Endocrinology, Bilbao, Spain; [6]Virgen del Rocío University Hospital, Endocrinology, Sevilla, Spain; [7]Hospital Universitario La Paz, Endocrinology, Madrid, Spain; [8]University Hospital 12 de Octubre, Endocrinology, Madrid, Spain; [9]Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain; [10]Hospital Clínic de Barcelona, Biochemistry and Molecular Genetics, Barcelona, Spain; [11]Sociedad Española de Endocrinología y Nutrición (SEEN), Madrid, Spain

Background
Thymic neuroendocrine tumor (THY-NET) accounts for almost 20% of multiple endocrine neoplasia type 1 (MEN1)-associated mortality. Diagnosis at early tumor stage is associated with improved survival.
Objective
To study the prevalence, clinical features and prognosis of THY-NET in MEN 1. To describe the overall causes of death among the registered MEN1 patients. To compare and discuss our results with the literature, identifying risk factors for the development and prognostic factors of survival of THY-NET.
Design and patients
Retrospective analysis of the 201-patient MEN1 cohort from the Spanish registry (REGMEN).
Results
THY-NET was detected in seven (3.5%) of 201 MEN1 patients, six (85.7%) were men and the mean age at diagnosis was 40.7 ± 10.5 years [range: 29–53]. Three were index cases and none had a prophylactic thymectomy performed. No particular genetic pathological variation was found to be associated with THY-NET. At presentation six were asymptomatic, and only one had chest pain; two developed Cushing's syndrome later on (10 and 12 y). All the patients were operated on with a mean tumor size of 6.1 ± 2.9 cm, corresponding to five intermediate (atypical) and two high grade NET. Six patients received SSA and further approaches on the progression were reoperation (a second time in 2, three times in 2 patients), radiotherapy (1), everolimus (4), INFalpha (1), temozolomide (2), cisplatin-etoposide (1). After a mean follow up of 9 ± 3.2 years only one patient is free of disease (3 cm, stage I) at 64 months. Two are alive with metastatic disease after 55 and 146 months of follow-up, and four have died after 10.3 ± 2 years (mortality 57.1%), at a mean age of 46.5 ± 8.9 y. The causes of death were cardiac failure secondary to local metastatic disease, pneumonia in a patient with Cushing's syndrome, Cushing's syndrome, and postsurgical complication of a lung metastasis. Among the whole MEN1 cohort, 17 deaths have been reported (8.5%). THY-NET accounted for 23.5% of the mortality. Other causes of death were: duodenopancreatic tumors (4), adrenocortical cancer (1), pituitary macroadenoma (1), and others (mesothelioma, hepatocellular-carcinoma, adenocarcinoma (2), endocarditis, pancreatitis, covid-19). Age of death was 12 years younger in THY-NET patients (58 ± 14.1 vs 46.5 ± 9 y).
Conclusion
We found a similar prevalence, male predominance and prognosis of THY-NET in Spanish MEN 1 to other European/American series. Advanced stage and ectopic Cushing's syndrome conferred worse prognosis. THY-NET is a rare but fatal component of MEN1. Screening and earlier detection of THY-NET is mandatory.

Prostate cancer (PCa) is one of the leading causes of cancer deaths among men population worldwide. This tumour pathology is commonly diagnosed through the determination of serum PSA levels. However, the diagnostic capability of PSA dramatically drops when considering patients with PSA levels lower than 10 ng/ml, the so-called "grey-zone"[1]. Therefore, additional non-invasive diagnostic biomarkers are urgently needed to substitute/complement PSA. In this sense, the ghrelin system has been found to be altered in PCa, whether the splicing variant In1-ghrelin plays a relevant role[2]. Additionally, it has been reported that serum In1-ghrelin levels are elevated in PCa patients[2]. However, the potential utility of urine In1-ghrelin levels in PCa diagnosis has not been explored. Therefore, this study aimed to analyse the diagnostic utility of urine In1-ghrelin levels in PCa. Herein, In1-ghrelin levels were determined by RIA in urine from an ample cohort of patients with PSA in the grey-zone ($n = 600$). Our results showed that urine In1-ghrelin levels were higher in PCa patients vs. patients with a suspect of PCa but negative biopsy result, whereas serum PSA levels did not differ between these two groups. Moreover, In1-ghrelin added significant diagnostic value to a clinical model consisting of age, suspicious digital rectal examination (DRE), previous biopsy, and PSA levels. Consistently, high In1-ghrelin levels [OR = 2.93, $P < 0.0001$], but not PSA levels [OR = 1.09, $P > 0.05$], were associated to an increased PCa risk. Moreover, urine In1-ghrelin levels were linked to PCa-aggressiveness parameters (e.g. tumour stage, lymphovascular invasion). Furthermore, several metabolic-factors [e.g. body-mass index (BMI), diabetes mellitus (DM), glucose, and insulin levels] were strongly correlated to urine In1-ghrelin levels as well as associated with PCa risk. Finally, a multivariate model consisting of metabolic [i.e. BMI, waist-circumference, DM, glucose, insulin, cholesterol, and Ghrelyn-O-acyl transferase (GOAT) levels] and clinical (i.e. age, DRE, previous biopsy, and PSA levels) variables, and In1-ghrelin levels showed high specificity and sensitivity to diagnose PCa in our patients cohort (AUC = 0.741, $P < 0.0001$). Taken together, our results pose the potential for urine In1-ghrelin levels as a useful clinical diagnostic and prognostic biomarker of PCa in patients with PSA in the grey-zone.

Introduction
Dysregulation of alternative splicing is emerging as a new hallmark of cancer. This dysregulation may originate from mutations and/or altered expression of specific components of the splicing machinery. Indeed, our group has shown that the expression profile of the splicing machinery is altered in several types of cancer, including endocrine-related cancers. However, to date, the status of alternative splicing and its putative dysregulation has not been reported in pulmonary neuroendocrine neoplasms (LungNENs), specifically typical and atypical pulmonary carcinoids.
Aims
The aim of this work was to explore the potential dysregulation of the splicing machinery in LungNENs and whether it contributes to splicing alterations and pathophysiology in these tumors.
Methods
A custom-made qPCR array was used to measure the expression of 45 components of the splicing machinery in tumor and non-tumor adjacent tissue samples of a cohort of 33 typical and atypical pulmonary carcinoids patients. Results were validated using a publicly available external cohort of 51 patients (GSE108055). Further analyses were made with immunohistochemistry in paraffin-embedded samples. Statistical analyses were made to explore the potential associations between expression levels of the components of the splicing machinery measured and relevant clinical parameters of patients. In addition, alternative splicing analyses were performed in an RNAseq of an independent cohort of 20 patients, to test whether intratumoral expression of key dysregulated components of the splicing machinery could be associated to an alteration of alternative splicing of specific molecular pathways.
Results
One third of the components of the splicing machinery were dysregulated in pulmonary carcinoids. Remarkably, a discrete subset of specific components of the major and minor spliceosome, as well as key splicing factors displayed significant associations to key clinical parameters, including tumor stage, node invasion and/or tumor dissemination. These results were validated in the external cohort of patients, and key components were selected based on their relevance and the association to clinical parameters. Alternative splicing analyses in the available RNAseq showed that the expression of these key components was correlated to altered patterns of alternative splicing.
Conclusions
Our results show that the splicing machinery is profoundly dysregulated in pulmonary carcinoids, where some of its components are associated to key clinical parameters of tumor malignancy. These results pave the way to employ novel avenues to study pulmonary carcinoids and discover new diagnostic, prognostic and therapeutic tools.

Endocrine-metabolic alterations such as obesity and metabolic syndrome are closely linked to the development of chronic liver diseases, from metabolic-associated fatty liver (MAFLD) to non-alcoholic steatohepatitis (NASH) and hepatocellular carcinoma (HCC). An emerging hallmark of endocrine-metabolic and hepatic diseases is the appearance or altered expression of pathological splicing variants (SVs). In fact, the components of the cellular machinery involved in the splicing process (spliceosome) represent pivotal players in the generation of SVs in different pathologies, suggesting their putative contribution to liver disease development/progression. Here, we aimed to explore the putative dysregulation and pathophysiological role of key spliceosome components (SCs) in liver disease. Specifically, expression (mRNA/protein) of key (n = 72) SCs and clinical implications were assessed in HCC patients with different aetiologies (alcohol consumption, viral infection, MAFLD/NASH) from two retrospective (n = 154 and n = 172) and six *in silico* [TCGA (n = 369), Wurmbach (n = 45), Roessler (n = 43), Roessler-2 (n = 445), Chen (n = 179) and Mas (n = 57)] cohorts. Functional and molecular consequences of siRNA-mediated *EIF4A3*-silencing were evaluated in liver-derived cell-lines (HepG2/Hep3B/SNU-387). Gene Set Enrichment Analysis (GSEA) and mutational landscape were analysed in TCGA patients with high EIF4A3 expression. Moreover, RNAseq from EIF4A3-silenced HepG2 cells were analysed. The results showed a profound dysregulation in the expression of 41,42% SCs analyzed (at mRNA/protein levels) in HCC vs control-tissues in all cohorts studied. Among them, *EIF4A3, SLM2, ESRP2, SRPK1* and *HNRNPA2B1* were the SCs more profoundly dysregulated in tumor samples, being EIF4A3 the element most consistently altered in the different cohorts. Expression levels of these SCs were associated with clinical (survival, recurrence) and molecular (oncogenic SVs expression) parameters of aggressiveness. Particularly, *EIF4A3* expression was higher in NASH-related HCC compared to other aetiologies, and high *EIF4A3* expression was associated with alterations in key cancer-related pathways (Cell Cycle Mitotic, DNA-Repair, etc.) and with relevant mutations (CTNNB1, TP53). Furthermore, *EIF4A3*-silencing *in vitro* resulted in reduced proliferation, migration, tumorsphere-/colony-formation and higher sensitivity to standard clinical treatments in HCC (e.g. lenvatinib). Finally, RNAseq showed that *EIF4A3*-silencing altered the expression and splicing pattern of multiple genes involved in 3 functional clusters (RNA splicing, translational initiation and metabolic-processes), including key genes associated to chronic liver disease progression (e.g., FGFR4). Altogether, these results demonstrate that the splicing machinery is profoundly dysregulated in liver cancer, wherein it may represent a promising source of novel diagnostic, prognostic or therapeutic targets worth to be explored.

Reassessment of the diagnostic criteria of insulinoma: A retrospective monocentric cohort study of 72-h fasting trial in 124 patients

Bonnet Fideline[1], Clara Devingenteuil[2], Anna Vaczlavik[2], Laura Bessiene[2], Christelle Laguillier-Morizot[1], Guillaume Assié[2], Helen Mosnier-Pudar[2], Benoît Terris[3], Lionel Groussin[2], Jean Guibourdenche[1] & Jerome Bertherat[2]

[1]Cochin Hospital, Hormonology, France; [2]Cochin Hospital, Endocrinology, France; [3]Cochin Hospital, Anatomopathology, France

Introduction
Fasting trial remains the gold standard to confirm the diagnosis of insulinoma, based on low blood glucose level concomitant with inadequate high insulin level. However, diagnostic criteria are not consensual. Glycemia and insulin thresholds differ between the different consensus statements : endogenous hyperinsulism diagnosis relies on a glycemia < 3 mmol/l associated with an insulin level > 3 mUI/l in Endocrine Society guidelines (2009) whereas in NANETS 2010 and ENETS 2012 consensus guidelines, diagnosis is based on a glycemia < 2,2 mmol/l concomitant with an insulin level > 6 mUI/l or

> 3 mUI/l, depending on the assays. It has been admitted that the previously used diagnostic insulin level cut-off is challenged by the more specific and sensitive currently routinely used assays.
Methods
We retrospectively analyzed fasting trials results from the 124 patients explored in the Endocrinology department of Cochin Hospital from February 2012 to July 2020 to reevaluate insulinoma diagnosis criteria in terms of glycemia, insulin and C-peptide levels. Insulin and C-peptide levels were determined by automated chemiluminescent sandwich immunoassays.
Results
On the 124 patients included, 51 presented an hypoglycemia < 2.5 mmol/l during fasting trial and 19 were diagnosed with insulinoma, histologically proven. In all insulinoma cases, glycemia nadir was < 2.5 mmol/l (min =1.3 mmol/l; max =2.3 mmol/l; median = 1.7 mmol/l) concomitant with an insulin level ranging from 2.6 to 51.7 mUI/l (median = 10.3 mUI/l) and a C-peptide level ranging from 0.22 to 1.58 nmol/l (median = 0.6 nmol/l). The only insulinoma case presenting an insulinemia < 3 mUI/l at the time of hypoglycemia, harbored a concomitant C-peptide level at 1.21 nmol/l. Such a discordance between insulin and C-peptide levels could only be explained by an hemolyzed blood sample, insulin being very sensible to hemolysis. Insulinoma diagnosis criteria based on a glycemia nadir < 2,5 mmol/l concomitant with an insulin level > 3 mUI/l and a C-peptide level > 0.2 nmol/l, applied to our retrospective cohort, had a sensibility of 95%, a specificity of 97%, a positive predictive value of 86% and a negative predictive value of 99%.
Conclusion
Using current insulin immunoassays, it seems reasonable to make the diagnosis of insulinoma on the occurrence of a glycemia < 2,5 mmol/l concomitant with a C-peptide level > 0,2 nmol/l associated with an insulin level > 3 mUI/l on non-hemolyzed blood samples.

Presence and pathophysiological role of sst5TMD4, an aberrant spliced variant of the somatostatin receptor subtype 5, in human high-grade astrocytomas

Miguel Garcia Garcia[1,2,3,4], Antonio C. Fuentes-Fayos[1,2,3,4], Cristobal Blanco-Acevedo[1,3,5], Juan Solivera[1,3,5], Manuel Gahete Ortiz[1,2,3,4], Justo P. Castaño[1,2,3,4] & Raul M. Luque[1,2,3,4]
[1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Córdoba, Spain; [2]Reina Sofia University Hospital (HURS), Cordoba, Córdoba, Spain; [3]Department of Cell Biology, Physiology and Immunology, University of Cordoba (UCO), Córdoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Córdoba, Spain; [5]Neurology Service University Hospital (HURS), Cordoba, Spain, Córdoba, Spain

Gliomas are derived from glial-cells and are the most common primary brain tumor, characterized by rapid growth and invasion. Astrocytomas are a subset of malignant gliomas which are classified, based on their agresiveness features, in low grades (I and II) to high grades (HGAs; III and IV), being grade-IV (glioblastoma multiforme; GBM) the most malignant and aggressive type. Current standard treatment for GBMs consists on surgery followed by radiotherapy/chemotherapy; however, this is only a palliative approach with an average post-operative survival of ~12–16 months. Therefore, there is a clear need for identification of novel therapeutic targets to treat this devastating pathology. In this context, the truncated splicing variant of the somatostatn receptor subtype-5, named sst5TMD4, which is produced by aberrant alternative splicing process, has been demonstrated to be overexpressed and associated with increased aggressiveness features in several endocrine-related tumours (e.g. pituitary, breast, prostate, thyroid and neuroendocrine tumors). However, the presence, functional role, and associated molecular mechanisms of sst5TMD4 in astrocytomas has not been explored. Therefore, the main objetive of this study was to carried out a comprehensive analysis to characterized the expression of sst5TMD4 in HGA human samples, and to determine its pathophysiological role by using human primary GBM cell cultures and GBM cell-lines (U-87 MG/U-118 MG). Our results revealed that sst5TMD4 splicing variant was significantly overexpressed in human HGA tissues [n = 34, grade III (n = 10) and grade IV (n = 24)] compared to healthy-control brain tissues (n = 4). Remarkably, overexpression of sst5TMD4 variant (with a specific plasmid) increased the proliferation and migration capacity, whereas sst5TMD4 silencing (by specific siRNAs) decreased proliferation and migration rate of GBM cells. Our data also indicate that the modulation of the level of expression of sst5TMD4 significantly altered key signaling pathways associated with tumor aggressiveness in GBM cells, including the decrease in pAKT/AKT ratio, a key pathway robustly associated with tumor progression and aggressiveness. Taken together, our results demonstrate that sst5TMD4 is overexpressed in human HGAs and its presence is associated to enhanced malignancy. Therefore, our data provide an original approach to use sst5TMD4 as novel diagnostic and/or prognostic biomarker and as a new target with therapeutic potential in this poor prognosis type of CNS tumors.

The role of VEGF expression in the development of papillary thyroid carcinoma in patients with lymphocytic thyroiditis

Nese Ersoz Gulcelik[1,2], Şafak Akın[1,2], Kadriye Aydin[1,3], Cisel Aydin Mericöz[4,5] & Aydan Usman[1]
[1]Hacettepe University, Faculty of Medicine, Endocrinology and Metabolism, Turkey; [2]University of Health Sciences, Gulhane Faculty of Medicine, Endocrinology and Metabolism, Turkey; [3]University of Health Sciences, Kartal Dr. Lutfu Kırdal Training and Research Hospital, Endocrinology and Metabolism, Turkey; [4]Hacettepe University, Faculty of Medicine, Pathology, Turkey; [5]Koc University, Faculty of Medicine, Pathology, Turkey

Background
Vascular endothelial growth factor (VEGF) has been implicated in angiogenesis of papillary thyroid carcinoma (PTC). As VEGF expression is increased in PTC and even in lymphocytic thyroiditis (LT), we hypothesized that VEGF may play a role in the development of PTC in patients with LT. In order to find an association between VEGF and these disorders, we examined both the tumoral and adjacent tissues of PTC patients with and without LT.
Methods
Fifty patients with PTC and 17 patients with nodular goiter were, 52.50 7.41 years old (range between 41 and 68), and 50.47 10.38 years old (range between 31 and 67), respectively. According to existing LT within the adjacent tumor tissue, patients with PTC further divided into two groups. The immunohistochemical analyses of VEGF were carried out in both tumor tissue and their adjacent tissue in patients with PTC. For this purpose, each sample was scored: a) for the intensity of the immunostaining and b) for the percentage of the labeled thyrocytes.
Results
The intensity of staining scores and percentage of labeled thyrocytes scores were found to be significantly higher in PTC group than in nodular goiter group (P < 0.001 and P < 0.001, respectively). There was no correlation between VEGF staining scores and age, body mass index, tumor size, tumor subtype, vascular invasion, extrathyroidal extension, and lymph node metastasis in PTC group. In the subgroup analyses of PTC, 17 (34%) patients had LT. The VEGF staining scores in adjacent tumor tissue were statistically significant higher in PTC with LT than in patients without LT (Figure 1). Tumor size, tumor subtype, multifocality, vascular invasion, extrathyroidal extension, and lymph node metastasis were similar in PTC with or without LT.
Conclusion
Our results imply that co-existing LT rises the expression of VEGF in the adjacent tumor tissues of patients with PTC. Future prospective cohort studies are needed to demonstrate whether increased expressions of VEGF is also associated with increased risk of developing PTC in patients with LT.

Motol University Hospital, Department of Ear, Nose and Throat, Prague, Czech Republic; [5]Charles University in Prague and Motol University Hospital, Department of Surgery, Prague, Czech Republic; [6]Charles University in Prague and Motol University Hospital, Department of Pathology and Molecular Medicine, Prague, Czech Republic; [7]University Hospital Kralovske Vinohrady, Department of Otorhinolaryngology, Prague, Czech Republic; [8]University Hospital Kralovske Vinohrady, Department of Pathology, Prague, Czech Republic; [9]Military University Hospital, Department of Otorhinolaryngology and Maxillofacial Surgery, Prague, Czech Republic; [10]Military University Hospital, Department of Pathology, Prague, Czech Republic

Objectives
Rearrangement involving one of the neurotrophic-tropomyosin receptor kinase (*NTRK*) genes belonging to the *NTRK* family represents a significant oncogenic event in thyroid cancer (TC). Recently, there has been a growing interest in testing and characterizing *NTRK* fusion genes because they are therapeutically targetable. This study aimed to determine a frequency, clinical and histopathological features of a large cohort of *NTRK* fusion-positive TC and mainly to determine the prognostic significance of *NTRK* fusion genes based on long-term follow-up of patients with TC harboring this mutation.
Methods
The cohort consisted of 989 different TC tissue samples. Based on the detected mutation, samples were triaged. Samples positive for the *BRAF*, *HRAS*, *KRAS*, *NRAS, RET*, *RET*/*PTC* or *PAX8*/*PPARG*γ mutation were excluded from the further *NTRK* fusion gene analyses. RNA from 259 samples was analysed using the *NTRK* Gene Fusions Detection Kit (AmoyDx) by Real-Time PCR (LC480, Roche) or using the FusionPlex Comprehensive Thyroid and Lung panel (ArcherDx) by next generation sequencing using MiSeq (Illumina).
Results
NTRK fusion genes were detected in 57 of 846 (6.7%) papillary thyroid cancer (PTC) and in 2 of 10 (20.0%) poorly differentiated thyroid cancer (PDTC). A total of eight types of *NTRK* fusions were found, including *ETV6*/*NTRK3*, *EML4*/*NTRK3*, *RBPMS*/*NTRK3*, *SQSTM1*/*NTRK3*, *TPM3*/*NTRK1*, *IRF2BP2*/*NTRK1*, *SQSTM1*/*NTRK1*, *TPR*/*NTRK1*. In PTC, a follicular growth pattern was identified in 78.0% of *NTRK* fusion-positive cases, and both cases of PDTC dedifferentiated from PTC with a mixed papillary and follicular growth pattern. Lymph node and distant metastases were found in 54.2% and 6.8% of cases, respectively. Initially within 2 years of postoperative treatment, 58.9% of *NTRK* fusion-positive patients had an excellent response (ER), 16.1% had an indeterminate response (IR) and 25.0% of patients had a structural incomplete response (SIR) to treatment. During the follow-up, response to treatment had an improving tendency. After 10 years of follow-up, 82.3% of patients had ER, 11.8% had IR, 5.9% had a biochemical incomplete response, no patient had SIR, and three patients died.
Conclusion
In summary, *NTRK* fusions are rare markers occurring mostly in PTC but also in PDTC. Patients without metastases had a favourable prognosis and patients with metastases often suffered from persistent disease. The genetic molecular testing of *NTRK* fusions is important not only for patient's diagnosis and prognosis, but also for possible targeted therapy with Trk inhibitors.

OC10.3

Predictive factors for recurrent non-diagnostic fine-needle aspiration biopsy in thyroid nodules

Vânia Benido Silva, Maria Teresa Pereira, André Carvalho & Cláudia Freitas
Centro Hospitalar e Universitário do Porto, Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal

Introduction
The most cost-effective, minimally invasive and accurate tool to discriminate benign from malignant thyroid nodules is a fine-needle aspiration biopsy (FNAB). However, 2%–24% of FNABs provide non-diagnostic results, which are a clinical challenge, particularly when this result is recurrent.
Aim
To determine the predictive factors for recurrent non-diagnostic FNAB in thyroid nodules.
Methods
We present a retrospective study including all non-diagnostic FNABs of thyroid nodules, performed in our appoiment between january 2016 and december 2019. Demographic and clinical data, the number and location of nodules, their ultrasound characteristics and the respective EU-TIRADS classification, their cytological results according to Bethesda's classification, and the moment when each FNAB was performed were recorded.
Results
Of a total of 1497 FNABs executed in the evaluated period, 494 (33.1%) were non-diagnostic. The FNAB was repeated in 225 (45.5%) nodules (76.4% in female's patient with a median age of 59 years [P25-P75:48.5–68.5]), of which 108 (48.0%) presented again a non-diagnostic result; 43.6%, 7.5% and 0.9% had a benign, indeterminate and malignant cytological diagnosis. The presence of a single nodule shows to be an independent predictive factor to recurrent non-diagnostic FNAB (41.7% vs 23.9%; OR 2.270; 95% CI 1.282–4.021; P = 0.005). Nodules with benign ultrasound characteristics classified as EU-TIRADS 2 have a reduced risk of a repeated non-diagnostic cytology (1.9% vs 9.4%; OR 0.182; 95% CI 0.039–0.840; P = 0.029). Gender (P = 0.421), patient's age (P = 0.632), cervical radiotherapy (P = 0.658), nodule's location (P = 0.755), levothyroxine (P = 0.336) or anti-thyroid drugs treatment (P = 0.400) and time to repeat FNAB (P = 0.952) did not significantly influence the cytological result of the second biopsy. Despite without statistical significance, the recurrently non-diagnostic nodules appear to be larger (median larger diameter 24 mm [P25-P75:18–31] vs 21 mm [P25-P75:17–30]; P = 0.288).
Conclusion
In this study we concluded that the risk of a *second non-diagnostic* result was significantly *higher* in patients with single thyroid nodules. In contrast, the presence of a nodule corresponding to EU-TIRADS 2 classification reduce the probability of this outcome.

OC10.4

Targeting TSHR and ICAM-1 for treatment of Graves' disease in BALB/c mice

Wei Zheng, Xuan Wang, Ning Li, Shen Wang, Jian Tan, Qiang Jia, Zhaowei Meng & Zhongying Rui
Tianjin Medical University General Hospital, Nuclear Medicine, Tianjin, China

Objective
In BALB/c mice with GD model, the TSHR and ICAM-1 were targeted for treatment, and new approaches to GD targeted therapy were explored.
Methods
The siRNA targeting TSHR and the ICAM-1 mAb specifically binding ICAM-1 were designed and synthesized. Thirty GD model mice were randomly divided into siRNA treatment group, ICAM-1 mAb treatment group, and untreated GD group, with 10 mice in each group, and 10 normal mice in a control group. Serum T_4, TSH, TSAb and TSBAb were measured before and after treatment. At the end of the treatment, weight and heart rate of each group were measured, thyroid uptake of $^{99m}TcO_4^-$, thyroid size and pathological changes were evaluated.
Results
After three treatments, the weights of mice in the siRNA group and the ICAM-1 mAb group were still lower than that of normal mice. The heart rate of the mice in the siRNA group and the ICAM-1 mAb group were significantly lower than that of the GD mice. Heart rate of mice treated with siRNA decreased significantly, close to that of normal mice. After treatment, T_4, TSAb and TSBAb levels in both the siRNA group and the ICAM-1 mAb group were significantly decreased, while serum TSH levels were significantly increased, and the above changes were statistically different from those in GD mice. There was no significant difference in the decreased levels of T_4 and TSBAb between the siRNA group and the ICAM-1 mAb group. The elevated TSH level and decreased TSAb level of mice treated with ICAM-1 mAb were significantly different from those treated with siRNA. After treatment, both the siRNA group and the ICAM-1 mAb group showed reduced uptake ability of $^{99m}TcO_4^-$–in part of the thyroid lobes, and reduced enlargement degree of the same lobes. The thyroid pathology of the treated groups showed that the absorption vacuoles of thyroid follicles were reduced, and the phenomenon of thinner colloids was improved. No obvious damage was observed in the heart, liver and kidneys of the mice.

Conclusions
Both the siRNA targeting TSHR and the ICAM-1 mAb specifically binding to ICAM-1 have therapeutic effects on GD model mice. The siRNA was better at controlling heart rate, and the ICAM-1 mAb was better at increasing TSH and decreasing TSAb. Each of the above treatment methods had its own advantages and had good application prospects, which can provide new ideas for GD targeted therapy.

External validation of AIBx, an artificial intelligence model for risk stratification, in surgically resected thyroid nodules

Kristine Swan[1], Johnson Thomas[2], Viveque Nielsen[3], Marie Louise Jespersen[4] & Steen Bonnema[5]
[1]Aarhus University Hospital, Department of ORL, Head–and Neck Surgery, Denmark; [2]Mercy Hospital, Department of Endocrinology, Springfield, United States; [3]Odense University Hospital, Department of ORL, Head–and Neck Surgery, Denmark;[4]Aarhus University Hospital, Department of Pathology, Denmark; [5]Odense University Hospital, Department of Endocrinology, Denmark

Background
Artificial intelligence algorithms can be used in classification of thyroid nodules to reduce subjectivity. External validation on images collected from different ultrasound machines and other institutions are vital before wider use of these algorithms. We retrospectively analyzed the performance of AIBx on thyroid nodules with surgically proven pathology.
Materials and methods
Patients harboring thyroid nodules 1–4 cm in size, who underwent thyroid surgery from 2014 to 2016 in a single institution, were included in this study. Medullary thyroid cancer, metastasis from other cancers, thyroid lymphomas, and purely cystic nodules were excluded. Results were compared with TI-RADS calculated by experienced physicians. A subgroup analysis was done on cytologically indeterminate nodules.
Results
Out of 329 patients, 257 nodules from 209 individuals met the eligibility criteria. 51 nodules (19.8%) were malignant. AIBx had a negative predictive value (NPV) of 89.2%. Sensitivity, specificity, and positive predictive values (PPV) were 78.4%, 44.2% and 25.8% respectively. Considering both TI-RADS 4 and TI-RADS 5 nodules as malignant lesions resulted in an NPV of 93%, while PPV and specificity were only 22.4% and 19.4%, respectively. NPV was 89.6% if only TI-RADS 5 nodules were considered malignant. TI-RADS predicted all Bethesda category III nodules as malignant, despite the fact that none of them were malignant on histology. In contrast, only 25% of nodules in the Bethesda category III were predicted to be malignant by AIBx. On subgroup analysis, AIBx had a NPV of 95.8% in classical papillary thyroid cancer, while TI-RADS had an NPV of 93.0%.
Conclusion
When applied to an external dataset consisting of ultrasound images obtained in a different setting than used for training, AIBx had comparable negative predictive values to TI-RADS. AIBx performed even better than TI-RADS in Bethesda category III and classical papillary thyroid cancer. These data prove the concept of AIBx for thyroid nodules, and this tool may help less experienced operators by reducing the subjectivity inherent to thyroid ultrasound interpretation.

Introduction
Primary hypothyroidism, which is one of the main endocrine complications of allogenic stem cells transplantation (allo-SCT), has been largely studied in children. Conversely, data on adults are still limited with a reported incidence widely ranging between 9 and 47%. Older age, multiple allo-SCT, chronic Graft vs Host Disease (cGVHD), prolonged immunosuppressive therapy and high-dose total body irradiation (TBI) have been indicated as potential risk factors. The aims of this observational, cross-sectional study were to assess the prevalence of post-allo-SCT hypothyroidism in adult recipients, to analyse its variation over time and to detect predictive factors.
Methods
Among 462 patients who underwent allo-SCT at our hospital between January 2010 and December 2017, 218 where alive and in active follow-up at the time of the study. Of them, 195 (M 107; F 88; median age 53.3 years) were recruited and divided into 3 groups according to time elapsed after allo-SCT (1–3 years: n 78; 3–5 years: n 50; >5 years: n 67). Data on pre-transplant TSH and fT_4 levels were available for all patients. After the transplant, TSH, fT4 and anti-thyroperoxidase antibodies (AbTPO) were evaluated.
Results
TSH levels were significantly lower before (median 1.7, IQR 1.2–2.4 µU/ml) than after allo-SCT (median 2.3, IQR 1.5–3.5 µU/ml; $P < 0.0001$). Forty-six (23.6%) patients developed post-transplant hypothyroidism, with a higher prevalence in females (F 35.2%, M 14.0%; $P < 0.001$) and at earlier time points (1–3 yrs: 28.2%; 3–5 yrs: 24%; >5 yrs: 17.9%). At the pre-transplant evaluation, patients who developed hypothyroidism showed higher TSH and lower fT_4 levels (TSH median 2.4, IQR 1.7–3.3 µU/ml; fT4 median 10.2, IQR 8.9–11.7 pg/ml) compared to those with preserved thyroid function (TSH median 1.5, IQR 1.1–2.1 µU/ml; fT4 median 11.2, IQR 10.0–12.1 pg/ml; $P < 0.0001$ and < 0.05, respectively). Patients with post-transplant hypothyroidism had higher prevalence of AbTPO positivity and of acute GvHD ($P < 0.05$ for both). Multiple regression analysis, corrected for time after allo-SCT, radiotherapy and acute GVHD, identified male gender as a negative predictor of hypothyroidism (OR 0.283, 95%IC 0.121–0.660; $P < 0.05$) and higher pre-transplant TSH levels as a positive one (OR 1.797, 95%IC 1.275–2.534; $P < 0.001$).
Conclusions
About one out of four patients developed hypothyroidism after allo-SCT, with a greater risk for females and in the presence of acute GHVD. Pre-transplant TSH levels seem to predict the onset of post-SCT hypothyroidism.

Background
Adrenocortical Carcinoma (ACC) is a rare aggressive cancer with a heterogeneous behaviour. Disease surveillance relies on frequent imaging, which has limited sensitivity and results in significant radiation exposure. Aim of the study was to investigate the role of circulating cell-free DNA (ccfDNA) as a biomarker for prognostication and disease monitoring in ACC.
Methods
ccfDNA was extracted from 1–4 ml EDTA-plasma using the Nonacus Cell3 Xtract or the Qiagen QIAamp MinElute ccfDNA kit and quantified by fluorimetry. The experimental cohort included 60 patients with ACC (22M/36F, 52 ± 15 yrs): 22 primary tumours (ACC-P) and 38 disease recurrences (ACC-R). Twenty-three patients with adrenocortical adenomas (ACA, 8M/15F, 55 ± 17 yrs) and 19 healthy subjects (9M/10F, 37 ± 9 yrs) served as controls. Targeted next generation sequencing was performed on 23 ccfDNA samples (8 ACC-P, 11 ACC-R, 4 ACA) using a customised panel

of 30 ACC-specific genes (Cell3 Target Nonacus) and Illumina NextSeq500 Sequencer. Leucocyte DNA was sequenced to discriminate germline from somatic variants. Sequencing data from corresponding tumour DNA (tDNA) were available for comparison in 13/19 ACC.

Results

ACC-P had the highest ccfDNA concentrations (1.23 ± 1.56 ng/µl) compared to ACC-R (0.31 ± 0.27 ng/µl, $P < 0.05$), ACA (0.16 ± 0.10 ng/µl, $P < 0.005$) and healthy subjects (0.12 ± 0.09 ng/µl, $P < 0.005$). In the entire ACC cohort, ccfDNA concentrations correlated with the tumour burden, i.e. size of primary tumours or local recurrence plus size and number of metastasis ($P < 0.001$, R = 0.57 by linear regression). In ACC-P, the ccfDNA levels correlated with the ENSAT tumour stage ($P = 0.059$), but not with Ki67 index ($P = 0.22$). Moreover, high pre-surgery ccfDNA levels tended to be associated with shorter recurrence-free survival, but the number of cases is still limited ($n = 11$, $P = 0.10$, HR 6.23, 95% CI 0.7–55.4). Among sequenced ccfDNA samples, 3 ACC-P (37%) and 3 ACC-R (27%), but no ACA, showed somatic mutations in at least one known driver gene (2 *CTNNB1*, 2 *TP53,* 2 *MEN1,* 2 *ZNRF3*). The variant allele frequency ranged between 1.9 and 30.9%. The ccfDNA sequencing matched with the t-DNA in 9 of 13 cases (i.e. 6 without somatic variants and 3 with superimposable mutations).

Conclusion

ccfDNA concentrations correlated with tumour burden in patients with ACC and may have utility in predicting disease recurrence. Targeted ccfDNA sequencing detected ACC-specific mutations in ~30% of ACC. Serial ccfDNA quantitative and genomic analysis may represent an efficient, non-invasive tool complementary to imaging to improve the disease surveillance in ACC. This will be investigated in a large cohort of operated patients.

Current systemic treatment options for patients with ACCs are far from being satisfactory. DNA damage/repair mechanisms, which involve e.g. ATM/ATR-signalling or RRM1/RRM2 encoded ribonucleotide reductase (RNR) activation commonly contribute to drug resistance. Moreover, also the regulation of RRM2b, the p53-induced alternative to RRM2, is of unclear importance for ACC. Upon extensive drug screening, including a large panel of classical chemotherapies (doxorubicin, etoposide, cisplatin, mitotane, gemcitabine, paclitaxel), phytochemicals (9-cis-retinoic-acid, Isoquercitrin) and molecular targeted inhibitors (Erlotinib, Linsitinib, Sorafenib, Sunitinib, XAV-939), we recently provided strong evidence for anti-tumoral efficacy of combined Gemcitabine (G) and Cisplatin (P) treatment against adrenocortical cells (NCI-H295R and MUC-1). However, accompanying induction of RRM1 and RRM2 expression also indicated developing G-resistance, an effect that was partially reversed upon addition of P. Our findings were confirmed for RRM2 protein (NCI-H295R: G: 2.51 ± 0.14, $P < 0.001$; P: 1.14 ± 0.85, ns; G+P 0.85 ± 0.10, ns vs controls; MUC-1: G: 3.84 ± 0.72, $P = 0.002$; P: 2.55 ± 0.44, ns; G+P 1.57 ± 0.22, ns vs. controls), RNR-dependent dATP-levels (NCI-H295R: G: 1.64%; P: 83.61%; G+P 124% vs controls; MUC-1: G: 13.33%; P: 101.11%; G+P 102.22% vs. controls) and modulations of related ATM/ATR-signalling (Chk1, Chk2, H2AX). The applied models carry different TP53-mutations from which both enabled significant induction of RRM2b-expression upon specific treatments. However, the P-induced reversal to baseline or below differed in both models. Finally, we screened for complementing inhibitors of the DNA damage/repair system targeting RNR, Wee1, CHK1/2, ATR and ATM applying MTT and BrdU assays. Many tested inhibitors demonstrated already as single agents significant anti-tumour potential (MTT NCI-H295R: untreated 100.0 ± 1.9%; COH29 (dual RRM1/RRM2-complex-inhibitor): 60.2 ± 6.2%, $P < 0.001$; Adavosertib (Wee1-inhibitor): 84.9 ± 3.0%, $P = 0.107$;Prexasertib (CHK1/2-inhibitor): 65.61 ± 1.5%, $P < 0.001$;VE822 (ATR-inhibitor): 101.2 ± 0.7%, $P = 0.999$; AZD0156 (ATM-inhibitor): 104.3 ± 8.2%,$P = 0.995$; MUC-1: untreated 100.0 ± 1.0;COH29 50.2 ± 1.5%, $P < 0.001$;Adavosertib 50.5 ± 2.6%, $P < 0.001$;Prexasertib 86.5 ± 0.9%, $P = 0.002$;VE822 89.7 ± 3.1%, $P = 0.024$;AZD0156 91.9 ± 1.3%,$P = 0.119$). Of note, the combination G, P and COH29 resulted in previously unreached total cell killing of both, NCI-H295R (untreated 100.0 ± 4.3%; G: 110.7 ± 20.1%, $P = 0.196$; P: 14.3 ± 0.4%, $P < 0.001$; G+P: 11.7 ± 1.2%, $P < 0.001$; G+P+COH29: 0.0 ± 0.1%, $P < 0.001$) and the commonly highly drug resistant MUC-1 cells (untreated 100.0 ± 1.3; G: 96.4 ± 9.6%, $P = 0.996$; P: 57.9 ± 6.3%, $P < 0.001$; G+P: 47.2 ± 4.2%, $P < 0.001$; G+P+COH29 0.0 ± 0.1%, $P < 0.001$;). Clinically, our analysis of TCGA and own patient samples revealed for both data sets significantly elevated expression levels of RRM2 ($P < 0.001$) but not RRM1 in ACC ($n = 33/30$) compared to normal adrenals ($n = 10/21$) and adenomas ($n = 22/20$). Higher RRM2 expression was correlated with larger tumour size ($P = 0.02$) and strong tendency towards poorer overall survival ($P = 0.05$). In summary, we provide evidence that RNR-modulating therapies might represent a new therapeutic option for ACC.

Background

The ESE-ENSAT guidelines emphasize the role of local therapies and suggest radiotherapy (RT) as an individualized treatment in patients with advanced ACC. However, the evidence for this recommendation is very low. The aim of this study was to retrospectively investigate the efficacy and tolerance of radiation therapy in advanced ACC.

Methods

We screened all patients in five European reference centers for ACC since 2000 for RT of advanced ACC. Primary endpoint was progression-free survival of the treated lesion (tPFS). Secondary endpoints were best objective response, overall progression-free survival, toxicity of the treatment, explorative analysis of predictive factors (e.g. size of lesions, Ki67 of the primary tumor, disease-free interval prior RT or time interval between primary diagnosis and RT).

Results

116 tumoral lesions with a median tumor size of 26 –(7–140) mm (local recurrences ($n = 23$), metastases in liver ($n = 6$), lung ($n = 33$), bone ($n = 39$), and other regions ($n = 15$)) in 76 patients (28 male, median age 47.5 (18–78) years) were identified. They were treated with various RT modalities (stereotactic body radiation therapy (SBRT) 35–50Gy ($n = 32$), 'non-SBRT' with 50–60 Gy ($n = 24$) or with 20–49 Gy ($n = 55$), single dose RT (SDRT) 12–25Gy ($n = 5$)). Median time between primary diagnosis and start of RT was 34.9 months, median number of therapies (including surgery) before RT was 3(1–17). Complete response was detected in 7 lesions (6%). 47 metastases showed partial response (40.5%), 48 were stable and in only 16 lesions (10%) progression was diagnosed at the first imaging after radiotherapy. Median tPFS was 7.3 (1–148.5) months, whereas overall

PFS was 4.4 (1–101) months. At last follow-up, 39 patients were still alive and the median overall survival was 18.5 (2.5–152) months. In comparison to non-SBRT with 50–60 Gy, risk for local recurrence was significantly higher in non-SBRT with 20–49Gy (multivariate adjusted HR 5.1; 95% CI 0.039–0.972; P = 0.046), but quite similar as to SBRT (HR 1.1; 95% 0.18–4.93; P = 0.95) and SDRT (HR 2.2 95% CI 0.11–1.96; P = 0.29). Higher age (P = 0.042) and ki67 index >15 % (P = 0.002) appeared to be important prognostic factors. Toxicities with grade 3 or higher did not occur.
Conclusions
Our study provides for the first time evidence from a larger cohort that radiotherapy is effective in a significant proportion of patients with advanced ACC. The retrospective nature and the size of the study are major limitations.

The management of post-operative recurrences in patients with adrenocortical carcinoma (ACC): The experience of San Luigi Hospital

Anna Calabrese, Soraya Puglisi, Vittoria Basile, Paola Perotti, Paola Berchialla, Anna Pia, Giuseppe Reimondo & Massimo Terzolo
San Luigi Gonzaga University Hospital, Clinical and Biological Sciences, Orbassano, Italy

Background
The management of post-operative recurrences of ACC remains controversial, although the current guidelines recommend a surgical approach whenever feasible with radical intent.
Aim
The aim of our study was to evaluate retrospectively the management of recurrences in patients with ACC. We collected data of 106 patients with ACC followed at the San Luigi Hospital for the management of recurrence. Median follow up was 34 months.
Outcome
Baseline characteristics of our patients were: 59.4% women, median age 46 yrs, 31.4% ACC were incidentally discovered, 52.4% patients reported symptoms related to hormone excess (72.7% cortisol) and 7.6% to tumor mass, 71.7% ACC were stage I-II ENSAT, 73.8% underwent open surgery, and all were macroscopically resected (R0 or Rx surgery). Median Weiss Score was 7, median ki67 20%, and 59.4% of patients underwent adjuvant mitotane treatment following surgery. Median RFS was 12 months (IQR: 6–23), and median OS was 64 months (IQR 34–162). ACC recurrences occurred as a unique lesion (group A) in 35.8%, multiple lesions in a single organ (group B) in 20.8%, and affecting multiple organs (group C) in 43.4%. Baseline characteristics of patients stratified by the type of recurrence did not differ between them. Local treatment (surgery, radiotherapy or RFA) was used in 100% of patients of the group A, 66.7% in group B, and 26% in group C. After treatment of recurrence, 60% of patients were free of disease. Stratifying patients by type of recurrences, we found a significantly better OS for group A (P < 0.001). Stratifying patients by treatment of recurrence, we found a significant better OS for patients who underwent local treatment (P < 0.001). This finding may be linked to the better outcome of local recurrences. None of the variables considered (sex, age, symptomatology, ACC stage, type of surgery, Weiss Score, ki67) was a factor predicting the type of recurrence in multivariate analysis.
Conclusion
We managed ACC recurrences mainly with a local approach, not only when recurrences occurred as a unique lesion, and we were able to attain a disease-free status in 60% of patients. The chance of future survival was better when ACC recurred as a unique lesion allowing a local treatment.

Background
The ESE-ENSAT guidelines suggest adjuvant mitotane for patients with adrenocortical carcinoma (ACC) at high risk of recurrence following radical surgery. This indication has a limited evidence base, lacking results from randomized controlled trials. No suggestion is available in low-risk patients, since studies did not stratify patients for prognosis. The randomized controlled study ADIUVO compared the efficacy of adjuvant mitotane (MIT) treatment vs. observation (OBS) in prolonging recurrence-free survival (RFS) in patients at low-intermediate risk of recurrence.
Methods
The main inclusion criteria were: stage I-III ACC, R0 surgery, and Ki-67 ≤10%. Patients were randomly assigned 1:1 to MIT or OBS. The primary endpoint of the study was RFS. Patients who refused randomization were eligible for the ADIUVO OBSERVATIONAL study. In this prospective, observational study, patients were managed as in ADIUVO except for randomization. A total of 91 patients were enrolled in ADIUVO, 45 in the MIT and 46 in the OBS arm. Baseline characteristics of patients were perfectly matched between the 2 arms: median age, 51 vs. 50.5 years; female, 73% vs 67%; stage I, 20% vs 26%; stage II, 67% vs 63%, stage III, 13% vs 11%; ACC secretion 44% vs 36%; Weiss 5 vs 5; respectively. In ADIUVO OBSERVATIONAL, 42 patients were treated with mitotane and 53 were untreated. Baseline characteristics of patients were matched between the 2 groups and with MIT and OBS groups in ADIUVO. Thus, the ADIUVO OBSERVATIONAL cohort was analyzed in parallel to deal with the difficult recruitment in ADIUVO.
Results
In the ADIUVO study, recurrences were 8 in the MIT and 11 in the OBS arm, while deaths were 2 and 5, respectively. RFS and overall survival (OS) did not significantly differ between the 2 arms. Tumor size was a predictor of RFS in multivariable analysis. In the OBS arm, the HR for recurrence was 1.321 (95% CI, 0.55–3.32, P = 0.54) and HR for death 2.171 (95% CI, 0.52–12.12, P = 0.29). The survival analysis in the ADIUVO OBSERVATIONAL study confirmed that of ADIUVO. Given the outcome of both studies, the NNT is 55.
Conclusions
ACC patients at low-intermediate risk of recurrence show a rather good prognosis (5-yr RFS of 75%) and do not benefit significantly from adjuvant mitotane. The results of the ADIUVO study do not support routine use of adjuvant mitotane in this subset of patients, who may thus avoid a potentially toxic treatment. This is an important step toward personalization of ACC care.

Investigating the role of cholesterol and lipid trafficking in mitotane resistance in adrenocortical carcinoma

Kate Warde[1], Yi Jan Lim[1], Felix Beuschlein[2], Hantel Constanze[2,3], & Michael Conall Dennedy[1,4]

[1]The Lambe Institute for Translational Research, Pharmacology & Therapeutics, Galway; [2]University Hospital Zurich, Endocrinology, Diabetes, and Clinical Nutrition, Zurich, Switzerland; [3]University Hospital Carl Gustav Carus Dresden, Medizinische Klinik und Poliklinik III, Dresden, Germany; [4]School of Medicine, National University of Ireland, Galway, Galway, Ireland

Introduction
Adrenocortical Carcinoma (ACC) is a rare aggressive cancer which carries a poor prognosis. Adjuvant mitotane improves survival but is limited by poor response rates and resistance following tumour recurrence. Mitotane's efficacy has been attributed to intracellular accumulation of toxic free cholesterol (FC) predominantly through inhibition of cholesterol storage through SOAT1. Yet SOAT1 specific inhibitors demonstrate inferior efficacy to mitotane in inducing ACC cell death. We hypothesize that mitotane's efficacy to induce toxic FC accumulation in ACC cells is also mediated through enhanced breakdown of lipid droplets (LDs).
Methodology
ATCC-H295R (mitotane sensitive) and MUC-1 (mitotane resistant) ACC cells were evaluated for neutral lipid content using BODIPY493/503 under baseline and cholesterol loaded conditions using Amnis ImageStream, additionally cells were treated with mitotane (H295R 20/40/50 μM; MUC1 – 50/100/200 μM) for 6 hrs. Analysis of LDs using CE-BODIPY and FA-BODIPY identified cholesteryl ester (CE) and triacylglycerol (TAG)-containing LDs, respectively. Lipid droplet-associated proteins (LDAPs) Perilipin (PLIN) 1–4 and hormone sensitive lipase (HSL) were evaluated using western blotting and PCR.
Results
Mitotane treatment, within its therapeutic range, decreased staining for neutral lipid droplets significantly in H295R. This was also reflected by decreased expression of LDAPs PLIN1 and PLIN3. Decreased LDs was associated with increased activation of HSL (pHSL and LIPE). However, this effect was only evident in MUC-1 at supratherapeutic 200 μM mitotane. H295R and MUC-1 demonstrated similar overall neutral LD numbers at baseline and under cholesterol supplementation. Expression of PLIN3 was high in both cell lines, while PLIN1, PLIN2 and PLIN4 demonstrated distinct LD profiles in each. Investigation of LD content showed H295R preferentially store CEs, while MUC-1 store only TAG, irrespective of cholesterol-loading. Mitotane treatment significantly reduces CE and TAG LD stores in H295R and MUC-1. Pharmacological inhibition of HSL decreases mitotane-induced toxicity and CE-LD reduction, however, does not affect TAG-LDs. Additionally, toxic mitotane increases glycerol production in H295R and MUC-1.
Conclusion
We highlight that LD breakdown and activation of HSL represents a putative additional mechanism for mitotane induced FC cytotoxicity in ACC. We also demonstrate significant overall differences in cholesterol handling and LDAPs between mitotane-sensitive and mitotane-resistant models, in particular, the absence of CE-LDs in MUC-1. However, inhibition of HSL and CE-LD breakdown does not fully attenuate mitotane toxicity. Increased glycerol production and decreased TAG-LDs following mitotane treatment highlights an additional toxic mechanism through TAG lipolysis. Further understanding of cholesterol and lipid handling in ACC offers potential for novel therapeutic exploitation, especially in mitotane-resistant disease.

Despite their therapeutic effectiveness, glucocorticoids' (GC) clinical usage is frequently limited due to the deleterious metabolic effects. GC-induced obesity arises from excessive fat accumulation in white adipose tissue (WAT) as well as suppressed thermogenic capacity in brown adipose tissue (BAT). Since the sympathetic nervous system (SNS) plays a fundamental role in adipose tissue biology, we examined the interaction between GCs and SNS signaling in the adipose organ. To that end, we modulated the SNS activity by altering the housing temperature of corticosterone-treated mice and respective controls to either 29°C, 22°C, or 13°C. Following four weeks of corticosterone treatment, mice housed at 29°C and 22°C gained more weight and accumulated more fat than their temperature-matched controls. Interestingly, mice maintained in the 13°C environment were protected from GC-driven weight gain and obesity. Additionally, the cold adaptation of mice effectively protected against GC-induced hyperglycemia, hyperinsulinemia and hyperleptinemia, all of which were readily observed at 29°C and 22°C. Furthermore, the sympathetic innervation as well as the thermogenic capacity of BAT were preserved in mice maintained at 13°C in spite of corticosterone treatment, whereas mice housed at 29°C and 22°C showed a marked reduction in both sympathetic nerve endings and thermogenic capacity following GC exposure. To test whether preservation of sympathetic activity is sufficient to prevent GC-induced dysmetabolism, we co-treated mice with corticosterone and CL-316.243 – a β3-adrenergic agonist. Selective activation of β3-adrenergic receptors not only averted the development of GC-induced fat accumulation and hyperinsulinemia, but also preserved the thermogenic capacity in BAT. Taken together, our data demonstrate that both cold-exposure, as well as β3-adrenergic activation, prevent the onset of GC-induced adipose dysfunction and related metabolic comorbidities. Thus, β3-adrenergic receptors can be considered a potential therapeutic target in the prevention of GC-induced obesity.

Improved glucose metabolism and decreased weight gain in leptin-resistant, IGFBP2-deficient, db/db mice induced by AZP-3404, a 9-amino acid analog of IGFBP2

Michael D. Culler[1], Stéphane Milano[2], Michel Ovize[2], Thomas Delale[2], Aart Jan van der Lelij, & David Clemmons[4]
[1]Amolyt Pharma, Cambridge, Massachusetts, United States; [2]Amolyt Pharma, Ecully, France; [3]Erasmus University Medical Center, Rotterdam, Netherlands; [4]New Paradigm Therapeutics, Chapel Hill, North Carolina, United States

Insulin-like growth factor binding protein-2 (IGFBP2) has been demonstrated to be a key mediator of the peripheral actions of leptin, and its deficiency is associated with impaired metabolic function. The metabolic activity of IGFBP2 can be localized to a unique heparin-binding domain (HBD-1) within its structure. AZP-3404 is a 9-amino acid analog of the IGFBP2 HBD-1 that has been demonstrated to increase glucose uptake by differentiated mouse myotubes in vitro, and to increase glucose disposal in leptin-deficient, and consequently IGFBP2-deficient, ob/ob mice. In the present study, we examined whether AZP-3404 could improve metabolic regulation in the db/db mouse which, as a result of a mutation in the leptin receptor, is leptin-resistant and consequently has elevated leptin levels but is IGFBP2-deficient. Nine-week old male db/db mice were treated with either vehicle or AZP-3404 at doses of 1, 3 or 6 mg/kg, sc, bid (n = 10/group). After 8 weeks of treatment, the impact on glucose disposal was assessed by administering an intraperitoneal glucose tolerance test (IPGTT; 1g glucose/kg, ip), following an overnight fast. All three doses of AZP-3404 produced similar increases in glucose disposal (AUC glucose decreased by 18.8, 21.4 and 23.1% with 1, 3 and 6 mg/kg AZP-3404, respectively) vs vehicle controls. Correspondingly, 4-hour fasted plasma insulin was decreased by 54, 48 and 52%, and the HOMA measure of insulin resistance was decreased by 55, 52 and 67%, following treatment with 1, 3 and 6 mg/kg AZP-3404, respectively, as compared with vehicle-treated mice. Over the 8 weeks of treatment, mice receiving vehicle gained an average 8.2 + 1.6 grams of body weight. Mice treated with AZP-3404 displayed a progressive decrease in body weight gain that began after 2 weeks and that continued through the 8 weeks of treatment, ultimately resulting in less than 50% of the weight gain observed in the vehicle-treated mice, and without an apparent change in food intake. Postmortem examination by micro-computerized tomography (μCT) imaging revealed decreases in both total and visceral fat mass that mirrored the AZP-3404-induced decrease in body weight gain, without effect on lean mass. These results, demonstrating both improved glucose metabolism and decreased body weight gain in the leptin-resistant, IGFBP2-deficient, db/db mouse, further confirms the ability of AZP-3404 to reproduce the metabolic

activity of IGFBP2, as well as its potential benefit as a novel therapy for disease states characterized by insulin resistance and/or obesity.

Comparative evaluation of empagliflozin, canagliflozin and sitagliptin cardioprotective effect in diabetic rats with experimental myocardial infarction

Anna Simanenkova[1,2], Sarkis Minasian[1,2], Tatiana Karonova[1,2], Timur Vlasov[2], Natalya Timkina[1], Aleksandra Khalzova[2], Oksana Shpilevaya[1], Anzhelika Shimshilashvili[1], Valeria Timofeeva[1], Yury Borshchev[1] & Mikhail Galagudza[1,2]

[1]National Medical Research Center. VA Almazov, Sankt-Peterburg, Russian Federation; [2]Pavlov First State Medical University of St. Petersburg, Sankt-Peterburg, Russian Federation

Background:
Myocardial infarction (MI) is one of the leading causes of mortality in patients with type 2 diabetes mellitus (DM), therefore it is essential to give preference to a glucose-lowering drug having most prominent cardioprotective properties. Sodium-glucose co-transporter-2 inhibitors (SGLT-2i) have demonstrated an ability to decrease heart failure manifestations, cardiovascular death frequency not having a certain influence on MI occurrence. On the other hand, the influence of SGLT-2i therapy on MI manifestations was not fully investigated, neither in clinical nor in experimental studies. Moreover, comparative study of the various SGLT-2i representatives' protective effects in experimental MI was not carried out within the framework of one study.
Aim
To evaluate the influence of empagliflozin (EMPA) and canagliflozin (CANA), in comparison with sitagliptin (SITA), on hemodynamic parameters and myocardial damage area in type 2 diabetic rats in experimental MI.
Materials and methods
Type 2 DM was modelled in Wistar rats by means of 4-week high-fat diet followed by nicotinamide 230 mg/kg and streptozotocin 60 mg/kg administration. 4 weeks after DM induction the following groups were made: «DM+SITA»–treatment with SITA 50 mg/kg, «DM+EMPA»–treatment with EMPA 2 mg/kg, «DM+CANA»–treatment with CANA 25 mg/kg per os once daily for 8 weeks. Animals in «DM» group remained untreated for the following 8 weeks. Rats in control group were fed with standard chow. 16 weeks after the experiment beginning transient global myocardial ischemia was modelled in all rats. Hemodynamic parameters (ischemic contracture, left ventricle diastolic pressure, left ventricle developed pressure, coronary blood flow) and myocardium necrosis area were evaluated.
Results
The necrosis area was larger in «DM» group, than in control one (P = 0.018). Infarction size in «DM+SITA» did not differ from that in «DM» group (62.92 (41.29; 75.84) and 57.26 (45.51;70.08) %, respectively, P = 0.554). Necrosis area in «DM+EMPA» and «DM+CANA» groups was smaller than in «DM» group (37.90 (20.76; 54.66) %, 46.15 (29.77; 50.55) vs 57.26 (45.51; 70.08) %, P = 0.008 and P=0.009, respectively). Necrosis size did not differ between «DM+EMPA» and «DM+CANA» groups (P = 0.630). Ischemic contracture in «DM+CANA» group was less prominent than under the use of all other glucose-lowering drugs. We observed increase of coronary blood flow in «DM+EMPA» group, in comparison with «DM», «DM+CANA» and «DM+SITA» groups.
Conclusions
SITA does not have cardioprotective effect in ischemia-reperfusion injury in diabetic rats. EMPA and CANA have similarly prominent infarct-limiting properties. EMPA is able to increase coronary blood flow, whereas cardioprotective action of CANA is associated with ischemic contracture diminishing.

Improvements in long-term appetite-regulating hormones in response to a combined lifestyle intervention for obesity

Susanne Kuckuck[1], Eline S. van der Valk[1], Anton J. W. Scheurink[2], Sjoerd A. A. van den Berg[3] & Elisabeth F. C. van Rossum[1]

[1]Obesity Center CGG, Erasmus Medical Center Rotterdam, Department of Internal Medicine, Rotterdam, Netherlands; [2]University of Groningen, Groningen Institute for Evolutionary Life Sciences, Groningen, Netherlands; [3]Erasmus Medical Center Rotterdam, Department of Clinical Chemistry and Department of Internal Medicine, Rotterdam, Netherlands

Introduction
Altered levels of hormonal appetite regulators have been observed in obesity (BMI ≥ 30.0 kg/m^2), most prominently increases of insulin and leptin (indicating resistance) as well as decreases of adiponectin–all of which are long-term energy regulators and adiposity signals. Disrupted signaling of these hormones may have detrimental effects on metabolism, but may also promote weight gain. Weight loss is often accompanied by normalizations of long-term adiposity signals, but findings concerning short-term appetite regulators after weight loss vary across interventions (e.g. very low calorie diets vs. exercise). Moreover, it is debated whether such weight-loss-induced hormonal changes may reflect a disposition for weight regain. Here, we investigated changes of long–and short-term appetite signals in response to an intensive 75-week combined lifestyle intervention (CLI) comprising a normocaloric healthy diet, physical activity and psychotherapy to promote improved long-term weight management.
Methods
For 39 patients, data on fasting serum levels of appetite-regulating hormones (leptin, insulin, adiponectin, GIP, PP, PYY, CCK, FGF21) were available. Hormone levels were correlated to BMI and compared across three time points: T0, T1 (after 10 weeks; initial weight loss) and T2 (after 75 weeks; weight loss maintenance).
Results
At T0, hormone levels were not associated with BMI. BMI decreased significantly from T0 (40.13 kg/m^2 ± 5.7) to T1 (38.2 ± 5.4, p < .001) which was maintained at T2 (38.2 kg/m^2 ± 5.9, P < .001). There were no significant changes in GIP, PP, PYY, CCK and FGF21. Leptin decreased from T0 (44.9 ng/nl ± 15.3) to T1 (33 ng/nl ± 14.8, P < .001) and T2 (38.6 ng/nl ± 16.0, P < .01), just like insulin which was significantly decreased at T1 (123 pmol/l ± 65, P < .05) and T2 (128 pmol/l ± 64, P < .05) compared to T0 (160 pmol/l ± 80). Adiponectin did not change between T0 (3.36 mg/ml ± 2.1) and T1 (3.2 mg/ml ± 2.1), but was increased at T2 (3.7 mg/ml ± 2.9, P < .01) compared to T1. T0-T2 BMI decrease correlated positively with T0-T2 decreases in leptin (r = .667, P < .001), insulin (ρ = .535, P < .001) and increases of adiponectin (r = .412, P < .01), but no other hormone. T0-T1 hormone changes did not predict T1-T2 BMI changes.
Conclusion
A 75-week CLI was associated with beneficial changes in the long-term energy regulators adiponectin, leptin and insulin, but no changes in short-term appetite-regulating hormones were observed despite significant weight loss. Initial changes in appetite-regulating hormones were not associated with subsequent weight regain. Overall, our data suggest that a CLI does not lead to adverse changes in appetite regulation, but rather long-term improvements such as e.g. increased leptin and insulin sensitivity.

Effects of the ghrelin gene-derived peptides on adipose browning and thermogenesis

Noemi Congiusta[1], Iacopo Gesmundo[1], Pasquale Pagliaro[2], Ezio Ghigo[1], Claudia Penna[2] & Riccarda Granata[1]

[1]University of Turin, Medical Science, Turin, Italy; [2]University of Turin, Clinical and Biological science, Turin, Italy

White adipose tissue (WAT) stores excess energy as triglycerides, while brown adipose tissue (BAT) dissipates energy through heat, acting as a defence against cold and obesity and as a positive regulator of metabolic functions. BAT thermogenic functions are mainly induced by mitochondrial uncoupling protein-1 (UCP-1), which induces uptake of lipids and glucose to sustain oxidation and thermogenesis in both brown and beige adipocytes. The ghrelin gene-derived peptides, acylated ghrelin (AG), unacylated ghrelin (UAG) and obestatin (Obe), are key regulators of energy homeostasis, as well as glucose and lipid metabolism. *In vivo* studies suggest that AG, via the growth hormone (GH) secretagogue receptor type 1a (GHS-R1a), exerts inhibitory effects on UCP-1 mRNA expression and noradrenaline release in BAT; moreover, ablation of GHS-R in mice increased BAT thermogenic functions. However, the role of the ghrelin peptides in adipose browning and BAT function is yet unknown. Thus, we aimed to assess the role of AG, UAG and Obe in promoting white adipocyte browning and on brown adipocyte thermogenic functions. 3T3-L1 preadipocytes and human mesenchymal stem cells (hMSC) were differentiated to white adipocytes for 9 and 21 days respectively. Browning was induced for 72 h with rosiglitazone and insulin,

in the presence or absence of AG, UAG and Obe. UAG and Obe, but not AG, increased the mRNA levels of BAT genes (Ucp-1, Cidea, Tmem26, Prdm16, Pgc-1α) and lipolytic genes (CPT-1a and Sirt1), while reducing the lipogenic gene C/EBP in 3T3-L1 and human adipocytes. UAG and Obe also increased the number of small lipid droplets, characteristics of brown adipocytes. The thermogenic role of the peptides will be next studied in rat T37i brown adipocytes. Overall, our findings indicate that Obe and UAG, but not AG may promote browning of adipocytes, leading to the identification of new potential therapeutic targets against obesity and metabolic diseases.

Molecular and functional mapping of POMC neuronal heterogeneity in obesity

Stéphane Léon, Vincent Simon, Samantha Clark, Nathalie Dupuy, & Daniela Cota, Carmelo Quarta
University of Bordeaux, INSERM, Neurocentre Magendie, U1215, Bordeaux, France

The brain is critically involved in the regulation of energy balance and glucose homeostasis. Depending on the levels of energy available in our body, the activity of a group of hypothalamic neurons expressing the neuropeptidergic marker proopiomelanocortin (POMC) changes and it plays a key role in maintaining energy balance. When POMC neuronal activity is altered, this can lead to impaired energy homeostasis and therefore to obesity. However, POMC neurons are highly diverse, and whether or not such heterogeneity is implicated in the development of diet-induced obesity (DIO) remains unknown. Here, we used a lineage-tracing approach in combination with immunofluorescence, fluorescent in situ hybridization, and ex-vivo hypothalamic slice electrophysiology, to characterize the molecular and functional heterogeneity of POMC neurons in control lean and DIO mice. Thanks to the genetic strategy employed, we have successfully 'traced' with a reporter protein POMC neurons in adult mice, thereby allowing to study these neuronal cells independently from the expression of their main marker POMC. Three subpopulations of POMC neurons could be identified: neurons expressing high levels of POMC (POMC-high), neurons with low POMC expression (POMC-low), and neurons with no POMC expression (POMC-'ghost'). Notably, chronic exposure to a high-fat diet (HFD) led to alterations in the peptidergic and molecular machinery of the POMC-high subpopulation, but did not affect POMC-low or POMC-ghost neurons. Thus, our data suggest that DIO leads to selective functional alterations in specific POMC neuronal clusters. The approach proposed may be used in the future to map the functional relationship between specific subpopulations of POMC neurons and obesity pathogenesis.

[1]Medizinische Klinik und Poliklinik IV, Klinikum der LMU München, Munich, Germany, Endocrinology, Munich, Germany; [2]Universitätskrankenhaus Hamburg-Eppendorf, Hamburg, Germany, Neurosurgery, Hamburg, Germany; [3]Division of Endocrinology, Radboud University Medical Centre, Internal Medicine, Nijmegen, Netherlands; [4]Université de Paris, Institut Cochin, INSERM, CNRS, Paris, France; [5]Center for Rare Adrenal Diseases, Hôpital Cochin, Endocrinology, Paris, France; [6]Division of Endocrinology, Hospital Universitário Clementino Fraga Filho, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [7]Division of Endocrinology and Diabetes, University Hospital Würzburg, University of Würzburg, Internal Medicine I, Würzburg, Germany; [8]University Hospital Tübingen, Neurosurgery, Tübingen, Germany; [9]Neurochirurgische Klinik und Poliklinik, Klinikum der LMU München, Munich, Germany; [10]Medicover Neuroendocrinology, Munich, Germany

Introduction
TP53 mutations have been rarely reported in pituitary tumours. Recently two exploratory exome sequencing studies have identified somatic TP53 mutations in a small number of functional corticotroph tumours (6/18 and 4/10) with USP8 wild type (wt) status, suggesting that they may be more frequent than previously thought. Nevertheless, the clinical impact of those mutations is still unknown.
Aim
To determine the prevalence of TP53 mutations in a cohort of USP8wt tumours and to identify clinical features associated with TP53 mutations.
Methods
We analysed samples from 54 patients with USP8wt corticotroph tumours, (47 females, 7 males), 43 diagnosed with Cushing's disease (CD) and 11 with corticotroph tumour progression after bilateral adrenalectomy/Nelson syndrome (CTP/NS). An additional cohort of 23 patients with USP8 mutant (mut) tumours was included for comparison (23 females, 14 CD and 9 CTP/NS). In total, 63 tumours were fresh frozen and 14 formalin-fixed paraffin embedded. The complete TP53 coding region was amplified by PCR with specific primers and sequenced using the Sanger method.
Results
8 single-nucleotide variants in 7 samples (prevalence 13% in USP8wt tumours) were annotated in ClinVar database as pathogenic, likely pathogenic, or uncertain significance but evidence of protein function alteration. All of them were predicted as pathogenic in the COSMIC database. Mutations were detected in heterozygosis and were located in exon 5 (c.398T>A, p.Met133Lys), exon 6 (c.644G>A, p.Ser215Asn), exon 7 (c.714T>A, p.Cys238X; c.718A>G, p.Ser240Gly; and c.773A>C, p.Glu258Ala), exon 8 (2 unrelated patients with c.818G>A; p.Arg273His) and exon 10 (c.1009C>G; p.Arg337Gly). One long deletion was found in one case, but no indels. No mutation was found in USP8mut samples. Mutations were more frequent in CTP/NS than in CD (36% vs 7%, P = 0.025). We found association with: older age at diagnosis (TP53mut 52 ± 21 vs. USP8mut 36 ± 12 vs. wt 41 ± 14 years old, P = 0.046; TP53mut vs USP8mut, P = 0.04), lower frequency of total tumour resection (TP53mut 0% vs. USP8mut 83% vs wt 63%, P = 0.015), higher invasion rate (TP53 100% vs USP8mut 44% vs wt 48%, P = 0.012) and lower survival (TP53mut 50% vs. USP8mut 95% vs. wt 94%, P = 0.012). After stratification in CD or CTP/NS Total resection and survival lost statistical significance but CTP/NS patients with TP53 mutations trended towards lower survival rate (25% vs 89% USP8mut, 86% wt, P = 0.069). No differences were found regarding tumour size or hormone levels.
Conclusion
TP53 mutations are more frequent in CTP/NS than in CD and may be related to a more aggressive tumour behaviour.

In vitro activity of glutamate decarboxylase types, 65 and 67 in GABAergic brain-regions sleeping-process related

Marisa Cabeza[1], Nayely Carrasco-Núñez[1] & Martha Romano[2]
[1]Universidad Autónoma Metropolitana-Xochimilco, Sistemas Biológicos, Mexico D.F., Mexico; [2]Cinvestav, Fisiología, Ciudad de México, Mexico

We determined *in vitro* activity of 17β-estradiol and or progesterone on glutamate conversion to GABA in different GABAergic regions from the brain of castrated and non-castrated rats. The glutamate decarboxylase catalyzes this conversion; there are two different isotypes of glutamate decarboxylase, GAD_{65} and GAD_{67}. Whereas GAD_{65} is a membrane enzyme, GAD_{67} is present in the supernatant obtained after centrifuging to 14,000 g. We treated three different groups of ovariectomized rats with increasing week-dose of 17β-estradiol, progesterone, and the combination of both for five weeks. We maintained one group of the ovariectomized rats as a control. After five weeks of treatment, we separated the rat-brain. We dissect the brain regions which have previously been related to the sleep process: mammillary bodies, *locus coeruleus*, *substantia nigra*, and the ascending reticular activating system. After homogenates and centrifuge these tissues, we incubating the membrane fraction and supernatant separately with tritiated-glutamate a pyridoxal phosphate. We assessed the decarboxylation of glutamate for the formation of a Schiff base, which was purified by thin-layer chromatography. We identified this Schiff base by its fluoresces at ş 302 nm. We quantify this conversion by counting the radioactivity present in the fluorescence zone. Results indicated that 17β-estradiol-treatment increased the GAD_{65} and GAD_{67} activity in all the studied brain-regions compared with those of the ovariectomized (vehicle-treated) control. In contrast, progesterone increased GAD_{65} and GAD_{67} activity only in the

ascending reticular activating system and *locus coeruleus*. Furthermore, 17β-estradiol plus progesterone-treatment also increased GABA synthesis in the ascending reticular activating system and *locus coeruleus* compared to the vehicle-treated control. However, the ovariectomized (vehicle-treated) control showed only GAD_{65} and GAD_{67} activity in the mammillary bodies and *substantia nigra*. The brain GABAergic structures studied are involved in the process of sleep. Therefore the increase of the GABA formation induced by 17β-estradiol is responsible for maintaining sleeping in rats. However, the progesterone role seems to be a regulator of this process because the *locus coeruleus* and the ascending reticular activation system are responsible for inducing the sleep-wake rhythm.

Cardiovascular and metabolic safety of growth hormone treatment in adult patients with growth hormone deficiency: real-world data from two large studies in the USA and Europe

Charlotte Höybye[1], Nicky Kelepouris[2], Navid Nedjatian[3]
[1]Karolinska University Hospital and Karolinska Institute, Department of Endocrinology, and Department of Molecular Medicine and Surgery, Stockholm, Sweden; [2]Novo Nordisk Inc., Plainsboro, United States; [3]Novo Nordisk Health Care AG, Zurich, Switzerland

Introduction
Evidence suggests that adults with growth hormone deficiency (AGHD) exhibit metabolic abnormalities that are typical of the metabolic syndrome and are risk factors for type 2 diabetes (T2D). Concerns about undesirable effects of growth hormone replacement therapy (GHRT) on glucose metabolism have been raised, but the risk of T2D from AGHD has mixed evidence. This analysis aims to evaluate cardiovascular (CV) and metabolic safety of GHRT in these patients in a real-world setting.
Methods
NordiNet IOS (NCT00960128) and ANSWER (NCT01009905) were observational, non-interventional studies that investigated the long-term effectiveness and safety of GHRT. This analysis includes pooled data from the AGHD population from the two studies (n = 1,275; 50.6% female). Baseline characteristics [mean (SD)] were: age at treatment initiation, 48.5 (13.7) years; growth hormone dose, 0.3 (0.2) mg/day; and body mass index, 29.9 (7.1) kg/m^2. We compared the proportion of patients with CV and metabolic risk factors above the clinical threshold at baseline and after 7 years of GHRT.
Results
The overall proportion of patients with increased CV and metabolic risk factors was not different from baseline after 7 years of follow up, except for the decrease in patients with high LDL-cholesterol (P = 0.03) and non-HDL-cholesterol (P = 0.03) (Table 1). The only statistically significant gender-specific result observed was the decrease in proportion of men with high non-HDL-cholesterol (P = 0.007).
Conclusion
GHRT in AGHD did not increase the percentage of patients with increased CV and metabolic risk factors. This analysis provides further insight into the safety of GHRT in AGHD.

Table 1 CV and metabolic risk factor changes from baseline to 7 years' follow-up

Risk factor thresholds	Patients included in this analysis *N*	Baseline *n* (%)	After 7 years *n* (%)	*P*-value*
FPG ≥ 126 mg/dl	58	4 (6.90)	4 (6.90)	1.0000
HbA_{1c} ≥ 6.5%	81	5 (6.17)	6 (7.41)	1.0000
SBP ≥ 130 mm Hg	130	61 (46.92)	65 (50.00)	0.7098
DBP ≥ 80 mm Hg	130	82 (63.08)	68 (52.31)	0.1025
Total cholesterol ≥ 4.0 mmol/l	88	83 (94.32)	82 (93.18)	1.0000
LDL-cholesterol ≥ 3.0 mmol/l	56	40 (71.43)	28 (50.00)	0.0328
HDL-cholesterol < 1.0 mmol/l (men) and < 1.3 (women)	84	21 (25.00)	21 (25.00)	1.0000
Non-HDL-cholesterol ≥ 3.4 mmol/l	82	65 (79.27)	51 (62.20)	0.0251

Growth hormone-releasing hormone (GHRH) promotes survival and proliferation of neural stem cells and reduces amyloid-β-induced toxicity

Dana Banfi[1], Iacopo Gesmundo[1], Michela Guglielmotto[2,3], Elena Tamagno[2,3], Ezio Ghigo[1], Andrew V. Schally[4] & Riccarda Granata[1]
[1]University of Turin, Division of Endocrinology, Diabetes and Metabolism, Department of Medical Science, Turin, Italy; [2]University of Turin, Department of Neuroscience, Turin, Italy; [3]University of Turin, Neuroscience Institute Cavalieri Ottolenghi Foundation (NICO), Turin, Italy; [4]University of Miami Miller School of Medicine, Division of Endocrinology, Department of Medicine, University of Miami Miller School of Medicine, Miami, Florida, Miami, United States

Neurogenesis, a process by which new neurons are generated from precursors, still persists in discrete regions of the adult hippocampus. The hippocampus is critical for learning and memory and is a main target of AD, which causes massive neuronal death, reduction in neurogenesis and impairment in cognitive functions. Therefore, preventing neuronal loss or increasing the production of new neurons may represent a potential therapeutic strategy to reduce AD-induced cognitive decline. Growth hormone-releasing hormone (GHRH), apart from promoting growth hormone (GH) secretion from the pituitary, exerts many extrapituitary functions, including stimulation of cell survival, cardioprotection and protection against diabetic retinopathy. Furthermore, expression of GHRH, as well as GHRH-receptor (GHRH-R) and its splice variants (SVs), has been demonstrated in different brain regions, including the cerebral cortex, cerebellum and brain stem cells. To date, however, the role of GHRH on neurogenesis and neuroprotection is still unknown. Thus, we aimed to investigate the role of GHRH on survival, proliferation, apoptosis and differentiation of rat hippocampal neural stem cells (NSCs), in stress conditions such as growth factor deprivation and amyloid-β peptide 1–42 ($A\beta_{1-42}$)-induced toxicity, and to define the underlying mechanisms. We found expression of both mRNA and protein for pituitary GHRH-R in NSCs. GHRH dose-dependently increased cell survival and proliferation and reduced apoptosis in NSCs cultured under both growth factor deprivation and exposure to $A\beta_{1-42}$; these effects were blocked by the GHRH antagonist JV-1–36. The underlying mechanisms involved $G\alpha_s$/cAMP/PKA/CREB signaling, as demonstrated the results obtained in the presence of specific inhibitors, and phosphorylation of ERK1/2 and PI3K/Akt. In addition, GHRH counteracted the effect of $A\beta_{1-42}$ on elevation of the proapoptotic protein BAX and inhibition of the antiapoptotic protein Bcl-2. Moreover, GHRH induced GSK-3β phosphorylation and counteracted the $A\beta_{1-42}$-induced inhibition of GSK-3β phosphorylation. Finally, the role of GHRH was examined on differentiation of NSCs into neuronal lineages, such as neurons, oligodendrocytes, and astrocytes. Interestingly, GHRH increased the mRNA levels of the neuronal marker *Tuj1*, while showing no significant effect on *GFAP* and *Ripk1*, specific for astrocytes and oligodendrocytes, respectively. Collectively, these results suggest a role for GHRH in preventing neuronal loss and in promoting neurogenesis, with potential therapeutic application of its agonistic analogs in neurodegenerative diseases, such as AD.

Potential therapeutic role of somatostatin and cortistatin in prostate cancer

Jesus Perez Gomez[1,2;3,4], Prudencio Sáez-Martínez[1,2;3,4], Juan M. Jiménez-Vacas[1,2;3,4], Vicente Herrero-Aguayo[1,2;3,4], Sergio Pedraza-Arévalo[1,2;3,4], Enrique Gómez-Gómez[1,2;3,4;5], Antonio J. León-González[1,2;3,4], Antonio J. [1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Córdoba, Spain; [2]Department of Cell Biology, Physiology and Immunology, University or Córdoba, Córdoba, Spain; [3]Reina Sofia University Hospital (HURS), Córdoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Córdoba, Spain; [5]Urology Service, HURS/IMIBIC, Córdoba, Spain

Somatostatin (SST), Cortistatin (CORT), Neuronostatin (NST) and their receptors [SST/CORT-receptors (sst1–5/sst5TMD4-TMD5) and NST-receptor (GPR107)] comprise a hormonal pleiotropic system involved in the regulation of multiple pathophysiological functions. Certain components of this system are dysregulated in endocrine-related cancers, including prostate cancer (PCa), wherein we have found that alterations in specific components of this regulatory system [i.e. NST-GPR107-circuit/sst1/sst5TMD4 (1–3)] influence their development and progression. However, a comparative, parallel study of the presence and therapeutic role of SST and CORT in PCa has not been reported hitherto. For that reason, we analysed functional parameters (cell proliferation and migration) in response to SST and CORT treatment (10^{-7}M) and to siRNA-induced CORT-silencing in different PCa-derived cell lines [androgen-dependent (AD): LNCaP, and androgen-independent (AI): 22Rv1 and PC-3, which are models of hormone-sensitive and Castration-Resistant PCa (CRPCa), respectively], and in the normal prostate cell-line RWPE-1. Moreover, western-blotting and quantitative real-time-PCR were implemented to determine the mechanisms of action associated to SST/CORT treatment and CORT-silencing in PCa cells. SST and CORT treatment significantly inhibited proliferation and migration capacity in AI-PCa cells, but not in AD-PCa or in normal cells. Mechanistically, the antitumor capacity of these peptides was associated to the modulation of important oncogenic signalling-pathways (i.e. AKT/JNK). Interestingly, among all SST-receptors, only sst5 was significantly overexpressed in AI-PCa cells compared to normal-cells, suggesting that the SST/CORT-actions observed in PCa-cells might be mainly exerted through sst5. Remarkably, CORT was highly expressed, while SST transcripts were not detected, in all prostate cell-lines analysed, suggesting that local endogenous CORT could be exerting antitumor actions in PCa-cells through an autocrine/paracrine mechanism. Supporting this idea, CORT-silencing drastically increased the proliferation rate of AI-PCa cells 22Rv1 and PC-3. Finally, CORT expression was correlated with key clinical parameters (i.e. Gleason Score and metastasis) in two *in silico* cohorts of PCa patients (Grasso/Taylor). Altogether, our results demonstrate that SST/CORT treatment reduced PCa aggressiveness in CRPCa-cells possibly via sst5 and through the alteration of key oncogenic signalling-pathways, suggesting that SST/CORT peptides might be used as therapeutic tool for CRPCa. Moreover, our data revealed that endogenous CORT is highly expressed in PCa cells wherein could exert an auto-regulatory role.

Background
MPOWERED, a large phase 3 trial, assessed maintenance of response to oral octreotide capsules (OOC; MYCAPSSA) compared to injectable somatostatin receptor ligands (iSRLs) in patients with acromegaly who responded to OOC and iSRLs (octreotide or lanreotide). OOC were recently approved in the US for patients with acromegaly who responded to and tolerated iSRLs.
Methods
Eligibility criteria included age 18 – 75 years at screening, acromegaly diagnosis, disease evidence, biochemical control (insulin-like growth factor I [IGF-I] < 1.3 × upper limit of normal [ULN] and mean integrated growth hormone [GH] < 2.5 ng/ml) at screening, and ≥6 months' iSRL treatment. Effective OOC dose was determined in a 26-week Run-in phase. Eligible patients (IGF-I < 1.3 × ULN and mean integrated GH < 2.5 ng/ml, week 24) were randomized to a 36-week controlled treatment phase (RCT), receiving OOC or iSRLs starting at week 26. The primary end point was a noninferiority assessment of proportion of patients biochemically controlled in the RCT (IGF-I < 1.3 × ULN using time-weighted average). Other end points included nonresponse imputation of the primary end point, landmark analysis using proportion of responders based on average of last 2 IGF-I values at end of RCT, and change from baseline RCT (week 26) IGF-I and GH levels.
Results
Of 146 enrolled patients, 92 entered the RCT (OOC, n = 55; iSRLs, n = 37). Both arms were well balanced for age, sex, and acromegaly duration. OOC demonstrated noninferiority to iSRLs in maintaining biochemical response, with 91% (CI, 80% – 97%) of OOC and 100% (CI, 91% – 100%) of iSRL groups maintaining control during the RCT. Of those responding at end of Run-in, 96% of patients on OOC maintained response during RCT. Using nonresponse imputation, 89% of OOC and 95% of iSRL groups were biochemically controlled in RCT. Landmark analysis of those responding at end of Run-in showed that 94% of patients in each group maintained response at RCT end. In both groups, IGF-I levels were stable in the RCT, average IGF-I at baseline and RCT end being 0.9 × ULN (OOC) and 0.8 × ULN (iSRL). Mean change in GH from RCT start to RCT end was -0.03 ng/ml (OOC) and +0.29 ng/ml (iSRL). Safety data were mostly similar between groups; the OOC group did not experience injection site reactions.
Conclusion
In this noninferiority trial in patients with acromegaly, OOC demonstrated maintenance of biochemical response compared to iSRLs. Results support the efficacy of OOC as a possible iSRL alternative.

Organoids as a model to study the impact of EDCs on the prostate gland.

Emma Bokobza[1], Victor Tiroille[1], Cyril Karamaoun[2], Médéric Argentina[3], Benjamin Mauroy[2], Charlotte Hinault[1], Frédéric Bost[1], Stephan Clavel[1], Nicolas Chevalier[4]

Endocrine disrupting chemicals (EDCs) produce adverse effects associated with numerous pathologies: neurological disorders, metabolic diseases, infertility and cancer for example. How EDCs interfere with the development of hormone-sensitive tissue is a major question in biology. In this study, we propose that the model of prostate organoids can be used to study the effects of EDCs on the development of the prostate gland. Indeed, the differentiation of adult stem cells (ASC) isolated from prostate into organoids recapitulate quite faithfully the development of the gland. We isolated ASC from mouse prostate (7 to 9 weeks) using flow cytometry. We cultured them in matrigel with a specific organoid medium containing dihydrotestosterone (DHT). These culture conditions allowed the proliferation and the differentiation of ASC. This resulted in a 3D cellular structure composed of an external basal cell layer, an internal luminal cell layer and a central cavity containing luminal cell secretions. Once developed, organoids could be stained and imaged using confocal microscopy in order to analyze phenotypes induced by EDCs. DHT is known as the main regulator of the prostate gland differentiation, we first explored the kinetics of DHT regulation. We showed that prostate organoid development was divided in two phases. The first one was a hormone-independent phase from day 0 (D0) to D4, during which a beta-catenin gradient was formed along organoids radius.

This gradient could control early differentiation of adult stem cells into luminal-like cells. The second phase, from D5 to D9, was DHT dependent and induced the late differentiation into secretory luminal cells leading to a lumen formation in the center of organoids. We investigated the effect of anti-androgenic compound DDE on lumen formation in prostate organoid. We used mathematical approaches to increase the robustness of our model and evaluate the actions of EDCs on normal differentiation and development of organoids. Moreover, we hypothesized that luminogenesis may involve ion channels whose expression or functionality are likely to be regulated by hormones, as previously reported in intestinal organoids. The interaction of DHT and DDE and the cystic fibrosis transmembrane conductance regulator (CFTR) is currently studied in prostate organoids. Thus, we present here the organoid model as a new screening platform to study the effects of EDCs on the prostate gland by combining an analysis of organoids morphological features with mathematical modeling.

Optimisation of a rapid, sensitive and cost-effective rat NIS iodide uptake assay

Robin Dickinson[1], Carol Murray[1], Larry Higgins[2] & Claudia McGinnis[1]
[1]Concept Life Sciences, Endocrine Toxicology, Dundee, United Kingdom; [2]H-Toxicology Consulting, Cupar, United Kingdom

Thyroid hormones are evolutionarily conserved iodine-containing regulators of metabolism and development (reviewed by Mullur *et al*. (2014)). A key process in synthesis of the effectors thyroxine and tri-iodothyronine is the uptake of iodide from the bloodstream into thyroid follicular cells by the sodium-iodide symporter channel (NIS) encoded by the solute-carrier gene SLC5A5. Perturbation of NIS activity by environmental chemicals can lead to rapid and potent changes in thyroid hormone signalling with concomitant harmful effects. Accordingly, an assay to assess the impact on iodide symport by small molecules is a valuable tool for identifying potential endocrine disruptors. The FRTL-5 cell line has been used to study NIS function for more than 40 years. They were isolated by growing thyroid explants in low serum media with a defined additive cocktail to maintain thyroid characteristics along with proliferative capability. They depend critically on presence of thyrotropin, without which proliferation and other thyroid functions are lost (Ambesi-Impiombato *et al*. (1980)). In 2010, a non-radioactive method to quantify iodide uptake by FRTL-5 cells in 96-well plate format was published (Waltz *et al*. (2010)). Here, modifications to the published method are presented that improve sensitivity (1.5pmol compared to 10pmol), with an optimized incubation period (7.5 minute uptake instead of 60 minutes) and improved linearity with regard to iodide concentration and uptake time. We observe similar IC_{50} values for the competitive inhibitors sodium perchlorate, sodium tetrafluoroborate and sodium thiocyanate. Finally, we present a modification to the cell culture medium that reduces costs by more than 20-fold through complete elimination of thyrotropin, whilst retaining proliferation and stable thyroid characteristics such as NIS function unchanged for more than 70 passages.

Background
In the 2002 outbreak of severe acute respiratory syndrome (SARS) a number of patients presented abnormalities in the thyroid functioning, neuroendocrine and calcium homeostasis. It was detected in autopsies from SARS Coronavirus (SARS-CoV) patients that the thyroid gland was significantly affected by the disease, with extensive injury and death of follicular and parafollicular cells. In the present SARS-CoV-2 pandemic some studies start to report acute thyroiditis and alterations in the levels of thyroid hormones [(triiodothyronine (T3), thyroxine (T4), thyroid stimulating hormone (TSH)]. Thyroid cells present high levels of mRNA expression of angiotensin-converting enzyme 2 (ACE2), the host receptor for SARS-CoV-2. It remains poorly studied the thyroid expression of proteins that predispose to SARS-CoV-2 infection and if thyroid cells can be a direct or indirect target of SARS-CoV-2 infection.
Aims
We aim to establish the expression of ACE-2, Furin and TMPRSS2 in thyroid from infected and uninfected patients. We aim also to investigate if thyroid cells can be directly infected by the SARS-CoV-2 and which are the putative consequences of this infection in the gland morphology.
Material and methods
In collaboration with Centro Hospitalar Universitário de São João and Universidade São Paulo, Brazil, we have access to autopsy thyroid samples (n = 15) and clinical data from patients infected with SARS-CoV-2. We evaluated the expression, in the autopsy thyroid samples and in a series of other thyroid lesions (normal, thyroiditis and tumors; n = 40), of the ACE2, Furin and TMPRSS2. We analyzed the autopsy thyroid samples for cleaved caspase 3 (apoptosis) and the IHC for viral proteins (spike and nucleocapsid).
Results/conclusions
Our results show positivity for cleaved Caspase 3 and extensive morphologic alterations in the necropsy thyroid samples. ACE2 expression was more intense and frequent in thyroid samples from infected individuals than in the control series. We detected signs of acute inflammation, just vasodilatation and no increased number of neutrophils. We are still evaluating the putative correlation of the inflammation with histologic features using digital pathology and immunohistochemistry. The autopsy thyroid samples will be studied with RNAscope for validation of SARS-CoV-2 RNA expression and other parameters: histological features, proliferation and immune response. We expect to disclose the (direct or indirect) effects of SARS-CoV-2 infection in thyroid gland and eventual consequences in thyroid function of recovered COVID-19 patients.

Evaluation of the hypothalamic-pituitary-adrenal axis suppression in kidney transplant recipients and its association with metabolic parameters

Anna Angelousi[1], Stathis Tsiakas[2], Efstathios Xagas[2], Fani Athanasouli[1], Smaragdi Marinaki[2] & Ioannis Boletis[2]
[1]National and Kapodistrian University of Athens, 1st Department of Internal Medicine, Endocrine Unit, Athens, Greece; [2]National and Kapodistrian University of Athens, Department of Nephrology and Renal Transplantation, Athens, Greece

Introduction
Corticosteroids are included in the maintenance immunosuppressive regimen in most kidney transplant recipients. Studies evaluating the effect of chronic low-dose glucocorticoid treatment on the hypothalamic-pituitary-adrenal (HPA) axis and the metabolic profile of these patients are limited.
Aim
The objective of the study was to evaluate the metabolic effects and the alterations of HPA axis regulation in stable kidney transplant recipients treated with long-term low-dose glucocorticoids.
Methods
A cross-sectional study was conducted including adult kidney transplant recipients on a stable immunosuppressive regimen followed in our center. Selected patients were transplanted for over a year and maintained an estimated glomerular filtration rate (eGFR)>54 ml/min/1.73 m^2 (CKD-EPI equation). Examined metabolic abnormalities included new-onset diabetes mellitus after transplantation (NODAT), central obesity and dyslipidemia as defined by IDF criteria. HPA axis evaluation encompassed measurements of morning (0800 hours) serum cortisol, adrenocorticotropic hormone (ACTH), dehydroepiandrosterone-sulphate (DHEAS) levels; 24-hour urine free cortisol excretion (UFC) and hair cortisol levels (HC). HC samples (2 cm length) were collected according to SoHT guidelines and measured by liquid chromatography tandem–mass spectrometry (LC–MS/MS). All hormonal functional tests were performed in the same laboratory. An intergroup analysis between patients who received glucocorticoids and those who did not was performed.

Results
Sixty-four kidney transplant recipients (males 67.2%) with a mean age of 53 ± 13.4 years and a median time from transplantation of 71 (IQR 25–147) months were included in the study. The mean eGFR was 70.1 ± 15.1 ml/min/1.73 min^2. Most patients (81.3%) were on a tacrolimus-based regimen, while prednisolone was used by 84.4% of subjects with a mean dose of 5 ± 1 mg/d. NODAT was observed in 17.2% of patients, 81.8% of whom were on glucocorticoids. Dyslipidemia was found in 67.2% of patients and central obesity in 62.5% of men and 50% of women. Glucocorticoid-treated patients had significantly lower median serum cortisol ($P < 0.001$), DHEAS ($P = 0.002$) and UFC ($P = 0.012$). ACTH and HC levels were also lower although not statistically significant ($P = 0.644$ and $P = 0.285$, respectively). Markedly suppressed UFC levels (< 6 μg/24 h) were found in 29.4% of glucocorticoid-treated patients correlating with decreased morning serum cortisol < 5 μg/dl) ($P = 0.01$), DHEAS ($P = 0.021$) and HC levels ($P = 0.899$). Among metabolic parameters, NODAT was associated with suppressed levels of UFC ($P = 0.041$) and HC ($P = 0.042$) in glucocorticoid-treated patients.
Conclusions
Chronic low-dose steroid-treated kidney transplant recipients exhibited HPA axis suppression and increased prevalence of NODAT. HC could be a potential adjunctive biomarker of adrenal insufficiency, although more studies are required to establish this marker.

Introduction
Following the onset of the COVID-19 pandemic in early spring 2020, there was a need to identify the burden of this infection on people with rare endocrine conditions. The European Registries For Rare Endocrine Conditions (EuRRECa) was launched in 2018 in collaboration with Endo-ERN, ESPE and ESE to support the needs of the wider endocrine community. The project consists of an e-reporting (e-REC) platform that allows monthly reporting of new clinical encounters.
Methods
The ESE's Rare Disease Committee, formed in April 2020, created a COVID-19 taskforce which disseminated the use of e-REC through broad condition specific study groups. The e-REC platform does not collect personally identifiable information and does not require individual patient consent. The platform was made available to all centres to report a new confirmed or suspected case of COVID-19 in a patient with an existing endocrine or metabolic bone condition.
Results
Since launching the e-REC platform for notification of COVID-19 infections in March 2020, a total of 21 centres from 10 countries have agreed to participate. Of these 21 centres, 10 were reporting patients < 18 yrs (ie children) and 14 were reporting those ≥18 yrs old (adults). Of the 21 centres, 16 (76%) centres from 9 (90%) countries have used e-REC to notify 100 cases of which 55 were confirmed COVID-19 infections and the remainder were suspected. The median number of cases reported per centre was 2 (range 1, 20) and the median number of cases reported per month was 11 (3, 28). Of the 100 cases, 93 were in adults. This total 100 cases can be further categorized as broad thematic categories of pituitary disorders (n, 36), adrenal disorders (n, 32), genetic (neuro)endocrine tumours (n, 12), thyroid disorders (n, 6), calcium/phosphate disorders (n, 6), bone dysplasia (n, 4), glucose and insulin disorders (n, 2), growth and genetic obesity disorders (n, 1) and disorders of sex development and maturation (n, 1).
Conclusion
The use of the e-REC platform for identifying COVID-19 infection in people with rare endocrine conditions has been accepted in several centres and the platform is open for new centres. The majority of cases that have been reported are in adults and a high percentage are confirmed cases. Preliminary data suggest that COVID-19 infections are being reported more often in some endocrine conditions and there is a need to understand the reason for these differences as well as the impact of the infection on these patients.

OC14.6

Endocrine disorders in patients with Fabry Disease: A comprehensive reference center study

Christina Bothou[1], Felix Beuschlein[1] & Albina Nowak[1,2]
[1]Department of Endocrinology, Diabetology and Clinical Nutrition, University Hospital Zurich (USZ) and University of Zurich (UZH), Zürich, Switzerland; [2]Psychiatry University Hospital Zurich, Department of Internal Medicine, Zürich, Switzerland

Fabry Disease (FD) is a rare X–linked metabolic storage disease characterized by a–galactosidase A deficiency and deficient lysosomal function. The patients suffer from diffuse organ manifestations due to the accumulation of the substrate globotriaosylceramide (Gb3), which are only partially reversed by the available enzyme replacement (ERT) therapies. Previous endocrinological studies in patients with FD included small patient numbers or focused on a certain organ. To investigate the function of the endocrine system in patients with FD, we conducted an observational prospective study and included 77 patients with genetically confirmed FD (26 men, 20/26 classic, 6/26 late–onset phenotype, 51 women, 41/51 and 10/51 respectively), who are systematically followed by our reference center. Within this cohort, 3/77 new cases of subclinical and 2/77 of manifest hypothyroidism were identified while no abnormalities in the GH/IGF-1 axis was found. All (77/77) patients had normal baseline ACTH and morning cortisol levels and unrestricted cortisol response upon short time synacthen testing (62/62). Several cases with altered renin–angiotensin–aldosterone system (RAAS) were detected but none of them included clinical or hormonal suspicion of primary aldosteronism and the discrepancies were explained in the context of chronic kidney disease (CKD) or antihypertensive medications. 11/77 patients were suffering from significant hypophosphatemia ($P < 0.80$ mmol/l), likely due to VitD deficiency. 25/77 patients had VitD deficiency (25(0H)VitD < 20 mg/l) and 25/77 had insufficiency (25(0H)VitD between 20 and 30 mg/l) despite the fact that 23/50 were substituted with cholecalciferol. In male patients, normal baseline testosterone, FAI and SHBG levels were documented with no indication of hypogonadism. In 1/33 women, primary infertility and estrogen substitution was reported and further 4/33 achieved pregnancy only following IVF. 5/33 patients had a history of miscarriages but all of them delivered children. One/33 women had clinical and biochemical features of PCOS. To our knowledge, this is the largest endocrine study in patients with FD. Our findings indicate presence of a range of endocrine conditions in patients with FD. Longitudinal and case/control studies will be required to provide indication whether these findings are caused by FD dependent mechanisms on endocrine organs or represent independent co-morbidities similar than in the general population. Overall, our study highlights the importance of actively seeking and diagnosing endocrine disorders in patients with FD with the goal to optimise their health care.

Differential steroidomic profiles of human visceral and subcutaneous adipose tissue before and after bariatric surgery-induced weight loss

Sofia Laforest[1,2;3,4], Scott Denham[3], Nina Denver[2,3], Laurent Biertho[4], Natalie Z.M. Homer[1,3], Ruth Andrew[1,3] & Andre Tchernof[4]
[1]University of Edinburgh, Centre for Cardiovascular Science, Queen's Medical Research Institute, Edinburgh, United Kingdom; [2]University of Strathclyde, Strathclyde Institute of Pharmacy and Biomedical Sciences, Glasgow, United Kingdom; [3]University of Edinburgh, Mass Spectrometry Core, Edinburgh Clinical Research Facility, Queen's Medical Research Institute, Edinburgh, United Kingdom; [4]Laval University, Centre de recherche de l'Institut universitaire de cardiologie et de pneumologie de Québec, Québec, Canada

Background
Obesity is closely associated with impaired adipose tissue function. Although bariatric surgery is the treatment of choice for severe obesity and its related conditions, there are conflicting data on the reversal of adipose tissue dysfunction after surgery-induced weight loss. We hypothesise that local steroid hormone availability influences fat deposition or mobilisation and that these changes track with weight loss improvements, because plasma steroid concentrations are altered in obesity. For the first time, we characterise markers of visceral (VAT) and subcutaneous (SAT) adipose tissue function including fourteen *in situ* endogenous steroids and their change after surgery-induced weight loss in humans.
Methods
Institutional approval and consent were obtained. SAT and VAT were collected in men (n = 15) and women (n = 23) before and after sleeve gastrectomy. A validated liquid chromatography-tandem mass spectrometry method was developed to determine steroid hormone amounts in adipose tissue. Principal component analysis was performed to establish global trends related to the impact of depot, sex, and time after surgery. Repeated mixed-models were used to investigate associations of steroid hormones measured by ESI-LC-MS/MS (oestrone, oestradiol, androstenedione, testosterone, 5α-DHT, 5α-androstanedione, DHEA, cortisone, cortisol, 11β-hydroxyandrostenedione, 11-ketoandrostenedione, 11β-hydroxytestosterone, 11-ketotestosterone, and 11-ketoDHT) and of several steroid-converting enzyme transcripts.
Results
Post-surgery samples were obtained on average 26 ± 6 months after baseline. Participants had a preoperative mean BMI of 53 kg/m^2 (range 38–65). VAT had higher amounts of glucocorticoids, androgens, and 11-oxy-androgens. Oestrogens were higher in SAT. After weight loss, testosterone and 5α-dihydrotestosterone adipose tissue amounts were increased only in men (P < 0.05). Oestrogen amounts were decreased in both sexes (P < 0.05). Aromatase expression was higher in men before weight loss and then decreased in both sexes (P < 0.01). Expression of *DHRS11*, an enzyme with oestrogenic 17β-HSD activity, was decreased in women after weight loss (P < 0.01). *AKR1C2*, *AKR1C3*, *HSD11B1*, *SRD5A1* and *SRD5A3* expression also decreased significantly in both fat depots (P < 0.05), but not cortisol nor cortisone amounts. The waist-to-hip ratio was positively associated with concentrations of testosterone, 5α-DHT, 11β-hydroxyandrostenedione, 11β-hydroxytestosterone, androstenedione and 11-ketoDHT in VAT, and with testosterone and 11β-hydroxytestosterone in SAT (P < 0.05).
Conclusions
This is the first study reporting extensive intra-adipose steroid profiling before and after weight loss in a sample of men and women with severe obesity, including newly characterised 11-oxy-androgens. We found that intra-adipose oestrogen amounts decreased, active androgens increased, and 11-oxy-androgens were stable following bariatric surgery. None of the steroids studied were directly associated with the degree of weight loss, suggesting other biological mechanisms at play.

Screening for mutations in isolated central hypothyroidism reveals a novel mutation in insulin receptor substrate 4 (IRS4)

Konrad Patyra[1,2], Kristiina Makkonen[1,2], Maria Haanpää[3,4], Sinikka Karppinen[5], Liisa Viikari[5], Jorma Toppari[1,2,5], Mary Pat Reeve[6] & Jukka Kero[1,2,5]
[1]University of Turku, Institute of Biomedicine, Research Centre for Integrative Physiology and Pharmacology, Turku, Finland; [2]University of Turku, Turku Center for Disease Modeling, Turku, Finland; [3]University of Turku, Department of Genetics, Turku, Finland; [4]Turku University Hospital, Department of Genomics and Clinical Genetics; [5]Turku University Hospital, Department of Pediatrics, Turku, Finland; [6]University of Helsinki, Institute for Molecular Medicine Finland, Turku, Finland

Background
Central hypothyroidism (CeH) is a rare condition affecting approximately 1:16000 – 100 000 individuals. Congenital forms can harm the normal development if not detected and treated promptly. The clinical and biochemical diagnosis especially of the isolated CeH can be challenging. The cases are not usually detected in the neonatal screening, which, in most countries, are focused on detection of the more prevalent primary hypothyroidism. Until now, five genetic causes for isolated CeH have been identified. Here we aimed to identify the genetic cause in two brothers with impaired growth and diagnosed with CeH at the age of 5 years. Furthermore, we evaluated the candidate gene variants in a large genetic database.
Methods
Clinical and biochemical characterization together with targeted next-generation sequencing (NGS) was used to screen the genetic etiology in a family of two brothers presenting with CeH. Screening of *insulin receptor substrate 4* (*IRS4*) variants was carried out in the FinnGen-database.
Results
A novel monoallelic frameshift mutation c.1712_1713insT, p.Gly572Trp fs*32 in an X-linked *IRS4* gene was identified in NGS analysis in both affected males and confirmed using Sanger sequencing. Their mother was an unaffected carrier. In addition to the declined growth at the presentation, central hypothyroidism and blunted TRH test, no other phenotypic alterations were found. The diagnostic tests included head MRI, thyroid imaging, bone age, and laboratory tests for thyroid autoantibodies, glucose, insulin and glycosylated hemoglobin levels. Examination of the *IRS4* locus in FinnGen (R5) database revealed the strongest associations to a rare Finnish haplotype associated with thyroid disorders (P = 1.3e-7) and hypothyroidism (P = 8.3e-7).
Conclusions
Here, we identified a novel frameshift mutation in an X-linked *IRS4* gene in two brothers with isolated CeH. Furthermore, we demonstrate an association of *IRS4* gene locus to a general thyroid disease risk in the FinnGen-database. These findings together confirm the role of *IRS4* in isolated central hypothyroidism.

Targeting PI3K and CDKs as effective therapeutic option for PPGLs in vitro and in vivo

Sebastian Gulde[1], Daniela De Martino[1], Hermine Mohr[1], Swapna Satam[1], Alessia Foscarini[2], Svenja Nölting[3,4] & Natalia S. Pellegata[1]
[1]Helmholtz Centre Munich, Institute for Diabetes and Cancer, Neuherberg, Germany; [2]University of Pavia, Department of Biology and Biotechnology, Pavia, Italy; [3]University Hospital, LMU Munich, Department of Medicine IV, Munich, Germany; [4]University Hospital Zurich, Klinik für Endokrinologie, Diabetologie und Klinische Ernährung, Zurich, Switzerland

Pheochromocytoma and Paraganglioma, collectively referred to as PPGLs, are rare, mostly benign neuroendocrine tumors arising from chromaffin cells of the adrenal gland or of extra-adrenal sites, respectively. Surgery is the first-line therapy for localized PPGLs. However, up to 17% of PPGLs show metastatic spread, and for these cases there is no curative treatment. Therefore, the identification of novel therapeutic approaches for advanced PPGLs is highly clinically relevant. We aimed to find a new targeted therapy option for PPGLs based on their molecular profile. We set out to target two of the most dysregulated pathways in PPGLs, i.e. the PI3K and the CDK4/6 pathways, using BKM120 (pan-PI3K inhibitor) and LEE011 (CDK4/6 inhibitor). We analyzed the effect of these two drugs, as single agents or in combination, on PPGL cell lines and on primary rat and human PPGL cells in vitro and in xenograft experiments *in vivo*. Our results showed a clear reduction in the viability of PPGL cell lines upon treatment with the two drugs used as single agents. More importantly, a beneficial effect of the drug combination was observed in both 2D and 3D culture conditions. Moreover, we saw reduced migration as well as inhibited clonogenic potential of PPGL cell lines treated with both BKM120 and LEE011 compared to the single treatments. Interestingly, also primary PPGL cells (from an endogenous rat model and from human patients) responded to the single treatments with BKM120 or LEE011, and showed a beneficial combinatorial effect of the

two drugs. Based on these promising in vitro effects, we engrafted PC12 cells in immunodeficient mice and treated them for 21 days with BKM, LEE and their combination. We observed a clear reduction of tumor growth in the groups treated with the single drugs, and even tumor shrinkage in mice treated with the drug combination. Overall, our novel approach to combine a PI3K with a CDK4/6 inhibitor emerged as a new effective therapeutic option for PPGLs, especially interesting for inoperable and metastatic cases.

Identification of a dose range for once daily oral paltusotine in patients with acromegaly that maintains IGF-1 levels when switching from long-acting somatostatin receptor ligand therapy

Murray B. Gordon[1], Monica Gadelha[2], Miklos Toth[3], Mirjana Doknic[4], Emese Mezosi[5], Harpal Randeva[6], Tonya Marmon[7], Rosa Luo[7], Michael Monahan[7], Ajay Madan[7], Scott Struthers[7] & Alan Krasner[7]
[1]Allegheny General Hospital, Allegheny Neuroendocrinology Center, Pittsburgh, United States; [2]Hospital Universitário Clementino Fraga Filho, Neuroendocrinology Research Center/Endocrinology Division, Brazil; [3]Semmelweis University, Department of Internal Medicine and Oncology, Budapest, Hungary; [4]University Clinical Centre of Serbia, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Beograd, Serbia; [5]University of Pécs Medical School, Department of Internal Medicine, Pécs, Hungary; [6]University Hospitals Coventry and Warwickshire NHS Trust, United Kingdom; [7]Crinetics Pharmaceuticals, San Diego, United States

Long-acting somatostatin receptor ligands (LA-SRLs) are a first line medical treatment for acromegaly but require monthly parenteral administration. Paltusotine (CRN00808) is a nonpeptide, small molecule somatostatin type 2 (SST2) receptor agonist with high oral bioavailability (70%), suitable for once daily, oral dosing. The recently reported results of the ACROBAT Edge study (NCT03789656) suggest that patients with acromegaly treated with injected SRLs can switch to once daily oral paltusotine while maintaining IGF-1 and that paltusotine appeared to be well tolerated. The dose-response relationship for paltusotine was explored using pooled data from patients with acromegaly who participated in the ACROBAT Phase 2 Edge and Evolve (NCT03792555) studies. Both studies were designed to evaluate the safety and efficacy of switching acromegaly patients receiving LA-SRLs to once-daily, oral paltusotine (n = 60). The switch to paltusotine occurred 4 weeks after last LA-SRL injection. Patients were treated with paltusotine at doses titrated upward based on target IGF-1 starting at 10 mg to a maximum of 40 mg per day for up to 13 weeks, followed by a 4-week paltusotine wash-out period. The change from baseline in IGF-1 during the treatment period and the rise in IGF-1 after paltusotine wash-out were used to measure the magnitude of paltusotine-related IGF-1 suppression. An evaluation of steady state IGF-1 changes as a function of paltusotine dose showed that 10 and 20 mg per day resulted in IGF-1 levels that were above baseline, whereas doses of 30 and 40 mg result in changes from baseline of near zero, indicating the 30 and 40 mg doses were equally effective in suppressing IGF-1 as prior monotherapy with injected LA-SRLs. A dose-response relationship was also observed when evaluating the magnitude of the rise of IGF-1 during paltusotine washout. Exposure-response modeling estimated the paltusotine concentration at which 80% of maximal pharmacological response (EC_{80}) is achieved. Simulations of 3 doses (20, 40 and 60 mg/day) of an improved formulation were performed to evaluate the likelihood of achieving this trough concentration of paltusotine in a population of patients. These simulations suggest that a dose range of 40 to 60 mg/day would result in daily trough concentrations that exceed EC_{80} and result in consistent IGF-1 suppression in patients with acromegaly. In summary, dose and exposure response analyses of clinical trial data in patients with acromegaly has identified a dose range of oral paltusotine expected to result in IGF-1 suppression similar to that of injected LA-SRLs.

The Importance of maternal thyroid hormone for programming the cardiovascular system in the male offspring

Mehdi Pedaran[1], Rebecca Oelkrug[2] & Jens Mittag[2]
[1]Institute for Endocrinology and Diabetes, Lübeck, Germany

Thyroid hormones play an essential role for the embryonal development of the cardiovascular system including its central control mechanisms. Particularly the latter critically depends on maternal thyroid hormone, as the embryo doesn't produce own thyroid hormone until late in pregnancy. However, the precise window of action has remained undetermined, and it is therefore unclear whether alterations in maternal thyroid hormone directly affect the offspring's cardiac function. To address this question, we used mice heterozygous for a mutant thyroid hormone receptor α1 (TRα1), which exhibit resistance to thyroid hormone in tissues relying on TRα1 such as the heart. This was combined with maternal thyroid hormone treatments, which reactivated the mutant receptor for defined periods of time, either in the first or the second half of pregnancy. Phenotyping the offspring animals, we observed a significant increase in heart weight of male and female wildtype mice born by mothers that received thyroid hormone during the first or second half of pregnancy. Interestingly, TRα1 mutants were protected from this effect suggesting an important role of the receptor for embryonal heart development. Most remarkably, we also found a significant increase in heart rate in male mice that were exposed to elevated maternal thyroid hormone in the second half of the pregnancy independently of their own genotype, while female mice were not affected. Taken together our findings demonstrate that maternal thyroid hormone is of particular relevance during the second half of pregnancy for establishing cardiac properties, with specific effects depending on TRα1 or gender. The data therefore advocate routine monitoring of thyroid hormone levels during pregnancy to avoid adverse cardiac effects in the offspring.

Genetic polymorphism (IP-10/CXCL10) and diabetes mellitus type 1

Sylvia Pashkunova[1], Teodora Daneva[2], Dimitar Vassilev[3], Nikolay Kostadinov[4], Stefan Tsonev[5], Joana Vangelova[6] & Detelina Vitanova[7]
[1]Millitary Medical Academy, Endocrinology and metabolic diseases, Sofia, Bulgaria; [2]Bulgarian Academy of Sciences, Bulgaria; [3]Faculty of Mathemathics and Informathics, Bulgaria; [4]University Hospital Burgas, Bulgaria; [5]Agrobioinstitute, Bulgaria; [6]Medical University, Varna, Bulgaria; [7]University of Library Studies and Information Technologies, Bulgaria

Introduction
The development of Diabetes mellitus type 1 (DMT1) is considered as an autoimmune pro-inflammatory process. Human enteroviruses are thought to be also a cause. These viruses influence beta cells and cause expression of immunological factors. The affected cells destroy the related beta cells. The aim of the work is to study the genetic polymorphisms in IP-10/CXCL10 and its receptors CXCR3 and TLR4 in order to predict expression of DMT1.
Related work
There has been increasing evidence of elevated serum levels and increased expression of IP-10/CXCL10 in the pancreatic islets before and during the early stages of DMT1. A strong expression of IP-10 was detected in the Langerhans islets of NOD mice. They spontaneously develop DMT1, what is also observed in newly diagnosed patients with DMT1.
Problem description and hypothesis
Major assumption is based on the hypothesis and experimental evidence that DMT1 is a result of a pro-inflammatory process mainly through IP-10/CXCL10 polymorphism, which interacts with the CXCR3 receptor on immune cells. Viral infections induce the expression of cytokines and CXCL10. They attract immune cells through the CXCR3 receptor and cause beta cell destruction and subsequently DMT1. By blocking of CXCL10 receptors in early stage emerges as an opportunity to prevent the beta cells destruction. The potential reasons for cell destruction, are hypothesized with some differences in gene encoding. This process is related to the receptor or to the ligand and leads to a different way of their interaction and stimulation.
Material and methods
The sources of our study are based on genetic polymorphisms which encode IP-10/CXCL10 and its receptors CXCR3 and TLR4 on the surface of immune cells. We isolate and cut genomic DNA from two patients' cohorts: with DMT1 and with healthy controls. We used different restriction enzymes of genes encoding different chemokines, and we came across to a difference in the gene encoding IP-10/CXCL10.
Results and discussion
The identification of this polymorphism reveals the possible mechanism and causes for the manifestation of DMT1. Based on the obtained results, we can contribute to a potential prognostic test for predisposition to DMT1. Chemokines are important participants in the attraction of specific subpopulations of inflammatory cells in the pancreas. The identification of this polymorphism would contribute to further progress in discovering of triggering mechanisms of the DMT1. Advances in the study of genetic

polymorphism of chemokines and their receptors is useful in predicting the onset of diabetes and preventing it.

Circulating myomiRNAs as biomarkers of Cushing's syndrome

Claudia Pivonello[1], Roberta Patalano[2], Mariarosaria Negri[1], Tatiana Montò[1], Feliciana Amatrudo[1], Nicola Di Paola[1], Marina Iacono[1], Chiara Simeoli[1], Rosario Ferrigno[1], Domenico Solari[3], Cristina De Angelis[1], Renata Simona Auriemma[1], Paolo Cappabianca[3], Annamaria Colao[1] & Rosario Pivonello[1]

[1]Federico II University, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Naples, Italy; [2]Federico II University, Dipartimento di Sanità Pubblica, Naples, Italy; [3]Federico II University, Department of Neuroscience, Division of Neurosurgery, Reproductive and Odontostomatological Sciences, Naples, Italy

Cushing's syndrome (CS) is a rare endocrine disease caused by a chronic exposure to endogenous cortisol or exogenous glucocorticoids (GCs). Among multiple comorbidities, impairment of skeletal muscle mass and strength affects 40–70% of patients with active CS and persist even after long-term disease remission. In pathological conditions, GCs excess sustain muscle atrophy and weakness affecting type II muscle fibers. Muscle-specific microRNAs, defined myomiRs, are involved in myoblast proliferation, differentiation and regeneration, and changes in myomiR levels were reported in several pathological conditions associated with muscle organization and function perturbations. The current study aims to explore changes in circulating myomiRs in patients with CS, characterized by muscle atrophy and weakness compared to heathy controls. To focus the clinical study on a specific myomiRs subset, C2C12, mouse myoblast cell line, differentiated into myocytes, was exposed to 1.4×10^{-6} M of hydrocortisone (HC), resembling high cortisol serum level (500 ng/ml) observed in CS patients, for 4,6,8 and 12 hrs and gene and protein expression of the atrophy-related genes Atrogin and Murf were investigated by RT-qPCR, Western Blot and immunofluorescence to assess the HC-mediated atrophic signaling. The myomiRs levels were evaluated in treated C2C12 and controls by miScript miRNA PCR array. Circulating myomiRs significantly overexpressed in HC-treated C2C12 were then investigated by RT-qPCR in 33 patients affected by CS and 12 sex–and age-matched healthy controls. HC induced muscle atrophic signals significantly increasing Atrogin and Murf gene and protein expression and a concomitant higher expression of miR-133a-3p, miR-122–5p and miR-200b-3p in C2C12 after 12 hrs of treatment. The evaluation of these myomiRs in CS patients revealed higher circulating levels of miR-133a-3p ($P < 0.0001$), miR-122–5p ($P = 0.0135$) and miR-200b-3p ($P < 0.0001$) compared to controls. ROC curves for miR-133a-3p (AUC 0.866 (95% CI 0.756–0.976, $P = 0.0002$) and miR-200b-3p (AUC 0.976 (95% CI 0.930–1.023, $P < 0.0001$) demonstrated that both myomiRs represent potential biomarkers to discriminate between CS and healthy subjects. Interestingly, linear regression analysis revealed that circulating levels of miR-133a-3p are directly correlated with 24h urinary free cortisol level ($r = 0.428$, $P = 0.026$) in the CS patients. In conclusion, this study confirmed that HC induces atrophic signals and myomiR overexpression in mouse muscle cells, and in humans, circulating miR-200b-3p and mainly miR-133a-3p levels are promising molecular markers of hypercortisolism.

Background

Serum B cell stimulating factor (BAFF) has been shown to be elevated in Graves' disease (Vannucchi 2012). In addition, BAFF and its receptor have been shown to be expressed on lymphocytes infiltrating the thyroid in Graves' disease and also on thyrocytes (Campi 2015).

Aims

We tested in a single-blind randomized controlled trial (EudraCT 2015–002127–26) whether the administration of the anti-BAFF monoclonal antibody belimumab (BMB), approved for therapy of SLE, is effective in active moderate-severe Graves' Orbitopathy (GO) as compared to first line treatment iv methylprednisolone (MP).

Methods

We randomized 27 patients with active, moderate severe GO and detectable serum TSH receptor antibodies (TRAb), euthyroid for at least 3 months, whether untreated or previously treated with iv steroids (relapsing GO). 14 received iv belimumab at 0,14, 28 days and then every four weeks for five cycles of infusion and 13 iv MP, 833 mg/ weekly for 6 cycles, followed by one cycle of 425 mg/week. The first dose of belimumab was associated to a full dose (833 mg) of MP (inception dose). Patient were studied at 12, 24 weeks (primary end point) and followed-up for 48 weeks. In addition to assessment of the CAS (primary end point), proptosis and the titers of TRAb (secondary end points) were also measured.

Results

In both groups of patients the CAS decreased significantly at 24 weeks ($P < 0.0001$). At 12 weeks patients on MP had a significantly lower CAS than those on BMB (4.75 ± 0.3 1.5 ± 0.5 vs 4.15 ± 0.2 2.54 ± 0.5, $P < 0.009$). At 24 weeks 12/13 patients on MP (CAS 1.00 ± 0.4) and 13/14 on BMB (CAS 1.38 ± 0.3) had inactive disease. Proptosis improved in all patients ($P < 0.05$) and in MP patients more significantly than BMB ($P < 0.04$). Serum TRAb levels decreased significantly ($P < 0.01$) in both groups of patients. Two patients in each arm developed optic neuropathy. BMB treatment was very well tolerated, with 1 major and 4 minor side effects vs 2 and 3, when compared to MP.

Conclusions

BMB is as effective as iv MP in the treatment of active GO, inducing inactivation in more than 92% of subjects. While its effect is somewhat slower than that of MP, its tolerability is very good. BMB is suggested to be an excellent alternative to MP when this is contraindicated or not effective.

Non-alcoholic fatty liver disease (NAFLD) is a spectrum of disease spanning from simple steatosis to non-alcoholic steatohepatitis (NASH) with risk of progression to fibrosis and eventually cirrhosis. Dysfunction of the gut-liver axis plays a role the progression to NASH. Intestinal damage and increased permeability can increase the delivery of pathogen-associated molecular patterns (PAMPs), such as LPS and intact bacteria, to the liver where they can activate the TLR4 signalling pathway, and drive hepatic inflammation. Previously, we have shown that the ALIOS diet (high fat/high fructose) causes hepatic steatosis, inflammation and fibrosis in both female and male mice. Here, we examine whether intestinal damage and increased permeability contribute to hepatic inflammation in ALIOS female and male mice. Female and male C57BL/6 mice were fed either normal chow (NC) or ALIOS (45% fat [30% trans-fat], 55% fructose: 45% glucose in H2O; $n = 10 - 17$ in each group) until 52-weeks of age. The TLR4 signalling pathway was upregulated in the ALIOS mice. In detail,

hepatic protein levels of TLR4, total and phosphorylated NF-κB were increased, as was mRNA expression of the NF-κB target genes *Tnfa, Il-1*β and *Ccl2*. Marker of macrophage infiltration, F4/80, was also increased at mRNA and protein level. Increased intestinal permeability can be caused by loss of intestinal integrity and failure of antimicrobial response of the epithelial barrier. Consistent with intestinal damage, ALIOS diet altered the structure of the intestinal mucosa. Crypt depth was decreased in the ileum and, in females only, in the colon. Villus length was unchanged in both sexes. Suggesting increased permeability, expression of key tight junction genes *occludin* and *ZO-1* were decreased in the colon of female, but not male, ALIOS fed mice. In addition, the antimicrobial and immune supporting genes *Reg3g*, *Defa5* and *Muc2* were decreased in the ileum of the female mice and colonic *Reg3g* and *Muc2* were decreased in both sexes. Suggesting increased bacterial translocation and reduced barrier function, the amount of hepatic bacterial DNA was increased in both female and male ALIOS fed mice, although LPS levels were comparable to controls. Collectively, ALIOS diet represents a robust model for investigating the pathogenesis of NAFLD and its progression to NASH as it recapitulates the majority of the molecular features of NASH, with increased intestinal permeability, increased bacterial translocation and increased hepatic TLR4 pathway activation.

Use of ^{11}C-methionine PET-CT scanning to guide management of acromegaly following primary therapy – A pragmatic prioritisation strategy to achieve maximal cost effectiveness

Roby Rajan[1], D Bhatt[1], S Philip[1], AJ Graveling[2], M Kamel[3], S Olson[2], F Mckiddie[2], D Gillett[4], W Bashari[4], M Gurnell[4] & P Abraham[1]
[1]Aberdeen Royal Infirmary, Department of Endocrinology, Aberdeen, United Kingdom; [2]Aberdeen Royal Infirmary, Department of Nuclear Medicine, Aberdeen, United Kingdom; [3]Aberdeen Royal Infirmary, Department of Neurosurgery, Aberdeen, United Kingdom; [4]Welcome–MRC Institute of Metabolic Science,Cambridge Biomedical Campus, Cambridge Endocrine Molecular Imaging Group, Cambridge, United Kingdom

Background
^{11}C-methionine (11C-Met) positron emission tomography co-registered with MRI is a new imaging technique used for functioning pituitary adenomas, permitting targeted intervention (Transphenoidal Surgery (TSS) or Radiotherapy)[1]. The ^{11}C-Met PET-CT scan has been available in our centre since Dec 2016. With limited availability in 2019/2020 (due to cyclotron refurbishment) we re-audited our patients to prioritise those most likely to benefit.
Methods/Results
Retrospective study of patients with acromegaly under active follow-up in a tertiary hospital. Fifty-one patients included (61% female, mean age 59 years) with median follow-up of 13 years with 23 on active treatment. Patients were categorised into groups according to acromegaly treatment status as outlined in the below table. Poor control defined as IGF1> 1.3 × ULN, suboptimal control defined as IGF1 1.1–1.3 × ULN. Eighteen patients from Groups 1, 2 and 3 (2017) were initially considered suitable for ^{11}C-Met PET-CT. Progress to date: five scanned; two declined; eleven pending. Of the five patients scanned, two underwent TSS and have been cured (cost saving of £46822 per annum). One patient awaits surgery and no surgical target was identified in two patients (both in Group 3). We have subsequently reassessed our prioritisation criteria for Group 3 and will now predominantly offer 11C-Met PET-CT if adverse effects to SSA therapy are experienced.

Group	Acromegaly Treatment Status	2017	2020
1a	Poor control on SSA/pegvisomant	7*	0*
1b	Poor control, SSA intolerant/unsuitable (may have tried DA)	0	2
1c	Suboptimal control on SSA	2	2
2	Good control, very high-cost medication pegvisomant/pasireotide	1	1
3	Good control, high-cost medication SSA	8	12
4	Poor control DA – switch to SSA	4	0
5	Good control on DA	2	3
6	Good control on no medication	27	29
7	Deceased/Lost to follow-up	0	2
	Total	51	51

*Comparing 2017 with 2020: 2 operated and cured, 1 moved to category 1b, 2 moved to category 1c, 2 moved to category 3
SSA–somatostatin analogue, DA–dopamine agonist.
Conclusion
^{11}C-Met PET-CT can help localise residual functioning pituitary adenomas in patients with uncontrolled acromegaly but no visible tumour on MRI. However, its availability is currently limited. We present a pragmatic prioritisation strategy targeting those with poor control, ideally prior at the point of consideration of expensive medication such as pegvisomant and pasireotide. There is potential to extend this strategy nationwide.

Introduction
Progressive and radioiodine-refractory thyroid cancer has poor outcomes and limited therapeutic options (i.e tyrosine kinase inhibitors) due to the transient efficacy of treatment and toxic effects. Therefore, combinatorial treatment with new therapeutic approaches are needed. Many studies link G Protein-Coupled Receptors (GPCRs) to cancer. The aim of this study is to present the first specific atlas of GPCRs expression in progressive and refractory thyroid cancer and identify new potential targets among theses GPCRs aiming at drug repositioning.
Methods
We analyzed samples from tumor and normal thyroid tissue from 17 patients with refractory thyroid cancer (twelve papillary thyroid cancers (PTC) and five follicular thyroid cancers (FTC)). We assessed the GPCR mRNA expression by using the NanoString technology with a custom panel of 371 GPCRs and we selected GPCRs differentially-expressed between normal and tumoral tissues. The data were compared with public repositories by bioinformatics analyses (GEO and TCGA data sets) and pharmacological databases. Finally, we screened approved drugs that target differentially-expressed GPCRs. Experiments were performed with primary human refractory thyroid cancer cells isolated from tumoral ascites by measuring cell viability (Cell Titer-Glo Luminescent Cell Viability Assay kit) and cell migration (IncuCyte S3 live cell imaging system).
Results
With our transcriptomic analysis, 4 receptors were down regulated in FTC (VIPR1, ADGRL2, ADGRA3 and ADGRV1). In PTC, 24 receptors were deregulated, seven of which identified also by bioinformatics analyses of published studies on primary thyroid cancers (VIPR1, ADORA1, GPRC5B, P2RY8, GABBR2, CYSLTR2 and LPAR5). Among all the differentially-expressed genes, 25 GPCRs are the target of approved drugs and some receptor feature was also associated with overall survival or progression-free survival. Drug screening in ascites-derived primary refractory thyroid cancer cells found three agents with antiproliferative effect and anti-migratory effect in the micromolar range.
Conclusions
For the first time, we performed GPCR mRNA expression profiling in progressive and refractory thyroid cancers. A preliminary drug screening identified candidate drugs that target GPCRs. These findings provide an opportunity to the identification of new therapeutic targets for drug repositioning and precision medicine in radioiodine-refractory thyroid cancer.

Prostate cancer (PCa) is one of the most common causes of cancer-related deaths in men worldwide. Therefore, more specific and non-invasive diagnostic biomarkers as well as novel therapeutic targets are urgently needed. As miRNAs have been proposed as promising elements for the identification of novel diagnostic and therapeutic tools for different pathologies, including cancer, we investigated the miRNA landscape in PCa and explored their putative diagnostic/therapeutic utility. Specifically, the miRNome of plasma samples from healthy (n = 18) and PCa patients (n = 19) was initially determined using an Affymetrix-miRNA array. The main changes were validated in two independent cohorts (n = 296 and n = 84) by quantitative real-time PCR. Additionally, *in silico* and *in vitro* assays in normal and tumor prostate cell lines were performed. Results from the array revealed that the expression of 104 miRNAs was significantly altered (P < 0.01) in plasma samples from PCa patients compared with healthy controls. Of note, 6 of these miRNAs also exhibited a significant ROC curve to distinguish between healthy and PCa patients with an AUC equal to 1. A systematic validation using two independent cohorts of patients demonstrated that miR-107 was the most profoundly altered miRNA in PCa (P < 0.0001) exhibiting an AUC equal to 0.75. Interestingly, miR-107 significantly outperformed the ability of PSA to distinguish between control and PCa patients, as well as between non-significant (Gleason Score = 6) and significant (Gleason Score ≥∈7) PCa patients, being its expression correlated with relevant clinical parameters (e.g. PSA and testosterone levels, tumor volume). Remarkably, all these comparisons were even stronger in obese patients (BMI > 30). Interestingly, we found that miR-107 levels were also dysregulated in PCa tissues (compared to non-tumor tissues) and in PCa cells (compared to non-tumor cells). Moreover, *in vitro* overexpression of miR-107 significantly reduced cell proliferation, migration and tumorsphere formation in PCa cells, and altered the expression of several genes critical in PCa pathophysiology, such as *FASN* and *CPT2* (implicated in cellular lipid metabolism), *SRRM1*, *SRSF2* and *TIA1* (involved in splicing process). Altogether, our data demonstrate that miR-107 might represent a new diagnostic and potential therapeutic tool in PCa, especially in patients under obesity condition.

Introduction
Endometriosis is a dysplastic disease affecting approximately 7–10% of reproductive–aged women. It is defined as the presence of endometrial-like tissue outside the uterine cavity. Disruption of circadian rhythm in night shift worker has been associated with menstrual irregularity and increased chance of developing endometriosis and ovarian tumors. The central circadian clock system located in hypothalamic suprachiasmatic nucleus (SCN) along with the peripheral clock system located in the reproductive tissues (endometrium) control the timing and length of the ovulatory cycle by regulating the expression of various hormones (i.e.gonadotropins, estradiol) which in turn regulate the expression of clock related genes and vise-versa. To best of our knowledge, no studies related to the alterations in expression profile of the core clock -genes in human endometriosis have been published to date.
Aim
Herein, we aimed to investigate the expression of the core clock related genes in paired eutopic and ectopic endometrial tissues.
Methods
27 patients with confirmed ovarian endometriosis were included in this study. 11 paired samples were collected from ovarian cysts (ectopic endometrial tissues) and normal endometrium (eutopic tissues) while further 8 ectopic and 8 eutopic endometrial tissues were collected from 16 different patients with the same diagnosis. The mRNA expression of Clock-genes (CLOCK, BMAL1,CRY-1, PER-2, ROR-α and REV-ERBb) was evaluated by qPCR in ectopic tissues and was compared with the eutopic tissues.
Results
The mRNA expression of PER-2 and CRY-1 genes was decreased in the total of ectopic tissues (n = 19) compared to the total eutopic tissues (n = 19) (P = 0.02,P = 0.02 respectively). A marginal reduction in the expression of CLOCK along with a marginal increase in REV-ERBb expression was noted (P = 0.06 and P = 0.09 respectively) in ectopic (n = 19) compared to eutopic tissues (n = 19). The mRNA expression of clock-genes in the ectopic (n = 11) compared to their paired eutopic tissues (n = 11) revealed that the expression of PER-2 and CRY-1 genes were significantly lower (P = 0.04,P = 0.04, respectively), whereas REV-ERBb levels was significantly elevated (P = 0.02). Additionally, a marginal decrease in the expression of clock gene in ectopic as compared to paired eutopic tissues was observed (P = 0.09). Of note, the mRNA levels of BMAL1 and ROR-α were not altered between our studied groups.
Conclusions
Our study demonstrates for the first time an altered expression of CLOCK,CRY1,PER-2,and Rev-ERBb in eutopic as compared to ectopic endometrial tissues indicating circadian clock disruption. However, the causal relationship of the altered expression pattern of these genes with the development of endometriosis needs further investigation.

Metformin and simvastatin in combination: drugs repositioning to impair high-grade astrocytomas progression

Antonio C. Fuentes-Fayos[1,2,3,4], Miguel Garcia Garcia[1,2,3,4], Juan M Jiménez-Vacas[1,2,3,4], Julia Martin-Colom[1,2,5], Carlos Doval-Rosa[1,2,5], Cristobal Blanco-Acevedo[1,2,5], Manuel Gahete Ortiz[1,2,3,4], Justo P. Castaño[1,2,3,4], Juan Solivera[1,2,5] & Raul M. Luque[1,3,4,5]
[1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain; [2]Reina Sofia University Hospital (HURS), Cordoba, Spain; [3]Department of Cell Biology, Physiology and Immunology, University of Cordoba (UCO), Cordoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Cordoba, Spain; [5]Neurology Service, HURS, Cordoba, Spain

Astrocytomas are a subtype of malignant gliomas characterized by rapid growth and high diffusion through the brain. Based on the agresiveness features, they are stratified from low grades (I and II) to high grades (HGAs; III and IV), being grade-IV [glioblastoma multiforme (GBM)] the most aggressive and one of the most common malignant cancers in the brain, with an overall survival from diagnosis of ~14 months. Current standard therapies to treat HGAs are not efficient and therefore, identification of new therapeutic tools to tackle HGAs is urgently needed. In this sense, many metabolic drugs have emerged as antitumor agents for several endocrine-related cancers demostrating different pleiotropic anti-tumoral effects. Among them, metformin and simvastatin are currently prescribed to treat T2D patients and hypercholesterolemia, respectively. Thus, our aims were to evaluate: i) the putative *in vivo* association between metformin and/or simvastatin treatment and key clinical parameters in HGA patients, and ii) the direct effects of metformin, simvastatin and their combination, on key functional endpoints and associated signaling mechanisms in GBM-cells. Specifically, an exploratory/observational retrospective cohort of patients with HGAs (n = 61; mean age: 63.9 ± 5.5) was analyzed, and human GBM-

cells (U-87 MG/U-118 MG cell lines and patient derived-HGA cell cultures) were used to measure a set of key functional parameters and signaling-pathways in response to metformin, simvastatin and their combination. We found that metformin/simvastatin combination showed an association to longer overall survival *in vivo*. Moreover, metformin and simvastatin exerted strong antitumor actions being able to inhibit proliferation, migration, tumorsphere/colony-formation, VEGF secretion and to induce apoptosis on HGA-cells *in vitro*. Notably, their combination further decreased, additively, these functional parameters compared with the individual treatments. These individual or combined actions were mediated through modulation of key oncogenic signaling-pathways (i.e. AKT/JAK-STAT/NFkB/TGFß pathways). Interestingly, an enrichment analysis uncovered an activation of TGFß pathway together with the AKT inactivation when metformin and simvastatin were administered in combination, which might promote to a senescence-associated secretory phenotype and then a senescence state transition. Altogether, our results demonstrate that metformin and simvastatin significantly reduce tumor aggressiveness features in HGAs, being this effect more potent (*in vitro* and *in vivo*) when both drugs are combined. Therefore, given the demonstrated clinical safety of biguanides (metformin) and statins (simvastatin), our results suggest a potential therapeutic role of these compounds, especially their combination, for the treatment and management of this devastating brain cancer.

The value of liquid and solid mixed meal tests to diagnose postprandial reactive hypoglycaemic syndrome

Frederique Van de Velde[1], Simon Helleputte[2], Arsène-Hélène Batens[1], Yves Van Nieuwenhove[3] & Bruno Lapauw[1]
[1]Ghent University Hospital, Endocrinology, Ghent, Belgium; [2]Ghent University Hospital, Rehabilitation Sciences, Gent, Belgium; [3]Ghent University Hospital, Gastro-Intestinal Surgery, Ghent, Belgium

Background
Precise diagnostics for postprandial reactive hypoglycaemic syndrome (PRHS) after gastric bypass surgery (GBS) are lacking. Oral glucose tolerance tests are advocated but might cause early dumping in this population and often cause hypoglycaemic values in a normal population.
Aim
To evaluate glycaemic responses during liquid and solid mixed meal tolerance tests (LMMTT and SMMTT) in a post-GBS population.
Subjects and methods
Twenty-two subjects (age 49 ± 10 years, BMI 29.8 ± 4.9 kg/m^2) who were at least one year after GBS, with or without subjective complaints of PRHS, and 14 age-matched control subjects (6 normal-weight, 8 obese) participated. With a 1-week interval, all underwent a 3-hour LMMTT and SMMTT (with equal caloric and macronutrient content). Serum glucose concentration was determined using hexokinase method, insulin with immunoassays (COBAS, Roche Diagnostics). Hypoglycaemic symptoms during testing were evaluated using a 4-point Likert scale for the Edinburgh Hypoglycaemia Scale (EHS) and divided into three EHS subcategories (autonomic, neuroglycopenic, malaise symptoms).
Results
In the GBS group, mean nadir glucose levels did not differ between LMMTT and SMMTT (70 ± 16 mg/dl vs 71 ± 15 mg/dl, $P > 0.05$). During LMMTT, three and 10 subjects had glucose levels < 54 mg/dl and < 70 mg/dl, respectively which did not differ from the SMMTT where this was two and 10 subjects, respectively ($P > 0.05$). During LMMTT, markedly higher maximal glucose and insulin levels were observed than during SMMTT (glucose: 186 ± 27 mg/dl vs 156 ± 27 mg/dl, $P < 0.001$; insulin: 169 (107– 240) mU/l vs 92 (71 – 146) mU/l, $P = 0.002$; respectively). Rates of increase and decrease were greater during LMMTT for both glucose ($P < 0.001$ and $P = 0.001$, respectively) and insulin ($P = 0.001$ and $P = 0.006$, respectively) levels. Short after ingestion (15' and 30'), there were more autonomic, neuroglycopenic and malaise symptoms and at 150' and 180' there were more autonomic symptoms during LMMTT vs SMMTT (all $P < 0.05$). No-one from the control group developed glucose levels < 54 mg/dl during either test whereas three and one developed glycaemia < 70 mg/dl during LMMTT and SMMTT, respectively. The control group had more autonomic symptoms during LMMTT (at 120' and 150') in comparison to the post-GBS group (all, $P < 0.05$).
Discussion
In a post-GBS population, although a LMMTT causes greater variability in glycaemic and insulinemic responses and development of PRHS symptoms (but also symptoms of early dumping) than a SMMTT, both tests do not differ in nadir glucose levels or frequency of hypoglycaemia. In addition, neither tests cause hypoglycaemic values in control subjects making them possible diagnostic tools for PHRS in post-GBS subjects.

Placental expression of neurokinin B and its receptor NK3R is increased in women with polycystic ovary syndrome: results of a preliminary study

Georgios Markantes[1], Fotios Markatos[2] & Neoklis Georgopoulos[3]
[1]University of Patras, School of Health Sciences, Division of Endocrinology-Department of Internal Medicine, Patras, Greecel
[2]University of Patras, School of Health Sciences, Department of Obstetrics and Gynecology, Patras, Greece; [1]University of Patras, School of Health Sciences, Division of Endocrinology-Department of Internal Medicine, Patras, Greece

Background
Women with polycystic ovary syndrome (PCOS) are at increased risk of pregnancy complications and poor pregnancy outcomes. Defective placentation is among the proposed mechanisms involved. Altered neurokinin B (NKB) placental expression has been associated with several conditions characterized by placental dysfunction, such as pre-eclampsia and intra-uterine growth retardation. However, the expression of NKB and its receptors has not been studied in placental tissue of women with PCOS.
Objective
To compare the placental mRNA expression of NKB and its receptors NK1R, NK2R and NK3R in women with PCOS and controls.
Methods
This was a single-center, prospective, case-control study. Women with PCOS according to the Rotterdam criteria (cases) and healthy pregnant women (controls) were enrolled at first prenatal visit and followed until delivery. Only women with spontaneous conception and singleton, uncomplicated, term pregnancies (10 PCOS and 10 controls) were included in the final analysis. All participants provided informed consent. At delivery, placental specimens were collected and immediately submerged in RNAlater solution. Samples were stored at -20ºC until analysis. The mRNA expression of NKB, NK1R, NK2R and NK3R was quantified by real-time PCR (RT-PCR). The relative mRNA expression was estimated by the ΔΔCT method, using β-actin as reference (housekeeping gene). Statistical analysis was performed using SPSS 25.0, and the level of statistical significance was set at 0.05 (two-sided).
Results
The placental mRNA expression of NKB and NK3R was significantly higher in PCOS women vs controls (2.4-fold, $P < 0.05$ for NKB and 7-fold, $P < 0.05$ for NK3R). No significant alterations were observed in the mRNA expression of NK1R and NK2R between the two groups. There was no statistically significant difference regarding age, BMI, caesarian section frequency, offspring sex and birth weight between women with PCOS and controls. The placental expression of NKB and its receptors was correlated neither with maternal age and BMI, nor with offspring birth weight.
Conclusions
The present study is the first to demonstrate increased placental expression of NKB and its receptor NK3R in women with PCOS. These findings support a potential role for NKB as a mediator of placental alterations characterizing PCOS. Expanding the number of participants is the necessary next step, in order to corroborate these preliminary findings. Furthermore, correlations between the placental expression of NKB, NK1R, NK2R, NK3R and PCOS phenotype, maternal sex steroids, glucose and insulin levels should be sought.
Keywords: polycystic ovary syndrome (PCOS), placenta, neurokinin B (NKB), NK3R.

Gβγ-mediated signaling regulates NIS abundance at the plasma membrane

Márcia Faria[1,2], Maria João Bugalho[1,3], Paulo Matos[2,4] & Ana Luísa Silva[1,5]
[1]Serviço de Endocrinologia, Hospital de Santa Maria-CHULN, EPE, Lisbon, Portugal; [2]BioISI- Biosystems and Integrative Sciences Institute, Faculdade de Ciências da Universidade de Lisboa, Lisbon, Portugal; [3]Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal; [4]Departamento de Genética Humana, Instituto Nacional de Saúde Doutor Ricardo Jorge, Lisbon, Portugal; [5]ISAMB- Instituto de Saúde Ambiental, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal

Introduction
The Sodium Iodide Symporter (NIS) is responsible for the active transport of iodide into thyroid cells. Most of differentiated thyroid carcinomas (TC) retain the functional expression of NIS, which allows the use of radioiodide (RAI) as the systemic treatment of choice for metastatic disease. Still, a significant proportion of patients with advanced thyroid cancer fail to respond to RAI therapy (refractory-TC), which makes their management very challenging. In addition to reduced NIS expression, the limited iodide uptake observed in cancer tissue is also a consequence of an impairment of plasma membrane (PM) targeting and retention of NIS. However, signaling cues potentially mediating the activation of pathway components leading to NIS functional expression at the PM, remain elusive. Using a proteomic approach, we have recently identified a set of proteins that interact with NIS selectively at the PM, potentially modulating its abundance and stability at the surface of TC cells. The G protein subunit gamma 12 (GNG12) was detected as a specific PM-interactor of NIS. This is one of twelve Gşsubunits in the human genome that can pair with Gβ subunits to form unique Gβγ complex combinations. Along with Gα, Gβγ are key regulators of G protein-coupled receptor (GPCR) signaling, having the ability to activate several signaling mediators such as kinases, GTPases or lipases.
Objective
To evaluate whether modulation of Gγ12 subunit would have an impact on NIS PM abundance.
Methods
The TPC1 thyroid cancer cell line stably expressing a full-length NIS construct containing an extracellular triple HA tag (NIS-HA-TPC1) was used to assess the PM levels of NIS upon siRNA-mediated knockdown of GNG12 expression. NIS PM levels were assessed using surface protein biotinylation assays coupled to WB detection of NIS-HA using anti-HA primary antibody. A non-radioactive iodide influx assay was used to further analyze the impact of GNG12 on NIS function by assessing the rate of iodide uptake.
Results
siRNA-mediated GNG12 depletion, although partial (ş30% reduction), was able to induce a 1.6-fold decrease in NIS cell surface levels and also impair iodide uptake efficiency, halving the influx rates in HA-NIS-TPC1 cells.
Conclusion
Our findings suggest that signaling cues that lead to the release and activation of Gβγ may act upstream of signaling pathways that enhance NIS expression in the PM. This supports the relevance of further studying the impact of modulating Gβγ-mediated signaling on NIS functional expression, as a potential approach to enhance the efficiency of iodide uptake.

Preoperative predictors and prognostic factors of recurrence of the parathyroid carcinoma – Data of a multi-center study

Julia Krupinova[1], Iya Voronkova[1], Alina Aynetdinova[1], Ekaterina Pigarova[2] & Natalia Mokrysheva[1]
[1]Endocrinology Research Center, Pathology of the Parathyroid Gland, Moscow, Russian Federation; [2]Endocrinology Research Center, Moscow, Russian Federation

Background
There are no specific markers for parathyroid carcinoma (PC) therefore, the development of algorithms for identifying high-risk patients is an urgent task.
Aims
To determine clinical and laboratory predictors of PC and identify the factors of a poor prognosis.
Materials and methods
A multi-center retrospective study included 242 patients with primary hyperparathyroidism (PHPT) who were divided into these groups: 50 patients with PC, 30 with atypical adenoma (AA), and 162 with adenoma of the parathyroid glands (PG). We compared clinical, histopathological, immunohistochemical (IHC), and genetic characteristics. Overall survival was assessed using the Kaplan-Mayer estimator. Cut-off for Ki-67 proliferation index was determined by ROC-analysis.
Results
The group of patients with increased risk of the PC included individuals with the levels of intact PTH >€443 pg/ml, Ca++ > 1.5 mmol/l, albumin corrected calcium > 3.2 mmol/l, alkaline phosphatase > 176 IU/l, size of the tumor > 22.5 mm and volume of the tumor > 2.6 cm^3, (P < 0.001). Heterogeneous structure is more typical to PC compared to the AA (P = 0,004 and P = 0,011), the same applies to indefinite contour (P = 0,001 и P = 0,011). The incidence of nuclear atypia was more common in PC and AA compared to benign adenomas (P < 0.001). There difference appeared to show in the frequency of pathological mitoses (P = 0.007) in patients with recurrent PC. The sensitivity of the IHC study of parafibromin expression as a marker of the *CDC73* germline mutation is 100% (95% CI: 59%–100%), specificity 86% (95% CI: 73%–95%). The overall five-year survival rate for patients with PC is 87%, ten-year survival rate is 80%, disease-free five-year survival–56%, ten-year–50%. Cut-off for Ki-67 proliferation index as a predictor as increased risk of recurrent PC is 14.5% with PPV = 100% (63 %; 100%), and NPV = 81% (64%; 93%).
Conclusions
We have identified clinical and laboratory predictors of malignant neoplasms of the PG and identified factors of poor prognosis. Genetic study of the *CDC73* gene is shown patients with a loss of parafibromin expression in the primary tumor or in metastases of PC according to the results of the IHC study. Patients with a Ki-67 proliferation index above 14.5% require closer follow-up due to the increased risk of PC recurrence. The patients with suspected PC should be timely referred to specialized centers with extensive experience in managing this pathology and thereby improve the patient's prognosis.

Salivary steroid and 11-oxygenated androgen profiles in patients with congenital adrenal hyperplasia on various glucocorticoid replacement regimens

Matthias Auer[1], Hanna Nowotny[1], Marcus Quinkler[2], Martin Bidlingmaier[1], James M Hawley[3], Jo Adaway[3], Brian Keevil[3], Richard Ross[4], John Porter[5] & Nicole Reisch[1]
[1]Medizinische Klinik and Poliklinik IV, Endocrinology, Munich, Germany; [2]Endocrinology in Charlottenburg, Berlin, Germany; [3]Manchester University Foundation NHS Trust, Department of Clinical Biochemistry, Manchester, UK; [4]University of Sheffield, Department of Oncology and Metabolism, Sheffield, UK; [5]Diurnal Ltd., Cardiff, UK

Context
11-oxygenated C19 steroids have recently gained attention as markers of androgen control in congenital adrenal hyperplasia (CAH) due to 21hydroxylase deficiency (21OHD). However, they have not yet been systematically investigated in the context of different glucocorticoid (GC) replacement regimens and in particular not in patients receiving new modified-release formulations.
Methods
Cross-sectional single center study including 26 men and 48 women with CAH and 14 male and 9 female controls. Saliva samples were collected at four times during the day starting with a morning sample after awakening. 24 patients were receiving conventional hydrocortisone three times a day, 15 patients Plenadren once in the morning, 19 patients twice-daily prednisolone and 16 patients twice-daily Chronocort. Salivary concentrations of 17hydroxyprogesterone (17OHP), androstenedione (A4), testosterone (T), 11βhydroxyandrostenedione (11OHA4) and 11ketotestosterone (11KT) were analyzed by LC–MS/MS. Sex-specific linear mixed-effects models corrected for hydrocortisone (HC) equivalence dosage and age were calculated to compare steroid profiles between groups.
Results
Once daily plenadren resulted in poor androgen control in both sexes in comparison to other GC replacement regimens as it was not able to suppress nightly rise of adrenal androgens. All investigated steroids in the Plenadren group were higher in the morning than in any other group. Mean overall salivary T levels in women on Plenadren (102.0 ng/ml; 95% CI 82.0–126.9) were actually as high as in control men (111.1 ng/ml; 95% CI 81.9–150.5) whereas on Chronocort they were comparable to controls and on prednisolone even lower. 11-oxygenated C19 steroids were only elevated on plenadren, where 11KT levels were greatly increased in both sexes. Females on chronocort and HC had lower 11KT levels compared to controls and 11KT was similar to controls on prednisolone. There was a strong natural diurnal rhythm in 11OHA4 and 11KT in healthy controls that was independent of 17OHP. Diurnal variance for 11-oxygenated C19 steroids was lowest in patients receiving chronocort. In accordance with the half-life of prednisolone and HC, most steroids showed a small peak around lunchtime in these groups, an effect that was limited to men.
Conclusions
Once daily Plenadren cannot mimic physiological cortisol secretion in CAH and therefore fails in suppressing the nocturnal androgen surge. Chronocort in contrast controls the overnight rise in 17OHP and the subsequent pathological generation of 11OHA4 and 11KT seen in CAH.

Tildacerfont for the treatment of patients with classic congenital adrenal hyperplasia: results from a 12-week phase 2 clinical trial in adults with classic CAH

Richard Auchus[1], Deborah Merke[2], Ivy-Joan Madu[3], Samer Nakhle[4], Kyriakie Sarafoglou[5], Michael Huang[6], David Moriarty[7], Chris Barnes[7] & Ron Newfield[8]
[1]University of Michigan, USA; [2]Eunice Kennedy Shriver National Institute of Child Health and Human Development, USA; [3]Diabetes Associates Medical Group, USA; [4]Palm Medical Group, USA; [5]University of Minnesota Medical School, USA; [6]Former employee of Spruce Biosciences, Inc., USA; [7]Spruce Biosciences, Inc., USA; [8]University of California San Diego, USA

Background
Congenital adrenal hyperplasia (CAH) due to 21-hydroxylase deficiency (21-OHD) is an autosomal recessive disorder characterized by insufficient cortisol production resulting in excess adrenocorticotropic hormone (ACTH) and adrenal androgen production. Standard-of-care therapy with glucocorticoids (GC) is suboptimal due to the difficulty of balancing control of the ACTH-driven androgen excess against the serious long-term side effects associated with chronic supraphysiologic GC exposure. Tildacerfont, a second-generation corticotropin-releasing factor type-1 (CRF_1) receptor antagonist, lowers excess ACTH, and thus has the potential to reduce adrenal androgen production and to allow for GC dosing closer to physiologic doses. A prior study demonstrated that tildacerfont was effective in reducing ACTH, 17-hydroxyprogesterone (17-OHP) and androstenedione (A4) after 2 weeks of therapy. Here we report results from an open-label 12-week extension study.
Methods
Subjects met either of the following criteria: 1) completion of prior study or 2) treatment naïve to tildacerfont with 17-OHP >800 ng/dl while on a stable GC regimen (excluding dexamethasone). Subjects were treated with oral tildacerfont at 400 mg once daily for 12 weeks. Efficacy and safety parameters were assessed at baseline through Week 12.
Results
Subject characteristics (n = 8) are as follows: median (range) age was 44.5 years (26–67 years; 5 females), median (range) body mass index 30.8 kg/m^2 (22–41 kg/m^2). In month 3, in the participants with poor control of disease at baseline (elevations in all key biomarkers: ACTH, 17-OHP, and A4) (n = 5), maximum mean percentage reductions for ACTH, 17-OHP and A4 were 84%, 82%, and 79%, respectively. In this subgroup, 60% of subjects achieved ACTH normalization and 40% achieved A4 normalization during treatment. Tildacerfont treatment maintained, and did not suppress, biomarkers in participants with good control of disease at baseline (A4 below upper limit of normal) (n = 3). Overall, tildacerfont was well tolerated with no serious adverse events.
Conclusions
This is the first study of 12 weeks' duration for a novel, non-steroidal mechanism-of-action agent for the treatment of 21-OHD. Results of this study show that tildacerfont was generally well-tolerated and effective in achieving meaningful reductions in ACTH and A4 in poorly controlled patients over 12 weeks. In addition, this is the first, non-steroidal therapeutic to show evidence of ACTH and A4 normalization over 12 weeks of therapy. Longer term future studies will evaluate whether treatment with tildacerfont can achieve further clinical benefits and allow reduction of GC doses while controlling relevant disease biomarkers.

Rationale for a reduced dexamethasone dosis in prenatal CAH therapy based on pharmacokinetic modelling

Nicole Reisch[1], Viktoria Stachanow[2], Uta Neumann[3], Oliver Blankenstein[3], Uwe Fuhr[4], Wilhelm Huisinga[5], Robin Michelet[2] & Charlotte Kloft[2]
[1]Medizinische Klinik IV, Klinikum der Universität München, Munich, Germany; [2]Department of Clinical Pharmacy and Biochemistry, Institute of Pharmacy, Freie Universitaet Berlin, Berlin, Germany; [3]Charité-Universitätsmedizin, Berlin, Germany; [4]Department of Pharmacology, Clinical Pharmacology, Hospital of the University of Cologne, Cologne, Germany; [5]Institute of Mathematics, Universität Potsdam, Potsdam, Germany

Context
Prenatal dexamethasone (Dex) therapy is used in female foetuses with congenital adrenal hyperplasia (CAH) to suppress adrenal androgen excess and prevent virilisation of the external genitalia. The prenatal dexamethasone dose of 20 µg/kg per day has been used for decades in prenatal CAH and is associated with risks for the treated mother and potentially for the unborn child. Despite the high medical need, no prospective, clinical studies had been conducted in order to determine a Dex dose with a scientific rationale.
Objective
We aimed to investigate a rationale of a reduced Dex dose in prenatal CAH therapy based on a pharmacokinetics-based modelling and simulation framework.
Design and methods
Population modelling was applied on a published dexamethasone study to develop a maternal dexamethasone pharmacokinetic model. By simulations, a typical pregnant population was separated into to receive either the 20 µg/kg per day Dex dose or reduced doses. Target maternal dexamethasone concentrations, identified from literature, served as threshold to be exceeded by 90% of patients at steady state to ensure foetal hypothalamic-pituitary-adrenal axis suppression.

Results
A two-compartment dexamethasone pharmacokinetic model was successfully developed. The simulations resulted in 7.5 µg/kg per day to be the minimum effective dose and thus our recommended optimised dose.
Conclusions
Based on our modelling and simulation results, the current experimentally used Dex dose seems 3-fold higher than needed, possibly causing harm in treated foetuses and mothers. The clinical relevance and appropriateness of this reduced dose should be tested in a prospective international clinical trial.

PEP1.4

Adrenocortical oncocytoma in a patient with classic congenital adrenal hyperplasia

Maria Cristina Baleanu[1], Găloiu Simona Andreea[1,2], Lavinia Popa[1], Iuliana Gherlan[1,2], Anda Dumitrascu[1] & Catalina Poiana[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Pituitary and Neuroendocrine Disorders, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucureşti, Romania

Introduction
Oncocytic neoplasms arising in adrenal tissue are extremely rare with nearly 150 cases being reported in literature. They are mostly nonfunctioning benign tumors, incidentally discovered, but 20% of them demonstrate elements of malignancy and up to 30% appear to affect hormone production.
Case report
A 35 years old female with primary amenorrhea, diagnosed with Congenital Adrenal Hyperplasia due to 21-hydroxylase deficiency at age of 2, who underwent feminizing genitoplasty 5 years after diagnosis, presented in our clinic complaining of abdominal pain, nausea, vomiting and hypotension. She was on treatment with 1 mg Dexamethasone daily with poor medication adherence. Clinical findings included: altered general condition, dry skin and mucosae, hirsutism, BP = 70/50 mmHg with orthostatic hypotension, HR = 100 bpm, intense spontaneous and on palpation pain located in the left iliac fossa and moderate abdominal dystension. Lab tests revealed an important inflammatory syndrome, normocytic normochromic anemia, hypoglycemia (65 mg/dl), high-normal potassium level (5 mmol/l), hyponatremia (131 mmol/l), hypocalcemia (8.3 mg/dl). She started IV hydrocortisone and oral fludrocortisone. Hormonal workup showed high 17-OH progesterone (> 20 ng/ml), low 0800 h cortisol (1.58 µg/dl), high ACTH (1362 pg/ml), high renin (170 pg/ml), normal aldosterone (243 pg/ml). Abdominal and pelvic MRI revealed on the superior pole of left adrenal gland a 55/60 mm tumoral mass with polycyclic contour and at the level of the left anexa another tumoral mass with cystic components, thick walls, with maximum diameters of 47/75 mm. After the acute episode remission, the patient was transferred to surgery unit where was performed left adrenalectomy with left anexectomy. Hystopatological exam established the diagnosis of adrenocortical oncocytic neoplasm with uncertain malignant potential and immunochemestry was positive in tumoral cells for inhibin A, Melan A, Calretinin, Synapto and negative for Chromogranin A, Ki67~ 2%.
Conclusion
Oncocytic adrenocortical neoplasm is a rare tumor of the adrenal gland which origin, biological behavior, diagnostic criteria and prognosis are controversial. To our knowledge, only one case of adrenocortical oncocytoma in a patient with congenital adrenal hyperplasia was previously reported in the literature. More data are needed for better management of these patients.

Modified-release hydrocortisone improves androgen excess and facilitates glucocorticoid dose reduction in patients with classic congenital adrenal hyperplasia: non-invasive monitoring in saliva and urine

Alessandro Prete[1,2,3], Elizabeth S. Baranowski[1,2,4], Lina Schiffer[1], Joanne E. Adaway[5], James M. Hawley[5], Brian G. Keevil[5], John Porter[6], Richard J. Ross[6,7] & Wiebke Arlt[1,2,8]
[1]Institute of Metabolism and Systems Research, University of Birmingham, Birmingham, UK; [2]Centre for Endocrinology, Diabetes and Metabolism, Birmingham Health Partners, Birmingham, UK; [3]Department of Endocrinology, Queen Elizabeth Hospital, University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK; [4]Department of Paediatric Endocrinology and Diabetes, Birmingham Women's and Children's Hospital NHS Foundation Trust, Birmingham, UK; [5]Department of Clinical Biochemistry, Wythenshawe Hospital, Manchester University NHS Foundation Trust, Manchester, UK; [6]Diurnal Ltd., Cardiff, UK; [7]University of Sheffield, Sheffield, UK; [8]NIHR Birmingham Biomedical Research Centre, University of Birmingham and University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK

Background
Standard glucocorticoid (GC) therapy in classic congenital adrenal hyperplasia due to 21-hydroxylase deficiency (21-OHD-CAH) is often inadequate in controlling adrenal androgen excess, leading to GC over-exposure and poor health outcomes. A novel modified-release formulation of hydrocortisone (MR-HC, Chronocort® Diurnal Ltd. UK) has been shown to improve circulating adrenal androgen excess in 21-OHD-CAH. We investigated whether saliva and 24-h urine could be used as non-invasive tools to monitor disease control by MR-HC.
Methods
This is a sub-study of the EudraCT 2015-000711-40 and 2015-005448-32 clinical trials. Patients with 21-OHD-CAH were randomised to either MR-HC or their standard GC treatment; at 6 months all were offered MR-HC. Throughout the study, GC replacement was titrated according to serum 17OHP and A4. 24-h urine and saliva day profiles were collected at baseline (standard GC), 6 months (standard GC vs. MR-HC), and 12 months (all on MR-HC). Saliva was collected by passive drool every 2 h between 0700 h and 2300 h. Samples were analysed by LC-MS/MS (saliva) and GC-MS (24-h urine) to measure the 21-OHD-CAH marker 17-hydroxyprogesterone (17OHP in saliva; 17HP, PT, and PTONE in urine), steroids of the classic androgen pathway (A4 in saliva; An and Et in urine), the 11-oxygenated androgen pathway (11OHA4 and 11KT in saliva; 11βOHAn in urine), and the alternative pathway to dihydrotestosterone (3α5α17HP in urine).
Results
12 patients (9 women; median age 42 years, range 21–68) were randomised to MR-HC (n = 4) or standard GC (n = 8). After six months, MR-HC led to a 97% decrease in salivary 17OHP (area under the curve, AUC, P 0.006), A4 (AUC -99%, P 0.029), 11OHA4 (AUC -97%, P 0.001), 11KT (AUC -100%, P 0.004), and urinary 3α5α17HP (97% median reduction, P 0.05) as compared to standard GC. A significant decrease in the 11KT/T ratio also indicated improved control of adrenal androgen excess. Urinary excretion of 17OHP and androgen metabolites also decreased on MR-HC, albeit non-significantly. This improvement in biochemical control was achieved on a lower daily GC dose of MR-HC compared to standard treatment at 6 months (MR-HC 23 mg (15–35 mg); standard GC 32 mg (25–38 mg)). At 12 months, MR-HC maintained excellent biochemical control, despite a further reduction of the median GC dose to 18 mg (10–40 mg).
Conclusions
MR-HC treatment facilitated a significant reduction of GC dose, with non-invasive steroid monitoring comprehensively reflecting biochemical disease control.

ARMC5 modifies cell redox state to regulate steroidogenesis and lipid metabolism in the adrenal cortex

Isadora Pontes Cavalcante[1], Marthe Rizk-Rabin[1], Karine Perlemoine[1], Christopher Ribes[1], Jerome Bertherat[1,2] & Bruno Ragazzon[1]
[1]Cochin Institute, EMD Department, France; [2]APHP, Cochin Hospital, Department of Endocrinology, Paris, France

Background
ARMC5 is a putative tumor suppressor gene that is frequently mutated in primary bilateral macronodular adrenal hyperplasia (PBMAH), a rare cause of Cushing's syndrome. The function of ARMC5 is poorly known, aside the fact that it regulates cell apoptosis and adrenal steroidogenesis in by mechanisms still unknown. Tumor suppressor genes play an important role in oxidative stress.
Methods
In this study we used as model the adrenocortical carcinoma cell line H295R. In order to investigate ARMC5 response to stress, cells were treated with Menadione and reactive oxygen species (ROS) production was measured by Cellrox assays with flow cytometry. Oxidative response genes and steroidogenic enzymes expression were investigated by qPCR, whereas p38 phosphorylation was investigated by western blotting.
Results
ARMC5 protein is differentially regulated in response to menadione-induced stress in H295R adrenocortical cells. Moreover, ARMC5 depletion

increases total intracellular ROS production (P <0.05) and causes an imbalanced transcription of pro and anti-oxidant genes leading to increased phosphorylation of p38 (P <0.05). ROS production and p38 pathway activation alter steroidogenesis. These effects are partially reversed by the anti-oxidant compound N-acetylcysteine (NAC) or the p38 inhibitor (SB203580). Finally, ARMC5 depletion leads to lipid droplets accumulation in the cell cytoplasm, associated to increased expression of APOE gene, important for cholesterol esterification.

Conclusion

Altogether, this study describes a new function of ARMC5 as regulator of the redox homeostasis and lipid metabolism in adrenocortical cells.

Adverse events of mitotane treatment in patients with adrenocortical carcinoma

Barbara Altieri[1], Mario Detomas[1], Otilia Kimpel[1], Marcus Quinkler[2], Letizia Canu[3], Massimo Mannelli[3], Anna Angelousi[4], Gregory Kaltsas[4], Yasir Elhassan[5], Silvia Della Casa[6], Maria Cristina De Martino[7], Felix Megerle[1], Cristina Ronchi[1,5], Kroiss Matthias[1,8] & Martin Fassnacht[1]
[1]University Hospital of Würzburg, Department of Internal Medicine I, Division of Endocrinology, Germany; [2]Endocrinology in Charlottenburg, Berlin, Germany; [3]University of Florence, Department of Experimental and Clinical Biomedical Sciences "Mario Serio", Florence, Italy; [4]National and Kapodistrian University of Athens, Department of Pathophysiology, Athens, Greece; [5]Institute of Metabolism and System Research, University of Birmingham and Centre for Endocrinology, Diabetes and Metabolism (CEDAM), Birmingham, UK; [6]Catholic University of the Sacred Heart, Division of Endocrinology and Metabolism, Rome, Italy; [7]Federico II University, Department of Clinical Medicine and Surgery, Naples, Italy; [8]Ludwig-Maximilians-Universität München, Medizinische Klinik und Poliklinik IV, Munich, Germany

Background

Mitotane represents the first-line medical treatment in most patients with adrenocortical carcinoma (ACC). Although adverse effects (AEs) due to mitotane are known to be frequent and may limit treatment, few systematic data are available. Aim of the study was to evaluate the AEs in ACC patients treated with mitotane monotherapy.

Methods

A retrospective multicenter study including 311 ACC patients (M:F = 111:200, median age 49 years) treated with mitotane as adjuvant therapy (n = 214, 68.8%) or in advanced disease (n = 97, 31.2%), was performed. Presence and grade of AEs were collected from medical records, retrospectively classified according to the CTCAE 5.0 criteria and correlated with duration of treatment, dosage administered and plasma concentrations of mitotane.

Results

Median duration of mitotane monotherapy was 20 (1–203) months, during which we observed a total of 3004 AEs with a rate *per* patients of 9.6 (0–30). The number of AEs significantly correlated with AUC of mitotane levels (P = *0.0001*, r_s = 0.23) and duration of treatment (P = *0.0002*, r_s = 0.21). Beside glucocorticoid insufficiency, the most frequent AEs were increase of gamma-glutamyl transferase (GGT, 88%), asthenia (68%), nausea (53%), hypercholesterolemia (54%), diarrhea (45%), increased transaminases, anorexia, and vertigo (36%, respectively). Apart from glucocorticoids, specific hormone replace therapy was administrated in 121/172 (70%) patients with hypothyroidism, 44/90 (49%) patients with hypomineralcortisolism, and 20/47 (42.5%) men with hypogonadism secondary to mitotane treatment. Statins and fenofibrate were used in 83/219 (37.9%) and 8/127 (6.3%) of patients with hypercholesterolemia and hypertrygliceridemia. Patients with short-term treatment (≤3 months) had a significantly lower probability to present asthenia (OR = 0.5, P = *0.01*), concentration impairment (OR = 0.2, P *<0.001*), ataxia (OR = 0.1, P = *0.007*), increased GGT (OR = 0.4, P = *0.004*) and SHBG (OR = 0.2, P *<0.001*), hypertriglyceridemia (OR = 0.3, P = *0.003*), hypothyroidism (OR = 0.4, P = *0.007*), hypomineralcortisolism (OR = 0.1, P = *0.01*) and gynecomastia (OR = 0.1, P = *0.008*) compared to those who received longer treatment (>3 months). Patients with advanced disease were treated for shorter time compared to those adjuvantly treated (median 9 vs 23 months, respectively, P *<0.0001*) and had a lower risk of aphasia (OR = 0.2, P = *0.04*) and dysarthria (OR = 0.5, P = *0.03*). Grade 4 AEs were reported in 24 cases (7.7%), including one case of peripheral neuropathy, leukopenia, and sepsis, 3 cases of severe adrenal crisis, and 4, 5, and 9 cases of hypertrygliceridemia, hypercholesterolemia and GTT increase, respectively. Mitotane was permanently discontinued due to AEs in 45 (14.5%) patients.

Conclusion

This is the first comprehensive overview of AEs by mitotane, which will be helpful in the daily clinical practice to prevent and manage toxicity, improving the patient's quality of life.

DOI: 10.1530/endoabs.73.PEP1.7

PEP1.8

Adrenal insufficiency with chronic hyponatraemia and normal basal cortisol level: time to review the investigation of hyponatraemia

Kalyan Mansukhbhai Shekhda, Maria Darda, Syed Bitat, Ali Rathore, Taofeek Ojewuyi & James Ahlquist
Southend University Hospital NHS Foundation Trust, Southend-on-Sea, UK

Adrenal insufficiency is serious, life-threatening condition. Classical features include nausea, malaise, weight loss and hypotension. It is usually diagnosed at a late stage only when it presents as adrenal crisis. We report a patient with autoimmune adrenal insufficiency who presented with chronic hyponatremia and a repeatedly normal serum cortisol level. A 66-year-old female was referred to endocrinology with a 12-month history of hyponatraemia (Na 125–131 mmol/l). She was feeling tired and sometimes dizzy. There was no weight loss. She was not taking any steroid or opioid therapy. On examination, she was euvolemic with no postural hypotension. Other systemic examination was normal. Investigations showed Na 125 mmol/l, K 4.3 mmol/l, with normal renal function, serum osmolality: 265 mmol/kg, urinary osmolality 375 mmol/kg, urinary sodium: 50 mmol/l, TSH: 1.51 mU/l, 0900 h cortisol 378 nmol/l (RR: 185–624 nmol/l). CT head and CT chest, abdomen and pelvis were normal. She was diagnosed with Idiopathic SIADH; she was treated with fluid restriction and briefly with demeclocycline. She travelled to Australia on holiday, where she was admitted for a saline infusion. A year later she re-presented with hyponatraemia. Further investigation showed Na 122 mmol/l, 0900 h cortisol 312 nmol/l, with no significant response in a short Synacthen test (basal cortisol 237 nmol/l, 30 min 245 nmol/l and 60 min 242 nmol/l), with ACTH 612 ng/l (RR: <50 ng/l), indicating adrenal insufficiency. Adrenal antibodies were detected. Addison's disease was diagnosed. She was treated with hydrocortisone and fludrocortisone. She felt much better after starting treatment; the sodium level rose to 142 mmol/l after treatment. This patient demonstrates that adrenal insufficiency may occur as a chronic condition, with hyponatremia and malaise but without weight loss or hypotension, and with no progression or crisis. ACTH responsiveness was significantly impaired without any change in the basal cortisol level. Clinicians should not rely on a normal basal cortisol level for excluding adrenal insufficiency in hyponatraemia, but should also consider the ACTH level or a short Synacthen test. It is not clear why autoimmune disease should damage ACTH-responsiveness before it affects basal cortisol secretion; a similar finding has been made in the context of adrenal metastasis.

Diabetes, Obesity, Metabolism and Nutrition

PEP2.1

MODY 5: a rare cause of diabetes and chronic kidney disease – a report of 10 cases

Sara Amaral, Ana Cláudia Martins, Ana Palha, Paula Bogalho, Ana Agapito & Jose Silva-Nunes
Centro Hospitalar Universitário Lisboa Central, Endocrinology, Diabetes and Metabolism Department, Lisbon, Portugal

Introduction

Maturity Onset Diabetes of the Young (MODY) affects 1–2% of diabetic patients. Subtype 5 (*HNF1*β mutation) is rare (~1% of all MODY subtypes) and extra-pancreatic manifestations are often present (chronic kidney disease (CKD), liver disease and/or genitourinary malformations).

Aim

To report and review confirmed MODY 5 cases in an Endocrinology Department.

Methods

Retrospective study of patients with *HNF1*β mutation followed between 2013 and 2020.

Results

We found 10 patients (6 female) with HNF1β mutation (7 index cases). The median age at MODY 5 diagnosis was 40.5 (IQR 35–58) years old.

Six patients were first classified as having type 1 diabetes and 4 as type 2. Diabetes was the first manifestation of MODY 5 in 50% of cases. The median age of diabetes diagnosis was 28 (IQR 16–40) years old. The average time between diabetes and MODY 5 diagnosis was 16.5 years old. Insulin therapy was prescribed in 8 patients (started at diabetes diagnosis in 75% of cases). The average diabetes evolution time was 19.4 years old. In 50% of the cases CKD in pediatric age was the first manifestation of MODY 5. These patients not only had progressive renal failure but also renal malformations: unilateral kidney hypoplasia (n = 1), bilateral kidney hypoplasia (n = 1) and solitary kidney (n = 1). Two patients were submitted to kidney, one to combined kidney and pancreas, and one to combined kidney and liver transplantations. All patients have functioning kidney graft. CKD was present in 7 patients. Additional long-term complications of diabetes include retinopathy (n = 3), peripheral neuropathy (n = 1) and ischemic cardiomyopathy (n = 1). Regarding other extra-pancreatic manifestations: cholestatic liver disease (n = 4) and genital malformation (bicornuate uterus) (n = 1). History of a first-degree relative with diabetes and/or nephropathy diagnosed at a young age was present in 71.4% (n = 5) of the index-cases.
Conclusions
Despite being a rare disease, MODY 5 is underdiagnosed and often classified as another type of diabetes. It should be considered in patients with diabetes and CKD especially at a young age, if family history is suggestive and nephropathy appears before/shortly after the diagnosis of diabetes. Presence of liver disease increases the degree of suspicion. Early diagnosis allows the risk of complications to be minimized and to carry out pre-conception genetic counseling.

PEP2.2

Type 2 diabetes clusters indicate diabetes duration key in fracture risk

Sam Ghatan, Fariba Ahmadizar, Ruolin Li, Carolina Medina, Carola Zillikens, Fernando Rivadeneira, Maryam Kavousi & Ling Oei
Erasmus MC, Rotterdam, Netherlands

Introduction
Individuals with type 2 diabetes mellitus (T2DM) are at an increased risk of developing fractures, despite higher mean BMI and BMD. Recently, clinically relevant sub-groups of T2DM have been characterised using biomarkers of glycemic metabolism.
Aim
Characterise T2DM sub-groups in a population-based setting and test for differences in fracture risk.
Methods
A total of 10019 Rotterdam Study participants were available with glycemic and (incident) fracture follow-up. Participants with T2DM (n = 1678) were partitioned in subgroups using K-means clustering based on: HOMA-B, HOMA-IR, age of diabetes onset, BMI and waist circumference measurements. Non-vertebral fracture risk was estimated across T2D subgroups using Cox proportional hazard models, adjusted for sex, age, BMI, collection cohort and prevalent T2DM.
Results
Four T2D clusters were defined each with relatively unique clinical characteristics namely, 1) advanced age of onset; 2) decreased insulin sensitivity; 3) beta-cell disfunction; 4) Obesity/high BMI. Individuals with prevalent and incident T2DM (independent of cluster) had lower risk of fracture than non-diabetics (see Forest plot). In contrast, individuals with prevalent T2DM (n = 1152) had increased risk of non-vertebral fracture (HR: 2.1, 95%CI: 1.65–2.76), than individuals without T2DM.
Conclusion
Despite that partitioning the heterogeneity of T2DM in clinically meaningful clusters opens the road to tailored prevention and care, our findings with prevalent T2DM indicate that disease duration (likely with inadequate glycemic control) is the main determinant of fracture risk. In line with this contention, the association between T2DM and fracture risk is not causal, as causality requires association with incident cases, as also confirmed by earlier Mendelian randomization studies. Future work, using genetically determined disease definitions and biomarkers will help unveil clusters of individuals with T2DM at increased risk of fracture.

PEP2.3

The rs10830963 polymorphism of the MTNR1B gene is associated with glucose metabolism in the Czech population

Daniela Vejrazkova[1], Marketa Vankova[1], Josef Vcelak[1], Veronika Cirmanová[1], Hana Krejčí[2], Kateřina Anderlová[2] & Bela Bendlova[1]
[1]Institute of Endocrinology, OME, Prague, Czech Republic; [2]1st Faculty of Medicine, Charles University and General University Hospital in Prague, Department of Obstetrics and Gynecology, Prague, Czech Republic

Introduction
The *MTNR1B* gene encodes a receptor for melatonin, a hormone that controls biorhythms. The gene is expressed primarily in the brain, but also in human pancreatic cells. Genetic studies suggest that variability in the *MTNR1B* gene is one of the factors sought to influence the pathophysiology of type 2 diabetes mellitus (T2DM). The single nucleotide polymorphism rs10830963 shows the strongest association. Our aim was to compare the distribution of the genetic variant rs10830963 among persons with different glucose tolerance. Subjects with impaired fasting blood glucose (IFG) and impaired glucose tolerance (IGT) during the oral glucose tolerance test (OGTT) were compared with controls. Another goal was to evaluate the possible associations of the polymorphism with insulin sensitivity (IS). Indices of IS, beta cell function and hepatic extraction were calculated and shape of glucose, insulin and C-peptide trajectories during the OGTT (monophasic, biphasic or more complex) were analysed.
Methods
A total of 1206 volunteers were examined biochemically, anthropometrically and underwent a 3 h OGTT (75 g glucose). Genotyping was performed on a TaqMan (LC480, Roche), the NCSS 2004 program was used for statistical evaluation.
Results
13 persons were diagnosed with T2DM, 119 had IFG or IGT and 1074 showed normal results. Higher frequency of minor and in relation to T2DM risk allele G was found in the IFG/IGT group (40.7% vs. 32.4% in controls, P = 0.01), OR = 1.57, CI 95% [1.06; 2.33], P = 0.03). The GG constellation was present in 23% of diabetics, in 17% of the IFG/IGT probands and in 11% of controls (Chi^2 = 11.2, P = 0.02). GG homozygotes showed slightly higher basal glycemia compared to CC homozygotes (P = 0.01) and also higher stimulated glycemia (AUCgly) in comparison with CC homozygotes (P = 0.002) and with heterozygotes (P = 0.004). GG genotype showed lower OGIS index of IS and lower HOMA-B and IGI indices of beta cell function. No association of the genotype with hepatic extraction or with the shape of glucose, insulin and C-peptide trajectories was observed.
Conclusion
In the sample of the Czech population we confirm the association of the G allele of the rs10830963 polymorphism in the *MTNR1B* gene with glucose metabolism. The risk allele G is more frequent in people with impaired glycoregulation and homozygous carriers of this allele show higher blood glucose levels during the OGTT and lower indices of IS and beta cell function.

Long-term clinical benefits with early combination therapy in patients with newly diagnosed type 2 diabetes from Europe: insights from the VERIFY study

Francesc Xavier Cos[1,2], Emanuele Bosi[3], Piermarco Piatti[4] & Päivi M Paldánius[5,6]
[1]Innovation officer, Institut Català de la Salut, Barcelona, Spain, Spain; [2]Associate professor Universitat Autonoma de Barcelona. Barcelona, Spain, Spain; [3]Diabetes & Endocrinology Unit, Diabetes Research Institute, San Raffaele Hospital and San Raffaele Vita-Salute University, Milan, Italy, Italy; [4]Cardio-Metabolism and Clinical Trials Unit, IRCCS San Raffaele Hospital, Milan, Italy, Italy; [5]Children's Hospital, Helsinki University and Helsinki University Hospital, Helsinki, Finland, Finland; [6]Research Program for Clinical and Molecular Metabolism, University of Helsinki, Helsinki, Finland, Finland

Objective
VERIFY demonstrated the long-term benefits of an early combination (EC) treatment strategy compared with initial metformin monotherapy (MET) followed by sequential intensification in a multiethnic population with

newly diagnosed type 2 diabetes mellitus (T2DM). The results for European patients enrolled in VERIFY are presented.
Methods
Adult patients with T2DM (≤2 years) and mild hyperglycaemia (glycated haemoglobin [HbA1c] 6.5–7.5%) were randomised 1:1 to either EC (vildagliptin plus metformin) or MET. The primary endpoint was time to initial treatment failure (TF), defined as HbA1c ≥7% at two consecutive scheduled visits after randomisation. If initial treatment did not maintain HbA1c <7%, patients on MET received vildagliptin. Time to second TF was when patients in both groups were receiving and failing on combination.
Results
Eligible patients from Europe (N = 1048) were assigned to EC (n = 523) or MET (n = 525). The 5-year incidence of initial TF was 45.3% with EC and 61.2% with MET. The median time to TF with MET was 36.6 (interquartile range 18.0–not reached [NE]) months; while for EC it was, 61.9 (29.9–NE) months. Risk of initial and secondary TF was reduced with EC when compared to MET (hazard ratio [HR] 0.59 [95% confidence interval {CI}: 0.50–0.70]; P <0.0001 and HR 0.84 [95% CI: 0.68–1.03]; P = 0.0898, respectively). A greater proportion of patients in the EC group had consistently lower HbA1c levels compared with MET group. Time to initial TF with EC was also lower for predefined subgroups of HbA1c, BMI, age, gender, smoking status, and estimated glomerular filtration rate. Overall safety and tolerability profile was similar between treatment groups; incidence of hypoglycaemic events was 0.3% with EC and 0.2% with MET.
Conclusion
Consistent with the global population, EC therapy provided greater and durable long-term benefits compared with the standard-of-care metformin monotherapy in patients with newly diagnosed T2DM from Europe.

Factors predicting insulin requirement in gestational diabetes mellitus

Salma Abadlia, Sebai Imen, El Amri Abir, Abdessalem Haifa, Raddadi Sarra, Bendag Nedra, Ounaissa Kamilia & Amrouche Chiraz
National Institute of Nutrition, Outpatient Department, Tunisia

Aim of the study
To identify the factors predicting insulin need in women with Gestational Diabetes Mellitus (GDM).
Methods
It was a retrospective study conducted in the National Institute of Nutrition between January 2018 and January 2019. Pregnant women referred for the management of GDM were included (n = 1000).GDM was defined according to the World Health Organisation as a glucose intolerance of variable severity with onset or first recognition during pregnancy. ANOVA and Pearson's chi-square tests were performed to compare clinical and biological characteristics of women with insulin therapy (IT) and those with nutrition therapy (NT).
Results
IT was initiated for 291 patients while the rest were maintained on NT (70.90%). Older women were significantly more likely to need IT (33.1±5.3 vs 32.6±5.1 years; P = 0.028).We found a significant association between educational attainment and the need for IT (P = 0.004). Family history of type 2 diabetes as well as personal history of GDM or foetal macrosomia increases the need for IT (P = 0.001, P = 0.002 and P = 0.025 respectively). Women with IT had more risk factors of GDM (P <0.001). All women having five risk factors had required IT.NT's failure was higher in obese women (36.60% vs 25.30%; P = 0.011). For women with IT, GDM was diagnosed at an earlier term (23.33 ± 6.8 vs 24.52 ± 7.1 weeks of gestation; P = 0.017). Fasting plasma glucose was higher in women with IT (5.25±1.07 mmol/l vs 4.67±0.60 mmol/l; P <0.001) as was Glycated hemoglobin (5.48±0.52% vs 5.23±0.38%; P <0.001).
Conclusion
Factors predicting insulin need may allow physicians to establish a concise scoring method for early identification of those women.

PEP2.6

The relationship between calibration accuracy and glycemic variability on CGM

Soichi Takeishi & Tatsuo Inoue
Inuyama Chuo General Hospital, Diabetes, Inuyama-City, Japan

The mean absolute relative difference (MARD) on CGM was reported with the various values approximately from 5% to 10%. The MARD in patients with type 1 diabetes was reported to be higher than that in patients with type 2 diabetes. Therefore, as one of the reasons why the reported MARD values varied, it cannot be denied that glycemic variability affects calibration accuracy. We examined relationships between calibration accuracy and glycemic variability on CGM. This is a prospective study where personal-CGM (GUARDIAN CONNECT) and professional-CGM (iPro2) were worn in parallel for 6 days (CGM attachment: day 1) and "blood glucose levels used to calibrate" (BGc) were obtained using "glucometers that were compliant with ISO15197:2013" (ISO) or "those not compliant with ISO15197:2013" (not-ISO) using a randomized crossover design. 25 type 2 diabetic inpatients were almost equally allocated to 2 groups (n = 13 and n = 12). ISO provided 11 BGc during days 2–3 and non-ISO provided those during days 4–5 in group 1 and vice versa in group 2. Every pre- and post-prandial and bedtime (7 times) BGc were obtained on days 2 and 5, and every pre-prandial and bedtime (4 times) BGc were obtained on days 3 and 4. Over days 2–3 and days 4–5, correlations between mean of 11 MARDs (Mean-MARD) and mean of two 24-h coefficient of variation [CV] (Mean-CV) were analyzed, on personal-CGM and professional-CGM. For ISO measurement, Mean-MARD correlated to Mean-CV on professional-CGM (r = 0.47 P = 0.02); however, Mean-MARD did not correlate to Mean-CV on personal-CGM. For not-ISO measurement, Mean-MARD did not correlate to Mean-CV on personal-CGM and professional-CGM. The results for ISO measurement show that inter-individual variability of accuracy for real-time calibrations may weaken the relationship between calibration accuracy and glycemic variability. The results for not-ISO measurement show that low calibration accuracy may lead to larger inter-individual variability of accuracy for calibrations, weakening the relationship between calibration accuracy and glycemic variability. In this study, professional-CGM calibrated using ISO may have revealed the relationship between calibration accuracy and glycemic variability. Patients using personal-CGM should consider possibility of having low calibration accuracy caused by high glycemic variability, that may be masked by real-time calibration.

PEP2.7

The possibility of inter-individual variability of accuracy for CGM and FGM sensors

Soichi Takeishi & Tatsuo Inoue
Inuyama Chuo General Hospital, Diabetes, Inuyama-City, Japan

There is little information regarding inter-individual variability of accuracy for CGM and flash glucose monitor (FGM) sensors. We studied the possibility of inter-individual variability of accuracy for CGM and FGM sensors. This is a prospective study. During hospitalization, 10 patients with type 2 diabetes wore a CGM [iPro2] and FGM [FreeStyle Libre Pro] in parallel over 24 h while every pre- and post-prandial "venous blood glucose levels" (VBG) were measured and used to calibrate CGM (n of VBG measurement = 60). We evaluated mean absolute difference (MAD) and mean absolute relative difference (MARD), derived from sensor glucose levels (SG) for CGM, measured every 5 min (MAD "5 min" and MARD "5 min") and extracted every 15 min (MAD "15 min" and MARD "15 min"), and derived from SG for FGM, measured every 15 min (MAD "FGM" and MARD "FGM"). The study participants correlated to the distribution of VBG (correlation ratio: η^2 = 0.38 P = 0.003). The study participants correlated to the distribution of MAD "5 min" and that of MAD "15 min" (η^2 = 0.27 P = 0.04998, η^2 = 0.27 P = 0.047, respectively); however, the study participants did not correlate to the distribution of MARD "5 min" and that of MARD "15 min". However, the study participants correlated to the distribution of MAD "FGM" and that of MARD "FGM" (η^2 = 0.57 P < 0.001, η^2 = 0.52 P < 0.001, respectively). The result of VBG may have been caused by patient-to-patient differences in glycemic control. The results of MAD for CGM may have been caused by the fact that higher VBG may lead to higher MAD. The results of MARD for CGM may have been caused by the fact that VBG are not associated with MARD because MARD is percentage of MAD to VBG. Compared of the result of MARD for FGM to the result of MARD for CGM, the correlation between the study participants and distribution of MARD "FGM" may suggest the inter-individual variability of accuracy for FGM sensors.

PEP2.8

Association of serum uric acid concentration with diabetic retinopathy and its severity

Rahma Khalaf, Zohra Hadj Ali, Yosra Htira & Faika Ben Mami
National Institute of Nutrition, Tunis, Tunisia

Background and aim
Diabetes is the leading cause of adult blindness due to retinopathy. Serum uric acid levels independently predict the development of micro vascular complications. In this study, we analyze the relationship between serum uric acid (SUA) levels with the development and the severity of diabetic retinopathy(DR) in patients with type 2 diabetes mellitus (T2DM).
Patients and Methods
A total of 100 Type 2 diabetes patients were enrolled. The presence of diabetic retinopathy was established by fundus examination. Hyperuricemia was defined as serum uric acid greater than 6 mg/dl (360 µmol/l). The study population was divided into two groups: group 1 (G1) consists of 50 patients with non complicated diabetes; group2 (G2) consists of 50 patients with diabetic retinopathy in absence of any other microvascular complications. The severity of DR was classified as non–proliferative diabetic retinopathy (NPDR), and proliferative DR (PDR).
Results
Out of 50 patients without DR (G1), there were 23 males and 27 females. Out of 50 patients with DR (G2), there were 22 males and 28 females. The mean age of the patients presented with and without DR was 58.88 and 56.88 years respectively. BMI and HbA1c did not statistically differ among the two groups (30.49 kg/m^2 vs 30.6 kg/m^2, 11.3% vs 11.1% respectively). Diabetes duration was longer in G2 compared to G1 (15.5 vs 9.06 years, $P = 0.1$). Hyperuricemia (serum uric acid >360 µmol/l) was more prevalent in group2 (26%) compared to group1 patients (18%). Mean serum uric acid levels were higher among patients with DR (336.36 µmol/l) compared to patients without DR (313.34 µmol/l) which was statistically not significant ($P = 0.2$). However, the concentration of SUA was significantly higher in patients with proliferative DR (373 µmol/l) compared to patients without DR or with NPDR (308 µmol/l), $P = 0.01$.
Conclusion
Patients with DR did not have significant elevation in serum uric acid levels than those without DR. However, an increased SUA levels were significantly correlated with the severity of DR.

Cushing's Disease (CD) is a rare condition characterized by an overproduction of ACTH by an ACTH-secreting pituitary tumor resulting in excess of cortisol release by the adrenal glands. Somatic mutations in the deubiquitinases USP8 and USP48, and in BRAF genes, have been reported in a subset of patients affected by CD. Aim of this study was to characterize the genetic profile of a cohort of 66 patients with ACTH-secreting tumors, searching for somatic mutations in USP8, USP48 and BRAF hotspot regions. 7 patients were found to carry USP8 somatic mutations in the 14-3-3 protein binding motif ($n = 5$ P720R, $n = 1$ P720Q, $n = 1$ S718del); 2 patients were mutated in USP48 (M415I); no mutation was identified in BRAF. In addition, a novel USP8 variant, G664R, located in exon 14, upstream the 14-3-3 protein binding motif, was identified in 1 patient. Functional characterization of G664R USP8variant was performed in murine corticotroph tumor AtT-20 cells. Transient transfection with the G664R USP8 variant resulted in a significant increase of ACTH release (201.1 ± 63.7% vs empty vector transfected cells, $P < 0.05$) and of cell proliferation (141.8±30.5% vs empty vector transfected cells, $P < 0.05$). Notably, USP8 proteolytic cleavage was enhanced in AtT-20 cells transfected with G664R USP8 (1.86 ± 0.58–fold increase of N-terminal USP8 fragment, vs WT-USP8, $P < 0.05$). Surprisingly, *In situ* Proximity Ligation Assay (PLA) experiments showed a significant reduction of PLA positive spots, indicating USP8-14.3.3 proteins colocalization, in USP8 G664R transfected cells with respect to USP8 WT transfected cells (−47.9±6.6%, vs WT-USP8, $P < 0.001$), thus suggesting a possible conformational rearrangement due to amino acid 664 replacement affecting the binding of USP8 with partner proteins. No significant difference in terms of ACTH secretion, cell proliferation and USP8 proteolytic cleavage were observed between G664R USP8 and S718del USP8 transfected cells. Immunofluorescence experiments showed that, contrary to S718del USP8 but similarly to WT-USP8 and other USP8 mutants, G664R USP8 display an exclusive cytoplasmic localization. In conclusion, recurrent somatic mutations were found in USP8 (10.6% vs 36.5% incidence of all published mutations) and in USP48 (3% vs 13.3% incidence) hot spot regions. A novel USP8 variant was identified in a CD patient. *In vitro* functional studies in AtT-20 cells suggested that this somatic variant might be clinically relevant in ACTH-secreting tumor pathogenesis.

Background
Injectable somatostatin receptor ligands (iSRLs) have been a mainstay in acromegaly treatment. Oral octreotide capsules (OOC; MYCAPSSA®) were recently approved in the USA. Results from the placebo-controlled CHIASMA OPTIMAL and open-label CH-ACM-01 studies showed an OOC safety profile consistent with that of iSRLs with no new or unexpected safety signals. Results of the MPOWERED trial have enabled a comparison of OOC safety and efficacy with iSRLs.
Methods
To enter MPOWERED, patients must have the following: acromegaly diagnosis, biochemical control of acromegaly (insulin-like growth factor I <1.3 × upper limit of normal; mean integrated growth hormone <2.5 ng/ml), and ≥6 months' iSRLs treatment (octreotide or lanreotide). Eligible patients entered a 26-week Run-in phase to determine the effective OOC dose; responders at week 24 then entered a 36-week randomized controlled treatment (RCT) phase receiving OOC or iSRLs. Safety was monitored as adverse events (AEs) in both arms throughout the trial, including the RCT.
Results
In the RCT, incidence of treatment-emergent adverse events (TEAEs) was similar between groups; 39 patients (70.9%) in the OOC group and 26 (70.3%) in the iSRL group had ≥1 TEAE. 19 patients (34.5%) in the OOC and 15 (40.5%) in the iSRL group had treatment-related TEAEs. Occurrence was similar for serious AEs (OOC, 5.5%; iSRL, 8.1%) as well as TEAEs classified as severe (OOC, 9.1%; iSRL, 10.8%). One patient in the OOC group discontinued due to a TEAE. The most common gastrointestinal TEAEs were flatulence (OOC, 25.5%; iSRL, 21.6%), nausea (OOC, 20.0%; iSRL, 8.1%), diarrhea (OOC, 10.9%; iSRL, 13.5%), abdominal pain (OOC, 9.1%; iSRL, 8.1%), and constipation (OOC, 5.5%; iSRL, 13.5%). AEs of interest were infrequent, including cholelithiasis (OOC, $n = 0$; iSRL, $n = 1$ [2.7%]) and secondary hypothyroidism (OOC, $n = 1$ [1.8%]; iSRL, $n = 0$). In the iSRL group, 32.4% of patients reported injection site reactions (ISRs) during the RCT, and 47% of patients reported ISRs as part of the Acromegaly Treatment Satisfaction Questionnaire, a newly validated patient-reported outcome tool.[1]

Conclusion
Safety results from MPOWERED align with prior trials, showing that the OOC safety profile is consistent with that of iSRLs as well as the acromegaly disease burden. No new or unexpected safety signals were identified during the trial. Safety results were mostly similar between OOC and iSRLs, although patients in the OOC group did not experience any ISRs.

PEP3.3

Insulinoma-associated protein 1 (INSM1) may serve as a sensitive and specific immunohistochemical and molecular biomarker of neuroendocrine differentiation in pancreatic neuroendocrine tumors (PNETs)

Darko Katalinic[1], Ivan Aleric[1], Aleksandar Vcev[1] & Elke Kattner[2]
[1]Faculty of Dental Medicine and Health and Faculty of Medicine, Department of Clinical Medicine and Department of Internal Medicine, Osijek, Croatia; [2]Herford Teaching Hospital, Department of Hematology and Medical Oncology, Herford, Germany

Introduction
Insulinoma-associated-1 (INSM1), encoded by the *INSM1* gene is key factor in pancreatic endocrine, sympatho-adrenal and pan-neurogenic development. It has also been identified in multiple tumors of neuroendocrine origin but not thoroughly investigated as a potential neoplastic biomarker. The aim of the study was to evaluated INSM1 as a semiquantitative immunohistochemical biomarker as well as quantitative reverse transcriptase polymerase chain reaction (qRT-PCR) biomarker for pancreatic neuroendocrine tumors (PNETs).
Material and Methods
Metastatic PNETs (liver metastases) specimens (n = 24) matched control (normal) tissue were surgically collected and INSM1 expression for tumor and control tissue was analysed by immunohistochemistry. Additionally, mRNA expression was determined by qRT-PCR.
Results
INSM1 expression was significantly increased in neoplastic vs nonneoplastic tissue. Using immunohistrochemistry, we found that INSM1 was not detected in any control, nonneoplastic, non-neuroendocrine tissue. In PNETs tissue, INSM1 was detectable by immunohistochemistry and qRT-PCR in 22 of total 24 specimens (91.66%). Compared to normal tissue specimens, the INSM1 showed significant overexpression in metastatic PNETs.
Conclusion
Our findings highlight that INSM1 may serve as a promissing, novel, neuroendocrine, immunohistochemical and molecular biomarker in patient diagnosed with PNETs.

PEP3.4

Benefits and harms of pituitary surgery for prolactinomas. A systematic review and meta-analysis

Marie Gry Rejkjær Sørensen[1], Mikkel Andreassen[1], Jakob Springborg[2] & Jesper Krogh[1]
[1]Rigshospitalet, Department of Endocrinology, Copenhagen, Denmark; [2]Rigshospitalet, Department of Neurosurgery, Copenhagen, Denmark

Objective
The objective of this systematic review was to assess the proportion of patients with prolactinomas that obtain remission or experience adverse effects after transsphenoidal surgery.
Design
A systematic review. Registered at PROSPERO, registration number CRD42020213002
Methods
A bibliographical search of PubMed and Embase was performed and last updated on September 30, 2020. Eligible studies were studies that included patients who had undergone transsphenoidal surgery for prolactinomas. A random effects analysis was used to calculate the weighted proportions.
Results
Sixty-five observational studies assessing the effect of transsphenoidal surgery for prolactinomas in 4472 patients, were included. The overall proportion of patients obtaining remission after surgery was 61% (95% CI 56 to 65; I^2 = 84%), while the proportion of patients with microprolactinomas and macroprolactinomas obtaining remission was 79.8% (95% CI. 74 to 85) and 52.7% (95% CI. 44 to 61), respectively. Patient mortality was reported as 0% in 14 studies with 1413 participants. Meningitis was observed in 2.7% and postoperative CSF leakage in 4.4%.
Conclusion
This systematic review found an overall remission rate across a range of studies to be 61% (95% CI 56 to 65), and a remission rate for microprolactinomas of 79.8% (95% CI 74 to 85) after transsphenoidal surgery. There are few reported side effects and giving the improving results of transsphenoidal surgery it could be considered first line treatment in selected cases.

PEP3.5

Endocrine function after tanssphenoidal surgery in patients with non-functioning pituitary adenomas: A systematic review and meta-analysis

Mathias Pedersen[1], Mikkel Andreassen[1], Jakob Springborg[2] & Jesper Krogh[1]
[1]Rigshospitalet, Department of Endocrinology, Copenhagen, Denmark; [2]Rigshospitalet, Department of Neurosurgery, Copenhagen, Denmark

Background
Surgical resection is indicated in patients with non-functioning pituitary adenomas (NFPA) causing visual defects or tumor growth in proximity to the optic chiasm. The aim of this study was to systematically assess the benefits and harms of pituitary endocrine function after transsphenoidal surgery in patients with NFPAs.
Methods
This study was conducted a systematic review that searched for potentially eligible studies in Pubmed and EMBASE from database inception to Oct 11, 2020. Inclusion criteria were studies reporting on pituitary function before and after transsphenoidal surgery in patients with NFPAs with a minimum follow-up of one month. The pre-specified primary outcomes were the proportion of participants with improved or deteriorated pituitary function after surgery, and Secondary outcomes was assessment of the effect of pituitary surgery on individual axis. This study was registered with PROSPERO (registration number: CRD42020210853).
Findings
Of the 6228 identified record, 17 studies enrolling 2623 participants were included. The proportion of participants with overall improved pituitary function was 45·0 percent (95% CI. 34·1 to 56·4; I^2 = 91%) while the proportion of participants with overall deterioration of pituitary function was 10·8 percent (95% CI. 6·6 to 17·2; I^2 = 92%) after surgery. Subgroup analysis suggested a positive association between year of publication and risk of pituitary failure. The most likely hormonal axis to recover after surgery was the adrenal axis.
Interpretation
The mean proportion of patients with pituitary recovery after transsphenoidal surgery was between 34 and 56% across studies, while the proportion of patients with new pituitary failure after surgery was between 7 and 17% across studies. These estimates were associated with large heterogeneity, which was not explained by subgroup analysis. However, the effect estimates did include important clinical effects and pituitary surgery for recovery of endocrine function may be considered in selected cases**.**
Funding
There was no funding source for this study.

PEP3.6

Comparative study of growth hormone stimulation levels in growth hormone deficient children vs children with idiopathic short stature

Sofia Leka-Emiri[1], Fani Athanasouli[1], Dimitra Tampouratzi[1], Maria Kafetzi[2], Eirini Dikaiakou[1], Vasilios Petrou[1], Elpis Vlachopapadopoulou[1] & Stefanos Michalakos[1]
[1]Endocrinology-Growth and Development, "P&A KYRIAKOU" Children's Hospital, Athens, Greece; [2]Biochemistry-Hormonology, "P&A KYRIAKOU" Children's Hospital, Athens, Greece

Introduction
Short stature (SS) assessment includes the documentation of growth hormone (GH) secretion via GH stimulation tests.

Objectives
To study retrospectively GH stimulation test results among Greek children with SS and investigate differences among GH deficient (GHD) children vs idiopathic short stature (ISS).
Methods
Data were collected retrospectively from 190 children who visited the pediatric endocrine clinic for the evaluation of SS. Age, gender, weight *z*-score, height *z*-score, BMI *z*-score, Tanner stages, bone age, annual growth rate, target height, insulin-like growth factor 1 (IGF-1) levels and GH stimulation test results were collected from the electronic medical records. GHD is defined as a serum peak GH concentration <10 ng/ml in a combination of two separate tests with glucagon (peak GH-G) and clonidine (peak GH-C). Both IGF-1 and GH were measured by a chemiluminescence sandwich type immunoassay on the analyzer Liaison XL, Diasorin.
Results
Eighty-four children (44%) were diagnosed with GHD, 56 (29%) with ISS, 38 with chronic disease (20%) and 12 with SGA (small for gestational age) (6%). All data concerning GHD and ISS children are summarized in table 1. IGF-1 levels did not differ significantly among ISS and GHD children. Pubertal children in both groups had significantly higher (*P*: <0.001) IGF-1 levels as compared to prepubertal: 283 ng/ml vs 156 ng/ml in ISS group and 258 ng/ml vs 138 ng/ml in GHD group. IGF-1 levels were not sex dimorphic in any group. Peak GH-G and peak GH-C were significantly higher in ISS versus GHD children but did not differ significantly in respect to sex/puberty.
Conclusion
GH stimulation test is of greater interest than IGF-1 levels alone in differentiating GHD from ISS children irrespective of puberty or sex.

Table 1. Values are presented as mean (s.d.). CA: chronological age, BA: bone age, SDS: standard deviation score, MPH: mid-parental height, BMI: body mass index.

	All (190)	ISS (56)	GHD (84)	*P* value

Transcriptome alteration landscape of pituitary neuroendocrine tumour tissue

Rihards Saksis[1], Kaspars Megnis[1], Raitis Peculis[1], Helvijs Niedra[1], Inga Balcere[2], Ilze Konrade[2], Liva Steina[3], Valdis Pirags[3] & Vita Rovite[4]
[1]Latvian Biomedical Research and Study Centre, Latvia; [2]Riga East Clinical University Hospital, Latvia; [3]Pauls Stradins Clinical University Hospital, Latvia; [4]Latvian Biomedical Research and Study Centre, Riga, Latvia

Pituitary neuroendocrine tumors (PitNETs) are non-metastatic neoplasms of the pituitary that may overproduce hormones leading to systemic disorders or tumor mass effects causing headache, vertigo, or visual impairment. The overall estimated clinical prevalence of PitNETs is 1 in 400 to 1 in 1000 people. Although the pathogenesis of PitNETs has been extensively studied the molecular factors underlying tumorigenesis, remission, and therapy response of PitNETs are still unclear. The studies of PitNET transcriptome profiles could give insight into pathogenesis mechanisms that promote tumorigenesis properties like growth, invasiveness, response to treatment. First-line medical treatment of somatotroph PitNETs is somatostatin analogues (SSA) and dopamine agonists (DA) that decrease tumour mass and induce antiproliferative effects on PitNET cells. This study aimed to determine differences in transcriptome signatures that are induced by SSA/DA therapy in PitNET tissue. In this study we selected tumour tissue of twelve patients with somatotroph PitNETs, half of the patients had SSA/DA treatment before surgery and the other half was treatment-naive. The transcriptome sequencing was carried out, differentially expressed genes (DEGs) were identified and protein–protein interactions and pathway analysis was performed. We discovered 34 upregulated and 6 downregulated DEGs in patients with SSA/DA treatment. Three tumour development promoting factors *MUC16*, *MACC1* and *GRHL2* were significantly downregulated in therapy administered PitNET tissue. Protein–protein interactions and pathway analysis revealed extracellular matrix Here, we demonstrate that somatotroph PitNETs can be distinguished based on their transcriptional profiles following SSA/DA therapy, therefore, SSA/DA treatment can cause changes in gene expression. The SSA/DA significantly downregulated several tumourigenesis contributing factors, including *MUC16*, *MACC1* and *GRHL2*. Genes that were upregulated did not have a direct influence on the antiproliferative functions in the PitNET cells. This suggests that SSA acts in a tumour suppressive manner. Collagen related interactions and pathways were enriched in our data implicating extracellular matrix involvement in antitumoural effects of drug treatment.

Temporary oral NaCl tablets safely increase serum sodium in hospitalised elderly patients with hyponatraemia secondary to refractory idiopathic syndrome of inappropriate diuresis (SIAD)

Julia Calvo Latorre, Russell Senanayake & Waiel A Bashari
Cambridge University Hospitals NHS Foundation Trust, Cambridge, UK

Introduction
Hyponatraemia is the most common electrolyte abnormality encountered within the inpatient setting and is associated with increased morbidity, mortality and length of hospital stay. It compromises a spectrum of symptoms, from being asymptomatic to varying degrees of neurological disturbances including gait abnormalities with increased risk of falls, confusion and rarely seizures. This is of particular relevance in the midst of an aging population worldwide and in the context of the current COVID pandemic, where measures are required to avoid lengthy hospitalisation. Syndrome of inappropriate diuresis (SIAD) remains the most common underlying cause. In addition to treating the aetiology, non-pharmacological treatment of SIAD include fluid restriction which is poorly effective. Medical treatment with demeclocycline and vaptans (vasopressin receptor antagonists) may offer reliable alternatives. However, these agents are not without risk, particularly where significant shifts in sodium levels are observed over a short time period. We propose the temporary use of sodium chloride (NaCl) tablets together with fluid restriction as an effective and safe way to treat refractory SIAD in hospitalised elderly patients, facilitating prompt discharge and reducing further risk of hospital-acquired morbidity.
Illustrative cases
We present two cases: 74-year-old and 82-year-old female patients who were admitted to the Cambridge University Hospitals NHS Foundation Trust between September and December 2020 and were found to be symptomatic with acute on chronic hyponatraemia. Clinical and biochemical assessment was consistent with SIAD, with chest and brain imaging excluding additional pathology. First line management involved commencement of an observed fluid restriction with a slow and limited improvement in the degree of hyponatraemia. Modified release NaCl tablets at a dose of 2.4 g twice daily were subsequently introduced whilst both patients remained on fluid restriction. Within 72 h of commencement of NaCl tablets, both patients improved clinically, with serum sodium correction to a level that was deemed safe for discharge (≥130 mmol/l). Their serum sodium did not increase more than 10 mmol/l in a 24-h period. A short course of oral NaCl tablets was recommended following discharge with follow up in the outpatient Endocrinology clinic.

Conclusion
The temporary use of oral NaCl tablets, in addition to fluid restriction, is a well-tolerated, safe and effective way to treat refractory SIAD in hospitalised elderly patients, thus facilitating early discharge and reducing the morbidity and mortality associated with prolonged hospital admissions.

Effect of oral contraceptives containing estradiol valerate vs. ethinyl estradiol combined with dienogest on biomarkers of coagulation – a randomized clinical trial

Annina Haverinen[1], Kaisu Luiro[1], Timea Szanto[2], Marika Kangasniemi[3,4], Leena Hiltunen[5], Susanna Sainio[5], Terhi Piltonen[3,4], Riitta Lassila[2], Juha Tapanainen[1] & Oskari Heikinheimo[1]
[1]Helsinki University Hospital and Helsinki University, Obstetrics and Gynecology, Helsinki, Finland; [2]Helsinki University Hospital, Coagulation Disorders Unit, Finland; [3]Oulu University Hospital, Obstetrics and Gynecology, Oulu, Finland; [4]Oulu University, PEDEGO Research Unit, Finland; [5]Finnish Red Cross Blood Service, Helsinki, Finland

Objective
To compare the effects of combined oral contraceptives (COCs) containing estradiol valerate (EV) and dienogest (DNG) with ethinyl estradiol (EE) and DNG on biomarkers of coagulation: thrombin generation (TG), prothrombin fragments F1+2 (F1+2) and D-dimer (D-Di). A DNG-only preparation was included as a control.
Background
COC use increases the risk of venous thromboembolism (VTE) 2-6-fold compared with non-use. Traditional COCs contain synthetic EE. However, COCs containing natural estrogens, estradiol (E2) or EV have recently been introduced, with the expectation of a reduced impact on coagulation and potentially a lower VTE risk.
Study design
We performed a randomized clinical trial and report here the secondary outcomes. Fifty-nine 18-35-year-old, healthy, normal-weight, non-smoking voluntary women were randomized to either EV+DNG (2 mg+2–3 mg, $n = 20$), EE+DNG (0.03 mg+2 mg, $n = 20$), or DNG-only (2 mg, $n = 19$) for nine weeks. Three women discontinued, two women with FV Leiden mutation were excluded and two samples could not be analyzed (EV+DNG $n = 18$, EE+DNG $n = 18$, DNG $n = 16$). We assessed TG (with Calibrated Automated Thombogram, TG-CAT), F1+F2 and D-Di at baseline and nine weeks of treatment. From the TG-CAT, we analyzed endogenous thrombin potential (ETP, total amount of thrombin), thrombin peak (highest concentration), lag time (time from initiation to thrombin burst), and time to thrombin peak (time from initiation to peak).
Results
Mean ETP increased +23% in the EV+DNG-group vs. +61% in the EE+DNG-group ($P < 0.01$), and peak thrombin increased +40 vs. +127% ($P < 0.01$). Mean lag time and time- to- peak thrombin decreased: −7% vs. −26% ($P < 0.01$) and −8% vs. −21% ($P < 0.01$). In the EE+DNG-group the within-group differences for all TG-CAT variables were significant ($P < 0.01$). In contrast, in the EV+DNG-group only the change from baseline in ETP and peak thrombin were significant ($P < 0.01$). Mean F1+2 and D-Di decreased in the EV+DNG and increased in the EE+DNG -group compared with baseline (EV+DNG F1+2 -9% vs. EE+DNG +16%, $P = 0.04$ and D-Di -0.4% vs. +10%, $P = 0.06$), In the DNG-only group, we did not observe any significant changes.
Conclusions
Our results indicate that the estrogen component accounts for most alterations in coagulation activity induced by COC use. We suggest that COCs containing E2/EV have less impact on thrombin generation and thereby likely decreased VTE risk compared with preparations containing EE. The actual VTE risk for E2-based COCs will be revealed in future epidemiological studies.

Immunological and inflammatory biomarkers in non-obese patients affected by PCOS, correlation between hormonal and metabolic parameters: preliminary data

Carmine Bruno[1], Edoardo Vergani[1], Cecilia Napodano[2], Krizia Pocino[2], Annunziata Stefanile[2], Francesca Gulli[2], Alessandro Oliva[1], Umberto Basile[2] & Antonio Mancini[1]
[1]Catholic University of the Sacred Heart, Dipartimento di Medicina e Chirurgia Traslazionale, Università Cattolica del Sacro Cuore, Rome – Italy; [2]Catholic University of the Sacred Heart, Dipartimento di Scienze biotecnologiche di base, cliniche intensivologiche e peri-operatorie, Università Cattolica del Sacro Cuore, Rome – Italy

Objective
Policystic ovary syndrome (PCOS) is a multifactorial disease characterized by reproductive and metabolic impairments. PCOS patients could present anovulation, hirsutism and infertility as well as higher prevalence of metabolic syndrome, glucose intolerance and diabetes. Insulin-resistance (IR) together with hyperandrogenism represent the main players, with reciprocal influences in a vicious circle: insulin promotes androgen secretion in thecal cells and hyperandrogenism has been related to adipose tissue dysfunction that lead to IR and hyperinsulinemia. Both factors contribute to create in PCOS patients a state of chronic low-grade inflammation (LGI), which may have an important role in the physiopathology of the disease; however, it is predominantly evaluated in obese PCOS. Therefore, we performed an observational case–control study to investigate inflammatory and immunological parameters, such as IgG subclasses and free light chains (FLCs) and hemolytic complement activity (CH50) in non-obese PCOS, evaluating their relations with metabolic and hormonal parameters.
Methods
36 subjects were studied: 16 PCOS patients (mean ± S.E.M. 27.13 ± 1.82 age; BMI 24.1±0.9 kg/m^2); 20 controls (aged 26.05 ± 0.73). Blood sample was collected for metabolic and hormonal parameters, IgG subclasses, k and λ FLCs, CH50. Hormones were measured by immunochemiluminometric assays; Metabolic parameters by enzymatic assays; subclasses of IgG, FLCs and CH50 were evaluated by turbidimetric method.
Results
PCOS patients showed significant lower IgG1, IgG2, IgG3 compared with controls (mean ± S.E.M. 3.76 ± 0.29 g/l, 2.63 ± 0.20, 0.62 ± 0.06, 0.34 ± 0.08 vs 6.49 ± 0.35, 4.28 ± 0.25, 0.84 ± 0.07, 0.33 ± 0.04, respectively) and higher levels of FLCs (k 12.22 ± 0.71 vs 6.03 ± 0.30, λ 10.10 ± 0.79 vs 8.04 ± 0.48 g/l) and CH50 (48.64 ± 2.65 vs 36.51 ± 1.38 U/ml); we found correlation between IgG2 and free-testosterone ($r = 0.72$, $P = 0.005$) and CH50 and vitamin D ($r = 0.54$, $P = 0.04$); an inverse correlation was found between IgG1 and, respectively, ACTH ($r = -0.57$, $P = 0.02$) and cortisol ($r = 0.78$, $P = 0.001$) in PCOS.
Conclusions
In the complex scenario of low-grade inflammation in non-obese PCOS, we showed lower levels of main subclasses of IgG and higher CH50 levels, suggesting involvement of other mechanisms other than "classical" pathway of complement activation; FLCs could be attractive to monitor inflammation degree, disease activity and influence on hormonal status.

Effects of a very low-calorie ketogenic diet on androgen levels in overweight/obese men: a single-arm uncontrolled study

Angelo Cignarelli, Eleonora Conte, Valentina Annamaria Genchi, Fiorella Giordano, Simona Di Leo, Sebastio Perrini, Annalisa Natalicchio, Luigi Laviola & Francesco Giorgino
University of Bari, Department of Emergency and Organ Transplantation, Bari, Italy

Low levels of testosterone and SHBG levels are often present in subjects with overweight and obesity; functional hypogonadism further alters the metabolic balance and may drag subjects in a sort of vicious cycle, reducing exercise and energy expenditure. The very low-calorie ketogenic diet (VLCKD) has been reported to rapidly reduce body weight, glycaemia and insulinemia, but its effects on total testosterone (TT) and SHBG levels are less clear. We thus aimed to evaluate the response of TT and SHBG circulating levels to a VLCKD in a cohort of overweight or obese nondiabetic male subjects. All subjects underwent a VLCKD for 4 weeks. Anthropometric parameters, oral glucose tolerance test (OGTT), bioelectrical impedance analysis, and blood testing for the measurement of glycaemia, insulin, TT, SHBG, LH, were performed before and after 1 and 4 weeks of VLCKD. Seventeen patients [mean age 41.3 (12.2) years, mean BMI 36.4 (5.2) kg/m^2, mean TT 2.5 (1.0) ng/ml, mean SHBG (24.2) nmol/l] were enrolled. After VLCKD treatment, body weight (−9.3 kg (1.8)), fat mass [−6.5 kg (2.1)] and BMI [−3.1 (0.7)]

significantly decreased, and a mean 14.9 ± 3.9% loss of the initial body weight was achieved. A significant increase of 0.49 (0.59) ng/ml and of 0.89 (0.91) ng/ml in serum TT levels was achieved after 1 and 4 weeks after VLCKD, respectively; similarly, a mean increase of 3.47 (4.73) and of 10.94 (12.87) in serum SHBG levels was achieved after 1 and 4 weeks, respectively. A stratification was further performed in high vs low responders in regard to TT variations after 1 week of VLCKD (>+0.44 vs <+0.44 ng/ml). While showing comparable variation of all variables analyzed, high responders differed only by the level of insulin sensitivity. Indeed, low responders, despite a comparable level of glycemia during OGTT, displayed a significantly higher level of insulinemia [area under curve: 25858 (11821) vs 13924 (11592)], indicating that they were more insulin-resistant vs high responders. This is the first study that evaluated the early response of androgen levels to institution of a VLCKD. VLCKD promotes a rapid effect on TT levels, especially in insulin-sensitive subjects with overweight or obesity. This highlights the tight relation between insulin action, energy balance, and testicular function. Further, VLCKD could be safely used to improve hypoandrogenemia, and possibly rescue obese patients from functional hypogonadism.

Insulin production by human spermatozoa in response to glucose stimuli

David F. Carrageta[1], Pedro F. Oliveira[2], Alberto Barros[3,4,5], Mariana P. Monteiro[1] & Marco G. Alves[1]
[1]Department of Anatomy, Unit for Multidisciplinary Research in Biomedicine (UMIB), Institute of Biomedical Sciences Abel Salazar (ICBAS), University of Porto, Porto, Portugal; [2]QOPNA & LAQV, Department of Chemistry, University of Aveiro, Aveiro, Portugal; [3]Department of Genetics, Faculty of Medicine, University of Porto, Porto, Portugal; [4]i3S – Instituto de Investigação e Inovação em Saúde, University of Porto, Porto, Portugal; [5]Centre for Reproductive Genetics Prof. Alberto Barros, Porto, Portugal

Introduction
Metabolic homeostasis in the testis is essential for a healthy spermatogenesis. Insulin is regarded as one of the most important intervenients in the metabolic regulation of spermatogenesis, where it acts directly on the differentiation of spermatogonia into primary spermatocytes or indirectly through the metabolic modulation of Sertoli cells. Additionally, insulin is hypothesized to play a major role on human spermatozoa capacitation, although the mechanisms that regulate its production and secretion remain to be disclosed.
Aim of the study
The main objective of this study was to estimate the capacity of insulin production by human spermatozoa and if they express PC1/3 and PC2, which are enzymes responsible for the cleavage of proinsulin. In addition, we hypothesized that insulin production could respond to glucose stimuli.
Materials and Methods
Seminal samples of normozoospermic men (n = 15) were collected and submitted to a density gradient centrifugation. Two fractions of spermatozoa were then collected according to their motility condition (high vs low motility). The expression of insulin, PC1/3 and PC2 mRNA was evaluated in both spermatozoa fractions by RT-qPCR. The protein expression of insulin, PC1/3 and PC2 in spermatozoa was evaluated by immunofluorescence. The fraction of highly motile spermatozoa was then incubated in a medium conferring capacitating conditions and supplemented with increasing glucose concentrations (in mM: 0, 5.5, 11 and 22). After 6 h, the concentration of insulin in the medium was quantified by ELISA.
Results
Insulin, PC1/3 and PC2 mRNA, as well as the respective proteins, are expressed in human spermatozoa. The mRNA expression was found to be higher in the highly motile spermatozoa. Additionally, human spermatozoa release insulin to the medium in a glucose concentration-dependent manner.
Conclusion
This study shows that human spermatozoa are able to produce and release insulin in a glucose concentration-dependent manner. Future studies are required to further evaluate the role of insulin on human spermatozoa capacitation and fertilization capacity, opening an exciting new line of investigation.

Effects of metformin withdrawal after long and short term treatment in PCOS: observational longitudinal study

Mojca Jensterle[1,2], NIka Aleksandra Kravos Tramsak[2] & Andrej Janez[1,2]
[1]University Medical Centre Ljubljana, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia; [2]Faculty of Medicine, University of Ljubljana, Slovenia

Background
Metformin plays a consolidated role in the management of polycystic ovary syndrome (PCOS). However, there is no clear answer on how long we should treat and on how long its beneficial impact sustain after we stop treatment. We compared the effects of metformin withdrawal after long-term (LT) and short term (ST) treatment in PCOS women that had previously well responded to metformin.
Methods
We conducted observational longitudinal study including 44 PCOS women (31 (28–36) years and BMI 32.5 (27.7.-34-9) kg/m^2) that were followed for 6 months after metformin withdrawal. Prior inclusion, ST group had been treated with metformin on average for 1.03 ± 0.13 year, LT group for 5.07 ± 2.52 years. We followed anthropometric, metabolic, reproductive parameters and eating behavior as assessed by TFEQ-R18.
Results
After metformin withdrawal, ST group gained significant amount of weight (from 92 (75.5.–107.3) kg to 96 (76–116) kg; P = 0.019). Weight tended to increase also in LT users (from 87 (75–103) to 87 (73–105) kg; P = 0.058). More women in LT group maintained stable weight (27% in LT group vs 15% in ST group). Eating behavior deteriorated in both groups. Withdrawal of metformin resulted in a decrease of menstrual frequency (6 (6–6) to 6 (4–6) menstrual bleeds per 6 months; P = 0.027) and in borderline increase of androstenedione (6.4 (4.6–7.6) to 7.8 (4.8–9.6) nmol/l; P = 0.053) in LT group. Waist circumference, HOMA and glucose homeostasis remained stable in both groups. There were no differences between groups at 6-month follow up.
Conclusion
Collectively, present study implies some metabolic and endocrine treatment legacy in both groups as well as some group-specific deteriorations in clinical parameters 6 months after metformin withdrawal.

PEP4.6

The effect of decamethylcyclopentasiloxane exposure to maternal mice in offspring behavior

Donglin Yi, Kang Min Kim, Bonn Lee, Minsu Lee & Eui-Bae Jeung
Chungbuk National University, Laboratory of Veterinary Biochemistry and Molecular Biology, College of Veterinary Medicine, Republic of South Korea

Decamethylcyclopentasiloxane(D5) is one of the most common chemical ingredient for cosmetic products, cleansing agents, hairdye, dry cleaning solvent and personal hygiene supplies. D5 is also known as estrogenic chemical. It can be absorbed through skin, airosol, and even oraly. People are exposed to D5 in daily environment. However, the risk of prenatal exposure to D5 has not yet been fully understood. Recent research shows that imbalance of dam's estrogen induces brain development disorder, in this study the effect of prenatal exposure of D5 on brain development were assessed by behavioral test of their pup. According to previous study, the estimated amount of daily exposure of D5 to human is around 0.6 mg/kg. Also, the systematical absorption ratio of D5 by oral is 10% in mice. Thus, we treated 3, 6, 12, 60 mg/kg of D5 with corn oil per a day to pregnant female mice from E10 through E19. All behavioral tests were performed after pups became 6 weeks old. In high dose treated D5 group showed decreased social behavior and cognitive ability in three chamber test. The impairment of memory and exploring ability were found on high dose D5 group pups in novel object test. These results show that maternal exposure to D5 impairs social ablilty and memory of pups. As pups were only exposed to D5 in prenatal period, these symptoms were caused by abnormal brain development while they were embryos. This study shows that maternal exposure to D5 cause the offspring's brain development disorders. Also, the results support the previous study that imbalance of estrogen disrupts brain development.

Functional ovarian reserve in women with infertility and euthyroidism: what is the role of thyroid autoimmunity?

Diana Alexandra Festas Silva[1], Tânia Carvalho[2], Ângela Maresch[3], Diana Catarino[1], Lúcia Fadiga[1], Joana Reis Guiomar[1], Leonor Gomes[1,2], Fátima Leitão[3], Paulo Cortesão[4], Teresa Almeida Santos[2,4] & Isabel PAIVA[1]
[1]Coimbra Hospital and University Centre, Endocrinology Department, Coimbra, Portugal; [2]Faculty of Medicine of the University of Coimbra, Coimbra, Portugal; [3]Coimbra Hospital and University Centre, Clinical Pathology Department, Coimbra, Portugal; [4]Coimbra Hospital and University Centre, Human Reproduction Department, Coimbra, Portugal

Introduction
Thyroid dysfunction is the most common endocrine disorder in women of childbearing age, and is associated with menstrual irregularities, anovulation and infertility. Whether it is thyroid function and/or thyroid autoimmunity (AI) that affects functional ovarian reserve remains to be clarified.
Aim
To evaluate the association between functional ovarian reserve and thyroid AI in women with infertility in euthyroidism.
Methods
Retrospective study of women with infertility, in euthyroidism, followed in a Human Reproduction Department, between May 2016 and January 2020. TSH, anti-thyroid peroxidase (TPO) antibodies, anti-thyroglobulin (TG) antibodies were measured. Functional ovarian reserve was assessed by anti-Müllerian hormone (AMH) levels with antral follicle count (AFC) performed by endovaginal ultrasound. Women with at least 1 of the following criteria were excluded: prior thyroidectomy, radioactive iodine treatment, cervical surgery/radiotherapy, oophorectomy, malignant/autoimmune pathology, chronic kidney disease, liver disease, polycystic ovary syndrome, current pregnancy and current medication with levothyroxine, methimazole or propylthiouracil. Results with P <0.05 were considered statistically significant.
Results
730 women were evaluated, with mean age of 34.9±3.9 years, with positive AI (≥ 1 positive antibody) present in 14.8% of cases. Anti-TPO antibodies were positive in 11.0% of patients and anti-TG antibodies in 7.0%. Mean TSH levels were 1.6±0.7 uUI/ml (NR: 0.4–4.0). Median body mass index (BMI) was 22.8 kg/m2 (IQR 5.1). Median AMH was 1.7 ng/ml (IQR 2.1), and mean AFC was 10.2±6.3. Patients with positive and negative AI did not differ significantly in age (P = 0.133), BMI (P = 0.784], AFC (P = 0.508) and AMH (P = 0.825). TSH levels were significantly higher in the positive AI group (2.0±0.8 vs 1.5±0.7 uUI/ml; P <0.001). In the univariate and multivariate analysis, only patient's age and AFC were predictive of AMH levels (P <0.001; P <0.001, respectively). TSH levels, BMI and thyroid AI were not predictive of AMH levels. In regard to AFC, in the univariate analysis, only age was predictive (P <0.001). TSH levels, BMI and thyroid AI were not predictive of AFC.
Conclusions
In this study we found that thyroid autoimmunity and TSH levels in the normal range, in women with infertility, apparently, do not have a predictive role for functional ovarian reserve.

Background
Prenatal dexamethasone treatment (Pdex) has been used since the 1980s to prevent virilization in female offspring suspected to have congenital adrenal hyperplasia (CAH). However, due to lack of strong evidence for its best practice as well as limited data regarding longterm adverse effects, use of dex is highly controversial. This study reveals the current medical practice regarding Pdex in female fetuses at risk of CAH due to 21hydroxylase deficiency (21OHD) in Europe.
Methods
A questionnaire was designed and distributed using Microsoft Forms, including 17 questions collecting quantitative and qualitative data. Thirty-six medical centres from 14 European countries responded and 28 out of 36 centres were reference centres of the European Reference Network on Rare Endocrine Conditions, EndoERN.

Results
36% (13/36) of the surveyed centres are currently providing Pdex. The treatment is initiated by different specialties i.e. pediatricians, obstetricians/gynecologists or geneticists. Regarding the starting point of Pdex, 15% of centres stated to initiate therapy as early as pregnancy is confirmed, 23% at 4 to 5 wpc, 31% at 6 wpc, and the rest at 7 wpc at the latest. A dose of 20 µg/kg/d is used and dose distribution among the centres varies between once to thrice daily. Prenatal diagnostics are conducted at 72% (26/36) of centres, which however mainly includes chorionic villous sampling ± genotyping of the sexdetermining region Y from maternal blood (SRYtyping) or amniocentesis and CYP21A2 genotyping. Noninvasive genetic testing from maternal blood is currently offered by one centre. The total number of pregnant women who received Pdex during the first trimester of pregnancy varied from 3 to 44 per centre (median = 10, total number of treated cases n = 197), while 0 to 13 cases (median = 5, total number of treated cases n = 70) were treated for the entire gestational period. A mean of 1.6 cases are treated at each centre per year. Registries for longterm followup are only available at 46% of the centres that are using Pdex. National registries are only available in 2 of the 14 corresponding countries.
Conclusion
This study reveals a high international variability and discrepancy on the use of Pdex across Europe. It highlights the importance of a European cooperation initiative for a joint international prospective trial to establish evidencebased guidelines on prenatal diagnostics, treatment and followup of pregnancies at risk for CAH. Evaluation of outcome and longterm health of already treated cases across Europe is highly recommended.

Thyroid

PEP5.1

A rare case of resistance to thyroid hormone with recurrent papillary thyroid carcinoma

Ragip Fatih Kural[1], Gonca Oruk[2] & Elif Ersen Kural[1]
[1]Katip Celebi University Ataturk Training and Research Hospital, Department of Internal Medicine, Izmir, Turkey; [2]Katip Celebi University Ataturk Training and Research Hospital, Department of Endocrinology and Metabolism, Turkey

Background
Resistance to thyroid hormone (RTH) involves an altered tissue response to thyroid hormones. RTH is characterized by increased serum thyroid hormone (TH) levels with nonsuppressed serum thyroid-stimulating hormone (TSH) levels. Herein, we report a rare case of RTH with recurrent papillary thyroid carcinoma (PTC).
Patient findings
A 38-year-old female patient was admited to outpatient clinic for the evaluation of neck swelling. She had no thyrotoxic symptoms and there was no family history of thyroid cancer. Physical examination revealed a 1 cm thyroid nodule and mildly enlarged thyroid gland. The initial laboratory examination revealed a normal level of TSH [(3.28 uIU/ml (0.35–5.5)] despite elevated levels of TH [(free T4: 2.11 ng/ml (0.74–1.52), free T3: 6.25 pg/ml (2.3–4.2)]. Thyroid autoantibodies were not detected against thyroglobulin, thyroperoxidase and TSH receptor. Normal pituitary gland was found in the MRI performed to exclude TSHoma. Thyroid ultrasonography (USG) showed multiple hypoechogenic nodules, the largest of which was 13x9x7 mm in diameter, in both lobes. Fine-needle aspiration was performed for the largest nodule with suspicious features of malignancy in the left lobe and the cytologic diagnosis was 'susupicious of malignancy' (*Bethesda Category* 5). She underwent total thyroidectomy with central lymph node dissection (LND). The histopathological results revealed classic PTC (tumor-node-metastasis staging; T1bN1bM0) in the left thyroid lobe with metastatic central lymph nodes. Tumor size was 1.3×0.7 cm. For to ensure the TSH suppression after surgery, levothyroxine therapy was initiated 150 mg/day. After six months of levothyroxine therapy her TSH level was still elevated (TSH 176.3 µIU/ml). Therefore the dose was gradually increased up to 300 mg/day. Recurrence of PTC with regional lymph node metastasis were revealed 12 months after surgery. She underwent re-surgery for complementary LND. Then she received radioiodine ablation therapy (150 mCi). In her last follow-up visit 18 months later, serum TSH level decreased to 33.2 uIU/ml. Serum free T4 and T3 levels were normal and thyroglobulin level was <0.20 ng/ml. She had no symptoms and signs of hypothyroidism. Also, her neck USG examination showed no pathological lymph node.
Conclusion
Only a few cases have been reported in the literature showing the coexistence of RTH and thyroid carcinoma. TSH suppression may not be obtained despite increasing doses of levothyroxine in patients with RTH and PTC, as was the case we report. Further studies are needed to reach a consensus on the management of thyroid carcinoma in patients with THR.

PEP5.2

Low-risk papillary thyroid carcinoma: outcome predictive factors in a cohort of patients not treated with radioiodine therapy after total thyroidectomy

Irene Gagliardi[1], Alessandro Mella[2], Roberta Rossi[2], Margherita Pontrelli[1], Martina Rossi[2] & Maria Chiara Zatelli[1,2]
[1]University of Ferrara, Section of Endocrinology and Internal Medicine, Department of Medical Sciences, Italy; [2]University Hospital of Ferrara, Unit of Endocrinology and Metabolic Diseases, Department of Oncology and Specialty Medicine, Ferrara, Italy

Background
Papillary thyroid carcinoma (PTC) is the most frequent thyroid malignant neoplasm. American Thyroid Association (ATA) guidelines don't specify how to follow-up low-risk PTC patients not receiving radioiodine therapy (RAI) after total thyroidectomy (TT). Indeed, there is no consensus among authors regarding the interpretation of thyroglobulin (TG) levels and ultrasound neck (US) findings during follow-up in these settings.
Aim
To evaluate outcome predictive factors in low-risk PTC patients treated with TT but not with RAI.
Patients and methods
This retrospective study was conducted on 61 patients who were followed-up for at least 12 months after TT. Assessment of TG, TG-antibodies (ATG) and US was performed after TT and then every 18-24 months. ATA Guidelines Classification system of response to therapy (excellent, biochemical and structural incomplete, indeterminate) was applied even if RAI was not administered. We define as "suspected disease progression/relapse" (sPR) the appearance/growth of thyroid remnants (TR) by US and/or the detection of increased serum TG and/or ATG levels.
Results
The median follow-up was of 41.6±17 months; 5% of patients showed sPR. A slightly higher risk of sRP was observed in patients ≥ 55 years. All patients with sPR had been diagnosed with a microPTC and presented an indeterminate response during follow-up. No differences concerning sex, age, TNM, histology, thyroiditis history were observed as compared to indeterminate patients without sPR. In patients with indeterminate response, TG and ATG levels were found slightly increasing during follow-up even if TSH target levels were achieved with L-thyroxine therapy. In the whole cohort, during follow-up ATG absence was not associated with increased TG levels; in patients with excellent response, a slight variation in TG levels was likely due to TSH levels fluctuation without sPR development. Most ATG positive patients become negative at the end of follow-up and none of them showed sRP. 63% of patients showed TR disappearance after 15±8 months.
Conclusion
Low-risk PTCs have a favorable outcome and the presence of TR is not a risk factor for relapse. However, microPTC could lead to sPR and careful follow-up is advised especially in older patients. Slight variations in TG levels in ATG/US negative patients could be due to TSH fluctuations rather than sRP development.

PEP5.3

Is the thyroid nodule location associated with the risk of malignancy?

Vânia Benido Silva, Maria Teresa Pereira, André Carvalho, Cláudia Freitas & Maria Helena Cardoso
Centro Hospitalar e Universitário do Porto, Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal

Introduction
Recent published studies suggest that the anatomical location of the thyroid nodule may be associated with different risks of malignancy. However, the results are still sparce and little consensual.

Aim
To evaluate the frequency of nodules on different locations of the thyroid gland and to determine whether their location correlates with different malignancy risks.
Methods
We present a retrospective study including all Fine-Needle Aspiration Biopsies (FNABs) performed in our department between January 2016 and December 2019. Demographic data, the number and location of nodules, their ultrasound characteristics and the respective EU-TIRADS classification, their cytological results according to Bethesda's classification and their histology were recorded. The nodule was considered benign in the presence of benign cytology or histology, and malignant when this diagnosis was confirmed histologically.
Results
From a total of 1497 FNABs included, performed in 1046 patients, 1004 had definitive diagnoses (934 [89.5%] benign; 70 [6.7%] malignant). The majority (86%) were done in female patients, with a median age of 56 years (P25–P75:47–66). The presence of a single thyroid nodule was associated with a higher rate of malignancy when compared to multinodular goiter (34.3% vs 22.1%, $P = 0.019$). The right lobe was the location with the highest description of nodules (452 [45.0%]), followed by the left lobe (425 [42.3%]) and the isthmus (127 [12.6%]). There were no differences regarding the risk of malignancy between these locations (7.7% vs6.4% vs 6.3% respectively; $P = 0.686$). In 686 patients, the longitudinal nodular position was documented (424 [61.8%] in the middle lobe; 206 [30.0%] in the lower lobe; and 56 [8.2%] in the upper lobe). Likewise, the rate of malignant lesions was not significantly more prevalent in any of these positions (8.0% vs 6.3% 10.7%, respectively; $P = 0.514$).
Conclusion
Although current literature has shown that thyroid nodule location can be an independent risk factor for a malignant lesion, our study could not confirm these data. In this large cohort of FNABs samples, we evidenced that there is no relationship between the anatomical location of the thyroid nodule and its risk of malignancy. Despite little consensus on this subject, some studies suggest that the isthmus and the lower lobe nodules have the highest risk, while others show this result in the middle lobe.

Pilot study with the luca device to optimize the diagnosis of thyroid cancer: preliminary results

Gloria Aranda Velazquez[1], Lorenzo Cortese[2], Sabina Ruiz[3], Mattia Squarcia[4], Felicia Hanzu[3], Irene Halperin[3], Davide Contini[5], Alberto Dalla Mora[5], Turgut Durduran[2] & Mireia Mora[3]
[1]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Group of Endocrine Disorders., Barcelona, Spain; [2]Institut de Ciències Fotòniques (ICFO), Barcelona, Spain; [3]Hospital Clinic, Endocrinology and Nutrition Department, Barcelona, Spain; [4]Hospital Clinic, Radiology Department, Barcelona, Spain; [5]Politecnico di Milano, Physic Department, Milan, Italy

Introduction
Diffuse optic techniques exploit the capability of penetration of near infrared light to investigate the properties and physiology of tissues. Based on this property, the LUCA device (Laser and Ultrasound Co-Analyzer of Thyroid nodules), a multi-modal device that combines two different diffuse optical techniques – time resolved and diffuse correlation spectroscopies – with ultrasound in the same transducer, has been developed with the aim of optimizing the study of the thyroid nodules.
Materials and Methods
Pilot study that included 11 controls without thyroid pathology (normal thyroid function and ultrasound with negative antibodies) and 31 patients with thyroid nodules (13 with benign nodules, 10 with multinodular goiter and 8 with malignant nodules all confirmed by histology study). All of them were assessed with the LUCA device, using a pre-established protocol. Measurement of both lobes and sternocleidomastoid muscles (MECM) was performed, in addition to nodule determination in patients. In the preliminary analysis using mixed linear effect models, 4 variables were assessed: total Hemoglobin concentration (THB), Tissue oxygen saturation (StO2), dispersion coefficient at a wavelength of 785 nm (μs) and blood flow index (BFI).
Results
The study in controls (54.5% women, 35.3 ± 6.2 years) showed that LUCA can differentiate between thyroid tissue and MECM (P <0.05 for the 4 variables). The study in patients with nodular pathology (77.4% women, 52.2 ± 2 years) has shown a wide variability of the variables studied. The study using ROC curve in patients with single nodules suggests that the model that combines μs of the nodule together with the difference in THB between the nodule and the ipsilateral MECM offers an AUC of 0.92 with a Sensitivity = 100% and Specificity = 77% to differentiate between benign and malignant nodules.
Conclusions
Although this is a preliminary analysis, current results suggest that diffuse optics could help to optimize the diagnosis of malignant thyroid nodules. The study needs to be expanded with other diffuse optics variables along with ultrasound variables.
This project has been carried out thanks to the granting of a HORIZON 2020, Nº: 688303.

PEP5.5

Association of microRNA expression with cervical lymph node metastases of thyroid carcinoma

Romena Laukiene[1,2] & Laima Ambrozaityte[1]
[1]Vilnius University Faculty of Medicine, Department of Human and Medical Genetics, Institute of Biomedical Sciences,, Vilnius, Lithuania; [2]Vilnius University hospital Santaros Klinikos, Center of Endocrinology, Vilnius, Lithuania

Background
Many microRNAs (miRNA) have been proposed as promising molecular markers of papillary thyroid carcinoma (PTC). However, there are limited data on the correlation between miRNA expression, and neck lymph node metastasis. Analysis of miRNAs expression data may improve perioperative decision making for patients with PTC, specifically in identifying patients harboring neck lymph node metastases (LNM).
Aim of the study
To determine and compare miRNA expression profiles of PTC with LNM and PTC without LNM and to determine the diagnostic utility of the detection of specific miRNAs in the preoperative assessment of thyroid nodules.
Methods
Sixty-two thyroid fine needle aspiration (FNA) samples with suspected thyroid carcinoma were collected in the prospective molecular study at Vilnius University hospital Santaros klinikos. Next generation sequencing was performed to characterize miRNA and gene expression profiles in these FNA samples. All 62 patients underwent thyroidectomy: 34 PTC without LNM, 14 PTC with LNM and 12 benign thyroid nodules were diagnosed histologically.
Results
Nine miRNAs were significantly differentially expressed between PTC with MTS compared with PTC without MTS (adjusted P value < 0.05; log2 fold change ≤ -1.0 or ≥ 1.0).
Conclusions
Analysis of miRNAs expression levels and detection of FNA miRNAs can be used for the pre-operative diagnosis of thyroid cancer cervical lymph node metastasis. To translate these data into clinical application, large cohort studies are required to examine the prognostic and diagnostic value of miRNAs panels.

Is the igf-1ec isoform a novel biomarker for advanced differentiated thyroid cancer?

Apostolos Karagiannis[1], Anastassios Philippou[1], Sofia Tseleni-Balafouta[2], Evaggelos Zebolis[1], Theodora Nakouti[3], Michael Koutsilieris[1]
[1]National and Kapodistrian University of Athens, Department of Physiology, Athens, Greece; [2]National and Kapodistrian University of Athens, First Department of Pathology, Athens, Greece; [3]Aristotle University of Thessaloniki, Fourth Department of Internal Medicine, Hippokration General Hospital, Thessaloniki, Greece

Background
Recent knowledge implicates a differential expression of the insulin-like growth factor-1 (IGF-1) mRNA splice variants (i.e., IGF-1Ea, IGF-1Eb and IGF-1Ec) in cancerous tissues, implying possible specific roles of the encoded IGF-1 protein isoforms in cancer biology. In particular, there is growing evidence that IGF-1Ec isoform may plays a distinct biological role

in various types of cancer. The aim of the present study was to investigate whether IGF-1Ec isoform expression is associated with a particular type of thyroid cancer.
Materials and Methods
Formalin-fixed paraffin-embedded tissue specimens of different types of thyroid cancer from 92 patients were assessed for IGF-1Ec expression profile by immunohistochemistry. In addition, thyroid cancer biopsies of different TNM staging histological types were evaluated for mRNA expression of the IGF-1Ec transcript by real-time polymerase chain reaction (rt-PCR).
Results
From the total number of 92 samples, 2 were anaplastic, 10 medullary, 4 hyperplasia of C-cell, 11 follicular, 5 hurtle cell carcinoma, 2 poor differentiated, 5 nodular hyperplasia, 1 lymphoma and 52 were papillary thyroid carcinomas. The age of the patients at the time of diagnosis or the tumor size did not affect significantly the IGF-1Ec expression. Among all types of cancer, IGF-1Ec was expressed in papillary differentiated thyroid carcinoma. Its expression/localization was mainly cytoplasmic and significantly positively associated with TNM staging and the presence of muscular and capsule cancerous invasion (P <0.05), while no differences were found regarding vascular or regional lymph node infiltration. Similarly, a differential profile was revealed regarding the mRNA expression of the IGF-1Ec transcript, which exhibited a higher expression in advanced papillary thyroid carcinoma.
Conclusion
The present data demonstrate that the expression of IGF-1Ec isoform in thyroid cancer is positively associated with more advanced stages of papillary thyroid carcinoma.

DOI: 10.1530/endoabs.73.PEP5.6

PEP5.7

Multifocality in papillary thyroid carcinoma. Is it always the same tumor?

Efrain Cordero-Vazquez.[1], Carmela Iglesias[2], Marta Sesé[2], Rosa Somoza[2], Javier Hernandez-Losa[2] & Carles Zafon[1]
[1]Hospital Universitario Vall d'Hebron, Endocrinology Department, Barcelona, Spain; [2]Hospital Universitario Vall d'Hebron, Pathology Department, Barcelona, Spain

Introduction
Multifocality is a common finding in papillary thyroid carcinoma (PTC), but its biological significance is not well established. In some cases not all foci present the same histological pattern.
Objective
To study the different histological patterns and molecular profiles of multifocal PTC (mPTC).
Material and methods
All patients with a confirmed diagnosis of PTC after total thyroidectomy in the period 2015–2019 at Vall d'Hebron Hospital Campus were included. At first, pathological reports were reviewed, and all mPTC cases were selected. In mPTC, all foci were evaluated by an expert pathologist to identify the coexistence of different patterns. In those cases, paired samples representative of the two major different foci were analyzed with the Next-Generation Sequencing (NGS) panel "Oncomine ™ Solid Tumor".
Results
A total of 74 (41.1%) of the 180 included patients had mPTC. Mean (± S.D.) age was 49.4 ± 13.6 years old, and 73% of them were women. In 10 (13.5%) of the 74 cases, two different histological patterns coexisted. In these, the size (median, IQR) of the primary focus (PF) was 12 (9–45) mm and that of the secondary focus (SF) was 5 (1–10) mm. The most frequent patterns of PF were: follicular (4) and conventional (2), while those of SF were: conventional (6) and follicular (4). In two of the 8 cases analyzed by NGS (25%), the panel showed a different molecular profile between the two paired samples. In the first case, the PF carried a BRAF (V660E) mutation and the SF had a KRAS (codon 61 – c.182A>G) mutation; and in the second case, both the primary as the secondary focus had the same PIK3CA mutation but the PF had a NRAS (codon 61 – c.182A>G) mutation, while the second case showed KRAS (codon 60 and 61 – c.180_181delTCinsAA) and EGFR mutations.
Conclusions
As it is already known, multifocality is a very common histological finding in PTC, but the fact that in some cases the different foci show different histological patterns and molecular profiles raises the possibility that they may actually be synchronous PTCs. This fact could have important diagnostic, therapeutic and prognostic implications.

Genetic profiles of aggressive variants of papillary thyroid carcinomas

Meihua Jin[1], Dong Eun Song[2], Jonghwa Ahn[1], Eyun Song[3], Yu-Mi Lee[4], Tae-Yon Sung[4], Tae Yong Kim[1], Won Bae Kim[1], Young Kee Shong[1], Min Ji Jeon[1] & Won Gu Kim[1]
[1]Asan Medical Center, Division of Endocrinology and Metabolism, Department of Internal Medicine, Seoul, Republic of South Korea; [2]Asan medical center, Department of Pathology, Seoul, Republic of South Korea; [3]Korea University College of Medicine and School of Medicine, Division of Endocrinology and Metablosim, Department of Internal Medicine, Republic of South Korea; [4]Asan medical center, Department of Surgery, Seoul, Republic of South Korea

Background
Aggressive variants of papillary thyroid carcinoma (PTC) have been described with increasing frequency and are associated with unfavorable clinical outcomes. However, limited data exists on the comprehensive genetic profile of these variants.
Method
We performed targeted next generation sequencing in 36 patients with aggressive variants of PTC and compared it to PTC from The Cancer Genome Atlas project and poorly differentiated thyroid cancers (PDTCs)/anaplastic thyroid cancers (ATCs) from the Memorial Sloan Kettering Cancer Center.
Result
BRAF mutation was the most prevalent (89%) in aggressive variants of PTC compared to that in other thyroid cancers. NRAS mutation was identified in one patient (3%), which was less frequent than in others TERT promoter mutation (17%) ranged between that of PTCs (9%) and PDTCs (40%). Tumor suppressor genes, ZFHX3, TP53, and CHEK2 were mutated in 14%, 3%, and 6% of aggressive variants of PTCs, respectively. The total accumulation rate of tumor suppressor gene mutations was 23%, which was significantly higher than that of PTCs (4%), and lower than that of ATCs (76%). Mutations in three functional groups, histone methyl transferases, SWI/SNF chromatin remodeling complex, and the PI3K/AKT/mTOR pathway were present in 11%, 14%, and 11% of samples, respectively.
Conclusion
Aggressive variants of PTC had higher BRAF and lower NRAS mutation prevalence than other thyroid cancers. The prevalence of mutations in the TERT promoter, tumor suppressor gene, and genes encoding three functional groups ranged between that of PTCs and PDTCs/ATCs. These genetic profiles might be associated with clinical outcomes of aggressive variants of PTC.

Comparative evaluation of bone turnover markers in diabetic rats treated with sitagliptin, canagliflozin, empagliflozin

Natalya Timkina[1], Anna Simanenkova[1,2], Oksana Shpilevaya[1], Aleksandra Khalzova[2], Anzhelika Shimshilashvili[1], Valeria Timofeeva[1], Timur Vlasov[2] & Tatiana Karonova[1,2]
[1]National Medical Research Center. VA Almazov, Sankt-Peterburg, Russian Federation; [2]Pavlov First State Medical University of St. Petersburg, Sankt-Peterburg, Russian Federation

Background and aims
Although bone fracture risk increases in DM, bone mineral density does not completely reflect bone fragility. It is important to explore other methods of osteoporotic fracture risk evaluation. Nowadays bone turnover markers (BTM) investigation is not widely used in clinical practice. On the other hand, the action of some glucose-lowering drugs on bone remodeling is not completely explored. The aim of this study was to investigate and to compare BTM in diabetic rats during treatment with sitagliptin (SITA), canagliflozin (CANA), and empagliflozin (EMPA).
Materials and methods
Type 2 DM was modelled in male Wistar rats by high-fat diet and streptozotocin+nicotinamide. 4 weeks after rats were divided into 4 groups: "DM" (n = 4), "SITA" (n = 4) (treatment with SITA 50 mg/kg 8 weeks) "CANA" (n = 4) (CANA 25 mg/kg for 8 weeks), "EMPA" (n = 4) (EMPA 2 mg/kg 8 weeks). Also, there was a control group "CRL" (n = 4) treated with vehicle. Blood glucose level (BGL) was studied every 3rd day during the experiment. Blood samples for BTM (osteocalcin, OCL, osteoprotegerin, OPG, RANKL) evaluation were obtained prior to euthanasia.

Results
Treatment with both SITA and EMPA led to moderate increase in OCL level compared with DM (19.57[17.85;24.44], 16.0[15.72;17.0] and 10.69[8.87;11.03] ng/ml respectively) though OCL level did not achieve CRL value (49.1[47.98;54.57]). OCL in "CANA" (9.06[6.21;16.87]) and "EMPA" (16.0[15.72;17.0]) groups was significantly lower than in "SITA" (19.57[17.85;24.44]) and "DM" (19.57[17.85;24.44]) groups. All antihyperglycemic drugs caused decrease in OPG: (6.28[3.06;9.99], 1.26[1.04;1.88] and 1.85[1.19;1.9] pmol/l for SITA, EMPA, CANA, respectively) compared with "CRL" (12.53[11.1;13.7]) and "DM" (14.58[6.12;15.65]). Both SGLT-2 inhibitors led to more prominent decrease in OPG level than SITA (P <0.01). RANKL level in SITA (248.38[220.81;300.96] pmol/l) and EMPA (254.1[231.62;284.0] pmol/l) groups did not significantly differ from CRL one (247.81[205.36;289.67]). At the same time, the use of CANA led to significant increase in RANKL (342.86[280.0;355.29]) in comparison with other glucose-lowering agents. However, the OPG/RANKL ratio did not differ between the CRL (0.53[0.38;0.66]) and DM (0.53[0.19;0.58]) groups and was higher compared with treatment groups (0.24[0.01;0.45] for SITA, 0.005[0.003;0.007] for EMPA and 0.005[0.003;0.007] for CANA). The lowest OPG/RANKL ratio was in the EMPA and CANA groups, with no differences between them.
Conclusions
Both EMPA and CANA decrease osteogenesis and increase bone resorption, while effect of CANA might be more pronounced which manifests in higher RANKL level.

The Hippo pathway is involved in human tumorigenesis and regeneration. Here, we investigated the Hippo co-activator YAP1 and the kinase LATS1/2 in tumors of the parathyroid glands, which are almost invariably associated with primary hyperparathyroidism. Compared with normal parathyroid glands (n = 3), where YAP1 was detectable in the cytoplasm and in the nucleus, parathyroid adenomas (PAds; n = 10) had YAP1 accumulation mainly at the nuclear level, while in parathyroid carcinomas it was reduced at both nuclear and cytoplasmic levels (n = 6; 4 samples harboring *CDC73* inactivating mutations and 2 samples harboring *MEN1* inactivating samples). The kinase LATS1/2, which phosphorylates YAP1 promoting its cytoplasmic degradation and preventing its nuclear accumulation and transcriptional activity, was variably reduced in PAds. *YAP1* and *MEN1* map on chromosome 11, which is frequently interested by loss-of-heterozygosity in PAds; of note, *YAP1* silencing appeared to reduce the expression levels of *MEN1*, while *MEN1* silencing increased *YAP1* expression in PAds-derived cell cultures and in HEK293A cells. Besides, YAP1 nuclear accumulation was induced by the calcium sensing receptor (CASR) agonist R568-mediated activation of the CASR in both PAds-derived cells and HEK293A cells transfected with CASR, and this effect was abolished upon the incubation with RhoA/Rho-associated coiled-coil-containing protein kinase (ROCK) inhibitors Y27632 and H1152. Lastly, CASR activation increased the expression of the YAP1 gene targets *CYR61*, *CTGF*, and *WNT5A*, and the effect was blunted by *YAP1* silencing, suggesting that CASR-induced YAP1 nuclear accumulation is transcriptionally active in PAds-derived cells. Besides, YAP1 silencing did not affect *PTH*, *CASR*, *TBX1*, and *VDR* expression in PAds-derived cells, while YAP1 signaling may be partially involved in R568-stimulated *GCM2* expression levels. Concluding, we provided evidence of the involvement of the Hippo pathway in human tumor parathyroid cells, suggesting a role as tumor suppressor for YAP1 and LATS1/2, and identifying the activation of a CASR-ROCK-YAP1 axis, where CASR activation induces YAP1 transcriptional action, and resistance to $[Ca^{2+}]_o$ may reduce YAP1 nuclear accumulation.

Characterization of sarcopenia via different DXA derived indices and associations with uc-dpMGP

Natascha Schweighofer[1,2], Moritz Strasser[1,2,3], Christoph Haudum[1,2], Albrecht Schmidt[4], Ewald Kolesnik[4], Thomas Pieber[1,2] & Barbara Obermayer-Pietsch[1]
[1]Medical University of Graz, Department of Internal Medicine, Division of Endocrinology and Diabetology, Graz, Austria; [2]CBmed GmbH, Center for Biomarker Research in Medicine, Graz, Austria; [3]FH JOANNEUM, University of Applied Sciences, Department of Health Studies, Institute of Biomedical Science, Graz, Austria; [4]Medical University of Graz, Department of Internal Medicine, Division of Cardiology, Graz, Austria

Sarcopenia is a degenerative loss of skeletal muscle mass, quality, and strength. It increases the risk of falls and fractures, is associated with cardiac and respiratory disease and cognitive impairment and leads to mobility disorders. It decreases quality of life, leads to loss of independence, placement in long-term care and finally death. A variety of indices and parameters can be used to define sarcopenia. According to literature, matrix-GLA-protein (MGP) is associated with bone parameters and cardiovascular risk. We therefore investigated whether uncarboxylated, dephosphorylated MGP (uc-dpMGP) is associated with muscle/fat mass parameters and with sarcopenia defined by dual-energy X-ray absorptiometry (DXA) derived indices and/or hand grip strength (HGS). We analysed data from the BioPersMed cohort (n = 966, 531 females, 435 males, mean age 58 ± 9 years), a prospective elderly cohort of asymptomatic subjects at cardiovascular risk. Uc-dpMGP was measured with IDS-iSYS Ina*K*tif MGP Kit (Immunodiagnostic Systems Holdings PLC, UK). Muscle and fat mass parameters were determined by Lunar iDXA (GE Healthcare GmbH, Austria): ALM: Appendicular lean mass [kg]; LMI: Lean mass index [kg/m^2]; FMI: fat mass index [kg/m^2]; LESM: lower extremity skeletal muscle mass [kg]; TSM: total skeletal mass [kg]; TSMI: total skeletal mass index [kg/m^2]; ALMI^{BMI}: ALM/BMI. HGS was measured via JAMAR@Hand Dynamometer (Patterson Medical, Ltd, UK). Sarcopenia was defined via HGS, SMI (skeletal muscle mass index), LESMI (lower extremity skeletal muscle mass index), AMMI (appendicular skeletal muscle mass index), ASM (appendicular skeletal muscle mass), ALMI (appendicular lean mass index) and with all parameters. Cut off values: HGS [kg]: males: <27; females: <16 (at the weaker hand); SMI [%]: males: <29.9, females: <23.5; LESMI [kg/m^2]: males: 5.1, females: 3.7; ASM [kg]: males: 20, females: 15; AMMI [kg/m^2]: males: 7, females: 5.5; ALMI [kg/m^2]: males: ≤ 65 years: 7.59, > 65 years: 7.64, females: ≤ 65 years: 5.47, > 65 years: 5.78. ALM (P = 0.004), LMI (P = 0.004), FMI (P <0.001), LESM (P = 0.004), TSM (P = 0.014) and TSMI (P = 0.004) correlated positively and ALMI^{BMI} (P <0.001) negatively with uc-dpMGP serum levels. Uc-dpMGP serum levels were significantly higher in persons with sarcopenia according to SMI (P = <0.001), HGS (P = 0.008), AMMI (P = 0.011), ASM (P = 0.001) and all parameters (P <0.001). The number of persons with sarcopenia varied between 29 to 224 according to parameters used for characterization. Uc-dpMGP serum levels might be useful as a biomarker in the characterization of sarcopenia. Dependent on the indices used for its definition.

A rare cause of persistent hyperparathyroidism

Iconaru Laura[1], Spinato Linda[2], Duttmann Ruth[2], Hambye Anne-Sophie[2], Devriendt Arnaud[2], Herchuelz Maxime[2], Mathey Celine[3], Karmali Rafik[2] & Bergmann Pierre[2]
[1]CHU Brugmann, Endocrinology, Bruxelles, Belgium; [2]CHU Brugmann, Bruxelles, Belgium; [3]Hospital Erasme, Bruxelles, Belgium

Ectopic parathyroid tissue remains a significant hurdle in the surgical management of hyperparathyroidism. In diagnostically challenging cases of persistent hyperparathyroidism, unusual ectopic locations of parathyroid adenomas must be considered in order to avoid numerous re-operative explorations and the associated risks to the patient. We present a 30-year-old female was referred to the endocrinology department for symptomatic hypercalcemia. Routine laboratory investigations showed a severe hypercalcemia (corrected serum calcium: 3.4 mmol/l), with an intact parathyroid hormone serum concentration of 269 ng/l. The serum phosphate was low (0.63 mmol/l) and urinary calcium was 5.1 mmol/24 hours (*N*). A ^{99m}Tc sestamibi scintigraphy showed a focus of radioactivity compatible with a hyperfunctioning lower right parathyroid. Thus, the lower right parathyroid gland was excised, with intra-operative testing for parathyroid hormone. Because the PTH value remained high the surgeon decided to remove 2.5 of the 3 remaining parathyroid glands, but the PTH value did not decrease. Pathology revealed 2 hyperplastic, 1 normal parathyroid gland and thymus gland instead of left lower parathyroid. A technetium (^{99m}Tc) sestamibi scan was performed, but the result was not conclusive. The patient underwent a Choline PET/CT, which showed a left retro-pharyngeal active nodule corresponding to a possible ectopic parathyroid tissue. The patient had a successful transoral removal of the lesion with normalization of serum calcium and iPTH after surgery. Pathology confirmed the presence of a parathyroid adenoma (3.2 × 1.7 × 1.2 cm, weighting 3.9 g). The genetic tests showed no mutations in the CDKN1B, MEN and RET genes. In conclusion, we reported a case with persistent hyperparathyroidism after cervical surgery, due to an ectopic retro-pharyngeal parathyroid adenoma for which different imaging techniques and particularly 18F-fluorocholine PET/CT were essential in guiding the surgical approach and enabling the surgeon to successfully locate and remove the ectopic parathyroid.

[1]1st Propedeutic Department of Surgery, AHEPA University Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Department of Minimal Invasive Endocrine Surgery, Interbalkan Medical Center, Thessaloniki, Greece; [3]Unit of Reproductive Endocrinology, 1st Department of Obstetrics and Gynecology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece; [4]Laboratory of Biological Chemistry, Faculty of Medicine, School of Health Sciences, Aristotle University of Thessaloniki, Thessaloniki, Greece; [5]Department of Surgery, Faculty of Medicine, Hashemite University, Zarqa, Jordan; [6]Department of General Surgery, Umraniye Education and Research Hospital, Health Sciences University-Medical Faculty, Istanbul, Turkey

Purpose
Intraoperative imaging of parathyroid glands (PGs) has been developed in order to reduce the risk of unintentional parathyroidectomy during total thyroidectomy. This novel modality is based on their intrinsic characteristic of autofluorescence (AF) after near-infrared light exposure. The aim of this study was to assess the effect of this method on the risk of unintentional PG excision (total or partial) during total thyroidectomy.
Methods
This was a single-blind, randomized, controlled trial including adult patients who underwent scheduled total thyroidectomy between December 2019 and March 2020. These patients were randomly allocated to two groups: one in which near-infrared autofluorescence imaging (NIRAF) was applied (NIR-group) and one without NIRAF (NONIR-group). Hormonal and biochemical assessment was performed pre- and 24 h post-operatively. AF findings and the number of PGs autotransplanted were recorded.
Results
One-hundred eighty patients were eligible. Unintentional (total or partial) PG excision rates during total thyroidectomy in the NONIR ($n = 90$) and NIR ($n = 90$) groups were 28.9% [95% confidence interval (CI) 19.8%–39.4%] and 14.4% (95% CI 7.7%–22.1%), respectively ($P = 0.02$). Furthermore, NIR reduced the risk of parathyroid tissue presence in the specimen sent for pathology (relative risk 0.51, 95% CI 0.28–0.92; $P = 0.02$). However, the number of PGs identified by NIR could not predict the risk of post-operative hypoparthyroidism.
Conclusion
NIRAF imaging during total thyroidectomy led to a significant reduction in PG excision rates. However, this modality did not result in the reduction of post-operative hypoparathyroidism or hypocalcemia risk.

PEP6.6

Cardiovascular events in adult patients with chronic hypoparathyroidism treated with rhPTH(1–84) compared with a historical control cohort

Sanjiv Kaul[1], Olulade Ayodele[2], Nicole Sherry[3], Elyse Swallow[4], Fan Mu[4], Richard Berman[4], Elvira Gosmanova[5] & Lars Rejnmark[6]

[1]Oregon Health & Science University, Portland, USA; [2]Shire Human Genetic Therapies, Inc., A Takeda company, Lexington, USA; [3]Shire Human Genetic Therapies, Inc., A Takeda company, Cambridge, USA; [4]Analysis Group, Inc., Boston, USA; [5]Albany Medical College, Albany, USA; [6]Aarhus University and Aarhus University Hospital, Aarhus, Denmark

This study investigated risk of cardiovascular (CV) events over a period of up to 5 years in adult patients with chronic hypoparathyroidism treated with recombinant human parathyroid hormone (1–84), rhPTH(1–84), compared with a historical control cohort of patients who did not receive rhPTH(1—84). The rhPTH(1–84)-treated patient cohort was derived from the NCT00732615 (REPLACE), NCT01268098 (RELAY), and NCT01297309 (RACE) clinical trials. A control cohort of adult patients who did not receive rhPTH(1–84) or rhPTH(1–34) was selected from the US Explorys electronic medical record database (Jan 2007–Aug 2019) using selection criteria similar to the enrolment criteria used in the trials. Index date was the day after initiation of treatment for the rhPTH(1–84) cohort and the day after the first calcitriol prescription for the control cohort. The primary outcome was the risk of a composite CV event (defined as any event of cerebrovascular disease, coronary artery disease, heart failure, or peripheral vascular disease) in the rhPTH(1–84) cohort compared with the control cohort through 5 years post-index. Patients with a CV event at baseline were excluded from the analysis. Risk of a CV event was assessed in a Kaplan–Meier analysis and a Cox proportional hazards model adjusted for demographic characteristics, baseline clinical conditions, and baseline serum calcium levels. The analysis included 113 patients in the rhPTH(1–84) cohort and 618 patients in the control cohort. Patients in the rhPTH(1–84) cohort, compared with the control cohort, were younger (mean±s.d. age, 47.8±12.0 vs 51.0±16.8 years; $P < 0.05$) and fewer had acute manifestations of hypoparathyroidism before the index date (22.1% vs 69.6%; $P < 0.001$). In a Kaplan–Meier analysis, rhPTH(1–84)-treated patients had a significantly reduced risk of developing a CV event over the 5-year follow-up period compared with patients in the control cohort (3.5% vs 16.3%; $P < 0.01$). The adjusted hazard ratio for developing a CV event associated with rhPTH(1–84) treatment vs no rhPTH(1–84) treatment was 0.23 (95% CI, 0.07–0.74; $P < 0.05$). This analysis is limited by differences in patient management under predefined clinical trial protocols for the rhPTH(1–84) cohort vs real-world clinical practice for the control cohort. Over 5 years, patients with chronic hypoparathyroidism treated with rhPTH(1–84) in clinical trials had a significantly reduced risk of CV events compared with a control cohort of patients who did not receive rhPTH(1–84). Further research is needed to better understand the mechanism underlying the association between chronic hypoparathyroidism and risk of developing a CV event.

PEP6.7

Change in estimated glomerular filtration rate in adult patients with chronic hypoparathyroidism treated with rhPTH(1–84) compared with a historical control cohort

Olulade Ayodele[1], Lars Rejnmark[2], Nicole Sherry[3], Elyse Swallow[4], Allison Briggs[4], Angela Lax[4] & Elvira Gosmanova[5]

[1]Shire Human Genetic Therapies, Inc., a Takeda company, Lexington, USA; [2]Aarhus University and Aarhus University Hospital, Aarhus, Denmark; [3]Shire Human Genetic Therapies, Inc., a Takeda company, Cambridge, USA; [4]Analysis Group, Inc., Boston, USA; [5]Albany Medical College, Albany, USA

Changes in estimated glomerular filtration rate (eGFR) over 5 years were evaluated in adult patients with chronic hypoparathyroidism. A cohort of patients treated with recombinant human parathyroid hormone (1–84), rhPTH(1–84), was derived from NCT01297309 (RACE) and NCT01199614 (HEXT) clinical trials. A historical control patient cohort with hypoparathyroidism who did not receive rhPTH(1–84) or rhPTH(1–34) were from the large national US Explorys electronic medical record database (Jan 2007–Aug 2019) using criteria similar to trial enrolment criteria. Index date was the day after treatment initiation for the rhPTH(1–84) cohort and the day after first calcitriol prescription for the control. The analysis included patients with eGFR ≥60 ml/min/1.73 m^2 during the 6 months before index date, ≥2 eGFR measurements ≥3 months apart during the 5 years on/after the index date, and ≥1 eGFR measurement at 5±0.5 years. For patients from RACE, baseline and study visit data after rhPTH(1–84) initiation were collected from antecedent trials. Changes in eGFR were assessed in linear mixed and multivariable models (adjusted for age/sex/race, baseline eGFR, history of hypercalciuria/hypertension/type 2 diabetes [T2D]/acute hypoparathyroidism manifestations/cardiovascular condition). There were 72 patients in the rhPTH(1–84) cohort and 174 in the control cohort. Before the index date, patients in the rhPTH(1–84) cohort, compared with the control, were younger (mean±S.D., 47.5±11.0 vs 53.9±15.5 years; P <0.01), and a lower proportion had acute manifestations of hypoparathyroidism (22.2% vs 69.0%; P <0.001) and T2D (2.8% vs 17.8%; P <0.001). Over 5 years, the difference in rate of eGFR change between the 2 cohorts was 1.45 ml/min/1.73 m^2 per year and 1.33 ml/min/1.73 m^2 per year, in unadjusted and adjusted linear mixed models, respectively (both P <0.001). Over 5 years, eGFR was relatively stable in the rhPTH(1–84) cohort, but declined in the control at a rate of −1.58 ml/min/1.73 m^2 per year (unadjusted model, P <0.001), and −1.57 ml/min/1.73 m^2 per year (adjusted model, P <0.001). By year 5, patients in the rhPTH(1–84) and control cohort were predicted to have eGFR changes from baseline of +1.51 ml/min/1.73 m^2 and −10.48 ml/min/1.73 m^2, respectively. Data interpretation is limited by differing patient management (ie, predefined trial protocols and clinical practice for the control). In patients with chronic hypoparathyroidism, the annual rate of eGFR decline over 5 years was significantly lower in patients treated with rhPTH(1–84) compared with controls not treated with rhPTH(1–84). These results support a prior analysis of data from the same trials and a regional US health record database.[1]

PEP6.8

Risk of chronic kidney disease in adult patients with chronic hypoparathyroidism treated with rhPTH(1–84) compared with a historical control cohort

Elvira Gosmanova[1], Olulade Ayodele[2], Nicole Sherry[3], Fan Mu[4], Allison Briggs[4], Elyse Swallow[4] & Lars Rejnmark[5]
[1]Albany Medical College, Albany, USA; [2]Shire Human Genetic Therapies, Inc., A Takeda company, Lexington, MA, USA; [3]Shire Human Genetic Therapies, Inc., A Takeda company, Cambridge, USA; [4]Analysis Group, Inc., Boston, USA; [5]Aarhus University and Aarhus University Hospital, Aarhus, Denmark

This study evaluated risk of chronic kidney disease (CKD) outcomes over a period of up to 5 years in adult patients with chronic hypoparathyroidism treated with recombinant human parathyroid hormone (1–84), rhPTH(1–84), compared with a historical control cohort of patients who did not receive rhPTH(1–84). The cohort of patients with chronic hypoparathyroidism treated with rhPTH(1–84) was derived from the NCT00732615 (REPLACE), NCT01268098 (RELAY), NCT01297309 (RACE) and NCT01199614 (HEXT) clinical trials. The control cohort of adult patients who did not receive rhPTH(1–84) or rhPTH(1–34) was selected from the US Explorys electronic medical record database (Jan 2007–Aug 2019), using criteria similar to the enrolment criteria used in the trials. Index date was the day after treatment initiation for the rhPTH(1–84) cohort, and the day after the first calcitriol prescription for the control cohort. Patients with CKD at baseline (defined as estimated glomerular filtration rate [eGFR] <60 ml/min/1.73 m^2 at the closest eGFR measurement before the index date) were excluded. All included patients had ≥1 eGFR measurement within 6 months before the index date and ≥2 eGFR measurements ≥3 months apart during the 5 years on or after the index date. The CKD outcome was defined as first occurrence of eGFR <60 ml/min/1.73 m^2 confirmed by a second measurement ≥3 months after. Risk of CKD was assessed in a Kaplan–Meier analysis and a Cox proportional hazards model adjusted for demographic characteristics, baseline clinical conditions, and baseline laboratory measurements. The analysis included 118 patients in the rhPTH(1–84) cohort and 478 patients in the control cohort. Patients in the rhPTH(1–84) cohort, compared with patients in the control cohort, were younger (mean±S.D. age, 45.3±11.4 vs 51.5±16.2 years; P <0.001) and a lower proportion had acute manifestations of hypoparathyroidism before the index date (15.3% vs 73.2%; P <0.001). In Kaplan–Meier analysis, rhPTH(1–84)-treated patients had a significantly reduced risk of developing CKD during follow-up compared with patients in the control cohort (11.0% vs 27.0%; P <0.01). The adjusted hazard ratio of developing CKD associated with rhPTH(1–84) treatment vs no rhPTH(1–84) treatment was 0.47 (95% CI, 0.25–0.88; P <0.05). Patients with chronic hypoparathyroidism treated with rhPTH(1–84) in long-term clinical trials had a significantly reduced risk of developing CKD compared with patients in a control cohort who did not receive rhPTH(1–84). These results should be viewed in light of possible treatment differences in the studied cohorts (ie, predefined trial protocols vs real-word practice for the control cohort).

Diabetes, Obesity, Metabolism and Nutrition

PEP7.1

Effects of testosterone therapy on morphology and grade of NAFLD in obese men with functional hypogonadism and type 2 diabetes

Kristina Groti Antonic
University Medical Center Ljubljana, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia

Aims
Non-alcoholic fatty liver disease (NAFLD) is emerging as a public health issue worldwide, is highly prevalent in patients with type 2 diabetes (T2D), and is linked to obesity, insulin resistance and atherogenic dyslipidemia. We aimed to evaluate effects of testosterone therapy (TTh) on morphology and grade of NAFLD in obese men with functional hypogonadism (FH) and T2D.
Research design and methods
55 obese males with FH and T2D participated in a two-year (first year double-blind, placebo-controlled study, second year follow-up) clinical trial. Total, calculated free and calculated bioavailable testosterone levels, fasting plasma glucose, glycated hemoglobin A_1c, lipids (total cholesterol, LDL cholesterol, HDL cholesterol, triglycerides), prostate specific antigen, routine blood tests (complete blood count, electrolytes, urea, creatinine, liver tests) were assessed at baseline, 12 and 24 months. Liver ultrasounds for NAFLD grade assessments were performed at the beginning and after two years. *T*-test and Wilcoxon's signed rank were used to detect changes from baseline. Normality of distribution of data was assessed with Shapiro–Wilk test.
Results
Participants were randomized into two groups. Group T (n = 28) received 1000 mg testosterone undecanoate (TU) both years of the study while group P (n = 27) received placebo first year and TU second year. Liver assessment showed improvement in NAFLD grades at statistically significant level (P <0.001) after two years of TRT. TTh normalized testosterone levels in both groups within first year and stayed in normal range after the second year of the study. No adverse events (prostate carcinoma, cardiovascular events) or side effects of TRT have been observed over the two-year course of this trial.
Conclusions
Two-year therapy with testosterone undecanoate normalized serum testosterone levels, reduced NAFLD grade, and quells the symptoms of hypogonadism in obese men with functional hypogonadism and T2D.

Nutrition, Las Palmas de Gran Canaria, Spain; [2]Hospitales San Roque Meloneras, Endocrinology & Nutrition, San Bartolome de Tirajana, Spain; [3]Hospitales San Roque Vegueta, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [4]Clinica Cajal, Family & Community Medicine, Las Palmas de Gran Canaria, Spain; [5]Centro de Salud Guanarteme, Las Palmas de Gran Canaria, Spain; [6]Hospital Universitario de Gran Canaria Dr. Negrín, Outpatient Hypertension Clinic, Las Palmas de Gran Canaria, Spain

Introduction
Anorexia nervosa is a severe and potentially lethal eating disorder. We report hereby the cases of two female-to-male transsexual patients whose anorexia nervosa was promptly resolved when they started gender-affirming hormone therapy.
Methods
Review of the patients' clinical records and of the relevant literature.
Case reports
A 15 year-old male transexual with Asperger syndrome and intense gender dysphoria did not start the recommended LHRH agonist treatment at the Tanner II puberty stage by age 11 because parental consent was not obtained. He developed a severe eating disorder diagnosed as anorexia nervosa which required interment in a specialized unit and forced nutrition. By his 14 birthday he weighed 34 kg with a height of 162 cm (BMI <13 kg/m^2). He had Tanner III axilarche and pubarche, Tanner II thelarche, and no menarche. At the age of 14 year 6 months parental consent for gender-affirming therapy was obtained and the patient began treatment with LHRH agonist and progressive transdermal testosterone treatment up to 60 mg/day. One year later his eating habits were normal, his BMI was 19.85 kg/m^2 (Height 177 cm, weight 62.2 kg), his FSH, LH and testosterone were in the normal male range and had no nutritional deficit except for low vitamin D. A 20 year-old male transsexual was interned due to extremely severe anorexia nervosa, with BMI < 11 kg/m^2, and inability to walk. He reported that he had gender dysphoria since childhood but had never expressed it. He had undergone female pubertal development with normal menses until the onset of anorexia nervosa, and had intense dysphoria centered in his breast development. When gender-affirming hormonal therapy and mastectomy were offered, he accepted nasogastric feeding and was discharged with parenteral testosterone treatment. 14 months later his eating habits are normal, his BMI is 20.4 kg/m^2, his FSH, LH and testosterone are in the normal male range and he has no nutritional deficit, but his mastectomy is still pending due to the COVID-19 pandemic.
Conclusion
In transsexual patients with severe gender dysphoria, a severe eating disorder (proposed name: dysphorexia), coherent with anorexia nervosa may be triggered by the desire to avoid the cisgender puberal transition. In these patients, gender-affirming hormone therapy can be extremely effective. We postulate that avoiding the cisgender puberal development with LHRH agonist treatment might be able to prevent the development of anorexia.

Dapagliflozin improves transaminitis in non alcoholic fatty liver disease among adults with type 2 diabetes

Hariballav Mahapatra[1,2], Laxminarayan Mahapatra[1], Monalisa Khuntia[1], Abhay Kumar Sahoo[2] & Soumya Sucharita[1]
[1]Sevayan Diabetes Centre, Puri, India; [2]IMS & SUM Hospital, SOA University, Bhubaneswar, India

Use of SGLT2 inhibitors are increasing worldwide due to its potential antihyperglycemic role. Additionally they have shown to be beneficial in reducing the cardiac and renal complications in diabetes. There are sporadic reports to show their effects on liver enzymes. We did a single centre, open label, prospective trial to evaluate the role of dapagliflozin on hepatic enzymes in diabetic patients with non alcoholic fatty liver disease (NAFLD). Abdominal sonography was used to diagnose NAFLD. Individuals who were on hepatotoxic drugs or other drugs that could alter the liver enzymes or those who were alcoholics or had a history of liver disease were excluded. None of the participants were prescribed SGLT2i before. Subjects were randomly assigned to receive either dapagliflozin or placebo. Fasting blood sample was collected for HbA1c, AST & ALT measurement at study enrollment and then after 12 weeks of intervention. Antidiabetic therapy was continued and no other change in the treatment regimen was made during the study period. Paired t test was adopted for the statistical comparison between the groups. A total of 232 patients (M/F 137/95) were recruited for the study, with 131 persons (M/F 73/58) in the dapagliflozin arm and 101 subjects (M/F 64/37) in the placebo arm. Mean values for duration of diabetes (10.9±7.0 and 11.0±6.1 years), HbA1c (8.6±1.8% and 8.8±1.2%), AST (43.6±10.1 mg/dl and 41.1±15.1 mg/dl) and ALT (47.5±12.2 mg/dl and 42.5±16.5 mg/dl) were comparable in both the groups at baseline. Post treatment, in contrast to the placebo arm, HbA1c in the dapagifozin arm declined significantly to reach 7.73±1.4% (P <0.001). Similarly, the aminotransferases showed substantial improvement in the dapagliflozin arm (P <0.05), whereas there was no change in those values in placebo arm (P 0.61). Dapagliflozin also helped to reduce body weight of the individuals significantly during the course of the therapy. In addition to reducing HbA1c and weight, Dapagliflozin also significantly improves transaminitis in diabetic adults with non alcoholic fatty liver disease.

Predictors of glucagon-like peptide-1 responses following oral glucose tolerance test in 3 ethnic groups of Malaysia

Shiau Chin Chong[1], Norlela Sukor[1], Sarah Anne Robert[2], Kim Fong Ng[3] & Nor Azmi Kamaruddin[1]
[1]The National University of Malaysia Medical Centre, Endocrinology Unit, Kuala Lumpur, Malaysia; [2]The National University Of Malaysia Medical Centre, Pharmacy, Kuala Lumpur, Malaysia; [3]Hospital Sultanah Aminah, Cardiology, Johor Bahru, Malaysia

Introduction
Glucagon-like peptide-1 (GLP-1) plays an important role in the pathophysiology of type 2 diabetes mellitus (T2DM). However, results from previous studies on the GLP-1 secretory responses in individuals with different glucose tolerance states remain controversial. This may be contributed by the heterogeneous characteristics of the patients recruited.
Aim
To examine whether GLP-1 secretion is affected by any of the demographic or metabolic parameters in 3 ethnic groups of Malaysian cohort.
Methods
In this cross sectional study, 171 subjects consisting of Malays, Chinese and Indians, were divided into normal glucose tolerance (NGT) (n = 57), prediabetes (n = 54) and T2DM (n = 60) after undergoing a 75 g oral glucose tolerance test (OGTT). Plasma total GLP-1 concentrations were measured at 0, 30 and 120 min during OGTT. As an index of GLP-1 secretory response, area under the curve (AUC) of GLP-1 (AUC_{GLP-1}) was calculated by trapezoidal rule. Relationships between parameters were examined by using stepwise multiple linear regression analyses.
Results
Using AUC_{GLP-1} as a depedent parameter, age, gender, ethnicity, systolic blood pressure (SBP), fasting total cholesterol and fasting triglyceride explained 27% (adjusted r^2) of the variation of GLP-1 response following OGTT. There was a strong positive association between increasing age and AUC_{GLP-1} (B = 44.81, P <0.001). Male had higher GLP-1 response to OGTT than female (B = −881.49, P = 0.043). Ethnicity was a significant determinant of AUC_{GLP-1} with the Indians exhibiting higher GLP-1 secretion than the Malays (B = 932.23, P = 0.005). AUC_{GLP-1} was negatively correlated with triglyceride (B = −676.38, P = 0.02). In contrast to our expectation, AUC_{GLP-1} was positively associated with increased SBP (B = 16.08, P = 0.039) and total cholesterol (B = 571.57, P = 0.031). No association was detected between AUC_{GLP-1} and body mass index, waist circumference, HbA1c, fasting insulin and fasting glucose.
Conclusions
In Malaysian cohort, older age, male and Indians had higher GLP-1 responses following OGTT. These demographic factors need to be taken into account when studying GLP-1 secretory responses between T2DM patients and healthy controls. Subjects with increased fasting triglyceride level had lower GLP-1 responses. The positive relationship between GLP-1 response and risk factors which increase insulin resistance such as high total cholesterol and increased SBP might involve an adaptive response and require further study.

Impact of SARS-CoV-2 lockdown and seasonal variations on diabetes compensation: a retrospective study in a tertiary setting in Switzerland

Stefan Zechmann[1], Leana Hotz[2], Stefania Di Gangi[3], Klaus Baumgartl[4], Andreas Plate[3] & Eliska Potlukova[5]
[1]University Hospital of Basel, Endocrinology, diabetes and metabolism, Basel, Switzerland; [2]University of Basel, Faculty of Medicine, Basel, Switzerland; [3]University Hospital of Zurich, Institute of Primary Care, Zurich, Switzerland; [4]University Hospital of Basel, Department of Information and Communications Technology, Basel, Switzerland; [5]University Hospital of Basel, Internal Medicine, Basel, Switzerland

Introduction
Metabolic compensation of patients with diabetes mellitus (DM) depends on psychosocial well-being and healthy lifestyle, both of which were influenced by the national lockdown in spring 2020 due to the SARS-CoV-2 pandemic. The goal of our study was to analyze the impact of Swiss national lockdown (17.3.2020–24.4.2020) on compensation of DM as expressed by the level of HbA1c.
Methods
We performed a retrospective observational study using electronic health records of the University Hospital Basel. Patients with DM with at least one HbA1c measurement before and one after the begin of the lockdown were included. The observation period was 16.12.2018–27.07.2020. Time periods three months before (winter) and four months after the begin of the lockdown (spring) were defined and compared to corresponding time periods one year before. Patient determinants affecting HbA1c values were identified using a mixed-model regression multivariable analysis.
Results
We included 1078 patients in our analyses (925 type 2 DM, 145 type 1 DM, 8 other). Metabolic compensation was susceptible to seasonal changes with HbA1c highest in January with mean (standard deviation, s.d.) 7.60% (1.68), and lowest in July with mean (s.d.) 7.29% (1.67). In patients with type 2 DM, HbA1c decreased more in spring 2020 as compared to 2019 (difference of means 2020 = −0.22%, 95% confidence interval (CI): −0.058, −0.39, $P = 0.008$; vs. difference of means 2019 = −0.15%, 95% CI: −0.33, 0.03, $P = 0.1$), respectively. The differences in type 1 DM were not significant. Subgroup analysis of 241 patients with HbA1c in all analyzed periods yielded no significant change in HbA1c after the lockdown. Inappropriate alcohol intake was identified as a risk factor for increased HbA1c after lockdown (OR 1.69, 95% CI: 1.03, 2.75). Number of hospitalizations per patient decreased significantly after the lockdown (winter 2019/2020 mean (s.d.) 1.42 (0.83) vs. spring 2020, 1.24 (0.55) $P = 0.028$). The lockdown led to no significant change in weight (mean difference = 1.72 kg, 95% CI: −5.07, 1.63, $P = 0.314$).
Conclusion
Metabolic compensation of patients with DM undergoes marked seasonal variations, with highest HbA1c in winter and lowest in summer. Contrary to expectations, HbA1c in patients with type 2 DM did not increase in four months after the begin of national lockdown but decreased to the same values as the year before.

Effect of Yogic technique Shavasana in T2DM patients on BP, blood sugar fluctuations and Sleep Quality

Shweta Saboo[1], Bharat Saboo[2], Aniket Inamdar[3] & Hemant Sharma[4]
[1]Choithram College Indore, Yoga, Shri Ram Talawali, India; [2]Prayas Diabetes Center, Diabetology, Indore, India; [3]Samarpan Clinic, Diabetology, Omerga, India; [4]Choithram College Indore, Yoga, Indore, India

Background
Diabetes is a multi-systemic disorder and psychosocial stress is a contributor for glycaemic derangement and resulting complications. Covid-19 has bought psychological stress and restriction of activity for many. Psychological risk factors such as anxiety and depression have been associated insomnia and fluctuations in BP and blood sugar values. Shavasana and other relaxation techniques have long been shown to reduce the stress. This relaxation can be utilized for reducing stress and resultant effects on health.
Aim
To see the effect of Shavasana a yoga-based stress reduction technique on blood sugar fluctuations, blood pressure rise and insomnia in diabetic patient during stressful situations during covid-19 Lockdown.
Method
120 patients, (35–65 years) with HTN and controlled T2DM in the past 2 years were randomly allocated to two groups of 60 persons each. Intervention was carried out at home base setting via web Parallel group – Shavasana group; and treatment-as-usual group (TAU). Therapeutic intervention comprised Shavasana practice 15 min daily at bedtime with walk for 15 min daily. The other 60 patients were only doing walk 15 min daily along with their usual treatment. (TAU Group). The participants were surveyed for blood sugar fluctuations, insomnia, ESS (Epworth Sleepiness Score), rise in BP more than 30 mmHg systolic from baseline measured daily.
Results
All patients completed intervention in the Shavasana practicing group. 2 patients left TAU group as they suffered other problems. Shavasana group had less incidence of blood sugar fluctuations 12% and 35% in TAU group. Insomnia was less in Shavasana group 13% as compare to TAU group 42 %. incidence of rise in systolic BP were 16% in Shavasana group as compared to 38% in TAU group. The Shavasana group had a lower ESS Score as compared to the TAU group.
Discussion
Shavasana based stress reduction techniques are beneficial in reducing stress and resulting in better sleep and less fluctuations in blood sugar and blood pressure values. There is a need to focus on these sorts of stress relaxation techniques as they could prove a handy tool in reducing the day-to-day stress and resulting adverse effects. Also, improvement in sleep quality and sleep patterns can promote health and reduce the adverse metabolic outcome due to insomnia. More studies should be conducted with various stress reduction techniques to see as to what helps most. These techniques can act as an additive treatment and reduce the pill burden and adverse outcomes.

The impact of dipper profile on diabetes complications. A study of 197 diabetic patients

Vitória Duarte, Catarina Ivo, David Veríssimo, Joao Silva, Luis Lopes, Dolores Passos, J Jácome Castro & Mafalda Marcelino
Hospital das Forças Armadas, Lisbon, Portugal

Background
Non-dipping of nocturnal blood pressure is common among people with type 2 diabetes (T2D) and hypertension. Although the mechanism underlying *the* blunted nighttime response is unclear, insulin resistance is thought to play a role.
Aims
This study aims to identify the pattern of nocturnal dipping of blood pressure in patients with T2D from a Portuguese population and its association with micro and macrovascular complications.
Methods
Data was collected from 197 patients with T2D and hypertension who had undergone 24 h ambulatory blood pressure (BP) monitoring. We assessed the correlations of different dipper profiles with the presence of diabetic complications. All statistical analyses were conducted using SPSS. Chi-square test was performed to evaluate the association between the variables. A P value ≤ 0.05 was considered to be significant.
Results
There were a total of 197 subjects (mean age 70) including 155 men and 42 women. The *mean time since diagnosis* of *diabetes* mellitus was 13.5 years. The prevalence of coronary artery disease (CAD), cerebrovascular disease, retinopathy and nephropathy was 20%, 13%, 9% and 29%, respectively. Normal dipping was observed in 33%, non-dipping in 39%, extreme dipping in 22% and 6% were risers. Regarding micro and macrovascular disease, 42% of dippers and extreme dippers presented at least one complication, versus 58% of non-dippers ($P < 0.05$). Non dippers and risers were significantly older ($P < 0.01$) with a higher prevalence of CAD ($P = 0.03$) and retinopathy ($P = 0.05$). No difference was found in other diabetes complications.
Discussion
Extreme dipping was found in more than a fifth of patients, reporting a higher prevalence than most studies. It has been proposed that extreme-dipping may have a significantly higher risk of silent myocardial ischemia. However, we found no increased risk of complications in this cluster. On the contrary, the prevalence of CAD in extreme dippers was 7% vs. 20% in dippers. Hypertension and nephropathy often coexist in patients with diabetes. Nonetheless, we did not observe any association between dipping status and nephropathy in this population. Our results indicate loss of nocturnal BP dipping as a risk factor for CAD and retinopathy in patients with T2D. This

highlights the importance of ambulatory BP monitoring, particularly in the elderly population. Therefore, targeted antihypertensive therapy should be implemented in order to restore normal circadian BP in patients with T2D.

Cholesterol-free ketogenic diet administration ameliorates experimental metabolic syndrome

Emanuela Agosti[1], Simone Reano[2], Alessia Provera[1], Laila Lavanya Gadipudi[1], Naresh Naik Ramavath[1], Antonio Colasanto[3], Davide Raineri[1], Emanuele Albano[1], Nicoletta Filigheddu[2], Marco Arlorio[3], Jean Daniel Coisson[3], Annalisa Chiocchetti[1], Salvatore Sutti[1] & Flavia Prodam[1]
[1]University of Piemonte Orientale, Department of Health Sciences, Novara, Italy; [2]University of Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [3]University of Piemonte Orientale, Department of Pharmaceutical Sciences, Novara, Italy

Background and aims
Metabolic syndrome (MetS) is a pathologic condition characterized by abdominal obesity, insulin resistance, hypertension, and dyslipidemia. The prevalence of MetS parallels the rise of obesity rate reaching pandemic proportions due to the increased consumption of high-calories-high-fat-high-carbohydrates low-fibers diet associated with a sedentary lifestyle. MetS is associated with a plethora of comorbidities as non-alcoholic fatty liver disease (NAFLD). Noteworthy, NAFLD is considered the hepatic manifestation of MetS, and it can further progress to non-alcoholic steatohepatitis (NASH) that, in its turn, can evolve to cirrhosis and hepatocellular carcinoma (HCC). Despite the clinical relevance of NAFLD/NASH, however, effective therapy is still lacking. Lifestyle changes, including diet and physical activity, are so far the most effective interventions in NAFLD. Referring to nutritional approaches, however, there is not a definitive agreement concerning the dietary regimen to introduce into clinical practice. In this study, we investigated the capacity of a cholesterol-free ketogenic diet (KD) to improve pathological parameters associated with experimental MetS.
Methods
MetS was induced in C57BL/6 mice by feeding with a cholesterol-enriched western diet (WD) up to 16 weeks followed by the switching to KD for further 8 weeks. WD and KD were chemical characterized through GC and SD-PAGE analysis.
Results
KD administration in MetS mice significantly improved the liver pathological manifestations by lowering the gene expression of pro-inflammatory/fibrogenetic markers such as CCl2, IL-12, CD11b, OPN, Gal-3, TGF-β and α1-procollagen. Furthermore, KD feeding decreased the hepatic content of triglycerides and the hepatocellular damage, as testified by the reduction in ALT release. These observations were further supported by the histological analyses that revealed a significant amelioration in the extent of steatosis, necro-inflammation, and collagen fibers deposition, as confirmed by the Sirius-red staining in KD-fed mice. Interestingly, KD reduced the splenomegaly observed in WD-fed mice suggesting a reduction in chronic systemic inflammation. Finally, KD feeding ameliorated WD-induced muscle atrophy as confirmed by the recovery of the gastrocnemius mass. Microbiota analyses are ongoing.
Conclusion
Altogether these results suggest that cholesterol-free ketogenic diet administration might represent a potential therapeutic strategy for MetS.

Vladimirsky Moscow Regional Research Clinical Institute, Russian Federation; [4]Novosibirsk State Medical University, Russian Federation; [5]Interregional Clinical Diagnostic Center, Russian Federation; [6]Northwestern University Feinberg School of Medicine, USA; [7]University of Belgrade, Serbia; [8]Antrium Multidisciplinary Medical Clinic, Russian Federation; [9]Hospices Civils de Lyon, France; [10] Chiasma Inc., Israel; [11]Chiasma Inc., USA; [12]Chiasma Inc., Israel; [13]Allegheny General Hospital, USA; [14]Vilnius City University Hospital, Lithuania; [15]Kaunas University Clinics, Lithuania; [16]Cedars Sinai Medical Center, USA; [17]Charité – Campus Mitte (Berlin), Germany

Background
Patients with acromegaly may have high symptom burden. The phase 3 MPOWERED trial assessed control of acromegaly by oral octreotide capsules (OOC; MYCAPSSA®) in comparison to injectable somatostatin receptor ligands (iSRLs) in patients responding to both OOC and iSRLs. iSRLs have been first-line medical treatment for patients with acromegaly for decades. OOC are newly approved in the US for patients previously controlled on iSRLs.
Methods
Eligibility criteria for MPOWERED included acromegaly diagnosis, biochemical control of acromegaly (insulin-like growth factor I <1.3 × upper limit of normal; mean integrated growth hormone, <2.5 ng/ml) and ≥6 months' iSRL (octreotide, lanreotide) treatment. Eligible patients entered a 26-week Run-in phase to determine the effective OOC dose; responders at week 24 then entered a 36-week randomized controlled treatment (RCT) phase receiving OOC or iSRLs. Acromegaly symptom number and severity (mild to severe, 1–3) were collected. Total score was calculated by summating all severity scores (Acromegaly Index of Severity [AIS]). Symptom results were assessed using total AIS score and proportion of patients experiencing individual symptoms.
Results
At beginning of Run-in, average AIS score of 92 randomized patients was 4.52, representative of symptoms experienced while previously receiving iSRLs. After 26 weeks' OOC treatment at end of Run-in, average AIS score was significantly reduced to 3.46 (P <0.001). More than 80% of patients on OOC improved or maintained AIS score during Run-in compared to baseline. Over this 26-week period, there was a significant reduction in extremity swelling (P = 0.01) and fatigue (P = 0.03). During the RCT, of patients randomized to OOC (n = 55), 73% maintained or improved AIS score, and 75% maintained or reduced overall number of active symptoms. In comparison, 68% of those randomized to iSRLs (n = 37) maintained or improved AIS score, and 70% maintained or reduced overall number of active symptoms.
Conclusion
Results from MPOWERED show that patients receiving OOC had significant improvement in number and severity of acromegaly symptoms after switching from iSRLs. These findings validate previous results from a phase 3 study of OOC in acromegaly in which patients switching to OOC from iSRLs showed significant reduction in joint pain, extremity swelling, and fatigue.[1]

Antioxidant response to DNA oxidative damage in adult growth hormone deficiency: a pilot study

Edoardo Vergani[1], Carmine Bruno[1], Francesco Guidi[1], Flavia Angelini[1], Paola Lanza[1], Luigi Aversa[1], Cesare Gavotti[1], Andrea Silvestrini[2] & Antonio Mancini[2]
[1]Catholic University of the Sacred Heart, Dipartimento di Medicina e Chirurgia Traslazionale, Università Cattolica del Sacro Cuore, Rome – Italy; [2]Catholic University of the Sacred Heart, Dipartimento di Scienze biotecnologiche di base, cliniche intensivologiche e peri-operatorie, Università Cattolica del Sacro Cuore, Rome – Italy

Adult growth hormone deficiency (GHD), a condition characterized by increased oxidative stress (OS), is related to augmented cardiovascular, metabolic and oncological risk. Thymidine-glycol (ThyG) (5,6-dihydro-5,6-dihydroxy-2'-deoxythymidine) is a marker of DNA oxidation produced when thymidine is damaged by hydroxyl radicals. It is considered a specific marker since it is not incorporated in RNA; while 8-OH-deoxyguanosine, a well-known marker of oxidative damage, is rapidly excised from DNA and excreted in the urine, ThyG remains in tissues, thus representing an appropriate marker for oxidative tissue

DNA damage. A case–control observational study has been performed to evaluate DNA oxidative damage analysing the production of ThyG in lymphocytes and its correlation with plasma antioxidant levels, evaluated as Total Antioxidant Capacity (TAC). GHD was diagnosed using GHRH 50 μg iv + arginine 0.5 g/kg test, with peak GH response <9 μg/l when BMI was <30 kg/m^2 or <4 μg/l when BMI was >30 kg/m^2. 16 patients, 9 males and 7 females, were classified as total GHD group; 11 patients, 5 males and 6 females, with GH peak between 9 and 16 ng/ml were considered as partial GHD group. Finally, 12 subjects, 7 males and 5 females, with GH peak > 16 ng/ml were included as control group. Age in total GHD group ranged from 37 to 70 years, in partial GHD group from 24 to 70 years and from 23 to 70 years in control group. Median ± interquartile BMI were 27.14 ± 2.85 kg/m^2, 26.23 ± 8.36 kg/m^2 and 22.51 ± 1.26 kg/m^2 in total GHD, partial GHD and control respectively. ThyG, TAC and IGF-1 have been determined respectively in lymphocytes, plasma and serum samples. ThyG levels were examined and interpreted with an optical microscope by three readers independently, who gave, respectively, a score from 1 to 5; the mean of the three evaluations was considered for each sample. When considering ThyG, we found a significant difference between total vs partial GHD and controls (mean ± S.E.M. 2.25 ± 0.4; 3.21 ± 0.47; 3.64 ± 0.49, respectively). Unexpectedly ThyG was lower in total GHD. The last datum was accompanied with a significant increase in plasmatic TAC, which was higher in total GHD vs the other two groups (70.00 ± 3.14; 47.14 ±ට.65, 43.75 ± 1.83 s, respectively). Our results showed that in adult GHD, the production of antioxidant species, in response to increased oxidative stress, could exert a protective effect on ThyG formation, and consequently on DNA intracellular damages.

Background
Oral octreotide capsules (OOC; MYCAPSSA®) are approved in the US for individuals with acromegaly who responded to and tolerated treatment with injectable somatostatin receptor ligands (iSRLs). Add-on cabergoline therapy has shown effectiveness in patients previously inadequately controlled with iSRLS.[1] The phase 3 MPOWERED trial assessed maintenance of response with OOC compared to iSRLs. Patients receiving OOC and ineligible for randomized controlled treatment (RCT) phase were eligible for a sub-study evaluating combination therapy with cabergoline, a dopamine agonist.
Methods
Patients who fail to respond to 80 mg/d OOC for ≥2 weeks during the 26-week Run-in phase, or ineligible to enter the RCT on 80 mg/d OOC, due to inadequate biochemical control (insulin-like growth factor I [IGF-I] ≥1.3 × upper limit of normal [ULN] to <2 × ULN or IGF-I <1.3 × ULN and mean integrated growth hormone [GH] ≥2.5 ng/ml) were eligible for sub-study combination OOC 80 mg/d and cabergoline ≤3.5 mg/week (fixed algorithm) for 36 weeks. End points included categorical changes in IGF-I and mean GH levels at sub-study end and adverse event (AE) incidence and severity. Echocardiogram was performed at sub-study start and every 12 weeks after.
Results
Of 146 patients enrolled in MPOWERED, 14 entered the combination sub-study, 9 having IGF-I ≥1.3 × ULN at sub-study start. Final cabergoline doses were 1 (n = 5), 2 (n = 3), 3 (n = 1), and 3.5 mg (n = 5) with 25.4-week (S.D., 14.1) mean treatment duration. Week 36 IGF-I improved in most patients (n = 12; 85.7%). Of 9 patients with IGF-I ≥1.3 × ULN at sub-study start, 5 (55.6%; 95% CI, 21.2%–86.3%) exhibited IGF-I decreased to predefined responder range (<1.3 × ULN) by week 36. AE incidence and nature with combined treatment were similar to known octreotide safety profile and acromegaly disease burden. There were no serious AEs or AEs leading to discontinuation of either sub-study drug.
Conclusion
We have shown for the first time the benefit of an all-oral combination treatment for acromegaly and avoidance of injection-related burdens. Addition of cabergoline to OOC yielded biochemical control improvement (IGF-I reduction) in patients inadequately controlled with OOC monotherapy. As both combination and OOC monotherapy safety profiles were similar, adjunctive cabergoline may be helpful in patients with acromegaly who do not achieve adequate biochemical control on OOC alone.

Whole exome sequencing (WES) reveals oligogenic aetiology in a case of combined pituitary hormone deficiency (CPHD)

Amalia Sertedaki[1], Elizabeth Tatsi[1], Ioannis Anargyros Vassilakis[1], Eirini Nikaina[2], Eirini Fylaktou[1], Nikoletta Iacovidou[3], Soultana Siahanidou[2] & Christina Kanaka-Gantenbein[1]
[1]National and Kapodistrian University of Athens, Division of Endocrinology, Diabetes and Metabolism, First Department of Pediatrics, Medical School, Athens, Greece; [2]National and Kapodistrian University of Athens, Neonatology Unit, First Department of Pediatrics, Medical School, Athens, Greece; [3]National and Kapodistrian University of Athens, Department of Neonatology, Medical School,Aretaieio Hospital, Athens, Greece

Background
CPHD is characterized by GH and at least one other pituitary hormone deficiency. Mutations in genes expressed in the developing head, hypothalamus, and/or pituitary cause CPHD. To date around 30 genes have been identified to be related to CPHD, however 85% of the cases remain with unknown molecular aetiology.
Patient and methods
A newborn boy (46,XY) delivered by CS due to IUGR with a birthweight of 2200 g, presented with refractory hypoglycemia and mild hypotonia. On physical examination he had micropenis with bilaterally palpable small testes. Endocrinological work up revealed secondary hypothyroidism, secondary adrenal insufficiency and hypogonadotropic hypogonadism (HH). MRI scan of the hypothalamic–pituitary region depicted hypoplastic anterior pituitary and ectopic posterior pituitary lobe with absence of pituitary stalk. WES was carried out on an Ion Torrent S5 platform, aligned to hg19 and annotated by Varaft. An *in silico* panel of 120 genes related to CPHD was employed to select variants (MAF values <1%). The pathogenic variants selected were verified by Sanger sequencing.
Results
Four heterozygous variants were found to be related to the patient's phenotype in four genes. Two of them were maternally inherited: *BMP4;* p.A42P and *NR4A*1; p.P148L and 2 paternally inherited: *GNRH;* p.Arg73X and *SRA1;* p.Q32E.
Conclusions
We speculate that a synergistic action of these gene variants may underlie our patient's phenotype. *BMP4* plays significant role in early organogenesis, pituitary development and function. *BMP4;* p.A42P has been described in a patient with tooth agenesis, however the *BMP4*; p.R300P has been reported in a CPHD and hypoplastic pituitary gland patient. *GNRH1*; p.Arg73X, has been described in a patient with HH. The *SRA1*; p.Q32E has been identified in a patient with HH and could probably explain the secondary adrenal insufficiency of our patient, since SRA1 regulates SF1 target gene expression by functioning as a coactivator in association with DAX1. *NR4A1* gene encodes for a protein, member of the steroid–thyroid hormone-retinoid receptor superfamily, which acts as a nuclear transcription factor and is highly expressed in the adrenals.

Osilodrostat provides sustained control of urinary free cortisol in patients with Cushing's disease: final results from a prospective, open-label study (LINC 2)

Maria Fleseriu[1], Beverly Biller[2], Jerome Bertherat[3], Jacques Young[4], Giorgio Arnaldi[5], Paul O'Connell[6], Miguel Izquierdo[7], Alberto Pedroncelli[8] & Rosario Pivonello[9]
[1]Oregon Health & Science University, Pituitary Center, Departments of Medicine and Neurological Surgery, Portland, USA; [2]Massachusetts General Hospital, Neuroendocrine and Pituitary Tumor Clinical Center, Boston, USA; [3]Hôpital Cochin, AP-HP and Université de Paris, Department of Endocrinology, Centre de Référence des Maladies Rares de la Surrénale, Paris, France; [4]Paris-Sud University and Paris Saclay University, Assistance Publique Hôpitaux de Paris, Bicêtre Hospital, Department of Endocrinology, Le Kremlin-Bicêtre, France; [5]Polytechnic University of Marche, Division of Endocrinology, Department of Clinical and Molecular Sciences, Ancona, Italy; [6]Novartis Ireland Limited, Dublin, Ireland; [7]Novartis Pharma AG, Basel, Switzerland; [8]Recordati AG, Basel, Switzerland; [9]Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Naples, Italy

Introduction
The oral 11β-hydroxylase inhibitor, osilodrostat, normalized mean urinary free cortisol (mUFC) in 79% (15/19) of patients with Cushing's disease at the end of the 22-week core LINC 2 study. Long-term efficacy and safety data following an optional extension phase are reported here.
Methods
Patients with clinical benefit at week 22 could continue receiving osilodrostat during the extension; dose adjustments were permitted based on efficacy/safety. Response status was assessed over time: controlled mUFC (≤ULN) or partially controlled mUFC (>ULN but ≥50% decrease from baseline). Efficacy and safety were assessed for all patients from core baseline to study end.
Results
Of 19 patients enrolled in the core study (female : male 14:5; mean [s.d.] age 36.8 years [8.4]), 16 entered the extension and 8 continued treatment until study end. Median (range) osilodrostat exposure was 282 weeks (2–351). mUFC decreased from 9.9xULN at baseline to ≤ULN by week 4, remaining stable thereafter. At each extension-phase assessment up to month 70, 50–88% of patients had controlled mUFC, and up to 18% were partially controlled. Mean (s.d.) percentage change in clinical signs from baseline to last assessment were: fasting plasma glucose, –10.8% (22.1) (baseline: 105.6 mg/dl [49.2]); HbA_{1c}, –2.1% (9.0) (baseline: 5.7% [0.7]); systolic BP, –3.3% (12.6) (baseline: 132.6 mmHg [11.6]); diastolic BP, –2.0% (10.4) (baseline: 85.0 mmHg [6.5]); BMI, –5.9% (8.8) (baseline: 30.7 kg/m^2 [7.0]). Nine patients discontinued treatment, mostly because of AEs or no longer requiring treatment (n = 3 each). The most common AEs during the overall treatment period were nausea (n = 10), adrenal insufficiency, and headache (n = 9 each). AEs related to hypocortisolism and adrenal hormone precursor accumulation occurred in 11 (mostly adrenal insufficiency, n = 9) and 12 patients (mostly hypertension, n = 4), respectively; most were grade 1/2 and managed with dose adjustment/interruption and/or additional therapy. Mean (s.d.) plasma ACTH increased from 1.8xULN (0.9) at baseline to 7.1xULN (12.3) at week 22 and 6.9xULN (12.6) at last assessment. Mean (s.d.) 11-deoxycortisol increased from 1.2xULN (1.3) at baseline to 13.6xULN (12.2) at week 22 and 3.6xULN (4.2) at last assessment. In females, mean (s.d.) testosterone increased from 0.8xULN (0.4) at baseline to 2.4xULN (2.1) at week 22 and 1.0xULN (0.9) at last assessment. AEs of hirsutism were reported in two female patients.
Conclusions
Osilodrostat provided rapid and sustained reductions in mUFC for up to 6 years of treatment, with improvements in clinical signs of hypercortisolism. Osilodrostat was well tolerated, with no new safety signals during long-term treatment.

PEP8.6

Can the follow-up imaging interval for non-functioning pituitary microadenomas be extended?

Ashley Han, Elena Varlamov & Maria Fleseriu
Oregon Health & Science University, Portland, USA

Background
Data on clinical characteristics and natural history of patients with non-functioning pituitary microadenomas (NFPmA) is limited to small-scale studies.
Methods
A retrospective evaluation of initial clinical presentation and natural history of patients with NFPmA (conservatively managed, years; 2004–2020) was undertaken. Initial symptoms, tumor size, and pituitary function were assessed. Exclusion criteria; surgery, radiation, dopamine agonists, pregnancy, radiologic findings of Rathke's cleft cyst. Patients on thyroid, glucocorticoid, sex hormone replacement, chronic opioids, or with traumatic brain injury were excluded from pituitary function analysis. Tumor size change ≥2 mm on pituitary MRI in any dimension was considered significant. SPSS was used for descriptive statistics, and STATA for incidence.
Results
A cohort of 262 patients with NFPmA (age 41.6±15.2 years; 64.9% female) was studied. Fatigue (77.1%) and headache (69.5%) were the most common presenting symptoms. Mean largest tumor dimension was 4.6±1.9 mm; 53% were <5 mm and 47% were 5–9 mm. Patients were taking thyroid (for primary hypothyroidism; 21.0%), 5.3% glucocorticoid, 2.7% growth hormone replacement, 0.4% desmopressin; 38.5% of females estrogen/progesterone and 22.1% of males testosterone. In patients with fully evaluable pituitary function, 94.5% had no deficiencies, 4.0% deficiency in 1-axis, and 1.5% in 2-axes (most commonly hypogonadism; 4.7% and growth hormone deficiency; 1.9%), 9.2% had drug-related and 1.5% transient hyperprolactinemia. During median MRI follow-up of 19 months, 8.7% of tumors grew, 38.5% shrunk, and 52.8% were stable. Growth incidence was 2.3/100 person-years (PYs) with a mean time-to-growth of 41.6±38.9 months. Tumors <5 mm and 5–9 mm showed no difference in growth. Tumor growth did not vary by sex. Mean time-to-growth was lower in patients ≥65 vs <65 years (14.5±7.9 vs 49.9±41.0 months, P = 0.01).
Discussion
Previous reported pituitary deficiency in patients with NFPmA ranges from 0 to 42%; our findings are on the lower end of this estimate. Interestingly, incidence of linear growth in our study was lower than volumetric growth in a previous study (2.3 vs 5.0/100 PYs), but percentage of enlarging microadenomas (8.7%) was similar to previously reported values (7.4–12.5%).
Conclusions
This is the largest single-center study of NFPmA with uniform clinical assessment and follow-up. Patients frequently reported fatigue and headache, without significant pituitary dysfunction. Enlarging tumors were rare and not associated with visual deficits or new hypopituitarism. Since time-to-growth was longer in younger patients, extending follow-up MRI timeline for microadenomas from current recommendations to up to 3-years in patients <65 years of age should be considered.

Russian hypothalamic and pituitary tumor registry (OGGO): current results

Alexander Lutsenko, Elena Przhiyalkovskaya, Zhanna Belaya, Olga Vikulova, Ekaterina Pigarova, Tatiana Zenkova, Elizaveta Mamedova, Tatiana Grebennikova, Larisa Dzeranova, Liudmila Rozhinskaya & Evgenia Marova
Endocrinology Research Centre, Moscow, Russian Federation

Background
Pituitary disease registries are major instruments of epidemiological and clinical data collection used worldwide.
Objective
To assess the data of pituitary tumor registry in Russia.
Material and methods
Patient records, retrieved from online platform of the Registry.
Results
Currently there are 9858 patients registered in Russian Hypothalamic and Pituitary Tumor Registry (OGGO): 4792 (49%) with acromegaly (AM), 2449 (25%) with prolactinoma (PRL), 870 (9%) with Cushing's disease (CD), 1155 (12%) with non-functioning adenomas (NFPA), 420 (4%) with other tumors of pituitary region and 172 (2%) with rare pituitary adenomas. Mean age of disease onset is 43.3 years for AM, 34.4 for PRL, 34.0 for CD, 43.5 for NFPA. Estimated diagnostic delays in patients with AM was 2.1 years, 3.3 years for CD, 1.5 years for PRL, 1.2 years for NFPA. Median age for AM is 64.0 years [53;71] (72% female), 49.0 [39;61] for CD (84% female), 47.0 [38.0;60.0] for PRL (80% female), 58.0 [44.0;68.0] for NFPA (72% female). Adenoma size was available in 2031 acromegaly patient records (1567 macroadenomas), 266 patients with CD (106 macroadenomas), 830 patients with PRL (442 macroadenomas), 468 patients with NFPA (253 macroadenomas). Neurosurgical treatment was performed in 2082 patients

with AM (54.0%), 292 patients with PRL (12.0%), 593 patients with CD (68.6%) and 289 patients with NFPA (25.4%). Radiotherapy was used in 714 cases of AM (15.4%), 47 PRL (1.9%), 188 CD (21.5%), 28 NFPA (2.4%). 106 patients with CD (12.3%) underwent bilateral adrenalectomy. Concerning medical treatment of patients with acromegaly (1705 patient records), somatostatin analogues were used in 1557 cases (91.3%), dopamine agonists – in 414 cases (24.3%), GH receptor antagonists – in 7 cases (0.2%). Patients with prolactinomas (870 patient records) were treated with dopamine agonists in 865 cases (99.5%). 7 patients were additionally treated with octreotide. Patients with CD received ketoconazole in 60 cases (66.7%), in 39 patients (43.3%) – dopamine agonists, 6 patients (6.7%) – somatostatin analogues. Medical therapy was used in 83 cases of NFPA: dopamine agonists were used in 77 patients (92.8%), somatostatin analogues – in 6 patients (7.2%).

Conclusions

Russian Hypothalamic and Pituitary Tumor Registry is an important tool for assessment of epidemiological data and has promising capabilities for the analysis of clinical characteristics. However, there is a lack of sufficient up-to-date information on medication treatment in patient records, which suggests that better monitoring is needed to achieve data continuity and integrity.

Background

Optimal management of patients with neuroendocrine tumours (NETs) is essential to ensure the best treatment results. This survey aimed to obtain a comprehensive picture of NET management in Poland by examining the pathway of patients with NETs throughout their diagnosis and treatment.

Methods

Physicians treating patients with NET in 17 Polish clinical centres/hospital wards, covering approximately 80% of patients with NET, were invited to complete an online questionnaire between August 20 and November 3 2020. The survey gathered information about the previous year (2019).

Results

In total, 138 NET specialists from 17 centres (6 oncological; 11 endocrinological), treated 4288 patients with NET in 2019 (27% of whom were newly diagnosed). Four centres managed more than 500 patients, and four managed fewer than 30. Patients were usually referred to NET treatment centres by surgeons, endocrinologists, or oncologists. About half (46%) of all patients with NET in 2019 were diagnosed accidentally. The average time from the first symptoms to diagnosis was 13 months. 54% of newly diagnosed patients with NET were previously misdiagnosed, usually with irritable bowel syndrome, inflammatory bowel disease, or psychosomatic disorders. Only 20% of all managed NETs were functional tumours. The most frequent initial symptoms were pain, diarrhoea, and flushing. The newly diagnosed NETs originated most frequently from the pancreas and midgut, with almost half of the patients presenting with metastases mainly to the liver and/or lymph nodes. After NET diagnosis, 27% of patients were referred to other wards, indicating the need for an interdisciplinary approach to treatment. A delayed treatment strategy (watch & wait) was used in 7% of patients; 36% underwent surgery to remove the primary tumours. 59% of all patients with NET received somatostatin analogues (SSA) as the first-line therapy; 84% who received peptide receptor radionuclide therapy (PRRT) had combined therapy with SSA. The Polish Network of Neuroendocrine Tumours guidelines, followed by the European Neuroendocrine Tumour Society (ENETS) guidelines, were regarded as the most helpful for therapy determination.

Conclusions

Our study provides important insights into the daily management of patient with NET in Poland, and may thereby contribute to the improvement of routine clinical practice and optimization of treatment outcomes.

Introduction

Insulinomas are the most common functional neuroendocrine tumours of the pancreas. Because previous data on the long-term prognosis of insulinoma patients are scarce, we wanted to study the morbidity and mortality in Finnish patients previously treated for an insulinoma.

Patients and methods

The Finnish insulinoma register consists of all adult patients diagnosed with an insulinoma in Finland during 1980–2010, including two patients with a MEN1 syndrome ($n = 79$). For each patient, 4 controls were chosen from the Finnish Population Register Centre, matched for age, gender and the place of residence, and alive at the diagnosis of the corresponding patient ($n = 316$). Morbidity due to endocrine, cardiovascular, gastrointestinal and mental disorders, and cancers was compared between the patients and controls by analysing the incidence rate ratios (RR) with the 95% Confidence Intervals (95% CI) using the Mantel–Haenszel method. Kaplan–Meier and Cox regression analyses were used to compare the overall survival (OS) of the patients and controls.

Results

Seventy (89%) of the insulinomas were non-metastatic and 9 (11%) were metastatic. The median length of follow-up after the insulinoma diagnosis was 11 (0.2–33) years for the patients and 12 (1.2–35) years for the controls. Morbidity due to thyroid disorders [RR 2.76 (95% CI 1.00–7.60], parathyroid disorders (RR not applicable), atrial fibrillation [RR 2.02 (95% CI 1.00–4.09)], intestinal obstruction [RR 18.65 (95% CI 2.09–166.86)], non-insulinoma pancreatic diseases [RR 13.04 (95% CI 2.12–20.36)], abdominal hernias [in patients with a non-metastatic insulinoma, RR 2.33 (95% CI 1.00–5.43)], breast cancer [RR 4.46 (95% CI 1.29–15.39] and kidney cancer (RR not applicable) was increased among insulinoma patients compared to controls, $P < 0.05$ for all comparisons. Postoperative disease progression or recurrence occurred in 6 (8%) of the 71 patients who underwent curative-intent surgery, the 5- and 10-year disease-free survival being 96% and 94%. The OS of patients with a non-metastatic insulinoma did not significantly differ from that of controls, but for patients with a metastatic insulinoma, the OS was significantly impaired, with a median survival of 3.4 years. In multivariate analyses, older age and distant metastases were associated with a decreased OS.

Conclusions

The long-term prognosis of patients with non-metastatic insulinomas is similar to the general population, except for an increased incidence of thyroid and parathyroid disorders, atrial fibrillation, intestinal obstruction,

non-insulinoma pancreatic diseases, abdominal hernias, and breast and kidney cancers. Metastatic insulinomas are rare, but entail a markedly decreased survival.

PEP9.2

Possible role of common RET polymorphisms in pheochromocytoma

Anna Skalniak, Ewelina Rzepka, Elwira Przybylik-Mazurek & Alicja Hubalewska-Dydejczyk
Jagiellonian University Medical College, Department of Endocrinology, Kraków, Poland

Background
In about 2/3 of pheochromocytoma patients, no pathogenic germline variant can be identified that might be responsible for the onset of the disease. However, in many patients, we observe the repeated appearance of one or more common polymorphisms in the gene *RET*. Each of them has been shown to be of no significance for pheochromocytoma and multiple endocrine neoplasm type 2 development, when analysed individually. We decided to test whether the co-appearance of more than one polymorphisms might have any impact on pheochromocytoma.
Materials and methods
51 pheochromocytoma patients with excluded pathogenic variants in the genes *RET, VHL, SDHB* and *SDHD* and with no clinical symptoms that would be indicative of neurofibromatosis type 1 were included in the study. The control group consisted of 51 healthy volunteers with no clinical symptoms that would indicate adrenal diseases and with negative family history for familial syndromes caused by pheochromocytoma-predisposing genes. The status of the following polymorphisms in the gene *RET* was evaluated by Sanger sequencing: rs1799939 (exon 11), rs1800861 (exon 13), rs1800862 (exon 14), rs2472737 (intron 14), rs1800863 (exon 15). Statistical analyses were performed with Statistica v13, with $\alpha = 0.05$ as statistical significance cutoff value.
Results
As expected, none of the polymorphisms differed between the patient and the control group when analysed independently. The groups did also not differ in the total number of the rarer variants identified nor the number of different polymorphisms present in the patient. Also, no disease-predisposing minimal haplotype has been identified by stepwise regression analysis. The pheochromocytoma group was then divided into three subgroups by unsupervised k-means clustering, based on the five analysed polymorphisms. Those three groups did not differ in means of age of disease onset, sex, localisation of the tumour, or PASS. However, significant differences were found for Ki-67 ($P = 0.0294$) and the hormonal status ($P = 0.0306$).
Conclusions
Although it is well established that common variants in *RET* are not responsible for the development of pheochromocytoma, their analysis might turn out useful in the prediction of a patient's clinical appearance. In order to draw final conclusions on the possible meaning of *RET* polymorphisms in the course of pheochromocytoma, a bigger number of patients needs to be analysed. However, our study indicates that this direction of research might be of clinical interest.

PEP9.3

Pneumocystis pneumonia following surgical resection of pulmonary carcinoid causing ectopic ACTH syndrome: a case report

Eugénie Van Mieghem[1], Vicky Nowé[2], Paul De Leyn[3], Herbert Decaluwé[3], Vandamme Timon[4] & Pascale Abrams[5]
[1]GZA Ziekenhuizen campus Sint Vincentius, Department of Internal Medicine, Antwerpen, Belgium; [2]GZA Ziekenhuizen campus Sint Vincentius, Department of Pneumology, Antwerpen, Belgium; [3]UZ Gasthuisberg Campus, Department of Thoracic Surgery, Leuven, Belgium; [4]University of Antwerp, Center for Oncological Research (CORE), Antwerpen, Belgium; [5]GZA Ziekenhuizen campus Sint Vincentius, Department of Endocrinology, Antwerpen, Belgium

Background
Cushing's syndrome due to ectopic ACTH secretion only accounts for 10% of all cases of Cushing's syndrome and is most often associated with pulmonary neuro-endocrine tumors. Treatment of ectopic ACTH syndrome is predominantly surgical with resection of the tumor. Following resolution of hypercortisolism, previously subclinical Pneumocystis jiroveci infection can become overt due to restored immune response.
Clinical Case
A 37 year old male was referred to the endocrinology outpatient clinic by his general physician with suspicion of secondary hypertension. Initial clinical evaluation revealed a Cushingoid appearance. Laboratory test results, including 24 h urine analysis, showed hypokalemia, elevated urinary free cortisol and elevated serum ACTH. MRI of the pituitary gland revealed absence of pituitary adenoma. Inferior petrosal sinus sampling suggested ectopic ACTH production. CT of the thorax and abdomen, followed by 68Ga-DOTANOC scan, was revealed a tumor in the right lower pulmonary lobe as the probable source of the ectopic ACTH production. Patient underwent surgical resection of the tumor with anatomopathological confirmation of typical carcinoid tumor with low proliferative index. Five days after surgery, patient presented to the emergency department with fever, dyspnea and a dry cough. Arterial blood gas analysis showed type I respiratory failure. Extensive bilateral peribronchial ground-glass opacities were seen on CT thorax. Laboratory test results showed important inflammation with elevated leucocyte count with neutrophilia and an elevated CRP. Patient was initially empirically started on intravenous amoxicillin/clavulanic acid antibiotic therapy and supportive treatment consisting of oxygen therapy and low molecular weight heparin. SARS-CoV-2 PCR on nasopharyngeal swab was negative. Bronchoscopy with broncho-alveolar lavage was performed with a positive PCR for Pneumocystis jiroveci. The diagnosis of bilateral Pneumocystis pneumonia (PCP), following resolution of an ectopic ACTH syndrome, was made. Amoxicillin/clavulanic acid was replaced by trimethoprim/sulfamethoxazole with favorable clinical evolution. A few months later patient is doing well and is almost fully recovered.
Clinical Lesson
Following resolution of hypercortisolism in Cushing's syndrome, subclinical Pneumocystis jiroveci infection can evolve into fulminant PCP due to immune reconstitution. During prolonged immune suppression, fungal lung burden of Pneumocystis jiroveci may accumulate, with development of extensive inflammatory reaction after abrupt decrease of cortisol levels. Especially in patients with ectopic Cushing syndrome the risk of developing PCP following surgical resection is considerable. Therefore timely chemoprophylaxis with trimethoprim/sulfamethoxazole must be considered in each patient treated for Cushing syndrome.

Parathyroid carcinoma presenting as ventricular bigeminy in pregnancy

Leher Gumber[1], Karthikeyan Sivasankaran[1] & Sardar Muhammad Shoaib Khan[2]
[1]Sherwood Forest Hospitals NHS Foundation Trust, General Medicine, Sutton in Ashfield, UK; [2]Sherwood Forest Hospitals NHS Foundation Trust, Consultant Diabetes and Endocrinology, Sutton in Ashfield, UK

Introduction
Parathyroid carcinoma is a very rare phenomenon with an estimated prevalence of 0.005% of all cancers. There have been fewer than ten cases of parathyroid carcinoma in pregnancy previously reported in literature. Clinical features are similar to primary hyperparathyroidism and the diagnosis is usually made on surgery or histology. We present a unique case of parathyroid carcinoma in pregnancy where ventricular bigeminy was the presenting feature.
Case report
A 38-year-old multiparous woman presented to the emergency department with severe palpitations in the second trimester of her fifth pregnancy. She also had headaches, dizziness and polydipsia. Admission laboratory results revealed severe hypercalcaemia (3.07 mmol/l), raised PTH (87 ng/l) and a mild hypophosphatemia (0.79 mmol/l). 12-lead ECG showed ventricular bigeminy. Initial management comprised of intravenous rehydration and beta-blockers. Further investigations included a 24-h ECG recording which showed ventricular bigeminy and high frequency premature ventricular contractions amounting to a burden of 26%. Echocardiography demonstrated a mildly dilated right atrium with good biventricular function. Neck ultrasound revealed a lesion in the posterior aspect of the right lobe of the thyroid. Despite drinking copious amount of fluids at home, she continued to have severe hypercalcaemia needing multiple hospital attendances for intravenous rehydration. Her case was reviewed in the endocrine multidisciplinary meeting where surgical management during pregnancy was deemed most appropriate given her recurrent hospital admissions and potential risks to foetal wellbeing. Consequently, she underwent a right

unilateral neck exploration at 23 weeks gestation. Intraoperative concerns of cancer led to an en-bloc resection of the right parathyroid and thyroid lobe. Histology results confirmed parathyroid carcinoma. Post-operatively, the patient recovered well and was biochemically hypothyroid thus treated with Levothyroxine. Gene testing did not reveal any known genetic causes of parathyroid carcinoma. She had regular growth scans, calcium and TSH monitoring for the remainder of the pregnancy and underwent an uncomplicated caesarean section (patient preference) at 39 weeks.
Conclusions
The vague nature of symptoms, entwined with overlapping features of pregnancy makes recognition of parathyroid carcinoma in pregnancy challenging. To our knowledge, this is the first case of parathyroid carcinoma presenting as ventricular bigeminy and highlights several key points. Firstly, the importance of early recognition and timely surgical management in reducing maternal and foetal complications. In addition, it illustrates the value of interprofessional collaboration between different specialities to provide good quality care and ensure optimal outcomes in potentially challenging and rare diseases.

PEP9.5

Endothelial and vascular function, biomarkers and clinical presentation in patients with small intestine NETs

Iiro Kostiainen[1], Milla Rosengård-Bärlund[1], Noora Karppinen[1], Piia Simonen[2], Janne Rapola[3], Riikka Lindén[3], Camilla Schalin-Jäntti[1] & Niina Matikainen[1]
[1]Helsinki University Hospital, Endocrinology, Abdominal Center, Helsinki, Finland; [2]Helsinki University Hospital, Cardiology, Heart and Lung Center, Helsinki, Finland; [3]Helsinki University Hospital, Radiology, Medical Imaging Center, Helsinki, Finland

Background
20–30% of patients with metastatic small intestine neuroendocrine tumours (SI-NETs) suffer from carcinoid syndrome (CS), i.e. diarrhea, flushing, and bronchospasm. Of these, 25–50% develop carcinoid heart disease (CHD) characterized by valve fibrosis and right heart failure. There are no early predictive markers of CHD, which typically is diagnosed in the advanced stage.
Aims of the study
To 1) detect possible early predictive alterations in endothelial and vascular function in carcinoid syndrome; 2) compare endothelial and vascular function in patients with and without increased S-5-HIAA; 3) study possible relationships between other biomarkers and clinical features with S-5-HIAA.
Subjects and methods
Sixty-six patients (50% men, mean age 64.2–8.8 years, duration of disease 75.7–57.6 months) with SI-NET treated at HUH. Biochemical and clinical features were assessed from electronic patient records and symptom questionnaire. Vascular and endothelial function was measured with pulse wave analysis (PWA), pulse wave velocity (PWV), and peripheral arterial tonometry (PAT). An expert abdominal radiologist assessed hepatic tumour load with a cutoff point of 10% for categorical statistical analysis. Patients were divided into two groups (high vs low) based on the upper limit of normal for the S-5-HIAA assay.
Results
fP-CgA (mean 164 vs. 3.0 nmol/l; P <0.001), weekly frequency of diarrhea (4.7 vs. 2.5 days; P = 0.011), use of somatostatin analogue (SSA; 97% vs. 81%; P = 0.034) and hepatic tumour load (P <0.001) differed significantly between the high vs low S-5-HIAA group. We found no differences in age, tumour Ki-67, S-proBNP (347 ng/l vs. 191 ng/l, P = 0.247), or prevalence of flush between the groups, neither in any vascular function measurements, including aortic systolic or diastolic pressure, systemic vascular resistance, aortic pulse wave velocity and rate controlled central augmentation index (C-AGPH HR75) between the groups. In the high S-5-HIAA group, S-5HIAA correlated inversely with C-AGPH HR75 (−0.363, P = 0.035). No such correlation was found in the low S-5-HIAA group (−0.303, P = 0.098).
Conclusions
Patients with increased S-5-HIAA concentrations are characterized by significantly higher fP-CgA, more frequent diarrhea and SSA use, and higher hepatic tumour load compared to those with normal S-5-HIAA. In patients with SI-NETs, S-5-HIAA did not predict endothelial dysfunction or increased arterial stiffness.

Characterization of signaling pathways and molecular mechanisms underlying kisspeptin response in pancreatic neuroendocrine tumor (panNETs) cells

Antonio C Fuentes-Fayos[1,2,3,4], Emilia Alors-Pérez[1,2,3,4], Sergio Pedraza Arévalo[1,2,3,4], Aura D. Herrera-Martínez[1,2,5], Jose Angel Días-Pérez[6], Teresa Caro[1,2,7], MARIA Angeles Galvez Moreno[1,2,5], Raul M Luque[1,2,3,4] & Antonio Jesús Martínez-Fuentes[1,2,3,4]
[1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain; [2]Reina Sofia University Hospital (HURS), Cordoba, Spain; [3]Department of Cell Biology, Physiology and Immunology, Cordoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Cordoba, Spain; [5]Endocrinology and Nutrition Service, HURS, Cordoba, Spain; [6]Endocrinology Service, San Carlos Clinical Hospital, Madrid, Spain; [7]Pathology Service, HURS, Cordoba, Spain

Pancreatic neuroendocrine tumors (panNETs) comprise several neoplasms in which a precise diagnosis and therapeutic treatment are hampered by their diversity and heterogeneity which in turn, hind the identification of common molecular signatures and the development of efficient therapeutic approaches. Subsequently, there are no clinical, biochemical, anatomopathological, immunohistochemical or molecular features capable to currently predict either tumor prognosis or post-surgical treatment for panNETs. In this sense, the KiSS/KiSS-R regulatory system has been documented to be expressed and play anti-tumoral actions in different endocrine-related tumors. In fact, we have previously showed the presence of KiSS/KiSS-R system in human panNET, and analyzed its relationship with several tumor distinctive clinical features associated to tumor prognosis. Specifically, we reported a higher KiSS- and a lower KiSS-R expression in panNET tumor tissues compared to their adjacent non-tumor tissues. Furthermore, KiSS expression appeared to be up-regulated in panNET samples from patients harboring metastatic disease, whereas KiSS-R expression was significantly lower when compared to samples from non-metastatic patients. On the other hand, we also reported the potential functional role of this regulatory system in BON-1 pancreatic cell line. Thus, we documented that proliferation and migration processes were regulated upon kisspeptin-10 (kp-10) treatment in naïve and KiSS1-R overexpressing cells. Ongoing analyses indicate that the anti-tumor actions of KiSS/KiSS-R system in BON-1 panNET cell line and in xenograft tumors derived from KiSS1-R overexpressing cells, involve the modulation of various oncogenic signaling pathways and different molecular mechanisms. Thus, proteomic analysis reveals a clear and general decline in the phosphorylation level of several components of MAPK and AKT oncogenic pathways after kp-10 treatment in both *in vitro* and *in vitro* experimental settings being this effect sensitized in several proteins by the KiSS-R overexpression. Furthermore, transcriptomic studies in BON-1 cells show the up-regulation and down-regulation of different genes after kp-10 administration. An ulterior enrichment analysis (KEGG/Reactome) reveal that these deregulated genes are associated to relevant pathways involved in pancreatic cancer, endocrine resistance and cell cycle among others. Altogether, our results provide original evidence for the presence and functional activity of the KiSS/KiSS-R system in panNETs, suggesting its potential role in the development and/or progression of this devastating pathology, and paving the way to explore its value as a novel biomarker and/or therapeutic target in panNETs.

Hypercalcaemia due to ovarian small cell carcinoma of the hypercalcaemic type (SCCOHT)

Annalisa Montebello & Mark Gruppetta
Mater Dei Hospital, Diabetes and Endocrinology, MSD2090, Malta

Background
Hypercalcaemia is commonly encountered during clinical practice. SCCOHT is a rare ovarian malignancy typically found in young women. In two thirds of patients, it causes a paraneoplastic hypercalcaemia which is usually asymptomatic.
Case Report
A thirty-seven-year-old lady, presented to casualty with a one -week history of worsening nausea, vomiting, anorexia, abdominal pain, polydipsia, and polyuria. On examination all clinical parameters were within normal

range. Her abdomen was distended but soft. Blood investigations revealed a corrected calcium level of 3.9 mmol/l. She was started on intravenous normal saline at one litre every six hours as acute management for hypercalcaemia. Additional tests revealed a PTH of <5 (15–65 pg/ml), a PTHrP of 5.7 (<1.5 pmol/l), a 25-hydroxyvitamin D level of 17 (30–100 ng/ml) and normal renal function. The combination of a low PTH together with a high parathyroid hormone related protein (PTHrP) suggests humoral hypercalcaemia of malignancy. A computed tomography scan of the abdomen showed a large, hypodense, soft tissue pelvic mass arising from the left ovary. A magnetic resonance scan of the pelvis confirmed an 18×12×5 cm mass arising from left tubo-ovarian region with areas of internal cystic change, internal necrosis, prominent venous drainage, and a peripheral enhancement pattern A bone scan showed no evidence of abnormal foci of increased tracer uptake throughout the skeletal system. Despite three days of continuous fluid replacement her serum calcium remained high. She received one dose of the intravenous bisphosphonate Zoledronic acid 4 mg which reduced her calcium to 2.38 mmol/l after 48 h reaching a nadir of 1.94 mmol/l within five days. She underwent a bilateral salpingo-oopherectomy and total abdominal hysterectomy. Histology showed a left SCCOHT with sheets of small, uniform, hyperchromatic cells together with a single cystic pseudofollicle; very typical for SCCOHT. She is receiving Cisplatin/Etoposide combination chemotherapy to be followed by pelvic radiotherapy. A repeat CT scan after 3 cycles showed no distant metastases. Her calcium levels have since remained normal, repeat PTHrP and PTH levels have normalised.

Conclusion

SCCOHT was initially reported in 1979 by Scully. Fewer than 500 cases have been reported worldwide. Abdominal pain is the most frequent symptom at 68%. At surgery 50% of patients have extra ovarian spread. It has a high rate of recurrence and overall survival is less than 10%. A combination of surgery, chemotherapy ± stem cell transplant and radiotherapy produce the best results.

Outcomes of a multicenter surveillance protocol in asymptomatic Succinate Dehydrogenase (SDH) B and C mutation carriers

Ana R. Romero LLuch[1], Suset Dueñas Disotuar[1], María C. Tous Romero[2], J. Ignacio Fernández Peña[3], J. Ignacio Cuenca Cuenca[4] & Elena Navarro[1]
[1]Hospital Universitario Virgen del Rocío, Department of Endocrinology, Seville, Spain; [2]Hospital Universitario Virgen Macarena, Department of Endocrinologym, Seville, Spain; [3]Hospital Universitario Virgen de Valme, Department of Endocrinology, Seville, Spain; [4]Hospital Universitario Virgen del Rocío, Department of Nuclear Medicine, Seville, Spain

Introduction

Based on the evidence available back then, in 2015 we developed a provincial multicenter protocol for screening and follow up of no-index patients with SDHB and SDHC mutations.

Objectives

1. To evaluate the performance of the protocol designed for the follow-up of asymptomatic SDHB and C carriers. 2. To describe the penetrance of manifestations associated with hereditary PGL-FEO syndromes type 3 and 4 in a provincial cohort of non-index carriers.

Methods

prospective observational study (January 2015–March 2019). Non-index SDH B and C mutations carriers were included. Once a year we determined catecholamines in a 24-h urine sample. Imaging and functional studies were established depending on type of mutation and catecholamines results. For SDHB+ we initially performed PET/CT with ^{18}F-DOPA and ^{18}F-FDG. For SDHC+ patients a head and neck MRI was requested if catecholamines were normal and ^{18}F-DOPA PET/CT if elevated. After the first negative screening, patients continued with imaging follow-up (MRI) every two years added to annual urine catecholamines. For quantitative variables, results are expressed as mean±s.d. for normally distributed data and as median [range] for nonparametric data.

Results

$n = 65$.

– SDHB ($n = 50$, 11 families). 54% men. Age at genetic diagnosis: 46.5 ± 17.7 years. Follow-up time 25.9 ± 16.7 months. Abnormal uptakes were detected in 14/40 cases with ^{18}F-DOPA and/or ^{18}F-FDG PET/CT (2 false positives for ^{18}F-FDG PET/CT and 12 true positives). Ten patients showed 11 lesions related to the syndrome: 5 abdominal PGL, 3 cervical PGL, 1 thoracic PGL, 1 pheochromocytoma and 1 medullary hyperplasia (60% functioning; age at diagnosis 35.2 [11–72] years; size 4.5 [1.1–10] cm). One metastatic case. Histological confirmation was obtained in 8/10 cases. Unrelated neoplasms were found in 2 patients (one lung squamous cell carcinoma and one large cell neuroendocrine carcinoma). The sensitivity and specificity of PET/CT with ^{18}F-FDG were 100% and 93.9% (87.5% and 100% with ^{18}F-DOPA). The penetrance was 22%.

– SDHC ($n = 15$, 2 families). 53% women. Age at diagnosis 49.9 ± 13.1 years. Follow-up time 26.9 ± 16.4 months. Only 2 patients showed lesions (one pituitary macroadenoma and one benign lymph node – false positive of MRI). The penetrance was 13.3%.

Conclusions

The proposed protocol detected PGL/FEO in 20% of non-index SDHB mutation carriers and only 60% had elevated catecholamines. In addition, it allowed us to detect other unsuspected neoplasms. The penetrance in SDHC mutation carriers is low, as expected.

A semi-automatic, non-radioactive 384-well high throughput screening DIO2 assay

Caroline Frädrich[1], Kostja Renko[2], Niklas Wiese[1], Anja Fischbach[1], Carola Seyffarth[3], Martin Neuenschwander[3], Jens Peter von Kries[3] & Josef Köhrle[1]
[1]Charité – Universitätsmedizin Berlin, Institute of Experimental Endocrinology, Berlin, Germany; [2]German Federal Institute for Risk Assessment, German Centre for the Protection of Laboratory Animals (Bf3R), Berlin, Germany; [3]Leibniz-Forschungsinstitut für Molekulare Pharmakologie, Screening Unit, Berlin, Germany

Thyroid hormone (TH) homeostasis depends on the coordination of several key events to maintain proper local TH signaling, including iodide uptake, hormone synthesis, metabolism, and elimination. The three isoenzymes, Deiodinases (DIO1-3), are essential components of hormone metabolism. They catalyze iodide release the outer and/or inner ring of TH structure to convert between their active and inactive forms. The activity of DIOs has been identified as an important endpoint regarding the screening of compounds for TH system disruption. The classical DIO assays rely on the liberation of radioactive iodide from a tracer substrate. Furthermore, substrate deiodination can also be followed by using mass spectrometry as readout. However, radioactively labeled substrate molecules are expensive, not always commercially available, legally restricted and limited in their half-life. Mass spectrometry involves costly and sensitive instrumentation and skilled personnel. To avoid these difficulties, we established a cost- and time-effective semi-automatic, non-radioactive 96-well DIO2 assay, based on the Sandell-Kolthoff (SK) reaction, and adapted it to the 384-well High Throughput Screening (HTS) plate format to identify inhibitors or activators of DIO2 activity from a small molecule compound library. A robust 384-well HTS platform for non-radioactive determination of DIO2-catalyzed iodide release by the SK method was developed. The SK reaction describes the reduction of yellow-colored cerium IV to non-colored cerium III by arsenic III. Reaction rate is increased in a concentration-dependent manner by presence of iodide and can be quantified photometrically. The development process included optimization of protein concentration using recombinantly expressed human DIO2 and incubation conditions (time, temperature, shaking, kinetics). Furthermore, assay performance parameters were examined such as linear measuring detection range and *Z*-factor. Several steps of the protocol were performed on and optimized for the Biomek Workstation (Beckman Coulter) platform. 50 µg total protein/reaction and 4 h incubation time at 37°C with an endpoint measurement at OD 20 min delivered the most robust parameters of the semi-automatic, non-radioactive 384-well HTS DIO2 assay with a *Z*-factor consistently above 0.5. The presented work demonstrated the successful setup of an HTS-screening platform, qualified to detect and initially characterize endocrine disruptors, affecting DIO activities. The respective HTS protocol provides the basis for further testing of large chemical libraries against DIO2, and can be adapted to other deiodinating enzymes, e.g. DIO1 and dehalogenases. Furthermore, its use to generate large data sets on libraries covering diverse chemical structures will enable the setup of predictive *in silico* tools by providing respective training sets.

Graves' disease and concurrent immune thrombocytopenia in a patient with albinism following alemtuzumab treatment for multiple sclerosis: a rare case report

Vasiliki Daraki[1], Eleni-Konstantina Syntzanaki[1], Vasileios Mastorodemos[2], Kalliopi Kontolaimaki[1], Maria Mytilinaiou[1], Maria Chrysoulaki[1], Maria Sfakiotaki[1], Grigoria Betsi[1] & Paraskevi Xekouki[1]
[1]University Hospital of Crete, Department of Endocrinology Diabetes and Metabolic Diseases, Heraklion, Crete, Greece; [2]University Hospital of Crete, Department of Neurology, Heraklion, Crete, Greece

Introduction
Alemtuzumab is an anti-CD52 antibody, leading to lysis and transient depletion of T and B lymphocytes. Its therapeutic effect is mediated by the alteration in immune repertoire that accompanies subsequent lymphocyte reconstitution. It is mainly used for the treatment of relapsing–remitting multiple sclerosis (RRMS). Common side effects are autoimmune diseases, including thyroid disease (>40%), immune thrombocytopenia (ITP, 1–3%) and nephropathy (<1%). Concurrent Graves' disease with other alemtuzumab-related autoimmune disorders have not been described so far.
Case-report
A 27-year-old female with oculocutaneous albinism and RRMS diagnosed in 2009, received three cycles of alemtuzumab between 2016 and 2018. Twenty-one months later, she presented to the emergency department with petechiae, purpura and tachycardia. Laboratory tests revealed severe thrombocytopenia, autoimmune hemolytic anemia, leukopenia and mildly elevated liver enzymes. Immunological and virological tests were negative. Thyroid function tests revealed hyperthyroidism with positive anti-Tg, anti-TPO and TSHR antibodies. Increased uptake in thyroid scan confirmed the diagnosis of Graves' disease. Of note, her family history is significant for thyroid dysfunction and rheumatoid arthritis. She was treated with low dose thiamazole and propranolol, as well as methylprednisolone and gamma globulin. Interestingly, a fluctuating course with alternating phases of hypo- and hyperthyroidism followed and ITP relapse was observed following treatment initiation. Currently, she is on concomitant treatment with thiamazole and thyroxine, and remains euthyroid with normal hematological and biochemical laboratory tests. Methylprednisolone was discontinued 2 months ago.
Discussion
Hyperthyroidism associated with ITP is rare, and only 160 cases have been reported so far. To our knowledge our case with Graves' disease and concurrent ITP after alemtuzumab is the first described in the literature. The exact mechanism of autoimmunity in alemtuzumab-treated patients with RRMS is poorly understood. It has been proposed that the quick/complete recovery of B lymphocyte numbers (6–12 months), versus the slower/partial recovery of T lymphocytes, during the reconstitution phase, is responsible for the enhanced production of autoantibodies. In addition, lymphocytes escaped from cytolysis undergo homeostatic proliferation, potentially setting up an exaggerated and self-oriented response behind adverse autoimmune events. In our case the production of both platelet-associated IgG, and antithyroid antibodies, may be responsible for the coexistence of both diseases. Another contributory factor may be the increased reticuloendothelial phagocytic activity induced by hyperthyroidism, which may shorten the platelet survival. Genetic predisposition as well as smoking, family history of autoimmunity, female gender, younger age, and early brainstem involvement may also have played a role to this unusual case.

Levothyroxine replacement reduces BMI, HbA1c, insulin resistance, LDL-C and triglyceride in overt primary hypothyroidism in Asian Indians

Supriya Indi[1], Vijayashree Thyagaraj[2] & Chitra Selvan[3]
[1]Aster CMI Hospital, General Medicine, Bengaluru, India; [2]Ramaiah Medical College, General Medicine, Bengaluru, India; [3]Ramaiah Medical College, Endocrinology, Bengaluru, India

Background
Dyslipidemia is relevant association of hypothyroidism and consists of raised levels of total cholesterol, apolipoprotein B, triglycerides, low density lipoprotein (LDL) cholesterol, and reduced levels of high density lipoprotein (HDL) cholesterol.Thyroid hormones also have a role in modulating glucose metabolism and insulin resistance. The aim of study was to assess glycemic status, Homeostasis model assessment–estimated Insulin Resistance (HOMA–IR), and fasting lipid profile in individuals with newly detected overt primary hypothyroidism and to evaluate HOMA –IR, glycemic status and fasting lipid profile after achieving euthyroid status.
Methods
54 interested participants with Overt Primary hypothyroidism attending clinic from October 2017 to May 2019 were included. Individuals with diabetes, individuals on treatment for dyslipidemia or on treatment which can affect weight like steroids, anticonvulsants were excluded. Parameters were compared before and after achieving euthyroid state.
Results
Mean age of participants was 42.37±16.45 years. 79.6% were women. The mean duration to achieve euthyroid state was 8.626+0.782 weeks. The mean TSH before initiation of Levothyroxine was 27.55 µIU/l and after achieving euthyroid state was 2.63 µIU/l. The mean BMI before and after treatment was 23.83 ± 2.32 kg/m2 vs 22.87 ± 1.82 kg/m2 which was statistically significant.There was a statistically significant reduction in FPG,PPPG, HbA1c after treatment. The mean FBS before and after treatment were 123.50 ± 35.7 vs 95.31 ± 11.45 mg/dl,PPBS was 137.76 ± 42.98 vs 107.02 ± 18.55 mg/dl, and HbA1c 5.55 ± 0.90 ± 5.09 ± 0.53 %. There was a statistically significant difference found in TC,TG, LDL before and after achieving euthyroid state. The mean TC, TG LDL(mg/dl) before and after treatment were 173.09 ± 42.4 vs 144.83 ± 28.15, 156.20 ± 95.29 vs 103.76 ± 37.33, 110.02 ± 36.01 vs 85.84 ± 26.43 (P <0.001) respectively. The mean HDL before and after treatment was 41.74 ± 12.51 vs 44.00 ± 9.73 (P value 0.097). The mean HOMA – IR and fasting insulin before and after treatment were 3.60 ± 3.02 vs 1.84 ± 0.61, 10.42 ± 6.26 vs 7.91 ± 2.73 respectively and the difference was statically significant. FBS, PPBS, HbA1c, Total cholesterol, Triglycerides, LDL, HOMA IR, Fasting insulin all had positive correlation with TSH and were statistically significant.
Conclusion
Levothyroxine replacement is associated with significant improvement in insulin sensitivity and significant reduction in BMI, total cholesterol, triglycerides, low density lipoprotein, however HDL-C increase did not meet statistical significance.

Efficacy of a combined administration of myo-inositol and vitamin D in patients with autoimmune thyroiditis

Ivan Pankiv, Nataliia Pashkovska, Galina Koval, Antonina Piddubna, Yuliya Marchuk, Nataliia Abramova & Iryna Tsaryk
Bukovinian State Medical University, Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine

Background and aim
Autoimmune thyroiditis (AIT) is one of the most common autoimmune diseases, affecting more than 10% of females and 2% of males in the overall population. Clinical evidence suggests that oral supplementation with myo-inositol (MI) and vitamin D (VD) is useful in the treatment of AIT. MI is a carbocyclic polyol precursor of phosphoinositide synthesis. It is involved in cell signaling and, precisely, as a second messenger regulating the activities of Thyroid Stimulating Hormone (TSH). The aim of this study was to investigate the efficacy of a combined administration of MI and VD in patients with AIT.
Patients and methods
74 outpatients (mean age 42.39 ± 8.2 years) with AIT were enrolled in this prospective randomized controlled trial from May to September 2019. A total of 74 patients with AIT having TSH levels between 4.0 and 6.0 µIU/ml, elevated serum thyroid peroxidase antibodies (TPO-Ab) and thyroglobulin antibodies (Tg-Ab), normal free thyroxine (fT_4) and free triiodothyronine (fT_3) levels were randomized into 2 groups: one receiving MI-VD and the other one VD alone. To provide additional information concerning thyroid tissue texture, high-resolution ultrasound scan of the thyroidal area was carried out.
Results
A significant decrease in serum TSH levels was noted in patients of group MI-VD compared prior and after treatment (P < 0.05), showing at baseline 5.18 ± 0.52 µIU/ml and 3.06 ± 0.48 µIU/ml over 6 months treatment. The decrement in control group before vs. post-treatment was not significant (4.93 ± 0.82 µIU/ml and 4.16 ± 0.81 µIU/ml). TSH, thyroid peroxidase antibodies (TPO-Ab) and thyroglobulin antibodies (Tg-Ab) levels were significantly decreased in patients treated with combined MI-VD after six months of treatment. Also, a significant free serum thyroxine (fT_4) increase

was observed in MI-VD group. In both groups at baseline plasma VD levels were not different (19.4 ± 3.7 ng/ml group MI-VD; 18.9 ± 2.8 ng/ml group VD). After 6 months treatment, VD values were significantly augmented in each group compared to baseline.
Conclusions
The administration of MI-VD is significantly effective in decreasing TSH, TPO-Ab and Tg-Ab levels. Such treatment restored euthyroidism in patients diagnosed with AIT.

PEP10.5

The prevalence of intestinal metaplasia in APCA positive patients with Graves' disease

Georgios Boutzios, Eleni Koukoulioti, Sofia Chatzi, Athina Karampela, Ilias Giovannopoulos & Athanasios Tzioufas
Medical School, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece

Introduction
A strong association between autoimmune atrophic gastritis and other autoimmune disorders has been well documented. The prevalence of gastric mucosa alterations in patients with thyroid autoimmunity is not well known. The aim of our study was to assess the prevalence of intestinal metaplasia in patients with Graves' disease (GD) and positive anti-parietal cell antibodies (APCA).
Methods
This is a single-center observational study in an outpatient clinic of autoimmune endocrinopathies at a Tertiary, General, University Hospital. Patients with GD and increased levels of thyroid-stimulating immunoglobulin (TSI >1.75 IU/l) were included in the study. Laboratory tests for TSH, T3, FT4, TSI, APCA, TgAbs, TPOAbs, blood count, liver enzymes and thyroid sonography were performed in all patients. All APCA positive patients underwent OGD.
Results
A total of 107 patients were analyzed, of whom females were 75.4% (81/107). The mean age and BMI of the patients were 46.5±14 years and 25.9±4.7 mg/kg^2 (18.7–36.8), respectively. TPOAbs were present in 65.5% (55/84), TgAbs in 47.6% (40/84) and APCA in 12.7% (9/71) of the patients. 14.6% (14/96) of the patients had undergone thyroidectomy. Personal history for other autoimmunities was present in 21.7% (18/83) and family history for thyroid autoimmunity in 49.5% (50/101) of the patients. 9/101 (8.9%) patients had PTC and 7/101 (6.9%) had other cancers. Histology in the 9 APCA positive patients revealed gastric atrophy in 55.6%, ECL hyperplasia in 33.3%, intestinal metaplasia in 44.4%, and *Helicobacter pylori* infection in 22.2% of the patients.
Conclusion
According to our study, intestinal metaplasia is a frequent finding in APCA positive patients with Graves' disease.

Influence of pro-inflammatory cytokines polymorphisms on the interrelationship between Graves' disease and diabetes

Celestino Neves[1,2], Joao Sergio Neves[1], Paula Soares[2,3,4], Luís Delgado[5], José Luís Medina[6] & Davide Carvalho[1,2]
[1]Department of Endocrinology, Diabetes and Metabolism, São João Hospital Center, Faculty of Medicine of University of Porto; [2]Institute for Research and Innovation in Health (iS), University of Porto, Porto, Portugal; [3]IPATIMUP-Instituto de Patologia e Imunologia Molecular, Universidade do Porto, Porto, Portugal; [4]Department of Pathology, Faculdade de Medicina da Universidade do Porto, Porto, Portugal; [5]Basic & Clinical Immunology, Department of Pathology, Faculty of Medicine, University of Porto, Porto, Portugal; [6]Faculty of Medicine of University of Porto, Porto, Portugal

Background
Graves' Disease (GD) is characterized by production of stimulating autoantibodies to thyrotropin receptor resulting in hyperthyroidism. Hyperthyroidism is associated with insulin resistance, hyperglycemia and ketosis. Our aim was to evaluate if single nucleotide polymorphism (SNP) in pro-inflammatory cytokines contributes to dysglycemia in GD.
Methods
We evaluated 98 patients with Graves' disease. Genetic variants in IL6-174 G/C, TNFA-308 G/A, IL1B-511 C/T, and IFNGR1-56 T/C were analyzed by real-time PCR. Patients were evaluated with oral glucose tolerance test with determination of glucose, insulin, C peptide and indexes of insulin resistance: HOMA-IR (homeostatic assessment insulin resistance index), HOMA-β (HOMA of β-cell function) and WBISI (whole-body insulin sensitivity index). Diabetes was defined according to ADA criteria. The associations of genetic variants with glycemic profile were evaluated with analysis unadjusted and adjusted for age and sex.
Results
The allele T in IL1B-511 C/T was significantly associated with a higher prevalence of diabetes (P = 0.029). The A allele in TNFA-308 G/A was associated with higher levels of fasting insulin in the adjusted analysis (P = 0.042) and higher levels of HOMA-β in both analyses (P = 0.027; P = 0.020). The T allele in IFNGR1-56 T/C polymorphism was associated with significantly higher mean values of fasting glucose (P = 0.047), as well as higher levels of C peptide (P = 0.026) in the unadjusted analysis.
Conclusions
SNP in pro-inflammatory cytokines may affect glycemic profile in patients with GD. These polymorphisms are associated with higher levels of fasting insulin and HOMA-β, increased fasting glucose and C peptide, and higher prevalence of diabetes.

PEP10.7

Novel coronavirus disease and Hashimoto's thyroiditis in children (series of clinical cases)

Olga Gumeniuk[1], Yuriy Chernenkov[1] & Georgiy Golovchenko[2]
[1]Saratov State Medical University, Saratov, Russian Federation; [2]University clinics 1 SGMU, Saratov, Russian Federation

The impact of novel coronavirus (COVID-19) infection in adult patients with endocrine diseases is well established, with the evidence showing a link between endocrine pathology and disease severity (A. Badawi, S.G. Ryoo, 2016, J. Yang *et al*, 2020, S. Cianfarani, A. Brancatella, 2020). The thyroid gland and the virus infection with its associated inflammatory-immune responses are known to be engaged in complex interplay (L. Scappaticcio, *et al*, 2020). To date, no study has reported data on the interaction between novel coronavirus infection and endocrine diseases (for example, thyroiditis) in children (BTA/SFE, 2020).
Aim
To study impact of COVID-19 on the thyroid in children with Hashimoto's thyroiditis.
Patients and methods
We observed 7 clinical cases of the disease in children after COVID-19. We studied retrospectively seven cases (6 girls and 1 boy, aged 10–18 y.o.) of Hashimoto's thyroiditis in children enrolled in the pediatrics department. A clinical examination, hormonal analysis (free thyroxine, T4f, thyroid-stimulating hormone,TSH, thyroid peroxidase antibody, TPO and thyroglobulin antibodies, ATG) and thyroid ultrasound examination (USE) were conducted.
Results
COVID-19 had been mild in all children. Before the COVID-19 (6 months earlier) all children had a normal thyroid volume (WHO) and function both were normal, TPO level was was within 100–600 E/ml (ref: < 5.6 E/ml), ATG level was within 50–200 IE/ml (ref: < 18 IE/ml). In the treatment of COVID-19, human recombinant interferon alpha-2b preparations were used. After COVID-19 all cases showed an increase in thyroid volume by 20–30% at thyroid USE. At laboratory exams in all children were found to have elevated TPO (to 1000 E/l and more), in one patient was found to had elevated ATG (to 500 IE/ml and more), in one girl developed subclinical hypothyroidism and another patient presented with hypothyroidism.
Conclusions
A clinical case study showed that novel coronavirus infection aggravates the thyroid in children with Hashimoto's thyroiditis. There is required careful thyroid monitoring in patients with Hashimoto's thyroiditis during the pandemic of COVID-19.

Transient hyperthyrotropinemia in outpatient children treated due to acute infections of the respiratory system

Katarzyna Adamczewska[1], Zbigniew Adamczewski[1,2], Magdalena Stasiak[1], Andrzej Lewiński[1,2] & Renata Stawerska[1,3]
[1]Polish Mother's Memorial Hospital – Research Institute of Lodz, Department of Endocrinology and Metabolic Diseases, Lodz, Poland; [2]Medical University of Lodz, Department of Endocrinology and Metabolic Diseases, Lodz, Poland; [3]Medical University of Lodz, Department of Pediatric Endocrinology, Lodz, Poland

Introduction
Diagnostics of thyroid dysfunctions is frequently based on the measurements of TSH serum concentration only. Currently, due to a tendency to minimize stressful situations for a child (such as venipuncture to take a blood sample), some tests (i.e. TSH assessment) are performed at the Primary Healthcare Centre while other diagnostic tests (e.g. during an infection) are run. If TSH serum concentration is outside the reference range, it leads to the implementation of the diagnostic procedure used in patients with a thyroid disorders. Clinical observations indicate that in a considerable number of these patients, a thyroid disease is not confirmed, and the results of the tests performed so far are in fact falsely positive. The aim of the study was to assess the incidence of transient hyperthyrotropinemia during acute infections of the respiratory system in generally well-being children without previously diagnosed thyroid disease.
Material
The study group consisted of 94 children (49 boys and 45 girls), aged 2.2–17.3 years, who were consecutive admitted to a single Primary Healthcare Centre due to acute respiratory infection during one year. Obese and undernourished children were excluded from the study, similarly to patients treated for thyroid diseases and those who displayed typical signs and symptoms of thyroid disorders. In every case, a complete blood count (CBC) test was performed and C-reactive protein (CRP) as well as TSH in serum was measured. The tests were run on the next day after the visit (at the morning after an overnight fasting). Next, the parents were asked to bring the child for a check-up examination $\geq$ 2 weeks after recovery. At the next visit, the patient's condition was evaluated again and a blood sample was taken in order to assess the same parameters: CBC, CRP and TSH.
Results
Among these children manifesting both with or without fever, regardless of the elevated CRP concentration and of the type of infection (viral or bacterial), elevated TSH values are found in about 10% of patients, and they go back to normal values after resolution of symptoms. A prospective analysis showed a reduction of TSH values in approx. 65% of all examined children, and the TSH results at the control time point were significantly lower than during acute infection.
Conclusion
It seems that TSH levels should not be assessed during an acute infection. If thyroid dysfunction is suspected, the examination should be performed in the healthy state.

Fascin-1, a novel-circulating marker for the prognosis of the metastatic adrenocortical carcinoma

Giulia Cantini[1], Letizia Canu[1,2], Giuseppina De Filpo[1,2], Tonino Ercolino[2], Laura Fei[1], Gabriella Nesi[3], Mario Maggi[1,2], Massimo Mannelli[1] & Michaela Luconi[1]
[1]University of Florence, Experimental and Clinical Biomedical Sciences, Florence, Italy; [2]Careggi University Hospital (AOUC), Florence, Italy; [3]University of Florence, Health Science, Florence, Italy

Fascin-1(FSCN1) is an actin-bundling protein expressed in several solid carcinomas and often associated to an invasive and aggressive phenotype as it is involved in cytoskeleton rearrangement and filopodia formation. Adrenocortical carcinoma (ACC) is a rare endocrine malignancy characterized by a poor prognosis, particularly when metastatic at diagnosis. Complete surgical resection of the tumor mass is the main therapy for ACC patients in addition to the adjuvant administration of mitotane. Therefore, it is necessary to identify new markers indicative of tumor progression for a better management and monitoring of the patients. In our previous work, we found that FSCN1 detected in tumor samples could represent a new prognostic biomarker for invasive ACC. The main objective of the present study was to assess if FSCN1 was also detectable in the bloodstream of ACC patients and its prognostic value. We demonstrated that FSCN1 can be detected both in serum and plasma samples of a small local cohort of ACC patients (n = 27) compared to healthy controls (n = 4), through a specific ELISA assay for human FSCN1. FSCN1 circulating levels resulted significantly higher in ACC compared to controls, (FI: 9.66±1.22, P <0.01). In addition, we longitudinally evaluated FSCN1 concentrations both in pre-operative blood samples as well after the resection of the tumor mass. Consistently, patients with stage III/IV showed levels of serum FSCN1 significantly higher than those in stage I/II both in pre- and post-surgery blood samples, (FSCN1pre: 22.8±1.1 vs 15.8±1.8 ng/ml, P <0.01; FSCN1post: 21.4±1.5 vs 18.0±0.8 ng/ml, P <0.05). In order to evaluate the prognostic power of circulating FSCN1, we performed Kaplan–Meier analysis of patients stratified in 2 groups of high and low FSCN1 serum levels (cut off value: median of FSCN1 distribution): the pre-operative but not the post-surgical levels of circulating FSCN1 can significantly predict tumour recurrence (Log Rank = 0.013), but nor overall survival (Log Rang = 0.317). In conclusion, these findings – though preliminary – suggest that circulating FSCN1 may represent a new non-invasive prognostic marker in ACC, in particular when measured before surgery and histological diagnosis.

Establishment of novel multidimensional models for the adrenal gland and adrenal tumors

Igor Shapiro[1], Mirko Peitzsch[2], Charlotte Steenblock[2], Stefan Bornstein[1,2] & Hantel Constanze[1,2]
[1]Department of Endocrinology, Diabetology and Clinical Nutrition, University Hospital Zurich (USZ) and University of Zurich (UZH), Zurich, Switzerland; [2]Medizinische Klinik und Poliklinik III, University Hospital Carl Gustav Carus Dresden, Dresden, Germany

The adrenal gland displays an important role in integrating neuronal, immune, vascular, metabolic and endocrine signals under a common organ capsule. The adrenal is the central organ of the stress response system, responsible for responses to acute and chronic stress stimuli and, thereby, playing a major role in numerous stress-related disorders. While for other diseases translational scientists developed programs to generate healthy cells to regenerate damaged tissues in patients, such approaches have been widely overlooked in other fields of endocrinology, except for type-I-diabetes. Moreover, tumor formation is very common in the adrenal gland and these tumors are furthermore highly heterogeneous. However, high throughput applications reflecting this heterogeneity and furthermore relevant 3D-structures in vitro are still widely lacking. Recently, we initiated the development of standardizable multidimensional models of adrenal organoids and tumor spheroids. For this purpose we utilized microwell plates providing stem cell quality clustering without adhesion, enormous scalability and medium change possibility. In a first step, we assessed for the human adrenocortical cell lines NCI-H295R and MUC-1 the impact of different cell numbers, incubation periods and methods of spheroid preparation. Based on these experiments we were able to successfully establish and dimensionally preserve stable tumor spheroids for both tumor models. Subsequent histological and immunohistochemical investigations revealed viable spheroids with characteristic cellular abundance and localizations for important tumor and steroidogenic marker such as Ki-67, SF-1 and 3betaHSD. Real time PCR analyses demonstrate no significant differences in SF-1 and Ki67 expression compared with monolayers. Our experiments indicate furthermore potential applicability for drug screenings. Treatment with 75 µM mitotane over 72 h revealed significantly decreased Ki67 Indices compared with untreated controls for both models (NCI-H295R: P <0.001; MUC-1; P <0.01) while adavosertib affected primarily MUC-1 spheroids (P <0.01). Moreover, we aimed at the development of bovine derived adrenal organoids and we are now also able to establish viable (H&E), as for organoids expected low/not proliferating (Ki67) and steroidogenic active (SF-1 and 3betaHSD) adrenal organoids. Preliminary data indicate furthermore mixed cell populations originating from both, adrenal cortex and medulla. Moreover, cell culture supernatants have been analyzed in a pilot experiment by LC–MS/MS and confirm specific secretion of hormones such as aldosterone, cortisol, and progesterone among others. In next steps, these models will be extended to human primary tumors of

adrenal origin and assessed regarding further applications and read outs. Thereby, we hope to provide new avenues for adrenal tissue replacement and mechanistic insights into adrenal (tumor) biology.

Identification of carbonic anhydrases III and IX in the adipose microenvironment of adrenocortical carcinoma

Laura Fei[1], Giulia Cantini[1], Alessio Nocentini[2], Letizia Canu[1,3], Patrizia Nardini[4], Giuseppina De Filpo[1,3], Tonino Ercolino[3], Gabriella Nesi[5], Mario Maggi[1], Daniele Bani[4], Massimo Mannelli[1], Claudiu T Supuran[2] & Michaela Luconi[1]
[1]University of Florence, Department of Experimental and Clinical Biomedical Sciences, Florence, Italy; [2]University of Florence, Neurofarba, Italy; [3]University of Florence, Careggi University Hospital, Italy; [4]University of Florence, Department Clinical Experimental Medicine, Italy; [5]University of Florence, Department of Health Sciences, Italy

The adipose tissue (AT) is an important endocrine organ. Upon energy imbalance, the adipose cells become dysfunctional, supporting the development of metabolic pathologies and tumours. The adipose cell is among the main actor of the tumor microenvironment, and is able to establish a crosstalk with the cancer cell resulting in a reciprocal reprogramming. Adrenocortical carcinoma (ACC) is a rare endocrine malignancy affecting the adrenal cortex. In the most aggressive forms, cancer cells infiltrate the visceral fat mass surrounding the adrenal, establishing a crosstalk between the tumour mass and the adipose microenvironment. Carbonic anhydrases (CAs) are a wide family of metalloenzymes with a relevant role in some pathologic conditions such as obesity and cancer. The objective of our study was to assess the distribution of the two CA isoforms, CAIII and CAIX, in AT (biotic samples of subcutaneous, SAT, and visceral,VAT, AT of obese and lean subjects) and in ACC tumor samples from a monocentric patient cohort by qRT-PCR, Western Blot and immunohistochemistry. We also evaluated their involvement in an in vitro coculture system between adipose stem cells, ASCs and adrenocortical cancer cells H295R, where coculture results in an increased aggressiveness and invasiveness, mimicking the interaction between adipose microenvironment and ACC in vivo. CAIII expression was higher in lean than in obese patients (SAT:FI = 26.9 ±Ð9.0,*P* = 0.01;VAT:FI = 5.2 ± 1.4,*P* = 0.01), while CAIX was mainly expressed in VAT than SAT of lean (FI = 480.5 ± 119.7, *P* = 0.01) and obese (FI = 361.4 ±Ð79.2,*P* = 0.000) subjects. CAIII expression in biopsies of ACCs stage I/II (*n* = 8) was significantly higher than in the aggressive ACC stage III/IV (*n* = 4)(FI = 4.0 ± 0.9,*P* = 0.001), while CAIX had an opposite behaviour (stage III/IV vs I/II FI = 5.7 ± 1.8,*P* = 0.03). CAIII and CAIX were also expressed in H295R. *In vitro* adipose differentiation of ASCs resulted in a significant increase of CAIII (adipo vs ASC FI = 54 ± 25,*P* = 0.04,*n* = 5) and CAIX (adipo vs ASC FI = 5 ± 1.5,*P* = 0.003,*n* = 5) expression. ASC-H295R cocultures resulted in an increased aggressiveness and invasiveness which was accompanied by a decrease in CAIII and an increase in CAIX expression in H295R cells in coculture vs monoculture, confirming the differences observed in ACC samples. In conclusion, our findings show an altered distribution of CAIII and CAIX expression in AT according to obesity condition, and in ACC, according to the tumor aggressiveness. Our data suggest a possible involvement of the two CAs in adipogenesis and tumor progression. We hypothesize an active role of CAIII and CAIX in the cross-talk between the adipose microenvironment and ACC, opening new prospective in the treatment of ACC with selective CA inhibitors.

Computerized tomography texture analysis in pheochromocytoma: correlation with clinical, biochemical, and histopathological data

Guido Di Dalmazi, Giulio Vara, Antonio De Leo, Alexandro Paccapelo, Lorenzo Tucci, Valentina Vicennati, Saverio Selva, Caterina Balacchi, Donatella Santini, Francesco Minni, Uberto Pagotto, Rita Golfieri & Cristina Mosconi
University of Bologna, Italy

Computerized tomography (CT) texture analysis (TA) provides a valuable amount of quantitative data on single voxels and their relationship in a target lesions, giving additional value to the CT scan. CTTA has been applied to several oncologic diseases. We aimed to correlate the data derived from CTTA of pheochromocytoma to clinical, biochemical and histopathological data in 30 consecutive patients. Pheochromocytoma was confirmed at histology. The CTTA was performed on unenhanced, late arterial, venous, and delayed phases images. We analyzed first and second order features and performed correlation with blood pressure levels, urinary metanephrines and histopathological parameters: Pheochromocytoma of the Adrenal gland Scaled (PASS) and Grading of Adrenal Pheochromocytoma and Paraganglioma (GAPP) scores, Ki67 values, and *SDHB* expression at immunohistochemistry. We performed a multivariate regression model to assess the correlations and a cluster analysis to identify a "radiomic signature". Urinary metanephrines correlated with skewness (b = 0.905, P <0.001), kurtosis (b = 0.337, P = 0.015), and mean value of the distribution of Hounsfield Unit (HU) in arterial phase (b = −0.007, P = 0.030). Urinary normetanephrines correlated with the maximum HU value (b = 31.649, P <0.001) and the energy in arterial phase (b = 97030.7, P = 0.007). Ki-67 showed a significant correlation with the standard deviation of HU values distribution in portal phase (b = 0.155, P = 0.001) and the skewness of distribution in unenhanced phase (b = −1.118, P = 0.047). PASS score showed weak correlation (R^2 = 0.182) with the tumor volume (b = 5.33x10^{-5}, P = 0.037). GAPP score was correlated with energy (b = 112.27, P = 0.006) and maximum HU value (b = 0.002, P = 0.003) in arterial phase, kurtosis in HU distribution of portal phase (b = −0.829, P = 0.023), and tumor volume (b = 2.25x10^{-5}, P = 0.008). Tissue expression of *SDHB* correlated with kurtosis of HU distribution in portal phase (b = 0.453, P = 0.031), and shape compacity (b = 3.856, P = 0.001). Two clusters were identified, based on radiomic features. When compared to cluster 2 (n = 7), cluster 1 (n = 18) showed higher compacity (15.4 vs 8.9, P = 0.001), lower volume (10.2 ml vs 42.7 ml, P <0.001), lower maximum HU value in unenhanced (86.1 vs 94.7, P = 0.040) and arterial (197.4 vs 241.9, P = 0.021) phase, and higher minimum HU value in portal phase (−24.2 vs −53.3, P = 0.046). Patients in cluster 2 had higher systolic and diastolic blood pressure at diagnosis, and a higher GAPP score (4 vs 6, P = 0.050). All patients with metastatic disease were included in cluster 2 (0% vs 28.6%), even though the difference was not significant (P = 0.070). CTTA provided useful parameter that may be helpful for a thorough preoperative characterization of the pheochromocytoma.

Pre-operative hypercortisolism and post-operative adrenal insufficiency in pheochromocytomas: a single center retrospective analysis of 168 patients

Eleni Kourti[1], Bonnet Fideline[2], Anna Vaczlavik[1], Rossella Libe[1], Laura Bessiene[1], Laurence Guignat[1], Mathilde Sibony[3], Lionel Groussin[1], Bertrand Dousset[4], Guillaume Assié[1] & Jerome Bertherat[1]
[1]Cochin Hospital, Department of Endocrinology, Paris, France; [2]Cochin Hospital, Department of Hormonology, Paris, France; [3]Cochin Hospital, Department of Pathology, Paris, France; [4]Cochin Hospital, Department of Endocrine Surgery, Paris, France

Introduction
Pheochromocytoma might be associated with hypercortisolism and post-operative adrenal insufficiency. The aim of this study is to determine the frequency of cortisol dysregulation before and after pheochromocytoma surgery.
Methods
Single center retrospective study of consecutive pheochromocytoma patients investigated in the Endocrinology department of Cochin Hospital before and after surgery from 2008 to 2020. Demographic characteristics, medical history, treatment, clinical examination, genetic analysis, hormone levels (dexamethasone suppression test, urinary free cortisol, plasma cortisol levels, preoperatively and ACTH-stimulation test postoperatively) as well as histology reports were reviewed.
Results
187 patients with pheochromocytoma underwent workup and surgery between 2008 and 2020. 168 patients were analyzed (19 cases excluded for insufficient data). Median age was 53 years old (18–89). 70 (42%) were men, 98 (58%) women. 8 patients (4%) had bilateral pheochromocytomas. Prior to admission, 50% of patients were on antihypertensive treatment and 25% had diabetes. The majority of pheochromocytomas were incidentalomas (87 cases, 52%), 37 patients (22%) presented with classic symptoms and 12 (7%) were diagnosed during a blood pressure workup. The other 12.5% (21 patients) presented with cardiovascular manifestations such as cardiac arrest and Takotsubo cardiomyopathy whereas 11 patients (6.5%) were found positive upon genetic disease monitoring (VHL, MEN2, NF1). Preoperative workup showed abnormal dexamethasone suppression

test (cortisol >50 nmol/l) in 30/168 (18%) and high urinary free cortisol in 18/168 (11%). 1 patient had adrenal insufficiency before surgery. 32 patients (19%) presented postoperative adrenal insufficiency: in 15 cases (9%), adrenal insufficiency was primary (due to bilateral adrenalectomy or previous unilateral adrenalectomy) and in 13 (7.7%) of central origin. 7/13 patients with post-operative corticotroph deficiency presented pre-operative biological hypercortisolism, while 6/13 had no abnormal preoperative investigations (4/6 having not received post-operative glucocorticoid before post-operative assessment). Histology showed coexistence of adrenocortical adenoma and pheochromocytoma in the same adrenal gland in 5 patients (3%), of whom 1 had signs of Cushing, elevated urinary free cortisol preoperatively, and adrenal insufficiency postoperatively. In 1 other case, pheochromocytoma cells stained with anti-ACTH antibody (this patient also presented signs of Cushing and elevated cortisol levels).

Conclusion

Possible cortisol excess is present in up to 18% of pheochromocytomas while demonstrated Cushing with histologic evidence for adrenal or ectopic Cushing and post-operative corticotroph deficiency is present in less than 5% of the cases. Post-operative glucocorticoid replacement therapy has to be discussed on an individual basis taking in account clinical and systematic hormonal pre-operative assessment.

Background

Benign adrenocortical tumours are found in 3–5% of adults and can be non-functioning (NFAT) or associated with cortisol excess. The latter group divides into patients with clinically overt signs (adrenal Cushing's syndrome, CS) and patients lacking CS signs (mild autonomous cortisol excess, MACE). The 1 mg-overnight dexamethasone suppression test (DST) further differentiates MACE into MACE-1 (possible MACE; post-DST cortisol 50–138 nmol/l) and MACE-2 (definitive MACE; post-DST cortisol >138 nmol/l). A recent systematic review and meta-analysis reported a high prevalence of metabolic syndrome in patients with benign adrenocortical tumours; however, large-scale prospective data are lacking.

Methods

We included 1305 patients with confirmed benign adrenal tumours recruited to the prospective ENSAT EURINE-ACT study (2011–2016). The prevalence of hypertension, resistant hypertension (defined as treatment with ≥3 anti-hypertensives), type 2 diabetes (T2D), T2D with insulin use, and need for with lipid-lowering medications in the EURINE-ACT cohort was compared to 5268 population controls from the 2014 cohort of the Health Survey for England, which monitors health trends in the UK. Multinomial logistic regression was used to obtain BMI-, age, and sex-adjusted odds ratios (aOR).

Results

Cortisol excess was highly prevalent, affecting 50.3% of patients (MACE-1 34.6%, MACE-2 10.7%, CS 5%). Patients carried an increased risk of hypertension, which gradually increased with the degree of cortisol excess: NFAT aOR 3.66 (95%CI 3.02–4.43); MACE-1 aOR 5.03 (3.96–6.40); MACE-2 aOR 6.72 (4.37–10.32); CS aOR 11.86 (6.50–21.65) (all P <0.001). Similarly, all groups presented with an increased risk of resistant hypertension: NFAT aOR 6.40 (4.72–8.68); MACE-1 aOR 7.43 (5.43–10.16); MACE-2 aOR 10.04 (6.36–15.86); CS aOR 31.37 (16.00–61.50) (all P <0.001). Furthermore, patients showed an increased risk of T2D: NFAT aOR 2.62 (2.00–3.44); MACE-1 aOR 2.75 (2.05–3.69); MACE-2 aOR 4.06 (2.45–6.71); CS aOR 11.00 (5.31–22.77) (all P <0.001). Patients with cortisol excess and T2D more often required insulin treatment: MACE-1 aOR 2.70 (1.58–4.62); MACE-2 aOR 4.24 (1.98–9.09); CS aOR 11.08 (3.62–33.90) (all P <0.001). The use of lipid-lowering drugs was also higher in patients with NFAT (aOR 2.11 [1.71–2.59]), MACE-1 (aOR 2.20 [1.75–2.76]), and MACE-2 (aOR 2.65 [1.80–3.89]) (all P <0.001).

Conclusions

Patients with benign adrenocortical tumours have an increased prevalence of cardiometabolic disease and present with a more severe phenotype. The risk increases with the degree of cortisol excess and is highest in CS and MACE-2. However, even NFATs carry a considerably increased cardiometabolic burden, which may be due to underlying autonomous cortisol secretion that is not picked up by currently employed biochemical testing.

All-cause mortality in adrenal insufficiency patients with primary and secondary adrenal insufficiency

Kanchana Ngaosuwan[1,2], Desmond Johnston[2], Ian Godsland[2], Jeremy Cox[3], Azeem Majeed[4], Jennifer Quint[5], Nick Oliver[2] & Stephen Robinson[3]

[1]Faculty of Medicine and Public Health, HRH Princess Chulabhorn College of Medical Science, Chulabhorn Royal Academy, Bangkok, Thailand; [2]Faculty of Medicine, Imperial College, Metabolism, Digestion and Reproduction, London, UK; [3]Imperial NHS trust, London, UK; [4]School of Public Health, Imperial College, London, UK; [5]National Heart and Lung Institute, Imperial College, London, UK

Background

Increased mortality risk of patients with adrenal insufficiency has been inconsistently reported. This might have resulted from the disparity of time and place of clinical care between the study patients and reference population. Also, data of patients with secondary adrenal insufficiency was limited as majority focused on other types of pituitary disorders. Therefore, we compared all-cause mortality of patients with primary and secondary adrenal insufficiency with individually matched controls.

Subjects

In a UK general practitioner database (Clinical Practice Research Datalink; CPRD), 6821 patients with adrenal insufficiency of any type (2052 primary adrenal insufficiency, 3948 secondary) were compared with 67564 matched controls (20366 primary, 39134 secondary).

Methods

Each study patient was individually matched with up to 10 controls who had the same sex, GP practice (representing place of clinical care and degree of deprivation), 5-year strata of the year of birth, and 5-year strata of the start of follow-up. Follow-up began on the latest of the date at which patients were diagnosed, registered to GP, or the GP provided standard information. Follow-up finished on the earliest date of death, or de-registering from the GP. All-cause mortality rate and the hazard ratio of the study patients relative to controls was analysed in overall and separately according to type of adrenal insufficiency.

Results

In adrenal insufficiency of any type, the mortality rate of the patients was significantly higher than controls (35.2 [95%CI, 33.4–37.0] vs. 21.0 [20.6–21.5] per 1000 person-years, P <0.0001) with a follow-up period of 40799

and 406899 person-years, respectively. The hazard ratio of mortality in adrenal insufficiency of any type was increased (1.68 [95%CI, 1.58–1.77], P <0.0001). In patients with primary adrenal insufficiency, the hazard ratio was 1.83 (95%CI, 1.66–2.02, P <0.0001), which was higher than those with secondary adrenal insufficiency (HR, 1.52 [95%CI, 1.40–1.64], P <0.0001).
Conclusion
With taking account of sex, age, time and place of clinical care, all-cause mortality risk remained increased in both primary and secondary adrenal insufficiency patients but more predominant in primary adrenal insufficiency.

Background
The aim of the study was to evaluate urine steroid metabolomics by gas chromatography–mass spectrometry (GC–MS) for the adrenocortical carcinoma (ACC) metastases` biomarkers detection in patients after the surgery.
Patients and methods
33 postoperative ACC patients were examined before and after the surgery. The median age was 47 years (41–60). The Weiss score was more than 3 points according to the histological analysis. 9 patients were disease-free in the early postoperative period (up to 12 months after surgery). Metastases were detected 1–5 years after the operation in 18 patients. The control group consisted of 25 patients with adrenocortical adenoma (ACA) without malignant features defined by the histological analysis. The median age was 52 (47–61) years. We studied urine steroid profile using gas chromatograph–mass spectrometer SHIMADZU GCMS – QP 2020. Statistical data was processed with software STATISTICA for WINDOWS (Version 10). Results comparison was made using Mann–Whitney test.
Results
The ACC`s main biomarkers urinary excretion (dehydroepiandrosterone (DHEA), 16α-DHEA, etiocholanolone (Et), pregnandiol (P2), pregnantriol (P3), pregnendiol (dP2), 16-hydroxypregnendiol (16-OH-dP2), pregnentriol (dP3), tetrahydro-11-deoxycortisol (THS) was determined using GC–MS. The abovementioned metabolites excretion rates were decreased in all disease-free postoperative patients as compared to the same patients` preoperative steroid profiles. Nevertheless, the 16α- DHEA, 16-OH-dP2, THS excretion was increased compared with control group. The 21-hydroxypregnendiol (21-OH-dP2), 20-on-3,11,17 and 21-pregnentetrol (20-on -dP4) were identified in the urine of all ACC recurrence patients. The increased 16-OH-dP2-3β excretion and decreased 16-OH-dP2-3α/16-OH-dP2-3β ratio (<2.0) were typical for ACC recurrence patients in comparison with disease-free patients. The 10 patients of the disease recurrence cohort had the THS, androgen (DHEA and its metabolites), progestogenes (P2, P3), 5-ene-pregnenes (dP2, dP3, 16-OH-dP2) increased excretion. While in the other 8 patients of the same cohort THS and 5-ene-pregnenes increase was observed.
Conclusion
ACC postoperative recurrence biomarkers were obtained using urinary steroid profiling. The study of androgen, progesterone, pregnenolone metabolites, THS, 3β,16,20-dP3, 21-OH-dP2, 21-OH-dP4 urinary excretion and 3α,16,20-dP3/3β,16,20-dP3 ratio is of particular importance for detecting the ACC metastases development in the early postoperative period.

Cellularity and lipolytic function of human perirenal and subcutaneous adipose tissues in patients with pheochromocytoma

Nathalie Boulet[1], Jessica Fontaine[1], Jean Galitzky[1], Anne Bouloumié[1], Matthieu Thoulouzan[2] & Philippe Caron[3]
[1]INSERM U1297, Institute of Cardiovascular and Metabolic Diseases, Toulouse, France; [2]Rangueil Hospital, Urology, Andrology and Kidney Transplant, Toulouse, France; [3]Larrey Hospital, Endocrinology, Metabolic Diseases and Nutrition, Toulouse, France

Pheochromocytomas are catecholamine-producing tumours with diverse cardiovascular and metabolic outcomes including insulin resistance and weight loss. However, impacts on adjacent and distal fat depots are not fully defined and more particularly concerning induction of beige/brown adipose tissue (AT). The aim of the study is to characterize the cellular composition, the metabolic function and the expression of brown AT markers in matched perirenal (PRAT) and abdominal subcutaneous AT (SAT) in association or not with pheochromocytoma. Paired biopsies from PRAT and SAT are collected from patients undergoing adrenalectomy for pheochromocytoma, cortisol-producing adrenal adenoma or non-secreting and benign adrenal tumours. AT are enzymatically digested to isolate mature adipocytes and stroma-vascular fraction (SVF) cells. The adipocyte diameter repartition is determined by image analysis, lipolytic activity by glycerol and free fatty acid quantifications in the presence of lipolytic pharmacological agents (isoprenaline, epinephrine, atrial natriuretic peptide ANP), and finally adipocyte gene expression is analysed by RT-qPCR approaches. The cellular composition of the SVF (progenitor, endothelial and immune cells) is determined by flow cytometry analyses. Our results demonstrate that, whatever the clinical context, PRAT adipocytes are less hypertrophied than paired SAT adipocytes, and that pheochromocytoma patients tend to exhibit smaller adipocytes whatever the AT depot. Multilocular brown-like adipocytes are observed in PRAT only and in patients with pheochromocytoma. Their presence is associated with higher beige/brown gene expression marker (UCP1, uncoupling protein 1). PRAT and SAT adipocytes show distinct lipolytic responses to beta-adrenergic receptor agonist (isoprenaline, epinephrine) and ANP in pheochromocytoma patients compared to others. In agreement, the transcriptomic profiles of adrenergic receptors, lipolytic enzymes and lipid droplet associated proteins are different according to AT depot. Finally, the distribution of progenitor cell subsets, macrophages and lymphocytes, specific of PRAT and SAT, is modulated in pheochomocytoma patients. Our study shows that PRAT exhibits specific cellularity and metabolic lipolytic function compared to SAT and both AT depots are different in pheochromocytoma patients. Finally, presence of brown-like multilocular and UCP1 positive adipocytes is only observed in PRAT from such patients.

PEP12.2

Growth factors and state of lipid peroxidation in hypertensive patients with type 2 diabetes mellitus

Sergiy Koval, Tatyana Starchenko, Larisa Rieznik & Marina Penkova
Government Institution "L.T. Malaya Therapy National Institute of the National Academy of Medical Science of Ukraine", Department of Arterial Hypertension and Prevention of Its Complications, Kharkiv, Ukraine

The combination of hypertension and type 2 diabetes mellitus (T2DM) greatly increases the risk of adverse cardiovascular events. Identification of factors which accelerate the development of atherosclerosis, it is important to more fully understand the mechanisms of progression of these diseases.
The aim is to study the relationship between levels of transforming growth factor-β1 (TGF-β1), insulin-like growth factor-1 (IGF-1) and lipid peroxidation in patients with essential hypertension (EH) and T2DM.
Methods
The study involved 76 p atients with grade 2 EH (40 men and 36 women, aged 48 to 60 years): 42 patients with EH with T2DM and 34 hypertensive patients without T2DM. In all patients, the development of EH preceded the development of T2DM. The control group consisted of 24 healthy individuals. The blood levels of TGF-beta1, IΦP-1 and malonic dialdehyde (MDA) were measured in all subjects.
Results
TGF-β1 and MDA blood levels were significantly higher in EH patients with T2DM compared with hypertensive patients without diabetes (p1 = 0.032 and p2 = 0.043, respectively) and with the control group (p1 = 0.018 and

p2 = 0.027, respectively). The level of IGF-1 in the blood of patients with EH and T2DM was significant lower compared with patients with EH without diabetes (P = 0.034) and with healthy individuals (P = 0.042). The levels of IGF in patients with EH without diabetes and in healthy individuals didn't differ. At the same time, in hypertensive patients with T2DM, positive correlations of blood levels of TGF-β1 with MDA (P = 0.003), as well as blood levels of TGF-β1 and MDA with low-density lipoprotein cholesterol (LDL-C) (P = 0.038 and P = 0.026, respectively) were revealed.
Conclusion
The established increase in the levels of TGF-β1 and lipid peroxidation products in combination with a decrease in the level of IGF-β1 creates conditions for the accelerated progression of atherosclerotic damage in hypertensive patients with T2DM.

PEP12.3

Association between triglyceride-glucose index (TyG) and serum urate concentrations in young adults

Tulio Loyola Correa[1] & Isabel Oliveira de Oliveira[2]
[1]Universidade Federal de Pelotas, Faculty of Medicine, Pelotas, Brazil; [2]Universidade Federal de Pelotas, Postgraduate Program in Epidemiology, Pelotas, Brazil

Background
Serum urate (SU) has been positively and independently associated with type 2 diabetes in observational studies, but causal roles remain unclear.[1] Triglycerides and glucose (TyG) index can be a useful and easily performed indicator of insulin resistance for daily clinical practice.[2] The aim of this study was to evaluate the association between SU and TyG index in 22-year-old participants of a birth cohort.
Materials and methods
During 1993, all live born babies in the city of Pelotas (Brazil) were invited to take part in a prospective study and sub-samples of this cohort were followed-up since then. At the 22-year follow-up, interviews and clinical measurements were performed and non-fasting blood samples were drawn from the participants. SU, blood glucose and triglycerides were evaluated by enzymatic-colorimetric assay. Insulin was assessed by electrochemiluminescence immunoassay. The TyG index was calculated as *Ln* [fasting triglycerides (mg/dl) × fasting glucose (mg/dl)]/2. The co-variables used were fasting period, body mass index, alcohol use disorder and systolic and diastolic blood pressure. Variables are shown as mean (±S.D.) or median (25–75 IQR). Sex-stratified linear regressions have been performed using STATA 13 and P <0.05 was considered statistically significant.
Results
The sample was composed by 1657 (46.3%) men and 1921 (53.7%) women of 22 years old. Mean (±S.D.) SU (mg/dl) was higher in men than in women (5.2±1.2 vs. 3.9±1.1); the same was observed for blood glucose (mg/dl) (91.7±25.7 vs. 88.5±20.9). Median (25–75 IQR) insulin (μU/ml) was also higher in men [20.5 (10.9; 39.3) vs. 18.4 (10; 34.2)]. Median (25–75 IQR) triglycerides (mg/dl) was higher in women [87 (63; 117) vs. 85 (62; 120)]. The adjusted linear regression coefficient (95%CI) between SU and TyG index was 0.50 (0.39; 0.61) for men and 0.41 (0.32; 0.51) for women; both with P <0.001. SU was positively associated with TyG index in both sexes, although there was no statistically significant association in adjusted analyses between SU and insulin concentrations.
Conclusion
The increase of SU was associated with increasing TyG index in early adult age, even when adjusted for potential confounders. The association of SU with TyG index may occur earlier than with serum insulin.

PEP12.4

Relationship between adiponectin, TNFα and SHBG in prepubertal children with obesity

Marta Ramon-Krauel[1], Maria Jesus Leal-Witt[1], Oscar Osorio-Conles[1], Montse Amat-Bou[1], Carles Lerin[1] & David Martinez[2]
[1]Institut de Recerca Sant Joan de Déu, Hospital Sant Joan de Déu, Endocrinology, Barcelona, Spain; [2]Vall d'Hebron Research Institute (VHIR), Autonomous University of Barcelona (UAB), Diabetes and Metabolism, Barcelona, Spain

Sex hormone-binding globulin levels are low in adult subjects with obesity when compared to normal-weight individuals. Obesity is associated with higher tumor necrosis factor alpha (TNFα) plasma levels and lower adiponectin levels. Moreover, we have recently elucidated the molecular mechanisms by which TNFα and adiponectin regulate hepatic SHBG production. The main objective of this study was to assess if the adult associations between TNFα, Adiponectin and SHBG are present in prepubertal children. We determined several morphometric and biochemical parameters in normal-weight and obese prepubertal children, as well as quantified plasma SHBG, TNFα-R1, and adiponectin levels. Our results showed that prepubertal children with obesity had decreased plasma SHBG levels compared to normal-weight controls (67 nmol/l vs 172 nmol/l). Importantly, SHBG plasma levels correlated significantly (P < 0.05) with TNFα (negatively, **ßstd** = −0.31) and adiponectin (positively, ßstd = 0.58) suggesting an important role of these two cytokines in determining plasma SHBG levels in prepubertal children. Furthermore, the results showed that plasma adiponectin levels are may play a more important role than TNFα in influencing plasma SHBG levels in our prepubertal population with obesity.

PEP12.5

Anthropometric and laboratory features of children with type 1 diabetes and coexisting autoimmune disorders

Natalia Volkova[1] & Anghalika Solntsava[2]
[1]2nd Children's Clinical Hostital, endocrinology, Minsk, Belarus; [2]Belarusian Research Center for Pediatric Oncology, Hematology and Immunology, Director, Minsk, Belarus

Objective
To determine predictive factors of co-existing autoimmunity in children with type 1 diabetes mellitus (T1D).
Material and methods
64 children with combined autoimmune pathology (T1D and autoimmune thyroid diseases or celiac disease) - main group, age 12.14±3.54 years) and 81 patients with only T1D (comparison group, age 11.57±3.34 years) were recruited. Groups were comparable in age (P = 0.34) and T1D duration (P = 0.81). Assessment of anthropometric parameters; biochemical blood parameters; glycosylated hemoglobin (HbA1c), vitamin D, thyroid hormones, antibodies to thyroid peroxidase (anti-TPO), glutamate decarboxylase (GAD) and zinc transporter8 (ZnT8) levels was carried out. The assessment of height and body mass index (BMI) was carried out using the *z*-criterion (who, 2007). Results were processed using Excel 10.
Results
In the main group 44 children had combinations of T1DM with autoimmune thyroiditis (AIT), 15 – celiac disease (CD), 3 – Graves' disease, 1 – AIT and CD. Children with T1D and autoimmune thyroid diseases had significantly higher *z*-scores of BMI (+0.24 vs −0.19, P = 0.019) and the prevalence of overweight (26.5 vs 12.0%, P = 0.029) than the comparison group. Children with concomitant thyroid diseases demonstrated higher triglycerides (P = 0.032) and very low density lipoproteins (P = 0.038) compared to the comparison group. Among the risk factors for autoimmune thyroid damage, the association of thyroid pathology with severe vitamin D deficiency (level <10 ng/ml) ($\chi 2$ = 6.848, P = 0.009, odds ratio (OR) 3.57, 95% confidence interval (CI) 1.07–5.46), female gender (OR 3.08, CI 1.48–6.36), GAD antibodies (OR 5.13, CI 1.23–21.35) and ZnT8 antibodies (OR 5.13, CI 1.23–21.35) was detected. Children with concomitant thyroid diseases and severe vitamin D deficiency had higher risk of diabetes decompensation (HbA1c>9%) compared with the patients with vitamin D concentration > 10 ng/ml (χ^2 6.848; OR 7.00; CI 1.50–32.72, P = 0.011). Association of CD with early (less than 4 years old) T1D onset (χ^2= 8.250; OR 7.022; CI 2.22–22.20, P = 0.003) and severe vitamin in D deficiency was established (OR 9.82; CI 5.27–17.34, P = 0.001).
Conclusions
1. Higher levels of HbA1c were detected in children with polyglandular autoimmune pathology and severe vitamin D deficiency.
2. Higher risk of autoimmune thyroid disease was found in patients with severe vitamin D deficiency, high levels of GAD ant ZnT8 antibodies, female gender and late puberty. Among the risk factors of CD early onset of T1D and severe vitamin D deficiency was detected.

PEP12.6

Serum leptin and urine cortisol to cortisone ratio are correlated in familiar partial lipodystrophy type I (Kobberling Syndrome)

Tommaso Daffara[1], Valentina Mancioppi[2], Marina Caputo[1,3], Ilaria Leone[1], Alice Ferrero[1], Caterina Pelosini[4,5], Ferruccio Santini[4], Gianluca Aimaretti[1], Giovanni Ceccarini[4] & Flavia Prodam[1,2,3]
[1]Università del Piemonte Orientale, Endocrinology, Department of Translational Medicine, Novara, Italy; [2]University of Piemonte Orientale, Division of Pediatrics, Department of Health Sciences, Novara, Italy; [3]Università del Piemonte Orientale, Department of Health Sciences, Novara, Italy; [4]University Hospital of Pisa, Obesity and Lipodystrophy Center, Endocrinology Unit, Italy; [5]University Hospital of Pisa, Chemistry and Endocrinology Laboratory, Italy

Background
In lipodystrophy (LD) adipose tissue function is impaired, leading to a severe metabolic syndrome. Familiar Partial LD (FPLD) type I (Kobberling Syndrome) overlaps with Cushing's syndrome phenotype. The latter and the metabolic impairment observed in FPLD1 may suggest a crosstalk between the HPA axis, assuming that leptin sensitivity is preserved in this context. We aimed to evaluate if leptin levels are associated with glucocorticoid activity in FPLD1.
Methods
12 adult patients (2 males, 10 females) with PLD were recruited. Physical parameters, plasma lipid profile, renal function, liver enzymes, glucose, HbA1c, and leptin levels were determined. 24-h urine cortisol (F) and cortisone (E) through LC–MS/MS analysis were also measured.
Results
Twelve adult subjects were classified as Köbberling syndrome after the genetic and immune exclusion of other LD forms. All of them presented increased waist circumferences, decreased hip circumference and peripheral skinfold thickness. All patients had type 2 diabetes under treatment (insulin with or without other antidiabetic drugs), with high HbA1c levels (8.2±0.3%). The patients were treated for high lipid levels (statin, ezetimibe, fibrates, omega 3, PCSK9 inhibitors alone or combined), with LDL in the target range in 33%, and triglycerides lower than 150 mg/dl in 26.6%. Leptin levels were in the lower range according to sex and BMI (29.5±5.5 µg/l). All subjects had correct serum cortisol suppression after an overnight 1-mg dexamethasone test. Leptin levels correlated in all the subjects and females alone with BMI (r: 0.623), HDL-cholesterol (r: 0.485), estimated glomerular filtration rate (eGFR, r: −0.687), and 24 h urine F/E ratio (r: 0.750), but not with urine F and E alone. F/E ratio was also correlated with eGFR (r: −0.457). Urine F/E ratio, in a stepwise model composed of significant variables, was positively predicted by leptin levels and BMI (R: 0.756, R2: 0.562, P <0.032).
Conclusion
In FPLD 1 (Kobberling), leptin levels are directly associated with the 24 h urine F/E ratio suggesting complex crosstalk among leptin, 11β-hydroxysteroid dehydrogenase 1 and 2 activity. Glucocorticoid sensitivity and renal impairment could contribute to the severity of the phenotype.

PEP12.7

Systems biology approach identifies key genes and related-pathways for childhood obesity

Daisy Crispim[1,2], Felipe Pellenz[2] & Tais Assmann[2]
[1]Hospital de Clinicas de Porto Alegre, Endocrine Division, Porto Alegre, Brazil; [2]Universidade Federal do Rio Grande do Sul, Post-Graduate Program in Medical Science: Endocrinology, Porto Alegre, Brazil

Introduction
Epidemiological studies have suggested that obesity during childhood increases the risk of developing metabolic comorbidities, such as type 2 diabetes, later in life. Childhood obesity is a complex disease whose molecular mechanisms are not completely elucidated. However, studies have demonstrated that approximately 65% of the variation associated with obesity is due to genetic factors. In this context, a system biology approach could contribute to the scientific knowledge regarding genetic factors related to childhood obesity onset.
Aim
To identify molecular mechanisms involved in childhood obesity by implementing a system biology approach.
Methods
Experimentally validated and computationally predicted genes related to Pediatric Obesity (C2362324) were downloaded from the DisGeNET v7.0 database. The protein–protein interaction (PPI) network was constructed using the STRING v11.0 database and analyzed using Cytoscape v3.8.2. The relevance of each node for the network structure and functionality was assessed using the degree and betweenness algorithms to define the hub-bottleneck genes. Functional and pathway enrichment analyses were performed based on Gene Ontology (GO) terms and KEGG Pathways.
Results
The search on the DisGeNET database retrieved 191 childhood obesity-related genes. After the PPI network analysis, 12 hub-bottleneck genes were identified: *INS, LEP, STAT3, POMC, ALB, TNF, BDNF, CAT, GCG, PPARG, VEGFA,* and *ADIPOQ*. These hub-bottleneck genes are involved in several biological processes, including regulation of gluconeogenesis, lipid export from cells, and response to vitamin E. Regarding KEGG pathways, these genes were enriched in adipocytokine signaling, insulin resistance, longevity regulation, thermogenesis, and cytokine signaling pathways.
Conclusion
Our approach identified 12 hub-bottleneck genes that are highly connected and probably have a key role in childhood obesity. Moreover, functional enrichment analyses demonstrated that they are enriched in several biological processes and pathways related to the underlying molecular mechanisms of obesity. These findings provide a more comprehensive information regarding genetic and molecular factors behind childhood obesity pathogenesis.

PEP12.8

Medicsen smartpatch: a new approach to diabetes management

Alejandro Ruiz & Rafael Danilo García
Medicsen, Madrid, Spain; Central University of Venezuela, Biochemistry, Caracas, Venezuela

Introduction
Diabetes, a metabolic disorder characterized by abnormal blood glucose levels, is a serious chronic disease that implies an important public health problem. Being Insulin the main hormone for modulating blood glucose levels, subcutaneous injections are the main way for its administration in the diabetes treatment. However, this way of administration can lead to poor patient compliance, apart from several side-effects. Although other ways of administration have been investigated, such as oral or inhaled insulin, these have enough drawbacks to not be consider as substitutes of subcutaneous injections. To face this problem, Medicsen is developing a Smartpatch that integrates a wide range of technologies, all of them tested in laboratory, with the purpose of ensuring the correct transport of insulin from the surface of the skin to the bloodstream using a non-invasive and painless way through a phenomenon induced by the sonophoresis.
Materials and methods
Several *in vitro* and *in vivo* tests have been performed in order to prove the efficacy and safety of the technology, allowing us to collect experimental evidence through different methodologies that demonstrate the therapeutic potential of the device. Among these methodologies there are permeability studies using Franz diffusion Cell and swine models (that prove efficacy of the technology) as well as safety studies, for both the insulin and the skin.
Results
All tests performed have been successfully accomplished with results indicating the lack of damage to either the insulin molecule, which maintains its biological function and stability, as seen in vivo, in HPLC studies or in the circular dichroism spectra of the samples, which shows no variability, reaching the characteristic minimum at 219 nm (s.d. ± 8.31) in all groups tested, or to the skin, which suffers none significant damage, as proven by electron microscopy evaluation of the skin or by ELISA and other biochemical assays in which changes in the expression and concentration of relevant skin cellular compounds such as TNF α and IL-2 were studied. Lastly, the technology proved to be effective in the delivery of insulin molecules through the skin in a non-invasive way, as observed in a Franz Diffusion Cell system and in the *in vivo* model of blood glucose reduction.
Conclusions
Results observed during *in vitro* and *in vivo* studies indicate that the technology developed by Medicsen is effective and safe for the patient. Following steps, including human trials, will be critical to fully demonstrate its potential in the treatment of diabetes.

Factors associated with Aryl hydrocarbon Interacting Protein (AIP) expression in gonadotroph pituitary neuroendocrine tumours (Pit-NETs)

Michela A. Polidoro[1], Tiziana Feola[2,3], Francesca Gianno[4,5], Valeria Palumbo[1], Antonietta Arcella[5], Roberta Morace[6], Michelangelo De Angelis[6], Felice Giangaspero[4,5], Vincenzo Esposito[6,7] & Marie-Lise Jaffrain-Rea[1,2]

[1]University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy; [2]Neuromed IRCCS, Neuroendocrinology, Pozzilli, Italy; [3]Sapienza University, Department of Experimental Medicine, Rome, Italy; [4]Sapienza University, Department of Radiological, Oncological and Pathological Sciences, Rome, Italy; [5]Neuromed IRCCS, Neuropathology, Pozzilli, Italy; [6]Neuromed IRCCS, Neurosurgery, Pozzilli, Italy; [7]Sapienza University, Department of Human Neurosciences, Rome, Italy

Introduction
AIP is a predisposing gene for GH/PRL-secreting PitNETs. Clinically non-functioning PitNETs (NFPT) occasionally occur in the setting of AIP germline mutations, sometimes arising from Pit-1 lineages. However, AIP overexpression has been observed in unselected NFPT and associations with the gonadotroph phenotype and/or tumour aggressiveness were suggested. We wished to evaluate the significance of AIP expression in gonadotroph tumours defined by the WHO 2017 classification.
Material and methods
Thirty-seven gonadotroph Pit-NETs (GnPT) were studied, displaying positive immunostaining for FSH/LH (n = 30) or SF1 only (n = 7). Male patients predominated (26M, 11F, median age 57 years (IQR 46-66)). Tumours were characterized for size, invasiveness and Ki-67 immunostaining. Gene expression of AIP, β−FSH, β−LH, SF1, Cyclins A2, B1 and D1 was evaluated in surgical samples and in 3 normal pituitaries (NP) by Real-Time qRT-PCR, based on a Taqman methodology using commercial probes and β−bactin as a housekeeping gene (Applied Biosystems). AIP immunostaining (AIP-IHC) was evaluated on paraffin-embedded sections by a semi-quantitative score (n = 31). Non-parametric tests (Wilcoxon and Spearman correlation) were used for statistical analysis.
Results
Gene overexpression of AIP was found in 18/37 GnPT (48.6%), tended to be more frequent in M (57.7 vs 27.3% in F, P = 0.09), and not significantly correlated with tumour size, invasiveness or Ki67. A single case of AIP downregulation was observed. AIP transcripts were significantly correlated with β-LH (ρ = 0.54, P = 0.0019) and cyclin A2 (= 0.35, P = 0.031), with a similar trend for β−FSH and SF1 (P = 0.06 each), but unrelated to Cyclin D1 or B1. AIP-IHC was significantly associated with AIP transcripts (ρ = 0.51, P = 0.010) and classified as high/moderate/low in 38.7%, 41.9%, 19.3% of the cases, with no male predominance and irrespective of tumour characteristics.
Discussion
Compared to NP, the proportion of AIP gene overexpression in GnPT (48.6%) is probably underestimated due to its normal mammo-somatotroph localization. Indeed, 80% of NFPT displayed clear AIP immunostaining (38.7% with a high score). Neither AIP gene or protein overexpression was significantly associated with tumour aggressiveness. A significant correlation was also found between AIP and Cyclin A2 transcripts. However, unlike cyclins D1 and B1, Cyclin A2 overexpression has not yet been associated with NFPT proliferation or invasion. Rather, AIP transcripts were associated with gonadotroph features, in particular β-LH.
Conclusion
AIP expression appears to be associated with the endocrine phenotype of GnPT rather than with their volume or invasiveness. The potential implications of these findings in the natural history of GnPT should be better defined.

PEP13.2

Use of free triiodothyronine level in central hypothyroidism management

Nacera El Bouzegaoui, Raad Ornella, Soyez Marion, Al Salameh Abdallah & Desailloud Rachel
Centre Hospitalier Amiens, Endocrinologie, Amiens, France

Introduction
There is no consensus about biological targets in patients with central hypothyroidism (CH). The main objective of this work was to characterize our patients with CH.
Design
We conducted a retrospective study at the University Hospital of Amiens. In our center, patients with CH are considered "well substituted" if the free thyroxine (FT4) is in the upper half of the reference interval and the free triiodothyronine (FT3) within the normal range. We studied the FT4/FT3 ratio in all and "well-substituted" patients and the determinants of FT4/FT3 in patients with normal FT3.
Results
124 patients were included between 01/07/2016 and 31/07/2018. CH was due to pituitary adenoma in 100 patients. The average dose-weight of levothyroxine was 1.34 µg/kg/day. The average FT4/FT3 ratio was 4.04 with a a physiological ratio (3.10–3.30) in only10 patients. 36% of the patients were considered "well substituted". They had a significantly higher TeBG (P = 0.028) and lower triglycerides (P = 0.044) ; the ratio was physiological in only 2 patients and ratio was higher in women than men: 4.54 vs 3.94 (P = 0.034). 101 of all patients had FT3 within the normal range. FT3 was significantly lower in obese patients (P <0.01). Patients with FT3 higher than the calculated median had a FT4/FT3 ratio closer to the physiological ratio.
Conclusion
Treatment of CH remains a challenge for the endocrinologist. It seems relevant to target a FT3 close or higher than the median, without considering the FT4 to obtain aphysiological FT4/FT3 ratio but the obtention of a clinical improvement has to be evaluated.

Key-words
central hypothyroidism, levothyroxine, free thyroxine, free triiodothyronine, FT4/FT3 ratio

PEP13.3

Natural history of nonfunctioning pituitary incidentalomas and adenomas. A systematic review and meta-analysis

Stefan Dukanovic, Mikkel Andreassen & Jesper Krogh
Rigshospitalet, Department of Endocrinology, Copenhagen, Denmark

Objective
The objective of this systematic review was to assess the incidence of growth, new pituitary endocrinopathies, and the incidence of surgery and/or radiotherapy in conservatively treated non-functioning pituitary adenomas/incidentalomas (NFPAs/NFPIs).
Method
A bibliographical search of Embase and Pubmed was conducted in order to identify eligible studies.
Results
33 Cohort studies including 1554 patients with a mean follow-up time of 3.8 years were extracted. During follow-up 482/1554 (31.02%) tumors grow corresponding to a risk of 6.4/100 (95% CI. 4.8 to 8.1; I^2 = 90) person years (py). Surgery was necessary in 136/1151 (11.82%) cases corresponding to a risk of 2.8/100py (95% CI. 1.9 to 3.4; I^2 = 58%). New endocrinopathies were observed in 76/901 (8.44%) patients corresponding to a risk of 1.4/100py (95% CI 0.7 to 2.1; I^2 = 74%). However, subgroup analysis suggested that growth of microadenomas occurred at a rate of 0.9/100 py (95% CI. 0.4 to 1.3; I^2 = 47%).
Conclusion
Conservatively treated NFPAs/NFPIs are in significant risk of growth, however, new endocrinopathies and active treatment is quite rare. Especially, the risk of growth in microadenomas was rarely observed. This, new evidence, supports differentiated follow-up protocols of NFPAs/NFPIs based on baseline tumuor size. However, the evidence was based on studies with methodological issues that need to be addressed in order to improve future decision making.

PEP13.4

Long term management in aggressive thyrotropinoma

Oana Stanca[1], Cristina Stancu[1], Anda Dumitrascu[2] & Corin Badiu[1]
[1]National Institute of Endocrinology, Thyroid Related Disorders, Bucharest, Romania; [2]National Institute of Endocrinology, Radiology, Bucharest, Romania

Introduction
Thyrotropinoma is a rare pituitary tumor (<2% of pituitary adenomas) arising from PIT1-lineage cells, which expresses and secrete TSH. In most cases, the etiology is unknown but rare cases have been described to arise in context of MEN 1 syndrome. Diagnosis is often delayed by confusion with primary hyperthyroidism, which determine the tumor to be already large and invasive at the time of diagnosis. GH and prolactin cosecretion is an increased factor of aggression. We present the case of a 17-year-old patient, female, diagnosed 10 years ago with a pituitary tumor with autonomous cosecretion of TSH and GH, in which the first symptoms were weight loss, sweating, fatigue and palpitations. Early imaging described a tumor size of 20/31/37 mm, with central necrosis and parasellar extension in the bilateral cavernous sinus, including the internal carotid artery, optic chiasm, with no limit to separate from the frontal gyrus. The patient underwent multiple operations (6 times) both transsphenoidal and transfrontal, in combination with gamma knife radiosurgery but without significant tumor control. The patology exam revealed pituitary adenoma positive for TSH and GH with a Ki67 proliferation index of 20%. The patient is negative for the AIP mutation. Under treatment with progressively increased doses of octreotide acetate and cabergoline, no tumor control was obtained. Thus, in 2017, the last transsphenoidal intervention was performed, followed by local pituitary radiotherapy, with secretory active tumor residue, for which lanreotide was administered in combination with cabergoline. The patient presents a stationary clinical and biological condition in the last 2 years, with a tumor remnant of 72/54/40 mm, with retro and left parasellar extension, with TSH values after dilution slightly decreasing (1020 IU/ml), with therapeutic efficacy of GH profile. The patient underwent total thyroidectomy for voluminous goiter in 2014, which revealed multifocal, encapsulated, papillary carcinoma, pT3b G1, radioiodotreated, currently cured. The patient has corticotroph insufficiency and diabetes insipidus in replacement therapy and a history of early puberty and hyperestrogenism TSH-induced.
Discussions
Thyrotropinoma, although a rare benign tumor, is a life-threatening disease, especially when associated with hormonal cosecretion and high rate of proliferation. The consequences determined by the mass effect (convulsions, headache, oculomotor paresis, blindness), post-surgical and post-radiotherapy complications (bacterial meningitis, corticotroph insufficiency, diabetes insipidus) as well as those after long administration of somatostatin analogues, represent a challenge in the evolution and the patient's long-term prognosis.

Cushing's syndrome and chronotype

Adriana Albani[1], Stephanie Zopp[1], Julia Simon[1], Frederick Vogel[1], Martin Reincke[1], Martha Merrow[2] & Marily Theodoropoulou[1]
[1]Ludwig-Maximilians-University; Medizinische Klinik IV; Endocrine Research Unit, München, Germany; [2]Institute of Medical Psychology, Faculty of Medicine, LMU Munich, München, Germany

Patients with Cushing's syndrome have a poor quality of sleep. However, little is known about their timing of sleep as regulated by the circadian clock, the so called-chronotype. Considering that patients with Cushing's syndrome lose their rhythmic circadian cortisol secretion and that corticosteroids act as synchronizer of the circadian clock in cells, aim of the study was to determine whether patients with Cushing's syndrome alter the timing of their sleep compared to a control population and, if so, whether this persists after remission of the disease. To this aim, we administered the Munich Chronotype Questionnaire (MCTQ) and collected data from 12 patients with Cushing's syndrome (mean age 45 ± 14), 58 patients in remission (mean age 48 ± 12) and 26 controls with no history of hypercortisolism (mean age 45 ± 12). The MCTQ analysis revealed that patients with Cushing's syndrome have a significantly shorter weekly sleep duration vs. patients in remission (05:10 ± 01:56 vs. 06:43 ± 01:36 P = 0.019). The Cushing's patients woke earlier on both workdays and work-free days vs. controls (P = 0.001 and P = 0.005 respectively) and vs. patients in remission (P = 0.011 and P = 0.009 respectively). The mean wake time of Cushing's patients on workdays and work-free days was at 0443 ± 0117 h and 0535 ± 0145 h respectively, while for control and remission groups sleep ended at 0618 ± 0119 h and 0604 ± 0120 h respectively on workdays and at 0721 ± 0140 h and 0717 ± 0137 h respectively on work-free days. The mid-sleep-time on free days "MSF" was earlier in patients with Cushing vs controls (P = 0.051) and vs remission (P = 0.094). The mid-sleep-time on free days corrected for the "oversleep" due to the sleep deprivation that people accumulate during the workdays (Midsleep time on Free days sleep-corrected, MSFsc) was significantly earlier in patients with Cushing vs. controls (P = 0.035). These data suggest that patients with Cushing's syndrome have an early chronotype due to wake-up time and that this alteration could recover after remission. It is noteworthy that the mean sleep-offset of the controls is almost the same compared to that of patients in remission. The MCTQ could be a new instrument in the complex and challenging diagnostic approach to Cushing's syndrome, and in the detection of recurrence. Based on our findings, we suggest that information on sleep timing should be routinely collected on patients suffering from Cushing's syndrome. This data will contribute to understanding how the homeostat and the circadian clock interact to yield consolidated sleep at a particular phase according to the individual.

Background
Improved patient-reported outcomes (PROs) are increasingly becoming a key treatment objective in acromegaly. Validated PROs were used to assess disease and treatment burden in the MPOWERED phase 3 trial in acromegaly, which also assessed safety and efficacy of oral octreotide capsules (OOC; MYCAPSSA®) compared to injectable SRLs (iSRLs).
Methods
Eligible patients had acromegaly diagnosis, biochemical control of acromegaly (insulin-like growth factor I <1.3 × upper limit of normal; mean integrated growth hormone, <2.5 ng/ml) and ≥6 months' iSRL treatment (octreotide or lanreotide). Eligible patients entered a 26-week Run-in phase to determine the effective OOC dose; responders at week 24 then entered a 36-week randomized controlled treatment (RCT) phase receiving OOC or iSRLs in a 3:2 ratio. The Acromegaly Treatment Satisfaction Questionnaire (Acro-TSQ) is a recently validated tool that includes 27 items in 6 domain scores for PROs in acromegaly.[1] Acro-TSQ data were collected at baseline (reflecting outcomes on iSRLs), end of Run-in (reflecting outcomes on OOC), and end of RCT (OOC or iSRLs).
Results
Of 146 enrolled patients, 92 entered RCT (OOC, N = 55; iSRLs, N = 37). Acro-TSQ scores at the end of Run-in (26 weeks' OOC treatment) were compared to baseline (iSRLs). In the 92 patients randomized, 3 of 5 Acro-TSQ domains (emotional reaction, treatment convenience, and treatment satisfaction) showed significant improvement at end of Run-in compared to baseline. Injection site interference was not assessed as no injection site reactions were observed with OOC. Other domains showed a nonstatistically significant pattern of improvement at end of Run-in when compared to baseline. Patients randomized to iSRLs in the RCT after receiving OOC in the Run-in (N = 37) reported more anxiety (RCT end, 53%; Run-in end, 29%) and frustration (RCT end, 45%; Run-in end, 34%) with iSRLs compared to OOC. Overall treatment satisfaction was higher while receiving OOC (Run-in end, 92%; after receiving iSRLs in RCT, 75%). Breakthrough symptoms were reported more frequently with iSRLs (31%) than OOC (15%) at the end of RCT.

Conclusion
Higher patient satisfaction, convenience and emotional well-being, and improved symptom control based on the newly validated Acro-TSQ PRO reporting tool were observed with OOC compared to iSRLs in patients enrolled in the MPOWERED trial.

PEP13.7

Hepcidin is lower in patients with acromegaly compared to healthy control subjects
Dorota Filipowicz, Aleksandra Krygier, Ewelina Szczepanek-Parulska, Maja Domagalska & Marek Ruchala
Department of Endocrinology, Metabolism and Internal Medicine Poznan University of Medical Sciences, Poland, Poznać Poland

Introduction
Hepcidin, main body iron regulator protein, decreases iron concentration available for erythropoiesis. Oppositely, excessive erythropoiesis in acromegaly patients (increased GH and IGF-1), may inhibit hepcidin production. GH stimulates bone marrow, whereas IGF-1 receptors are expressed in erythrocytes. Exogenous GH administration in healthy subjects reduced hepcidin level. The role of hepcidin in iron metabolism of acromegaly patients has not been established. This prospective, cross-sectional study evaluated for the first time the hepcidin level in relation to iron parameters in newly diagnosed acromegaly patients.
Materials&Methods
We included 25 patients (16 men and 9 women) of mean age 49 ± 17 years at the time of acromegaly diagnosis, expressed by elevated IGF-1 and GH level. Control group consisted of 25 healthy subjects matched by age and sex (CS). Applied exclusion criteria were pregnancy, breastfeeding, anaemia, haemolysis, haemorrhage, hemochromatosis, inflammation, neoplasms, kidney and liver diseases, autoimmune diseases, supplementation of iron, vitamin B12, folic acid and erythropoietin or hormonal treatment. Bioacvite form, Hepcidin-25, was measured in serum by high-sensitive ELISA (DRG Instruments GmbH, Germany). GH and IGF-1 serum concentrations were analysed by Hitachi Cobas e601 chemiluminescent analyser (Roche Diagnostics). To adjust IGF-1 to age and gender, percent over the upper limit of normal rage was used in some calculations (%IGF-1). Additionally, blood and iron parameters (complete blood count, haemoglobin, haematocrit, ferritin, iron) were evaluated.
Results
The median serum hepcidin concentration was significantly lower in acromegaly patients than in CS (9.8 vs 21.3 ng/ml, $P = 0.003$). Low hepcidin level in the acromegaly group was observed in both males (13 vs 23.9, $P = 0.03$) and females (7.6 vs 21.3, $P = 0.09$). Hepcidin correlated negatively with IGF-1 ($P < 0.05$, rho = −0.44) in acromegaly patients. The positive correlation was seen between iron concentration and%IGF-1 in acromegaly male subgroup ($P < 0.05$, rho = 0.532). Ferritin level was significantly lower ($P = 0.02$) in acromegaly males (94 ng/ml), than in healthy male subgroup (184 ng/ml). Red blood cell and iron parameters were within normal ranges in all subjects.
Conclusions
Acromegaly is characterized by diminished hepcidin serum concentration without concomitant iron and complete blood count abnormalities. Presumably, somatotropin axis disturbances in the course of acromegaly, may negatively impact hepcidin, which might be a mechanism aiming to increase iron availability for cells excessive replication resulting in tissue overgrowth, seen in acromegaly. This has to be proved in further studies.

PEP13.8

Use of antisense oligonucleotides as a therapy for Cushing's disease
Elizabeth Kemp[1], Hanan Eltumi[1], Jacob Whatmore[1] & John Newell-Price[1]
[1]University of Sheffield, Oncology and Metabolism, Sheffield, UK

Background
Cushing's disease (CD) is caused by high levels of blood cortisol resulting from excess secretion of adrenocorticotropic hormone (ACTH) from an anterior pituitary corticotroph adenoma. Clinical manifestations include diabetes, hypertension, osteoporosis, and depression. If untreated, CD has an increased mortality of five-fold owing to cardiovascular comorbidities, stroke or raised vulnerability to infection. Currently, transsphenoidal surgery is considered the first-line treatment but remission is achieved in only 65% of cases and the relapse rate is high. Furthermore, medical treatments are often accompanied by unpleasant side-effects. Antisense therapy is a technique for suppressing gene expression at the level of translation using antisense oligonucleotides (ASOs) against the mRNA of interest.
Aims
To investigate antisense therapy as a treatment for CD by targeting ASOs against ACTH-encoding POMC mRNA thereby reducing secretion of the hormone. To transfect mouse AtT20 cells (cells that secrete high levels of ACTH) with ASOs against POMC at varying doses to determine which is the most effective at reducing ACTH secretion.
Methods
An AtT20 cell line that secretes high levels of ACTH was used as the in vitro model system. ASOs were designed to specifically target exon 3 of the POMC gene. Transfection of AtT20 cells was carried out using Lipofectamine, and secreted ACTH levels were determined by immunoassay. Statistical analysis was done using ANOVA; P values < 0.05 considered significant.
Results
ASOs that targeted POMC exon 3 (ASO-2 and ASO-3) were transfected into AtT20 cells at 10 and 100 nM. Control ASOs were ASO-1 (matched to POMC sense strand) and ASO-4 (a scrambled version of ASO-3). Experiments included untreated AtT20 cells and AtT20 cells treated with transfection reagent or ASOs alone. The results of six experiments indicated that ACTH secretion from AtT20 cells was reduced after transfection with ASO-2 and ASO-3 at 100 nM (ANOVA, $P = < 0.05$) and 10 nM (ANOVA, $P < 0.05$) when compared with untreated AtT20 cells. ASO-1 and ASO-4 had no effect on ACTH secretion by AtT20 cells (ANOVA, $P > 0.05$).
Conclusions
ASOs against POMC can reduce ACTH secretion from AtT20 cells and may be useful as a novel therapy for CD.

Is initial hypocalcemia related to poorer outcomes in COVID-19 patients?
Helena Alves, Marta Almeida Ferreira, Lucia Almeida, Sara Correia, Diogo Ramalho & Maria João Oliveira
Centro Hospitalar de Vila Nova de Gaia/Espinho, Department of Endocrinology, Vila Nova de Gaia, Portugal

Introduction
Although most patients with COVID-19 have mild symptoms, some develop severe manifestations of the disease, leading to hospitalization and death. Previous studies reported that calcium played a central role in viral infections and replicative mechanisms of SARS-CoV. Hypocalcemia is a common finding among these patients. The aim of this study was to investigate the prevalence of hypocalcemia in a population of COVID-19 patients and to evaluate its clinical implications.
Material and Methods
Was performed a retrospective study that included adult COVID-19 patients admitted to the emergency department (ED) from March 15 to September 15, 2020, with ionized calcium (IC) measured in blood gas analysis. Demographic and clinical data were collected. Hypocalcemia was defined as calcium level below 1.18 mmol/l. Patients with comorbidities and on therapies influencing calcium metabolism were excluded. Assessed outcomes included hospitalization, length of stay and death. Statistical analysis was conducted with SPSS 3.5.0; the effect of IC on the outcomes was determined using generalized linear models; significance level considered was $\alpha = 0.05$.
Results
We included 179 patients (50.3% male; median age = 69 years); 138 patients required hospitalization. Hypocalcemia was present in 78.8% (n = 141) of the patients admitted to ER, and in 71.7% (n = 99) of the hospitalized patients. Assessing the relation between the IC value at admission in the ED and hospitalization, it was found that there is a statistically significant association between hypocalcemia and requirement of hospitalization, especially for patients with less than 60 years of age ($P = 0.033$). Among the hospitalized patients, the IC value wasn't related with the length of stay ($P = 0.24$). Of the 138 hospitalized patients, 28.2% (n = 39) died. The IC value wasn't related with death ($P = 0.29$).

Conclusion
Hypocalcemia was present in a significant number of patients in this population. Hypocalcemia on admission is significantly related with hospitalization need. This finding may have relevance in clinical practice, as the presence of hypocalcemia in an arterial blood gas analysis at admission in the ED may alert to the need of hospitalization, especially among patients below 60 years-old.

Selenium, zinc, and vitamin D supplementation affect the clinical course of COVID-19 infection in Hashimoto's thyroiditis

Zelija Velija Asimi[1,2], Almira Hadzovic-Dzuvo[2,3] & Djinan Al Tawil[2]
[1]University Sarajevo School of Science and Technology, Internal medicine – Endocrinology and Diabetology, Ilidža, Bosnia and Herzegovina; [2]Outpatient Clinic with a Daily hospital "Dr Al Tawil", Sarajevo, Bosnia and Herzegovina; [3]University of Sarajevo, Sarajevo, Bosnia and Herzegovina

Introduction
Adequate supply of zinc, selenium, and vitamin D is essential for resistance to other viral infections, immune function, and reduced inflammation. Low levels of micronutrients are associated with adverse clinical outcomes during viral infections. Vitamin D improves the physical barrier against the virus and stimulates the production of antimicrobial peptides. It can prevent cytokine storms by reducing the production of inflammatory cytokines. Selenium enhances the function of cytotoxic effector cells. Furthermore, selenium is important for maintaining T cell maturation and function, as well as for producing T cell-dependent antibodies. Our goal was to determine the effects of selenium, zinc, and vitamin D supplementation on recovery from COVID-19 in patients with pre-existing Hashimoto's thyroiditis.
Methods
A cohort observational study was conducted. Adult patients with pre-existing Hashimoto's thyroiditis admitted to the "Dr. Al-Tawil" outpatient clinic with COVID-19 from March 15 to December 31, 2020 were included. Of the 356 Hashimoto's patients who had COVID-19 infection, 270 (75.8%) took supplements and 86 (24.2%) did not.
Results
Most Hashimoto's patients (93%) who had COVID-19 were euthyroid. The study showed that Hashimoto's patients (24.2%) who did not take selenium, zinc and vitamin D increased their risk of adverse outcomes from COVID-19 infection. In those who did not take supplements, 28% required hospitalization. There were no deaths. After adjusting for age, gender, BMI, smoking status, we found an association between the absence of supplements and the risk of hospitalization, and invasive mechanical ventilation. Patients with Hashimoto's thyroiditis who had COVID-19 infection and who had previously taken supplements such as selenium, zinc, and vitamin D had milder clinical outcomes, or no symptoms compared to those who did not receive supplements who had a moderate or severe outcome (P <0.05).
Conclusions
For the treatment of people with Hashimoto's thyroiditis who become infected with COVID-19, the addition of selenium, zinc, and vitamin D3 could be beneficial. Randomized controlled trials and large population studies should be performed to evaluate these recommendations.
Keywords
COVID-19, Hashimoto thyroiditis, micronutrients, selenium, zinc, vitamin D

Multi-omics approach to analyze the molecular pato-physiology of the low T3 syndrome, observed in COVID-19 patients

Salvatore Sciacchitano[1], Claudia De Vitis[1], Michela D'Ascanio[1], Andrea Petrucca[2], Gerardo Salerno[2], Rachele Amodeo[3], Andrea Sacconi[4], Valentina Salvati[5], Giulia Piaggio[6], Luisa de Latouliere[6], Alberto Ricci[1] & Rita Mancini[1]
[1]Sapienza University of Rome, Clinical and Molecular Medicine, Roma, Italy; [2]Sapienza University of Rome, Neuroscience, Mental Health and Sense Organs, Rome, Italy; [3]Sant'Andrea Hospital, Flow Cytometry Unit, Clinical Laboratory, Rome, Italy; [4]Regina Elena National Cancer Institute, UOSD Oncogenomica ed Epigenetica, Rome, Italy; [5]Regina Elena National Cancer Institute, Scientific Direction, Rome, Italy; [6]Regina Elena National Cancer Institute, UOSD SAFU Unit, Rome, Italy

We have previously shown that Low T3 syndrome is associated with serum markers, radiologic and clinical scores of COVID-19 severity and it can be considered as a novel biomarker of the severity of the disease (Endocrine Abstracts 2020, 70 AEP1091). With the aim to analyze the mechanisms that are at the basis of this condition as well as the pathways involved, we applied an integrative approach of multi-omics data. We performed: i) *multiplex cytokine assay*, using the Bio-Plex Pro Human Cytokine 27-Plex Immunoassay and a panel of cytokines and growth factors, ii) *immune phenotyping by CyTOF analysis*, using the Maxpar Direct Immune Profiling Assay, analyzed with the Maxpar Pathsetter automated package and visualized with the high-dimensional Cauchy Enhanced Nearest-neighbor Stochastic Embedding (Cen-seð map and iii) *transcriptome analysis by NanoString*, using the nCounter PanCancer human IO 360 panel. We analyzed data from 4 patients affected by COVID-19, 2 with low FT3 serum values (≤ 1.7 pg/ml) and 2 with normal FT3 serum values (> 1.7 pg/ml and < 3.71 pg/ml). Results were compared to those obtained in 2 healthy control subjects. The study was approved by our Institutional Ethical Committee (RIF. CE 5773_2020). Cytokine assay indicated that some cytokines, namely IL-1b, IL-1ra, IL-6, IL-8, IL-10, IP-10, MCP-1 and MIP-1a, were increased in COVID-19 patients with low FT3 syndrome, some, namely IL-4, IL-7, IL-12, IL-13, Eotaxin, PDGF-bb and RANTES, were reduced and some others, namely IL-2, IL-9, IL-17A, FGF-basic, MIP-1b and TNF-a, were unchanged. CyTOF analysis indicated that Low T3 Syndrome in COVID-19 patients was associated with a reduction in CD45+, CD3+ T lymphocytes and CD19+ B lymphocytes, while there was an increase in CD3-/CD56+ NK cells as well as in CD14+ Monocytes. Finally, NanoString analysis showed a different expression pattern, with divergent allocation on the Principal Component Analysis plot and identified four genes, namely NLRP3, IFIT3, CD38 and CD79B, that were clearly deregulated in COVID-19 patients with Low T3 syndrome. NLRP3 was clearly downregulated while the IFT3, CD38 and CD79B were upregulated. In conclusion, we were able to identify, in our COVID-19 patients, specific immune and gene expression signatures associated with the occurrence of the Low T3 syndrome. Our approach allowed us to obtain insights on the mechanisms and on the pathways involved in the thyroid hormone regulation of immune response to SARS-CoV-2 infection and to identify new molecules of potential clinical utility in the management of severe COVID-19.

PEP14.4

SARS-CoV-2: potential trigger for a cerebral venous thrombosis associated to subacute de Quervain's thyroiditis?

Juan-Antonio Ruiz-Gines[1], MIGUEL-ANGEL RUIZ-GINES[2], Maria-Piedad Picazo-Perea[2], Patricia Fuentes-Bullejos[2], David Melguizo-Melguizo[2] & Maria-Carmen Lorenzo-Lozano[2]
[1]Lozano Blesa University Clinical Hospital, Neurosurgery, Zaragoza, Spain; [2]Virgen de la Salud University Hospital, Laboratory Medicine, Toledo, Spain

Context
Thyroiditis is defined as an inflammation of the thyroid gland. There are several kinds of thyroiditis, and they can be associated with either increased, decreased, or normal thyroid function (triphasic-course). Subacute granulomatous thyroiditis, also known as subacute thyroiditis (SAT), giant-cell thyroiditis, or de Quervain thyroiditis, is a self-limited thyroiditis characterized by neck pain and thyroid dysfunction. Generally, it is preceded by an upper respiratory tract infection, which supports the viral or postviral origin (parotitis, Coxsackie, Influenza, adenovirus and echovirus). The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) that began in Wuhan, China, has spread rapidly worldwide and is triggering more cases of thyroid disease. Routine assessment of thyroid function during hospitalization for COVID-19 is not recommended by the clinical management guidelines. However, worsening of pre-existing thyroid dysfunction (i.e. differentiated thyroid cancer [DTC], Hashimoto thyroiditis [HT]) or *de novo* (SAT), possibly caused by infection itself, should not be missed, to avoid misleading work-up, unnecessary medicalization, and its potential negative prognostic impact.
Objectives
The aim of this case is to report a SAT related to the triggering factor for SARS-CoV-2 infection and associated with a cerebral venous thrombosis (CVT).

Methods
A 49-year-old woman who, in the context of a SARS-CoV-2 pandemic, was referred to the Emergency-Department for fever, neck pain radiated to the jaw, palpitations and sinus tachycardia (110 bpm) without structural heart disease, intense headache, predominantly occipital and right temporal, associated with nausea, vomiting and visual disturbances, occurring 7 days after a SARS-CoV-2-positive oropharyngeal swab.
Results
A CT-scan was performed, which revealed a hyperdense image of the superior longitudinal sinus which, after intravenous administration of contrast, presented a filling defect in its interior, suspecting CVT. MRI and MRA confirmed the absence of flow in the right transverse and longitudinal sinus. A congenital thrombophilia study was conducted. The *G20210A* mutation of the prothrombin gene was evidenced in heterozygosity (A/G). Thyroid-function-tests: TSH <0.005 µIU/dl, FT4 8.7 ng/dl, TPOAb 0.84 IU/ml and TSHrAb <1 IU/l. CRP 33 mg/l and ESR 52 mm. Hemogram: lymphocytic leukocytosis. Thyroid-ultrasound: hypertrophic, heterogeneous gland (multiple diffuse hypoechoic areas), without significant vascularization. The patient had no history of thyroid disease.
Conclusions
We reported a case with a clinical suspicion of SAT associated CVT potentially related to SARS-CoV-2 infection as a triggering factor (underlying hypercoagulability-state) in presence with other acquired or hereditary prothrombotic factors. Physicians should be aware of possible connections between SARS-CoV-2 with thyroid and neurologic disfunctions or additional clinical manifestations, which should be investigated by prospective studies.

PEP14.5

Macro-TSH as a cause of refractory hypothyroidism in a covid-19 patient: description of the first case

Miguel-Angel Ruiz-Gines[1], Maria-Piedad Picazo-Perea[1], Juan-Antonio Ruiz-Gines[2], Julia Sastre[3], Mercedes Agudo-Macazaga[1], Esther Martin-Torres[1], Aurora Lopez-Martos[1] & Maria-Carmen Lorenzo-Lozano[1]
[1]Virgen de la Salud University Hospital, Laboratory Medicine, Toledo, Spain; [2]Hospital Clínico Universitario Lozano Blesa, Neurocirugía, Zaragoza, Spain; [3]Virgen de la Salud University Hospital, Endocrinology, Toledo, Spain

Context
The effects of COVID-19 on the thyroid axis remain uncertain. Recent evidence has been conflicting, with Euthyroid-Sick-Syndrome-ESS, thyrotoxicosis or suppression of thyroid-function-tests (TFTs) reported which can lead to inadequate diagnoses and treatments.
Objective
The aim of this case report is to describe, for the first time, a possible interference of macro-TSH in a patient with SARS-CoV2 and thyroid carcinoma.
Case report
56-year-old male evaluated in the Emergency-Department for fever, fatigue and cough. Chest-X-rays: lung parenchyma with multiple bilateral ground-glass areas suggestive of viral pneumonia in the context of the COVID-19 pandemic. Positive RT-PCR nasopharyngeal swab.
Patient's medical-history
Parathyroidectomy (hyperparathyroidism secondary to parathyroid adenoma) and total thyroidectomy (multinodular goiter). Fine Needle Aspiration (FNA) of dominant nodule in left-*thyroid-lobe*: negative for malignancy. Multifocal papillary microcarcinoma (right-*thyroid-lobe* [3.3 mm] and left-*thyroid-lobe* [4.0 mm]) as an incidental finding; without ablative treatment with I131. Replacement therapy: Levothyroxine 137 µg/day. During admission, TFTs were developed, and we observed that TSH levels increased compared to previous studies. The Levothyroxine was readjusted (150 µg/day). Malabsorption (parenteral nutrition) and/or incorrect dose are ruled out. TFTs can seem discordant/incongruent with the clinical picture, so we decided to develop a study of possible interference.

Results*	Sample-1	Sample-2
TSH (0.5–4.0 µU/ml)	0.33	40.03
FT4 (0.8–2.0 ng/dl)	0.66	0.83
FT3 (1.7–4.0 pg/ml)	1.43	1.81

Conclusion and discussion
We identified a possible interference of non-functional macro-TSH complexes (mostly TSH-IgG) in the determination of thyrotropin in patients with underlying thyroid pathology and infection by SARS-CoV2 performed on immunoassay platforms. *Interference-detection* and mitigation methods: serial dilutions and precipitation with polyethylene-glycol-PEG (currently the most widely used technique to detect macro-TSH) vs. gel-filtration-chromatography (expensive and not available most Hospitals). Heterophilic-antibodies (HAMA) and Rheumatoid-Factor: negatives. An exceptional finding, not described to date and, on many occasions, forgotten or underestimated, since can lead to incorrect diagnoses and treatments. Thyroid function should not be assessed in seriously ill patients unless there is a thyroid dysfunction. The thyroid dysfunction caused in COVID-19 presents a dynamic evolution with a tendency towards progressive recovery. It is essential to take into account this fact that allows an adequate quality of care and patient safety in the context of COVID-19. Screening macro-TSH should be developed before hormone replacement therapy by discordant results.

Patient-Sample-2	Results
TSH	40.036

Higher incidence of COVID-19 in patients with adrenal insufficiency compared with background statistics

Christine Yedinak[1] & Ian Louis Ross[2]
[1]Oregon Health & Sciences University, Neurosurgery, Portland, USA; [2]University of Cape Town, Cape Town, South Africa

Introduction
Worldwide, 100 million people have been diagnosed with COVID-19. Patients with adrenal insufficiency (AI) are assumed, on the basis of expert opinion, to be at higher risk of infection.
Aim
To determine the patient reported incidence and potential risk factors of infection with COVID-19, for patients diagnosed with AI.
Method
A 42 item questionnaire (inclusive of AI diagnosis, COVID-19 symptoms, testing and concomitant diseases in 2020) was vetted by a panel of endocrine specialists and patients with AI from Patient Advocacy groups worldwide and distributed via associated websites and social media. Participation was voluntary and anonymized. Descriptive and crosstabs (Chi-squared) analysis was performed using SPSS27.
Results
Completed surveys included $N = 1292$ participants from 43 countries. 40/494 patients (screened for COVID-19) tested positive (31 female (78%): mean age 39.9 years (range 1.0–68.0). Highest incidence $N = 19$ (47.5%) was found in those 40–60 years, with a mean duration of AI of 12.7 years (range 0.17–42.0) years. Reported ethnic composition Caucasian + European 35 (87.5%), Hispanic in 3 (7.5%), African-American in 1 (2.5%) and in 1(2.5%) who did not declare this. The positive tests largely correlated with those with the greatest number of participants: UK (35%), USA (35%) and Brazil (17.5%), whereas, the total positive tests from the combination of Finland, Sweden, Estonia, Australia and Netherlands represented (12.5%) patients. COVID-19 positive patients were found to have pre-existing cardiovascular disease (16.6%) and

pulmonary disease (27.7%). Of the COVID-19 positive cohort, participants with congenital adrenal hyperplasia (CAH) reported a significantly higher incidence of COVID-19 (12.9%, $P = 0.001$) compared with other diagnoses.
Discussion
At the time of the survey, 100 million patients worldwide were diagnosed with COVID-19, whereas 1292 participants with adrenal insufficiency completed the questionnaire, representing 12.9% of the expected numbers of respondents, based on an average prevalence of adrenal insufficiency of 100 per million. Of those who completed the questionnaire, 494 participants had been screened for COVID-19 and only 40 (8%) who tested positive, representing an annual incidence of 3.1%, which is slightly higher than the worldwide incidence of COVID19 of 1.25%.
Conclusion
Although this survey is biased by self-election, we detected a slightly higher than background incidence of COVID-19 infection for patient with AI. This may be concerning as patients with adrenal insufficiency are potentially at greater risk from respiratory illness due to impaired natural killer cell function. In particular, patients with CAH may be at especially greater risk for COVID-19.

Beyond the huge impact on physical health, coronavirus disease-19 (COVID-19) epidemic represents a significant psychological stressor, causing effects on mental health. The psychological distress of the epidemic and consequent mass quarantine on patients with hypocortisolism, particularly frail and vulnerable to infections and stress, is unknown. The current multicentre, web-survey-based, case-control study evaluated the psychological impact of COVID-19 quarantine in a large cohort of patients with hypocortisolism. The study was performed on 478 patients with hypocortisolism adequately treated with glucocorticoids, of which 363 with adrenal insufficiency (AI)(215F, 148M, 47.61 ± 12.44 years) and 115 with congenital adrenal hyperplasia (CAH)(75F, 40M, 38.84 ± 13.23 years), matched with 478 Italian healthy controls. Major disabilities, ongoing/recent hospitalization, psychiatric illnesses/medications, COVID-19 infection/suspicion represented exclusion criteria. All patients with hypocortisolism were informed on required glucocorticoid dose adjustments in case of intercurrent illnesses and stress conditions. AddiQoL, General Anxiety Disorder-7 (GAD-7), Perceived Stress Scale (PSS), Patient Health Questionnaire-9 (PHQ-9), Specific Psychotic Experiences (SPEQ), Ego-Resiliency Revised Scale (ER89-R), and 18-items Psychological Well-Being (PWB) questionnaires were telematically and anonymously administered to participants during the last 3-weeks of quarantine, lasted 2 months in Italy; higher scores of GAD-7, PSS, PHQ-9 and SPEQ indicated higher anxiety, perceived stress, depression, and psychosis, whereas lower scores in AddiQoL, ER89-R and PWB indicated lower QoL, resiliency and psychological well-being. In the whole cohort of patients, GAD-7 ($P < 0.001$), PHQ-9 ($P < 0.001$) and PWB-environmental mastery ($P = 0.043$) scores appeared significantly higher, whereas ER89-R related to openness to life experience (ER89-R-OL) ($P = 0.003$) and PWB-self-acceptance ($P = 0.004$) scores significantly lower in patients than in controls. AI patients reported significantly lower AddiQoL ($P < 0.001$) scores than CAH patients, with significantly higher PSS ($P = 0.022$) scores in AI than CAH females, and higher ER89-R-OL ($P = 0.035$) scores in AI than CAH males. During quarantine, 64 (13.4%) patients, 53 (14.6%) AI and 11 (9.6%) CAH patients required glucocorticoid dose increase, with females reporting a significantly higher prevalence of glucocorticoid dose increase than males (16.9% vs 8%, $P = 0.0057$). In conclusion, patients with hypocortisolism suffered increased anxiety and depression, associated with a dissatisfaction feeling of self and a reduced resiliency, although reporting a higher sense of mastery in managing the environment, being able to choose contexts suitable to personal needs. Moreover, AI patients reported a worst QoL than CAH patients, with higher perceived stress in females, and higher resiliency in males. Therefore, an empowerment of psychological counseling for these vulnerable patients during COVID-19 should be considered by national health-care services.

Introduction
In response to the COVID-19 pandemic, delivery of medical education has transitioned from predominantly in-person teaching to virtual platforms. Simulation-based learning is a successful teaching modality to develop clinicians' knowledge and skill, while safeguarding patients. Simulation has traditionally been performed via face-to-face role play, however many of its principles can be adapted for remote use. We explored the effectiveness of the Simulation via Instant Messaging - Birmingham Advance (SIMBA) model as a method of delivering virtual, simulation-based medical education during the COVID-19 pandemic.
Methods
Six SIMBA sessions were conducted between July 2019 and October 2020, focussing on different topics in the field of endocrinology (namely adrenal, pituitary ($n = 2$), thyroid and diabetes ($n = 2$)). In each session, transcripts based on real-life anonymised data were used to simulate clinical cases. During simulation, participants interacted with moderators (trained medical students and junior doctors) through WhatsApp and assessed patients as they would in real life, formulating a diagnosis and management plan. Simulation

was followed by an interactive discussion with experts in the relevant field, delivered by Zoom. Wilcoxon Signed Rank test was used to investigate the effect of SIMBA on participants' self-reported confidence in approaching clinical scenarios, measured using Likert scale. Acceptance and relevance of the simulated cases were also analysed.
Results
236 participants completed pre- and post-SIMBA evaluation forms and were included in analysis. Self-reported confidence in participants' approach to the simulated cases was significantly improved following SIMBA: [overall (n = 236) (P <0.001); pituitary 1.0 (n = 24) (P <0.001), diabetes 1.0 (n = 17) (P <0.001), adrenal (n = 33) (P <0.001), thyroid (n = 37) (P <0.001), pituitary 2.0 (n = 79) (P <0.001), diabetes 2.0 (n = 46) (P <0.001)]. 94.5% (n = 207/219) strongly agreed/agreed SIMBA sessions accommodated their personal learning style and 90.9% (n = 199/219) strongly agreed/agreed the sessions were engaging. 96.4% (n = 188/195) and 93.8% (n = 183/195) strongly agreed/agreed that the content was impactful at both a personal and professional level respectively. Participants felt that SIMBA improved their clinical competencies in patient care [57.4% (n = 112/95)], professionalism [32.3% (n = 63/195)], patient management [86.2% (n = 168/195)], systems-based practice [45.6% (n = 89/195)], practice-based learning [71.8% (n = 140/195)] and communication [25.1% (n = 49/195)].
Conclusion
SIMBA is an effective virtual teaching model which improves clinicians' confidence in managing various conditions in endocrinology. Participants felt the simulated cases were relevant to their clinical practice and suited their learning style. Further research is needed to explore whether this increased confidence level translates to better real-life performance.

Diabetic euglycemic ketoacidosis in newly diagnosed type 1 diabetes mellitus during A ketogenic diet

Beril Turan Erdogan[1], Himmet Durmaz[2], Nagihan Bestepe[1], Berna Ogmen[2], Didem Ozdemir[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara City Hospital, Department of Endocrinology and Metabolism, Turkey; [2]Yildirim Beyazit University Faculty of Medicine, Ankara City Hospital, Department of Endocrinology and Metabolism, Turkey

Background
Diabetic ketoacidosis (DKA) is one of the most serious complications of diabetes. It is characterised by the triad of hyperglycemia (blood sugar >250 mg/dl), ketosis and metabolic acidosis (arterial pH <7.3 and serum bicarbonate <18 mEq/l). Rarely these patients can present with blood glucose (BG) levels of less than 200 mg/dl, which is defined as euglycemic DKA.
Case
A 22-year-old female patient applied to the primary care physician with tingling and numbness in the hands. Fasting blood glucose was 205 mg/dl with normal renal and liver function tests in the first laboratory evaluation and then suggested to apply to the endocrinology clinic. After learning about high blood sugar level, she avoided foods containing carbohydrates and followed a ketogenic diet. She is 160 cm tall and 45 kg heavy. The patient referred to the endocrinology clinic with nausea two weeks later. Her plasma glucose level was 86 mg/dl with an HbA1C of%10.3. HbA1C measurement was repeated and confirmed to be high. She was diagnosed with diabetes. Her laboratory assessments revealed an elevated anion gap of 20.9, increased urinary and plasma ketones, and metabolic acidosis. Low hCG values excluded pregnancy The diagnosis of euglycemic DKA was made, and treatment with intravenous fluids and insulin was initiated, then the patient improved.The C-peptide level was 0.42 μg/l (n:0.81–3.85 low normal). Anti-glutamic acid decarboxylase and anti-insulin antibodies were negative, while the anti-islet cell antibody was positive. There was no one with diabetes in her family. She was screened for liver diseases and glycogen storage diseases, and no pathological condition was detected.
Conclusion
We present a type 1 diabetic patient diagnosed with euglycemic DKA. The possible aetiology of euglycemic DKA includes decreased caloric intake, heavy alcohol consumption, the recent use of sodium-glucose cotransporter 2 inhibitors, chronic liver disease and glycogen storage disorders. DKA in pregnancy has also been reported to present with euglycemia. Our patient had euglycemic DKA triggered by the ketogenic diet. Euglycemic DKA can be missed or inadequately treated in patients presenting with euglycemia on initial presentation. Recognising this condition in newly diagnosed patients can also be a challenge for physicians.

Monocarboxylate transporter 8 deficiency leads to autophagy-induced persistent cathepsin-mediated thyroglobulin processing triggered by insufficient L-type amino acid transporter 2 functionality

Vaishnavi Venugopalan[1], Alaa Al-Hashimi[1], Jonas Weber[1], Maren Rehders[1], Janine Golchert[2], Georg Homuth[2], Francois Verrey[3], Janine Kirstein[4], Heike Heuer[5], Ulrich Schweizer[6], Eva Wirth[7] & Klaudia Brix[1]

The thyroid gland functions in supplying thyroid hormones (TH) to the body periphery, which is enabled by cathepsin-mediated thyroglobulin proteolysis and TH translocation across membranes by the Mct8, Mct10, and Lat2 transporters. Previously, we showed that cathepsin K-deficient mice feature normal thyroid phenotypes which is, in part, due to the functional compensation through cathepsin L upregulation that is independent of the classical hypothalamus–pituitary–thyroid axis. These results imply that intrathyroidal TH-sensing mechanisms exist. Since cathepsin K deficiency correlated with increased Mct8 protein amounts, we aimed to understand if TH transporters are part of such thyroid auto-regulatory mechanisms. Therefore, in a murine model, we analyzed phenotypic differences in thyroid function arising from combined cathepsin K and TH transporter deficiencies, i.e. in *Ctsk*$^{-/-}$/*Mct10*$^{-/-}$, *Ctsk*$^{-/-}$/*Mct8*$^{-/y}$, and *Ctsk*$^{-/-}$/*Mct8*$^{-/y}$/*Mct10*$^{-/-}$. Our results show that, albeit impaired TH export, *Ctsk*$^{-/-}$/*Mct8*$^{-/y}$/Mct10$^{-/-}$ mice feature thyrotoxic stress-triggered autophagy induction, which results in persistent thyroglobulin proteolysis due to enhanced lysosomal biogenesis. Furthermore, we aimed to elucidate what triggers autophagy in *Ctsk*$^{-/-}$/*Mct8*$^{-/y}$/*Mct10*$^{-/-}$ thyroid glands. Lat2 has been implicated as a sensor of amino acids in kidney and muscle, where it is believed to activate mTORC1, a negative regulator of autophagy. Since TH as iodothyronines are amino acid derivatives, we propose that Lat2 might be involved in sensing of intrathyroidal cytosolic TH states in *Ctsk*$^{-/-}$/*Mct8*$^{-/y}$/*Mct10*$^{-/-}$ mice, thereby inducing autophagy when TH export is lacking. Although no significant changes were observed in Lat2 mRNA levels in the triple-deficient thyroids in comparison to wild-type controls, Lat2 immunoblotting showed significantly reduced protein amounts. In addition, immunofluorescence staining demonstrated decreased Lat2-specific signals, while Lat2 sub-cellular localization in thyrocytes of *Ctsk*$^{-/-}$/*Mct8*$^{-/y}$/*Mct10*$^{-/-}$ mice remained unaltered, suggesting a direct link between diminished Lat2 and autophagy induction in *Ctsk*$^{-/-}$/*Mct8*$^{-/y}$/*Mct10*$^{-/-}$ mice. To support this hypothesis, we investigated autophagy-mediated lysosomal biogenesis in Lat2 deficiency. Indeed, Lat2 deficiency was accompanied by enhanced cathepsin levels and activity, increased autophagosome formation, and enhanced autophagic flux. Collectively, we conclude that insufficient Lat2 functionality in triple-deficient mice leads to a reduction in intrathyroidal TH sensing capabilities, thereby failing to activate mTORC1, and consequently triggering autophagy. In addition, autophagy induction results in the biosynthesis of lysosomal proteins which could explain the enhanced cathepsin-mediated thyroglobulin degradation and Lat2 protein instability in *Ctsk*$^{-/-}$/*Mct8*$^{-/y}$/*Mct10*$^{-/-}$ mice.

PEP15.3

TGF-β increase caspase activation and migration in typical bronchial carcinoids

Patricia Borges de Souza, Irene Gagliardi, Mariano Martelli, Maria Rosaria Ambrosio & Maria Chiara Zatelli
University of Ferrara, Section of Endocrinology and Internal Medicine, Department of Medical Sciences, Cona, Italy

Introduction
Typical bronchial carcinoids (TBC) are rare well-differentiated neuroendocrine neoplasms (NEN) of the lung whose management can still be very challenging. In fact, the gold-standard treatment for TBC is total resection of the primary tumour; however, in case of metastatic disease adjuvant therapy with the mTOR inhibitor everolimus (eve) might

be recommended. Unfortunately, prognosis may be very poor in cases showing moderate response rates to eve, since resistance to treatment is not uncommon. Previous studies have reported TGF-β's ability to activate mTOR pathway and induce epithelial to mesenchymal transition (EMT) in cervical cancer. Moreover, preliminary results from our lab showed an overexpression of TGF-β/SMAD signalling and caspase activation in TBC cells, as well as an interplay between this pathway with the PI3K/mTOR pathway.
Aims
The present study focused on understanding how TGF-β signalling could interfere with TBC pathophysiology, which might possibly explain the reduced sensibility of these neoplasms to eve.
Materials and Methods
In vitro functional assays such as cell viability, migration, and caspase 3/7 activation were performed in the TBC cell line NCI-H727. Cell viability and caspase activation were performed by using specific kits, whereas migration was assessed through wound healing assay. Cells were treated with the mTOR inhibitor eve and TGF-β alone or combined with IGF-1 and paclitaxel (pac), considered as positive and negative controls, respectively.
Results
TGF-β or eve treatment alone had no effect on cell viability, whereas their combination reduced it by >10% vs. control (P = 0.009). TGF-β increased caspase activation by 14% vs. control (P = 0.04) and this effect was not accompanied by apoptosis induction. TGF-β also induced migration by 40% vs. control, whereas combined treatment with eve abrogated this effect by reducing it by 27% vs. control (P <0.0001). Moreover, combined treatment of TGF-β and pac significantly increased migration by >50% vs. pac treatment alone (P = 0.03), indicating that TGF-β was responsible for the observed increased migration in these cells, whereas combination with IGF-1 had no further effect vs. IGF-1 treatment alone.
Conclusions
TGF-β-induced caspase activation and cell migration could explain EMT and associated malignancy features found in many TBC. Given the interplay between TGF-β and mTOR, inhibition of both pathways could represent an alternative for the treatment of these NEN, which are orphans of an effective therapeutic algorithm.

PEP15.4

Selection of the most effective genetic tests for the diabetes mellitus risk prediction in Belarus

Maxim Lushchyk[1], Maxim Ameliyanovich[2], Hanna Tuzava[1], Irma Mosse[2] & Larissa I. Danilova[1]
[1]Belarusian Medical Academy of Postgraduate Education, Endocrinology Department, Minsk, Belarus; [2]Institute of Genetics and Cytology of the National Academy of Sciences of Belarus, Laboratory of Human Genetics, Minsk, Belarus

Introduction and background
According to world diabetes-focused organizations (EASD and IDF) the number of patients with type 2 diabetes mellitus (T2DM) and obesity is increasing tremendously all over the world. The FTO gene (Fat mass and obesity-associated gene) was noticed during GWAS-study at 2007, when it's multiple polymorphic variants were detected, many of which were associated with obesity and T2DM. Significant differences in allele prevalence in between populations were observed. So minor allele rs9939609 polymorphic variant is found in 34–44% of European, 11–20% of Asian and 17% of Latin-American population. There are no similar data on Belarusian population.
Aims
The aim of the study was the detection of the most relevant genetic marker for the prediction T2DM.
Methods
We have formed 2 groups of patients to determine FTO allele frequency and it's association with T2DM. 1st group – 116 patients with T2DM (72 female, 44 male), with an age of 51.2±8.2 years, and BMI 32.6±7.4 kg/m^2. 2nd – Control-group (151 female, 96 male) with an age of 34.9±9.5 years, BMI 24.1±3.9 kg/m^2. Peripheral blood lymphocytes were used for DNA extraction using Nucleosorb-A ("Primetech", Belarus) kits. Genotyping of 13 FTO-gene polymorphic variants (rs10852521, rs11075990, rs1121980, rs1421085, rs1477196, rs17817449, rs3751812, rs4783819, rs7206790, rs8047395, rs9939609, rs9940128, rs9941349)was made using TaqMan® probes (Applied Biosystems, USA).
Results
The minor allele rs9939609 prevalence was 41.3% in or study, that corresponds with European population data. The strongest association with the T2DM was detected for rs9941349 (P = 0.007) plymorphysm. For minor T/T variant carriers odds ratio (OR) was 2.74, and for heterozygos – OR = 1.96. Also highly associated with T2DM were G/G rs11075990 (OR = 2.36), A/A rs1121980 (OR = 2.35), T/T rs3751812 (OR = 2.26), A/A rs9939609 (OR = 2.49), C/C rs1421085 (OR = 2.09) and A/A rs9940128 (OR = 2.19). There were no other significant associations.
Discussion
The analysis of linkage disequilibrium block showed high linkage of rs11075990, rs1121980, rs1421085, rs17817449, rs3751812, rs9939609, rs9940128, rs9941349 polymorphisms (P <0.001, r2 0.92–0.97). These variants form 2 highly prevalent haplotypes – A/G/T/T/G/T/G/C (51.4%) č G/A/C/G/T/A/A/T (42.9%), other variants do not exceed 2%, what allows genetic testing only by rs9941349 polymorphism.
Conclusion
Stable haplotype prevalence allows effective prediction of the FTO-gene polymorphism through detection of rs9941349 variant, what is highly predictive for T2DM estimation.

PEP15.5

Pheochromocytoma secreting IL-6; an atypical presentation

María Laura García[1], Ana Paula Lisdero[1], Mariana González Pernas[1], Romina Speroni[1], Ana Segarra[1], Jimena Otero[1], Elbio Genovesi[1], Susana Belli[2] & Aizhar Giselle Mumbach[3]
[1]Sanatorio Méndez, Endocrinology, Buenos Aires, Argentina; [2]Instituto Fleming, Endocrinology, Argentina; [3]Sanatorio Méndez, Endocrinology, Argentina

Pheochromocytoma (PCC) is a rare tumor that arises from the adrenal medulla, usually presents with headache, sweating and palpitations due to excessive catecholamine release. However, PCC may secrete neuropeptides, hormones and cytokines, such as interleukin-6 (IL-6)) resulting in unusual clinical manifestations. A 48-year-old woman with a previous history of type 1 neurofibromatosis (NF1) and hypertension was referred to discarded PCC. Laboratory tests revealed leukocytosis and thrombocytosis with increased erythrosedimentation rate (ESR) and elevated urinary metanephrine (table 1). Abdominal CT revealed a left bilobed adrenal tumor 33 × 32 mm in the largest dimension (40 HU). Oncohematological and myelodysplastic disease were discarded (mutation JAK2- V617F, trasloc 9-22 and bcr-abl were negative). She had no fever but cytokines secretion was suspected and IL-6 was elevated (table1). Uneventful laparoscopic adrenal surgery was performed. After surgery all biochemical parameters were within the reference range and blood pressure normalization was achieved.
Discussion
It has been previously described that PCC may secrete cytokines with systemic inflammatory response syndrome (SIRS). IL-6 is a multifunctional molecule that plays an important role in hematopoiesis and immune and inflammatory responses. IL-6 over-production can be either ascribed directly to the tumor or indirectly accounted for tumoral production as a consequence of the high levels of circulating catecholamines. Symptoms relief, inflammatory marker and hematologic parameters normalization following the decrease in IL-6 level after tumor resection strongly supports the role of IL- 6 in the unusual presentation of our case. Our patient had mild hypertension despite high catecholamine levels and could be explained by the increased nitric oxide synthesis due to IL–6 activity, which might have led to vasodilation.
Conclusion
PCC may be a cause of paraneoplastic syndrome with marked increase in the levels of inflammatory markers. IL-6 appears to be the primary mediator. PCC has to be considered in the vast differential diagnosis of oncohematological and myelodysplastic syndromes when common causes are ruled out.

Table 1	At diagnosis	After surgery	Reference range
White blood cells account (WBC)	20530	9300	4000–10 000
Neutrophilia	81%	60%	40–65
Platelets(uL)	635000	339000	150 000–400 000
ESR (mm/h)	50	15	0–22
Urinary Metanephrine (ug/24hs)	673	67	30–180
Urinary Normetanephrine (ug/24hs)	119	202	< 451
Urinary Adrenaline (ug/24hs)	53	<2	< 20
Urinary Noradrenaline (ug/24hs)	265	34	< 80
IL-6 (pg/ml)	11.4	<2	LSN 5.9

Background
Diabetic retinopathy is the leading cause of blindness in working-age adults in developed world. Derangements of ubiquitine-proteasome system and telomere length have been associated with microangiopathy in diabetes. Until now, limited data are available on above markers in diabetic retinopathy in type 1 diabetes (T1D).
Aim
The aim of this work was to compare serum proteasome concentration and telomere length in patients with different stages of diabetic retinopathy and T1D in Latvia and Lithuania.
Methods
186 Latvian and 120 Lithuanian patients with type 1 diabetes were enrolled. Patients were stratified according to severity of diabetic retinopathy. Group of severe retinopathy included patients with proliferative retinopathy and status post laser-photocoagulation. "No retinopathy" group included patients with nonproliferative/no retinopathy. Proteasome concentration was measured by ELISA. Telomeres were evaluated by real-time qPCR with a relative telomere length method using a reference gene and expressed as (□CT). Statistical analysis was performed in programme R. Wilcoxon rank sum test followed by Ancova on ranks was used to compare the locations of biomarkers distributions between the groups of retinopathy and to adjust for covariates (diabetes duration, waist/hip ratio, serum triglycerides, estimated glomerular filtration rate (eGFR), country).
Results
Subjects in the group of severe retinopathy (n = 119) compared to "no retinopathy" (n = 187) were statistically significantly older (44 (35–53.5) vs. 31 (24.5–44) years), had longer duration of diabetes (28 (22–36) vs. 16 (12–21.5) years), higher serum creatinine concentration and lower estimated glomerular filtration rate, higher serum triglyceride and waist–hip ratio, as well as higher prevalence of other complications of diabetes. We observed lower serum proteasome concentration in the group of severe retinopathy (130 (90–210) ng/ml, vs. "no retinopathy" 150 (100–240) ng/ml), difference was significant after adjustment for covariates, P = 0.024. Median telomere length was higher in the group of severe retinopathy (ΔCT 0.21 (0.12–0.28 vs "no retinopathy" 0.18 (0.1–0.28), difference was significant after adjustment for covariates, P = 0.036.
Conclusion
In this study, we demonstrated differences in proteasome concentration and telomere length between patients with different stages of diabetic retinopathy.

Adherence to levothyroxine treatment and factors related with adherence in hypothyroid patients

Ahmet Dirikoc[1], Birgul Genc[2], Didem Ozdemir[1], Abbas Ali Tam[1], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Ankara Yildirim Beyazit University, Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey

Objectives
Adherence to treatment is one of the most important parameters that affect the success of the treatment in hypothyroidism. We aimed to evaluate the use and adherence to treatment and determine the factors that are related to adherence in patients on levothyroxine therapy.
Materials and Methods
Patients older than 18 years old and using levothyroxine for hypothyroidism were recruited. Demographical, sociocultural and clinical statuses of patients were determined. The practices of using levothyroxine and compliance were evaluated through a questionnaire. Thyroid hormones and antibodies were obtained from medical records. Those who answered the frequency of not using/skipping the drug as never/rarely, sometimes and frequently/often were grouped as high, medium and low adherence, respectively. Data of high, medium and low adherence patients were compared.
Results
A total of 335 patients – 282 (84.18%) female and 53 (15.82%) – male were included. Mean age was 47.36±12.50. 330 (98.50%) patients were taking levothyroxine in the morning and 332 (99.10%) were taking fast. The period between the drug and meal was 15 min in 66 (19.88%), 30 min in 170 (51.20%), 45 min in 25 (7.53%), at least 1 h in 63 (18.98%) patients, while 8 (%2.41) patients were taking it just before or during the meal. Among 145 (45.03%) patients who use a medication that may interfere with the absorption of levothyroxine, 66.66% were using it in less than 2 h of levothyroxine. There were 218 (65.08%) high, 98 (29.25%) medium and 19 (5.67%) low adherence patients. Drug adherence was not associated with sex, age, marrital and working status, smoking, alcohol use, the cause and duration of hypothyroidism, presence of comorbid disease and thyroid hormones. The rate of patients graduated from primary school was higher in low adherence and rate of patients graduated from university was higher in high adherence groups (P = 0.008). Familial history of thyroid disease was associated with high adherence (P = 0.013).
Conclusion
We showed that drug adherence is medium or low in 34.92% of hypothyroid patients, and education level and familial thyroid disease were related with high adherence. Although majority of patients take levothyroxine at fast, 22.29% eat less than 30 min after taking the drug. In addition, a considerable amount of patients using medications that inhibits the absorption of levothyroxine did not leave required time between two medications. For effective treatment of hypothyroidism, it is important to increase drug compliance and inform patients about hypothyroidism and levothyroxine.

Aggressive follicular thyroid carcinoma in a patient with Carney complex

Paula Maria Fernandez-Trujillo-Comenge[1], Alba Hernandez-Lazaro[1], Ricardo de Leon-Durango[1], Agnieszka Kuzior[2], Manuel Esteban Nivelo-Rivadeneira[1], Ana Delia Santana-Suarez[1], Claudia Arnas-Leon[2], Carmen Acosta-Calero[2], Paula Gonzalez-Diaz[3] & Francisco Javier Martinez-Martin[2]
[1]Hospital Universitario de Gran Canaria Dr. Negrin, Endocrinology and Nutrition, Las Palmas de Gran Canaria, Spain; [2]Hospitales San Roque, Endocrinology and Nutrition, Las Palmas de Gran Canaria, Spain; [3]Centro de Salud de Arucas, Primary Healthcare, Arucas, Spain

Introduction
Carney Complex is a rare syndrome characterized by lentiginosis cutis and/or blue nevi, multiple endocrine neoplasia and non-endocrine tumors (cutaneous, mucosal, mammary or cardiac myxomata, bone osteochondromyxoma, psammomatous melanotic schwannoma, multiple ovarian cysts, multiple mammary ductal adenoma). Most cases are familiar, with autosomal dominant heredity and penetrance close to 100%. It is caused by a variety of mutations that activate the PKA (Protein Kinase A) pathway, inactivating mutations of the PRKAR1A gene being the most frequent. The endocrine manifestations may include PPNAD (primary pigmented nodular adrenocortical disease) Cushing syndrome, acromegaly (rarely gigantism), hyperthyroidism and LCCSCT (large cell calcifying Sertoli cell tumors). Most of the Carney Complex-associated neoplasms are benign, but in a few patients a particularly aggressive variant of follicular thyroid carcinoma has been described. Malignant tumors such as ovarian, pancreatic, gastric or hepatic carcinoma are also associated with the Carney Complex.

Methods
Review of the patient's Clinical Record and of the relevant literature.
Clinical Case
A 56 year old man of black African descent was referred to the Endocrinology Clinic due to a cervical mass in the context of Carney Complex. No relatives of his have been diagnosed. Since his adolescence he had intense facial lentiginosis and scattered blue nevi. The diagnostic workup revealed bilateral nodular adrenocortical disease, small myxomata in both atria, with normal pituitary, adrenal and thyroid function and normal glucose tolerance. The atrial myxomata were resected without complications and the cardiac function is normal. The thyroid ultrasonography revealed multinodular goiter with dominant nodules measuring 3.5 cm (craniocaudal) in the left thyroid lobe adjacent to the isthmus, and 2.7 cm in the right lobe, with multiple cervical adenopathies. Ultrasound guided FNAC was performed, with both dominant nodules and 4/7 adenopathies positive for non-oncocytic follicular thyroid carcinoma (Bethesda IV, ATA stage IV-A, T2(m)N1bM0), Total thyroidectomy with radical cervical lymphadenectomy was performed, but plasma thyroglobulin was 97 ng/ml with negative antithyroglobulin antibodies. A rhTSH stimulated radioiodine scan was performed and the patient received 100 mCi of ^{131}I but the response was poor and plasma thyroglobulin remained high (78 ng/ml). A PET-CT scan did not reveal abnormal activity beyond the cervical region. The patient has been referred to Oncology for kinase inhibitor therapy.
Conclusions
Although most of the tumors associated with Carney Complex are benign, the existence of malignant tumors of diverse origins must be ruled out. An aggressive variant of follicular thyroid carcinoma is a particularly ominous possibility.

Adrenocortical carcinoma treatment in the Netherlands: An analysis from the Netherlands Cancer Registry from 2014 to 2019

Rebecca Steenaard, Marieke Rutjens & Harm R. Haak
Maxima Medisch Centrum, Internal Medicine, Eindhoven, Netherlands

Background
Adrenocortical carcinoma (ACC) is a rare disease with often poor prognosis. Previous research has shown that surgery in a Dutch Adrenal Network (DAN) center increases the chance of survival. We aim to explore the determinants and survival of patients with ACC recently treated in the Netherlands both within and outside DAN centers.
Methods
We analyzed retrospectively collected data from 172 adult patients with newly diagnosed ACC and 97 patients with recurrence or new metastases, registered between 2014 and 2019 in the Netherlands Cancer Registry. Differences in survival were analyzed with cox-regression analysis.
Results
More than half of the new cases presented with advance disease (25.7% stage III, 34.6% stage IV) and the median survival was 29 months. The majority of treatments occurred within a DAN center (87.2% of surgery, compared to 50% between 1999 and 2009; and 94.5% of medical treatment). There were no differences in patient characteristics between the centers apart from a relatively high number of patients with stage IV disease outside DAN centers (47.2% vs. 28.7%). Adrenal resection and mitotane therapy both resulted in a significant survival benefit (resection HR 0.29, CI95%[0.17–0.49]; mitotane HR 0.61, CI95%[0.37–0.99], corrected for stage). Still, a remarkable proportion of patients with advanced disease received no mitotane treatment (23.8% DAN, 89.5% non-DAN, 39.0% total). Due to the small number of patients treated outside DAN centers, survival benefits could not be tested.
Conclusions
Centralization of ACC care in the Netherlands has improved since the previous report, but a further improvement in centralization of surgery can be made. Adrenal resection and mitotane treatment remain the main form of treatment, with a clear survival benefit. Further research is necessary to determine why mitotane treatment is withheld a large proportion of patients with advance disease.

Characteristics of pheochromocytomas/paragangliomas in Flemish population

Sofia Maria Lider Burciulescu[1], Guy T'Sjoen[2,3], Corin Badiu[4] & Lapauw Bruno[2,3]
[1]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Ghent University Hospital, Gent, Belgium; [3]Ghent University, Gent, Belgium; [4]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Introduction
Pheochromocytomas (PHEO) and paragangliomas (PGL) are rare neuroendocrine tumors of the autonomic nervous system, originating from neural crest. Despite the same embryological origin, there are some differences between them.
Aim
We searched for differences in method of discovery, clinical and biochemical phenotype, of sporadic vs hereditary PHEO/PGL in a cohort of Flemish patients.
Material and methods
A retrospective analysis of electronic medical records of sixty-seven consecutively registered patients diagnosed or treated with hereditary or sporadic PHEO/PGL in a tertiary care center from Belgium between 2002–2020, was performed. Patients were divided according to anatomic location (PHEO vs. PGL) and according to presenting with sporadic or hereditary PHEO/PGL.
Results
We identified 38 women and 29 men, aged 50 ± 19 years (range 13–85). At diagnosis, 42(63%) had PHEO, 25(37%) had PGL. Patients with PHEO presented more frequently with sporadic than hereditary disease [34 (81%) vs. 8 (19%)] than patients with PGL [9(36%) vs.16 (64%)] respectively. Mean age at diagnosis was significantly higher in PHEO patients (55 ± 17 years in PHEO vs.40 ± 18 years in PGL, $p = 0.001$). The diagnosis was done either due to PHEO/PGL related symptoms [PHEO:21(50%);PGL:13(52%)], discovered incidentally (27) or due to genetic screening (6) [PHEO: 21(50%); PGL: 12(48%)]. In our patient cohort, following CV events were known at diagnosis: myocardial infarction(MI)[PHEO: 8(19%); PGL:1(4%)], Takotsubo cardiomyopathy [PHEO:2; PGL:2], arrhythmias [PHEO:3; PGL:0] and stroke [PHEO:1; PGL:0]. All PHEO and about two-thirds of PGL were hormonally functional. Metanephrine levels were higher in PHEOs than in PGLs ($P < 0.02$). Tumor diameter was 44 (17–200) mm in PHEO vs. 30 (11–110) mm in PGL. Metanephrine levels were correlated with tumor diameter in PHEOs vs. PGLs. ($P < 0.02$).An interesting aspect is related by the differences in tumor localization of sporadic vs hereditary PPGLs. 61.7 % of sporadic PHEOs and 77.7% of sporadic PGLs and had right lateralization while 62.5% of hereditary PHEOs and 50% of hereditary PGLs had left lateralization. PGLs were mostly HNPGLs (12), followed by abdominal(16), pelvic(16) and thoracic(1) PGLs.
Conclusion
PGLs have a higher hereditary predisposition, therefore are diagnosed at younger age than PHEOs. Although both PHEO and PGL in about half of cases were diagnosed due to related symptoms, patients with PHEO more often presented with cardiovascular co-morbidities which is presumably related to their hormonal activity.

Effective metyrapon treatment of a case of neonatal cushing syndrome of unknown origin

Zsofia Gacs[1], Borbála Tobisch[2], Ágnes Sallai[1], Viktória Kemény[1], Henriett Butz[3] & Edit Varga[1]
[1]Semmelweis University, 2nd Department of Pediatrics, Budapest, Hungary; [2]Észak-Közép-budai Centrum., Új Szent János Kórház és Szakrendel, Budapest, Hungary; [3]Semmelweis University, Department of Laboratory Medicine, Budapest, Hungary

Neonatal Cushing syndrome (CS) is a rather rare disease. The majority of these few cases are of ACTH dependent origin or caused by a unilateral adrenal tumour (carcinoma or adenoma), however ACTH independent bilateral hyperplasias stand for only a few percent of all cases. The management of neonatal CS depends on the underlying cause – if found in time - of the disease. In the past the survival rate of children with CS was low, new and renewed medical attempts have improved this over the last decades. Our patient was born in March 2020 after an apparently uneventful pregnancy on 35. gw with 1850 g birthweight. At 4 weeks an excessive weight gain was recognized, and the first laboratory findings indicated severe hypercalcaemia (3,27 mmol/l), extremely high cortisol (1777,7 nmol/l) and suppressed ACTH level. These findings altogether indicated an ACTH-independent form of neonatal CS. Abdominal MRI revealed a bilateral micronodular hyperplasia of the adrenal gland. As his clinical condition was quite unstable due to consequences of hypercortisolism present (severe hypercalcaemia, hyperglycaemia, hypertension, ventricular hypertrophy, hepatopathy, muscle weakness) an asap conservative treatment administration was decided. Metyrapon has a long history in endocrine diagnostics, but its use as a therapeutic option is newfangled. An oral solution was induced in our case which proved to be effective in decreasing the cortisol levels; in order to avoid hypadrenia a 'block&replace' method was started. As the oral tolerability of Metyrapon was poor, after a few attempts we switched to rectal administration. Some of the consequences of hypercortisolism resolved in days/weeks/months, but hypertension, tachycardia, muscle weakness and slow weight gain is still present. At the age of 3 months café-au-lait spots appeared on the back and in the perianal region indicating a possible presence of McCune-Albright syndrome which concurred the MRI finding. To have the proper diagnosis both the blood sample and the skin biopsy was investigated for the presence of GNAS/PRKAR1A mutations, but no mutations were found. As the patient still needs a proper diagnosis of his condition, meaning that the prognosis of the disease (e.g. the self-limiting nature as seen in some cases) is still unknown his care is planned to be conservative with all supporting treatments needed (beta-blocker, physiotherapy) and thorough screening of all possible symptoms of diseases causing neonatal CS.

Background
Residual adrenocortical function (RAF) is present in one third of patients with autoimmune Addison's disease (AAD), yet its clinical significance remains unknown.
Objective
To investigate if biomarker profiles of cardiovascular disease and inflammation are different in patients with AAD and RAF compared to patients without RAF and healthy controls.
Material and methods
24 patients with autoimmune Addison's disease and 24 healthy controls matched for age, sex, and body mass index were included. Blood was sampled at 8 h. Before sampling, patients with AAD had abstained from any GC replacement for at least 18 hours. Nine of the 24 AAD patients had RAF, defined as detectable levels of serum cortisol and 11-deoxycortisol in a medication fasting morning blood sample (1). Blood samples were analyzed for 176 unique plasma proteins (biomarkers) using two 92-plex Olink Proteomics panels: Cardiovascular disease II (CVD II) and Inflammation.
Results
Biomarker expression significantly differed for 13 of the 92 biomarkers of CVD and 11 of the 88 biomarkers of Inflammation (two of which were included in both panels) between AAD patients with RAF, without RAF, and healthy controls (Kruskal-Wallis test, $P \leq 0.010$). The 13 CVD biomarkers were ADM, CEACAM8, FGF-23, GAL-9, HAOX1, IL-6, LOX-1, RAGE, SRC, STK4, THBS2, TNFRSF10A, and XCL1. The 11 inflammation biomarkers were CCL-19, CXCL-10, CXCL9, FGF-23, IL-10, IL-6, LAP TGF-beta1, MCP-1, ST1A1, TNFRSF9, and TRAIL. For nine of the 13 CVD biomarkers and ten of the 11 Inflammation biomarkers, the difference in biomarker expression was only significant between patients without RAF and healthy controls, in which patients with RAF had expression levels in between the two other groups. All but three of the 13 CVD biomarkers (LOX-1, SRC, STK4) and two of 11 inflammation biomarkers (LAP TGF-beta1, ST1A1) had higher expression in patients with and/or without RAF compared to healthy controls. For two of the 13 CVD biomarkers (STK4 and RAGE), expression levels significantly correlated with medication fasting morning cortisol (STK4 $r = 0.477$, $P < 0.025$ and RAGE $r = 0.495$, $P < 0.019$) in patients with AAD. No significant correlations were found between the 11 inflammation biomarkers and cortisol levels.
Conclusion
In AAD, patients with RAF have distinct biomarker profiles of cardiovascular disease and inflammation compared to patients without RAF as well as healthy controls. The findings suggest that RAF in AAD may be clinically significant and warrants further investigation.

The role of Chchd2 protein in adrenal tumorigenesis

Athanasios Moustogiannis[1], Angeliki Karapanagioti[2], Narjes Nasiri-Ansari[2], Giorgos Zografos[3], Chrysanthi Aggeli[3], Georgios Kyriakopoulos[4], Theodosia Chorefitaki[3], Anastassios Philippou[1], Gregory Kaltsas[5], Evanthia Kassi[2] & Anna Angelousi[6]
[1]National and Kapodistrian University of Athens, Department of Experimental Physiology, Medical School, Athens, Greece; [2]National and Kapodistrian University of Athens, Department of Biological Chemistry, Medical School, Athens, Greece; [3]General Hospital of Athens 'G. Gennimatas', Athina, Greece; [4]Evaggelismos, Athina, Greece; [5]National and Kapodistrian University of Athens, 1st Department of Propaedeutic Internal Medicine, Athens, Greece; [6]National and Kapodistrian University of Athens, 1st Department of Internal Medicine, Athens, Greece

Background
Recent data have shown the anti-apoptotic effect of Chchd2 mitochondrial protein through the Bcl-2/Bax pathway in various cancers. Bax is regulated primarily by proteins-members of Bcl-2 family and mainly the Bcl-2 protein, which has been found to prevent Bax from accumulating in mitochondria. In response to apoptotic stimuli, Chchd2 decreases and loses its mitochondria localization accompanying by decreased Bcl-2/Bax interaction and increased Bax homo-oligomerization. Thus, Chchd2 negatively regulates the apoptotic cascade upstream of Bax oligomerization. Although, the direct interaction of antiapoptotic Bcl-2 with Bax protein has already been studied, data on the regulatory role of Chchd2 on the expression of Bcl-2/Bax are scarce.
Aim
We aimed to study the expression of *CHCHD2, BCL2* and *BAX* genes at mRNA and protein level in human adrenocortical neoplasms.
Methods
Twenty-four fresh frozen human adrenal tissues including 7 cortisol-secreting adenomas (CSAs), 9 non-functional adrenal adenomas (NFAs) and 8 adrenocortical carcinomas (ACCs) samples were collected. *CHCHD2, BCL2* and *BAX* mRNA and protein expression were determined by qPCR and immunobloting, respectively. The expression of the abovementioned genes was compared with the paired adjacent normal adrenal tissues used as control group.
Results
BCL2 mRNA expression was significantly up-regulated in ACCs compared to benign adrenocortical neoplasms and adjacent normal tissues. *BCL2* mRNA expression was up-regulated in all benign adrenocortical neoplasms compared to their paired adjacent normal tissues without reaching however statistical significance. *BAX* mRNA expression was significantly down-regulated in ACCs compared with benign adrenocortical neoplasms and adjacent normal adrenal tissues. *BAX* mRNA expression was also down-regulated in all benign adrenocortical neoplasms compared with their paired adjacent normal tissues, although not statistical significant. *CHCHD2* mRNA expression was significantly up-regulated in ACCs compared to normal adrenal tissues. *CHCHD2* mRNA expression was also up-regulated in all benign adrenocortical neoplasms compared with their paired adjacent tissue although not statistical significant. Western Blot analysis confirmed the results of qPCR analysis.
Conclusions
This study showed that the expression of both *BAX* and *BCL2* apoptotic genes was altered in adrenocortical neoplasms compared to adjacent normal tissues implying a disturbance of the apoptotic pathway in these neoplasms and perhaps in adrenal tumorigenesis. Moreover, the significant overexpression of *CHCHD2* in ACCs could contribute to the understanding of its role in the clinical behaviour of these neoplasms although functional studies with a larger sample size are required.

Salivary profiles of 11-oxygenated androgens follow a diurnal rhythm in patients with congenital adrenal hyperplasia

Hanna F. Nowotny[1], Matthias K. Auer[1], Christian Lottspeich[1], Heinrich Schmidt[2], Ilja Dubinski[2], Martin Bidlingmaier[1], Jo Adaway[3], James Hawley[3], Brian Keevil[3] & Nicole Reisch[1]
[1]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, LMU München, Munich, Germany; [2]Department of Pediatric Endocrinology, Dr. von Haunersches Children's Hospital, Klinikum der Universität München, LMU München, Munich, Germany; [3]Department of Clinical Biochemistry, Manchester University Foundation NHS Trust, Manchester Academic Health Sciences Centre, Southmoor Rd, Manchester, United Kingdom

Background
Routine biochemical assessment in patients with congenital adrenal hyperplasia (CAH) includes measurement of serum 17–hydroxyprogesterone (17OHP), androstenedione (A4) and testosterone (T) and their metabolites in urine. Several studies have also described 11–oxygenated 19–carbon (110 × C19) steroids as a clinically relevant androgenetic source and highlighted their potential as markers for evaluation of adrenal androgen excess in patients with 21-hydroxylase deficiency (21OHD).
Methods
Cross–sectional single center study including 34 patients with classic 21OHD (men = 14; women = 20) and 32 BMI- and age–matched controls (men = 15; women = 17). Saliva was collected at five different timepoints throughout the day adjusted to intake of glucocorticoid medication. Salivary concentrations of the following steroids were analyzed by LC–MS/MS: 17OHP, A4, T, 11β–hydroxyandrostenedione (11OHA4) and 11–ketotestosterone (11KT).
Results
Similar to the previously described rhythmicity of 17OHP, 11OHA4 and 11KT concentrations followed a distinct diurnal rhythm in both patients and controls with highest concentrations in the early morning and declining throughout the day (11OHA4: male patients Δ_{mean} = 79%; male controls Δ_{mean} = 81%; female patients Δ_{mean} = 33%; female controls Δ_{mean} = 91%; 11KT: male patients Δ_{mean} = 64%; male controls Δ_{mean} = 60%; female patients Δ_{mean} = 49%; female controls Δ_{mean} = 81%). Significant correlations between the area under the curve (AUC) for 17OHP and 11KT ($r(P)_{male}$ = 0.741**; $r(P)_{female}$ = 0.842****), and 11OHA4 ($r(P)_{male}$ = 0.385^{ns}; $r(P)_{female}$ = 0.527*) were observed in patients but not in controls. P-value ≤ 0.05 (*), ≤ 0.01 (**), ≤ 0.001 (***), ≤ 0.0001 (****).
Conclusions
This study is the first to describe the diurnal rhythm of 11oxC19 steroids in salivary profiles in both healthy controls as well as patients with CAH due to 21OHD. Adrenal 11oxC19 androgens are clearly secreted following a diurnal pattern. This should be considered when evaluating their utility for monitoring treatment control.

Unnecessary cosyntropin stimulation tests for nonclassic congenital adrenal hyperplasia (NCAH) – shall the cut-off value of 17-hydroxyprogesterone be revised?

Bartosz Domagała[1], Malgorzata Trofimiuk-Muldner[2], Anna Krawczyk[3], Joanna Topór-Kołkowska[3], Anna Skalniak[2], Elwira Przybylik-Mazurek[2], Dorota Pach[2] & Alicja Hubalewska-Dydejczyk[2]
[1]University Hospital in Krakow, Department of Endocrinology, Kraków, Poland; [2]Jagiellonian University Medical College, Chair and Department of Endocrinology, Kraków, Poland; [3]Jagiellonian University Medical College, Students' Scientific Group of Endocrinology at the Department of Endocrinology, Kraków, Poland

Cosyntropin stimulation test is the gold diagnostic standard used to test for NCAH. Genetic testing is not currently considered to be the primary diagnostic tool for NCAH. Still, it may be helpful in establishing a diagnosis if other results are unequivocal or for genetic counselling purposes. The study aimed at verifying the currently accepted threshold of 17-hydroxyprogesterone (17OHP) level (≥ 2.0 ng/ml) at which a cosyntropin stimulation test should be performed.
Material and methods
The retrospective study included 343 patients referred for a cosyntropin stimulation test due to suspected NCAH. Serum 17-OHP was measured with ELISA assay using Ledect96 Microplate Reader before, 30 minutes and 60 minutes after a 250 µg of cosyntropin intravenous injection. CYP21A2 gene sequencing by the Sanger method was performed in 30 patients of the group. NCCAH diagnosis was made if cosyntropin-stimulated 17OHP level exceeded 10.0 ng/ml. Detection of a pathogenic variant was considered a positive result of the genetic test. The ROC curve was determined, and the cut-off point with the highest sensitivity and specificity was established in both groups. The study was approved by the Ethics Board of JUMC. Results. A total of 79 patients were diagnosed with NCCAH based on cosyntropin stimulation test results (22 patients in the genetically screened group). The baseline 17OHP cut-off value that qualified patients best for testing was 2.79 ng/ml in the whole group, with sensitivity and specificity of 77.2% and 91.3%, respectively. The sensitivity and specificity for a guideline-recommended cut-off point (17OHP ≥ 2.0 ng/ml) was 86.1% and 76%, respectively. Pathogenic variants of the CYP21A2 gene were found in 9 patients. If a pathogenic variant was found, baseline 17OHP cut-off which qualified subjects best for testing was 2,88 ng/ml with 77.8% sensitivity and 47.6 % specificity. However, for 17-OHP cut-off ≥ 2.0 ng/ml, these values were 77.8 and 35.7%, respectively. Conclusions. Our results suggest considering an upward shift in the 17OHP threshold at which patients suspected for NCAH should be referred for further evaluation. This may reduce the number of unnecessary cosyntropin stimulation tests, particularly since patients with a mild phenotype (or asymptomatic) frequently may not require any treatment.

Zona glomerulosa derived Klotho does not regulate aldosterone synthesis in young mice

Cong Tang[1], Ye Xie[1], Alessia Scapin[1], Dominique Loffing[2], David Breault[3], Johannes Loffing[2] & Felix Beuschlein[1]
[1]University Hospital Zurich (USZ) and University of Zurich (UZH), Department of Endocrinology, Diabetology and Clinical Nutrition, Switzerland; [2]University of Zurich (UZH), Institute of Anatomy, Switzerland; [3]Boston Children's Hospital, Division of Endocrinology, United States

Klotho (Kl), initially identified as an antiaging gene, plays a critical role in the regulation of renal and adrenal dependent fluid homeostasis. A previous study reported that haplodeficiency of Kl in mice resulted in increased aldosterone synthase (CYP11B2) expression, elevated plasma aldosterone and high blood pressure. This phenotype was presumed to result from diminished Kl expression in zona glomerulosa (zG) of the adrenal. To examine whether Kl expressed in zG is indeed a critical regulator of aldosterone synthesis, we generated a tamoxifen-inducible, zG-specific mouse model of KI deficiency by crossing Kl-flox mice with Cyp11b2-CreERT mice (zG-Kl). Tamoxifen-treated Cyp11b2-CreERT animals (zG-Cre) served as controls. Rosa26-mTmG reporter mice were used for Cre-dependent lineage-marking. Two weeks after tamoxifen induction, the specificity of the zG-Cre line was verified using immunofluorescence analysis to show that GFP expression was restricted to the zG. RNAScope *in situ* hybridization revealed a 65% down-regulation of Kl mRNA expression in zG of zG-Kl mice at 12-weeks of age compared to control mice. Despite this, zG-Kl mice exhibited no difference in adrenal Cyp11b2 expression or plasma aldosterone levels compared to control mice independent of sex. These results suggest that zG-derived Kl *per se* does not significantly regulate aldosterone synthesis in young adult mice. Further studies are required to investigate the role of adrenal Kl in aldosterone synthesis in aged mice.

Effects of adrenalectomy on arterial hypertension, glucose and lipid metabolism in patients with mild autonomous cortisol secretion: preliminary results of a Randomized Clinical Trial

Sofia Frigerio[1,2], Valentina Morelli[1], Carmen Aresta[3], Elena Passeri4, Flavia Pugliese[5], Sabrina Corbetta[4,6], Alfredo Scillitani[5], Maura Arosio[1,2] & Iacopo Chiodini[7,8]
[1]Fondazione IRCCS Cà Granda-Ospedale Maggiore Policlinico, Unit of Endocrinology, Milano, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Italy; [3]Istituto Auxologico Italiano, IRCCS, Department of Endocrinology and Metabolism, Milano, Italy; [4]IRCCS Istituto Ortopedico Galeazzi, Endocrinology and Diabetology Service, Milano, Italy; [5]'Casa Sollievo della Sofferenza' IRCCS, Unità Operativa di Endocrinologia, San Giovanni Rotondo, Italy; [6]University of Milan, Department of Biomedical, Surgical and Dental Sciences, Milano, Italy; [7]Istituto Auxologico Italiano, IRCCS, Unit for Bone Metabolism Diseases and Diabetes & Lab of Endocrine and Metabolic Research, Milano, Italy; [8]University of Milan, Department of Medical Biotechnology and Translational Medicine, Milano, Italy

Introduction
The management of patients with adrenal incidentaloma (AI) and mild autonomous cortisol secretion (MACS) is debated. This randomized study aimed to evaluate the effects of adrenalectomy on arterial hypertension (AH), glucose and lipid metabolism.
Methods
We consecutively evaluated 626 AI patients (referred to 3 Italian Centers between 06/2016 and 02/2020). According to the inclusion criteria, we

enrolled 61 patients (45 F) with MACS (cortisol level after 1mg overnight dexamethasone suppression test, 1 mgDST, between 1.8 and 5 µg/dl). Patients were randomized in surgery (Group 1, n = 29) or conservative follow-up groups (Group 2, n = 32). Three patients from Group 1 withdrew their consent. Blood pressure (BP) and glyco-metabolic parameters were evaluated at baseline and after 6 months. The study is ongoing.
Results
So far, 40 patients (15 in Group 1 and 25 in Group 2, mean age 64.4 ± 10.4 years, adenoma diameter 2.8 ± 0.7 cm, 1 mgDST 3.3 ± 1.6 µg/dl) have completed the 6 months follow-up. At baseline the two groups were comparable for all characteristics. In particular, 8 patients from Group 1 and 16 from Group 2 were hypertensive; 11 from Group 1 and 14 from Group 2 were dyslipidemic; 3 and 6 patients, respectively in Group 1 and in Group 2, were diabetic. After 6 months, in Group 1, 8 patients (57.1%) improved BP (in particular 2 hypertensive patients passed from a grade 1 AH to a high-normal BP and other 2 hypertensive patients passed from a grade 2 to a grade 1 AH), only 2 (14.3%) worsened BP control; in Group 2, BP improved in 5 patients (20%), but worsened in 8 (32%), (P = 0.05). Glycemic control improved in 1 patient of both groups, but worsened in 4 patients of Group 2 and in 1 of Group 1 (16% vs 6.7%); in the subgroup of diabetic patients, only 2 non-operated patients worsened glycemic control at follow-up. Insulin-resistance, evaluated by HOMA-IR, remained steady in Group 1, while it showed a worsening trend in Group 2: 2.7 ± 2.1 at baseline vs. 6.0 ± 10.2 at 6 months (P = 0.07). LDL-cholesterol levels improved in 4 patients of Group 1 (26.7%) and in 2 patients of Group 2 (8.3%); on the other hand, they worsened in 4 patients of Group 1 (26.7%), and in 4 patients Group 2 (16.7%).
Conclusion
These preliminary data suggest that, in MACS-patients, adrenalectomy has a beneficial role on glucose and lipid metabolism, but above all on AH.

Gennimatas' General Hospital, Athens, Greece; [7]TYPET-Mutual Health Fund of National Bank of Greece Personnel, Athens, Greece

Background
Extranodal non-Hodgkin lymphoma (NHL) is a rare condition that accounts for less than one-third of patients with NHL at diagnosis. The heart or the endocrine organs (adrenals) involvement is extremely rare.
Objective
We report an unusual case of extranodal B-cell NHL: DLBCL (diffuse large B-cell non-Hodgkin lymphoma) presenting with heart and bilateral adrenal involvement.
Design-results
A 72-year-old male patient presented to our Endocrinology Unit for investigation of 3.8 cm right adrenal mass, diagnosed by abdominal ultrasound and thereafter by computed tomography (CT) because of abdominal pain. On admission, a repeated adrenal CT scan identified bilateral adrenal masses of 6.7 cm on right adrenal gland compressing the inferior vena cava and 3.7 and 3.6cm on left adrenal gland. Thorax CT scan revealed a 4.6cm mass in the right atrium wall extending from the drainage of the superior vena cava to the drainage of the inferior vena cava. Heart MRI confirmed the previous finding. Left ventricular ejection fraction was 55%. Adrenal hormonal baseline and dynamic investigation [cortisol post-overnight dexamethasone suppression test and aldosterone post-saline infusion test] excluded autonomous cortisol or aldosterone secretion. Urinary metanephrine and normetanephrine excretion were normal. Cortisol response after a short synacthen test excluded adrenal insufficiency. A CT-guided adrenal biopsy revealed the presence of a DLBCL, with triple expression of bcl2, bcl6, C-MYC(+70%). Cell proliferation index Ki-67 was 99%. Positron emission tomography scan (PET-CT) showed hyper-metabolic infiltrative masses involving the right atrium (SUVmax 21.2) and both adrenal glands (SUVmax 20.5). Virology tests for Epstein Barr virus and HIV were negative. Bone marrow aspiration, trephine biopsy and cerebrospinal fluid analysis were negative for lymphoma infiltration. Karyotype was normal and MRI brain spectroscopy was negative for CNS lymphoma detection. The patient was asymptomatic. Under the care of the haematology team systemic immunochemotherapy with R-DA-EPOCH (rituximab, dose adjustment etoposide, prednisone, vincristine, cyclophosphamide and doxorubicin) and high dose methotrexate for CNS prophylaxis were administrated. After the completion of six cycles of immunochemotherapy, a marked decrease of lymphoma infiltration in the post-chemotherapy imaging CT and MRI scans was found. Left ventricular ejection fraction was 66%. The treatment was complicated with reversible paralytic ileus, due to vincristine neurotoxicity, which was omitted from the next immunochemotherapy cycles.
Conclusions
An extremely rare case of an extranodal DLBCL stage IVE with both adrenal and heart involvement is described. The selection of the appropriate treatment modality can lead to profound response and improve patient's outcome.

The role of estimated glucose disposal rate as a predictor of insulin resistance, NAFLD and major adverse cardiovascular events in type 1 diabetes mellitus

Jonathan Mertens[1,2,3], Christophe De Block[2,3], Eveline Dirinck[2,3] & Sven Francque[1]
[1]Antwerp University Hospital, Gastroenterology and Hepatology, Edegem, Belgium; [2]Antwerp University Hospital, Endocrinology, Diabetology and Metabolism, Edegem, Belgium; [3]University of Antwerp, Laboratory of Experimental Medicine and Paediatrics, Wilrijk, Belgium

Background and Aims
People with type 1 diabetes (T1D) have an increased risk of cardiovascular disease (CVD) despite insulin therapy to treat hyperglycaemia. Insulin resistance may be a contributing factor to CVD. Insulin resistance is strongly associated with NAFLD, which is increasingly linked to CVD. The estimated glucose disposal rate (eGDR) correlates well with the euglycemic clamp, which is the gold standard to assess insulin resistance in T1D, but is unsuited for clinical practice or large studies. This study aimed to assess the association between eGDR, NAFLD and CVD.
Methods
Adult T1D subjects were consecutively screened for liver steatosis using ultrasound (US), the Fatty Liver Index (FLI) and controlled attenuation parameter (CAP). Secondary causes of liver steatosis were excluded, implying that liver steatosis was due to NAFLD in all cases. The eGDR was calculated based on hypertension, HbA1c and waist circumference. CVD was assessed based on documented major adverse cardiovascular events (non-fatal myocardial infarction, non-fatal ischemic stroke or peripheral vascular disease in need of therapeutic intervention).
Results
CVD was present in 34 out of 355 subjects. Divided into tertiles (<5.39,5.39–7.79,>7.79), 36.6% expressed low eGDR; 32.7% intermediate eGDR and 30.7% high eGDR. The eGDR is inversely associated with insulin resistance. There was moderate correlation between eGDR and FLI (r = 0.68, P < 0.001) and weak correlation with US (r = 0.33, P < 0.001) and CAP (r = 0.50, P < 0.001). In the low eGDR group (= insulin resistant group) was not only steatosis (38.5% vs. 11.2% (intermediate eGDR) and 12.8% (high eGDR)), but also composite CVD (18.5% vs. 6.0% and 2.8%) significantly more present (P < 0.001 for both). Low eGDR (OR: 4.2 [2.2–8.2], P < 0.001), but not BMI or dyslipidaemia was independently associated with US-defined NAFLD. Low eGDR was also independently associated with FLI-determined NAFLD (OR: 5.5 [1.7–17.6], P = 0.004) together with BMI (OR: 1.6 [1.4–1.9], P < 0.001). Low eGDR (OR: 8.0 [2.3–27.4], P = 0.001) and NAFLD (OR: 2.7 [1.2–6.1], P = 0.022 (US-defined), OR: 2.9 [1.4–6.0], P = 0.005 (FLI-defined)) were independently associated with CVD, but presence of metabolic syndrome, dyslipidaemia and BMI were not.
Conclusions
Insulin resistance, as assessed by eGDR, is prevalent in T1D. eGDR correlates with the presence of NAFLD. Both eGDR and NAFLD correlate with major cardiovascular adverse events.

Niemann-Pick disease and endocrine disorders: A case report

Wafa Benothman, Maha Kacem, Ghada Saad, Safa Khaldi, Asma Benabdelkrim, Amel Maaroufi, Molka Chaeib, Yosra Hasni & Koussay Ach
CHU Farhat Hached, Endocrinology department, sousse, Tunisia

Introduction
Acid sphingomyelinase-deficient Niemann–Pick disease (NPD) is a lysosomal lipid storage disorder. We report a new case of Hashimoto thyroiditis associated to primary adrenal insufficiency (PAI) likely of infiltrative process occurring in NPD type B patient.
Observation
A 24-year-old Tunisian female patient was followed up in our endocrinology department for Hashimoto thyroiditis. Two years later, she was diagnosed with PAI. Laboratory studies showed elevated serum ACTH concentration (165 pg/ml), low morning serum cortisol concentration, and an abnormal cosyntropin stimulation test. PAI investigations were ensued. The patient had negative adrenal antibody test. Computed tomography imaging demonstrated a left adrenal mass of 3 cm with a density of 31 HU associated to a hepatosplenomegaly and diffuse infiltrative lung disease. Multifocal systemic tuberculosis was highly suspected. However, therapeutic test showed no response. The endocrine work up showed no hormonal secretion of the adrenal lesion that remained stable. Laboratory data showed prediabetes, dyslipidemia and cytolysis with thrombocytopenia and anemia. A bone marrow aspiration was in favor of NPD. On the grounds of these results the diagnosis of NPD type B was confirmed.
Conclusion
No cases of the coexisting of NPD with PAI and Hashimoto thyroiditis have been reported to our knowledge. Further studies are needed to ascertain whether multiple glandular dysfunction should be anticipated in NPD type B.

Epidemiology, clinical course, and genetic analysis of pheochromocytomas/paragangliomas: A single centre tertiary care experience over 16 years from crete-greece

Maria Chrysoulaki[1], Florentia Fostira[2], Vasiliki Daraki[1], Grigoria Betsi[1], Maria Sfakiotaki[1], Maria Mytilinaiou[1], Katerina Bouki[1], Konstantinos Stathias[1], Konstantinos Spanakis[3], Panagiotis-Nikolaos Tsakalomatis[1], Eleni-Konstantina Syntzanaki[1], Kalliopi Kontolaimaki[1], Rodanthi Vamvoukaki[1], Konstantinos Nastos[4] & Paraskevi Xekouki[1]
[1]University Hospital of Heraklion, University of Crete, Medical School., Endocrinology & Diabetes Clinic, Heraklion, Greece; [2]National Centre for Scientific Research 'Demokritos', Molecular Diagnostics Laboratory, Athens, Greece; [3]University Hospital of Heraklion, University of Crete, Medical School., Department of Medical Imaging, Heraklion, Greece; [4]Attikon University Hospital, National and Kapodistrian University of Athens, 3rd Department of Surgery, Athens, Greece

Background
Pheochromocytomas (PHOEs) and paragangliomas (PGLs) are rare neuroendocrine tumors originating from chromaffin cells. PHEO/PGL incidence ranges between 2–8/million, with 10–49% of these tumors being detected incidentally during imaging performed for other reasons. Up to 40% of PHEOs/PGLs patients have disease-specific germline pathogenic variants. This study aimed to investigate the epidemiology, clinical course, and genetic background of PHEOs/PPGLs in a Greek tertiary reference centre.
Methods
We retrospectively reviewed the data of 21 PHEOs/PGLs patients seen at the Endocrine Clinic of the University Hospital of Heraklion, Crete, Greece, between 1998–2020. Demographic, histopathology and follow-up data were collected. Germline DNA, extracted from patients' peripheral blood, was subsequently analyzed by a 94-cancer gene panel, followed by MLPA. All participants have signed informed consent.
Results
In total, 21 patients with a mean age of 46.52 ± 18.34 years were included. There was a male predominance (men, n = 15 [71.4%]; women, n=6 [28.6%]). Sixteen patients (76.2%) had PHEO, 4 (19%) had PGL and one patient (4.76%) had both PHEO/PGL. Ten patients (62.5%) had right-sided PHEO, 5 (29.41%) left-sided and 2 (11.76%) bilateral. PGL locations included: retroperitoneum (40%), head/neck (20%), multiple organs (20%), pericardium (20%). Twelve patients (57.1%) presented as an incidentaloma, 8 (38%) as a suspected PHEO and 1 (4.8%) was screened because of neurofibromatosis-1 syndrome. The mean age at presentation did not differ between patients with incidentaloma and suspected PHEO (47.5 ± 14.22 vs 57 ± 14.59 years, P = 0.16). PGLs patients tended to be younger, compared to PHEO (33.4 ± 25.63 vs 51.5 ± 14.32 years, ns). Overall, 15 patients (71.42%) had hypertension: 58.33% of incidentaloma group and 87.5% of PHEO suspected group. Males more frequently presented with incidentaloma (66.66%), and females with PHEO suspected symptoms (60%). Most patients had secreting PHEO/PGL (71.42%). Eighteen patients (85.71%) were operated, while 3 (14.28%) preferred conservative management. The mean tumor maximum diameter was 6.3 ± 2.4 (range 3–11 cm). In most cases the Pheochromocytoma of Adrenal Gland Scaled Score was <3 consistent with benign potential. Although the genetic analysis is still ongoing, primary results revealed the presence of germline pathogenic variants in five patients and more specifically, three in succinate dehydrogenase (SDHx) subunits, all of which developed metastatic disease, and one in each of RET and NF1. Fourteen patients (66.66%) are in remission, four patients (19.04%) have stable disease and three patients (14,28%) showed disease progression. This is the first attempt to collect, report and characterize PHEO/PGL in Greece.

Differential phenotype of bilateral macronodular adrenal hyperplasia and other bilateral adrenal lesions with associated subclinical hypercortisolism. Study of 98 patients

Nuria Bengoa Rojano, Maria Fernandez Argüeso, Eider Pascual-Corrales, José I. Botella-Carreter & Marta Araujo-Castro
Ramón y Cajal University Hospital, Endocrinology and Nutrition, Madrid, Spain

Purpose
To evaluate the prevalence of bilateral macronodular adrenal hyperplasia (BMAH) in patients with adrenal incidentalomas (AIs) and analyse the differential phenotype of patients with BMAH compared to other bilateral adrenal lesions which do not meet BMAH definition (non-BMAH), with associated possible or confirmed autonomous cortisol secretion (ACS).
Methods
Retrospective study of patients with AIs diagnosed between 2013 and 2019 in the Hospital Ramón y Cajal (n = 730). Patients with bilateral disease and associated possible or confirmed ACS were included (n = 98). Possible ACS was defined as a DST > 1.8 µg/dl without specific clinical signs of Cushing syndrome, and confirmed ACS when cortisol post-DST was > 5.0 µg/dl. BMAH diagnosis was established in patients with hyperplasia and bilateral adrenal nodules > 1 cm and associated possible or confirmed ACS.
Results
Inclusion criteria were fulfilled by 98 out of the 730 patients with AIs included in the RCUH ADRENAL INCIDENTALOMA database. BMAH was confirmed in 31 patients (4.2% of AIs and 31.6% of bilateral AIs with possible or confirmed ACS). Patients with BMAH presented a higher prevalence of ACS (OR 4.1, 95% CI 1.38 to 12.09, P = 0.010), but differences disappeared after adjusting by tumor size and total adenomatous mass (adjusted OR 2.3, 95% CI = 0.65–8.27, and OR 2.3, 95% CI 0.47 to 11.21, respectively). However, no significant differences in the cardiometabolic profile of both groups were observed. Tumor size and total adenomatous mass were significantly higher in patients with BMAH (30.2 ± 12.16 vs 24.3 ± 8.47, P = 0.010 and 53.9 ± 20.8 vs 43.3 ± 14.62, P = 0.023). After a median follow-up of 33.7 (range 3.7 to 194.8) months, no differences in the risk of developing comorbidities was observed between BMAH and non-BMAH. Aberrant receptors study was performed in 5 patients with BMAH, being positive in three patients (in the metoclopramide test in two patients and in the metoclopramide and mixed food test in another). Two patients with BMAH underwent unilateral adrenalectomy, with improved of cardiometabolic and hormonal alterations, one patient (study positive for mixed food test) was treated with lanreotide with no response and other (one of the patients with a positive metoclopramide test) with amitriptyline, without response neither.
Conclusion
BMAH is relatively common in patients with incidentally detected bilateral adrenals lesions with associated subclinical hypercortisolism. The higher prevalence of ACS in BMAH compared to non-BMAH is related with the higher tumor size and total adenomatous mass in patients with BMHA, but no differences in the cardiometabolic profile was observed between both groups.

Effect of retinoic acid on adrenal primary cultures from patients with Cushing's disease

Francesca Pecori Giraldi[1,2], Antonella Sesta[2], Laura Tapella[1], Maria Francesca Cassarino[2] & Luigi Castelli[3]
[1]University of Milan, Department Clinical Sciences & Community Health, Milan, Italy; [2]Istituto Auxologico Italiano IRCCS, Neuroendocrinology Research Laboratory, Cusano Milanino (MI), Italy; [2]Ospedale San Carlo, Department Surgery, Paderno Dugnano (MI), Italy

Retinoic acid, a major modulator of adrenal development and differentiation, has also been shown to inhibit ACTH secretion by tumoral corticotropes. Recent clinical trials in patients with Cushing's disease revealed that retinoic acid exerts beneficial effects in these patients (1,2). Of note, the decrease in cortisol secretion during retinoic acid administration was more pronounced than the change in ACTH levels (1) suggesting a direct action at adrenal level. Aim of the present study was to evaluate the effect of retinoic acid on cortisol secretion and on genes involved in steroidogenesis and retinoic acid action in adrenals from patients with Cushing's disease
Methods.
Adrenal specimens from six patients with Cushing's disease were incubated with retinoic acid with and without ACTH. Cortisol secretion was measured by immunoassay and expression of genes involved in steroidogenesis (*CYP17A, STAR, LIPE, MC2R, DAX*-1, *SF*-1) as well as retinoic acid action (*RARA, RARB, LXR, PPARD, COUP-TF1, SREBP1, mND1, mND6*) were evaluated by real-time RT-PCR.
Results.
Incubation with 10–100 nM retinoic acid increased spontaneous cortisol secretion and expression of *STAR* and *CYP17A*. As expected, retinoic acid increased *RARA*, *RARB* and *SREBP1*. In wells treated with 10 nM ACTH, retinoic acid markedly diminished *MC2R*, thus blunting ACTH receptor upregulation, and no stimulatory effect on cortisol secretion or steroidogenic enzyme synthesis was observed. ACTH itself increased ligand-induced *RARB* expression, possibly enhancing sensitivity to retinoic acid.
Conclusions.
Our results indicate that retinoic acid stimulates spontaneous cortisol secretion but, in presence of ACTH, the decrease in adrenal ACTH receptor overrides this effect. These findings support the hypothesis of a direct adrenal action in patients with Cushing's disease.

Typical obese patient with an adrenal incidentaloma is a menopausal female with an unilateral nonfunctioning tumor – a single centre experience

Ljiljana Marina[1], Antoan Stefan Sojat[2], Svetlana Vujovic[1], Milina Tancic-Gajic[1], Zorana Arizanovic[2], Jelena Milin Lazovic[3], Aleksandra Kendereski[1], Dunja-Simona Petkovic[4], Kristina Saravinovska[4], David Stankovic[4], Natasa Rosic[4] & Miomira Ivovic[1]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Faculty of Medicine, University of Belgrade, Serbia, Department for Obesity, Metabolic and Reproductive Disorders; [2]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Department for Obesity, Metabolic and Reproductive Disorders, Serbia; [3]Institute of Medical Statistics and Informatics, Faculty of Medicine, University of Belgrade, Serbia, Serbia; [4]Faculty of Medicine, University of Belgrade, Serbia

Introduction
The connection between obesity and tumorigenesis has been well established.
Aim
The aim of this study was to elucidate if there are any demographic and functional differences in adrenal incidentalomas (AI) with respect to different body mass index (BMI) categories.
Patients and methods
This was an observational, cross sectional study. The AI cohort consisted of 680 patients that underwent functional hormonal assesment in our Clinic. After exclusion of patients with overt adrenal hyperfunction, malignant adrenal tumors, adrenal cysts and metastasis, the total studied group consisted of 560 patients: 385 female and 175 male. Based on BMI, we have stratified them in three groups, 18.5–25 kg/m^2 (135 patients, 22.44 ± 2.03 kg/m^2, 56 ± 11 years), 25–30 kg/m^2 (219 patients, 27.63 ± 1.41 kg/m^2, 58 ± 11 years) and > 30 kg/m^2 (206 patients, 33.91 ± 3.53 kg/m^2, 59 ± 9 years). Based on cortisol level after 1 mg overnight dexamethasone suppression test, AI were identified as nonfunctional AI (NAI) (≤ 50 nmol/l), those with possible autonomous cortisol secretion (PACS) (> 51 nmol/l) or autonomous cortisol secretion (ACS) (> 138 nmol/l).
Results
Female sex was predominant in all BMI groups (M/F %: 22.6/77.4, 40.5/59.5 and 27.1/72.9). However, obese and normal weight patients had significantly higher frequency of females when compared to overweight patients ($P < 0.001$). Obese patients were significantly older then the other two BMI groups ($P = 0.008$). Overweight and obese AI patients were more likely to have NAI ($P < 0.001$) whereas normal weight AIs were more likely to have either PACS or ACS ($P < 0.001$). All three BMI groups had predominantly more unilateral then bilateral AIs (70.7/29.3%, 79.1/20.9% and 77.8/22.2%). There was no difference in frequency between unilateral and bilateral AIs with respect to BMI group ($P = 0.172$). There was a significant positive correlation between patients› age and BMI ($r = 0.097$, $P = 0.022$). There was no significant difference in the size of AI between the groups ($P = 0.292$).
Conclusion
Our results imply that the typical obese patient with an AI is very likely to be a menopausal female with an unilateral nonfunctioning tumor. They also add to the body of evidence that obesity plays an important role in the adrenal tumorigenesis. However, there is yet to be determined which came first: the hen or the egg?

Cost-effectiveness of empagliflozin plus metformin vs metformin alone as first-line therapy in patients with type 2 diabetes mellitus: An australian perspective

Dina Abushanab[1], Danny Liew[1], Clara marquina[1], Daoud Al-Badriyeh[2] & Zanfina Ademi[1]
[1]Monash Univeristy, School of public health and preventive medicine, Melbourne, Australia; [2]Qatar University, College of Pharmacy, Qatar

Background
Sodium-glucose cotransporter 2 (SGLT2) inhibitors are potentially an attractive option for initial combination therapy with metformin for type 2 diabetes mellitus (T2DM), which may help patients to achieve adequate glycaemic control and reduce cardiovascular disease (CVD). Empagliflozin has been shown to be superior compared to other SGLT2 inhibitors in reducing all-cause and cardiovascular mortality in patients with T2DM.
Aims
To evaluate the cost-effectiveness of first-line empagliflozin added to metformin vs metformin alone in patients with newly diagnosed T2DM and established CVD in Australia.
Methods
A Markov model was constructed to simulate cardiovascular events occurring in Australians currently aged 50 to 84 years with newly diagnosed T2DM and existing CVD. The cycle length was one year, and the base-case time horizon was five years. The model consisted of two health states: 'Alive' and 'Dead'. Clinical inputs were based on data from Empagliflozin Cardiovascular Outcome Event Trial in Type 2 Diabetes Mellitus Patients-Removing Excess Glucose. Costs and utilities were extracted from published sources. The analyses were performed from an Australian public healthcare system perspective and from a societal perspective, with the latter ascribing the Australian Government's 'value of statistical life year' (VoSLY, AUD 213,000) to each year lived by a person. The main outcome was the incremental cost-effectiveness ratio (ICER) per quality-adjusted life-year gained (QALY) and years of life saved (YoLS). Future outcomes were discounted at a rate of 5% per anum. Sensitivity analyses were undertaken confirm robustness of the results.
Results
First-line use of empagliflozin in addition to metformin reduced overall cardiovascular events by 0.82% and death by 7.72% over five years, compared to metformin alone. There were 0.2 YoLS per person and 0.16 QALYs gained, at a net healthcare cost of AUD 4,408. These equated to incremental cost-effectiveness ratios of AUD 22,076 per YoLS and AUD 28,244 per QALY gained. The gains in VoSLY equated to AUD 42,530 per person, meaning that from a societal perspective, the intervention was cost saving.

Conclusion
First-line use of empagliflozin added to metformin appears to be a cost-effective strategy for the management of Australians with newly diagnosed T2DM and CVD.

Klinefelter syndrome: Beyond hypogonadism

Inês Vieira[1], Margarida Bastos[1], Luísa Ruas[1], Dírcea Rodrigues[1,2], Leonor Gomes[1,2] & Isabel Paiva[1]
[1]Coimbra Hospital and University Center, Endocrinology, Portugal; [2]University of Coimbra, Faculty of Medicine, Portugal

Introduction
In Klinefelter syndrome, hypergonadotropic hypogonadism is the most prominent endocrine-metabolic disorder. However, a higher prevalence of cardiovascular risk factors has also been reported.
Objectives
In a sample of individuals with Klinefelter Syndrome (KS): – to document the diagnostic context; – to assess the prevalence of cardiovascular risk factors (CVRF) and compare it with a control group; – to analyse the influence of age at diagnosis and hormone replacement therapy (HRT) on CVRF.
Materials and methods
A sample with KS under 55 years of age and an equal number of age-matched male control subjects were selected.
Results
Study group with 32 KS subjects, mean age 29.5 ± 8.6 years. Diagnosis on average at 17.5 ± 12.3 years of age due to learning/behavioral issues (25.0%), infertility (25.0%), phenotype (21.4%), delayed pubertal development (21.4%) and prenatal diagnosis (7.1%). Karyotype (n = 28): 82.8% 47XXY, 6.9% 46XY/47XXY, 3.4% 48XXXY and 6.9% 49XXXY. All of the subjects had hypergonadotropic hypogonadism, 93.8% decreased testicular volume, 46.2% gyneco/adipomastia and 32.1% cryptorchidism. In those in which it was evaluated (n = 8), the presence of azoospermia was constant. HRT was started in 93.8% at a median age of 15.5 ± 12.0 years. In the last 5 years, these patients had an average of 56.2 ± 37.3% of the total testosterone levels within the reference values, 36.4 ± 35.6% below and 5.9 ± 19.8% above. The vast majority of KS (78.1%) had some CVRF: 15.6% pre-diabetes, 6.3% diabetes, 53.1% dyslipidemia, 46.9% overweight, 18.8% obesity and 6,3% hypertension. The overall prevalence of CVRF was higher than that of the control group (25 vs 15, P = 0.010), with: higher prevalence of dysglycemia (7 vs 0, P = 0.011) and dyslipidemia (17 vs 8, P = 0.021); more overweight/obese individuals without reaching statistical significance (21 vs 32, P = 0.079); similar prevalence of hypertension (2 vs 3, P = 1,000). There was no significant correlation between higher number of CVRF and age at diagnosis (P = 0.333), age at HRT initiation (P = 0.281) or the percentage of testosterone assays within reference values (P = 0.753).
Conclusions
This sample is composed mainly of young patients, with a variable context of diagnosis, but in general precocious. Even so, an elevated prevalence of CVRF was registered, higher than that of the control group. Although sample size is a limiting factor, the data does not suggest an influence of early diagnosis and HRT on CVRF.

Aryl hydrocarbon receptor Interacting Protein (AIP) status in a functional adrenal adenoma occurring in a patient with a germline AIP mutation

Tiziana Feola[1,2], Roberta Capelli[3], Francesca Gianno[1,4], Chiara Compagnoni[3], Claudio Letizia[5], Giorgio De Toma[6], Antonio Ciardi[4], Giuseppe De Vincentis[4], Felice Giangaspero[1,4], Alessandra Tessitore[3] & Marie-Lise Jaffrain-Rea[1,3]
[1]Neuromed IRCCS, Neuroendocrinology, Pozzilli, Italy; [2]Sapienza University, Department of Experimental Medicine, Rome, Italy; [3]University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, Coppito (AQ), Italy; [4]Sapienza University, Department of Radiological, Oncological and Pathological Sciences, Rome, Italy; [5]Sapienza University, Department of Translational and Precision Medicine, Rome, Italy; [6]Sapienza University, Department of Surgery P. Valdoni, Rome, Italy

Introduction
Aryl hydrocarbon receptor Interacting Protein (AIP), a pituitary tumour suppressing gene located in 11q13, is the most common predisposing gene for early-onset and familial acromegaly. Fifteen years after its identification, there is little evidence of AIP involvement in non-pituitary tumors. We had the opportunity to study AIP status in a cortisol-producing adenoma operated in an AIP mutation carrier.
Case-report
A 43-year-old woman was followed-up as a carrier of a familial R304X AIP mutation. Her sister, first degree cousin and son had developed acromegaly but she had no evidence of pituitary disease. However, an incidental and asymptomatic right adrenal mass of 26 mm was found on abdominal US, with MRI suggesting an adrenocortical adenoma. The only biochemical abnormality was abnormal suppression of cortisol after a 1mg O/N dexamethasone suppression test. At the age of 46, because of a progressive mass increase with autonomous cortisol secretion confirmed by a I131-norcholesterol scintigraphy, she was operated on by laparoscopic surgery. The diagnosis of adrenocortical adenoma, larger than expected (max 45 mm), without cellular atypia, was confirmed, with multiple foci of mielopoma. The patient gave consent for the study of AIP status in the tumour. RT-PCR amplification of the AIP gene (exon6) on tumour and adjacent normal adrenocortical tissue DNA showed the presence of the wild-type and mutated allele in both samples, as confirmed on leukocyte DNA. AIP-immunostaining was positive on normal and tumour cells. After post-operative corticotroph insufficiency, glucocorticoid replacement therapy was progressively reduced and withdrawn 5 months later. She is currently eucortisolic, and the left adrenal gland is normal. None of her acromegalic relatives had evidence of adrenal abnormalities.
Discussion
Adrenocortical adenomas may be encountered more frequently in acromegalics. To the best of our knowledge, four cases of adrenocortical tumors (1 non-functioning, 3 androgen-secreting) were reported with sufficient details in AIP-related acromegalics and LOH at the AIP locus was found only in a corticosurrenaloma.
Conclusion
The study of tumour AIP status in an unusual cortisol-secreting adenoma developing in a familial context of germline AIP mutations, in the absence of acromegaly, favors the hypothesis that the R304X mutation was not involved in adrenal tumorigenesis. Rather, it suggests LOH at the AIP locus is not an early event in adrenocortical tumors, although AIP expression may be lost due to somatic chromosomal abnormalities, including loss of genetic material in chr 11 and in particular LOH in 11q13.

The association between adrenal adenomas' size, autonomous cortisol secretion and metabolic derangements

Jonathan Bleier[1,2], Jana Pickovsky[3], Boris Fishman[1,2], Zohar Dotan[2,4], Amir Tirosh[2,5] & Gadi Shlomai[1,2,5]
[1]Sheba Medical Center, Internal medicine D, Ramat Gan, Israel; [2]Tel Aviv University, Sackler faculty of medicine, Tel Aviv-Yafo, Israel; [3]Sheba Medical Center, Department of Radiology, Ramat Gan, Israel; [4]Sheba Medical Center, Department of Urology, Ramat Gan, Israel; [5]Sheba Medical Center, Institute of Endocrinology, diabetes and metabolism, Ramat Gan, Israel

Objective
Autonomous cortisol secretion (ACS) is the most common hypersecretion syndrome present in patients diagnosed with adrenal incidentalomas (AI). ACS is associated with various metabolic derangements. Thus far, very few and mostly inconclusive data exists regarding the association between AI's radiological characteristics and hormonal functionality. In this study we assessed the associations between radiological characteristics of incidentally discovered adrenal findings, ACS, and metabolic abnormalities.
Methods
We prospectively collected data from 77 patients evaluated for adrenal incidentalomas in a large tertiary medical center between December 1st, 2017 and October 31 st, 2020. Post -Dexamethasone suppression test (DST) morning cortisol levels were used to diagnose ACS, and the association between AI's radiological features, post-DST morning cortisol levels and metabolic outcomes was analyzed.
Results
Maximal adenoma diameter linearly correlated with post-DST morning cortisol levels (R = 0.474, P < 0.01.). This correlation translated to a linear correlation between maximal adrenal adenoma diameter and metabolic parameters, mainly fasting plasma glucose and glycated hemoglobin levels (R = 0.58, P < 0.01 and R = 0.56, P < 0.01, respectively). Moreover, we

demonstrate that the linear correlation between maximal adenoma diameter and post -DST cortisol is greatly intensified in patients meeting the criteria for the metabolic syndrome. Additionally, we show that patients with ACS, have larger adrenal adenomas than patients harboring non-functioning adenomas (27 mm, Vs. 20.3 mm, respectively, $P < 0.01$), and that adenomas sized ≤ 13.9 mm are likely to be non-functional with a sensitivity of 90%.
Conclusions
The diameter of incidentally found adrenal lesions is positively associated with ACS and abnormal glucose homeostasis. Our data suggest that initial adrenal adenoma diameter may be an adjunct for the risk stratification for ACS and its associated metabolic morbidity.

Introduction
Irisin is a molecule secreted from skeletal muscle and contributes to maintenance of metabolic homeostasis leading to increased energy expenditure and reducing the risk of obesity and diabetes. Literature data suggest that patients with Cushing disease have lower irisin values than controls and remission of hypercortisolism increases these values. Moreover, other plasma inflammation markers implicated in the pathogenesis of atherosclerosis, including TNF-alpha and IL-6, are increased in Cushing's syndrome patients. Few data are available in mild autonomous cortisol secretion (MACS) patients. In this randomized study we aimed to evaluate the effects of adrenalectomy on circulating irisin, IL-6 and TNF-ήlevels in patients with adrenal incidentaloma (AI) and MACS.
Methods
Among 626 AI patients (referred to 3 Italian Centers between 06/2016 and 02/2020), according to the inclusion criteria, we consecutively enrolled 61 patients (45 F) with MACS (cortisol level after 1mg overnight dexamethasone suppression test, 1 mgDST, between 1.8 and 5 μg/dl). Patients were randomized in two groups: surgery (Group 1, $n = 29$) or conservative follow-up (Group 2, $n = 32$). Three patients from Group 1 withdrew their consent to surgery. Irisine, TNF-alpha, IL-6 levels, anthropometric, and glyco-metabolic parameters were evaluated at baseline and after 6 months. The study is ongoing.
Results
So far, 40 patients (15 in Group 1 and 25 in Group 2, mean age 64.4 ± 10.4 years, adenoma diameter 2.8 ± 0.7 cm, 1mgDST 3.3 ± 1.6 μg/dl) have completed the 6 months follow-up. At baseline the two groups were comparable for clinical and biochemical characteristics. After 6 months we found that only in group 1 irisin levels increased over time (13.1 ± 1.8 ng/ml at baseline vs 26.2 ± 15 ng/ml at 6 months, $P < 0.05$) whereas TNF-alpha and IL-6 levels did not change in both groups. At baseline, TNF-alpha and IL-6 levels were correlated to HOMA-index levels ($r = 0.408$, $P = 0.015$, $R = 0.425$, $P = 0.011$, respectively), that, in turn, significantly correlated with BMI and waist circumference. The TNF-alpha levels were also correlated to the fibrinogen levels ($r = 0.360$, $P = 0.031$). We did not find any correlation between TNF-alpha and IL-6 levels and parameters of cortisol secretion (1 mgDST, ACTH, urinary free cortisol/cortisone and midnight salivary cortisol levels). Unexpectedly, we found a strong positive correlation between irisin levels and 1 mgDST ($r = 0.625$, $P = 0.001$), we suppose for a mechanism of peripheral resistance, but not with other metabolic parameters.
Conclusion
These preliminary data suggest that, in MACS-patients, irisin levels increases after surgery, whereas they remain steady after a conservative follow-up.

Impact of adrenal insufficiency on female sexual function: A preliminary study

Virginia Zamponi, Rossella Mazzilli, Roberta Maggio, Pina Lardo, Soraya Olana, Giuseppe Pugliese, Antongiulio Faggiano & Antonio Stigliano
Endocrine-Metabolic Unit, Sant'Andrea University Hospital, Rome, Italy; Department of Clinical and Molecular Medicine, University of Rome 'Sapienza', Rome, Rome, Italy

Introduction
Adrenal insufficiency is a clinical condition that leads to depletion of glucocorticoids, mineralocorticoids and androgens. While in men adrenal androgen deficiency is not clinically significant for testicular testosterone synthesis, in women so far androgen treatment is suggested for the reduction of libido and depression. However, no data is currently available on female sexual function.
Primary endpoints
1) To study the prevalence of Female Sexual Dysfunction (FSD) in women with adrenal insufficiency; 2) To compare the obtained data with a healthy control group.
Secondary endpoints
1) To evaluate the correlation between FSD and sexual distress in patients with adrenal insufficiency; 2) To study the impact of different glycoactive-therapies on sexuality; 3) To evaluate the correlation between FSFI-6 total scores and cortisol and ACTH levels.
Patients and methods
22 women with adrenal insufficiency and 23 healthy women were recruited as controls. A clinical investigation was carried out, including anamnesis, physical examination, serum cortisol and ACTH dosage. In addition, Female Sexual Function Index-6 (FSFI-6) and Sexual Distress Scale (SDS) questionnaires were administered to the patients.
Results
The prevalence of FSD (total score < 19) was significantly higher in women with adrenal insufficiency (15/22; 68.2%) compared to controls (2/23; 8.7%; $P = 0.001$). Regarding the questionnaire items, a significantly different score was found for desire ($P < 0.001$), arousal ($P = 0.0006$), lubrication ($P = 0.046$) and overall sexual satisfaction ($P < 0.0001$) in women with adrenal insufficiency compared to controls. A significant inverse correlation was found between FSFI-6 total scores and sex-related distress ($r = –0.65$; $P = 0.0011$), a significant direct correlation was found between FSFI-6 total scores and cortisol plasma levels ($r = 0.55$; $P = 0.035$). No statistically significant differences for any of the FSFI-6 items or total score was found between women treated by hydrocortisone or cortisone acetate and women treated by a modified release hydrocortisone formulation. No statistically significant correlations were found between ACTH plasma levels and total score for the FSFI-6 questionnaire.
Conclusions
A higher prevalence of FSD was found in women affected by adrenal insufficiency compared to the group of healthy women. Desire seems to be the most impaired part of sexual response. Moreover, sexual dysfunction in this population seems to be related to sexual distress and cortisol serum levels. Further studies on larger series are needed to confirm these data on this sensitive issue.

Adrenal cysts – a rare entity

Nádia Mourinho Bala, Nuno Raposo, Sílvia Guerra, José Maria Aragüés & Cristina Valadas
Hospital Beatriz Ângelo, Endocrinology, Portugal

Introduction
Adrenal cyst lesions are uncommon and only a few large series have been reported. The pathogenesis is unclear. Currently, adrenal cystic lesions are

categorized into endothelial cysts, pseudocysts, epithelial cysts and parasitic cysts. In most cases they are found incidentally in asymptomatic patients or in patients with non-specific gastrointestinal symptoms. We describe three cases of adrenal cysts.
Case report
Case 1: Female patient, 50-year-old, with essential arterial hypertension. An adrenal mass in the right adrenal gland was diagnosed incidentally after an abdominal ultrasound. The CT scan showed a 55 mm cystic lesion with a partially calcified wall, under 20 HU. The laboratory evaluation suggested a non-functional lesion. The patient was submitted to a laparoscopic adrenalectomy. The pathology examination revealed an adrenal cyst with 60 mm of larger axis, with no recognizable epithelial tissue and with a partially calcified wall. Case 2: A 55-year-old female patient, with a previous history of ovarian teratoma, mammary fibroadenomas and arterial hypertension. A nodular cystic lesion in left adrenal gland was diagnosed incidentally after a renal ultrasound that was requested due to recurrent urinary tract infections. The patient underwent a CT scan that showed a cystic lesion, with low density and homogenous content, with 66 mm of larger axis. The laboratory evaluation suggested a non-functional lesion. The patient was submitted to a laparoscopic left adrenalectomy. The pathological examination showed an epithelial cyst with 70 × 50 × 30 mm. Case 3: 56-year-old female patient, with no relevant personal history. An adrenal lesion with 58 mm larger axis, homogenous, with water density, was diagnosed in a lumbar CT scan requested due to a back pain. The laboratory evaluation suggested a non-functional lesion. The patient underwent a MRI that showed a cystic nodular formation with benign characteristics. After 2 years of tight surveillance the cystic nodule is now smaller in size, with 43 mm of larger axis.
Discussion
Adrenal cysts are rare entities, however, due to a significative increase in the demand of imaging exams, the incidence has grown. The choice of treatment is not always clear. In most cases, when the larger axis is above 4 cm the complete excision may be considered an option. In one of the cases described, the patient underwent tight medical vigilance, with a reduction in the size of the cyst and no signs of malignancy 2 years after the diagnosis.

One train may hide another: Scleromyositis in a patient with peripheral adrenal insufficiency

Derbel Abir, Snoussi Mouna, Guermazi Mouna, Frikha Feten, Dammak Chifa, Raida Ben Salah, Marzouk Sameh & Bahloul Zouhir
Chu Hedi Chaker, Internal Medicine, Sfax, Tunisia

Introduction
Patients with primary adrenal insufficiency (PAI) may have musculoskeletal symptoms. However, the association of such endocrinopathy with scleromyositis is extremely rare and has not been reported formerly to our acknowledge. Herein we report this association.
Case report
A 32-years old female with one year history of profound global weakness was referred to internal department in April 2006, for suspicion of polymyositis. Diagnosis of PAI was established in endocrinology department in September 2005 in front of clinical signs associating fatigue, muscle weakness, gastrointestinal complaints, weight loss and hyperpigmentation. Moreover hormonal evaluation (Short synachten test revealed baseline morning cortisol at82.5 ngl/mL and at 147 ng/ml at 60th minutes/ normal ACTH = 25 pg/ml). Further investigations excluded tuberculosis infection, adrenal hemorrhage or neoplasia. Anti adrenal antibodies were also negative. Treatment by hydrocortisone substitution (30 mg/day) was prescribed. Nevertheless, musculoskeletal symptoms persisted leading to inability to walk. Three months later, she experienced dyspnea, arthralgia, and dysphagia. Physical examination revealed Raynaud's phenomenon, cutaneous sclerosis in the face and the trunck and digital ulcers. The body temperature was at 38°C, the blood pressure was at140/90 mm Hg, the heart rate was at 100 bpm. She had proximal muscles deficiency. Electrocardiogram revealed right branch block. Doppler-echocardiography found low systolic function (26%) and enlarged right cavities with high pulmonary arterial pressure (76 mmHg). Computed tomography ruled out pulmonary embolism and revealed interstitial lung disease. Biological findings found elevated transaminases (AST/ALT: 200/110 iu/l) and high muscular enzymes (CK:465 iu/l). Immunologic analysis found high anti nuclear antibodies (1/1280). Myositis immunoblot was negative. Electromyography showed a myogenic syndrom. MRI revealed significant bilateral amyotrophic muscles of the thigh with fatty degeneration of posterior and medial muscles. Muscle biopsy was normal. Gastro-duodenal endoscopy showed peptic esophagitis. Manometry demonstrated peristaltic disorder in lower esophagus. Scleromyositis with severe cardiac involvement was retained. Steroid therapy was started (1 mg/kg/day) with 3pulses of methyl prednisolone associated to immunosuppressant (cyclophosphamide) and symptomatic treatment based on diuretics, ACE inhibitors and colchicine. Clinical course was favorable. Control echocardiography after one month revealed improvement of left ventricular function (60%). The patient has been followed up for over 13 years with favorable course.
Conclusion
This case underlines the importance of seeking endocrinopathies in patient with unexplained musculoskeletal symptoms. However, that should not under diagnose autoimmune myopathies disorders like scleromyositis.

Oral and dental manifestation of Allgrove syndrome: A case report

Ben Salah Dhoha, Hana Charfi, Elleuch Mouna, Safi Wajdi, Mnif Fatma, Mnif Mouna, Charfi Nadia, Rekik Nabila, Hadj Kacem Faten & Abid Mohamed
Hedi Cheker, Endocrinology, Sfax, Tunisia

Introduction
Triple-A syndrome, also known as Allgrove syndrome, is a rare autosomal recessive disorder. It is a multisystemic disease with an estimated prevalence of 1 per 1 000 000 individuals The 3 features of this syndrome are achalasia, adrenal insufficiency, and alacrima. Recently, dental impairment has been the subject of several case reports and reviews. However, this abnormality remains under-diagnosed.
Purpose
This article reports a patient with multisystemic features of the syndrome with particular attention to premature loss of permanent teeth.
Case report
We represent the case of a 23-year-old male patient with no family medical history, born to consanguineous parents. He was diagnosed with adrenal insufficiency at the age of 3 after a hypoglycemic and hyponatremia seizure with low cortisol and elevated ACTH level. He was treated with oral hydrocortisone. Medical examination showed hyperpigmentation, microcephaly, delayed developmental milestones and dysmorphic facial features: narrow face, long philtrum, down-turned mouth. Further examination confirmed achalasia and dysphagia. The Allgrove syndrome was then suspected and confirmed when genetic analysis identified the mutation of the AAAS gene (IVS14 + 1G). He had esophageal dilatation on 2 occasions (2000 and 2011) with real improvement of dysphagia. At the age of 6, the patient started having gingivitis and dental caries. Due to tendency to eating sweet foods and poor oral hygiene, the teeth have decayed rapidly. Also, due to inadequate root length remaining after the removal of decay, all of them were extracted. Because of economic problem, he had implant treatment for only his upper teeth when he was 20-years-old. However, the implant was only successful for 2 years and then the patient started losing his teeth again.
Conclusion
Triple A syndrome is a multisystemic disease needing multidisciplinary management: endocrinology, gastrology, ophthalmology and dentists. The prevention and management of bucco-dental complications associated with xerostomia and achalasia are essential to minimize the loss of permanent teeth and improve the quality of life.

Adrenal steroid profiling in the diagnostics of partial enzyme defects in the adrenals. Establishment of normal cut-off levels using LC-MS/MS

Grethe Åstrøm Ueland[1], Sandra R. Dahl[2], Paal Methlie[1], Eystein Husebye[3] & Per Medboe Thorsby[2]
[1]Haukeland University Hospital, Department of Medicine, Bergen, Norway; [2]Oslo University Hospital Aker, Hormone Laboratory, Department of Medical Biochemistry, Oslo, Norway; [3]University of Bergen, Department of clinical medicine, Bergen, Norway

Background
Non-classical congenial adrenal hyperplasia (NCCAH) is an important differential diagnosis in women with acne, hirsutism, menstrual abnormalities and infertility. To diagnose NCCAH can be challenging, and currently used cutoff levels are based on unstandardized immunological assays, no longer in use.

Objective
Define LC-MS/MS based cut-off levels for steroid hormones, to improve diagnosis of NCCAH and other less common partial enzyme defects in the adrenals.
Methods
Basal and cosyntropin stimulated serum samples were collected from 83 healthy adults (52% women), 23–68 years of age. Twenty-two patients evaluated for possible NCCAH were used as a validation cohort. LC-MS/MS determined cut-offs for basal and cosyntropin stimulated 17-OHP, 21-deoxycortsiol (21-DF), 11-deoxycortisol (11-DF), deoxycorticosterone (DOC), corticosterone (B), 17-hydroxypregnenolone (17-OH Preg), cortisone (E), and dehydroepiandrosteron (DHEA) were defined by the 2.5 and 97.5% percentile in healthy subjects respectively.
Results

Table 1 shows basal (0 min) and cosyntropin stimulated (60 min) lower (2.5%) and upper (97.5%) cut-off levels for the steroid hormones studied.

Steroid (nmol/l)	0 min		60 min	
	2.5 %	97.5%	2.5 %	97.5%
17OHP	0.30	5.5	1.5	9.3
11DF	0.22	2.5	0.91	5.1
21DF	< 0.25	< 0,25	0.26	1.9
DOC	0.07	0.39	0.26	1.3
B	1.4	57	45	142
17OHPreg	3	–[a]	7	33
E	25	74	25	62
DHEA	4	57	8	114

[a]not calculated: many results < mLOQ; No significant differences were found between the genders, or between age groups.

Table 2 shows how these cut-off levels are applied on the validation cohort, consisting of 18 patients classified as healthy and three patients with verified NCCAH. One patient was impossible to classify, and is omitted from **Table 2**.

Steroid (nmol/l)	Patient 1		Patient 2		Patient 3		Healthy validation cohort (n = 18)	
	0 min	60 min	0 min	60 min	0 min	60 min	0 min	60 min
17OHP	< 5.5	> 9.3	< 5.5	> 9.3	< 5.5	> 9.3	All < 5.5	n = 1 > 9.3
21DF	> 0.25	> 1.9	< 0.25	< 1.9	< 0.25	< 1.9	All < 0.25	All< 1.9

All three women with verified NCCAH showed one or more parameters above the defined upper cut-off levels.
Conclusions
We propose that serum steroid profiling by LC-MS/MS should be applied as the initial screening test for NCCAH and other rarer enzyme defects in the adrenals. Our data supports that the cosyntropin stimulation test is still needed in the work-up of this patient group.

Aim
Pheochromocytoma and paraganglioma are rare neuroendocrine tumors, that can be diagnosed incidentally or with symptoms that may be confused with other diseases. In our study, we aimed to demonstrate our clinical biochemical and pathological experiences with pheochromocytoma and paraganglioma cases.
Method
The clinical, biochemical, radiological, and pathological data of a total of 79 patients diagnosed with pheochromocytoma between 2006 and 2021 at Marmara University School of Medicine Endocrinology and Metabolic Diseases Polyclinic were evaluated retrospectively.
Results
The mean age of the 79 patients was 51.7 ± 15.0 years, and 46.8 ± 15.6 years at the time of diagnosis. The majority of patients were female (Female/Male:48/31). The percentage of patients diagnosed incidentally was 53.2%, while 32.9% of patients were diagnosed due to hyperadrenargic symptoms, and 14.0% of them were diagnosed during screening for hereditary conditions. The most frequent symptoms were hypertension (49.4%), palpitation (39.2%) and perspriation (30.4%). Median tumor size in MR imaging was 45.5 mm (range: 7–170 mm) and the lesion size correlated significantly ($P < 0.0001$, $r = 0.5390$) with the urinary normetanephrine levels. Tumor localization was left adrenal in 30.4%, right adrenal in 27.8%, bilateral adrenal in 17.7%, and paraganglioma in 21.5% of patients. Eight patients (10.1%) were Von Hippel-Lindau, three patients (3.8%) were multiple endocrine neoplasia (MEN) type 2A, two patients (2.5%) were MEN type 2B, one patient (%1.3) each was neurofibromatosis type 1 and familial pheochromocytoma. Hereditary pheochromocytomas were diagnosed at younger ages, and bilateral lesions were more prevalent in them (both $P < 0.0001$). 64 patients were operated, others refused the operation or left the follow-up. The mean of tumor size in pathology report was 57.2 ± 27.5 mm. Malign pheochromocytoma was detected in 12 patients (15.2%), half of them was hereditary. Postoperative in the first year, urinary metanephrine, normetanephrine and vanilmandelik acid values of all patients decreased compared to preoperative values significantly (all of them $P < 0.0001$). A total of 5 patients died during the follow-up period, one of them was malignant. Three of the malignant ones received chemoradiotherapy. The clinical and biochemical characteristics of malignant and benign ones were similar. Pathological findings will be re-evaluated.
Conclusion
Hereditary syndromes should be kept in mind in young and bilateral cases. Since there is no clinical or biochemical test to distinguish malignant and bening, malign pheochromocytoma should also be considered, especially in hereditary cases.

Effects of sorafenib, a tyrosin kinase inhibitor, on adrenocortical cancer cell line

Lidia Cerquetti[1], Barbara Bucci[2], Salvatore Raffa[3], Pina Lardo[1], Roberta Maggio[1], Chiara Simonini[1], Elisa Petrangeli[4], Vincenzo Toscano[1], Giuseppe Pugliese[1] & Antonio Stigliano[1]
[1]Endocrinology – Sant'Andrea Hospital, Sapienza University of Rome, Clinical and Molecular Medicine, Rome, Italy; [2]San Pietro Hospital, Lab Unit, Rome, Italy; [3]Lab Unit – Sant'Andrea Hospital, Sapienza University of Rome, Clinical and Molecular Medicine, Rome, Italy; [4]Department of Experimental Medicine Sapienza University of Rome, Experimental Medicine, Rome, Italy

The lack of an effective medical treatment for adrenocortical carcinoma (ACC) has prompted the, search for better treatment protocols for ACC neoplasms. Sorafenib, a tyrosine kinase inhibitor has exhibited effectiveness in the treatment of different human tumors. Therefore, the aim of this study was to understand the mechanism through which sorafenib acts on ACC, especially since treatment with sorafenib alone is sometimes unable to induce a long-lasting antiproliferative effect in this tumor type. The effects of sorafenib were tested on the ACC cell line H295R by evaluating cell viability, apoptosis and VEGF receptor signaling which was assessed by analyzing VE-cadherin and β-catenin complex formation. We also tested sorafenib on an *in vitro* 3D cell culture model using the same cell line. Apoptosis was observed after sorafenib treatment, and coimmunoprecipitation data suggested that the drug prevents formation VEGFR-VE-cadherin and β-catenin proteins complex. These results were confirmed both by ultrastructural analysis and by a 3D model where we observed a disaggregation of spheres into single cells, which is a crucial event that represents the first step of metastasis. Our findings suggest that although sorafenib induces apoptotic cell death a small portion of cells survive the treatment and have characteristics of a malignancy. Based on our data we recommend against the use of sorafenib in patients with ACC.

Incidental detection of adrenal hyperplasia and mortality in patients with suspected SARS-CoV-2 Infection

Giuseppe Reimondo[1], Federica Solitro[2], Soraya Puglisi[1], Davide Casale[2], Giorgia Maria Tiranti[2], Anna Perini[1], Alessandra Cultrera[1], Valeria Caramello[3], Adriana Boccuzzi[3], Anna Pia[1], Massimo Terzolo[1] & Andrea Veltri[2]

[1]Internal Medicine, Department of Clinical and Biological Sciences, University of Turin, San Luigi Gonzaga Hospital, Orbassano, Italy; [2]Diagnostic and Interventional Radiology Unit, Department of Oncology, University of Turin, San Luigi Gonzaga Hospital, Orbassano, Italy; [3]Emergency Medicine, San Luigi Gonzaga Hospital, Orbassano, Italy

Many patients affected by SARS-CoV-2 disease (COVID) have associated comorbidities (arterial hypertension, obesity, diabetes mellitus, thrombophilia) that are also tied to autonomous cortisol secretion. However, the prevalence of diseases of the adrenal glands in COVID patients is presently unknown. Since the visualization of the adrenal glands is almost always available in chest CT performed in patients with suspected or confirmed SARS-CoV-2 infection, the evaluation of adrenal morphological disorders in such patients appears of interest. We assessed a prospective consecutive series of 402 patients (M 222, 55.2%; F 180, 44.8%) with a median age of 76 years (IQR 64–84 years), admitted to the emergency department for suspected SARS-CoV-2 infection. One hundred patients had a PCR-confirmed diagnosis of infection on a nasopharyngeal swab (24.9%). All patients underwent a chest CT study including the adrenal region. We found an altered adrenal morphology in 100 patients (24.9%): 62 subjects (15.4%) had adrenal hyperplasia (67.7% unilateral, 32.3% bilateral) and 38 (9.5%) discrete adrenal nodules (89.4% unilateral, 10.6% bilateral). The median size of adrenal nodules was 16 mm (10–50 mm) with a median density of 10 HU (-41–42 HU). In 17 patients with adrenal hyperplasia, a previous CT was available for comparison: in all cases an increase in thickness was evident at admission (median increase 1.95 mm, range 1–15). COVID patients had a non-significant higher frequency of adrenal nodules and hyperplasia (12% vs 8.6%, P = NS and 17% vs 12%, P = NS, respectively). Sixty-three patients (16%) died. They were older (80 vs 74 years, P = 0.001), had a higher frequency of adrenal hyperplasia (25% vs 14%, P = 0.03), more frequent active cancer disease (37% vs 19%, P = 0.003) and COVID (23% vs 13.2%, P = 0.02). In a multivariate model, adrenal hyperplasia is an independent risk factor for mortality (OR 2.52, 1.15–5.55, P = 0.02), as well as age (OR 1.04, 1.01–1.07, P = 0.005), active oncological disease (OR 3.06, 1.44–6.49, P = 0.004), and COVID (OR 2.88, 1.38–6.01, P = 0.005). This is the first study reporting the prevalence of morphological alterations of adrenal glands in suspected COVID patients. The frequency of discrete adrenal nodules (9.5%) is in line with the high prevalence of adrenal incidentalomas in elder subjects. The finding that adrenal hyperplasia is associated with an increased risk of mortality suggests that it may be the consequence of an exaggerated activation of the HPA axis due to a highly stressful condition.

Repeated hormonal and radiological evaluation of hypertensive patients is necessary for correct primary aldosteronism diagnosis and treatment

Agnieszka Łebek-Szatańska, Dorota Leszczynska, Karolina Nowak, Agata Tuszynska, Wojciech Zgliczynski & Lucyna Papierska

Centre of Postgraduate Medical Education, Departement of Endocrinology, Warszawa, Poland

Background

Primary aldosteronism (PA) constitutes the most common form of hormonal hypertension. However, it is very often misdiagnosed and incorrectly managed. Detection rates are inadequately low and the interpretation of hormonal results is impossible in some patients . Subtype evaluation with its several limitations represents another problematic issue. We describe the cases of two young primary aldosteronism patients with complicated history and a few-year follow-up until the final diagnosis.

Case description

CASE 1. 26 year-old female with grade I arterial hypertension, still hypertensive on betaxolol, with hypokalaemia despite potassium supplementation, was admitted for hormonal testing. 4 years earlier she had undergone evaluation for primary aldosteronism with strongly positive screening test results (aldosterone 23 ng/dl, plasma renin activity, PRA 0.312 ng/ml/min, aldosterone-to-renin ratio, ARR 74), but no further conclusions. Abdomen computed tomography (CT) had been normal and she hadn't been given spironolactone because of her reproductive age. She was allergic to iodinated contrast agents, so adrenal venous sampling (AVS) hadn't been performed. We repeated biochemical testing which again confirmed primary aldosteronism. Another abdomen CT revealed left adrenal adenoma sized 7.5 mm in diameter. The patient was finally successfully adrenalectomized with biochemical and clinical remission. CASE 2. 37 year-old male was referred to the Department of Endocrinology due to resistant hypertension despite 4-drug therapy (with thiazide) for the last 2 years, associated with inadequate, deep hypokalaemia. Laboratory work-up revealed medium-high, non-suppressible aldosterone levels, but with repeatedly non-suppressed direct renin concentrations (18–110 μIU/ml). The results didn't change despite drug withdrawal, making PA diagnosis questionable. Renal stenosis was excluded and adrenal glands were described as normal in CT. Two years later, the evaluation was performed again. The hormonal profile changed as direct renin concentrations were substantially lower (2,95–15 μIU/ml). ARR converted to positive and saline infusion test confirmed PA. Another CT revealed left adrenal adenoma sized 9 mm in diameter. NP59 scintigraphy showed nonspecific bilateral radionuclide uptake, so the patient is waiting for AVS.

Conclusions

Hypokalaemia of unknown origin in young patients is very indicative of PA. Non-suppressible aldosterone levels with non-suppressed renin or PRA are the laboratory findings of unexplained significance. In the case 2, they might have represented an early stage of the disease. Regular ambulatory check-up with repeated hormonal screening as well as another radiological evaluation may enable the final diagnosis in high-risk, but somehow unequivocal, cases.

Unilateral extramedullary adrenal plasmocytoma: A case report

Nabila Bahar[1], Martin Colard[2], Michael Vouche[3], Valerio Lucidi[4], Corvilain Bernard[1] & Natacha Driessens[1]

[1]Cliniques Universitaires de Bruxelles Hôpital Erasme, Endocrinology, Brussels, Belgium; [2]Cliniques Universitaires de Bruxelles Hôpital Erasme, Hematology, Brussels, Belgium' [3]Cliniques Universitaires de Bruxelles Hôpital Erasme, Radiology, Brussels, Belgium; [4]Cliniques Universitaires de Bruxelles Hôpital Erasme, Digestive Surgery, Brussels, Belgium

We present the case of an octogenarian with a major history of lambda light chain myeloma which was treated by a first-line lenalidomide and dexamethasone from June 2018 to September 2019. Patient had also hypertension and valvular heart disease (mechanical valve and anticoagulation by acenocoumarol). In September 2019, a right adrenal mass was incidentally discovered by a renal ultrasonography made for acute kidney injury. The abdominal CT-scan confirmed the presence of a large heterogeneous mass (5 cm) of high density (38 UH) on unenhanced attenuation in the right adrenal gland. 18F-FDG PET-CT showed a moderate FDG-uptake in the adrenal mass and two myelomatous bone lesions (one recent vertebral compaction of L2 and a lesion of the anterior arch of the 5th right rib). Adrenal mass showed high signal in T2 ponderation and in diffusion, without significant fat content on MRI imaging. The lesion characteristics allowed to exclude a benign adenoma and were in favor of a malignant nature. Hormonal evaluation did not demonstrate excessive cortisol (midnight salivary cortisol < 2.5 nmol/l) or other sexual steroids secretion [total testosterone 7.92 nmol/l (N: 6.68–25.70), DHEAs 1.56 μmol/l (N: 0.44–3.34), androstenedione < 0.2 ng/ml (N: 0.1–3.0), oestradiol < 25 ng/l (N: 27.1–52.2)]. Dexamethasone suppression test was not performed because of the treatment with methylprednisolone for the myeloma. 24-hours urine fractionated metanephrines and catecholaminesmeasurements were in the normal ranges. The hypothesis of a non-secreting pheochromocytoma was possible while non-secreting adrenocortical carcinoma (ACC) or metastasis were less probable, especially in the absence of autonomous cortisol secretion for a voluminous ACC and the absence of the localization of a primitive elsewhere for a metastasis. After a multidisciplinary discussion, a biopsy of the mass was performed before removing this neoplastic mass. Anatomapathological examination of the specimen concluded to a lambda light chain monoclonal plasmocytoma, as a rare complication of the myeloma. Solitary plasmacytomas occur most frequently in bone but can also be found outside bone in soft tissues. Extramedullary plasmacytoma (EMP) accounts for only 3% of plasma cell malignancies and adrenal plasmocytomas are extremely rare. Indeed, at our best knowledge, this is the tenth reported case of adrenal plasmacytoma.

Among the reported cases, three showed a bilateral gland involving. This case highlights the need of excluding differential diagnoses before surgical treatment of an adrenal neoplasm and the necessity of multidisciplinary input in the management of adrenal tumors.

A rare association of pheochromocytoma, contralateral nonfunctioning adrenal adenoma, and renal angiomyolipoma

Raoua Naouar, Bilel Ben Amor, Hanene Sayadi, Houda Ben Salem, Ines Bayar, Héla Marmouch & Inès Khochteli
Fattouma Bourguiba University Hospital, Endocrine Department, Monastir, Tunisia

Introduction
Bilateral adrenal incidentalomas represent about 15% of adrenal incidentalomas. Their investigation and management are less discussed and more challenging than unilateral incidentalome. A special attention is required because they are more likely to be pathologic. When associated with a synchronous extra-adrenal tumor, the first diagnosis is adrenal metastasis, but this is not always true. Here we present a rare association of pheochromocytoma, contralateral nonfunctioning adrenal adenoma, and renal angiomyolipoma.
Case presentation
A 69-year-old female, with a history of resistant hypertension, diabetes mellitus and hypercholesterolemia was admitted in our endocrine department for exploration of bilateral adrenal incidentalomas associated with a left renal tumor. She had no family history of endocrine neoplasms. On physical examination, there was no goiter or thyroid nodules. Adrenal insufficiency was ruled out by a normal synachten test. Routine laboratory testing were normal except uncontrolled diabetes. Hormonal investigations showed a high level of urinary fractionated metanephrines (2.3 fold above the upper limit of normal). Basal cortisol level, overnight dexamethasone suppression test, and aldosterone renin ratio were normal. Contrast enhanced computed tomography had shown a typical angiomyolipoma in the upper pole of the left kidney with two adrenal gland masses measuring at right 37 mm with a density of 38 HU and at left 15 mm with a low density (–3 HU). SPECT/CT Metaiodobenzylguanidine (mIBG) scintigraphy was performed and had detected abnormal fixation in the right gland. After 10 days of preoperative preparation, the patient underwent successful right adrenalectomy and the histopathologic features were consistent with pheochromocytoma. After surgery, urinary fractionated metanephrine level was normal and the hypertension was controlled with only monotherapy.
Conclusion
Bilateral adrenal tumors require a meticulous work-up, including hormonal investigation, morphological and functional imaging studies, in order to establish the correct diagnosis and to assess the perioperative risks. The association of adrenocortical and adrenomedullary tumors with renal angiomyolipoma described in our case is not common. It can be sporadic or may result from inherited disorders or multiple neoplasia syndromes.

Initial therapy with empagliflozin in addition to metformin vs standard therapy alone for patients with type 2 diabetes mellitus and cardiovascular disease in qatar. A cost-effectiveness analysis

Dina Abushanab[1], Daoud Al-Badriyeh[2], Danny Liew[1] & Zanfina Ademi[1]
[1]Monash Univeristy, School of Public Health and Preventive Medicine, Melbourne, Australia; [2]Qatar University, College of Pharmacy, Doha, Qatar

Background
Sodium-glucose cotransporter 2 (SGLT2) inhibitors have been shown to reduce deaths and cardiovascular events in patients with type 2 diabetes mellitus (T2DM), but are currently not used as first-line therapy.
Objective
To evaluate the cost-effectiveness of introducing empagliflozin into the current standard care (metformin monotherapy) for patients with newly diagnosed T2DM and existing cardiovascular disease (CVD).
Methods
A lifetime horizon Markov decision analytic model was developed from the perspective of Qatari healthcare system to compare first-line empagliflozin combined with metformin vs metformin monotherapy for patients aged 50 to 79 + years with T2DM and existing CVD. Two health states were considered: 'alive' and 'dead'. Patients entering the model transitioned to non-fatal myocardial infarction, non-fatal stroke, hospitalisation for heart failure, hospitalisation for unstable angina, death from cardiovascular or non-cardiovascular causes. Efficacy, healthcare costs, and health state utilities were ascertained from published sources as well as publicly available sources in Qatar. The main outcome was the incremental cost-effectiveness ratio (ICER) per quality-adjusted life-year gained (QALY) and years of life saved (YoLS). Base-case multivariate uncertainty analysis was considered for this study. Costs and outcomes were discounted at 3% per annum. Sensitivity analyses were conducted to evaluate parameter uncertainty.
Results
Adding empagliflozin to current standard care led to additional 1.9 YoLS and 1.5 QALYs with an incremental cost of QAR 56,869 (USD 15,619), which equated to an incremental cost-effectiveness ratio of QAR 30,675 (USD 8,425) per YoLS and QAR 39,245 (USD 10,779) per QALY. Sensitivity analyses showed the findings to be robust.
Conclusions
First-line empagliflozin combined with metformin appears to be a cost-effective therapeutic option for patients with T2DM and CVD in Qatar.

AEP34

Metabolic, renal and cardiovascular status in patients with primary hyperaldosteronism

Faten Cherchir, Ibtissem Oueslati, Meriem Yazidi, Fatma Chaker & Melika Chihaoui
La Rabta hospital, university of Tunis El Manar, Faculty of medicine, Endocrinology, Tunis, Tunisia

Introduction
Primary hyperaldosteronism (PHA) is an increasingly prevalent cause of endocrine hypertension. It is characterized by unregulated aldosterone secretion with an excessive activation of mineralocorticoid receptors, inducing volume expansion, hypokalemia, endothelial dysfunction and fibrotic processes in the renal and cardiovascular systems. The aim of this study was to assess the metabolic, renal, and cardiovascular status in patients with primary hyperaldosteronism.
Methods
We conducted a retrospective study in 40 patients with a primary hyperaldosteronism (aldosterone-producing adenoma: n = 24; adrenal hyperplasia: n = 16). Clinical and biological data were collected. Electrocardiogram and cardiac ultrasound were analyzed in all participants. Cardiovascular risk was assessed using Framingham Risk Score (FRS).
Results
There were 24 (60%) women and 16 (40%) men, with a mean age at the diagnosis of hypertension of 40.3 ± 10.9 years. Overweight, obesity, prediabetes, diabetes mellitus, dyslipidemia, and metabolic syndrome were diagnosed in 37, 50, 30, 32, 45, and 70% of cases, respectively. Hypokalemia was present in 30 patients (75%). Kalemia was negatively correlated with plasma aldosterone level (r = –0.387; P = 0.015). Albuminuria and chronic renal failure were found in 53 and 17% of cases, respectively. The average 10-year FRS was 19.6 ± 12.3%. It was significantly correlated with age (r = 0.675, $P < 10^{-3}$), fasting glucose level (r = 0.395, P = 0.012), glycated hemoglobin (r = .503, P = 0.009), triglycerides level (r = 0.485, P = 0.002), and creatinine level (r = 0.502, P = 0.001). However, FRS was not correlated with aldosterone and renin levels. Twenty five percent of patients had a low risk, 20% had a moderate risk and 55 % had a high risk. Thirty percent of cases had a subepicardial ischemia, 63% had a left ventricular hypertrophy and 10% had a low left ventricular ejection fraction. A history of stroke was found in 17% of patients.
Conclusion
Primary hyperaldosteronism is associated with a high prevalence of metabolic disorders and renal disease. These complications are significantly associated with the cardiovascular risk.

24-Hour blood pressure profile in patients with adrenal insufficiency

Irina Chifu[1], Kristina Krause[1], Adrian Zetsche[1], Carolin Scheuermann[1], Stephanie Burger-Stritt[2] & Stefanie Hahner[1]
[1]University Hospital Würzburg, Endocrinology and Diabetes, Würzburg, Germany; [2]Uppsala University Hospital, Endocrine Oncology, Uppsala, Sweden

Introduction
Retrospective analyses suggest that patients with adrenal insufficiency (AI) have an increased risk for cardiovascular diseases which was mainly attributed to non-physiological cortisol profiles and/or supraphysiological replacement doses.
Material and methods
We analyzed the 24-hour blood pressure (BP) profiles in patients with primary (PAI) and secondary (SAI) AI. BP threshold criteria for hypertension and dipping status of the 2018 ESC/ESH guidelines were used (24-h: ≥ 130 and/or ≥ 80, daytime: ≥ 135 and/or ≥ 85, night-time: ≥ 120 and/or ≥ 70, non-dippers: nocturnal BP drop < 10%). Results were correlated with daily intake of gluco-/mineralocorticoids, serum electrolytes, plasma-renin-concentration (PAI), salivary cortisol (SC) profile (06:00/12:00/16:00/20:00/22:00), 24-hour urinary free cortisol, BMI, waist-to-hip ratio and comorbidities.
Results
Fifty-two patients (30 PAI/22 SAI, age 55 (21–88), 36 females) were included. Twenty-two patients (11 AI/11 SAI) received antihypertensive treatment. Mean 24-h BP values were 124 ± 14/76 ± 10 mmHg (daytime 127 ± 15/79 ± 11, night-time 116 ± 18/69 ± 11). Prevalence of hypertensive 24-h BP was 42% (12% in patients without known hypertension), without differences between AI and SAI. Night-time hypertension was more prevalent than daytime hypertension (50% vs 35% in the whole cohort, 20% vs 8% in patients without known hypertension). Twenty-eight patients (14 AI/14 PAI) were classified as non-dippers. 20:00- and 22:00-SC levels were higher in patients with hypertensive compared to patients with normal 24-h BP (0.062 vs 0.02 $P = 0.01$, 0.054 vs 0.016 $P = 0.004$) regardless of antihypertensive treatment. Daily glucocorticoid intake was higher in patients with hypertensive 24-h BP (22.5(10–60) vs 20(15–30) mg $P = 0.035$).
Conclusion
Ambulatory hypertension and non-dipping were frequent in this small cohort of patients with AI and showed an association with supraphysiological glucocorticoid doses and exposure to glucocorticoids in the late afternoon/evening. However, validation in larger cohorts is warranted.

The acute effects of milk intake on calcium homeostasis and cardiovascular outcome: A randomized, crossover trial in postmenopausal women

Rasmus Espersen[1,2] & Lars Rejnmark[1,2]
[1]Aarhus University, Department of Clinical Medicine, Aarhus N, Denmark; [2]Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Aarhus N, Denmark

Introduction
The importance of calcium intake from dairy has been investigated in several studies with discrepant results. Meta-analyses have shown beneficial effects of dairy intake on cardiovascular health with an inverse association between intake and cardiovascular disease. However, a recent trial has suggested an increase in blood pressure in the hours following intake of 1000 mg of calcium citrate compared with placebo. So far, it has not been investigated whether milk intake causes similar effects on indices of cardiovascular health.
Materials and methods
We enrolled twenty postmenopausal women with vitamin D insufficiency aged between 60 and 80 years in this randomised crossover trial conducted during winter and spring. With at least ten days washout period in-between, the participants received either 500 ml of water or semi-skimmed milk with 200 µg of cholecalciferol added. Pulse wave analysis and velocity (PWV) were made twice using the SphygmoCor XCEL (AtCor Medical, Sydney, Australia): in the morning with the participants in a fasting state prior to and 4h after the intervention.
Results
Compared to water, milk increased plasma levels of ionized calcium by 1.61 pp ($P = 0.023$) and by 1.83 pp ($P = 0.053$) after 2h and 4h, respectively. Concomitantly, PTH levels decreased by 14.22 pp ($P = 0.005$) after 2 h and by 23.63 pp ($P = 0.001$) after 4 h. However, despite these changes, the two types of intervention did not cause changes as measured 4h after the intervention in indices of cardiovascular health in terms of PVW ($P = 0.557$), central diastolic blood pressure ($P = 0.599$), central systolic blood pressure ($P = 0.403$), mean arterial pressure ($P = 0.671$), pulse pressure ($P = 0.443$), aortic augmentation ($P = 0.915$), aortic augmentation index ($P = 0.782$), heart rate ($P = 0.341$), and pulse transit time ($P = 0.987$). We found no carry-over effect or period effect.
Discussion
The effects of dairy intake on cardiovascular health do not seem to occur acutely. Thus, the inverse relationship between dairy intake and cardiovascular disease seen in previous studies might be owing to long-term intake. Based on this study, milk intake is safe concerning immediate cardiovascular responses.

Natural history of nonfunctioning adrenal incidentalomas: A 10-year longitudinal observational study

Mojca Jensterle[1], Tomaž Kocjan[1], Matej Rakusa[1], Andrej Janez[1], Peter Popovic[2] & Ana Podbregar[1]
[1]University Medical Center Ljubljana, Department of Endocrinology, Diabetes and Metabolic Disease, Ljubljana, Slovenia; [2]University Medical Center Ljubljana, Ljubljana, Slovenia, Clinical Institute of Radiology, Ljubljana, Slovenia

Objective
There are few data on long-term follow-up of patients with nonfunctioning adrenal incidentalomas (NFAIs). We aimed to determine the natural history of NFAI at 10 year follow-up. We also evaluated the associations between baseline body mass index (BMI) and changes of NFAIs' and patients' characteristics at follow-up period.
Design
Longitudinal observational study.
Patients
We included 67 patients (20 (29.9%) males, 47 (70.1%) females, mean age 57.9 (52.3–63.9) years and BMI 27.42 (24.07–30.56) (kg/m^2)) presenting with NFAI. Twenty patients had BMI < 25 kg/m^2, 21 BMI 25–30 kg/m^2 and 26 had BMI > 30 kg/m^2 at the initial presentation. The mean follow-up period was 10.5 (9.1–11.9) years.
Measurements
Clinical, laboratory and computed tomography (CT) characteristics were assessed and compared with baseline.
Results
Progression to mild autonomous cortisol excess (MACE) was observed in 22 % patients. The progression rate was significantly higher in overweight and obese subjects, given that 5% progression rate was observed in patients with baseline BMI < 25 kg/m^2, 33.3% in a group with BMI 25–30 kg/m^2 and 26.7% in a group with BMI > 30 kg/m^2. Clinically significant tumor enlargement ≥ 10 mm occurred in 8.9% patients. Prevalence of cardiometabolic disorders at follow-up was significantly higher than at baseline, especially in groups with initial BMI ≥ 25 kg/m^2. At follow-up, 37.9% of patients had additional CT changes in kidneys, 21.2% in gastrointestinal tract, 18.2% in liver region, and 10.4% in pancreas, mostly cysts. Three patients with BMI > 30 kg/m^2 were referred to further diagnostics to rule out possible malignant disease incidentally found by CT imaging, unrelated to NFAI.
Conclusion
Duration of the follow-up period is an important factor in characterizing the natural history of NFAI. Higher baseline BMI might predict the long-term likelihood of change in hormonal activity and occurrence of metabolic disorders in patients with NFAI. The clinical significance of the highly prevalent concomitant CT findings in this population and the potential role of periodic CT reassessments in obese subjects with NFAI need further evaluations.

Low-renin hypertension with normal or high aldosterone levels is a cause of severe hypertension, and can be diagnosed by applying endocrine society hyperaldosteronism guidelines

Xavier Pérez Candel[1], Elvira Ramos[2], Elvira Barrio[3], Jorge Gabriel Ruiz Sánchez[1], Martín Cuesta Hernández[1], Mario Pazos[1], Sara Mera Carreiro[1], Blanca Bernaldo Madrid[1], Alfonso Calle[1] & Isabel Runkle[1]
[1]Hospital Clínico San Carlos, Endocrinology and nutrition; [2]Hospital

Puerta del Hierro, Endocrinology and nutrition; [3]Hospital Ramón y Cajal, Endocrinology and nutrition

Low-renin hypertension (LRH) with normal or elevated aldosterone levels is considered part of the spectrum of aldosterone-associated hypertension, and can cause poorly-controlled hypertension. We studied patients diagnosed with LRH, comparing their clinical and biochemical characteristics with patients diagnosed with primary hyperaldosteronism (PHA).
Methods
Retrospective. Diagnosis in a general Endocrinology out-patient clinic over 8 years, with strict application of Endocrine-Society Guidelines for PHA screening/diagnosis. Aldosterone/Renin (ARR) screening on medication, except for mineralocorticoid-receptor blockers or amiloride was positive when ≥ 20 (aldosterone and direct renin measured by Radioimmunoassay in pg/ml). Captopril challenge test (CCT) was positive for PHA on doxazosine and/or long-acting verapamil and/or hydralazine if aldosterone level ≥ 130 and/or ARR ≥ 50 2 hours post-25 mg captopril. Patients negative for PHA with normal/high basal CCT aldosterone, together with basal ARR ≥ 50 or low renin throughout CCT, were diagnosed with LRH. Clinical characteristics of both groups were compared. Parametric values expressed as mean (SD); non-parametric values as median [interquartile range]. SPSS 25.
Results
Diagnosis: 46 patients PHA, 80 LRH. Age at diagnosis: PHA: 57.0 (SD:11.2), LRH: 64.7 (SD:12.9), $P = 0.001$. PHA: 21/46 (46%) women, LRH: 16/80 (20%), $P < 0.001$.
Moderate hypertension
PHA: 21/46 (45.7%), LRH: 52/80 (65%), $P = 0.04$. Severe Hypertension: PHA 25/26 (54.3%), LRH: 28/80 (35%), $P = 0.04$. Resistant hypertension: PHA: 16/46 (34.8%) vs LRH: 5/80 (6.3%), $P < 0.0001$. All aldosterone and ARR levels were significantly higher in PHA than LRH, with screening and basal CCT values showing overlap. Renin levels were not significantly different at screening, nor throughout CCT. At screening, PHA vs LRH respectively: Aldosterone: 284.3 (SD:202.1) vs 206.11 (SD:99.3), $P = 0.023$. Renin: 3.8 (SD: 4.9) vs 5.2 (SD:4.6), $P = 0.13$. ARR: 109.9 (SD:8.5) versus: 52.9 (SD: 33.6), $P < 0.0001$. Baseline CCT: PHA vs LRHT respectively: Aldosterone 296.2 (SD: 194.5) vs 146.3 (SD:56.7), ($P < 0,001$). Renin 3.0 (SD:3.7) vs 3.3 (SD: 2.15), $P = 0.54$. ARR: 162 (SD: 126.0) vs 57.7 (SD: 38.9). $P < 0.001$. 2-hour CCT: PHA vs LRH respectively: Aldosterone 221.57 (SD:117.3) vs 80.3 (SD 37.2), $P < 0.001$. Renin: 2.15 [1.25–4.0] vs 3.2 [2.2–4.8] $P = 0.53$. ARR: 69.3 [52.1–165.8] vs 22.6 [12.6–37.0], $P = 0.001$.
Conclusions
LRH can be diagnosed with the CCT when applying Endocrine-Society PHA guidelines. This entity was more frequent in a general Endocrinology out-patient clinic than PHA, and over a third of patients had severe HT. Given LRH's previously-described favorable response to mineralocorticoid-receptor blockers, we believe that LRH should be diagnosed, and specifically treated as an aldosterone-associated hypertension.

Increasing incidence of primary aldosteronism – yet an underdiagnosed disorder

Eleftheria Gkaniatsa[1], Eva Ekerstad[2], Emanuela Gavric[3], Penelope Trimpou[1], Daniel S. Olsson[1], Gudmundur Johannsson[1] & Oskar Ragnarsson[1]
[1]Department of Internal Medicine and Clinical Nutrition, Institute of Medicine at Sahlgrenska Academy, University of Gothenburg and The Department of Endocrinology, Sahlgrenska University Hospital, Gothenburg, Sweden, Gothenurg, Sweden; [2]Department of Internal Medicine, Norra Älvsborgs Länssjukhus, Trollhättan, Sweden; [3]Department of Endocrinology and Diabetes, Kungälvs Sjukhus, Kungälv, Sweden

Context
Primary aldosteronism (PA) is the most common cause of secondary hypertension. Yet, the incidence of PA in the population has not been studied.
Objective
To estimate the incidence of PA in western Sweden.
Design and methods
Patients who had received a diagnostic code for PA between 1987 and 2016 were identified in the Swedish National Patient Registry. Assessment of clinical and biochemical data retrieved from patient records was used to validate the diagnosis. The annual incidence of PA was calculated by using the number of inhabitants in the Västra Götaland County as reference.
Results
Of 570 identified patients, 473 (83 %) had confirmed PA. Eligible for the incidence analysis were 416 patients, 248 (60%) men and 168 (40%) women, diagnosed with PA between 1987–2016. The median (mean) age at diagnoses was 56 ± 12 years. The median (interquartile range) annual incidence was 2 (1–2) cases per million between 1987 and 1996, 6 (4–9) cases per million between 1997 and 2006 and 17 (12–24) cases per million between 2007 and 2016. At the end of the study (December 31st 2016), 386 patients with confirmed PA were alive and living in the Västra Götaland County, giving a prevalence of 231 cases per million (0.022%).
Conclusions
Despite increasing detection rate, PA is still underdiagnosed. Given the serious consequences of untreated PA, the noticeable low prevalence at the end of the study illustrates a need for measures aiming at increasing the awareness of PA among health care providers.

A Clinically silent, non-secretory phaeochromocytoma

Megan Lewis, Ahmed M Gharib Ahmed & Paul Lambert
Musgrove Park Hospital, Endocrinology and Diabetes Department, Taunton, United Kingdom

Adrenal incidentalomata are a common finding on cross-sectional imaging of the abdomen. Further assessment is required to differentiate benign adrenal masses from adrenocortical carcinomas and hormone-secreting tumours. Phaeochromocytomas are rare catecholamine-secreting tumours arising from chromaffin cells of the adrenal medulla. They classically present with symptoms and signs of catecholamine excess including headache, sweating, hypertension and tachycardia. However, with increased use of abdominal cross-sectional imaging it is becoming more common to discover asymptomatic phaeochromocytoma through assessment of adrenal incidentalomata.
We describe a 63-year-old man presenting with renal colic. Cross-sectional imaging of his renal tract with CT showed a 5 mm stone in the proximal ureter, but also a 40 mm right adrenal mass with indeterminate characteristics (attenuation value of 30–40 HU). He had no symptoms of catecholamine excess, no family history of phaeochromocytoma and was normotensive. Investigations for adrenal hormone excess, including 24-hour urinary metanephrine excretion, were normal. Interval imaging showed a 5 mm increase in maximum diameter over 6-months and a decision was made, based on size change and imaging characteristics, to proceed to a right laparoscopic adrenalectomy.
Surgery proceeded uneventfully without pre-operative alpha adrenoreceptor blockade. In particular intra-operative blood pressure remained stable between 100–170 mmHg systolic and 60–90 mmHg diastolic. Histological examination of the tumour showed appearances typical of phaeochromocytoma.
This report describes a rare case of a patient with an adrenal incidentaloma who underwent adrenalectomy based on radiological size and appearance criteria and in whom post-operative histology demonstrated a phaeochromocytoma despite normal 24-hour metanephrine levels; a non-secretory phaeochromocytoma. It highlights the changing presentation of phaeochromocytoma from classical symptomatic disease to more incidental asymptomatic disease. However, it is very rare to see asymptomatic disease with no biochemical evidence of catecholamine excess.

A case of adrenergic myocarditis in pheochromocytoma mimicking COVID-19 pneumonia

Meriem Adel, Imen Rojbi, Marwa Majdoub, Nadia Mchirgui, Youssef Lakhoua, Ibtissem Ben Nacef & Karima Khiari
Charles Nicolle Hospital, Tunis, Tunisia, Endocrinology, Tunis, Tunisia

Introduction
Pheochromocytomas are rare catecholamine-producing neuroendocrine tumors derived from the sympathetic or parasympathetic nervous system.

The clinical presentation of pheocromocytoma has varying forms, which makes diagnosing it challenging. Here, we report a case of Adrenergic cardiomyopathy mimicking COVID-19.
Case report
A 40-year-old woman with a history of pulmonary edema during cesarean delivery 4 years ago with an ad integrum normalization of cardiac function was admitted to the emergency for acute shortness of breath. Three days before her admission she presented epigastralgia, vomiting and myalgia. On physical examination: temperature: 37.9°C, blood pressure: 100/60 mmHg, HR:100 bpm, peripheral oxygen saturation 100% with oxygen therapy at 15 l/min. The chest CT revealed bilateral asymmetric ground glass opacities extended to the 2 pulmonary fields, lobe and interseptal thickening, that could be compatible with covid-19 pneumonia. The day following the admission, the patient presented an acute chest pain with tachycardia, peripheral oxygen saturation 88% with oxygen therapy at 15 l/min, confusion and eventually a cardiac arrest. The patient was successfully resuscitated, intubated, and mechanically ventilated. The electrocardiogram showed a sinus tachycardia at 110 bpm with ST segment depression in the infero-lateral leads. Transthoracic echocardiography (TTE) revealed left ventricular septal hypokinesis with ejection fraction (LVEF) 40%. Blood examinations returned the following values: troponin: 9 ng/ml;BNP: 1558 pg/ml. The diagnosis of myocarditis was brought up: hypoxemia, localized depolarization disorder, echocardiographic findings and abnormal cardiac biomarkers. A second chest scan has showed the disappearance of ground-glass opacities. The Sars-Cov2 pneumonia was eliminated because of a negative PCR, serologies and the quick disappearance of the ground-glass opacity. An abdominal computed tomography showed a liquid mass on the left adrenal gland, measuring 5.2 × 4.6 cm, with well-defined borders thickened in places. After the improvement of her condition, the patient was extubated and referred to the endocrinology department for further exploration. Holter monitoring of blood pressure has eliminated any hypertensive peaks. Laboratory tests of urine catecholamines metabolites showed increased Normetanephrine (1.3 the standard level), but normal metanephrine. A second TTE revealed a normal heart function: FEVG 70 %. Cardiac MRI, performed 16 days after, was normal. Left surrenalectomy was performed. Histopathological evaluation confirmed the diagnosis of pheochromocytoma.
Conclusion
Pheochromocytoma can present itself with normotensive cardiomyopathy. Adrenergic cardiomyopathy is a rare entity with a variable clinical presentation. This case demonstrates the importance of considering pheocromocytoma in cases of myocarditis without a cardiac etiology.

AEP42

A case of adrenal tuberculosis mimicking non-functioning adrenal incidentaloma

Dhruti Hirani, Tasneem Ladha, Shaila Khan, Zaib Hilal, Fausto Palazzo & Tannaz Vakilgilani
St Mary's Hospital, Department of Diabetes and Endocrinology, London, United Kingdom

A 77 year old gentleman was referred to the endocrinology team following the incidental finding of an adrenal nodule on computer tomography (CT) colonography. Following this, dedicated CT of the adrenal showed a 4cm nodule with an attenuation of 30 Hounsfield Units. Biochemical investigation found no evidence of adrenal insufficiency or functional hormone production. Subsequent imaging by magnetic resonance imaging (MRI) and further CT showed stable appearances in size of the lesion, however concern remained regarding the risk of malignancy. Fluorodeoxyglucose-positron emission tomography was then performed, and this found moderate to intense activity in the area. The patient underwent adrenalectomy. Histopathology of the adrenal mass showed necrotising granulomatous inflammation, raising suspicion of adrenal tuberculosis (TB) and although acid-fast bacilli were not isolated on culture, TB ELISpot was positive. Differential diagnoses included sarcoid and granulomatosis with polyangiitis. The latter was considered unlikely given the clinical history and serum angiotensin-converting enzyme levels were not elevated. Multidisciplinary discussion decided this was likely a case of latent TB. Systemic anti-TB treatment was not initiated due to absence of symptoms and lack of evidence to suggest TB at other body sites. Less than 2% of adrenal incidentalomas are due to isolated adrenal TB[1]. TB is the most common cause of primary adrenocortical insufficiency caused by infection[2]. Adrenal tuberculosis is thought to rarely mimic non-functioning adrenal incidentaloma. Future development of imaging techniques and frequency of imaging will likely increase detection of non-functioning incidentalomas. This case suggests the importance of considering TB as a differential diagnosis whilst investigating non-functioning adrenal incidentalomas.

Evaluation of metabolic profile and thyroid disease in non functional adrenal insidentaloma patients

Ragip Fatih Kural[1], Gonca Oruk[2] & Elif Ersen Kural[1]
[1]Katip Celebi University Ataturk Training and Research Hospital, Department of Internal Medicine, izmir, Turkey; [2]Katip Celebi University Ataturk Training and Research Hospital, Department of Endocrinology and Metabolism, izmir, Turkey

Aim
Nonfunctional adrenal incidentalomas (NFAI's) are often associated with a high prevalence of insulin resistance (IR). The relationship between IR and thyroid diseases, as well as, thyroid cancer (TC) in patients with NFAI is not yet understood. The aim of this study is to determine the frequency of thyroid disease and TC in NFAI patients and to investigate any possible association of thyroid disease with IR and metabolic disturbances in NFAI patients.
Material and method
In our study, patients with NFAI and patients with normal adrenal imaging between 2010 and 2020 were evaluated retrospectively. 126 patient with NFAI and 114 patient with normal adrenal imaging were included in the study. Fasting blood glucose (FBG), fasting insulin, lipid profile, C-reactive protein (CRP), serum free triiodothyronine (fT3), free thyroxine (fT4), thyroid stimulating hormone (TSH), thyroid autoantibody (anti-Tg and anti-TPO) levels, thyroid ultrasonography and thyroidectomy results were registered retrospectively. IR was evaluated using homeostasis model assessment (HOMA-IR).
Results
There were no significant differences between NFAI and the control group in terms of age and gender. The average BMI of NFAI group was higher than the control group (29.5 ± 4.9 vs 27.4 ± 4.7, $P < 0.001$). Fasting insulin, HOMA-IR, total cholesterol, LDL cholesterol and serum CRP levels were significantly higher in the NFAI group ($P < 0.05$). FBG, HDL cholesterol, triglyceride, TSH, fT3 levels were similar in both groups. NFAI group had lower mean fT4 levels than the control group ($P = 0.027$). NFAI group had higher prevalence of positive anti-TPO and anti-Tg antibodies than the control group (%36.5 vs 23.7% and 29.4% vs 17.5%, respectively) ($P = 0.031$, $P = 0.032$, respectively). At least one thyroid nodule was detected in 89 (70.6%) NFAI group compared to 48 (42.1%) in the control group ($P < 0.001$). In NFAI group; there were 3 patients (2.4%) with diffuse goiter, 6 patients (4.8%) with uninodular goiter, 34 patients (27.0%) with multinodüler guatr (MNG), 3 patients (2.4%) with toxic MNG, 1 patient (0.8%) with Graves disease.TC was detected in 9 (7.1%) of NFAI group. MNG and TC were significantly more common in patients with NFAI ($P < 0.001$, $P = 0.046$, respectively).
Conclusion
In our study it was found that patients with NFAI had an elevated risk of IR and metabolic disturbance. Also it was detected that patients with NFAI have increased risk of autoimmune thyroiditis, nodular thyroid disease, MNG and TC. Therefore, it would be appropriate to screen NFAI patients with thyroid function test and thyroid ultrasonography as well as metabolic parameters.

Bilateral adrenal masses caused by extramedullary hematopoiesis detected by 18F-FLT PET/CT

Fatma Nur Korkmaz[1], Özgür Demir[1], Elgin Ozkan[2], Mine Araz[2], Özlem Küçük[2], Koray Ceyhan[3] & Demet Çorapçıoğlu[1]

[1]Ankara University School of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara University School of Medicine, Department of Nuclear Medicine, Ankara, Turkey; [3]Ankara University School of Medicine, Department of Pathology, Ankara, Turkey

Introduction
Extramedullary hematopoiesis (EMH) refers to hematopoiesis occurring outside the bone marrow. Pathologic EMH can be caused by thalassemias or disorders in the hematopoietic system. Sites of EMH can be widespread however, most common localizations are in the spleen, liver, and lymph node
Case report
A 22-year-old male patient was referred to the endocrinology department for bilateral adrenal masses found on computed tomography (CT). The patient had been followed up at the hematology department for thalassemia major with 2 units of erythrocyte suspension replacement per month, occasionally less frequently because of patient's incompatibility. Splenectomy was done at the age of 6. Abdominal CT revealed a 50 × 35 mm mass in the right adrenal gland and 45 × 33 mm mass in the left adrenal gland. The patient had no symptoms and signs compatible with functioning adrenal adenoma such as involuntary weight gain, hypertension, etc. There was no anorexia, weight loss, smoking history associated with malignancy. The patient's height was 161 cm, weight was 68 kg, and BMI was 26.2 kg/m^2. Blood pressure was 125/75 mmHg and pulse was 65 beats/min and rhythmic. Leucocyte: 11 900, Hb:10.7 g/dl, Htc: 34%, PLT: 76 7000, Ferritin: 700 ng/ml. Adrenal functioning tests revealed no functioning. Abdominal MRI showed a 34 × 46 mm, well-circumscribed, solid mass in the right adrenal gland and 33 × 44 mm solid mass in the left adrenal gland, in out-of-phase sections without significant signal loss. The signaling feature might be compatible with an low-fat-content adenoma or non-adenomatous mass. Positron emission tomography (PET) with fluorodeoxyglucose (18F-FDG) done for malignancy exclusion showed mild FDG uptake in both adrenal masses (SUVmax for the left and right adrenal masses 2.3 and 2.4, respectively) with no other pathological uptake. Bilateral adrenal masses were thought to be due to EMH. Fluorothymidine (18F-FLT) PET imaging was performed. FLT-PET demonstrated peripheral nonhomogeneus increased FLT uptake in both adrenal glands with SUVmax 8.2 in the left adrenal gland and SUVmax 6.7 in the right adrenal gland. EMH was confirmed by adrenal biopsy from the periphery of the left adrenal gland where intense FLT uptake was observed.
Conclusion
Bilateral adrenal masses due to EMH are very rare in the literature. 18F-fluoro-3-deoxy-L-thymidine (18F-FLT) is a DNA precursor and its uptake is related to the proportion of DNA synthesis in hematopoietic cells. 18F-FLT PET/CT offers a unique and non-invasive method for three dimensional localization and quantification of functional bone marrow. It can be used to differentiate masses that could be due to EMH in atypical locations.

The role of E47 in patients with endogenous cortisol excess

Wei Zhang[1], Hanna F. Nowotny[1], Stephanie Zopp[1], Martin Bidlingmaier[1], Martin Reincke[1], Henriette Uhlenhaut[2,3] & Nicole Reisch[1]
[1]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, LMU München, Munich, Germany; [2]Molecular Endocrinology, Institutes for Diabetes and Obesity & Diabetes and Cancer IDO & IDC, Helmholtz Zentrum Muenchen (HMGU) and German Center for Diabetes Research (DZD), Munich, Germany; [3]Metabolic Programming, TUM School of Life Sciences Weihenstephan and ZIEL Institute for Food & Health, Munich, Germany

Context
E47 is a transcription factor mostly known for its role in B and T cell lineage commitment. Recently E47 was identified as a modulator of glucocorticoid receptor target genes, its loss protecting mice from metabolic adverse effects of glucocorticoids. Patients with Cushing's syndrome (CS) suffer from an endogenous glucocorticoid excess due to tumour formation associated with a variety of metabolic comorbidities seriously affecting patients' health status.
Objective
To analyze the role of circulating E47 in blood of patients with endogenous glucocorticoid excess.
Design, setting, and participants
Retrospective cohort study including 120 female patients with CS (ACTH-dependent=79; ACTH-independent = 41) and 26 healthy female controls. Whole blood samples were drawn in the morning after over-night fast.
Outcome measures
E47 mRNA expression levels in whole blood samples of two different CS subgroups, pre- and post-surgery as well as after ACTH stimulation and dexamethasone suppression test in controls and correlation analysis between E47 gene expression and complications of CS.
Results
Mean E47 gene expression levels were significantly lower in patients with overt CS (n = 29) compared to patients in remission (n = 91; P = 0.0391). E47 gene expression in the pre-surgery subgroup of patients (n = 18) with CS was significantly lower than post-surgery (n = 102; P = 0.0215) also in pre /postsurgery data sets of the same patients (P = 0.0166, n = 14). Gene expression also showed significant differences in overt vs. remission (P = 0.016) and pre vs. postsurgery (P = 0.008) subgroups in patients with ACTHindependent (adrenal) CS. Administration of 1 mg dexamethasone overnight did not change E47 mRNA expression. Stimulation with Synacthen resulted in a significant decrease of E47 mRNA expression 30 minutes after i.v. injection compared to baseline measurements. E47 gene expression showed a positive correlation with total serum cholesterol (P = 0.003), low density lipoprotein cholesterol (P = 0.015) measurements and waist-arm-ratio (P = 0.014) in the subgroup of patients with CS in remission.
Conclusions
Generally, the level of E47 mRNA presents with a high level of dispersion both in CS patients and controls. E47 appears to be a GC-dependent gene that is upregulated in situations with endogenous GC excess potentially aiming at reducing metabolic glucocorticoid side effects.

High-normal serum uric acid levels in Type 2 diabetes patients with atherosclerotic cardiovascular diseases

Rahma Khalaf, Zohra Hadj Ali, Yosra Htira & Faika Ben Mami
National Institute of Nutrition, Tunis, Tunisia

Background and aim
Hyperuricemia is linked to a variety of diseases such as atherosclerotic cardiovascular disease (ASCVD). There are controversial data concerning the significance of high-normal values of serum uric acid (SUA) in patients with T2DM and cardiovascular disease. The aim of the study is to assess SUA levels in Type 2 diabetes mellitus (T2DM) patients with ASCVD.
Patients and methods
This retrospective study was performed in 70 T2DM patients. All patients had treated hypertension and hypercholesterolemia. Participants were divided into 2 groups: Group1(G1) consists of 35 patients with ASCVD, Group2(G2) consists of 35 patients without ASCVD ASCVD includes previous acute coronary syndrome (myocardial infarction or unstable angina), coronary revascularization, stroke, transient ischaemic attack and peripheral arterial disease. Diabetes duration, SUA, glycosylated hemoglobin (HbA1c), LDL-cholesterol (LDL-C), triglyceride (TG), systolic and diastolic blood pressure and body mass index (BMI) were assessed.
Results
G1 consists of 22 men and 13 women. G2 consists of 22 women and 13 men. The mean age of the patients presented with and without ASCVD was 58.5 and 54.5 years respectively. SUA levels in ASCVD patients were higher compared to patients without ASCVD (341.5 µmol/l vs 272 µmol/l, P = 0.09). Diabetes duration was longer in G1 compared to G2 (13.5 vs 11.6 years, P = 0.06). HbA1c level and BMI did not statistically differ (11.15 % vs 11.08 %, P = 0.63; 36.31 vs 33.1 kg/m^2, P = 0.7 respectively). Values of systolic and diastolic blood pressure did not statistically differ in study groups (135 mmHg vs 129 mmHg, P = 0.5; 75 vs 80 mmHg, P = 0.26 respectively). TG levels were higher in G2 (3.44 mmol/l vs 1.9 mmol/l, P = 0.06) while LDLC levels did not statistically differ between two groups (2.99 vs 2.44 mmol/l, P = 0.9).
Conclusion
T2DM patients with ASCVD have higher SUA levels compared to group 2.HbA1c level, BMI, systolic and diastolic blood pressure and LDL-C did not statistically differ between two groups. Further studies are necessary to assess significance of SUA as an independent risk factor for development of ASCVD in T2DM patients.

Associations between the atherogenic index of plasma, cardiovascular and metabolic risk in patients with primary hyperaldosteronism

Faten Cherchir, Ibtissem Oueslati, Meriem Yazidi, Fatma Chaker & Melika Chihaoui
La Rabta hospital, university of Tunis El Manar, Faculty of medicine, Endocrinology, Tunis, Tunisia

Introduction
Primary hyperaldosteronism (PHA) represents the most common cause of secondary hypertension. It is associated with a high risk of cardiovascular diseases (CVD), suggesting that aldosterone is implicated in the development of early atherosclerosis. Clinical studies have shown that atherogenic index of plasma (AIP) predicts cardiovascular risk. The aim of this study was to assess the associations between atherogenic index of plasma and cardiovascular and metabolic risk in patients with PHA.
Methods
We conducted a retrospective study including 37 patients with PHA. Clinical data and lipid profiles were obtained from patient's medical file. AIP was calculated as $\log_{10}$ (TG/HDL-C). It was categorized into low risk: < 0.1, moderate risk: [0.1–0.24] and high risk: > 0.24. The cardiovascular risk was assessed using Framingham Risk Score (FRS).
Results
There were 23 (62%) women and 14 (38%) men, with a mean age of 56.8 ± 12.6 years. Smoking, obesity, diabetes mellitus, dyslipidemia and metabolic syndrome were present in 27, 49, 32, 46, and 68% of cases, respectively. Low HDLc level, hypercholesterolemia, and hypertriglyceridemia were found in 65, 19, and 41% of cases, respectively. The mean level of AIP was 0.20 ± 0.25 in all patients, 0.26 ± 0.21 in patients with metabolic syndrome vs 0.07 ± 0.27 in those without metabolic syndrome (P = 0.014). AIP was positively correlated with age (r=0.372, P = 0.023) body mass index (r = 0.445, P = 0.006), total cholesterol level (r = 0.402, P = 0.014), triglycerides level (r = 0.708, $P < 10^{-3}$), FRS (r = 0.437, P = 0.007), and negatively correlated with HDLc level (r = 0.628, P < 10–3). No association with aldosterone level (P = 0.305) or aldosterone-to-renin ratio (P = 0.942) was found. According to AIP category, 32% (12) were in low risk group, 30% (11) were in moderate risk and 38% (14) were in high risk of CVD. An AIP level > 0.24 was positively associated with a FRS > 20% (Odds Ratio = 5.7, P = 0.022).
Conclusion
PHA is involved in atherosclerotic process because of endothelial dysfunction, myocardial fibrosis and lipid metabolism alteration. Our study underlines the power of AIP as a predictive biomarker of cardiovascular and metabolic risk, independently of aldosterone levels.

AEP48

Lipid paradox in acute myocardial infarction

Sara Correia, Diogo Ramalho, Lucia Almeida, Helena Alves, Gustavo Melo & Maria João Oliveira
Vila Nova de Gaia, Endocrinology, Vila Nova de Gaia, Portugal

Introduction
Some studies have shown low-density lipoprotein cholesterol (LDL) and triglyceride (TG) levels were significantly lower in high-Killip (III + IV) patients compared with low-Killip (I + II) patients and in those who died after acute myocardial infarction (AMI) compared with those who survived beyond 30 days, which they called lipid paradox. Elevated levels of LDL and triglycerides are important risk factors for cardiovascular disease, and there appears to be a minor role in the acute phase of AMI. In fact, triglyceride fatty acids are the main source of energy, LDL appears to be critical for cell membrane synthesis and both are essential for cell synthesis.
Material and methods
In an attempt to demonstrate whether total cholesterol (TC), LDL, a high density lipoprotein (HDL) and TG can influence Killip's classification, as well as early post-AMI mortality, we reviewed the clinical processes of patients with type 1 diabetes. 2 admitted by EAM to our hospital. We performed a statistical analysis using SPSS version 25.0. A value of P < 0.05 was considered statistically significant.
Results
In a total of 129 patients with type 2 diabetes, they were admitted to our hospital with AMI. Of these, 65.9% were male and their ages vary between 35 and 90 years, with an average age of 68.27 ± 10.71 years. The median HbA1c at admission was 7.5% (AIQ = 1.5). Of the sample, 18.6% had current smoking habits, 20.9% had previous smoking habits and 21.7% had chronic kidney disease. Regarding other co-morbidities, we verified the occurrence, in most patients, of arterial hypertension (86%) and overweight / obesity (72.9%). TG levels were lower in those who died compared to those who survived beyond 30 days (P = 0.04), however there was no association between this and patients classified as high Killip compared to patients with low Killip (P = 0.75). As for the level of TC, LDL and HDL, its influence on early mortality and Killip's classification was not found. High Killip severity was associated with in-hospital mortality in 30 full days (P = 0.013).
Conclusion
Lower levels of TG were related to a higher rate of early mortality. The small sample size may have constituted a bias, impeding the demonstration of a relationship between LDL and the other variables under study. Other studies with more patients need to be carried out to clarify these data.

Hair cortisol levels in patients with adrenal incidentalomas compared to healthy controls

Fani Athanasouli, Chrysoula Mytareli, Evangelia Andreadaki, Foteini Petychaki, Akrivi Savelli, Nikos Asonitis & Anna Angelousi
National and Kapodistrian University of Athens, 1st Department of Internal Medicine, Endocrine Unit, Athens, Greece

Background
Adrenal incidentalomas (AI) are present in 3–10% of the general population. Up to 20% of them may have autonomous cortisol secretion (ACS). However, subclinical hypercortisolism isn't clearly defined. The 1mg dexamethasone suppression test (ODST) is the most widely accepted for the screening of these patients. Recent data suggest that hair cortisol should be considered as a routine test for the screening of Cushing syndrome.
Aim
To compare hair cortisol levels in patients with AIs and healthy controls along with the 'classical' functional diagnostic tests.
Methods
Twenty-nine consecutive patients with AIs followed in the 1st Department of the Endocrine Unit of Laiko Hospital were included in our protocol. Hormonal functional tests were analysed and compared to 29 matched healthy controls. Primary or secondary adrenal malignant lesions were excluded. Hair cortisol measurement was also performed and compared with baseline morning (8.00) cortisol, adrenocorticotropic hormone (ACTH), and 1-mg ODST. Hair cortisol samples (2 cm length) were collected according to SoHT guidelines and measured by liquid chromatography tandem–mass spectrometry (LC–MS/MS). ACS was defined in patients displaying at least two biological abnormal markers including increased urinary free cortisol, or suppressed plasma ACTH, or 1 mg-ODST > 1.8 μg/dl in patients with adrenal tumors.
Results
Age, sex and BMI didn't differ between two groups. Hypertension, hyperlipidemia and diabetes mellitus prevalence was similar in both groups. The studied population included 22 cases of non-functional AIs (NFAIs), 6 cases with ACS and 2 cases with aldosterone-producing adenomas (1 patient had concomitant secretion of cortisol and aldosterone). Although mean baseline blood cortisol levels were found higher and ACTH levels lower in patients with AIs compared to controls, no statistical significant difference was reported. 1-mg ODST was not statistical significant different between patients with NFAIs and controls groups. However, DHEAS levels were statistically significant suppressed in patients with AIs compared to controls. Mean hair cortisol levels were within the normal range and found similar in both groups. Hair cortisol showed no correlation with blood cortisol levels, ACTH and 1 mg ODST.
Conclusions
Our series didn't find significant differences in baseline blood serum cortisol, ACTH and post-1 mg-ODST cortisol levels between patients with AIs and healthy controls. Hair cortisol levels confirmed blood analyses and were similar in patients with AIs and controls. Hair cortisol could be a simple and low-cost routine test for screening and follow-up patients with AIs and studies with larger sample size should be conducted.

Incidentally diagnosed bilateral pheochromocytoma accompanied by urothelial carcinoma of the bladder

Damla Tufekci, Yasemin Emur Gunay, Ahmet Suat Demir, Muhammet Cuneyt Bilginer, Hulya Coskun, Irfan Nuhoglu, Ozge Ucuncu & Mustafa Kocak
Karadeniz Technical University Faculty of Medicine, Karadeniz Technical University Faculty of Medicine, Department of Endocrinology and Metabolism, Trabzon, Turkey, Trabzon, Turkey

Introduction
Adrenal abnormalities can be detected incidentally during the imaging performed for malignancies. These abnormalities may include adrenal pathological conditions independent of primary malignancies. Pheochromocytomas detected as part of some familial syndromes are often bilateral.In this report, we present a case of isolated sporadic bilateral pheochromocytoma that was incidentally detected during malignancy workup and staging, which is a rare occurrence.
Case presentation
The 51-year-old female patient was referred to our clinic due to the detection of bilateral adrenal mass on positron emission computed tomography (PET-CT) that was performed following the surgery for urothelial carcinoma of the bladder. The patients 24-hour urine and plasma catecholamines indicated approximately 30 times higher values of metanephrine and normetanephrine (Table 1). Fundus examination indicated grade 1–2 hypertensive retinopathy. On 24-h Holter monitoring, mean blood pressure was 152/98 mmHg. Abdominal magnetic resonance imaging (MRI) showed a lesion that was isointense in T1-weighted images and slightly hyperintense in T2-weighted images without signal loss in the external phase sequence, measuring 43 × 23 mm in the right adrenal gland and 26 × 29 mm in the left . Based on these findings, the patient was diagnosed as bilateral pheochromocytoma and the patient was negative for Von Hippel-Lindau (VHL) and RET gene mutations. Bilateral cortex-sparing surgery was performed .The catecholamine levels of the patient decreased postoperatively. The pathological result was reported as pheochromocytoma, with a diameter of 4.5 cm on the right side and 5 cm on the left, which was positive for s-100, synaptophysin, chromogranin, and neuron-specific enolase (NSE) and had a low ki-67 index. The PASS (pheochromocytoma of the adrenal gland scaled score) score was 1 and 3 for the right and left glands, respectively. No pathological lesion was detected in the adrenal glands in follow-up imaging.
Conclusion
Almost 5–10% of pheochromocytomas occur bilaterally. Although bilateral masses are rare, they do not have any syndromic features. Nevertheless, the number of pheochromocytoma cases detected in the presymptomatic stage is increasing due to the growing use of advanced imaging techniques and genetic tests.
Keywords: Bilateral pheochromocytoma, adrenal incidentaloma, urothelial carcinoma

Table 1. Clinical characteristics

TEST	Preoperative value	Reference value	Postoperative value
Plasma Metanephrine	608.71 pg/ml	≤ 90	15.5
Plasma Normetanephrine	5877.92 pg/ml	≤ 180	177.68
Plasma Adrenaline	168.81 ng/l	≤ 90	66.86
Plasma Noradrenaline	895.32 ng/l	≤ 500	189.72
Urine Metanephrine	1496.51 µg/24 h	50–250	88.95
Urine Normetanephrine	8370.15 µg/24 h	100–500	369.96
Urine Adrenaline	51.6 µg/24 h	0–20	7.32
Urine Noradrenaline	145.76 µg/24 h	15–80	45.83

Occult aldosteronoma mimicking degenerative spine disease

Sintija Sausa[1,2], Zanda Priede[1,3], Janis Gardovskis[1,3], Rita Niciporuka[1,3], Unda Jukone[1,2], Santa Ivanova[1,2], Valdis Pirags[1,2] & Natalija Fokina[1,2]
[1]Pauls Stradins Clinical University Hospital, Latvia; [2]University of Latvia, Latvia; [3]Riga Stradins University, Latvia

68 years old Caucasian women presented to the emergency department (ED) with complains of stiffness, intolerable pain in lumbosacral region and inability to walk for last two days. The common pain-relieving medications did not subdue her pain. The patient had experienced similar episodes for two years, provoked by remaining in fixed position or after having carbohydrate rich meal. Pain usually persisted for a few minutes and symptoms disappeared after light exercise. Her complains were attributed to lumbar spondylosis and treated with analgesics. Her medical history revealed that she had been admitted to ED due to hypertensive crisis and epistaxis 7 times over last 8 years. She was on maximal dose of perindopril and amlodipine. Further neurological examination revealed asymmetrically decreased strength in lower extremity muscles and asymmetrical proximal leg paraparesis, more pronounced on the left side. Deep tendon reflexes in lower extremity were similar, without pathological reflexes. Sensitivity and the rest of the examinations were normal. Magnetic resonance imaging of the spine ruled out a compressive–expansive condition, CT of the brain showed no relevant changes. Nerve conduction study revealed bilateral carpal canal syndrome dxt > sin, severe grade; sensory-motor polyneuropathy in the legs, axonal-demyelinating; chronic, old L3-L4 sin root damage. BP was 128/80 mmHg. In laboratory tests serum potassium was 3.2 mmol/l, sodium 138.0 mmol/l, creatinine 56.0 µmol/l. ECG showed normal sinus rhythm, heart rate was 70 beats per minute and patient denied any history of dysrhythmias. Due to family history of multiple gastrointestinal cancers, abdominal CT scan with contrast was performed, thus concurrently left side adrenal adenoma of 2 cm in size was detected. The patient was consulted by endocrinologist, plasma aldosterone concentration (PAC) and direct renin concentration (DRC) was assessed. PAC was 9.47 ng/dl, DRC was 0.59 ng/l. PAC/DRC ratio was 15.8 ng/dl/ng/l. According to Endocrine Society Clinical Practice Guidelines 2016 the lowest range of PAC/DRC ratio for diagnosis of primary hyperaldosteronism is 3.8–7.7 ng/dl/ng/l. A council of endocrinologist, endocrine surgeon and radiologist decided to perform left side laparoscopic adrenalectomy. Histopathological examination determined tumour with large compact cells with lipid rich cytoplasm, sign of adrenal cortex clear cell adenoma. After surgery patient improved rapidly with significant reduction of presenting symptoms. She had no further episodes of spine and leg stiffness. We are reporting the unusual case of primary hyperaldosteronism with hypokalemic periodic paralysis mimicking lumbar spondylosis and treated ineffectively with analgesics for several years.

Oligosymptomatic positive SDHB gene mutation paraganglioma

Andra-Maria Olteanu[1], Ruxandra Capota[1], Nicoleta Dumitru[1,2], Daniel Diaconu[1] & Adina Ghemigian[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Introduction
Endocrinopathies represent about 1–3% of secondary hypertension.The non-head-neck paragangliomas are rare neuroendocrine tumors that arise from the ganglia of the sympathetic nervous system. About 75% are intra-adbdominal,thus they are often mistaken for adrenal pheocromocitoma.They usually secret normetanephrine and chromogranin A, which are responsible of 0.2–0.6% of secondary hypertension.
Objective
A case report of a young man with a 6 years history of paroxysmal, well tolerated hypertension.
Case report
A 26-year-old male presented in our clinic with a long-term history of hypertension crisis associated with palpitations, headache, cold sweats and tremor, triggered by physical effort and mental stress, that attenuated spontaneously in the last two years. Abdominal MRI performed 2 years ago suggested a vascular tumor on the left adrenal gland (40/42/46 cm). The urinary metanephrines were elevated. No treatment was performed at that time.
Results
Current laboratory studies point out both an elevated plasma and urinary normetanephrine level as well as chromogranin A. Matinal cortisol and ACTH were normal. The MRI revealed one tumoral node (48/44/47.5 cm)

without demarcation in relation to the pancreas, left paraaortic, focally adjacent to the splenic and left renal vascular pedicle. Paraganglioma was suspected and treatment with alpha1-selective adrenergic receptor blockers was initiated, followed by beta-adrenergic receptor blockers. This treatment has been prescribed for 2 weeks as preoperative preparation. Laparoscopic surgery was performed without any complications. Postoperative, the blood pressure values were maintained in normal range. Immunocytochemical analysis showed that tumor cells were positive for chromogranin A, S100, synaptofisin and Ki67 3%, with a GAPP score =3/10. The histologic features combined with the immunocytochemical and ultrastructural findings confirmed the diagnosis of paraganglioma. Genetic testing showed a germline mutation in the SDHB gene. Follow-ups after the 1st, 3rd, 6th, 12th, 24th months after surgery revealed normal hormonal profile and negative PET-CT scan.
Conclusion
Although our patient has multiple negative risk factors (young age, voluminous tumor, SDHB gene mutation), the clinic was oligosymptomatic and the evolution was favorable, without any recurrence at the present.

Pheochromocytomas: Diagnosis, treatment and clinical outcomes

Nada Derkaoui, Rami Imane, Salma Ben Yakhlef, Siham Rouf & Hanane Latrech
Mohamed VI University Hospital Center Oujda, Endocrinology Diabetology and Nutrition department, Oujda, Morocco

Introduction
Pheochromocytomas originate in the adrenal medulla. Although rare, they can be lethal through their cardiovascular complications. They may be sporadic or come in the context of hereditary syndroms. The aim of our work is to describe the clinical, biological and radiological features of these tumors and assess the clinical outcomes after surgical treatment.
Materials and methods
Our study is retrospective descriptive, involving 21 patients presenting pheochromocytomas, followed in our Endocrinology-Diabetology and Nutrition Department.
Results
The mean age of our patients was 46.3 ± 16.3 years with a sex ratio H/F of 0.4. History of hypertension was present in 52.3% of cases and diabetes in 46% of cases. In 52.3% of patients the pheochromocytoma was discovered while exploring adrenal incidentaloma, 4.7% in the context of inherited disorders, especially multiple endocrine neoplasia type 2, and 42.8% in the course of symptoms. 52.6% of cases presented with the complete Menard Triad, 36.8% reported abdominal pain, and only 26% experienced weight loss. All of them had elevated 24-h urinary fractionated metanephrines, varying from 4 up to more than 100 times the normal value, with an average of respectively 12 and 11 times the normal value for metanephrine and normetanephrine. Abdominal CT scan was performed for all patients revealing unilateral tumors in 79% of cases and bilateral in 21% of cases. The mean size of the tumor was 42.1 ± 26.2 mm (11–103). Before surgery, 38% of our patient received α1blockers preparation 15 days before surgery. During the intervention, only 37% presented hypertensive peaks without further complications. In post-operative follow-up, a good blood pressure control was achieved and antihypertensive treatment was reduced in all of our hypertensive patients. As for glycaemic control, the mean HbA1c dropped from 8.1% ± 1.7 before surgery to 6.6% ± 1.3 three months after. Antidiabetic treatment was permanently stopped in 22% of cases concluding to the diagnosis of secondary diabetes mellitus, and significantly reduced in the rest. In our series, 71.4% of pheochromocytomas were sporadic, 23.8% secondary to MEN1 and only 4.7% in Van Hippel Lindau Disease.
Discussion–conclusion
Pheochromocytomas are rare but dangerous tumors due to the catecholalmines over production and the potential cardiovascular complications. The preoperative treatment with α1blockers at least 10–14 days before surgery prevents and limits peroperative hypertensive peaks, arrhythmia and circulatory complications. Surgery remains the gold standard treatment with good post-surgical outcomes. Pheochromocytomas may be associated with familial syndroms like NEM2 and VHL or hereditary mutations of succinate dehydrogenase subunits (SHD). Therefore, genetic testing seems relevant especially if the patient present a familial history of pheochromocytomas.

Adrenal function recovery after successful surgery for Cushing

Alexandra Marin[1], Daniel Mihai[1], Andra Caragheorgheopol[2] & Corin Badiu[3]
[1]National Institute of Endocrinology, Thyroid related disorders, Bucharest, Romania; [2]National Institute of Endocrinology, Immunology, Bucharest, Romania; [3]'Carol Davila' University of Medicine and Pharmacy, Thyroid related disorders, Bucharest, Romania

Background
Cushing syndrome (CS) is caused by prolonged exposure to elevated cortisol levels and it's classified as either ACTH-dependent or ACTH independent CS. The most common form of endogenous ACTH CS is Cushing disease (CD); ACTH-independent CS is caused by various adrenal abnormalities. First-line therapy in CS is the resection of the underlying tumor in all cases. After surgical cure of CS, most patients develop transient secondary adrenal insufficiency (SAI) requiring postoperative glucocorticoid (GC) replacement. The aim of this study is to review the time to normalization of adrenal function after surgical cure of CS.
Patients and Methods
This study is based on the review of 34 patients cured by surgery, after being diagnosed either with CD (15) or ACTH-independent CS with overt CS (19) in our endocrinology department between 2010–2020. All patients were declared cured of CS with postoperative SAI. GC replacement was started for basal plasma cortisol < 5 mg/dl or a stimulated plasma cortisol < 20 mg/dl, using synthetic ACTH with follow-up at 3, 6, 9 months and 1 year or more in selected cases in order to see the duration of SAI.
Results
Data showed that they received GC replacement for a period of time that ranged from 4 to 27 months, 2 of them with permanent SAI. The decision of ceasing therapy was based on a stimulated cortisol value ≥ 20 mg/dl, without any evidence of SAI symptoms after that. Patients with CD required a longer period of substitution (a mean of 17.5 months) than patients with ACTH-independent CS (a mean of 13.3 months).
Conclusions
Successful surgery in CS leaves behind SAI, requiring a long term steroid substitution. The decision of whom to treat is based on many clinical and biochemical data, besides absolute cortisol values.

Pulmonary metastasis of a pure oncocytic adrenocortical neoplasm after a 2 years follow up

Clothilde Wagner[1], Sarah Mansour[1], Niculina Racolta[1], Philippe Keller[2], Pramod Rao[3], Marie-Claire Tortel[4], Veronique Lindner[5] & Agnes Smagala[1]
[1]Civil Hospital 'Louis Pasteur', Endocrinology and Diabetes Department, Colmar, France; [2]Civil Hospital 'Louis Pasteur', Surgery Department, Colmar, France; [3]Civil Hospital 'Louis Pasteur', Interventional Radiology Department, Colmar, France; [4]Civil Hospital 'Louis Pasteur', Pathology Department, Colmar, France; [5]University Hospital 'Hautepierre', Pathology Department, Strasbourg, France

Oncocytic adrenocortical neoplasms (OAN) were first described by Kakimoto *et al*. in 1986. Since then, only 160 cases have been reported in the literature. There are 3 categories of OANs: pure oncocytic, mixed oncocytic and ordinary adrenocortical with focal oncocytic changes. Although the majority of OANs are considered benign tumors, certain OANs may present similar characteristics to adrenocortical carcinoma, correct histological caractherisation is therefore crucial. OANs should be assessed using the Lin-Weiss-Bisceglia (LWB) score as the Weiss score may overestimate the malignant nature of these tumors.
We report the case of a 52-year-old man without medical history, addressed for exploration of a large adrenal mass discovered on self-palpation. The patient was completely asymptomatic, with no clinical sign of hormonal hypersecretion. Hormonal testing showed very high DHEAS levels and slightly elevated 17-OH progesterone. CT scan found a 17 × 16 × 11 cm, heterogeneous left adrenal mass, with calcifications and 34 HU spontaneous density. Open left adrenalectomy was performed, with an anatomopathological examination in favor of a 25 × 16.5 × 15 cm OAN weighing 2800 g, considered malignant according to the LWB score. After 2 years of CT scan monitoring every 6 months, a 8 mm pulmonary nodule was detected. The FDG-PET-CT was consistent with increased uptake in the micronodule and in an infracentrimetric lumbo-aortic lymphadenopathy. Biopsy of the pulmonary micronodule confirmed the metastatic origin of the initial OAN.

After discussion in the COMETE multidisciplinary meeting, radiofrequency ablation of the pulmonary nodule was performed and the patient was started on adjuvant Mitotane treatment. CT and PET-FDG assessment carried out 4 months later did not find any increased uptake in the lumbo-aortic lymph node previously described. Pure functional OAN diagnosis, management and follow-up are still controversial. Due to the uncertain evolution profile of these tumors, close monitoring is still recommended in order not to ignore local or distant recurrence. Given the rarity of these tumors, no studies concerning adjuvant therapies have been performed. Each case must be discussed in multidisciplinary meetings of expert networks.

Paraganglioma in pregnancy: The need for a multidisciplinary approach

Ana Rita Elvas[1], Bárbara Araújo[2], Joana Couto[1], Raquel G. Martins[1], Sandra Paiva[2], António Lobo[3], Fernando Santos[4], Isabel Paiva[2] & Fernando Rodrigues[1]
[1]IPO Coimbra, Endocrinology Department, Coimbra, Portugal; [2]Centro Hospitalar e Universitário de Coimbra, Endocrinology Department, Coimbra, Portugal; [3]Centro Hospitalar e Universitário de Coimbra - Maternidade Dr. Daniel de Matos, Obstetrics and Gynaecology Department, Coimbra, Portugal; [4]Centro Hospitalar Tondela - Viseu, Epe, Obstetrics and Gynaecology Department, Viseu, Portugal

Introduction
Paragangliomas (PGL) of the urinary bladder are an extremely rare entity. During pregnancy, PGL can carry higher risk of foetal and maternal mortality, which can be significantly reduced when the diagnosis is made antepartum and adequate multidisciplinary management and surveillance is started. However, despite clinical stability, delivery complications rates are still higher than in the general obstetric population.
Case description
We present a 29-year-old SDHB mutation carrier with a functional urinary bladder PGL diagnosed at the age of ten. She had a past history of hypertension, cardiomyopathy and retinopathy and experienced several recurrences of the disease, requiring two surgical interventions. In 2008, she presented uncontrolled high blood pressure and began treatment with an α-adrenergic receptor antagonist (αAA). Concurrently, vertebral bone lesions were identified and she was submitted to radiotherapy. A year later αAA was withdrawn as she was asymptomatic, with persistently normal metanephrines and stable vertebral bone lesions. Considering the patient's desire for pregnancy and after explaining the risks inherent to her clinical condition, she was referred to maternity unit for close monitoring. She was followed regularly throughout pregnancy and ambulatory blood pressure (BP) monitoring at 15 weeks revealed slightly high diastolic BP but no medical therapy was required. Repetitively normal levels of free plasma metanephrines, 3-methoxytyramine and chromogranin A were observed. She delivered vaginally at 36 weeks and during labour presented with significantly high BP requiring labetalol bolus. Aminotransaminases were elevated (10 times above reference value) and thrombocytopenia (< 20 000/ul) was detected. She was admitted to the intensive care unit with the diagnosis of HELLP syndrome and progressed satisfactorily afterwards. Her postpartum recovery was uneventful.
Discussion
We present a challenging case of a pregnant woman with known metastatic PGL. Even though she presented a HELLP syndrome, there is no data regarding the relationship between these two entities. PGL is not an absolute contraindication, but it does represent a risk factor for potential complications during pregnancy. It is important for the clinician to respect the maternal wiling, after adequate information of the risks involved. The decision to treat with an αAA requires a fine balance between reducing the risk of hypertensive peaks and the risk of uteroplacental insufficiency.

The prevalence of metabolic and cardiovascular complications in patients with pheochromocytoma

Sahar Abidi, Nadia Khessairi, Marwa Ben Jemaa, Wafa Grira, Fatma Chaker & Melika Chihaoui
Rabta Hospital, Endocrinology, Tunis, Tunisia

Introduction
Phaeochromocytomas are rare neuroendocrine tumors secreting high levels of catecholamines, able to exert serious metabolic and cardiovascular effects. Glucose intolerance are common complications that require an early recognition and treatment.
Methods
A retrospective study was conducted to assess the prevalence of metabolic and cardiovascular complications in 35 patients diagnosed with pheochromocytoma in the endocrinology's department of Rabta hospital from 2006 to 2020.
Results
The average age was 47 ± 11 years [23–72]. glucose tolerance disorders were diagnosed in 51.7% of cases; 44.8% had type 2 diabetes, one patient had moderate fasting hyperglycemia and one had glucose intolerance. 72% of the patients had dyslipidemia. For the cardiovascular complications, hypertension was found in only 20 patients (76.9%). An ultrasound myocardium imaging was practiced in 21 patients. myocardial amyotrophy was detected in only 9.1% of patients with all having a conserved left ventricular ejection fraction.
Conclusion
The recognition of early catecholamine-induced alterations in patients with pheochromocytoma is important to prevent at least morbidity and mortality before surgical treatment.

Diabetes and adrenal incidentaloma

Marwa Jemaa, Nadia Khessairi, Sahar Abidi, Fatma Chaker, Wafa Grira & Melika Chihaoui
Rabta Hospital, Endocrinology, Tunis, Tunisia

The term adrenal 'incidentaloma' is referring to an adrenal mass discovered incidentally during an abdominal imaging exam not motivated by the exploration of an adrenal pathology. The prevalence of diabetes in incidentaloma is high therefore a cortisol secretion should be searched. This is a retrospective study conducted on 100 patients with adrenal incidentaloma. These patients are divided into two groups; the first group is made up of diabetics (G1: $n = 31$) and the second of non-diabetics (G2: $n = 69$). The clinico-biological profile in the two groups was compared. The diabetics were older (64 vs. 56 years; $P = 0.03$). There was a slight female predominance in both groups (74% vs 52%; $P = 0.03$)). The majority of diabetics with incidentaloma had dyslipidemia (51% vs 22%; $P = 0.04$). Arterial hypertension was significantly more frequent in the diabetic group (74% vs. 47%; $P = 0.01$). Non-secretory adenoma was slightly more frequent in non-diabetic group (79% vs 70%). Cushing and Conn adenoma were more frequent in diabetic group. There was no pheochromocytoma in that group. The search for the secretory character of an adrenal mass is strongly recommended. Diabetes is common and is frequently secondary to the secretion of catecholamines and mineralocorticoids and cortisol.

Computed tomography in diagnosis of non-functional adrenal adenoma

Tatyana Chzhen & Tatyana Kiseleva
Ural State Medical University, Department of Faculty Therapy And Endocrinology, Yekaterinburg, Russian Federation

Background
Adrenal incidentaloma (AI) is an adrenal mass discovered accidentally during abdominal or chest imaging techniques not aimed to adrenal gland assessment. The management of non-functional adrenal adenomas (NFAI) at least 4 cm is still a matter of debate as it is unclear whether imaging can be used to characterize their potential malignancy. Moreover, the risk of new hypersecretion in nonoperated tumors is uncertain. Our aim was to better characterize these large NFAIs.
Objective
Description and assessment the radiological parameters of NFAI on computed tomography (CT).
Materials and methods
We performed a retrospective study in City Hospital No. 40 in Yekaterinburg from January 2009 to December 2019, involving 89 operated patients NFAI. For all patients, we assessed history, physical examination, radiological

parameters of NFAI by CT scan (native Hounsfield unit [HU]), maximum diameter and blood investigations (glycated haemoglobin, adrenocorticotropic hormone, aldosterone, renin, aldosterone/renin ratio, normetanephrine, metanephrine, dehydroepiandrosterone sulphate, cortisol and 1 mg overnight dexamethasone suppression test).
Results
Criteria for the diagnosis of malignant NFAI were: a combination of size and HU. 89 operated patients NFAI consist of 3 groups. 1 – the group with native CT < 10 HU (*n*-44): adrenal mass 5.87 ± 2.98 cm (95% CI 4.99–6.75 cm), aged 46.16 ± 12.02 years (95% CI 42.61–49.71 years), observation time before surgery 2.21 ± 3.13 years (95% CI 1.28–4.05 years); 2 – the group with native CT inhomogeneous density (*n*-14): adrenal mass 5.60 cm (IQR 4.0–6.75 cm), aged 60.5 years (IQR 47.5–63.25 years), observation time before surgery 0.5 years (IQR 0.38–1.44 years). 3 – the group with native CT ≥ 10 HU (*n*-31): adrenal mass 6.0 ± 3.13 cm (95% CI 4.9 – 7.1 cm), aged 45.39 ± 13.52 years (95% CI 40.63 – 50.15 years), observation time before surgery 2.27 ± 3.02 years (95% CI 1.21 – 3.34 years).
Conclusions
Patients treated by adrenalectomy had tumors > 5.6 cm, high or different density areas CT ($P < 0.05$).

Assessment of glucolipid metabolism in patients with nonfunctional adrenal incidentaloma

Jie Li[1], Jiaxin Zhang[1], Guimei Yang[1], Xintong Hou[1], Dan Yang[1], Jing Yang[1], Yi Zhang[2] & Yunfeng Liu[1]
[1]First Hospital of Shanxi Medical University, Department of Endocrinology, Taiyuan, China; [2]Shanxi Medical University, Department of Pharmacology, Taiyuan, China

Backgrounds
The study aimed to explore the characteristics of glucolipid metabolism in patients with nonfunctional adrenal incidentaloma(NFAI). And investigate the relationship between these factors and insulin resistance, islet beta cell function.
Methods
This study enrolled eight patients with nonfunctional adrenal incidentaloma and five healthy controls(HCs). These data were recorded including body measurements, blood biochemical indicators, and the body composition measured by double energy X-ray absorptiometry(DEXA) technique. In addition, blood glucose levels were indicated by flash glucose monitoring system, which better showed blood variability(GV) according to calculating related parameters and analyzinyg several period times including nocturnal, fasting, and postprandial periods. Furthermore, the correlation between glucolipid metabolism and insulin resistance, islet beta cell function were analyzed in the NFAI group.
Results
As compared with HCs, NFAI group showed higher BMI, larger waistline and wasist hip rate(WHR), and lower HDL-c(all $P < 0.05$). Besides, related indicators with regard to indicators of glucose metabolism and body fat distribution showed no significant difference compared with those of HCs. As for FGMS, all indices indicating GV were not found significant differences compared with those of HCs except lower PT1(the percentage of blood glucose values less than 3.9 mmol/l during the day). Furthermore, the correlation analysis revealed that HbA1c% and FINS were positively correlated with HOMA-IR index, while BMI, neck circumference and lean weight of trunk were negatively correlated with HOMA-β cell function(all $P < 0.05$).
Conclusion
Compered with HCs, there are abnormalities glucoliqid metabolism and fat distribution changes in patients with NFAI. And fat distribution affect function of islet cells.

Table 1. Parameters with statistical sense in NFAI and HCs

Parameters	NFAI	HCs	P value
BMI(kg/m^2)	26.44 ± 1.93	23.20 ± 1.82	0.012
Waistline(cm)	92.89 ± 5.61	75.56 ± 4.57	0.000
Hipline(cm)	102.15(101.28.103.78)	94.50(91.50.102.55)	0.127
Wasist hip rate(WHR)	0.89 ± 0.04	0.79 ± 0.02	0.000
HDL-C(mmol/l)	1.09 ± 0.23	1.63 ± 0.18	0.001
PT1	1.05 ± 1.15	6.76 ± 5.98	0.031

Table 2. The correlation analysis

HOMA-IR		
	R value	**P value**
HbA1c(%)	0.771	0.025
FINS(mmol/l)	0.684	0.006
HOMA-β		
	R value	P value
BMI(kg/m^2)	–0.890	0.003
Neck circumference(cm)	–0.767	0.026
Trunk lean mass(g)	–0.851	0.007

Cushing's syndrome induced galactorrhoea in a non - lactating female: clinical case

Raimonda Klimaite[1,2], Saule Cyrolyte[2], Ieva Meskinyte[2], Raimondas Valickas[3], Albertas Dauksa[2,4] & Birute Zilaitiene[1,2]
[1]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Kaunas, Lithuania; [3], Department of Radiology, Hospital of Lithuanian University of Health Sciences, Kauno klinikos, Kaunas, Lithuania; [4]Institute of Digestive Research, Medical Academy, Faculty of Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania

Introduction
It has been observed that in patients with depression and anxiety disorders dopamine secretion is suppressed, therefore prolactin secretion increases. Prolonged hypercortisolemia causes a variety of psycho-emotional changes that may affect dopamine secretion.
Case
A 36-year-old woman was admitted to the Hospital of Lithuanian University of Health Sciences Kauno Klinikos due to a 10-year-lasting galactorrhoea, sleep disorder, mood swings, anxiety attacks, menstrual cycle disorder, and a high blood pressure (BP). Gestational diabetes, preeclampsia, and eclampsia were confirmed in 2010, during the pregnancy. After the childbirth the state has gotten worse, the discharge from the nipples has not disappeared after stop of breastfeeding. Breast ultrasound and biopsy, head MRI were performed because of the galactorrhoea – no pathology were observed. Three groups of antihypertensive drugs were prescribed, but hypertension was still poorly controled. There was no history of other medication, head or chest trauma. No physiological or organic causes of hyperprolactinemia were found.
Physical examination
BMI – 29.76 kg/m^2, central distribution of adipose tissue. Facial hyperaemia. Pink stretch marks were observed: 1.5 cm wide on the arm, thigh, and abdomen area. Hirsutism based on the Ferryman-Gallwey score – 8. Milky white nipples discharge was observed. Thyroid I°- firm, uneven. BP 158/103 mmHg, HR 83 bpm. Other systems: no abnormalities detected.
Laboratory tests
Metanephrine, normetanephrine, aldosterone, renin, thyroid hormones - all in normal ranges. Prolactin 914 mu/l (n.r. 105–548), macroprolactin 78 proc. Head MRI - pituitary area without pathology. Overnight 1 mg Dexamethasone suppression test (DST) - pathological, cortisol after DST 382.9 nmol/l (*n.* < 50). Low-dose Dexamethasone suppression test (LDDST) - pathological, no cortisol suppression. ACTH 0.4 pmol/l (1.63–14.15). Abdominal CT scan: in the left adrenal gland an oval, well-defined 5.8 × 3.8 cm mass, heterogeneous with calcifications, very vascularized, accumulates contrast. Patient was diagnosed with ACTH-independent Cushing's syndrome. A laparoscopic left adrenalectomy was performed. Histological results - adrenocortical adenoma. Post-operative treatment included Hydrocortisone 30 mg/p replacement therapy. Patient's sleep quality and psycho-emotional state improved, galactorrhoea subsided completely within 1 week post-operation. Prolactin 352–294 mu/l.
Conclusion
Physiological and organic causes of hyperprolactinemia were not identified. Since the patient suffered from long-term psycho-emotional alterations dues to hypercortisolemia and cessation of galactorrhoea were observed after the surgical treatment of adrenal adenoma, galactorrhoea can be considered as

Cushing's syndrome complication. To our knowledge, a few similar clinical cases have been reported where galactorrhoea was attributed to psycho-emotional disorders in the context of the other diseases.

Patients with congenital adrenal hyperplasia show an adverse cardiovascular risk profile compared to patients with autoimmune adrenalitis

Hannes Beiglböck, Magdalena Bögl, Paul Fellinger, Matthaeus Metz, Greisa Vila, Anton Luger, Siegfried Trattnig, Alexandra Kautzky-Willer, Martin Krssak, Michael Krebs & Peter Wolf
Medical University of Vienna, Internal Medicine 3, Endocrinology and Metabolism, Vienna, Austria

Background
Despite adequate hormone replacement therapy, evidence suggests an increased mortality in patients suffering from primary adrenal insufficiency, mainly because of cardiovascular diseases. Congenital adrenal hyperplasia (CAH) and autoimmune adrenalitis (AI) are two entities with a different pathophysiological background and might therefore show divergent cardiovascular risk profiles.
Methods
9 patients with CAH (female $n = 4$; age: 39 ± 11years; weight: 71 ± 12 kg; equivalent dose of hydrocortisone:19 ± 7 mg/day) and 9 patients with AI (female $n = 4$; age: 43 ± 9years; weight: 73 ± 15 kg; equivalent dose of hydrocortisone: 24 ± 7 mg/day) under stable glucocorticoid substitution therapy were investigated. Fasting blood was drawn to evaluate glucose- and lipid metabolism. Standardized blood pressure measurements and magnetic resonance imaging and spectroscopy measurements were performed to assess cardiac function, myocardial (MYCL) & hepatic lipid content (HCL) and abdominal fat mass.
Results
Fasting glucose (91 ± 10 vs 80 ± 7 mg/dl; $P = 0.021$), HbA1c (5.44 ± 0.3 vs 5.1 ± 0.4%; $P = 0.044$) and blood pressure (124 ± 8/80 ± 6 vs 113 ± 10/71 ± 6; $P = 0.031$) were higher in CAH compared to AI. This was paralleled by an increase in HCL (5.8 ± 5 vs 1.8 ± 1%; $P = 0.0549$) and abdominal fat mass (251 ± 130 vs 378 ± 119 mm^2; $P = 0.047$). No differences in heart function (Ejection fraction: 56 ± 4 vs 59 ± 8%; P = n.s) and MYCL (0.28 ± 0.2 vs 0.25 ± 0.1%; P = n.s.) were observed. Patients with CAH were treated more frequently by evening doses of glucocorticoids (6/9 vs 1/9) or others than hydrocortisone (5/9 vs 0/9).
Conclusions
CAH is associated with an adverse cardiovascular risk profile compared to AI, despite a comparable dose of daily glucocorticoid substitution. This might be explained by a more unphysiological timing of replacement therapy or the more frequent use of longer-acting glucocorticoids in patients with CAH, as well as by the adverse metabolic effects of hyperandrogenemia in women.

Gennimatas', 3rd Department of Surgery, Athina, Greece; [2]Evaggelismos, Department of Pathology, Athina, Greece; [3]Royal Free London NHS Foundation Trust, Department of Hepato-Pancreato-Biliary Surgery and Liver Transplantation, United Kingdom; [4]Medical School, National and Kapodistrian University of Athens, Department of Biological Chemistry, Athina, Greece; [5]Medical School, National and Kapodistrian University of Athens, 1st Department of Internal Medicine, Athens, Greece; [6]General Hospital of Athens 'G. Gennimatas', epartment of Pathology, Athina, Greece; [7]Medical School, National and Kapodistrian University of Athens, Endocrine Oncology Unit, 1st Department of Propaupedic Internal Medicine, Athens, Greece

Background
Adrenocortical carcinoma (ACC) is a rare but very aggressive endocrine malignancy with poor survival. Histopathology is important for diagnosis, while in some cases immunohistochemical markers and gene profiling of the resected tumor may be superior to current staging systems to determine prognosis.
Aim
Herein, we aimed to present the 20year experience at a tertiary Hospital in patients with ACCs and correlate the immunohistochemical characteristics of ACCs with the clinical and morphological characteristics of the tumors and the survival of the patients.
Material and methods
45 patients with ACC operated in a single center were included in the study. The tumor size and weight and the disease stage (ENSAT classification) were examined along with Weiss score and Helsinki score. Immunohistochemical expression of Inhibin-a, Melan A, Calretinin, Ki67, Synaptophysin, p53, Vimentin, CKAE1/AE3 was also examined.
Results
45 patients were diagnosed with ACC. The male to female ration was 1:1.37. The median age at diagnosis was 55.5 years (IQR 19–77). ENSAT stage I, II, III and IV was 6.6%, 62.3%, 26.7% and 4.4%, respectively. The median size of ACCs was 9 cm (IQR 3.5–22 cm) and the median weight 127 gr (IQR 18–1400 gr). The median follow up period was 18 months (IQR 1–96). Twelve patients (31.58%) had ≤ 1-year survival and 17 (44.74%) demonstrated ≤ 5-year survival. Survival was significantly higher in patients with stage I–II as compared to patients with stage III–IV ACC (62 ± 8.7 months vs 31 ± 12.1 months, $P = 0.02$). A significant correlation between tumor volume ($P = 0.011$, $r = 0.418$), diameter ($P = 0.005$, $r = 0.449$), weight ($P = 0.04$, $r = 0.339$) and Weiss score was observed. An association between Weiss score and the expression of vimentin ($P = 0.02$) was also observed. A larger tumor diameter > 10 cm ($P = 0.007$), tumor volume > 500 cm^3 ($P = 0.0003$), tumor weight > 300 gr ($P = 0.03$), Ki-67 index > 4% ($P = 0.04$), Weiss score > 5 ($P = 0.001$), Helsinki score > 8 ($P = 0.06$) were significantly associated with shorter overall survival (OS) in the univariable analysis. The expression of Melan A and lower expression of Ki-67 (≤ 4) were independently associated with longer OS time ($P = 0.01$). No statistical significance was observed regarding the correlation between IHC markers and ENSAT staging (I/II vs III/IV).
Conclusion
Adrenocortical carcinoma is a rare and very aggressive endocrine malignancy. The most important factors that determine long-term prognosis of ACC are the disease stage at diagnosis, the Weiss score, and the Ki67 index. Immunohistochemical markers such as Melan A could also serve as prognostic factors.

The clinical, paraclinical, etiological and therapeutic profile of adrenal incidentalomas

Yasmine Mouelhi, Nadia Khessairi, Wiem Madhi, Meriem Yazidi, Wafa Grira & Melika Chihaoui
Rabta Hospital, Endocrinology, Tunis, Tunisia

Objective
Describe the clinical, paraclinical, etiological and therapeutic profile of adrenal incidentalomas.
Material and methods
Retrospective study, conducted on 100 patients previously hospitalized in the endocrinology department of the university hospital center RABTA, following the fortuitous discovery of an adrenal mass over a period of 10 years.
Results
The mean age of the patients was 58 years (24–82 years), the sex ratio (M/F) was 0.69 and the mean BMI was 30.05 kg/m^2 (16.18–48.00 kg/m^2). The most frequent finding circumstances of adrenal incidentaloma were abdominal pain (36 cases) and lumbar pain (17 cases). Bilaterality was objectified in 33.7% of the cases. The size of the AIs varied between 3 mm and 120 mm on the right with an average of 31 mm, and between 6 mm and 110 mm on the left with an average of 24 mm. Hormonal assessment revealed hypercorticism in 10 patients (11.5% of patients), pheochromocytoma in 6 patients (6.9%), Conn's adenoma in 4 patients (4.6%), and a non-secretory nodule in 67 patients (77% of patients). Only sixteen (16) patients underwent adrenalectomy.
Discussion
Due to the development of medical imaging techniques, the incidental discovery of adrenal masses has become increasingly common. Adrenal incidentalomas constitute an entity with varied, sometimes even serious, etiologies, the exploration of which must be rational and well codified.

Nephrotic syndrome following resection of an adrenal incidentaloma: A case report

Maria Batool[1], Eamon Leen[2], Siobhan Glavey[2], Seamus Sreenan[2] & John Mcdermott[2]
[1]Connolly Hospital Blanchardstown, endocrinology, Dublin, Ireland; [2]Connolly Hospital Blanchardstown, Dublin, Ireland

A 69 year old man had a 5 cm right adrenal lesion discovered incidentally while being investigated for a deterioration in previously well-controlled hypertension. Routine investigations including serum albumin were normal. Further investigation confirmed a non-functioning adrenal lesion. MRI revealed a 'non-fat-containing T1 hyperintense indeterminate adrenal lesion with speckling of T2 hyperintensity, not typical for adenoma, hyperplasia, myelolipoma, haemangioma or pheochromocytoma'. An uncomplicated laparoscopic adrenalectomy was performed. Histology revealed a 118 g adrenal neoplasm, modified Weiss score 0, with abundant hyaline deposits. 3 months later the patient complained of peripheral oedema. Investigations revealed a serum albumin of 24 g/l and 14 g of proteinuria in 24 hours. Serum protein electrophoresis revealed a monoclonal IgA type lambda band. Renal biopsy revealed amorphous material displaying apple green birefringence on staining with Congo Red, which stained with antibodies to lambda light chains, confirming AL amyloid. Therefore the patient's resected adrenal specimen was retrieved and stained with Congo Red, revealing apple green birefringence in the walls of the blood vessels, confirming the presence of amyloidosis. Although adrenal gland involvement in secondary amyloidosis is common, adrenal involvement in primary amyloidosis is less well described. This case illustrates the indolent nature of primary amyloidosis, prior to the development of often catastrophic symptoms. Consideration should be given to Congo Red staining of resected pathologic specimens containing hyaline deposition, to potentially allow for earlier recognition of this devastating disease. A pathophysiologic link between the patient's incidentaloma, adrenalectomy, and onset of nephrotic syndrome remains a matter for conjecture.

Recurrence of a malignant corticosadrenaloma

Henricia Laurinda Pangui, Nassim Essabah Haraj, Siham El Aziz & Asmaa Chadli
Chu Ibn Rochd, Endocrinology, Casablanca, Morocco

Introduction
The adrenal cortex is a rare malignant tumor at the expense of the adrenal gland, very aggressive because of its invasion, its metastatic potential and its five (5) year survival at 40% with a high risk of locoregional relapse.
Case presentation
We report the case of a 17-year-old patient with a history of long-term corticosteroid therapy over 3 years and secondary amenorrhea for 2 years, who was admitted in April 2019 for the management of hyper androgenism. On clinical examination, the general condition was preserved with a notion of moderate weight gain, she presented a severe hirsutism rated at 32 on the Ferriman and Gallway score without signs of virilization, signs of hypercorticism with a cunshingoid facies.. The hormonal balance noted a CLU raised to 3 times the normal, i.e. 616 nmol/24 h (30–200), SDHEA > 27 µmol/l (1.3–8), testosterone at 20 nmol/l or 6 times the normal, methoxylated derivatives were normal. The cervico-thoraco-abdomino-pelvic CT scan performed revealed the presence in the right adrenal gland of a hypodense tissue mass with areas of necrosis measuring 6 × 6 × 7 cm, pushing back the IVC and the upper pole of the right kidney, with multiple cervical nodes. A right adrenalectomy with detachment of the adhesions and conservation of the right kidney was performed, the postoperative was complicated by acute adrenal insufficiency for which the patient was substituted. The pathological examination was in favor of a malignant adrenal cortex classified as stage 3 by ENSAT with an intermediate prognostic risk. At 6 months of follow-up there was a clear regression of clinical signs, at 12 months there was a reappearance of hirsutism, the control of the abdomino-pelvic CT noted a hypodense formation of 41 × 36 mm at the expense of the right adrenal gland. in connection with a local recurrence. Iterative adrenalectomy was performed, with confirmation on pathological examination of a recurrence of adrenal cortex associated with fibromyxoid changes.
Discussion and conclusion
The malignant adrenal cortex has a poor prognosis with a high risk of recurrence especially at stage 3 and 4 of ENSAT, wide surgical excision appears to reduce the risk of relapse according to some authors but treatment with mitotane or poly chemotherapy should be considered.

Diagnosing Cushing's syndrome due to Ectopic ACTH secretion warrants high Index of Suspicion- phenotypical features may not always present

Rana Siddique & Anupam Brahma
West Suffolk Hospital, Bury St Edmunds, United Kingdom

Patients with Cushing's syndrome usually have characteristic phenotypical features but this is not always true in case of Ectopic ACTH secretion. This is mainly because this develops more acutely and underlying malignancy can cause significant weight loss. We report a 71 years old male with background of Prostatic malignancy who was found to have new profound hypokalaemia which was resistant to treatment. There were no signs of Cushing's syndrome but index of suspicion was high given persistent hypokalaemia on background of known malignancy, metabolic alkalosis and hypertension. Random cortisol came significantly elevated which failed to supress after overnight 8 mg Dexamethasone suppression test. ACTH was significantly high. He was planned for medical management given progression of malignancy and was started on metyrapone which resolved the hypokalaemia. Unfortunately patient died within 2 months due to progression of underlying malignancy. It is important to recognise such cases of hypokalaemia early, to appropriately deal with excess cortisol production.

Primary hyperaldosteronism. A clinical profile of the disease without arterial hypertension

Ifigenia Kostoglou-Athanassiou[1], Lambros Athanassiou[1], Panagiotis Spyropoulos[2], Eleni Xanthakou[3], Athanasios Fortis[4], Thomais Kalogirou[4] & Panagiotis Athanassiou[5]
[1]Asclepeion Hospital, Voula, Department of Endocrinology, Athens, Greece; [2]Endocrinologist, Athens, Greece; [3]Endocrinologist, Sparti, Greece; [4]Asclepeion Hospital, Voula, Second Department of Medicine, Athens, Greece; [5]St. Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece

Primary hyperaldosteronism may be due to an adrenal adenoma and is an increasingly recognized cause of secondary arterial hypertension. The disease causes hypokalemia and is usually treated surgically by excision of the adrenal adenoma. However, it appears that it may present with a clinical profile without arterial hypertension. The aim was to describe three cases of primary hyperaldosteronism who presented with hypokalemia and an adrenal adenoma with normal blood pressure. A cohort of three patients is described who presented with hypokalemia in all cases and mild diabetes mellitus in one case. All patients were female, aged 51, 54 and 72 years at the time of diagnosis. Diagnostic evaluation revealed the presence of a small adenoma in the left adrenal gland in two cases and in the right adrenal in one case. Aldosterone levels were elevated while renin was suppressed. In all patients blood pressure levels were normal. Spironolactone was administered in small doses for the management of hypokalemia. During follow up all patients continued to have hypokalemia, however blood pressure levels remained within the normal range. Primary hyperaldosteronism may present with severe arterial hypertension, persisting even after surgical excision of the adrenal adenoma which causes the disease. In many cases surgical treatment is considered successful if drug treatment for hypertension is reduced post surgically. Additionally, the disease may cause significant damage in the target organs affected by hypertension, namely, the heart and kidneys. It appears that although primary hyperaldosteronism is a cause of secondary arterial hypertension, the disease may present with a clinical phenotype without hypertension. This poses new therapeutic alternatives to the clinician. The disease may be managed by follow up, surgical excision of the adenoma being an option, if the clinical profile of the disease changes and creates new problems for the patient.

Quality of life in children diagnosed with non-classic congenital adrenal hyperplasia

Maria João Ferreira[1], Rita Moita[2], Marta Borges-Canha[3], Rita Santos Silva[2], Sofia Ferreira[2], Carla Costa[2], Davide Carvalho[3] & Cíntia Castro-Correia[2]
[1]Department of Endocrinology, Diabetes and Metabolism of Centro Hospitalar Universitário de São João, E.P.E.; [2]São João Universitary Hospital Center, Department of Medical Pediatrics, Porto, Portugal; [3]São João Universitary Hospital Center, Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal

Introduction
Non-classical congenital adrenal hyperplasia (NC-CAH) is a chronic disease characterized by excessive androgen production. Affected children may have their quality of life negatively affected by the awareness of a medical condition, symptoms of hyperandrogenism and the burden of daily medication administration. Pediatric Quality of Life Inventory 4.0 (PedsQL) is a validated tool to assess health-related QoL (HRQoL).
Methods
Cross-sectional study involving 16 patients with NC-CAH followed in the pediatric endocrinology department. NC-CAH patients whose parents were literate and who agreed to participate were included. Anthropometric data was collected and PedsQL was applied to the patients and their parents. Patients were divided into five different groups according to age: 2–4, 5–7, 8–12 13–18 years-old. Control group consisted of healthy individuals from the instrument's validation studies for the Portuguese population (for children aged 5–7 and 8–12) and the standard control population used in the PedsQL validation study (for children aged 2–4 and 13–18).
Results
Overall, there were no differences between the study population and control groups, with the exception of the parent's score results of children aged 8–12. Its results showed physical health and emotional dimension' scores significantly higher, while psychosocial health's score and total scale score were significantly lower than the control group.
Conclusion
HRQoL scores are not negatively affected by NC-CAH on most group ages, with the exception of the parents' reports on HRQoL of children aged 8–12. Further studies with a greater number of patients are needed to determine the impact of this chronic disease on the HRQoL of children.

Metabolic profile and cardiovascular risk assessment in subclinical cushing's syndrome

Dhoha Ben Salah, Abdelmouhaymen Missaoui, Mouna Elleuch, Oumeyma Trimeche, Fatma Mnif, Nadia Charfi, Mouna Mnif, Nabila Mejdoub, Hadj Kacem Faten & Abid Mohamed
Hedi Chaker University Hospital, Endocrinology Departement, Sfax, Tunisia

Introduction
Subclinical Cushing's syndrome (SCS) is an endocrine disorder characterized by an autonomous cortisol secretion in patients bearing adrenal adenomas in the absence of specific signs of hypercortisolism. The cortisol excess is known to be associated with metabolic comorbidities such as obesity, hypertension, glucose intolerance, and dyslipidemia increasing the incidence of cardiovascular events. The objective of this study was to describe the clinical and biochemical features in patients diagnosed with SCS and assess their metabolic and cardiovascular risk (CVR).
Methods
Medical charts of 40 patients diagnosed with SCS and who had been hospitalized between 1990 and 2020 in the Endocrinology Department of Hedi Chaker University Hospital, Sfax, Tunisia were reviewed. Clinical, biological, and radiological data were analyzed. The CVR was assessed using the SCORE charts.
Results:
Among our 40 patients, 57.5% were female. The average age of diagnosis was 56.82 ± 14.94 years. The 2-day low-dose Dexamethasone suppression test was adopted as a confirmatory endocrine work-up showing mean cortisol and ACTH levels of 68.93 ± 63.56 µg/l and at the 31.34 ± 34.47 pg/ml, respectively. The adrenal incidentalomas were unilateral in 76.4% and at the left side in 58.4%. The most common adrenal lesions were adenomas (73.7%) and hyperplasia (23.7%). The mean adenomas size was 3.17 ± 1.79 cm. A marked metabolic phenotype and insulin-resistance were featured in 82.5% of patients with 12.8% overweighted and 51.3% obese. Conspicuous abdominal fat distribution was noted in 75% of men and 90.9% of women with mean waist-circumferences of 97.88 and 104.82 cm respectively. Hypertension was encountered in 62.5% with a mean systolic blood pressure of 142.2 ± 12.11 mmHg. As for the glucose intolerance: 32.5% had type 2 diabetes mellitus and 35% presented with pre-diabetes. The mean fasting plasma glucose was 6.61 ± 1.77 mmol/l. Dyslipidemia affected 42.5%. The mean total-cholestérol and triglycerides levels were 5.51 ± 1.42 and 2.14 ± 1.98 mmol/l respectively. Considering the SCORE risk, three CVR categories were characterized: low, moderate, and high risk groups representing 37.5%, 30%, and 32.5% consecutively. Adrenalectomy was undergone in 40% of cases.
Conclusion
The SCS is linked to several pronounced metabolic comorbidities especially worsen glucose and lipid profile exposing to a higher CVR. The surgical or conservative management of this condition should be discussed on a case-by-case basis regarding the absence of widely accepted guidelines.

The insulin tolerance test (ITT) in the assessment of the adrenal axis

Sahar Abidi, Wafa Grira, Nadia Khessairi, Ibtissem Oueslati, Meriem Yazidi, Fatma Chaker & Melika Chihaoui
La RABTA hospital, Endocrinology, Tunis, Tunisia

Introduction
The insulin tolerance test (ITT) is the gold standard for the assessment of the integrity of the hyopothalamo-pituitray adrenal axis. it's major drawbacks are the mandatory presence of an experienced physician and continuous supervision to detect any complication. Our study aims to evaluate the indications and the outcomes of the ITT performed in our department.
Patients and methods
We conducted a retrospective study of 38 patients with suspected adrenal insufficiency (AI) who underwent the ITT over two years (2018–2019) in our endocrinology department. The patients had 12 hours fasting prior to the test. Intravenous insulin (actrapid) was administrated. The insulin dose was determined from body weight and adjusted based on insulin resistance: 0.2 IU/Kg if the patient was considered to be insulin resistant and 0.1 IU/Kg in other cases. Four blood samples for glucose and cortisol measurements were taken: before the insulin injection (T0), at blood glucose < 50 mg/dl (T1), at 15 min (T2) and at 30min (T3) after achieved hypoglycemia. A meal was given at the moment of hypoglycemia after T1 measurements.
Results
The ITT was performed in 38 patients (10 male, 28 female). The mean age was 40.6 ± 16.4 years (range 10–72 years). Fourteen patients underwent the test for underlying pituitary adenoma, 14 patients for clinical symptoms (7 patients) or biological assessments (7 patients) (hypoglycemia, low cortisol levels.) suggesting an AI, 2 patients for a traumatic brain injury, 2 for pituitary surgery, 2 for bilateral adrenalectomy and 2 for associated autoimmune disease. Adequate hypoglycemia (venous plasma glucose < 50 mg/dl was achieved in 36 patients (94, 7%), of that 8, 7% had no symptoms, while only 2 patients had neuroglucopaenic symptoms. There were no significant adverse events recorded. Eight patients showed an adequate cortisol response (> 18 µg/dl) with a mean serum cortisol 12.5 ± 3.8 µg/dl (T0), 15.9 ± 3.5 µg/dl (T1), 19.11 ± 2.8 µg/dl (T2) and 20.6 ± 1.9 µg/dl (T3). Twenty-eight patients showed an inadequate cortisol response, their levels of serum cortisol were: 8.3 ± 2.9 µg/dl (T0), 7.9 ± 2.7 µg/dl (T1), 10.9 ± 2.8 µg/dl (T2) and 12.4 ± 3.9 µg/dl (T3).
Conclusion
The ITT is a safe test when conducted in optimal settings. The insulin dose should be well determined to obtain appropriate hypoglycemia. Additional time and number of sampling are required to avoid misclassification and to increase the specificity of the test.

Metabolic impact of glucocorticoid substitution in Addison's disease

Wajdi Safi, Dhoha Ben Salah, Sidina Mohamed Elmoctar, Mohamed Abdallahi Mohamed Ahmed, Nadia Charfi, Fatma Mnif, Nabila Rekik, Mouna Mnif, Faten Hadj Kacem & Mohamed Abid
Hedi Chaker Hospital, Endocrinology, Sfax, Tunisia

Introduction
Recent studies in patients with Addison's disease have shown that this condition, even if treated, is fraught with significant morbidity and even excess mortality. The objective of our study was to determine the deleterious effects of long-term glucocorticoid replacement mainly on the metabolic level.
Methods
Retrospective study, carried out at the Endocrinology and Diabetology Department of Hédi Chaker Sfax University Hospital, which involved 32 patients with Addison's disease that has been evolving for more than 15 years.
Results
The average age was 58.53 years with a predominance of women. The mean duration of follow-up was 17.87 years. The hydrocortisone dose was initially 32.5 mg/d, at the end of 27.9 mg/d. There was gradual weight gain, an increase in body mass index and waist circumference. The prevalence of MS was 3.12% at diagnosis and 35.71% after treatment duration greater than 15 years. At the end of the follow-up, 28.57% of the obese patients against 7.14% at the discovery of the disease were noted, 25% of the hypertensive and type 2 diabetic patients all appeared throughout the follow-up, 42.85% of the dyslipidemic patients. Factors favoring the occurrence of the metabolic syndrome were the duration of the disease and the weight loss on discovery of the disease.
Conclusion
Adjustment of replacement therapy during Addison's disease is an issue in view of the morbidity and mortality associated with overdose. Regular monitoring and a personalized therapeutic approach are necessary to improve the prognosis of his patients.

Late night salivary cortisol and Cushing's syndrome

Kawthar El ARBI[1], fatma mnif[1], Manel Naifar[2], Asma Zargni[1], Khouloud Boujelben[1], Fatma Makni Ayadi[2], hadj kacem faten[1] & Abid mohamed[1]
[1]Hedi Chaker Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Habib Bourguiba Hospital, Department of biochemistry, Sfax, Tunisia

Introduction
The thresholds of late night salivary cortisol (LNSC) vary widely among studies due to differences in assay methodologies and in control groups. We aimed to verify the analytical performance of the LNSC by electrochimiluminescence assay (ECLIA) and to establish cut-off values of LNSC for the screening of Cushing's syndrome (CS).
Methods
Patients with suspected CS underwent screening tests including LNSC and 1 mg Dexamethasone Suppression Test (DST). Subjects with abnormal response underwent a 2 mg DST, ACTH assessment and complementary radiological explorations. For the analytical evaluation, the study was performed with guidance from the clinical and Laboratory Standard Institute.
Results
A total of 56 patients with mean age 58.1 years and sex ratio 1.15 were finally enrolled. 22 patients from 56 had clinically CS (group A), 7 patients had subclinical CS (groupB) and 8 patients had a pseudo CS (group C). Goup D (n = 19) was composed of non-functioning adenomas. Reference range for LNSC was 1.06–1.58 ng/ml. LNSC was correlated with nocturnal serum cortisol (r = 0.56, P = 0.004), with serum cortisol after 1 mg DST (r = 0.82, P = 0.04) and after 2 mg DST (r = 0.89, P < 0.001) but not with serum creatinine. BMI was correlated with serum cortisol after 1 mg de DST but not with salivary cortisol. Using a 2.48 ng/ml threshold derived from ROC curve analysis, the sensitivity and specificity of LNSC to identify CS was 84.6% and 69.4% respectively. The intra assay and inter assay coefficients of variation were 9.84% and 10.5% respectively. The detection and quantification limits for salivary cortisol measurement were 0.05 ng/ml and 0.08 ng/ml respectively.
Conclusion
Our data confirm the usefulness of late night salivary cortisol measurement as an initial and simple test for screening for Cushing's syndrome, using an automated ECLIA.

Spontaneous testicular necrosis revealing a pheochromocytoma

Clothilde Wagner[1], Bastien Bouldoires[2], Sarah Mansour[1], Niculina Racolta[1], Marc Schneider[3] & Agnes Smagala[1]
[1]Civil Hospital 'Louis Pasteur', Endocrinology and Diabetes Department, Colmar, France; [2]Civil Hospital 'Louis Pasteur', Internal Medicine Department, Colmar, France; [3]Civil Hospital 'Louis Pasteur', Urology Department, Colmar, France

Pheochromocytoma is a rare tumor of the adrenal medulla, responsible for excessive secretion of catecholamines. Symptoms include the classic triad: headache, palpitations and sweating, usually accompanied by hypertension. We report the case of a pheochromocytoma diagnosed following an episode of testicular necrosis. A 72-year-old patient with history of psoriasis and prostate resection underwent emergency surgery for increased testicular pain suspicious of testicular tumor. Pathological examination revealed testicular necrosis due to vascular damage. The patient was addressed to internal medicine consultation for etiological assessment of the vascular lesion. Testing for autoimmune etiology including SAPL, AAN and ANCA antibodies, as well as for a thromboembolic pathology were negative. A full body CT scan found a 14 × 16 mm right adrenal adenoma (60% absolute washout) and a 32 × 29 mm heterogeneous mass of the left adrenal. The left adrenal mass was hyperfunctional in MIBG scintigraphy. Hormonal exploration found plasma normetanephrines increased 3 × normal, with normal plasma metanephrines and normal plasma dopamine and no other abnormality. Chromogranin A was slightly increased. On further interrogation, the patient reported some palpitation episodes several months earlier. A 24 h ECG was performed finding rare atrial and ventricular extrasystoles. First surgery attempt was unsuccessful, with tachycardia followed by bradycardia and cardio respiratory arrest with successful CPR. The patient finally underwent left adrenalectomy by laparotomy with hemostasis splenectomy. Anatomo-pathological examination confirmed a 2 cm left adrenal pheochromocytoma with an estimated PASS score of 6. Normalization of plasma normetanephrines was observed after surgery. This is, to our knowledge, the first case in the literature of a non-traumatic, spontaneous testicular necrosis revealing a pheochromocytoma. There are a few observations of skin necrosis or distal ischemia revealing a pheochromocytoma, however these remain rare. The hypothesis put forward is the appearance of ischemic lesions after adrenergic discharges. Sympathetic hypertonicity would be at the origin of vascular spasms and an alteration of the microcirculation.

Bilateral pheochromocytoma in von hippel-lindau syndrome revealed by a hemangioblastoma

Elyes Kamoun[1,2], Imen Rojbi[1,2], Rihab Laamouri[1,2], Marwa Majdoub[1,2], Chayma Besrour[1,2], Youssef Lakhoua[1], Nadia Mchirgui[1,2], Ibtissem Ben Nacef[1,2] & Karima Khiari[1,2]
[1]Hospital Charles Nicolle, Tunis, Tunisia; [2]Medical School of Tunis, Tunis, Tunisia

Introduction
Von Hippel-Lindau (VHL) syndrome is an autosomal dominant disease resulting in a susceptibility to develop central nervous system and retinal hemangioblastomas, endolymphatic sac tumors, renal clear cell carcinoma and pheochromocytoma. Pheochromocytoma occurs usually at a younger age and tends to be bilateral in VHL syndrome. Herein, we describe a case of VHL syndrome with cerebellar hemangioblastoma, bilateral pheochromocytoma and kidney tumor.
Case report
A 34-year-old woman was operated on a cystic axial cerebellar tumor revealed by a high intracranial pressure syndrome, which was confirmed to be a cerebellar hemangioblastoma. She was referred to our department for complementary investigations. On physical examination, she had a triad including headaches, palpitations and diaphoresis. She had a blood pressure of 150/90 mmHg with orthostatic hypotension. On laboratory investigations, she had an iron deficiency anemia, a thrombocytosis, an elevated chromogranin A at 404 ng/ml (4 times normal) and urinary fractionated metanephrines superior to 3 times normal. The adrenal computed tomography scan found a 43 * 49 * 51 mm adenoma in the right adrenal gland and 38 * 44 * 68 mm in the left one, and 123I-metaiodobenzylguanidine (MIBG) scintigraphy detected a bilateral uptake confirming the diagnosis of bilateral pheochromocytoma. The other manifestations of VHL syndrome were assessed, eliminating a retinal hemangioblastoma, endolymphatic sac tumors, and founding a 15 mm kidney tumor. Genetic testing confirmed the diagnosis of VHL syndrome. She was operated on with bilateral

adrenalectomy and histology confirming the complete surgery of a bilateral pheochromocytoma with PASS = 2. In post-operative evaluation, the patient didn't have any symptoms and was no longer hypertensive.
Conclusion
This case highlights the importance of screening all manifestations associated with VHL syndrome to initiate an early treatment for all tumors, cerebellar, adrenal and renal in our patient. The follow-up must be done for the patient and her family, and imaging in our case must reassess any pancreatic mass, especially if chromogranin a remains elevated, considering the possibility of pancreatic neuroendocrine tumor.

Quality of life in patients with classical form of congenital adrenal hyperplasia- deficiency of 21 hydroxylase

Jana Vrbikova[1], Prajsova Jitka[2] & Eva Dragomirecka[3]
[1]Institute of Endocrinology, Clinical, Prague 1, Czech Republic; [2]National Institute of Mental Health, Clinical, Klecany, Czech Republic; [3]Faculty of Philosophy, Charles University, Department of Social Work, Prague 1, Czech Republic

Literary data concerning quality of life in adult patients with classical form of 21 hydroxylase deficiency (21 CAH) are sparse and discrepant. Our aim thus was to explore quality of life in a group of young adults with 21CAH attending regularly tertiary reference care centre. We used WHOQuOL Bref questionnaire and we administered it to 45 21 CAH patients of age 28.6 ± 8 yrs and we compared the results with the data from 111 age matched controls from healthy Czech population. 21 CAH have lower score in the domain of physical health (15.2 ± 2.47,vs 16.14 ± 2.4; $P = 0.036$) and in the domain environment (15 ± 2.16, vs 13.36 ± 2.09; $P = 0.001$). We did not find any correlation between biochemical results (lipids, 17 OH progesterone,androstendion, testosteron) or between BMI and blood pressure and the respective domains of the questionnaire. We did not find any correlation between total dose of used glucocorticoids /hydrocortisone equivalent/and any domain in the questionnaire. Concerning comparison of different steroids used for the treatment, the patients treated with prednison have higher scores in domains of physical health í(16.2 ± 1.7 vs 14.5 ± 2.3 for hydrocortison, $P = 0.038$, and 13.6 ± 2.4 for dexametason, $P = 0.029$) and environment (16 ± 1.6 vs 14.1 ± 2.1 for hydrocortison, $P = 0.01$ and 13.1 ± 2.0 for dexametason, $P = 0.006$). We conclude that young adult 21 CAH patients still have worse quality.of life in the domain concerning physical health than their healthy peers. On the contrary, they have higher quality of life in the domain enviroment, which could be explained by good family support. The best scores of patients treated with prednison could be explained probably by more convenient dose schedule than that for hydrocortison. Supported by Ministry of Health, Czech Republic - conceptual development of research organization (Institute of Endocrinology - EU, 00023761)'

Hyperthermia differentially affects cortisol and aldosterone secretion under stimulated conditions

Padraig Donlon[1], Nathan Mullen[1], Kate Warde[1], Anna Bottiglieri[2], Grazia Cappiello[2], Laura Farina[2], Matthew Basel[3], Martin O'Halloran[2], Punit Prakash[3], Paula O'Shea[4] & Michael Conall Dennedy[1]
[1]National University of Ireland Galway, Adrenal Research Laboratory, Lambe Institute for Translational Research., Galway, Ireland; [2]National University of Ireland Galway, Translational Medical Device Laboratory, Lambe Institute for Translational Research, Galway, Ireland; [3]Kansas State University, Department of Electrical and Computer Engineering, Manhattan, United States; [4]University Hospital Galway, Clinical Biochemistry, Ireland

Introduction
Primary Aldosteronism (PA) is the commonest secondary cause of hypertension. Mainstay therapy, adrenalectomy resects both hypersecreting and adjacent normal tissue. It is therefore only suitable for patients with unilateral disease (40% cases), whom are surgical candidates. Thermal therapy presents a plausible minimally invasive therapy, to target and disrupt hypersecreting aldosterone producing adenomas (APA), while also preserving adjacent normal adrenal cortex.

Methodology
Adrenocortical cell lines (H295R and HAC15) were treated with hyperthermia for 15 minutes using a water bath at temperatures between 37–65°C. Cell death and apoptosis were analysed immediately and at 24 hours and 48 hours post hyperthermia using Annexin V/Propidium Iodide (PI) (flow cytometry), and Calcein/PI (fluorescence microscopy). Steroidogenesis was analysed following hyperthermia (i) measuring cytosolic calcium flux in response to angiotensin II (ANGII) using Flou-4 staining (flow cytometry); (ii) analysing steroidogenic enzyme expression (RT-PCR/Western Blotting); and (iii) measuring cortisol and aldosterone in cell supernatants (chemiluminescent assays). Cells were also stimulated with forskolin for assays of steroidogenesis.
Results
Hyperthermia induced necrotic cell death without apoptosis. Percentage cell death was significantly higher at 50°C-65°C (95.41 ± 5.74% vs control 9.17 ± 3.01%, $P < 0.0001$). Cytosolic calcium changes in response to ANGII were lower above 55°C-65°C in H295R (−36.33 ± 7.06 Ca + Response vs control 10.67 ± 1.76 Ca + Response, $P < 0.001$) and above 45°C-65°C in HAC15 (−43.33 ± −12.36 Ca + Response vs control 4.43 ± 1.57 Ca + Response, $P < 0.002$). Intracellular stored calcium was also diminished with increasing hyperthermia in both cell lines. CYP11B1 (−31.6 ± 2.8 DDCt vs control, $P < 0.0001$), CYP11B2 (−11.3 ± 4.9 DDCt vs control, $P < 0.0001$), and HSD3B2 (−42 ± 9.8 DDCt vs control, $P < 0.0001$) enzyme gene expression was decreased at 45°C and above in HAC15 cells. CYP11B2 (−9.3 ± 2.5 DDCt vs control, $P < 0.0001$), and HSD3B2 (−15 ± 1.3 DDCt vs control, $P < 0.0001$) enzyme gene expression decreased significantly in H295R cells. Measurement of cortisol decreased with heat treatment ≥ 45°C (22.35 ± 4.49 nmol/l vs control 117.7 ± 25 nmol/l, $P < 0.0001$) while aldosterone output was unaffected at temperatures below 50°C.
Conclusion
Hyperthermia induces necrotic cell death in adrenocortical cell lines at temperatures > 50°C. Cortisol steroid secretion is more susceptible to sublethal hyperthermia when compared to aldosterone. Knowledge of the differential effects of hyperthermia at lethal and sublethal doses on steroidogenesis and steroid secretion is critical when designing thermal ablation systems for adrenal use and warrant consideration during treatment planning for thermal ablation of APA.

Bilateral adrenal leiomyoma mimicking adrenal malignancy: A rare case report

Mohammad Bilal Jajah[1], Asim Hassan[2], Mohammed Haj Elamin[2] & Abdulkareem Almalki[2]
[1]West Suffolk NHS Foundation Trust, Diabetes and Endocrinology, Bury St Edmunds, United Kingdom; [2]Alhada Armed Forces Hospital, Taif, Saudi Arabia

Background
Adrenal leiomyoma is a rare benign soft tissue tumor, it is even more unusual if presenting bilaterally; 21 cases have been reported in the literature and only six had bilateral involvement; 5 in the pediatric population and only one in an adult patient. Radiological appearance may frequently be confused with malignancy especially if large, calcified and with central necrosis. We report a rare case of bilateral, large, calcified, non-functioning adrenal leiomyoma in a 20-year-old female, who was suspected for a malignancy preoperatively.
Clinical case
A 20 year-old-female presented with chronic abdominal discomfort, fatigue, and inability to gain weight. On examination, she was normotensive, underweight with BMI of 15.6 kg/m^2, and there were no stigmata of Cushing's syndrome, Addison's disease or pheochromocytoma. A contrast CT scan of the abdomen revealed the presence of bilateral well-defined suprarenal lesions measuring 8.5 × 8.5 × 7.2 cm and 4.7 × 4.2 × 3.5 cm on the right and left side, respectively. The lesions showed large central areas of necrosis with multiple punctate calcifications and heterogenous peripheral enhancement. The radiological differential diagnosis included adrenal cortical carcinoma, adrenal metastasis, infectious etiology, and bilateral pheochromocytoma. Her hormonal assays showed normal free cortisol and catecholamine metabolites in the urine and normal serum androgens. The patient underwent a successful right adrenalectomy. Resected specimen measured 10 × 9.5 × 7.5 cm. Histology revealed a well-circumscribed and pseudo-encapsulated smooth muscle tumor comprised of bland, spindle-shaped cells. The panel of immunohistochemical stains supported the diagnosis of leiomyoma. Postoperatively, the symptoms improved, she

gained 4 kg weight over the following 4 months, and short Synacthen test confirmed an intact adrenal function. To avoid lifelong adrenal insufficiency and after discussion with the patient, we agreed to leave the left adrenal mass and follow it by serial imaging. There was only a minimal increase in the size over the following 4 years (5.5 × 4.5 × 3.8 cm).
Conclusion
Adrenal leiomyoma is an extremely rare adrenal tumor and can be confused with adrenal malignancy. Therefore, it should be considered in the differential diagnosis of adrenal incidentalomas. In the case of bilateral etiology, permanent adrenal insufficiency and longterm replacement therapy can be avoided in certain population by removing the larger tumor and continuous follow-up for the other side.

DOI: 10.1530/endoabs.73.AEP78

Hypokalemia in a patient with severe SARS-CoV-2 infection

Kostoglou Athanasiou Ifigenia[1], Sofia Nikolakopoulou[2], Alexandra Konstantinou[2], Lambros Athanassiou[2], Alexandros Spyrantis[2], Olga-Maria Spyropoulou[2], Olga Mascha[3], Charilaos Samaras[2], Ioannis Bliziotis[2] & Panagiotis Athanassiou[4]
[1]Asclepeion Hospital, Voula, Department of Endocrinology, Athens, Greece; [2]Asclepeion Hospital, Voula, Covid Department, Athens, Greece; [3]Asclepeion Hospital, Voula, Department of Biochemistry, Athens, Greece; [4]St. Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece

Hypokalemia has been observed in cases of the new SARS-CoV-2 infection. It has been suggested that hypokalemia may be a sensitive biomarker of disease severity and the requirement for invasive mechanical ventilation requirement in COVID-19 pneumonia. The aim was to describe the case of a patient with severe SARS-CoV-2 pneumonia who developed severe hypokalemia. A patient, male, aged 52, presented with fever and dry cough. He was found to be positive for the SARS-CoV-2 infection. He was hospitalized. During his hospitalization he was found to have hypokalemia, serum K^+ 3.2 mmol/l. His condition stabilized and he was discharged to be followed-up at home. The patient did not have an adrenal adenoma or hyperplasia or history of hypokalemia. However, 2 days later he developed fever and his cough deteriorated. He was hospitalized again. He was found to have pneumonia. K^+ was 2.9 mmol/l, plasma renin 1.0 pg/ml and aldosterone 17 ng/dl. Potassium was administered. A CT of the abdomen was performed which did not show any evidence of an adrenal adenoma or adrenal hyperplasia. Diuretics were not administered. Hypokalemia persisted despite potassium administration and spironolactone was administered along with dexamethasone for the treatment of pneumonia. Following discharge from the hospital the patient recovered and spironolactone was discontinued. The SARS-CoV-2 virus invades cells via a spike which attaches to the ACE2 receptor. The attachment of the virus to the ACE2 receptor causes an imbalance between angiotensin II and angiotensin I systems favoring the angiotensin II system. This imbalance may result in the development of frank hyperaldosteronism in cases of severe SARS-CoV-2 virus infection. This increase in activity of the angiotensin II system causes systemic inflammation and may be involved in the pathogenesis of dry cough characterizing the infection. Hypokalemia has been proposed as a marker of disease severity in the new SARS-CoV-2 infection. However, results are as yet inconclusive and more studies are needed to assess the relationship between SARS-CoV-2 severity infection and hypokalemia.

A giant nonfunctioning adrenocortical carcinoma: A case report

Chayma Besrour, Imen Rojbi, Marwa Majdoub, Rihab Laamouri, Elyes Kamoun, Youssef Lakhoua, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Hospital Charles Nicolle, Endocrinology-Diabetology, Tunis, Tunisia

Introduction
The adrenocortical carcinoma(ACC) is a rare malignant tumor arising from the adrenal cortex, it is usually associated to abnormal hormone secretion, but sometimes it is nonfunctioning, leading to a delayed diagnosis with a locally advanced and/or a metastatic disease.
Observation
We report the case of a 42 year-old woman with no medical history who consulted for chronic epigastralgia. On physical examination, a palpable mass in the right flank was found. Her vital signs were within the normal range and the body mass index was at 25.96 kg/m^2. An abdominal CT-scan revealed a giant retroperitoneal highly vascular tissue mass, encapsulated, well circumscribed and containing areas of necrosis,measuring 18.4 × 13 × 21.5 cm in diameter. Its origin couldn't be clearly defined, it pushes the liver up and to the left, lowers the right kidney, comes into contact with the diaphragmatic dome and rolls the inferior vena cava, suggesting a high potential of malignancy. In front of this giant mass, the biological exploration didn't show any excess of hormone secretion; plasma free normetanephine 0.35 nmol/l < 0.93 mmol/l, plasma free metanephrine < 0.10 nmol/l, cortisol 305 nmol/l, overnight dexamethasone suppression test: cortisol 32 nmol/l < 50 nmol/l, testosterone 0.27 ng/ml, SDHEA 215 µg/dl (normal level 42–307 µg/dl). A tumor biopsy was performed and the histo-pathological examination concluded to an adrenocortical carcinoma. The patient was presented to a multidisciplinary team meeting (endocrinology, urology, oncology), that decided that the tumor was inoperable due to its intimate contact with the vascular structures. As for mitotane treatement, it is not available in our country.
Conclusion
This case is one of the most rare cases of a giant nonfunctioning adrenocortical carcinoma that was reported in the literature. In fact, ACC is an aggressive tumor with poor prognosis.When doable and in the absence of disseminated metastasis, surgery remains the mainstay treatement and has better outcomes than chemotherapy alone. However adjuvant chemotherapy has shown a good effect on the duration of recurrence-free period and on the overall survival.

Bone consequences of high dose denosumab to treat an aneurysmal bone cyst, an example of the European Reference Network support

Giulia Del Sindaco[1,2,3], Pablo Berlanga[4], Laurence Brugieres[4], Eric Thebault[4], Giovanna Mantovani[1,2], Philippe Wicart[5,6] & Agnès Linglart[3,5,7]
[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [3]AP-HP, Hôpital Bicêtre, Service d'endocrinologie et diabète de l'enfant, Platforme d'expertise des maladies rares, Le Kremlin-Bicêtre, France; [4]Gustave Roussy Cancer Center, Department of Pediatric and Adolescent Oncology, Villejuif, France; [5]AP-HP, Centre de Référence des maladies rares du métabolisme du Calcium et du Phosphate, filière OSCAR, Paris, France; [6]Necker - Enfants Malades University Hospital, Department of Pediatric Orthopedic Surgery, Paris, France; [7]Université de Paris Saclay, INSERM, U1185, Le Kremlin-Bicêtre, France

Aneurysmal bone cysts (ABCs) are rare pseudotumoral bone lesions with potential aggressive behavior due to the extensive destruction of surrounding bone. Besides surgery, denosumab has been investigated as a treatment for benign fibro-osseous lesions. As for ABCs, pediatric experience is limited, reporting mainly beneficial effects on lesions growth and associated pain. Some reports included well known side effects associated with denosumab, such as the rebound hypercalcemia at discontinuation. In addition, denosumab in young patients may affect both bone modeling and remodeling, even if consequences on the growing skeleton have not been characterized. We describe the case of an 8-year old boy diagnosed with a spinal ABC not accessible to surgery. Denosumab was administered subcutaneously weekly for 4 weeks and then monthly for one year, with optimal clinical response and calcification of the tumor. Six months after the discontinuation of denosumab, the patient developed severe hypercalcemia that required administration of a loop diuretic and intravenous infusion of zoledronic acid to restore normal serum calcium values. Because of tumor recurrence, denosumab was resumed at similar doses and intervals. After a few months, a new episode of hypercalcemia occurred while on denosumab tapering, 3 months after an injection. At this point, the tumor was stable, and denosumab was stopped. The parents and the patient gave their consent to share clinical data on the Clinical Patient Management System (CPMS), an IT platform for clinical consultations between European Reference Networks. The panel of experts from the BOND ERN and the ERN for rare endocrine disease met, and 6 monthly zoledronic acid infusions were initiated in order to control the rebound hypercalcemia post-denosumab therapy. To now, four infusions have been performed, allowing calcium levels to remain below the upper limit of normal. In parallel to rapid changes of mineral homeostasis, we observed an amplified bone remodeling in response to denosumab. After 1 year of treatment, the patient developed sclerotic metaphyseal bands visible on radiographs. Sclerotic lines partially vanished during wash-out periods

or when the injections of denosumab were spaced. Moreover, the patient developed over the years of denosumab therapy lower limb deformities, i.e. genu valgum, which required bilateral epiphysiodesis. Our experience confirms the efficacy of denosumab in treating ABCs, and suggests the importance of monitoring systematically growth, limb deformities, and mineral homeostasis in children and adolescents receiving denosumab. In addition, this report highlights the support of ERNs in the management of patients affected with rare diseases.

Correlation between parathyroid adenoma volume and markers of calcium-phosphate metabolism in patients with primary hyperparathyroidism

Inna Yankova, Gergana Ivanova, Alexander Shinkov & Roussanka Kovatcheva
Medical University of Sofia, Department of Endocrinology, Sofia, Bulgaria

Introduction
In primary hyperparathyroidism (PHPT) the chronic overproduction of parathormone (PTH) is mostly due to a solitary adenoma.
Aim
The aim of our study was to examine the relationship between calcium-phosphate metabolism and the volume of the parathyroid adenoma (PTA) in patients with PHPT.
Material and methods
The study included 195 patients with biochemical data of PHPT and solitary PTA, visualized on ultrasound. Patients with secondary hyperparathyroidism, multiple PTA and familial forms of PHPT were not included in the study. Patients' mean age was 57.9 (± 11.5) and 88.7% were females. Serum calcium, inorganic phosphate, PTH, 25-hydroxyvitamin D, creatinine and alkaline phosphatase (ALP) were measured. Glomerular filtration rate (GFR) was calculated through CKD-EPI equations. In all patients, the PTA was localized and measured by ultrasound. The PTA volume was calculated using the formula of a rotating ellipsoid.
Results
The median PTA volume was 0.49 cm^3; IQ range 0.22–1.19. It correlated positively with serum calcium and PTH (r = 0.33; P < 0.001 and r = 0.34; P < 0.001 respectively) and negatively with serum inorganic phosphate (r = –0.32; P < 0.001). A significant inverse relationship was found between the PTA volume and serum 25-hydroxyvitamin D level (r = –0.339; P < 0.001). The PTA volume was significantly related to BMI (r = 0.29; P < 0.001) and ALP (r = 0.17; P = 0.02) whereas there was no significant correlation with patients' age and GFR (P = 0.52 and P = 0.23 respectively).
Conclusion
In patients with PHPT and a solitary PTA, there is a positive association between PTA volume and the biochemical markers of disease activity.

Efficacy and safety of long-term treatment with monthly calcifediol soft capsules in vitamin D deficient patients

Esteban Jódar[1,2], Jose Luis Perez-Castrillon[3,4], Antonio Dueñas[3,4], Gonzalo Hernandez[5], Nieves Fernandez[5] & Sandra Pamela Chinchilla Gallo[5]
[1]Hospital Universitario Quirónsalud Madrid, Spain; [2]Universidad Europea, Madrid, Spain; [3]Hospital Universitario Río Hortega, Valladolid, Spain; [4]Universidad de Valladolid, Valladolid, Spain; [5]Faes Farma, Leioa, Spain

Background
Vitamin D has shown to play a role in multiple diseases due to its skeletal and extraskeletal actions (such as immunomodulation). In this sense, vitamin D deficiency has become a worldwide health issue. Few supplementation guidelines mention calcifediol treatment, its optimal dosing and treatment duration, despite being the direct precursor of calcitriol and the biomarker of vitamin D status.
Objectives
To assess the efficacy and safety of long-term treatment with calcifediol soft capsules compared to cholecalciferol (vitamin D3) in vitamin D deficiency.
Methods
This was a Phase III-IV, double blind, randomised, controlled, multicentre clinical trial. Postmenopausal women with baseline levels of 25(OH)D < 20 ng/ml were randomised 1:1:1 to calcifediol 0.266 mg/month for 12 months, calcifediol 0.266 mg/month for 4 months followed by placebo for 8 months, and cholecalciferol 25 000 IU/month for 12 months.
Results
303 patients were enrolled, and 298 were included in the ITT population. There were no significant differences in terms of demographic variables, and the mean basal 25(OH)D levels were 13.2 ± 3.7 ng/ml. After 4 months of treatment, 25(OH)D levels over 30 ng/ml were reached by 4.3 times more patients in calcifediol group than in cholecalciferol group. The superiority of calcifediol over cholecalciferol in terms of increasing 25(OH)D levels was shown throughout the 12 months. However, the biggest difference was observed after the first month of treatment (mean change = 9.7 ± 6.7 and 5.1 ± 3.5 ng/ml in both calcifediol groups combined and in cholecalciferol group, respectively). After month 4, the increase in 25(OH)D levels remained fairly stable during the next 8 months of treatment. However, those patients in the group of calcifediol + placebo, despite having mean 25(OH)D levels of 28.5 ng/ml at month 4, went back to basal levels after withdrawal of treatment (16.1 ± 6.0 ng/ml at month 8 and 14.4 ± 6.0 ng/ml at month 12). Regarding safety, no patient reached 25(OH)D toxic levels (> 100 ng/ml), with 64.4 ng/ml being the highest concentration reported during the study. No relevant treatment-related safety issues were reported in any of the groups studied.
Conclusion
Calcifediol is efficient, faster and more potent than cholecalciferol in raising 25(OH)D levels. After 4 months of treatment, calcifediol 0.266 mg/month reaches its maximum efficacy within safe 25(OH)D levels, remaining fairly stable when treatment continues. Discontinuation of calcifediol supplementation lowers 25(OH)D levels back to baseline, suggesting that long-term treatment is safe and necessary.

Non-nuclear cataracts in hypoparathyroidism are associated with biochemical control of the disease

Guido Zavatta[1,2], Peter Tebben[1] & Bart L. Clarke[1]
[1]Mayo Clinic, Rochester, United States; [2]University of Bologna, Italy

Introduction
A high calcium-phosphate product is thought to increase the risk of soft tissue calcification in hypoparathyroidism, including cataracts. Based on small case series, cataracts in hypoparathyroidism typically develop in the posterior subcapsular region of the lens. However, the mechanism of cataract formation is still not well understood.
Materials and methods
In a large cohort of 1014 patients with biochemically confirmed hypoparathyroidism diagnosed between 2000 and 2020, we identified those with incident non-traumatic cataracts. Etiology and date of diagnosis of hypoparathyroidism were determined by medical records review. Information on type of cataract, date of surgery and complications after surgery was also collected. Three age- and sex- matched controls with cataracts without hypoparathyroidism were selected for each case.
Results
A total of 96 patients received a new diagnosis of cataracts over this 20-year interval. Of these, 81 had postsurgical and 15 nonsurgical hypoparathyroidism. Median age at hypoparathyroidism diagnosis was 50.0 ± 19.2 years (range, 0–80), and duration of hypoparathyroidism was 17.1 ± 15.0 (0.6–56) years, with no significant differences between postsurgical and nonsurgical groups. Median age at diagnosis of cataracts was 70.4 ± 13.8 (range, 17–88), with older age in the postsurgical group (71.0 ± 10.2 vs. 58.2 ± 22.7, P = 0.028). We identified four categories of cataracts (nuclear sclerosis or age-related, cortical, posterior subcapsular and combined forms)in 57 patients with hypoparathyroidism and 198 controls. Age-related cataracts were the most frequent form in controls (82.8%), while these were less frequent (59.6%) in patients with hypoparathyroidism. Opacities in the cortical and subcapsular portion of the lens were much more common in hypoparathyroidism (40.4% vs. 17.1%), and combinations of the three types were more common in hypoparathyroidism compared to controls (17.5% vs. 2.5%). The lower tertile of time-weighted average of serum calcium (K = –0.244, P < 0.001, N = 191) and the higher tertile of time-weighted average of serum phosphate (K = 0.183, P = 0.026, N = 148) were associated with greater prevalence of cortical, posterior subcapsular and combined forms of cataracts in the total study population. Posterior subcapsular cataracts alone were equally common in patients and controls (8.8% vs. 10.1%, P = NS). Nonsurgical hypoparathyroidism had the highest prevalence of non-age-

related cataracts (8/15, 57%). Hypoparathyroidism did not affect age of diagnosis, type, or complications of cataract surgery, including posterior capsule opacification after surgery.
Discussion
Peripheral damage to the lens is characteristic of hypoparathyroidism and may be correlated with hypocalcemia and hyperphosphatemia. Control of these biochemical abnormalities may reduce the risk of this complication.

Total and free vitamin D metabolites in female primary hyperparathyroidism patients

Lingqiong Meng[1], Chi Su[2], Sue A Shapses[1] & Xiangbing Wang[3]
[1]Rutgers University, Department of Nutritional Sciences, United States; [2]Rutgers University, Graduate School of Biomedical Science, United States; [3]Rutgers University, Department of Medicine, United States

Background
Primary hyperparathyroidism (PHPT) is a common endocrine disorder accompanied by low total 25-hydroxyvitamin D [25(OH)D] levels. The 25(OH)D is converted to its biologically active form, 1.25-dihydroxyvitamin D [1.25(OH)$_2$D] that then circulates as bound or free forms. Free 1.25(OH)$_2$D concentrations in patients with PHPT have not previously been examined and understanding this is important to better assess vitamin D status.
Objective
To evaluate total and free 1.25(OH)$_2$D and hormone-to-prohormone [1.25(OH)$_2$D/25(OH)D] 'activation ratio' in patients with PHPT and healthy controls.
Methods
Female patients with PHPT and healthy controls (n = 30/group), matched for age and body mass index, were enrolled. Serum levels of calcium, intact parathyroid hormone (iPTH), vitamin D binding protein (DBP), albumin, total 25(OH)D and 1.25(OH)2D levels were measured. The activation ratio of vitamin D was calculated as total 1.25(OH)$_2$D/25(OH)D. Calculated serum free 25(OH)D and 1.25(OH)2D levels were also reported.
Results
Compared to control subject, patients with PHPT had lower total 25(OH) D and DBP levels (P < 0.001). There were no significant differences in free 25(OH)D or total 1.25(OH)$_2$D levels between two groups; but free 1.25(OH)$_2$D levels were about 26% higher in the PHPT patients compared to controls (P < 0.001). The free (but not total) 1.25(OH)$_2$D level was inversely correlated with DBP (P < 0.01). The activation ratio was significantly higher in patients with PHPT (P < 0.01). The free 1.25(OH)$_2$D levels and activation ratio were positively correlated with iPTH (r = 0.35, P < 0.01) and calcium levels (r = 0.33, P < 0.01). The activation ratio was highly correlated with levels of total and free vitamin D metabolites (P < 0.001).
Conclusion
Patients with PHPT had significantly higher free 1.25(OH)$_2$D levels and activation ratio compared to control subjects. We suggest that total vitamin D levels may not be an accurate estimate of true vitamin D nutritional or functional status. The activation ratio may be a good predictor of free vitamin D levels in these patients.

A rare case of hypercalcemia in pregnancy- a diagnostic conundrum

Tasneem Ladha[1], Maura Moriarty[1], Shaila Khan[1], Min Yi Tan[2], Tannaz Vakilgilani[1], Vassiliki Bravis[1], Lynne Sykes[2], Christina Yu[2], Alexander Comninos[1], Jeremy Cox[1], Stephen Robinson[1] & Rochan Agha-Jaffar[1]
[1]Imperial College Healthcare NHS Trust, St Mary's Hospital Endocrinology, United Kingdom; [2]Imperial College Healthcare NHS Trust, St Mary's Hospital Obstetrics, London, United Kingdom

Hypercalcaemia in pregnancy is a rare but important finding, given the associated potential risks to mother and baby. These include hypertension, pancreatitis, nephrolithiasis and renal failure in the mother and intrauterine growth restriction, neonatal hypoparathyroidism/hypocalcaemia and stillbirth in the baby (1). We present the case of a 26-year-old female with a background of PTH-independent hypercalcaemia of unknown aetiology. This was initially detected at age 6 months when she was investigated for frontal bossing in Poland. Relevant family history includes that of her two siblings who have chronic kidney disease with renal cysts. Following confirmation of pregnancy, her biochemistry revealed an adjusted calcium of 3.55 mmol/l (her pre-pregnancy levels were 2.62 mmol/l-2.65 mmol/l) (reference range 2.20–2.60 mmol/l) and a PTH of < 0.3 pmol/l (reference range 1.6–7.2 pmol/l). She was initially treated with intravenous fluids, encouraged to establish a low calcium diet and subsequently maintain oral hydration. In view of a creatinine of 122 umol/l (reference range 55–110 umol/l), renal obstetric input was sought, and an ultrasound demonstrated medullary nephrocalcinosis. Further investigations demonstrated the following: 25-OH Vitamin D 250 nmol/l (reference range 70–150 nmol/l), 1.25-OH Vitamin D 267 pmol/l (reference range 55–139 pmol/l) and Fibroblast-Growth-Factor-23 240 H RU/ml (reference range < 100 H RU/ml). PTH-Related-Peptide results are pending. Subsequent targeted genetic testing demonstrated a compound heterozygous mutation in *CYP24A1*, resulting in hypercalcaemia due to excess active vitamin D metabolites (2). To address persistent maternal hypercalcaemia (> 3.00 mmol/l with conservative measures) and reduce the risk of perinatal hypoparathyroidism, she was commenced on subcutaneous calcitonin from 20 weeks gestation (intermittent dosing of 50–100 units repeated when calcium > 2.80 mmol/l). She is now 32 weeks gestation and undergoing close monitoring with regular biochemistry and growth scans, given the risk of growth restriction associated with hypercalcaemia. Here we describe a rare but important cause of hypercalcaemia and its exacerbation and management in pregnancy. Maternal hypercalcaemia was worsened by pregnancy-induced physiological changes, including increased vitamin D-driven calcium gut absorption as well as 1-alpha hydroxylase placental expression (1). An excellent response to calcitonin therapy has resulted in calcium levels safely maintained between 2.55–2.67 mmol/l during pregnancy.

Effect of parathyroidectomy on early diastolic dysfunction assessed with ventricular mass index in patients with primary hyperparathyroidism

Georgios Tzikos[1], Christina Manani[1], Aggeliki Chorti[1], Sykaras Evaggelos[2], Evangelia Boura[1], Foteini Adamidou[3], Ioannis Pliakos[1] & Theodosios S. Papavramidis[1]
[1]Aristotle University of Thessaloniki, Medical School, Thessaloniki, Greece; [2]Aristotle University of Thessaloniki, department of Physical Education and Sport Science, Thessaloniki, Greece; [3]Hippocration General Hospital, Endocrinology Department, Thessaloniki, Greece

Introduction
Primary hyperparathyroidism (PHPT) is characterized by excessive secretion of parathyroid hormone (PTH) from one or more parathyroid glands. PTH has a central role in the regulation of calcium and phosphate and the classic disorder causes primarily hypercalcemia associated with renal and bone manifestations. Non-classical symptoms are also present including cardiovascular, gastrointestinal, psychiatric, neuro-cognitive disorders. Regarding cardiovascular manifestations it is well established that patients with PHPT experience higher cardiovascular morbidity and mortality. Left ventricular structure has been shown to be affected in PHPT and patients present with increased left ventricular mass, which is regarded as a strong, independent factor of cardiovascular mortality. Both serum calcium levels and parathyroid hormone (PTH) have been reported to be associated with left ventricular hypertrophy.
Aim of the study
The aim of the study was to test whether curative parathyroidectomy (PTX) could contribute in decrease of left ventricular mass, leading to reverse of harmful effects of PHPT on cardiovascular system, in patients suffering from primary hyperparathyroidism.
Methods
We prospectively evaluated 10 patients scheduled to undergo parathyroidectomy for primary hyperparathyroidism (9 women and 1 man, with mean age 59.1 [± 10.5] years, mean BMI 26.4 [± 5.0], PTH at diagnosis 11.93 [± 3.14] pg/ml, and serum calcium 11.13 [± 0.47] mg/dl. Patients had

no history of heart disease (including hypertension, atrial fibrillation, valve disease and diabetes).
Echocardiographic evaluation was conducted by a single investigator with GE Vivid S5 ultrasound instrument and left ventricular end-diastolic dimension (LVEDD), interventricular septal thickness at end-diastole (IVSd) and posterior wall thickness at end-diastole (PWd) were measured. Left ventricular mass (LVM) was calculated as follows: LVM (g) = 0.8 × 1.04 [(LVEDD + IVSd + PWd)3 - (LVEDD)3] + 0.6. Left ventricular mass index (LVMI) was calculated as LVM divided by body surface area. Normal ranges were assumed as 43–95 g/m^2 for women and 49–115 g/m^2 for men.
Results
All patients had a normal LVMI before parathyroidectomy (mean LVMI 67.30 [± 17.04], and they were assessed 2 days before and 3 months after curative surgery. 3 months after PTX mean LVMI was reduced in all patients with mean values of 63.10 [14.16] g/m^2.
Conclusion
LVMI was reduced in all patients 3 months after parathyroidectomy. Despite the fact that LVM was within normal range before surgery the study showed a decrease in the mean LVMI for all patients. This is indicative that an early diastolic dysfunction exists in PHPT patients independent of other risk factors and it is normalized after surgery.

Bone mineral density evolution following long-term simultaneous pancreas-kidney transplantation in type 1 diabetes

Sílvia Santos Monteiro[1], Tiago Silva Santos[1], Diana Borges Duarte[1], Catarina Pereira[1], Filipa Silva[2], La Salete Martins[2] & Jorge Dores[1]
[1]Centro Hospitalar e Universitário do Porto, Department of Endocrinology, Diabetes and Metabolism; [2]Centro Hospitalar e Universitário do Porto, Division of Nephrology and Transplant

Introduction
Simultaneous pancreas-kidney transplantation (PKT) has a beneficial effect on the evolution of chronic complications in type 1 diabetic (T1D) patients with terminal chronic kidney disease (CKD). However, the CKD-mineral and bone disorder (CKD-MBD) remains a frequent complication. There are a few studies addressing the long-term evolution of bone mineral density (BMD) in these patients.
Aim
To characterize baseline BMD and evaluate its long-term evolution in patients with T1D undergoing PKT.
Methodology
A retrospective cohort, including patients submitted to simultaneous pancreas-kidney transplantation in our tertiary center, between 2000 to 2017. The evolution of BMD was assessed by DEXA. Only patients with baseline value and minimum follow-up of 2 years were included.
Results
Seventy-three patients were included, mostly male (53.4%), with a mean age at transplantation of 35.6 ± 5.9 years. At transplantation, mean T-score of the lumbar spine (LS) and femoral neck (FN) was –1.68 ± 1.12 and –2.15 ± 0.77, respectively. Seventy-five percent presented low bone mass (LBM = osteopenia + osteoporosis) in LS and 90% in FN, with 32.9% having criteria for osteoporosis in LS and 35.6% in FN. On the multivariate analysis, male gender (OR 3.59, P = 0.03) and low BMI (OR 0.78, P = 0.03) were significantly associated with lumbar LBM, but not in the femur. At a long term, BMD significantly improved in LS (ΔT-score + 0.41, P < 0.001) and FN (ΔT-score + 0.29, P = 0.01), in a median time of 4 years after PKT. 57.5% maintained LMO in the LS and 86.3% in the FN, with 12.3% achieving osteoporosis criteria in the LS and 16.4% in the FN. There was a positive correlation between BMI and BMD of LS (r = 0.31, P = 0.02) and FN (r = 0.36, P = 0.005). Pancreas graft failure (P = 0.03) was a predictive factor for osteoporosis in FN, but not in the LS.
Conclusion
In the absence of information available on the Z-score, which is best applicable to most of these patients, the use of the T-score shows more than a quarter of T1D patients undergoing PKT to achieve osteoporosis criteria. The significant improvement in BMD may result from metabolic correction with PKT and physiological mineral capitalization of the skeleton that still occurs at these age groups. The evolution of BMD was positively associated with BMI, due to a greater efficiency of the nutritional balance with transplantation.

Normalization of SIAD-induced hyponatremia stimulates osteoblast function

Laura Potasso[1,2], Julie Refardt[1], Christian Meier[1,2] & Mirjam Christ-Crain[1,2]
[1]University Hospital Basel, Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]University of Basel, Clinical Research, Basel, Switzerland

Background
Hyponatremia is associated with increased risk of bone fragility and fractures. *In vitro* studies suggest a role of hyponatremia in stimulating osteoclast activation, whereas other studies rather revealed a possible role of acute hyponatremia in impairing osteoblast function. We aimed to assess whether and how correction of hyponatremia in hospitalized patients with the syndrome of inappropriate antidiuresis (SIAD) has an impact on bone metabolism.
Material and methods
This is a pre-defined secondary analysis of 83 hospitalized patients with SIAD undergoing a randomized treatment for 5 days. Biochemical markers of bone resorption (CTX) and bone formation (PINP) were collected in serum at baseline and after the intervention (day 5). Bone formation index (defined as PINP/CTX) was calculated. Patients with steroid therapy (n = 6), fractures (n = 10), or whose data were missing (n = 16) were excluded from the analysis.
Results
Out of 58 patients, 27 (47%) were normonatremic at day 5. These patients showed a 47.9 points higher bone formation index (95% CI 16.7–79.2, P = 0.0035) compared to patients with persistent hyponatremia at day 5. This observation was independent of age, sex, BMI, smoking habits, randomization arm, as well as baseline sodium and cortisol levels. Serum CTX increased similarly in the two groups (P = 0.76), whereas serum PINP increased in patients with normal sodium after intervention (P = 0.04), but not in persistent hyponatremic patients (P = 0.38).
Conclusions
Normalization of hyponatremia in hospitalized patients with SIAD results in an increased bone formation rate, suggesting a stimulation of osteoblast function.

Fibrosis 4 score is associated with bone density measures in postmenopausal women

Eleni Armeni[1], Areti Augoulea[1], Stavroula Paschou[1], Anastasia Palaiologou[2], Georgios Kaparos[2], Konstantinos Panoulis[1] & Irene Lambrinoudaki[1]
[1]Second Department of Obstetrics and Gynecology, Aretaieio Hospital, School of Medicine, National and Kapodistrian University of Athens; [2]Hormonal and Biochemical Laboratory, Aretaieio Hospital, School of Medicine, National and Kapodistrian University of Athens

Introduction
The routine assessment of postmenopausal women involves screening for cardiometabolic risk factors and bone health. Evaluation of the liver function is not commonly performed, even though this could be easily performed with the use of indirect markers, such as the Fibrosis 4 score. Recent evidence supports an association between liver cirrhosis and bone turnover, affecting both the trabecular and the cortical bone. Therefore, we aimed to explore the possible link between postmenopausal osteoporosis and liver function, expressed according to the values of the Fibrosis 4 (Fib4) score.
Methods
This was a cross-sectional study of 8.363 postmenopausal women, retrieved from a University Menopause Clinic. Details of the personal and medical history were retrieved from the departmental database, including osteoprotective drug intake. Participants underwent a fasting blood test, in the context of their routine assessment in the Department, for estimation of biochemical and hormonal parameters. Moreover, we performed a bone density scan (DEXA) of either the lumbar spine (LS) or the femoral neck (FN) for evaluation of possible underlying osteoporosis.
Results
Mean age of our women was 56.7 ± 7.5 years, with a mean menopausal age of 8.87 ± 6.9 years and BMI 26.9 ± 4.7 kg/m^2. Correlation analysis between Fib4 values and bone parameters was as follows: LS-BMD, r = –0.083; LS-Tscore = –0.099; FN-BMD, r = –0.085; FN-Tscore r = –0.093,

P-value < 0.001 in all cases. The presence of osteoporosis in the lumbar spine only was associated with higher values of Fib4 score (1.14 ± 0.35 vs 1.08 ± 0.49, *F* = 5.509, *P*-value = 0.019, ANCOVA adjusted for age, menopausal age, BMI, smoking, alcohol, intake of calcium/bisphosphonates, type 2 diabetes, thyroid-stimulating hormone levels). Fib4 values > 1.45 vs lower levels were associated with 2.147 times higher risk for LS-osteoporosis (*P*-value = 0.001) in combination with the effect of age, calcium/bisphosphonates intake, BMI and HDL cholesterol. No associations were observed between FN-osteoporosis and values of Fib4 score either in dichotomous or continuous manner.
Discussion
These results are indicative of lower BMD in patients with higher values of Fib4 score, affecting particularly the LS-region. These findings are compatible with data available on patients with established cirrhosis. Differences between the lumbar and femoral skeletal region with regards to the amount of trabecular bone might be an explanation of the differing associations observed in this study. Further case-control studies are needed to confirm these findings.

Primary hyperparathyroidism: Differences in presentation between older and younger patients

Katarina Mlekus Kozamernik[1,2], Mojca Jensterle[1,2], Luka Ležaić[1,3], Marko Hočevar[1,4], Soncka Jazbinsek[1], Katarina Remec[1], Andrej Janez[1,2] & Tomaž Kocjan[1,2]
[1]University of Ljubljana, Medical faculty, Ljubljana, Slovenia; [2]University Medical Centre Ljubljana, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia; [3]University Medical Centre Ljubljana, Department for Nuclear Medicine, Ljubljana, Slovenia; [4]Institute of Oncology Ljubljana, Department of Surgical Oncology, Ljubljana, Slovenia

Introduction
The incidence of primary hyperparathyroidism (PHPT) increases with age; however, the clinical presentation might change with aging. We aimed to compare the clinical presentation of older and younger patients with PHPT.
Methods
We retrospectively analyzed the biochemical status, renal involvement, and bone mineral density (BMD) of patients who were diagnosed with PHPT at our endocrine clinic from 2004 to 2016. Patients over 65 years of age were compared to younger patients.
Results
We included 426 adult patients (339 women and 87 men) with PHPT. There were 231 patients over 65 years with a mean age of 73.4 (SD 5.3) years and 195 younger patients with a mean age of 52.2 (10.0) years. Gender distribution was similar with 49 (21.2%) males in older group and 38 (19.5%) males in younger group (*P* = 0.66). Older patients had biochemically less florid disease at presentation with a lower mean serum calcium: 2.72 (0.25) mmol/l vs. 2.79 (0.29) mmol/l; *P* = 0.01, lower urinary calcium: 5.18 (4.0) mmol vs. 8.39 (4.6) mmol; *P* < 0.01 and higher phosphate: 0.84 (0.15) mmol/l vs.0.8 (0.18) mmol/l; *P* = 0.02, but also higher creatinine: 83.56 (31.92) µmol/l vs. 72.23 (26.32) µmol/l; *P* < 0.01, lower estimated glomerular filtration rate: 68.4 (18.1) ml/min vs. 79.4 (14.5) ml/min; *P* < 0.01 and lower 25-OH vitamin D levels: 39.63 (22.41) nmol/l vs. 43.92 (21.53) nmol/l; *P* = 0.02. PTH and alkaline phosphatase levels did not differ between groups. Fewer older patients had nephrolithiasis and/or nephrocalcinosis than younger patients (56 out of 231 or 24.2% vs. 78 out of 195 or 40%; *P* < 0.01). BMD was significantly lower in older patients than in younger patients at the total hip (0.786 (0.157) g/cm^2 vs. 0.876 (0.150) g/cm^2; *P* < 0.01), femoral neck (0.640 (0.113) g/cm^2 vs. 0.717 (0.125) g/cm^2; *P* < 0.01) and at one-third distal radius (0.564 (0.108) g/cm^2 vs. 0.625 (0.100) g/cm^2; *P* < 0.01). There were no differences in BMD at the lumbar spine. Finally, 139 out of 231 older patients (60.2%) were diagnosed with osteoporosis, which was found in only 71 out of 195 younger patients (36.4%; *P* < 0.01).
Conclusion
Based on our study, patients with PHPT who are older than 65 years present with biochemically less florid disease and less nephrolithiasis/nephrocalcinosis, but with more severe bone impairment than younger patients.

Primary hyperparathyroidism – a contemporary picture based on 100 patients from the last decade

Mihail Boyanov[1], Deniz Bakalov[1], Vera Karamfilova[1], Antoaneta Gateva[1], Yavor Assyov[1], Emanuela Zaharieva[2], Kirilina Atanasova[2], Galina Sheinkova[2], Adelina Tsakova[1] & Zdravko Kamenov[1]
[1]University Hospital Alexandrovska, Medical University Sofia, Department of Internal Medicine, Clinic of Endocrinology and Metabolism, Sofia, Bulgaria; [2]University Hospital Alexandrovska, Clinic of Endocrinology and Metabolism, Sofia, Bulgaria; [3]University Hospital Alexandrovska, Medical University Sofia, Department of Clinical Laboratory and Clinical Immunology, Central Clinical Laboratory, Sofia, Bulgaria

Primary hyperparathyroidism (PHPT) is being more and more frequently diagnosed.
Objective
to describe the clinical presentation and the main laboratory and imaging findings in a group of patients with PHPT diagnosed during the last 10 years. Materials and Methods: This was a retrospective cross-sectional study with data review from the last 10 years. Secondary causes for elevated PTH were excluded. The symptoms and signs of hypercalcemia/HPT were reviewed. Serum calcium (total, albumin-corrected and ionized; sCa, corrCa, iCa +), phosphates (P), magnesium, creatinine, alkaline phosphatase, beta-crosslinks were measured. The intact parathyroid hormone (iPTH) and 25(OH)-vitamin D were determined by electro-hemi-luminescence (Elecsys, Roche Diagnostics). Neck ultrasound (US) was used as first localization study. Half of the participants underwent fine-needle aspiration biopsy (FNAB) with cytology and needle-washouts for iPTH. One fourth was assessed by Single-Photon Emission Tomography (SPECT-CT). Data on bone density (from DXA), fractures and renal stones (from renal US) were collected.
Results
100 patients met the study criteria – 95 were women. Most of them were in their 5th and 6th decades. The median corrected sCa was 2.73 mmol/l, iCa+ – 1.39 mmol/l, P – 0.88 mmol/l, iPTH – 14.5 pmol/l and 25(OH)D – 54.0 nmol/l. Normal sCa was registered in 20 participants (20%), while normal sP – in 67.0%. The neck US located single lesions (parathyroid adenoma) in 81% - behind or below the left inferior pole of the thyroid gland in 33 cases (33%) and contra-laterally in another 33%. FNAB of the suspicious lesion had been performed in 51% of the study subjects. The cytology confirmed the presence of parathyroid cells in 22 cases (43.1%), Bethesda II thyroid nodules in 21 cases (41.2%), Bethesda III nodules in 2 cases (3.9%) and insufficient samples (Bethesda I) in 5 cases (9.8%). SPECT-CT from 27 patients identified a suspicious left parathyroid in 11 cases, as well as three ectopic locations. Reduced eGFR and low bone mass were more prevalent than in the general population. Fractures however were not more frequent. Data from renal ultrasound were available in 77% and revealed chronic pyelonephritis without stones in 8 patients (10.4%) and renal stone disease – in 37 patients (48.0%).
Conclusion
Mild to moderate hypercalcemia is frequently the first clue to the diagnosis of PHPT. SPECT-CT seems to be replaced by US-guided FNAB with needle washout measurements of iPTH. Altogether the picture of PHPT is shifting towards milder and asymptomatic (and probably earlier) forms of the disease.

Quantifying the real-world clinical and economic burden of chronic hypoparathyroidism on secondary care in England: A multi-arm, retrospective cohort study

Neil Gittoes[1], Kamran Iqbal[2], Claudio Marelli[3], Helene Vintderdag[3], Ismail Azzabi Zouraq[3], Jay Were[4] & Nin Dass[2]
[1]Queen Elizabeth Hospital, United Kingdom; [2]Takeda UK Limited, United Kingdom; [3]Takeda Pharmaceutical Company Limited, Switzerland; [4]Health iQ Limited, United Kingdom

Background
Chronic hypoparathyroidism (hypoPT) predisposes patients to comorbidities such as cardiovascular/cerebrovascular disease, infection, mental illness, and renal impairment often associated with an increased burden to healthcare systems. Suboptimal disease control is common with standard therapy. The objective of this study was to quantify and assess differences in the clinical and economic burden on secondary care among patients with post-surgical and non-surgical chronic hypoPT in England.

Methods
This multi-arm, retrospective cohort study was conducted using secondary care data collected between April 2014 and March 2019 by the Hospital Episode Statistics (HES) database records of patients with chronic hypoPT. Diagnosis of hypoPT was defined as the presence of ≥ 2 hypoPT ICD-10 codes reported ≥ 180 days apart. Patients with hypoPT must have had ≥ 1 HES interaction ≥ 360 days from the index date (inpatient, outpatient, or accident and emergency) to be included in this analysis. Data of patients with post-surgical and non-surgical chronic hypoPT were compared with those of patients with hypothyroidism and those who underwent thyroid surgery, respectively, for better understanding of clinical/economic burden against a broader patient population.
Results
The universal hypoPT cohort (n = 4.087) included data from post-surgical (n = 993) and non-surgical (n = 2.959) hypoPT patients and others (n = 135, defined as ICD-10 codes indicating both post-surgical and non-surgical hypoPT diagnoses). The prevalence of hypoPT and 1, 2 or 3 + comorbidities was consistently higher in non-surgical vs post-surgical hypoPT patients. Most comorbidities were significantly more frequent in non-surgical and post-surgical groups vs their respective comparators. The most common comorbidities included neuropsychiatric conditions (55.0% vs 55.1%; 55.2% vs 29.1%, P < 0001), renal insufficiencies (22.6% vs 12.9%; 35.4% vs 4.5%, P < 0.0001 both) and infections (25.3% vs 19.1%; 31.2% vs 7.4%, P < 0.0001 both). Healthcare resource utilization (HCRU) was higher in non-surgical and post-surgical hypoPT patients vs their respective comparator group (12.9 vs 6.5; 20.2 vs 2.4) in terms of longer mean spells per patient during inpatient visits and a lower proportion of outpatient appointments referred by a GP (17.8% vs 28.4%; 18.9% vs 41.6%). In the universal, post-surgical, and non-surgical cohorts, 0.2%, 0.5% and 0.1%, respectively, accrued annual inpatient and outpatient costs of > £60.000 per patient, mainly driven by renal comorbidities.
Conclusion
This study highlights the burden of disease, prevalence of comorbidities, and unmet medical needs in patients with hypoPT, as well as a high economic burden on the healthcare system in England by chronic hypoPT patients with a primary cost driver being renal complications across all cohorts.

'Primary hyperparathyroidism: Relationship between localisation of adenoma and calcium level'

Huma Khan, Alice Wills & Theingi Aung
Royal Berkshire Hospital, Diabetes and Endocrinology, Reading, United Kingdom

Aim
To assess relationship between serum calcium level and localization studies and management outcome.
Methodology
Retrospective analysis of data for patients referred by primary care for hypercalcemia from 1/3/2019 to 1/3/2020 to the Endocrinology department at Royal Berkshire Hospital. The sample size was 63 which excluded normo-calcemic hyperparathyroidism as well as MEN1/2 patients.
Results
The average age of cohort was 68.6 years with female preponderance (80.5%). The average referral adjusted calcium was 2.8 mmol/l and PTH was 12.5 mmol/l. End organ damage in the form of osteopenia and osteoporosis was highly prevalent at 60.3%. The sensitivity for USS was 47.6% and MIBI was 50.8%. The concordance between the two modalities was 71.4%. The lower limit of adjusted serum calcium level cut off for positive USS was 2.65 mmol/l and for positive MIBI was 2.62 mmol/l with p value of 0.00025. In terms of management outcome, 57.1% of cohort were referred to ENT team for surgery and the rest were conservatively managed.
Discussion
Hypercalcemia forms a significant proportion of referrals to endocrinology service. Primary hyperparathyroidism is the most common cause of hypercalcaemia, with an estimated prevalence of about 1–7 cases per 1000 adults.[1] This study reiterated the established expected demographics of patients with primary hyperparathyroidism i.e., female preponderance with increasing prevalence in older adults [2]. Half of the referrals were asymptomatic. About two third of the cohort had osteopenia and osteoporosis, a criterion that enables eligibility for surgical intervention if appropriate. The pick-up rate of parathyroid USS and scintigraphy were comparable at around 50%, with a discordance of 28.6% between them. The lower limit for adjusted calcium above which both the USS and SestaMIBI provided positive finding was 2.62 mmol/l which is reassuringly just above the lower limit cut off for NICE diagnostic criteria for hypercalcemia. It is important to note though that normo-calcemic hypercalcemia were not included in this study. With respect to management outcome, a significant 57.1% of cohort were referred to ENT team for targeted (63.9%) or exploration surgery (36.1%) depending on image findings. The rest were conservatively managed with either cinacalcet (34.6%) or wait and watch approach (65.4%). It is interesting to note that 80% of patients with adenoma on USS translated to a surgical outcome. This held true even in the event of discordance with MIBI scan, revealing this modality being favoured by ENT team.

High dose short term glucocorticoid (gc) treatment seems to have no long term negative effect on bone mineral density (bmd) of newly diagnosed multiple sclerosis (ms) patients

George Simeakis[1], Katerina Saltiki[1], Nikolaos Fakas[2], John Koutsikos[3], Kostas Athanasiou[3], George Papatheodorou[4], Athanasios Papatheodorou[5], Evangelia Zapanti[1], Maria Anagnostouli[6], Maria Alevizaki[1] & Evangelos Terpos[7]
[1]School of Medicine, National and Kapodistrian University of Athens, Division of Endocrinology Diabetes and Metabolism, Department of Clinical Therapeutics, Athens, Greece; [2]401 Military Hospital of Athens, Neurology Department, Athens, Greece; [3]401 Military Hospital of Athens, Department of Nuclear Medicine, Athens, Greece; [4]401 Military Hospital of Athens, Center for Molecular Biology – Research Unit, Athens, Greece; [5]251 Air Force General Hospital, Department for Biomedical Research, Athens, Greece; [6]School of Medicine, National and Kapodistrian University of Athens, 1st Neurology Department, Athens, Greece; [7]School of Medicine, National and Kapodistrian University of Athens, Department of Clinical Therapeutics, Athens, Greece

Objectives
High-Dose-Intravenous-Steroid-Treatment-(HDIST) represents the first choice of treatment for MS relapses. Although chronic oral GC-administration is associated with bone loss there are still conflicting data regarding HDIST.
Methods
25 newly-diagnosed MS-patients (10-women) were prospectively enrolled meeting the following eligibility criteria: age 18–45 yrs, fully ambulatory, women with normal menstruation. Exclusion criteria: history of any chronic disease, previous GC-treatment in any dosage regimen. Patients received 1000 mg-Methylprednisolone intravenously daily for 5 consecutive days. 7/25pts were excluded due to mobility impairment, 8/25 were lost to follow-up. In the remaining 10pts (6-men) serum levels of: Calcium, Phosphorus, Albumin, Magnesium, Creatinine, 25-OH-D, Parathyroid-Hormone-(PTH), Thyroid-Hormones-(TH), Bone-fraction-Alkaline-Phosphatase-(BALP), N-terminal-propeptide-procollagen-type-1-(P1NP), C-terminal-peptide-type-of-collagen-(CTx), Receptor-Activator-of-Nuclear-Factor-Kappa-β-Ligand-(RANK-L), Osteoprotegerin, Sclerostin, Dickkopf-1-(DKK-1), Periostin, Interleukins-(IL)-1ή6.17 were determined prior to GC-administration and consecutively the days: 2–4–6-90 and months: 6–12–18–24. BMD of both hips and lumbar spine as well as whole-body measurement of adipose/lean tissue were assessed with Dual-X-ray-Absorptiometry-(DXA)-scan, prior to GC-administration and consecutively every six months.
Results
Bone formation markers, P1NP and BALP, showed an initial non-significant fall (P1NP day 6:–0.414 ± 0.128 ng/ml, BALP day 4:–0.864 ± 0.334 μg/l) followed by a significant increase in day 90 (P1NP: + 0.567 ± 0.13 ng/ml, P < 0.05, BALP: + 1.838 ± 0.464 μg/l, P < 0.05). No other significant changes were observed. A transient non-significant fall of BMD was observed at all sites 6-months after GC-administration, which subsequently appeared to be restored while in the lumbar spine this trend for reduction continued up to 24-months. The percentage changes of Periostin levels from baseline to 24-months correlated positively with the changes in total-left-hip-BMD and left-trochanter-BMD (r =+ 0.709, P = 0.022 and r =+ 0.77, P = 0.009, respectively) and negatively with CTx (r = 0.806, P = 0.005). The changes in CTx levels negatively correlated with the changes in left-trochanter-BMD (r =–0.782, P = 0.008). A positive correlation of the changes in left-femoral-neck-BMD with the changes in Body-Mass-Index-(BMI) was observed (r = +0.661, P = 0.038). The percentage changes of 25-OH-D levels form baseline to 24-months negatively correlated with the changes of IL-1β from baseline to 3 and 6 months (r = −0.806, P = 0.005 and r = −0.867, P = 0.002, respectively).

Conclusions
In spite of the small sample this is the first-to our knowledge-prospective study aiming to elucidate the impact of HDIST on BMD and simultaneously on biochemical parameters of bone metabolism in newly-diagnosed MS-patients; high dose short term GC administration seems to have no long term negative effect on BMD in this group of patients. The observed transient increase in bone formation markers -90 days after GC administration-probably indicates a high bone turnover phase as a 'response' to the transient adverse effects of GC on bone-metabolism. More prospective studies with larger sample size on similarly selected patients should be performed.

Normocalcemic primary hyperparathyroidism – an early stage of hypercalcemic hyperparathyroidism?

Bárbara Filipa Araújo[1], Sara Esteves Ferreira[2], Teresa Rodrigues[3], Cátia Andreia Araújo[1], Lúcia Fadiga[1], Sandra Paiva[1] & Isabel PAIVA[1]
[1]Coimbra University Hospital, Endocrinology Department; [2]Baixo Vouga Hospital Centre, Endocrinology Department; [3]Coimbra University Hospital, Clinical Pathology Department

Introduction
Primary hyperparathyroidism (PHPT) is a common endocrine disorder and classically associated with hypercalcemia (HHPT). There is a newest variant of PHPT, defined by normal albumin-corrected calcium levels - normocalcemic PHPT (NHPT) – which may represent an early stage of HHPT. Nevertheless, there is limited data on how this variant presents clinically and biochemically.
Aim
To evaluate the demographic, biochemical and clinical profile of NHPT, comparing with HHPT.
Methods
Retrospective single center study that included subjects with a confirmed diagnosis of PHPT followed at our hospital from November 2019 to November 2020. We excluded patients with malignancies and under treatment with glucocorticoids, cinacalcet, bisphosphonates and denosumab. Patients were categorized in two groups – HHPT and NHPT – whether they had hypercalcemia or not, respectively. Nephrolithiasis was documented by kidney ultrasound. Bone mineral density (BMD) at lumbar spine, femoral neck and one-third distal radius was documented by Dual-energy X-ray absorptiometry (DXA).
Results
We included 30 patients with HHPT and 28 with NHPT. The mean age was 59 ± 15 and 61 ± 15 years in NHPT and HHPT, respectively. There were predominantly females (80% NHPT and 78.6% HHPT). The group of NHPT presented with lower levels of PTH (122 pg/ml [101–142] vs 309 pg/ml [216–389], $P < 0.001$), albumin-corrected serum calcium (9.7 mg/dl [9.1–10.0] vs 11.4 mg/dl [11.1–12.2], $P < 0.001$), and higher phosphate concentration (3.6 mg/dl [2.7–4.3] vs 2.8 mg/dl [2.3–4.1], $P = 0.028$). There were no differences between groups in nephrolithiasis (40% NHPT vs 53.6% HHPT, $P = 0.300$), in femoral neck T score (−1.05 [−2.25; −0.63] vs −1.35 [−2.10; −1.20], $P = 0.159$) and lumbar spine T score (−1.45 [−2.70; −0.58] vs −2.35 [−3.20; −1.28], $P = 0.093$). Patients in the NHPT group showed a higher one-third distal radius T score compared to HHPT (−1.05 [−2.93; −0.08] vs −2.50 [−2.75; −1.70], $P = 0.028$). The prevalence of osteoporosis was 25% in NHPT and 41.7% in HHPT ($P = 0.246$). The prevalence of osteopenia at femoral neck and distal radius was lower in the NHPT group (40% vs 70.8%, $P = 0.040$).
Conclusion
Considering biochemical and clinical features, NHPT appears to represent an early stage of HHPT. However, it presents with high rates of nephrolithiasis and osteoporosis, reinforcing the need to recognize and treat this entity according to defined criteria. BMD at distal radius was more preserved in NHPT, corroborating the association with cortical, but not trabecular, bone loss. Therefore, one-third distal radius BMD should be assessed in all patients with PHTP.

Osteoporosis and prevalent vertebral fractures are associated with insulin resistance in non-diabetic postmenopausal women

Eleni Armeni[1], Areti Augoulea[1], Stavroula Paschou[1], Anastasia Soureti[2], Georgios Kaparos[3], Dimitrios Rizos[3], Aris Antoniou[2], Konstantinos Panoulis[1] & Irene Lambrinoudaki
[1]Second Department of Obstetrics and Gynecology, Aretaieio Hospital, School of Medicine, National and Kapodistrian University of Athens, Greece; [2]First Department of Radiology, Aretaieio Hospital, School of Medicine, National and Kapodistrian University of Athens, Greece; [3]Hormonal and Biochemical Laboratory, Aretaieio Hospital, School of Medicine, National and Kapodistrian University of Athens, Greece

Introduction
Recent evidence suggests a possible link between prediabetes and lower density in postmenopausal populations. Moreover, earlier data suggest a link between diagnosis of diabetes and lower levels of bone density in women after the menopausal transition. We aimed to evaluate the possible association between insulin resistance and a diagnosis of lumbar or hip osteoporosis and/or prevalent fractures of the lumbar spine.
Methods
This cross-sectional study included 322 postmenopausal women, retrieved from the Menopause Clinic of Aretaieio Hospital. Women with insulin resistance (homeostasis model assessment, HOMA-IR > 5) clinically overt cardiovascular disease, diabetes mellitus, untreated thyroid dysfunction, gynecological malignancy or endometrial thickness of more than 5 mm were excluded. Blood samples were obtained to perform biochemical and hormonal assessment including markers of bone turnover. Bone density at the lumbar spine (LS) and femoral neck (FN) was estimated using DXA. Lumbar spine plain radiographs were performed to assess for the prevalence of vertebral fractures (VFs).
Results
The prevalence of VFs was 7.5% (24/322), while LS-osteoporosis was identified in 8.8% (19/216) and FN-osteoporosis was identified in 14.8% (31/209) women. Bone density measures correlated with HOMA-IR (LS, T-score r-coefficient = 0.149, P-value = 0.028; FN, BMD r-coefficient = 0.143, P-value = 0.040; FN, T-score r-coefficient = 0.147, P-value = 0.033), age, menopausal age. Markers of bone turnover did not associate with HOMA-IR, glucose or insulin levels. Osteoporosis vs normal bone density/osteopenia was related with lower levels of HOMA-IR, especially at the lumbar spine (LS: 1.2 ± 0.4 vs 1.7 ± 0.9, P-value = 0.018; FN: 1.3 ± 0.6 vs 1.6 ± 0.9, P-value = 0.091), as well as with higher age and follicular stimulating hormone levels. Logistic regression analysis showed that the prevalence of VFs associated inversely with HOMA-IR levels (1st vs 4th quartile, 2.5% vs 7.5%, P-value 0.018 after bootstrapping for 1000 samples), adjusted for age, BMI, FSH, E2. Presence of LS-osteoporosis associated inversely with HOMA-IR levels (1st vs 4th quartile, 13.7% vs 1.8%, P-value = 0.030 after bootstrapping for 1000 samples) as well as menopausal age, adjusted for the same variables. Presence of FN-osteoporosis associated inversely with HOMA-IR levels (1st vs 4th quartile, 16.9% vs 4.5%, P-value = 0.040 after bootstrapping for 1000 samples), adjusted for the same variables.
Conclusion
The development of VFs, LS- as well as FN-osteoporosis is inversely associated with insulin resistance, as estimated by levels of HOMA-IR, in a non-diabetic postmenopausal population.

The bone impact of body composition, adipokines and FGF23-Klotho axis in active acromegaly

Stefana Bilha[1], Anca Matei[1], Daniela Constantinescu[2], Mariana Pavel-Tanasa[2], Raluca Mogos-Cioncu[1], Petru Cianga[2], Cristina Preda[1] & Dumitru D. Branisteanu[1]
[1]'St. Spiridon' Hospital, 'Grigore T. Popa' University of Medicine and Pharmacy, Endocrinology Department, Iasi, Romania; [2]'St. Spiridon' Hospital, 'Grigore T. Popa' University of Medicine and Pharmacy, Immunology Department, Iasi, Romania

Introduction
Body composition (BC), adipokines and the fibroblast growth factor-23 (FGF23) - Klotho axis interfere with bone metabolism and also suffer important modifications in acromegaly. We aimed to investigate their influence upon bone in active acromegaly, compared to controls.
Methods
We performed a cross sectional study, investigating the adipokines (leptin, adiponectin, resistin) secretion pattern, BC parameters and FGF23-α-Klotho axis and their impact upon bone mineral density (BMD) and turnover, respectively, in 35 patients with active acromegaly (Acro), compared to sex, age and body mass index (BMI) - matched healthy controls (Ctl).

Results
Acro had higher lumbar and femoral neck Z-scores ($P < 0.05$), respectively, and a lower trunk-to-leg fat ratio compared to Ctl. Serum adipokines, but not FGF23, differed significantly in the two groups, with lower leptin ($P < 0.001$) and elevated adiponectin ($P < 0.001$) and resistin ($P = 0.001$) concentrations in the Acro group. Resistin was also higher in non-diabetic Acro compared to Ctl (15.9 ± 4.26 ng/ml vs 6.59 ± 0.66 ng/ml, $P = 0.048$). Age (negative), lean mass and trunk-to-leg fat ratio (positive) were the main independent BMD predictors in regression analysis in both Acro and Ctl. Adiponectin and resistin negatively correlated with BMD at various sites ($P < 0.05$) and α-Klotho was positively correlated with osteocalcin ($r = 0.52$, $P = 0.003$) in the Acro, but they lost significance after adjusting for age and BC.
Conclusions
Acromegalic patients display important BC, adipokines and bone changes. Age and BC were the main independent BMD predictors in active acromegaly, similar to the general population. Although serum adipokines showed an altered profile, related to the metabolic changes seen in acromegaly, they were not found to have independent bone actions.

Recurrent primary hyperparathyroidism due to ectopic retropharygeal adenoma

Guermazi Mouna, Snoussi Mouna, Derbel Abir, Frikha Feten, Dammak Chifa, Raida Ben Salah, Marzouk Sameh & Bahloul Zouhir
Chu Hedi Chaker, Internal Medicine, Tunisia

Introduction
The ectopic parathyroid adenoma (EPTA) is the most common cause of failed parathyroid surgery. Most often localisations are intra-thymic and intra-mediastinal adenomas. We report a rare presentation of a symptomatic parathyroid adenoma located in ectopic retropharyngeal position diagnosed after surgical treatment of primary hyperparathyroidism (PHPT).
Obsevation
A 42-year-old female was referred to internal medecine department with fortuitous discovery of hypercalcemia. She had no medical history and there was no family history of multiple endocrine neoplasia syndrome or parathyroid disorder. On physical examination, her blood pressure was 100/65 mmHg. There was no palpable neck mass. Electrocardiogram was normal. Laboratory investigations revealed an elevated serum calcium level at 3.04 mmol/l [2.2- 2.6 mmol/l], hypophoshatemia of 0.52 mmol/l [0.81–1.62 mmol/l]. Serum parathyroid hormone level was markedly increased 287.7 pg/ml [15–65 pg/ml]. Urinary calcium rate was elevated. Her thyroid function test was normal. Diagnosis of hypercalcemic crisis resulting from PHPTwas retained and surgical treatment was indicated. Preoperative Neck US showed left mediolober thyroid nodule TIRADS4 and parathyroid scintigraphy showed lower cervical fixation and left upper plolarhypofixation corresponding to parathyroid adenoma. The patient underwent a lower right paratyroidectomy with an upper left loboisthmectomy. Histological examination showed left lobe adenoma and right lower parathyroid hyperplasia. The postoperative course was favorable. Three months later, she presented recurrent hypercalcemia, hypophosphatemia and increased PTH level at three times normal rate. Neck US and scintigraphy were negative for PTA or thyroïd disease. Cervical CT showed an ectopic retropharyngealparathyroid adenoma which previously had been dismissed as a nonpathological lymph node. The patient was referred again for revesion surgery.
Discussion
PHPT is commonly the result of parathyroid adenoma, less frequent the result of hyperplasia or multiple adenomas. Excision of adenoma is currently curative for primary PHPT but surgery failure and recurrent hypercalcemia are usually due to ectopic adenoma. Retropharygeal space is rarely reported as an area for EPTA.It is thought to be due to the common embryologic origin of the superior parathyroid gland and the apex of the piriform sinus from the fourth branchial pouch.The goal of preoperative imaging in PHPT is not only to identify solitary PTA or multigland disease but also to detect ectopic adenoma.
Conclusion
This case highlights the retropharyngeal space as an important and rare ectopic site for parathyroid adenoma that must be researched carefully before surgery to avoid surgical revision. We insist on using multiple imaging technics to increase the chance for detection of ectopic adenomas.

Denosumab rebound effect associated with breast cancer recurrence – a coincidence? Case report

Katerina Zajickova[1] & Petr Kasalicky[2]
[1]Institute of Endocrinology, Praha 1, Czech Republic; [2]Affidea Prague, Praha 4, Czech Republic

Denosumab discontinuation leads to loss of bone mineral density (BMD) achieved with treatment and in some patients to multiple vertebral fractures (VFx). Beyond bone, antiresorptive agents such as denosumab may affect breast cancer biology. We report a 69-year-old woman treated with the aromatase inhibitor anastrazole for breast cancer who suffered from five spontaneous vertebral fractures after denosumab cessation. Initially, she received four years of ibandronate followed by three years of denosumab (6 injections) as antiosteoporotic treatment. On denosumab her BMD significantly improved (increase of 12% in lumbar spine and 4.8% in hip BMD); after attaining nonosteoporotic BMD the treatment was withdrawn. Six months after the last injection of denosumab peroral ibandronate was administered. Despite ibandronate treatment, 13 months after stopping denosumab, C-terminal collagen cross links (CTX) increased 14-fold in comparison with their values on denosumab, demonstrating accelerated bone resorption, and hip BMD fell by 7.5%. Furthermore, VFx occurred 11 and 13 months after stopping denosumab. At the same time local breast cancer recurrence was diagnosed after six years of remission. The patient underwent left mastectomy followed by trastuzumab treatment. Bone scintigraphy and spine magnetic resonance imaging ruled out bone metastasis and confirmed osteoporosis- related fragility vertebral compressions. Denosumab was resumed and after three injections BMD significantly increased (increase of 17.5% in lumbar spine and 7.4% in hip BMD). The patient postponed one injection to avoid the risk of osteonecrosis of the jaw linked to dental treatment. CTX increased and BMD dropped again significantly (decrease of 21% in lumbar spine and 8.5% in hip BMD). Denosumab was reinitiated for the third time and has been continued. This case illustrates a rebound effect after denosumab cessation in a postmenopausal woman treated for breast cancer. Neither pretreatment nor subsequent postdenosumab treatment with ibandronate prevented high bone turnover, bone loss, and VFx. Denosumab decreases the risk of fractures and, moreover, may provide an adjuvant survival benefit in breast cancer patients. Denosumab discontinuation is, however, associated with a rapid reversal of its effect in bones. Whether this rebound effect has also negative clinical implications for breast cancer recurrence remains to be elucidated. Supported by MZČR - RVO (Institute of Endocrinology - EU, 00023761).

Association of preoperative factors and postoperative hypocalcemia after parathyroidectomy for primary hyperparathyroidism

Alina Aynetdinova[1], Anna Eremkina[1], Olga Yu. Rebrova[2], Elena Kovaleva[1] & Natalia Mokrysheva[3]
[1]Endocrinology Research Center, Department of parathyroid disease, Moscow, Russian Federation; [2]Endocrinology Research Center, Institute of Higher and Additional Professional Education, Moscow, Russian Federation; [3]Endocrinology Research Center, Director, Moscow, Russian Federation

Background
Parathyroidectomy (PTE) is the basic treatment for symptomatic primary hyperparathyroidism (PHPT). It is also recommended for some asymptomatic patients. However, PTE can be followed by some complications such as postoperative hypocalcemia.
Aim
To evaluate association of demographic, clinical, laboratory factors, preoperative cholecalciferol supplementation and hypocalcemia after PTE in patients with PHPT.
Methods
478 patients with PHPT were included in retrospective study, 256 of them had postoperative hypocalcemia (group 1) and 222 hadn't (group 2). The data were obtained from the PHPT registry and the qMS medical information system. The demographic, clinical and laboratory features were compared between groups using Mann-Whitney and Chi-square tests. Cut-off for serum 25(OH) vitamin D (25(OH)D) was determined by ROC-analysis. Bonferroni correction was used for multiple comparisons.

Results
Hypocalcemia was identified in 54% cases (95% CI 49%–58%). Median and quartiles of age were 57 [47; 64] in group 1 and 59 [47; 64] in group 2. Median levels of serum parathyroid hormone (PTH), total calcium, albumin-corrected and ionized serum calcium, alkaline phosphatase (AP) and osteocalcin were significantly higher in group 1 (223.3 vs 165.7 pg/ml, 2.90 vs 2.81 mmol/l, 2.85 vs 2.72 mmol/l, 1.36 vs 1.32 mmol/l, 142 vs 111 IU/l, 64 vs 48.6 ng/ml, respectively, $P < 0.001$ for all), and phosphorus and serum 25(OH)D were lower in group 1 (0.81 vs 0.89 mmol/l, 15.9 vs 19.1 ng/ml, $P = 0.002$). Severe osteoporosis was more frequent in group 1 (14% vs 7%, $P = 0.003$). Taking cholecalciferol before PTE is associated with a lower incidence of postoperative hypocalcemia (27% vs 59%, $P < 0.001$, OR = 0.254, 95% CI 0.147–0.440). Cut-off for serum 25(OH)D as a predictor of postoperative hypocalcemia is 21.6 ng/ml with PPV = 61%, 95% CI 57%–64%, and NPV = 64%, 95% CI 56%–72%.
Conclusion
PTH, laboratory factors of calcium and bone metabolism, as well as severity of osteoporosis are associated with hypocalcemia in patients with PHPT after PTE. Taking cholecalciferol before PTE reduces the odds of postoperative hypocalcemia by 2–6 times.

Although primary hyperparathyroidism (PHPT) can be successfully cured by parathyroidectomy (PTX) and indications for surgery are well defined, a considerable number of patients do not get operated on. By evaluating referrals for PTX in our academic hospital, we might improve our approach to the care of these patients. We retrospectively reviewed patients' hospital records with newly diagnosed PHPT between 2014 and 2020. Biochemical and clinical parameters along with results of diagnostic tests were collected. Among 123 retrieved patients, 26 were not sent for surgery by a referring clinician (nonsurgical group) and they were compared with 66 patients that underwent PTX. The remaining 31 patients were unwilling to undergo surgery, lost from follow up or their workup and surgery were postponed. The statistical analysis was performed by χ^2 test, parametric tests, and multivariate logistic regression. The comparison between the nonsurgical group and the PTX group found that the age of non-operated patients was higher, but they had no more comorbidities. Non-operated patients had lower serum calcium at first presentation, lower PTH and calciuria, but higher serum phosphate. There were also more normocalcemic PHPT patients in the nonsurgical group. The presence of PHPT complications (osteoporosis, fractures, and urolithiasis) was similar between groups and so was the presence of at least one indication for surgery. The sonographic size of enlarged parathyroid glands did not differ between groups. The nonsurgical group had significantly fewer positive findings on ultrasound, FNA cytology, PTH washout, and sestamibi scan. At least two concordant imaging tests (ultrasound, sestamibi scan, or 4DCT) were significantly less frequent among non-operated patients. In a logistic regression model, the absence of concordant imaging tests was the only independent predictor for the nonsurgical approach (OR 14, 95% CI 3.9–50.2, $P < 0.001$). Parathyroid disease localization should not be a criterion for surgery, but these results emphasized a tendency to obtain concordant imaging prior to the referral for PTX. This impression also emerged in our multidisciplinary team meetings and similar real-life data were already encountered in different settings. In practice, this means opting for focused minimally invasive surgery and potentially a lower risk of persistent and recurrent disease, especially in rare multigland disease. The asymptomatic nature and the option for pharmacological intervention in the control of the PHPT complications also seem to discourage surgery. Further improvements in imaging methods and genetic testing to exclude multigland hereditary hyperparathyroidism might contribute to overcoming barriers to PTX.

F18-choline PET/CT for primary hyperparathyroidism localization

Ines Lobo[1], Patricia Martin Rojas[1], Paola Parra Ramírez[1], Oscar Moreno Domínguez[2] & Cristina Álvarez Escolá[1]
[1]Hospital Universitario La Paz, Endocrinology, Madrid, Spain; [2]Hospital Universitario La Paz, Madrid, Spain

Objective
Surgery is the only curative treatment for primary hyperparathyroidism. Minimally invasive parathyroidectomy is superior in terms of cure and complication rates and is less costly than inpatient bilateral cervical exploration. Preoperative localization of parathyroid adenoma by imaging is a requirement for outpatient minimally invasive surgery. One of the most frequently used imaging techniques for parathyroid adenoma localization is Tc99m-sestaMIBI SPECT/CT plus cervical echography. However, one-fourth to one-third of patients have non-localizing disease with usual techniques, needing to undergo bilateral cervical exploration. Some factors associated with negative MIBI-SPECT/CT results are presence of thyroid nodules, lower PTH and calcium levels, parathyroid gland of 12 mm or less and previous cervical surgeries. Recent studies suggest the superiority of F18-choline PET/CT for parathyroid adenoma localization, with a reported sensitivity of 80–90% in patients with negative or inconclusive MIBI SPECT/TC. It also showed a superior accuracy for the detection and correct localization of small adenomas. The aim of this study is to evaluate the efficacy of F18-choline PET/CT in patients with negative or inconclusive MIBI SPECT/TC/echography.
Methods
A retrospective observational study was designed in 15 patients with PHPT, studied between 2018 and 2020, with a negative or inconclusive result in echography + MIBI SPECT/TC and a F18-choline performed afterwards. We analysed the efficacy of this imaging technique and described our patient's characteristics associated with non-localized adenoma with usual techniques.
Results
15 patients (13 women) were included. Mean age was 63 years old. 4 of them had underwent previous cervical surgeries (2 had previous parathyroidectomy, the other 2 had underwent hemithyroidectomy for thyroid nodules). Mean PTH was 138 pg/dl and mean adjusted calcium was 10.45 mg/dl Mean urine calcium excretion in 24 h and the Ca/Cr index were, respectively, 270 mg/24 h and 0.37 mg/mg. 66% (10/15) had T-score < –2.5. 20% (3/15) had nephrolithiasis. All of them had normal kidney function. 54% of patients had concurrent thyroid nodules. 18-choline PET/CT localized hyperfunctioning parathyroid adenomas in 80% of patients with non-localized adenoma with usual image techniques. Mean adenoma size in PET/TC was 7 mm.
Conclusions
F18-choline PET/CT is a valuable tool in localizing parathiroid adenomas not localized with usual techniques (Tc99m-sestaMIBI and echography), specially for those cases with lower calcium and PTH leves and smaller gland size. This will lead to a greater number of patients who are candidates for minimally invasive parathyroidectomy, resulting in more cured patients and less number of complication rates.

Evaluation of bone quality by dxa-based bone strain index in primary hyperparathyroidism

Gaia Tabacco[1], Anda Mihaela Naciu[1], Carmelo Messina[2], Luca Rinaudo[3], Roberto Cesareo[4], Stefania Falcone[5], Silvia Manfrini[1], Nicola Napoli[1], John Bilezikian[6], Fabio Massimo Ulivieri[7] & Andrea Palermo[1]
[1]Campus Bio-Medico, Unit of endocrinology and Diabetes, Rome, Italy; [2]IRCCS Istituto Ortopedico Galeazzi, Milan, Italy; [3]TECHNOLOGIC Srl, Turin, Italy; [4]UOS Malattie Metaboliche, Santa Maria Goretti Hospital, latina, Italy; [5]Unit of Endocrinology and Metabolic Diseases, CTO A. Alesini Hospital, University Tor Vergata, Rome, Italy; [6]College of Physicians & Surgeons, Columbia University, Department of Medicine, Division of Endocrinology, new york, United States; [7]Casa di Cura La Madonnina, Milan, Italy

Backgroud
Primary hyperparathyroidism (PHPT) is associated with impaired bone quality and increased fracture risk. Reliable tools for the evaluation of bone quality parameters are not yet clinically available. Bone Strain Index (BSI) is a new metric for bone strength based on Finite Element Analysis from lumbar spine and femoral neck dual X-ray absorptiometry images.

Aim
To assess the lumbar spine (LS), femoral neck (FN), and total hip (TH) BSI in PHPT compared to controls.
Design
Cross-sectional study. Outpatient clinic
Patients
44 PHPT and 39 age- and sex-matched control subjects.
Main outcome measures
LS-BSI, FN-BSI, TH-BSI.
Results
TH bone mineral density (BMD) and 1/3 distal radius BMD were lower in the PHPT group than in controls (TH 0.802 ± 0.13 vs 0.872 ± 0.09, $P < 0.05$; radius 0.565 ± 0.07 vs 0.620 ± 0.06, $P < 0.001$). There were no differences between groups in trabecular bone score (TBS) and T-score adjusted for TBS. BSI was significantly higher at LS (2.20 ± 0.58 vs 1.94 ± 0.48, $P = 0.003$), FN (1.66 ± 0.39 vs 1.40 ± 0.36, $P = 0.003$) and TH (1.46 ± 0.3 vs 1.24 ± 0.25, $P = 0.001$) in PHPT. LS-BSI showed moderate accuracy for detecting vertebral fractures [(area under the ROC curve 0.68 (CI:0.52–0.848)]. The best cut-off was set at 2.12 (sensibility 72%, specificity 64%, accuracy 67.4%).
Conclusion
BSI, a DXA-derived bone quality index, is impaired in PHPT and may help to identify PHPT subjects at high risk of fractures.

Ectopic parathyroid hormone as a rare aetiology of hypercalcemia with rhabdomyosarcoma: A new treatment strategy with Zoledronic Acid and Denosumab

Fatih Kilci[1], Ugur Demirsoy[2], Jeremy H Jones[3] & Filiz Mine Cizmecioglu-Jones[1]
[1]Kocaeli University, Pediatric Endocrinology & Diabetes, Kocaeli, Turkey; [2]Kocaeli University, Pediatric Oncology, Kocaeli, Turkey; [3]Kocaeli University, Department of Academic Writing, Kocaeli, Turkey

Introduction
Paraneoplastic hypercalcemia is extremely rare in the pediatric population, requiring urgent treatment. Pediatric malignancy-related hypercalcemia (PMRH) has been associated with rhabdomyosarcoma (RMS). Hypercalcemia with elevated parathyroid hormone (PTH), ectopic PTH secretion, is rarer (< 1% of cases). Reports of the use of Zoledronic Acid (ZA) as a second line bisphosphonate are limited. The monoclonal antibody, Denosumab, which inhibits RANKL-mediated osteoclast activity may be effective when bisphosphonates are not. The aim of presenting this case of PMRH secondary to ectopic PTH secretion was to highlight the benefits of ZA as a first choice bisphosphonate and Denosumab as an alternative therapy.
Case
The patient was diagnosed at 12.5 years with alveolar RMS. He had three subsequent relapses. Multiple bone metastases first appeared at 15.5 years but he remained normocalcemic until 17.5 years when serum calcium (Ca) was 14.9 mg/dl, ionized-Ca 2.36 mmol/l, phosphate 3.27 mg/dl, alkaline phosphatase 154 U/l, PTH 249 pg/ml, and 25-OHD 15 ng/ml; urinary Ca/Cr ratio 0.77. The patient was dehydrated and debilitated. Nephrocalcinosis and primary hyperparathyroidism were excluded by ultrasonography. Aggressive hydration and furosemide didn't reduce hypercalcemia. ZA was given immediately (see Table 1). Although a good response was obtained following the first ZA cycle, there was a decrease in response to successive cycles. A single dose of Denosumab was given after the third ZA infusion, resulting in normocalcemia 72 hours later. There were no further hypercalcemic episodes while PTH remained elevated (755 pg/ml). Hypophosphatemia occurred, requiring treatment.

Table 1. Response to treatment modalities

Time after presentation	Treatment	Ca (mg/dl)	Phosphate (mg/dl)	PTH (pg/ml)	Ca (mg/dl) 48-hours after treatment
Presentation	ZA cycle 1	14.6	2.64	249	11
4 weeks	ZA cycle 2	18.2	2.41	1231	11.9
5 weeks		13.7	1.65	831	
6 weeks	ZA cycle 3	19.1	3.79		15.8
6 weeks and 3 days	Denosumab	15	2.98		12.1

Discussion and conclusion
RMS is a non-parathyroid tumor but may cause hypercalcemia through ectopic PTH secretion. PTH mRNA has been identified in RMS cells, implying activation of the gene and direct secretion of PTH. There is *in vitro* evidence that ZA directly sensitizes RMS cells to γδ T-cell cytotoxicity. Thus, for treatment of RMS with hypercalcemia there may be a two-fold benefit in using ZA. PMRH was likely due to ectopic PTH production. We believe ZA should be the bisphosphonate of choice in hypercalcemia with RMS while Denosumab is a new option in ZA-refractory cases; both are safe and effective.

Mineral and bone disorders in patients after combined kidney-pancreas or kidney transplantation

Irina Maganeva, Irina Larina, Anastasia Severina, Alina Aynetdinova, Anna Eremkina, Minara Shamkhalova & Natalia Mokrysheva
Endocrinology Research Center, Moscow, Russian Federation

Background
The kidney or kidney-pancreas transplantation corrects many of the metabolic or biochemical abnormalities associated with chronic kidney disease (CKD); however, mineral bone disease (MBD) and cardiovascular pathology remain frequent in transplant recipients. This happens especially in patients who have long history of secondary hyperparathyroidism (SHPT), as well immunosuppressive therapy plays an important role in the progression of MBD.
Aim
To evaluate the main biochemical parameters and manifestations of MBD in patients after combined kidney-pancreas or kidney transplantation.
Methods
We divided all patients in two groups: #1 ($n = 36$) – after combined kidney-pancreas transplantation (cKPT), #2 ($n = 22$) – after isolated kidney transplantation (iKT). The duration of follow-up varies from 1 month to 2 years. Data analysis was performed with the Statistica 13 (StatSoft, USA). Quantitative data were assessed for normal distribution using the Shapiro-Wilk's W-test. Bonferroni correction was used for multiple comparisons (p0). A prognostically significant model was considered at $P < 0.05$.
Results
We did not find any significant differences in the parameters of phosphorus-calcium metabolism between two groups: albumin-adjusted calcium (AAC) 2.3 mmol/l [2.2; 2.5] vs 2.3 mmol/l [2.3; 2.4]; PTH 80 pg/ml [80.2; 149] vs 95.8 pg/ml [83.9; 241.5], phosphorus 1.1 mmol/l [0.9; 1.2] vs 1.2 [0.9; 1.4], $P > 0.05$ for all. The prevalence decreased BMD on DEXA was 77.8% in group #1 and 50% in group #2 (Tbs 1.4 [1.3; 1.4] vs 1.5 [1.4; 1.6], $P > 0.05$). Vascular calcification was detected in 42% after cKPT and in 27% after iKT. We assessed the levels of FGF23 and Fetuin A: 0.7 pmol/l [0.4;2.1] vs 4.8 pmol/l [0.7;4.0] and 32 5240.0 ng/ml [27 2590.0; 38 2030.0] vs 29 4507.3 ng/ml [24 0010.0; 35 0830.0] respectively, $P > 0.05$ for all. However, osteoprotegerin was significantly higher in patients after iKT (90.6 pg/ml [59.1; 136.1] vs 61.5 pg/ml [48.8; 98.7], $P = 0.04$). We didn't find any association between the presence of calcification in our patients according to the instrumental examination and the levels of FGF23, Fetuin-A and osteoprotegerin.
Conclusion
Our research detected the high prevalence of bone disorder and vascular calcification in patients after cKPT and iKT. These disturbances are associated with increased morbidity and mortality, therefore, regular follow-up is required to establish the optimal therapeutic strategies. Further research is much needed.
Keywords
Mineral and bone disorders, hyperparathyroidism, kidney transplantation, combined kidney and pancreas transplantation, osteoporosis, extraskeletal calcification.

New variant of the casr gene (c.2459c > t) associated with primary hypoparathyrodism – a case report

Mariana Lavrador[1], Adriana Lages[2], Bárbara Araújo[1], Luísa Barros[1] & Isabel Paiva[1]
[1]Centro Hospitalar e Universitário de Coimbra, Endocrinology Department, Coimbra, Portugal; [2]Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal

Background
Autosomal dominant hypocalcaemia, caused by either inherited or de novo mutations in calcium-sensing receptor gene (CASR), is biochemically characterized by the presence of hypocalcaemia, hypercalciuria and inappropriately low levels of PTH. Receptor-activating mutations induce an increase sensitivity to calcium by parathyroid and renal cells, leading to suppression of PTH synthesis and consequently hypocalcaemia. Clinical manifestations are variable: from asymptomatic individuals to severe disease forms with neonatal seizures. Some of the associated comorbidities include intellectual disability, neuropsychiatric symptoms, basal ganglia calcification, and nephrolithiasis.
Case report
Female child, referred to medical consultation at 11 years old due to poor growth (< p3). History of a 36 weeks delivery due to intrauterine growth restriction, and birth weight of 2050g (< p5). Past medical history of congenital kidney hydronephrosis submitted to surgery at 2 years old; double J-stent placement and lithotripsy due to renal pelvic stones at 13 years old. Followed by paediatric nephrology since age 10 due to bilateral renal lithiasis and recurrent UTIs. Deficient neurodevelopment due to intellectual disability. Bilateral pallidal, anterior frontal subcortical and cerebellar calcifications were also found, even though without specific associated neurological complaints. No family disease was found. Initial evaluation showed Tanner stage I, bone age of 10 years and absence of dysmorphisms. Analytical study revealed: Ca^{2+} 1.8 mmol/l (2.19–2.66), phosphate 2.02 mmol/l (0.95–1.75), hypomagnesemia and an inappropriately low PTH level of 13.1 pg/ml (16–87 pg/ml). A diagnosis of primary hypoparathyroidism was set. Supplementation with calcium carbonate/lactogluconate (875 mg + 1132 mg/day) and calcitriol 1µg/day was started. To perform an etiological study, a karyotype and a search for mutations in critical regions of 22q11 chromosome were made, but no changes were identified. At the age of 18, the patient started the follow up in a tertiary adulthood hospital centre. An additional molecular study revealed the presence of a possible pathogenic variant c.2459C > T(Ser820Phe) in the *CASR* gene, in heterozygosity. Currently, the patient remains under the same therapeutic regimen, without worsening of the hypocalcaemia.
Discussion and conclusion
Poor height progression was the basis for this patient's study, allowing the diagnosis of hypocalcaemia and related complications. The identification of a c.2459C > T(Ser820Phe) CASR gene variant found in heterozygosity has been previously described in patients with hypocalcaemia and hypoparathyroidism, being classified as a probable pathogenic variant. Its more recent detection explained the clinical features showed, as well as provided an adequate genetic counselling for the patient and family.

PET/CT with 11C-methionine in the diagnosis of primary hyperparathyroidism

Karina Pogosian[1], Tatiana Karonova[1,2], Liubov Yanevskaya[1], Gleb Berkovich[1], Uliana Tsoy[1], Daria Ryzhkova[1] & Elena Grineva[1]
[1]Almazov National Medical Research Center, Saint Petersburg, Russian Federation; [2]Pavlov First State Medical University of Saint Petersburg, Saint Petersburg, Russian Federation

Background
Primary hyperparathyroidism (PHPT) is the third most common endocrine disorder mainly caused by a single parathyroid adenoma. The localization of the parathyroid adenoma is useful for increasing the recovery rate of PHPT, and reducing the complication rate. Conventional localization techniques include neck ultrasound, Tc99m-MIBI-SPECT and CT. However, each one of those has its limitations; particularly in cases of ectopic, or multiple parathyroid adenomas. 11C-methionine PET/CT may be a useful tool for patients who test negative/inconclusive with other techniques.
Aims
To compare sensitivity, specificity of 11C-methionine PET/CT in comparison to conventional imaging techniques.
Materials and methods
We analyzed the data of 59 patients diagnosed with PHPT from 2016 to 2020. All of them underwent ultrasound and a second confirmation test (mainly Tc99m-MIBI-SPECT). In case the result was negative or inconclusive, a third test was administered (mainly CT). In 2019–2020 11C-methionine PET/CT was used as last-line localization technique in 13 patients. All patients underwent parathyroidectomy and pathological findings were used in order to evaluate the characteristics of imaging modalities.
Results
We conducted a single-centre study at the Almazov National Medical Research Centre in order to evaluate the utility of 11C-methionine PET/CT. Sensitivity of PET/CT was 100 %, CT and Tc99m-MIBI-SPECT showed a bit lower sensitivity, at 91% and 84% respectively. The least sensitivity, 71% was ultrasound. The estimated specificities of PET/CT, CT, Tc99m-MIBI-SPECT and ultrasound were 86%, 73%, 79%, 70% respectively. Relatively low specificities of CT and Tc99m-MIBI-SPECT may explain why 37/59 patients required three techniques (ultrasound, CT, Tc99m-MIBI-SPECT). Though 11C-methionine PET/CT was performed in 9/59 as a third-line, and in 4/59 as a forth-line technique, this method showed the highest sensitivity and specificity.
Conclusion
11C-methionine PET/CT demonstrated the highest sensitivity and specificity and may be a valid alternative to conventional imaging in order to elude negative/inconclusive results. In patients with ectopic or multiple lesions, it can help avoiding bilateral cervical exploration, and persistent hyperparathyroidism.

Frequency of metabolic syndrome in Paget's disease of bone

Selvinaz Erol[1], Esra Cil Sen[1], Feyza Yener Ozturk[1], M. Masum Canat[1], Birkan Alayci[2] & Yuksel Altuntas[1]
[1]University of Health Sciences, School of Medicine, Sisli Hamidiye Etfal Training and Research Hospital, Department of Endocrinology and Metabolism,, istanbul, Turkey; [2]University of Health Sciences, School of Medicine, Sisli Hamidiye Etfal Training and Research Hospital, Department of internal medicine, Turkey

Objective
Scanty data about glucose metabolism, hypertension and metabolic syndrome (MS) have been reported in Paget's disease of bone (PDB) to be related with increased cardiovascular mortality. We aimed to determine prevalence of metabolic syndrome in PDB and to determine the relationship between metabolic syndrome and bone-specific alkaline phosphatase levels.
Patients and methods
Twenty three patients with PDB and 23 age, sex and body mass index (BMI) matched controls were recruited to the study from the outpatient clinics of Endocrinology. All participants were evaluated using the International Diabetes Federation (IDF)-2006 metabolic syndrome criteria. Parameters of bone and mineral metabolism were assessed.
Results
Seventeen of 23 (%73) patients had MS while 8 of 29 (% 27) controls had metabolic syndrome. Difference between groups was statistically significant. Compared with controls, patients group had higher prevalance of anti-hypertensive medication usage and impaired glucose tolerance. While ALP level was statistically higher in patients group, calcium, phosphate, albumin and HDL levels were lower in patients ($P < 0.05$). There was a significant correlation between ALP level and hypertension medication ($P = 0.0045$, $r = 0.27$).
Conclusion
To the best of our knowlegde, this is the first study evaluating the prevalance of MS in patients with PDB. The result of this study indicate that individuals with PDB may also exhibit metabolic disturbances associated with cardiovascular risk. Therefore, these patients should also be regularly monitored for metabolic syndrome.

Is necessary long-term follow-up of all patients with primary sporadic hyperparathyroidism undergoing parathyroidectomy?

Ana Castro[1], Andrea Cruz[1], Rocío Revuelta[1], Almudena Vicente[1], Julia Sastre[1], Enrique Castro[1], Manuela Mollejo[2] & Miguel Carrasco[1]
[1]Complejo Hospitalario de Toledo, Endocrinology and Nutrition, Toledo, Spain; [2]Complejo Hospitalario de Toledo, Pathology, Toledo, Spain

Introduction
Post parathyroidectomy cure in primary hyperparathyroidism (PHPT) is defined as normocalcemia six months after surgery. The frequency of persistent or recurrent post-surgical disease according to lengthy follow-up studies varies between 1% and 14%.

Objective
To determine if there is a subset of patients with cure criteria 6–12 months after parathyroidectomy that would not require long-term follow-up.
Methods
The medical records of 156 patients with PHPT who underwent initial parathyroidectomy in our hospital between 2005 and 2017, were retrospectively reviewed. Patients with a history of multiple endocrine neoplasia syndrome, and secondary or tertiary hyperparathyroidism were excluded. Cure was defined as a normal level of serum calcium and parathyroid hormone (PTH) 6–12 months after surgery. Disease-free survival was calculated by the Kaplan-Meier method.
Results
The mean age was 56.4 years (± 12.7), with 80.3% being women. Mean follow-up time was 71.2 months (1–180). 141 patients met cure criteria (91.6% cure rate). There was no significant difference in age between cured and not cured (56.7 vs 56.4 years, $P = 0.9$). Three patients had recurrent disease. The mean time to recurrence was 80 months (range 60–120). Disease-free survival was 90.2% and 88% at 2 and 10 years respectively. 75% of the cured patients had preoperative imaging that was concordant to intraoperative findings and a decrease in intraoperative PTH (IOPTH) > 50%, compared to 50% of the not cured patients ($P = 0.17$). Disease free survival was 91% at 5 years in patients met these two criteria. The absence of abnormal parathyroid tissue in the histological study was more frequent in not cured patients (25% vs 2.9%) ($P < 0.01$).
Conclusions
Patients operated on for sporadic PHPT and cured at 6–12 months who present preoperative imaging concordant with surgical findings, a decrease in IOPHT > 50% and abnormal parathyroid tissue in the histological study, probably would not require routine long-term follow-up.

The challenge of genetic workup in hypercalcaemia suspected hyperparathyroidism

Hana Ellingham, Christo Albor, Hassan Ibrahim, Ayaz Hussain, Solat Hasnain & Jawad Bashir
Basildon University Hospital, Basildon, United Kingdom

The commonest cause of hypercalcaemia is primary hyperparathyroidism (PHPTH). The diagnostic work up includes paired blood samples for serum corrected calcium, parathyroid hormone (PTH) and vitamin D levels. But in young patients, rare genetic conditions could be contributing towards hypercalcaemia and hence could produce a diagnostic challenge. We report hypercalcaemia work up in two young females where genetic tests were required.
Case 1
A 19yr girl presented with fatigue and osmotic symptoms. She is noted to have mild hypercalcaemia (2.61–2.77 mmol/l) since the age of 13 yrs. Her PTH was persistently high (7.8–14.4 pmol/l) with normal vitamin D (71–83 nmol/l) supporting a diagnosis of primary hyperparathyroidism. Her urinary calcium excretion suggested possibility of familial hypocalciuric hypercalcaemia (FHH). Her parathyroid imaging showed bilateral parathyroid adenomas and she was also noted to have raised prolactin along with a pituitary incidentaloma. Her case was discussed in MDT. Since she was a teenager with PHPTH with multiple gland involvement, it was decided to exclude multiple endocrine neoplasia (MEN). Due to her low urinary calcium excretion, it was also advised to exclude FHH. Genetic tests were sent for both conditions and were reported as normal. Her parathyroid imaging (4D CT scan, SESTAMIBI and Ultrasound) was reviewed in MDT again it was decided to proceed with right superior parathyroidectomy. This resolved hypercalcemia (corrected calcium = 2.39 mmol/l, PTH = 2.8 pmol/l). Histology confirmed parathyroid adenoma.
Case 2
A 42 yr lady presented with incidental hypercalcaemia (2.7–3.05 mmol/l) with normal PTH on routine blood tests. She had mild symptoms of constipation, fatigue, lower back pain. There was no osteoporosis or nephrocalcinosis on DEXA and US scans, respectively. Parathyroid imaging (4D CT scan, SESTAMIBI and Ultrasound) failed to identify any adenoma. Her urinary calcium excretion was low which suggested possibility of familial hypocalciuric hypercalcaemia (FHH). The genetic tests for FHH were organised which confirmed heterozygous mutation for CASR supporting the diagnosis of FHH type 1. The patient was reassured with no further treatment of her hypercalcaemia however, genetic work up was offered for her family to avoid unnecessary work up in incidental hypercalcaemia. Both these cases highlight important message of genetic workup in cases of hypercalcaemia with suspected hyperparathyroidism. In teenage patients with multi-gland disease and those with imaging negative primary hyperparathyroidism one should consider doing genetic tests for MEN and FHH. This avoids unnecessary interventions and also prevents missing serious conditions associated with MEN.

4D-CT – is it useful in Hyperparathyroidism?

Catarina Ivo, Vitória Duarte, David Veríssimo, João Silva, Luís Lopes, Dolores Passos, João Jácome de Castro & Mafalda Marcelino
Armed Forces Hospital, Endocrinology Department, Portugal

Introduction
Primary Hyperparathyroidism (PHPT) results from one or more parathyroid glands hyperfunction. It is recommended that the preoperative location of the parathyroid lesion be performed with cervical ultrasonography and sestamibi-scintigraphy. Recently 4-Dimensional Computed Tomography (4D-CT) has revealed anatomic, morphologic and functional precision for detecting those lesions, either for typical or ectopic location. This study evaluates the diagnostic value of 4D-CT in the preoperative location and whether the severity of PHPT interferes with the success of this location.
Methods
Retrospective study with 34 patients attending with diagnosis of PHPT that performed 4D-CT for parathyroid lesion location. Variables such as age, gender, calcium (Ca), phosphorus (Ph), parathormone (PTH), cervical sonography, sestamibi-scintigraphy and 4D-CT were analysed. In patients who underwent surgical treatment we also analysed surgical criteria, histology and Ca, Ph and PTH postoperative values.
Results
34 patients were evaluated, with mean age of 67 years, 55.9% female. 73.5% had PHPT diagnosis and 26.5% had normocalcemic HPT. At diagnosis, patients had mean values of Ca, Ph and PTH of 10.7 mg/dl, 2.8 mg/dl and 161.2 pg/dl respectively. All patients performed cervical sonography, sestamibi-scintigraphy and 4D-CT. Positive location occurred in 70.6% (29.4% sonography; 38.2% scintigraphy and 55.9% 4D-CT). From those with identified lesion, 83.3% had one lesion and 16.7% multi-glandular lesions. There was a statistically significant positive correlation between the increase measure of Ca, Ph and PTH and the success of identifying the lesion, either in the 4D-CT or in any of the imaging tests ($P < 0.01$ in all). 9 patients underwent surgical treatment and all of them had image exams identifying a lesion (mean dimension of 16.3 mm). From those, 30% were evident on sonography, 60% on scintigraphy and 100% on 4D-CT. All patients were cured after surgery. After histological analysis of the respective lesions, there was a sensitivity of 100% for 4D-CT, 50% for scintigraphy and 40% for ultrasound.
Conclusion
4D-CT revealed to be a useful and reliable exam in the preoperative location of patients with PHPT. In patients that underwent surgical treatment, this image exam has shown a sensibility of 100%, result overlapping the literature (> 90%). Calcium, phosphorus and parathormone values seems to influence the success of lesion location.

The effect of food supplement with calcium and vitamin D3 administration on calcium homeostasis and falls incidence in patients with high fracture risk undergoing medical rehabilitation

Larisa Marchenkova & Valeriia Vasileva
National Medical Research Center for Rehabilitation and Balneology of Ministry of Health of Russian Federation, Somatic rehabilitation, anti-aging and reproductive health department, Moscow, Russian Federation

Background
Vitamin D and calcium deficiencies is of particular importance in older patients undergoing medical rehabilitation and having a high risk of fractures. Preventing falls and fractures, including during the course of rehabilitation, is an important challenge that can be addressed in these patients, in particular through improved nutrition and vitamin D and calcium supplementation.
Objectives
To evaluate the effect of long-term calcium and vitamin D3 intake on calcium homeostasis and fall's rate in patients with high fracture risk starting rehabilitation course.

Methods
The study enrolled 119 men and women aged 50–80 y.o. with high absolute fracture probability by FRAX who started medical rehabilitation. 41 patients have been receiving antiresorptive therapy already comprised group 1, other patients were randomized into groups 2 (n = 39) and 3 (control, n = 39). In groups 1 and 2, a food supplement containing calcium citrate 1000 mg and vitamin D3 600 IU was prescribed for 12 months. All patients undergo laboratory examination, food calcium intake and fall assessment at baseline, in 6 and 12 months
Results
Daily calcium intake in the study sample (n = 119) was 782.9 ± 243.4 mg. Vitamin D deficiency was detected in 38.4% of the examined. An increase in 25(OH)D level was noted in groups 1 and 2 after 6 and 12 months (P < 0.01). Patients in group 1 showed an increase in serum osteocalcin and calcium levels after 6 and 12 months (P < 0.05). In group 3, there was an increase of immunoreactive parathyroid hormone levels after 6 (P < 0.05) and 12 months (P < 0.01), C-terminal telopeptide of type I collagen level and alkaline phosphatase activity after 12 months (P < 0.05). In group 1, there was also a decrease in proportion of patients who fell after 6 months (χ^2 = 4.97, P = 0.026) and a decrease in the total number of falls after 12 months (χ^2 = 4.89, P = 0.027). Group 2 showed a decrease in the number of patients who fell after 6 and 12 months (χ^2 = 48.58, P = 0.0034 at both stages of the study) and the number of falls in general after 6 months (χ^2 = 6.02, P = 0.0142).
Conclusion
The obtained data allow us to recommend prescription of dietary supplements containing calcium and vitamin D3 as a part of complex rehabilitation of patients with high fracture risk.

Vitamin D deficiency is a key element in COVID-19 hypocalcemia

Luigi Di Filippo[1,2], Agnese Allora[1,2], Anna Maria Formenti[1,2], Laura Castellino[1], Francesca Perticone[1], Massimo Locatelli[3], Stefano Frara[1,2] & Andrea Giustina[1,2]
[1]IRCCS Ospedale San Raffaele, Endocrinology Unit, Milano, Italy; [2]Università Vita-Salute San Raffaele, Institute of Endocrine and metabolic Sciences, Milano, Italy; [3]IRCCS Ospedale San Raffaele, Laboratory Medicine Service, Milan, Italy

Hypocalcemia has been recently identified as a major biochemical distinctive feature of COVID-19, predicting poor clinical outcomes. Besides the calcium-dependent viral mechanisms of action and the enhanced cellular permeability to calcium ions, we previously hypothesized that hypovitaminosis-D could be a predisposing factor to hypocalcemia. Actually, high prevalence of vitamin D (VD) deficiency in COVID-19 patients (pts) was reported by several studies, but, to date, only few tried to investigate the role of hypovitaminosis-D on calcium and parathyroid hormone (PTH) levels. We aimed at evaluating the relationship between calcium, PTH and VD in COVID-19 pts. Patients admitted to San Raffaele University Hospital for COVID-19 from February 2020 were enrolled in this study. We excluded pts with comorbidities and therapies influencing calcium and VD metabolism. Ionized and total calcium, 25OH-Vitamin D and PTH levels were evaluated at admission in hospital. VD insufficiency and deficiency were defined as VD level below 30 ng/ml and 20 ng/ml, respectively. We defined hypocalcemia for ionized calcium (Ca^{2+}) level below 1.18 mmol/l and total calcium (tCa) level below 2.1 mmol/l. Hyperparathyroidism was defined as PTH above 65 pg/ml. A total of 88pts were included in the study. Median (IQR) tCa and Ca^{2+} levels were 2.15 (2.05–2.22) mmol/l and 1.14 (1.11–1.18) mmol/l, respectively. Low total and ionized calcium levels were found in 36.5% and in 72.9% of pts, respectively. Median (IQR) VD levels were 16.3 (11.2–23.9) ng/ml. VD insufficiency and deficiency were observed in 88.6% and in 68.2% of pts, respectively. Median (IQR) PTH levels were 46.2 (37.4–64.5) pg/ml and hyperparathyroidism was detected only in 23.9% of pts. No significant differences were found in serum PTH levels between patients with VD insufficiency vs. sufficiency (46.5 (38.2–65.3) vs. 41 (27.5–63.4) pg/ml) and between hypocalcemic vs. normocalcemic pts (Ca^{2+} 49.5 [37.7–65.7] pg/ml vs. 48.5 [37.2–56.6] pg/ml; P = 0.15). Linear regression analyses showed a positive correlation between VD and tCa (P = 0.017; r = 0.26). A borderline significant negative correlation between VD and PTH (P = 0.049; r =–0.21) was also detected. Finally, PTH negatively correlated with Ca^{2+} levels (P < 0.001; r =–0.35). In conclusion, we confirmed a high prevalence of hypocalcemia in COVID-19 pts and showed for the first time that it occurred largely in the context of marked hypovitaminosis-D not adequately compensated by secondary hyperparathyroidism, the reasons of which need to be explored. Since hypocalcemia may be marker and cause of severe clinical consequences in COVID-19, we can hypothesize that VD supplementation may play a relevant role in COVID-19, also possibly preventing hypocalcemia.

Transient hypocalcaemia and definitive hypoparathyroidism after total thyroidectomy in Graves' disease

Bruno Bouça[1], Sara Amaral[1], Miguel Vasques[1], Nuno Monteiro[2], Ana Crespo[2], José Coutinho[2], Paula Tavares[2], Paula Bogalho[1] & José Silva-Nunes[1]
[1]Centro Hospitalar Universitário de Lisboa Central – Hospital de São José, Endocrinology, Diabetes and Metabolism, Lisboa, Portugal; [2]Centro Hospitalar Universitário de Lisboa Central – Hospital de São José, Surgery, Lisboa, Portugal

Introduction
Hypocalcaemia is a complication of total thyroidectomy (TT) and may be more frequent in patients with Graves' disease. The reason for this increased risk is unclear and its occurrence has been associated with: ophthalmopathy severity, preoperative calcaemia and reimplantation of parathyroid glands.
Objectives
To evaluate the risk factors for transient hypocalcaemia (TH) and definitive hypoparathyroidism (DH) in patients undergoing total thyroidectomy for Graves' disease.
Methods
Retrospective study of patients with Graves' disease, who underwent TT between January/2016 and January/2020. Patients with histological diagnosis of malignant thyroid neoplasm or concomitant hyperparathyroidism were excluded. Clinical and laboratory data were collected from clinical files. In the statistical analysis, SPSS software (version 25.0) was used. The variables are expressed as mean and standard deviation, calculating the relative risk (RR) and considering a 95% confidence interval.
Results
49 patients (out of 71 operated) were selected according to the inclusion/exclusion criteria, 73.5% were men. Prevalence of TH was 49.0% and of DH 8.2%. There were no statistically significant differences between patients without (WPH) or with (PH) postoperative hypocalcaemia according to age, interval between diagnosis and surgery, gland weight, serum TSH, FT4, FT3, TRAB levels at diagnosis, or preoperative calcaemia. In the PH group, postoperative PTH levels were significantly lower (58.6 ± 5.9 vs. 23.9 ± 5.5 pg/ml; P < 0.01) and the length of hospital stay was significantly higher (4.3 ± 0.5 vs. 2.8 ± 0.1 days; P = 0.02). There was a statistically significant correlation between preoperative TRAB and postoperative PTH (r =–0.14; P < 0.05). For the 5 patients who underwent reimplantation of at least 1 parathyroid gland, all had hypocalcaemia: definitive hypoparathyroidism – 3; transient hypocalcaemia – 2. Thyroid orbitopathy was present in 30 patients (61%); these patients did not have a higher RR for occurrence of hypocalcaemia (RR = 0.77 [0.5–1.23]), transient hypocalcaemia (RR = 0.8 [0.47–1.39]) or definitive hypoparathyroidism (RR = 0.63 [0.1–4.12])
Conclusion
In this study, we found a high prevalence of postoperative hypocalcaemia and a correlation between postoperative PTH levels and TRAB levels at diagnosis. The reimplantation of at least 1 parathyroid gland predicts high risk for occurrence of hypocalcaemia, since in this sample all patients subjected to this intervention presented transient or definitive hypoparathyroidism. On the other hand, it was not found an association between orbitopathy and calcium-related postoperative complications.

European Registries for Rare Endocrine Conditions (EuRRECa): The use of an e-reporting tool for registering calcium and phosphate conditions

Ana Luisa Priego Zurita[1], Jillian Bryce[2], Salma Rashid Ali[3], Diana-Alexandra Ertl[4], Corinna Grasemann[5], Gabriele Haeusler[4], Lars Rejnmark[6], Faisal Ahmed[1,2,3], Natasha Appelman-Dijkstra[1] & Agnès Linglart[7]
[1]Leids Universitair Medisch Centrum, Department of Medicine, Division of Endocrinology, Leiden, Netherlands; [2]University of Glasgow, Office for Rare Conditions, Glasgow, United Kingdom; [3]University of Glasgow, Developmental Endocrinology Research Group, Royal Hospital for Children, Glasgow, United Kingdom; [4]Medical University of Vienna,

Comprehensive Center for Pediatrics, Department of Pediatrics and Adolescent Medicine, Division of Pediatric Pulmonology, Allergology and Endocrinology, Wien, Austria; [5]Ruhr-Universität Bochum, Department of Pediatrics- Saint Josef-Hospital, Bochum, Germany; [6]Aarhus University, Department of Endocrinology and Internal Medicine, Aarhus, Denmark; [7]Bicetre Hospital AP-HP, Department of Pediatric Endocrinology and Diabetology for Children, Le Kremlin-Bicêtre, France

Introduction
The European Registries for Rare Endocrine Conditions (EuRRECa) project was launched in February 2018 and aims to support the needs of the endocrine and bone community by facilitating the collaboration between patients, health care professionals and researchers across Europe and beyond. It is closely linked to the European Reference Networks on Rare Endocrine Conditions (Endo-ERN) and Rare Bone Diseases (ERN BOND) with its registry EuRR-Bone. EuRRECa is open to all professionals involved in endocrine care, providing two different tools: a core registry that includes new and existing cases and an electronic reporting tool (e-Reporting of Rare Conditions) for newly encountered cases.
Objective
To describe the user community characteristics and the generated data on the Calcium and Phosphate condition group via the electronic reporting tool, e-REC (e-Reporting of Rare Conditions) in the period July 2018 to December 2020.
Methods
Clinicians willing to participate are provided with access to e-Rec and receive invitations to complete a monthly return to report new cases of conditions that are included in Endo-ERN and ERN BOND. e-REC does not collect personally identifiable information and when a case is reported a unique ID is generated and provided to the user to be stored locally at reporting centres.
Results
Between July 2018 and December 2020 a total of 38 centres from 18 different countries reported cases in this condition group. Of these, 26 are Endo-ERN and 11 are ERN BOND members and 16 participate in both. A total of 163 adults and 144 children were newly diagnosed with a Calcium and Phosphate condition. Amongst adults, the most frequently reported conditions were hypoparathyroidism (n = 66), hyperparathyroidism including parathyroid cancer (n = 47) and X-linked hypophosphataemia (n = 13). In children pseudohypoparathyroidism (n = 44), hypoparathyroidism (n = 23) and X-linked hypophosphataemia (n = 27) were the most reported.
Conclusion
The number of centres joining the project and reporting cases continues to grow. e-REC is a promising tool enabling clinical networks to objectively map conditions and related activity. This highlights that genetic disorders are the most frequent cause of calcium and phosphate disturbances in children and provides a better understanding of the occurrence of the rare endocrine and bone conditions. Wide dissemination of the use of the platform is essential.

Skeletal and bone defects in Turner syndrome

Nisrine Bouichrat, Messaoudi Najoua, Marouan Karrou, Ikram Mahroug, Siham Rouf & Hanane Latrech
Mohamed VI University Hospital Center, Oujda, Department of Endocrinology-Diabetology and Nutrition, Oujda, Morocco

Introduction
Turner syndrome is one of the most common chromosomal disorders, with a reported prevalence of 1/2500 live females. It is characterized by short stature, ovarian failure, malformative, autoimmune, skeletal and bone abnormalities. The objective of our work is to study the prevalence of skeletal and bone malformations in our Turnerian patients.
Material and method
This is a retrospective descriptive study realized in 17 patients followed for a Turner syndrome at the Endocrinology-Diabetology and Nutrition Department of the Mohammed VI University Hospital Center of Oujda. The data collected were analyzed using SPSS 25 software.
Résultats
The mean age of diagnosis was 16.4 ± 12.4 years. Shorte stature was the most frequent reason for consultation in 47% of cases, followed by amenorrhea in 35.3%. Statural retardation was present in all patients, with short legs in 47.1%. Kyphosis was reported in 5.8% of cases with erosions on the anterior surfaces of the vertebrae and layered cervical vertebral compression on MRI, scoliosis in 11.7% and bradymetacarpia in 5.8% of cases. Vitamin D deficiency was objectively diagnosed in all patients with a mean of 18.9 ± 7.2 ng/ml. Osteoporosis (spine and femurs) was observed in 17.6% of cases in patients diagnosed in adulthood with primary amenorrhea not substituted on the hormonal level.
Discussion-conclusion
Skeletal and bone deformities are common during turner syndrome. Osteoporosis is still a real problem with its high fracture risk, hence the importance of early hormonal replacement, adequate intake of calcium products and correction of vitamin D deficiency.

AEP118

A retrospective review of the management of skeletal effects following thyroid stimulating hormone suppression therapy (tshst) in patients treated for differentiated thyroid carcinoma (dtc)

Deepa Beeharry[1], Simra Ahmed & Dushyant Sharma[2]
[1]Liverpool University Hospital NHS Foundation Trust, Diabetes and Endocrinology, Liverpool, United Kingdom; [2]University Of Liverpool, Medical School, Liverpool, United Kingdom

Background
Thyrotropin Stimulating Hormone Suppression Therapy (TSHST) in Differentiated Thyroid cancer (DTC) patients can result in reduced bone mineral density (BMD) which is a potential serious problem [1]. Studies on the effects of TSHST on BMD have demonstrated conflicting results [2–5]. There is insufficient guidance regarding the degree and duration of TSHST in the context of skeletal effects despite multiple existing guidelines.
Aim
To conduct a retrospective review of the current management of the skeletal effects of DTC patients against current guidelines.
Methods
Data was collected on patients with DTC on TSHST from the Liverpool University Hospital database in the last 15 years.
Results
73% (45/62) of patients with DTC aged between 21 to 85 years were included in the study. 42% (19/45) including 5 men, 4 pre-menopausal women and 10 postmenopausal women had at least one DEXA scan whereas 58% (26/45) had no DEXA. Only 31.6% (6/19) had two or more DEXA scans. Average time from starting TSHST to first DEXA was 4.5 years (SD 4.5). 60% (6/10) of patients within 12 months of surgery and radioiodine treatment had a recorded TSH level with only 50% (3/6) having a TSH level < 0.1 mu/l as recommended by the British Thyroid Association(BTA)[6]. All pre-menopausal women had a single normal DEXA with 75% (3/4) on vitamin D. All men had osteopenia with 66.7% (2/3) showing optimal vitamin D levels on replacement and 1/3 with inadequate levels. 40% of post-menopausal women with osteopenia were on vitamin D and 10% with osteoporosis on bisphosphonates. 50% (5/10) of post-menopausal women had TSH levels of < 0.05 for > 5 years (average 12.8 years, SD 1.1) but no documented FRAX as recommended by BTA[6]. A retrospective risk stratification using the Sheffield Fracture Risk Assessment (FRAX) tool [7] showed the average risk of a major and hip fracture in post-menopausal women was higher at 10.6% and 2.4% respectively compared to 5.1% and 1.5% in men. 22.2% (2/9) of post-menopausal women met the treatment threshold.
Conclusion
This study highlights important factors in the surveillance and management of skeletal effects. Achieving optimal TSH suppression and monitoring long-term skeletal effects of TSHST would be more effectively achieved by establishing local protocols specifying frequency of blood tests (thyroid function test, vitamin D levels), individual target TSH ranges and introducing the FRAX tool. This would identify at risk patients, determine timing of DEXA scans and guide treatment in the appropriate age group.

Interest of the 'single photon emission tomography computed tomography' in an atypical location of a parathyroid adenoma

Mohamed Masmoudi[1], Mehdi Hasnaoui[1], Rihab Lahmar[1], Rihab Guizani[1,2] & Mighri Khalifa[2]
[1]Tahar Sfar Hospital mahdia, ENT department, mahdia, Tunisia; [2]Tahar Sfar Hospital Mahdia, ENT department, Sfax, Tunisia

Objective
Illustrate the interest of imaging: Single photo emission tomography or Computed tomography in the topographic diagnosis of parathyroid adenomas.
Observation
A 67-year-old man, with renal lithiasis presenting a clinical-biological picture of primary hyperparathyroidism with renal bone and colic pain. PTH was 463.2 pg/ml, calcemia 3.4 mmol/l. Cervical ultrasound objectified a lesion suspected of parathyroid adenoma. A first scan objectified a hyperfixative focus that projects against the lower pole of the thyroid.The patient had surgery. No post-operative problem were referred. We noted a persistence of elevated serum PTH and calcemia values. Pathology examination found a benign thyroid nodule. A SPECT/CT was then performed objecting a hyperfixative focal spot whose scanno-scintigraphic configuration corresponds to a very posterior nodular formation of 20 mm right lateral-esophageal and prevalent at D2. The diagnosis of atypical parathyroid localization was retained. The patient had a surgical revision with a right lower parathyroid adenoma of 30 * 20 mm near the pre-vertebral plan. Post-operative outcomes were simple with clinical improvement and normalization of biological numbers.
Conclusion
The SPECT/CT plays a decisive role in the management of patients with persistent or recurrent hyperparathyroidism. It is most often used to visualize atypical parathyroid adenomas and to guide the surgeon.

AEP120

An unusual case of primary hyperparathyroidism due to hyperplasia resembling tertiary hyperparathyroidism

Michele Mantega[1], Abdul Mateen[1], Sultana Azam[1], Bhavna Sharma[1], Shivashankar Seechurn[1], Denis Remedios[1], Mufaddal Moonim[2], Aimee DiMarco[2] & Mushtaqur Rahman[1]
[1]Northwick Park Hospital, United Kingdom; [2]Hammersmith Hospital, United Kingdom

Primary hyperparathyroidism is a common endocrine condition; 80% due to a parathyroid adenoma. We present an unusual case of a 69-year old white European female, who presented first in 2012 with mild hypercalcaemia (< 2.8 mmol/l), osteoporosis, hypertension and type 2 diabetes. Pharmacotherapy included Bendroflumethiazide, but no phosphate supplements. Investigations revealed primary hyperparathyroidism and dual-modality scanning showed no evidence of an adenoma, although hyperplasia was suggested on ultrasound. Molecular analysis showed no CASR mutation, making familial hypocalciuric hypercalcaemia unlikely. She was discharged to follow-up in primary care with advice to refer if the plasma adjusted calcium was above 2.9 mmol/l consistently, which was the practice prior to UK NICE 2019 guidance. There had been no other change to her health; she had normal vitamin D level without supplementation and no renal disease. She presented 8 years later with severe hypercalcaemia (peak plasma adjusted calcium 3.5 mmol/l), but with few symptoms. Plasma PTH was 30 pmol/l and the concern was of malignant transformation. Treatment included IV 0.9% sodium chloride, sc calcitonin, IV pamidronate and then PO cinacalcet; the thiazide was stopped. The hypercalcaemia was fairly resistant to cinacalcet, which she found difficult to tolerate. Dual modality imaging showed similar findings for the Sestamibi scan to the previous scan: no tracer retention to suggest an adenoma. The ultrasound scan showed evidence of thyroiditis on the right and possible right inferior parathyroid adenoma. She underwent four-gland exploration which was complicated by a severe nodular thyroiditis but demonstrated significant enlargement of the left superior (2 g) and right inferior (1 g) parathyroids (both excised) and a normal left inferior parathyroid. Histological features were more consistent with hyperplasia than adenoma and with features seen in tertiary hyperparathyroidism. The patient's biochemistry normalised postoperatively. This case illustrates an unusual progression of primary hyperparathyroidism hyperplasia progressing to more autonomous parathyroid hormone production. The histopathology would be seen usually in tertiary hyperparathyroidism associated with severe nephropathy, but this patient had normal renal function. This progress can also be seen in secondary hyperparathyroidism due to chronic hypovitaminosis D, but our patient was vitamin D replete. Thiazide-associated hypercalcaemia tends to be seen in older females and persists after drug withdrawal. We may speculate whether the lack of response to cinacalcet points to thiazide-associated renal PTH resistance, leading to increased PTH and promotion of hyperplasia; but the association of thiazides with hyperparathyroidism is inconsistent, some studies showing no effect on PTH levels.

The endocrine effects of lithium treatment. Report of a case

Ifigenia Kostoglou-Athanassiou[1], Georgios Giannopoulos[2], Lambros Athanassiou[3], Alexandros Nomikos[4], Athanasios Fortis[5] & Thomais Kalogirou[5]
[1]Asclepeion Hospital, Voula, Department of Endocrinology, Athens, Greece; [2]Asclepeion Hospital, Voula, Second Department of Surgery, Athens, Greece; [3]Asclepeion Hospital, Voula, Department of Rheumatology, Athens, Greece; [4]Asclepeion Hospital, Voula, Department of Pathology, Athens, Greece; [5]Asclepeion Hospital, Voula, Second Department of Medicine, Athens, Greece

Lithium is considered a mainstay treatment option for the management of bipolar affective disorder. However, lithium administration is characterized by endocrine effects. The aim was to present the case of a patient who was on treatment with lithium for many years for the management of bipolar affective disorder and presented with a large parathyroid adenoma causing clinical hyperparathyroidism with severe hypercalcemia who was successfully treated by surgical excision of the adenoma and hypothyroidism. A patient, aged 68 years, presented with severe hypercalcemia, calcium levels on admission 13 mg/dl and difficulty in walking due to osteoporosis. PTH levels on admission were 300 pg/ml. After rehydration and diuretic treatment for the management of hypercalcemia, cinacalcet was administered at a dose of 30 mg twice daily for the management of hypercalcemia. Diagnostic evaluation revealed the presence of a large parathyroid adenoma situated inferiorly to the left thyroid lobe. Surgical treatment was undertaken and the parathyroid adenoma was successfully excised. Histology revealed a large cystic parathyroid adenoma. During follow up calcium levels normalised and the patient improved clinically. During follow up a TSH level of 6.7 mIU/l was noted. Thyroxine was administered. Lithium administration for the management of bipolar affective disorder is used successfully for many years. However, it may cause many endocrine effects. It may cause hypothyroidism and hypercalcemia due to hyperparathyroidism. Hypothyroidism is easily managed by thyroxine administration. However, hyperparathyroidism is usually due to one or more parathyroid adenomas or parathyroid hyperplasia. The optimum management of parathyroid adenomas in the case of long-term lithium treatment is surgical and usually controls hyperparathyroidism. In other reports most cases of hyperparathyroidism in the context of lithium treatment were due to one or more parathyroid adenomas. In conclusion, the case of a patient presenting with endocrine disease, namely primary hyperparathyroidism and hypothyroidism due to long term lithium administration is described. The disease was successfully treated with surgical excision of the parathyroid adenoma and thyroxine administration.

Ectopic parathyroid adenomas: where to find them?

Mahin Reza, Solat Hasnain, Christo Albor, Ayaz Hussain, Hassan Ibrahim & Jawad Bashir
Basildon University Hospital, Basildon, United Kingdom

Hypercalcaemia due to primary hyperparathyroidism (PHPTH) is fully curable by parathyroidectomy. Occasionally recurrent hypercalcemia presents as a results of either residual adenoma, recurrent disease or an ectopic parathyroid gland. The most challenging cases are those with ectopic glands which are not identified on usual surgical neck exploration. We present a similar case that went through multiple surgeries for recurrent hypercalcemia. A 79-year-old lady initially was diagnosed as primary hyperparathyroidism (in 2009) with symptomatic hypercalcaemia (2.84–3.0 mmol/l) and raised PTH (8.8–11 pmol/l). Multiple parathyroid imaging modalities (CT scan neck, SESTAMIBI and Ultrasound) failed to identify any adenoma. She underwent first surgical exploration in 2010 and three parathyroid glands were removed (both right glands and left superior gland). One gland was suspected to be adenoma. Histology confirmed hyperplastic parathyroid glands. Postoperative biochemistry didn't normalise and she continued to have persistent primary hyperparathyroidism (Corrected calcium = 2.79 mmol/l, PTH = 10.3 pmol/l). She had osteoporotic wrist fracture. Further imaging to identify parathyroid adenoma was done (CT scan neck and chest with contrast) in 2012. No adenoma was identified again and the plan was to proceed with another surgical neck exploration in 2012. The residual hyperplastic parathyroid left inferior parathyroid gland could not be located and PHPTH was not resolved postoperatively (Corrected calcium = 2.66 mmol/l, PTH = 8pmol/l, Vitamin D of 20 nmol/l). Due to low vitamin D levels, it was thought to be mild secondary hyperparathyroidism.

Low dose Cholecalciferol was advised to prevent further growth of the remaining hyperplastic gland and subsequent end organ damage. Vitamin D repletion failed to correct the Calcium (2.6–2.8 mmol/l) and PTH levels (9–10 pmol/l). In view of symptomatic hypercalcaemia with ongoing end organ damage it was decided to reimage her with newer modalities and explore for ectopic mediastinal parathyroid adenoma. 4D CT scan identified an ectopic parathyroid adenoma in the left trachea-oesophageal groove posterior and inferior to the lower pole of the left lobe of thyroid gland. A 3rd neck exploration in 2020 successfully excised the ectopic parathyroid tissue which was confirmed to be adenoma on histology. The biochemistry was normalised (Ca 2.24 mmol/l, PTH 2.8 pmol/l) and her symptoms settled. The ectopic parathyroid adenomas (3–4% of all parathyroid adenomas) occur as a result of embryonic migration during foetal development. The actual prevalence of mediastinal parathyroid adenomas is unrecognized but it ranges from 6–30%. Surgical neck exploration can be facilitated by use of modern imaging techniques like 4D CT scan (sensitivity = 96.7%, specificity = 95.7%) to identify ectopic parathyroid glands.

Prevalence, characteristics, and associated factors of Fahr's syndrome in permanent hypoparathyroidism

Faten Cherchir[1], Ibtissem Oueslati[1], Meriem Yazidi[1], Seif Boukriba[2], Fatma Chaker[1], Habiba Mizouni[1] & Melika Chihaoui[1]
[1]La Rabta hospital, university of Tunis El Manar, Faculty of medicine, Endocrinology, Tunis, Tunisia; [2]La Rabta hospital, university of Tunis El Manar, Faculty of medicine, Radiology, Tunis, Tunisia

Introduction
Fahr's syndrome (FS) is a rare neurodegenerative disorder. It's characterized by abnormal calcifications in basal ganglia and cerebral cortex inducing neuropsychiatric disorders and cognitive impairment. The aim of our study was to assess the prevalence of FS, its characteristics, and its associated factors in patients with permanent hypoparathyroidism.
Methods
We conducted a cross-sectional study including 38 patients with chronic hypoparathyroidism. A brain computed tomography scan was performed to all participants. Clinical and biological data were collected. The adherence to treatment was evaluated using Girerd adherence scale.
Results
There were 30 (82%) women and 8 (20%) men with a mean age of 53 ± 15.9 years. Neck surgery was the most frequent etiology of chronic hypoparathyroidism (66%). FS was diagnosed in 40% of cases (n = 15) with a sex-ratio of 2.75. Clinical manifestations included amnestic disorders, depressive mood, psychotic symptoms, tetany crisis and seizures in 80, 47, 27, 27, and 20% of cases, respectively. Brain CT-scan showed bilateral intracerebral calcifications located in the central gray nuclei (67%) or diffuse symmetric calcifications (33%). The prevalence of FS increased with the duration of hypoparathyroidism (P = 0.048) and decreased with the patient age at the diagnosis (P = 0.028). Amnestic disorders (Odds Ratio = 5.143, P = 0.043), poor adherence to treatment (Odds Ratio = 6, $P < 10^{-3}$), and hypomagnesemia (Odds Ratio = 98, $P < 10^{-3}$) were positively associated with FS. However, calcium level, PTH level, and coexisting vitamin D deficiency were not associated with FS.
Conclusion
Patients with chronic hypoparathyroidism are most likely to develop intracranial calcifications because of phosphocalcic metabolism disorders and blood-brain barrier alteration, leading to various neuropsychiatric manifestations. This study highlights the importance of adequate treatment and medication adherence to prevent Fahr's syndrome.

The natural history of hypoparathyroidism according to the database of endocrinology research centre

Elena Kovaleva[1], Anna Eremkina[1], Alina Aynetdinova[1] & Natalia Mokrysheva[2]
[1]Endocrinology Research centre, Department of Parathyroid Disorders, Moscow, Russian Federation; [2]Endocrinology Research centre, Director, Moscow, Russian Federation

Background
Hypoparathyroidism is a rare disorder characterized by hypocalcemia and hyperphosphatemia due to absent or inadequate parathyroid hormone secretion. Data on effective treatment strategies and predictors of long-term complications have only recently began to emerge. The epidemiological information regarding chronic hypoparathyroidism in Russia is strictly limited that prompted this research.
Aims
To estimate the clinical course, demographic features and treatment regimes in patients with chronic postsurgical and nonsurgical hypoparathyroidism.
Materials and methods
The database of patients with chronic postsurgical and nonsurgical hypoparathyroidism from Endocrinology Research Centre was used for retrospective analysis. The study included 357 patients from 61 regions of the Russian Federation. The descriptive statistics are presented by medians (Me) and the first and third quartiles (Q1; Q3) and by absolute and relative frequencies.
Results
Hypoparathyroidism was most frequent in women (85.4%) at the age of 43 [32; 52] years. The prevalence of chronic postsurgical hypoparathyroidism was 86%, most often it occurs after thyroid surgery, especially because of thyroid carcinoma and multinodular goiter. In a subanalysis of patients who underwent thyroid surgery hemi- and thyroidectomy were noted in 7% and 93% respectively. Nonsurgical hypoparathyroidism was registered in 14% of patients (n = 50: idiopathic (28), autoimmune (13) and other genetic form of disease (9) with. Less than a half of the study group had target indicators of serum calcium and phosphate levels (32% and 47%, respectively) despite ongoing treatment. Among the disease complications, kidney disorders were detected in 38%, visual disturbance in 14%, brain calcification in 6%, arrhythmias in 7% and neuropsychiatric symptoms in 8%. Conventional therapy with calcium supplements and activated vitamin D analogues was noted in 71% of patients. The mean dose of calcium supplements was 1837 mg/day (per elemental calcium) and 1.74 mg/day for alfacalcidol.
Conclusions
This study represents one of the first large-scale epidemiological assessments of chronic postsurgical and nonsurgical hypoparathyroidism in Russian Federation. Longitudinal prospective studies are necessary to permit a better understanding of the clinical manifestations, short- and long-term complications, and therapeutic approaches of disease. Being aware of our current management of this rare disease is the first step to improving our clinical approach in the future.

Summer sunshine exposure and vitamin d status in young and middle age poles: is 30 ng/ml Vitamin D cut-off really suitable for the polish population?

Magdalena Basinska-Lewandowska[1], Andrzej Lewinski[2,3], Wojciech Horzelski[4] & Elzbieta Skowronska-Jozwiak[2,3]
[1]'Your Family Doctor', General Practice Surgery, Lodz, Poland; [2]The Medical University of Lodz, Department of Endocrinology & Metabolic Diseases, Łódź, Poland; [3]'Polish Mother's' Memorial Hospital Research Institute, Department of Endocrinology & Metabolic Diseases, Łódź, Poland; [4]The University of Lodz, Department of Mathematics & Computer Science, Lodz, Poland

Background
There is no universal consensus regarding vitamin sufficiency status with values either above 20 ng/ml, or 30 ng/ml being quoted as denoting 'sufficient' status. We have endeavoured to assess the effects of summer sunshine exposure on vitamin D status from a single GP practice in central Poland.
Subjects and methods
We measured concentrations of vitamin D, parathyroid hormone (PTH), creatinine and total calcium in 132 subjects (56 males), age 29.36 ± 13.57 years (range 6–50 years), BMI 25.32 ± 6.33 kg/m^2 in spring and subsequently in autumn (n = 125).
Results
There was an overall increase in vitamin D concentrations from 18.1 ± 7.39 ng/ml to 24.58 ± 7.72 ng/ml, $P < 0.001$, accompanied by a decrease in PTH from 44.4 ± 17.76 pg/ml to 36.6 ± 14.84 pg/ml, $P < 0.001$, without significant change in calcium concentrations (P = 0.65). Vitamin D concentrations were lower in spring in males (16.5 ± 6.82 ng/ml vs 19.38 ± 7.62 ng/ml, P = 0.02, for males & females, respectively), but these sex differences became insignificant in autumn (23.8 ± 7.11 ng/ml vs 25.36 ± 8.1 ng/ml, P = 0.24). In spring only 5.3% were vitamin D

sufficient for a 30 ng/ml cut-off, with an increase to 23.2% in autumn, $P < 0.001$. In contrast, where a 20 ng/ml cut-off was employed, then vitamin D sufficiency was found in 34.1% in spring and in 66.4% individuals in autumn, respectively, $P < 0.001$. Correspondingly, vitamin D deficiency was noted in 62.1% and 29.6%, $P < 0.001$ (spring vs autumn), for a 20 ng/ml cut-off, but only in 17.4% (spring) and 2.4% (autumn), $P < 0.001$ for a 12 ng/ml vitamin D cut-off. In multivariate analysis neither BMI, nor age were important determinants of summer vitamin D increase, if at least two week period of holiday leave was taken into account ($P < 0.001$).
Conclusions
Holiday leave for at least two weeks is the strongest determinant of an increase in vitamin D concentrations. If the majority of healthy individuals fail to reach a 30 ng/ml vitamin D cut-off after summer sunshine exposure, then this raises the question, whether such cut-off is too high, and a 20 ng/ml vitamin D sufficiency cut-off should be universally employed.

AEP126

How frequent is vitamin D toxicity? Data from the national survey of endocrinologists in Russia

Ekaterina Pigarova[1,2], Alexandra Povaliaeva[2], Artem Yu. Zhukov[2], Valentina Glazieva[3], Larisa Dzeranova[1,2], Liudmila Rozhinskaya[1], Eugenia Marova[1], Irina Belovalova[4] & Ivan Dedov[4]
[1]Endocrinology Research Centre, Neuroendocrinology and bone diseases, Moscow, Russian Federation; [2]Endocrinology Research Centre, Institute of education, Moscow, Russian Federation; [3]Moscow State University, Moscow, Russian Federation; [4]Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Clinical guidelines for the prevention and treatment of vitamin D deficiency in adults were formulated and implemented into clinical practice by the Russian association of endocrinologists in 2014. While having multiple health benefits, in some cases, prescribing vitamin D supplements may be accompanied by its toxicity, which has various manifestations and exert potentially dangerous health consequences.
Aim
To study the frequency and key features of vitamin D toxicity in 'real-life' clinical practice settings.
Materials and methods
710 healthcare professionals took part in an online survey in January 2021. Endocrinologists accounted for 79% of respondents while 21% of survey participants were doctors of other specialties, 94% were women, all age groups from 20 to 65 + years old were presented nearly equally.
Results
16.2% of interviewed doctors had met with a toxicity of vitamin D: once – 42%, twice – 25.2%, three times – 21% and 11.8% reported 4 or more cases over the course of their clinical practice. The most common reasons for toxicity of vitamin D were the intake of an increased doses of colecalciferol initiated by the patient (58.3%) or by the doctor (36%), as well as the intake of active metabolites of vitamin D (24%). Somewhat less often, doctors observed an overdose due to an inaccuracy in the drug concentration indicated by the manufacturer (the actual was higher than stated) – in 22.3%. Least often, doctors met with an overdose due to a genetic defect of CYP24ñ1 (11.4%), granulomatous (sarcoidosis, histiocytosis, tuberculosis, etc.) (8%) or lymphoproliferative diseases (4.6%). About 70% of doctors always refer for a blood calcium evaluation along with 25(OH)D, 77.2% also check parathyroid hormone levels and 24% – calcium levels in 24 h urine.
Conclusions
Endocrinologists are often faced with an overdose of vitamin D. Particular care should be taken when prescribing high doses of colecalciferol or active metabolites/analogues of vitamin D without regular monitoring of the parameters of calcium-phosphorus metabolism, as well as when patients take them on their own.

Large parathyroid adenomas: unusual clinical characteristics

Anastasia-Konstantina Sakali[1], Christos Bagias[2], Pinelopi Thoda[1], Eleftheria Mparmpa[1], Dimitra Pappa[1], Eleni Georgiou[1], Ioannis Gountios[1], Stelios Tigas[2] & Alexandra Bargiota[1]
[1]University Hospital of Larissa, Department of Endocrinology, Metabolism and Diabetes, Larissa, Greece; [2]University Hospital of Ioannina, Department of Endocrinology, Ioannina, Greece

Introduction
The differential diagnosis between benign and malignant parathyroid neoplasms may be challenging and should always be based on clinical and histological criteria. We are presenting a case series of three patients with clinical, biochemical and imaging findings supporting the presence of a malignant neoplasm but histological findings confirming the diagnosis of a parathyroid adenoma.
Case 1
A 24-year-old man presented with acute pyelonephritis in the presence of obstructive urinary tract calculi of the right kidney. Laboratory examination was indicative of primary hyperparathyroidism (PHPT) (Total Ca = 17mg/dl, PTH = 1000 pg/ml). Parathyroid ultrasound imaging demonstrated a 3 cm tumor under the left lobe of the thyroid gland. Plain radiographs revealed the presence of multiple osteolytic lesions in the humeri, femurs and pelvic bones, as well as subperiosteal bone resorption of the finger phalanges of the hand.
Case 2
A 32-year-old woman was admitted in the ICU due to acute pyelonephritis and sepsis in the presence of obstructive urolithiasis of the right kidney. Laboratory examination was indicative of PHPT (Total Ca = 13.5mg/dl, PTH = 1500 pg/ml). Parathyroid ultrasound imaging demonstrated a 6.5 cm tumor under the right lobe of the thyroid gland. Plain radiographs revealed the presence of pepper pot appearance of the skull, subperiosteal resorption in the middle phalanges of the second finger of the hands as well as the appearance of floating tooth syndrome.
Case 3
A 52-year-old woman presented with bilateral urolithiasis and laboratory results indicative of PHPT (Total Ca = 13mg/dl, PTH = 504 pg/ml). She had a history of parathyroidectomy of 2.5 hyperplastic parathyroid adenomas and was receiving treatment with cinacalcet due to persistent hypocalcaemia. CT imaging revealed the presence of a 5 cm tumor in the mediastinum originating from the right inferior parathyroid gland. Plain radiographs revealed the presence of brown tumors in the right femur and ilium. All three patients underwent surgical removal of the parathyroid tumors and histopathological examination confirmed the presence of parathyroid adenomas. In all cases, postsurgical PTH concentrations returned to normal range, while the patients developed hungry bone syndrome and were offered calcium and alfacalcidol supplementation.
Conclusion
Large parathyroid adenomas may present with severe clinical manifestations such as osteitis fibrosa cystica, severe urolithiasis, as well as extremely high PTH and calcium concentrations, even in young-aged patients. Since the biological behavior of such adenomas is not definite, long-term surveillance is essential.

COVID-19 and impaired calcium metabolism upon admission to the hospital

Irina Maganeva, Anna Eremkina, Ekaterina Bibik, Anna Gorbacheva, Elena Kovaleva, Alina Aynetdinova & Natalia Mokrysheva
Endocrinology Research Center, Moscow, Russian Federation

Introduction
There is evidence of the interaction between the main parameters of calcium-phosphorus metabolism, vitamin D and the course of a new coronavirus infection. Moreover, hypocalcemia is one of the most frequent biochemical disorders and is associated with severity of the disease, increased likelihood of hospitalization, need for mechanical ventilation, and poor prognosis in COVID-19.
Objective
To estimate the main parameters of calcium-phosphorus metabolism in patients with COVID-19 upon admission to our hospital.
Material and methods
A single-center study was carried out at the Endocrinology Research Centre, Moscow. We included 60 patients (aged ≥ 18 years) with acute respiratory infectious diseases related to COVID-19 (CoV). Baseline biochemical investigations, including serum calcium, phosphate, albumin, 25-hydroxyvitamin D, parathormone, as well as instrumental assessment of the COVID-19 severity were performed before any specific immunotherapy. Statistical analysis was conducted with Statistica 13 (<<StatSoft>>, USA). A p-value of < 0.05 was considered statistically significant.
Results
The prevalence of hypocalcemia (for albumin-adjusted calcium (Ca_{adj}) < 2.15 mmol/l) and vitamin D deficiency (< 20 ng/ml) was 36.7 and

86.7%, respectively. Lower saturation (SpO2) was observed in patients with the lowest Ca_{adj} (P = 0.002) and 25(OH) D levels (P = 0.001). Moreover, lower Ca_{adj} was related to lower values of SpO2 (OR 12 725.213, 95% CI 2.661–60 863.931.6) and vice versa Ca_{adj} > 2.17 mmol/l was associated with SpO2 > 93% with a probability of 71–92%. In addition, there were no associations between total and albumin-adjusted calcium levels and 25(OH) vitamin D (p1 = 0.061 and p2 = 0.339, respectively). Patients with severe COVID-19 pneumonia (computer tomography (CT) scan grade 3–4) compared with those with less grades (CT 1—2) had significantly lower total Ca and albumin (P < 0.001 for all). In 11.6% of cases, the level of 25(OH)vitamin D was less than 5 ng/ml. Decreased vitamin D levels were associated with higher CRP values (OR 0.892, 95% CI 0.8—0.995) and lower SpO2 (OR 1.227, 95% CI 1.028—1.465). Patients with normal and increased (10 pg/ml or more) IL-6 levels have significant differences in total calcium (2.25 [2.18; 2.38] mmol/l vs 2.15 [2.07; 2.23] mmol/l; P < 0.001) and albumin (44.5 [42; 47] g/l vs 39, 5 [36; 42] g/l; P < 0.001) concentrations.
Conclusion
The hypocalcemia and vitamin D deficiency are highly prevalent in patients with severe course of COVID-19 with the need for hospitalization. Further research is required to determine the impact of impaired calcium-phosphorus metabolism on COVID-19 to develop the optimal therapeutic strategies.

CDC73 associated primary hyperparathyroidism and essential tremor

Eliška Svobodová[1], Pavla Rehorkova[2], Josef Vcelak[3], Jitka Moravcova[3], Barbora Havlinova[1], Filip Gabalec[1] & Jan Cap[1]
[1]University Hospital Hradec Kralove, The 4th Department of Internal Medicine – Hematology, Hradec Králové, Czech Republic; [2]Parendo, Hradec Králové, Czech Republic; [3]Institute of Endocrinology, Prague, Czech Republic

Objective
Primary hyperparathyroidism (PHPT) is a common endocrine disorder affecting 2% of the population aged 55 years or older. Primary hyperparathyroidism is due to parathyroid adenoma in about 85% of cases, parathyroid hyperplasia in about 15% of cases, and parathyroid carcinoma in less than 1% of cases. Familial parathyroid disorders are responsible for 10% of the PHPT cases and include among other disorders caused by parafibromin malfunction. Parafibromin is a tumour-suppressor protein that regulates apoptosis, cell-cycle transition, grow factor gene expression and tumour-associated wingless-type (Wnt) pathway. The loss of parafibromin tumour-suppressor function is associated with parathyroid tumours. Parafibromin is coded by gene CDC73 (cell division cycle 73, previously HRPT2). Immunohistochemical assay of parafibromin has limited validity, therefore it is recommended molecular-genetic analysis of the gene CDC73. The spectrum of disorders associated with mutations of the gene CDC73 includes such phenotypes: HPT-JT syndrome (hyperparathyroidism-jaw tumor syndrome), isolated familial hyperparathyroidism and parathyroid carcinomas. Here, we are presenting a case of a family with primary hyperparathyroidism, which was manifested by adenomas of the parathyroid gland for most members of the family. Associated comorbidity in 4 members of the family was an essential tremor.
Methods
Molecular-genetic analysis of 17 genes from DNA obtained from peripheral blood leukocytes (Parathyroid NGS panel, Endocrinological institute): AIP; AIRE; AP2S1; CASR; CDC73; CDKN1A; CDKN1B; CDKN2B; CDKN2C; GATA3; GCM1; GCM2; GNA11; MEN1; PTH; RET; STX16 and then examination of segregation of causal mutation in 14 family members (3 generations).
Results
Causal mutation of the gene CDC73 was detected. It is a deletion of 4 nucleotides NM_02 4529.4:c.520_523delTCTG; p.(Ser174LysfsTer27) in 7th exon, which causes premature stop of parafibromin synthesis in 200th amino acid.
Conclusion
Disorders associated with CDC73 are autosomal dominant inherited. The mutation is inherited from the affected parent with a 50% probability or arises de novo. Patients with CDC73 associated disease should be observed by an endocrinologist in regular terms. It includes an annual examination of PTH and calcium levels, dental examination and periodic ultrasound of the pelvis and kidneys.

The benign course of MEN I disease. Implications for treatment

Lambros Athanassiou[1], Ifigenia Kostoglou-Athanassiou[2], Panagiotis Spyropoulos[3], Eleni Xanthakou[4], Olga Mascha[5], Athanasios Fortis[6], Thomais Kalogirou[6] & Panagiotis Athanassiou[7]
[1]Asclepeion Hospital, Voula, Covid-19 Department, Athens, Greece; [2]Asclepeion Hospital, Voula, Department of Endocrinology, Athens, Greece; [3]Endocrinologist, Athens, Greece; [4]Endocrinologist, Sparti, Greece; [5]Asclepeion Hospital, Voula, Department of Biochemistry, Athens, Greece; [6]Asclepeion Hospital, Voula, Second Department of Medicine, Athens, Greece; [7]Saint Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece

MEN (multiple endocrine neoplasia) I disease represents a compilation of multiple endocrine neoplasms affecting a patient in the course of a life-time. It thus represents a phenotype which has survived over many years. Pituitary neoplasms, lipomas and parathyroid hyperplasia are observed in the disease. The aim was to describe a patient with MEN I disease who presented with lipomas and acromegaly in his early adulthood and developed primary hyperparathyroidism in his senior years. A patient presented with lipomas at the age of 35 years. At the age of 36 years acromegaly was diagnosed as the patient had increased perspiration, weight gain, increased growth of his hands and feet and headaches. A diagnostic evaluation revealed the presence of acromegaly due to a pituitary tumor in the left side of the pituitary gland. The pituitary tumor was excised transsphenoidally. Following the surgical removal of the pituitary adenoma the patient improved dramatically and lost 10 kg of weight within a few weeks. Thirty-six years later a thyroid ultrasound was performed which showed a nodule inferior to the left thyroid lobe. A diagnostic evaluation revealed increased PTH levels 76 pg/ml, mildly elevated blood calcium levels 10.1 mg/dl and normal 24 h urinary calcium levels. Bone mineral density was normal. An abdominal ultrasound was performed which did not reveal the presence of kidney stones. The diagnosis of mild hyperparathyroidism was made. Conservative management was decided. MEN I disease is a genetic disease which has been transmitted in families allowing the survival of the patients and the genotype and corresponding phenotype. Moreover, primary hyperparathyroidism in the case of MEN I is due to parathyroid hyperplasia. Additionally, some of the tumors present in MEN I patients may be completely silent for many years. It is therefore proposed that the management of hyperparathyroidism should preferably be conservative as it is due to parathyroid hyperplasia and may be mild. Hence, surgical removal, if decided should lead to the excision of more than one parathyroid glands. Additionally, complete removal of the parathyroid glands leads to hypoparathyroidism, a disease known for its notoriously difficult management. Thus, in the management of tumors diagnosed in the course of MEN I conservative management should be considered, if clinical findings are mild and the tumor does not cause obstructive or other size related manifestations.

Hypercalciuria and associated mineral metabolism disorders in osteopenic/osteoporotic patients: effects of treatment with thiazide diuretics

Federico Nicoli[1], Giorgia Dito[2], Gregorio Guabello[3], Matteo Longhi[3] & Sabrina Corbetta[4]
[1]Endocrinology and Diabetology Service, IRCCS Istituto Ortopedico Galeazzi, Department of of Biotechnology and Translational Medicine, University of Milan, Milan, Italy; [2]Endocrinology and Diabetology Service, IRCCS Istituto Ortopedico Galeazzi, Milan, Italy; [3]Rheumatology Unit, IRCCS Istituto Ortopedico Galeazzi, Milan, Italy; [4]Endocrinology and Diabetology Service, IRCCS Istituto Ortopedico Galeazzi, Department of Biomedical, Surgical and Dental Sciences, University of Milan, Milan, Italy

Hypercalciuria may represent a challenge during the workup for osteoporosis management. The present study aimed: 1) to describe the phenotype associated with hypercalciuria in vitamin D-repleted (serum 25OHD > 20 ng/ml) osteopenic/osteoporotic patients, focusing on kidney, bone and mineral metabolic features; 2) to analyze the effects of thiazides and anti-resorptive drugs on urine calcium excretion (UCa) and mineral metabolism markers. Seventy patients (67 postmenopausal females; mean ± SD age 63.5 ± 7.8 years)

with hypercalciuria (UCa > 4.0 mg/kg body weight/24 h on two determinations) were retrospectively enrolled in a real-world setting. Median (interquartile range) UCa was 5.25 (4.60–6.50) mg/kg/24 h. Kidney stones occurred anamnestically/by imaging in 28% of patients, whose UCa was similar to that of patients without kidney stones [5.2 (4.4, 6.7) vs 5.2 (4.6, 6.5) mg/kg/24 h]. By means of bone densitometry scan (n = 66), osteoporosis was diagnosed in 65% of patients at lumbar site and in 45% at femour site; 50% of patients experienced at least one fragility fracture. Clustering analysis considering the 3 correlated variables serum calcium, phosphate and PTH, identified 3 clusters of hypercalciuric patients: cluster 1 (n = 27) included patients with normal mineral profile, cluster 2 (n = 33) included patients with relatively elevated PTH, normocalcemia and normophosphatemia, resembling normocalcemic hyperparathyroidism, while cluster 3 (n = 10) included patients with a primary hyperparathyroidism-like profile, suggesting a certain degree of autonomous PTH secretion from parathyroid glands. After a follow up of 2.2 ± 1.3 years, 56 patients were reevaluated; 40 patients were treated with thiazides (13 with hydrochlorothiazide, 27 with indapamide). Concomitant therapies were: bisphophonates (n = 12), denosumab (n = 14), calcium salts (n = 15). Thiazides induced a mean 41% reduction in UCa and 64% of patients obtained UCa < 4.0 mg/kg/24 h. Hydrochlorothiazide and indapamide reduced UCa at a similar extent (–2.3 ± 0.9 vs –2.6 ± 1.2 mg/kg/24 h). Multiple logistic regression analysis showed that: 1) thiazides induced a consistent UCa reduction (r^2 = 0.330), though the effect did not reach significance (P = 0.08), while bisphosphonates and denosumab did not affect UCa; 2) increases in PTH levels were induced by bisphosphonates (P = 0.02) and denosumab (P = 0.02), but not by hypercalciuria, but the effects were limited (r^2 = 0.059); 3) similarly, reduction in calcium levels were induced by bisphosphonates (P = 0.02) and denosumab (P = 0.01), but not by hyperecalciuria, with clinically inconsistent effects (r^2 = 0.04 and r^2 = 0.08, respectively). In conclusion, in elder osteoporotic patients, hypercalciuria is associated with kidney stones in about one fourth of patients and with a wide range of impaired PTH secretion. Thiazides normalized urine calcium excretion in about 2/3 of patients.

Bone mineral density evolution after Denosumab withdrawal

Mª Rosa Alhambra Expósito, Ana Barrera-Martín, Ángel Rebollo-Román, José Manuel Quesada Gómez & Maria Angeles Galvez Moreno
Hospital Universitario Reina Sofía, Endocrinology and Nutrition, Córdoba, Spain

Introduction
Denosumab (Dab) withdrawal is associated with a quick loss in bone mineral density (BMD) and a high risk of multiple vertebral fractures. It is still not stablished which strategy best prevents BMD loss after Dab discontinuation.
Aim
Compare the use of bisphosphonates for one year after Dab withdrawal versus a tapering Dab regimen in terms of BMD and fracture occurrence.
Methods
Descriptive retrospective study including 20 patients with osteoporosis treated with Dab, whose treatment was retired after achieving their BMD target (T-score ≥ –2 SD). One group received weekly alendronic acid and the other group followed a tapering regimen (two doses every 9 months and then two annual doses). Bone turnover markers and BMD were measured before starting Dab, before withdrawing it and one year after withdrawal.
Results
20 patients. 90% (18) women. Mean age: 62.65 years. Mean treatment time of 51.85 (20.11) months. 2 patients with history of osteoporotic fractures. In 9 patients (45%) Dab was tapered and 11 patients (55%) received alendronic acid weekly. There are no differences as long as age, initial BMD or history of osteoporotic fractures between groups. There is a statistically significative reduction in BMD (1.043 ± 0.084 to 0.091 ± 0.093; P = 0.011) and T-score (–1.03 ± 0.43 to –1.63 ± 0.75; P = 0.012) in lumbar spine one year after in the group where Dab was tapered. There are not differences in the evolution of lumbar spine BMD either in the group who received bisphosphonate or in the whole sample. There are neither statistically significative differences in hip BMD in any of the groups, neither globally nor individually. Between groups there are not statistically significative differences in BMD, T-score or percentage of BMD modification one year after Dab withdrawal.
Conclusions
After Dab withdrawal using a bisphosphonate is a safe strategy and it is not associated with BMD loss in our series. In neither of the groups where fractures one year after Dab discontinuation.

Serum and urinary calcium level in Latvian patients with sarcoidosis at the time of diagnosis – 2013–2018 data

Ieva Ruza[1,2] & Aiga Plegermane[2]
[1]Riga Eastern Clinical University Hospital, Latvia; [2]Riga Stradins University, Latvia

Keywords
Sarcoidosis, serum, 24 h urine, calcium.
Introduction
Sarcoidosis is a systemic disease of unknown etiology that is defined by the formation of granulomas in different organ systems. Due to these pathologies, there may be an increase in serum and 24 h urine calcium that can have a clinical impact on the course of the disease.
Aim
The goal of this study was to assess the changes in total serum calcium and 24 h urine at the time of diagnosis in new cases of sarcoidosis from 2013 till 2018, as well as to calculate an annual disease incidence rate.
Materials and methods
In a retrospective study, medical records of all patients who were screened due to suspected sarcoidosis (n = 1271) in the Riga Eastern University Hospital's 'Clinic of Tuberculosis and Lung Diseases' between the 1st of January 2013 and 31st of December 2018 were analyzed. For further analysis, only patients with first-time histologically and/or clinically confirmed diagnosis of sarcoidosis (n = 956; 507 men and 449 women) were selected, and only the data from the first episode was evaluated. The information was obtained from patients' case files and medical records in the centralized hospital information system.
Results
On average, there were 159 (ranging from 140 to 182) new sarcoidosis cases (approximately 46.96% women and 53.04% men) per year, with an annual incidence rate calculated between 6.92 (2013) and 9.16 cases (2015) per 100.000 population in Latvia. Patients' age ranged from 16 to 84 years with mean age of 39 ± 13.4 years. The highest number of newly diagnosed sarcoidosis was in the age group of 30–39 years (n = 315 or 33%; 114 women (25.39%) and 201 men (29.64%)). Serum calcium level was evaluated in 664 patients (69.46%), hypercalcaemia was detected in 9.2% cases (n = 61), there was no significant association found between elevated serum calcium and gender. 24 h urine calcium level was evaluated in 716 patients (74.89%), hypercalciuria was detected in 17.6% cases (n = 126). 24-h urine calcium was significantly higher in men, regardless of units used (mg (P < 0.001); mmol (P < 0.011)). Pearson Chi-Square test showed that men had a tendency to hypercalciuria (3.5), but women – to hypocalciuria (2.4).
Conclusions
Many patients lack serum and/or 24 h urine calcium levels evaluated at the time of the diagnosis of sarcoidosis. Hypercalcaemia was observed in 9.2% cases, but hypercalciuria – in 17.6%. No significant association was found between serum calcium level and gender, but 24 h urine calcium level was significantly higher in men.

FGF23 secreting mesenchymal tumor of the foot: Localizing pitfalls

Alina Sucaliuc[1], Anghel Diana[2], Ioan Cristescu[3] & Daniel Grigorie[1,4]
[1]National Institute of Endocrinology, Bucharest, Romania; [2]Valcea County Hospital, Rm Valcea, Romania; [3]Floreasca Emergency Hospital, Bucharest, Romania; 4Carol Davila University of Medicine, Bucharest, Romania

Tumor-induced osteomalacia (TIO) is a rare paraneoplastic syndrome of chronic hypophosphatemia caused by the production of FGF23 in a typically small, benign, mesenchymal tumor. The diagnosis is often delayed and finding the tumor is sometimes challenging. We present a case of a 50 yrs old woman with TIO, referred to our clinic for progressive muscle weakness, diffuse bone pain and fractures, extensively investigated for 3 years. 2 years before admission she had a vertebroplasty for severe L5 vertebral fracture and in the last 12 months she suffered multiple moderate thoracic and lumbar vertebral fractures. At presentation she was unable to stand or walk without help. Laboratory findings: hypophosphatemia 1.1 mg/dl, phosphate renal wasting (phosphaturia 0.56 g/l; TmP/GFR = 0.36 mg/dl/l), Alkaline Phosphatase 462 U/l (40–150), normal serum Calcium, 25OHD 20 ng/ml, PTH 58 pg/ml, high bone turnover – CTX 0.640 ng/ml (0.162–0.436), P1NP 152 ng/ml (15–74), osteocalcin 26 ng/ml (11–43); no proteinuria/aminoaciduria/glucosuria, normal urinary electrolytes. The very high FGF23 level (5495 pg/ml, normal range 26–110) in this context suggested the diagnosis of TIO and

the patient was referred for 68Ga PET-CT. Despite specific recommendation for whole body scanning, both feet were excluded from imaging exam and no tumor was found. Oral phosphates and alfacalcidol were started, with clinical improvement and modest increase in phosphate levels. At follow-up a plantar tumor was found by palpation in the soft tissue beneath the first left metatarsal, confirmed by ultrasonography and subsequently by MRI. Tumor resection completely resolved the symptoms and rapidly normalized the biochemistries. The biopsy revealed a mesenchymal tumor, with giant osteoclast-like cells, mitoses, areas of osseous metaplasia.
Conclusion
A thorough head-to-toe physical examination and functional imaging are essential for tumor localization.

Osteoporosis treatment following osteoporotic fractures- data from a single medical center

Osnat Tell-Lebanon[1], Rachel Hava Rosenblum[1], Eyal Yaccobi[2,3], Nissim Ohana[2,3], Orit Twito[1,3] & Pnina Rotman-Pikielny[1,3]
[1]Meir Medical Center, Metabolic Bone Diseases Service, Endocrine Institute, Kfar Saba, Israel; [2]Meir Medical Center, Orthopedic Department, kfar saba, Israel; [3]Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel

Background
Most post-osteoporotic fracture patients do not receive osteoporosis treatment, although it reduces risks for additional fractures. This retrospective, observational study reviewed osteoporosis evaluation and treatment following typical osteoporotic fractures.
Methods
We identified patients with hip, vertebral, humerus or radius fractures, examined in Meir Medical Center, January-December 2017. Exclusion criteria were: not a Clalit Health Services member, high energy or pathologic fracture, or 30-day post-operative mortality. Primary endpoint was osteoporosis drugs issued within 12-months of fracture. Secondary endpoints were bone density testing and mortality.
Results
Of 928 patients diagnosed, 346 (37%) were excluded. 582 (78.6 ± 11.1 years-of-age, 75.8% women) were included: 321 (55.5%) hip, 84 (14.1%) humerus, 33 (5.6%) vertebra, 144 (24.7%) radius. Hip fracture patients were older, with more previous fractures. Osteoporosis drugs were issued to 26.5%; humerus fracture received the least (21.4%) and vertebral fracture, the most (30.3%), $P = 0.51$. Treatment related to age, gender or previous fracture, was similar. Bone density testing was done in 23.2% of patients, with vertebra (39.4%) and radius (34%) the most. One-year mortality after hip fracture was 12.1%, with humerus (3.6%), vertebral (3%) and radius (1.4%) ($P = 0.0$). Logistic regression demonstrated that previous treatment (OR = 7.4, 95% CI 3.6–15.2), bone density testing (OR = 4.4, 95% CI 2.6–7.4) and endocrinology visit (OR = 2.6, 95% CI = 1.4–4.6) were the most significant discriminating factors associated with osteoporosis treatment.
Conclusions
Fewer than one-third of patients received pharmacotherapy within a year post-fracture. Since pharmacotherapy reduces future fractures and mortality, we encourage medical staff, including orthopedic surgeons, rehabilitation team and general practitioners to increase awareness of their importance.

Relationship between muscle function and trabecular bone score (TBS) in Type 2 diabetes mellitus

Maria Hayon Ponce[1], David Blanquez Martinez[2], Mª del Carmen Serrano Laguna[1], Maria Dolores Aviles Perez[1], Beatriz Garcia Fontana[1] & Manuel Muñoz Torres[1]
[1]Bone Metabolic Unit, Endocrinology and Nutrition Division. Universitary Hospital Clínico San Cecilio., Granada, Spain; [2]Hospital Pharmacy Division. Universitary Hospital Clínico San Cecilio., Granada, Spain

Context
The incidence of Type 2 diabetes mellitus (T2DM) is increasing and muscle strength and function are reported to be decreased in patients with T2DM compared to healthy controls.However, the relation between bone and muscle remain unclear.
Objective
Our aims was to examine bone health parameters [by Dual energy X-ray absorptiometry (DXA) and trabecular bone score (TBS)] and muscle strength (by hand grip) in T2DM patients.
Design
Cross-sectional observational study
Setting
Tertiary care hospital
Patients
60 T2DM patients (60% males and 40% postmenopausal women) aged 49–85 years.
Measures
Anthropometric and metabolic parameters were determined. Bone mineral density (BMD) of the lumbar spine(LS), femoral neck(FN) and total hip(TH) and TBS were assessed using DXA and TBS iNsight Software. Hand grip strength (kg/cm^2) was measured with a jamar hydraulic hand dynamometer (5030j1; jackson, MI).Handgrip strength < 30 kg (male) or < 20 kg (female) was defined as low muscle strength. Data were analysed using SPSS 25.0.
Results
60 patients with T2DM were studied. Mean age of T2DM patients was 66.3 ± 8.31 years. Mean HbA1C was 7.7 ± 1.1%. 73.3% had poorly glycemic control (HbA1c > 7.5%).95.8% of female and 91.7% of male had low muscle strength.Hand-grip strength was positively correlated with TBS ($R = 0.321$, $P < 0.01$) and with TH- BMD ($R = 0.268$, $P < 0.05$).
Conclusions
Our study show that the reduction of muscle strength was significantly associated with decreased bone mass and deteriorated bone microarchitecture in T2DM patients.

Predictive factors for postoperative hypoparathyroidism after total thyroidectomy

Tiago Santos[1], André Carvalho[1], Cláudia Freitas[1], Raquel da Inez Correia[2], Moreira da Costa[2] & Maria Helena Cardoso[1]
[1]Centro Hospitalar e Universitário do Porto, Endocrinology, Diabetes and Metabolism, Portugal; [2]Centro Hospitalar e Universitário do Porto, Surgery, Portugal

Introduction
Hypoparathyroidism (hypoPT) is one of the most complications after thyroid surgery, usually as transient hypocalcemia. Permanent hypoPT due to permanent parathyoid lesion, despite being less frequent, is associated to long term consequences for both objective and subjective well-being and should be prevented. Identifying predictive factors associated with post-thyroidectomy hypoPT is thereby crucial.
Aim
To investigate predictive factors for permanent hypoPT after total thyroidectomy(TT).
Materials and methods
This retrospective study enrolled patients submitted to total thyroidectomy in Centro Hospitalar e Universitário do Porto from January 2017 to June 2019. Patients without post-operative follow up were excluded. Postoperative hypoPT was defined by iPTH < 15 pg/ml, calcium levels < 2.15 mmol/l or patients' requirement on daily vitamine D and calcium suplementation to avoid symptoms of hypocalcaemia. It was classified as permanent if parathyroid gland function has not recovered within six months after surgery. We investigated possible predictive factors for permanent postoperative hypoPT such as gender,age, thyroid specimen weight, histologic diagnosis of the specimen, presence of substernal goiter or autoimune thyroid disease, postoperative PTH and calcium levels.
Results
From a 357 total thyroidectomy procedures performed during the study's period, two-hundred and fifty two patients were included for the analysis, with a higher predominance of the female gender (84.1%) and a mean age at thyroid surgery of 54.2 ± 13.6 years. Twenty patients patients with permanent hypoPT were identified (5.6% from all TT performed). A lower postoperative PTH level (median 28.0 vs 49.0 pg/ml, $P < 0.001$), lower postoperative (median 2.24 vs 2.38 mmol/l, $P = 0.026$) and 3-months postoperative calcium levels (median 2.28 vs 2.36 mmol/l, $P < 0.001$) were associated with permanent hypoPT. Substernal goiter (16.1% vs 5.3%, $P = 0.006$) was also associated with permanent postoperative hypoPT. We did not found any statistically significant difference regarding risk for permanent hypoPT according to age ($P = 0.61$), gender ($P = 0.60$), thyroid specimen weight (0.12), autoimune thyroid disease ($P = 0.38$) or diagnosis of malignancy ($P = 0.78$).

Conclusions
In our current study, low postoperative PTH and calcium levels, and presence of substernal goiter were associated to permanent hypoPT. Understanding the factors associated with permanent HypoPT can assist in adequately monitoring these patients in the postoperative period and preventing hypocalcaemic events

Continuous rhPTH(1–34) Treatment in Chronic Hypoparathyroidism

Miguel Saraiva[1], Ana Catarina Chaves[2], Guilherme Assunção[1], Joana Saraiva[3] & Rui Carvalho[1]
[1]Centro Hospitalar e Universitário do Porto, Endocrinology, Diabetes and Metabolism; [2]Centro Hospitalar do Tâmega e Sousa, Endocrinology, Diabetes and Metabolism; [3]Centro Hospitalar e Universitário de Coimbra, Endocrinology, Diabetes and Metabolism

Introduction
Hypoparathyroidism still remains the only hormone-deficiency related disorder whose standard treatment is not based on replacing the missing hormone. In the last few years, there has been growing evidence on the use of recombinant human PTH, mostly with subcutaneous injections of rhPTH(1–34). More recently, some clinicians have tried to administer teriparatide through a continuous delivery system using insulin pumps.
Case report
A 31-year-old woman was referred to our Department for further evaluation of chronic severe hypocalcemia due to iatrogenic postsurgical hypoparathyroidism. She was chronically medicated with high doses of calcium, cholecalciferol, calcitriol, magnesium, indapamide and subcutaneous teriparatide injections. However, she still reported hypocalcemia symptoms on a daily basis and she frequently needed treatment with intravenous calcium perfusions due to episodes of severe hypocalcemia. During hospitalization, oral supplementation doses were progressively titrated up to 5g/day of elemental calcium and 4µg/day of alphacalcidol, with supervised treatment to rule out noncompliance. Despite these measures, six episodes of symptomatic severe hypocalcemia were documented, requiring treatment with intravenous calcium infusions. Our team then decided to implement a continuous subcutaneous perfusion of rhPTH(1–34) through an insulin pump. We slowly titrated the infusion rate up to 0.5 IU/h (30 mg/day). After that, no more severe hypocalcemia episodes occurred and we were able to reduce the oral supplementation doses. The treatment was monitored daily by clinical evaluation, dosing of serum ionized calcium and calculation of the urinary calcium:creatinine ratio. 4 months after hospital discharge, the patient remained with a rhPTH(1–34) infusion rate of 0.5 IU/h but it had been possible to fully suspend oral supplementation therapy. Her serum calcium level consistently remained within normal range and no other episodes of hypocalcemia occurred.
Discussion
The only way to effectively restore long-term calcium homeostasis in our patient was to start a continuous subcutaneous infusion of rhPTH(1–34). With this regimen, there was no need to maintain calcium or vitamin D supplementation. To our knowledge, this case represents the first report of successful treatment of hypoparathyroidism with a continuous perfusion of a PTH analogue in Portugal. We now have to closely monitor the incidence of potential adverse effects.

Metabolic disorders in patients with primary hyperparathyroidism

Ekaterina Bibik[1], Ekaterina Dobreva[1], Anna Eremkina[1], Alina Aynetdinova[2] & Natalya Mokrysheva[3]
[1]Endocrinology Research Centre, Parathyroid glands pathology, Moscow, Russian Federation; [2]Endocrinology Research Centre, Registry department, Moscow, Russian Federation; [3]Endocrinology Research Centre, Director, Moscow, Russian Federation

Background
The nonclassical complications of primary hyperparathyroidism (PHPT) can include metabolic syndrome associated with cardiovascular diseases. According to clinical studies, an increased incidence of diabetes mellitus, insulin resistance, obesity, dyslipidemia and other disorders are observed in patients with PHPT regardless of the severity of the disease. The aim of this study is to estimate metabolic parameters in patients with PHPT compared to healthy volunteers.
Material and methods
19 patients with PHPT (15 women, 4 men; median age 36years [30; 40]) underwent biochemical and hormone evaluation, standard oral glucose tolerance test with 82.5g glucose monohydrate, euglycemic hyperinsulinemic clamp and bioelectrical impedance analysis of the body composition before surgery. The exclusion criteria were the GFR < 60 ml/min/1.73 m^2, severe comorbid illnesses, body mass index (BMI) ≥ 32 kg/m^2, diabetes mellitus, using drugs affected glucose and calcium balance. Control group (n = 19) was sex-, age- and BMI-matched without pathology of parathyroid glands (median serum albumin-adjusted calcium (Ca_{adj}) 2.25 mmol/l [2.19; 2.29], PTH 38.3 pg/ml [29.6; 43.5]).
Results
All patients had symptomatic PHPT (median Ca_{adj} 2.8 mmol/l [2.61; 2.96], PTH 137.8 pg/ml [106.1; 209.5]) and 18 had normal glucose metabolism according to standard tests (in 1 man glucose intolerance) – median fasting plasma glucose 5.06 mmol/l [4.77; 5.24], 2-hour postload plasma glucose 5.51 mmol/l [4.56; 6.88], HbA1c (NGSP) 5.3% [5.0; 5.5]. 10 patients (52.6%) had normal weight, 8 (42.1%) – overweight and 1 person (5.26%) – obesity I, besides 36.8% patients had features of visceral obesity. PHPT patients had higher serum triglycerides and lower 25(OH)D_3 level comparing to control group (1.19 [0.93; 1.32] vs 0.8 [0.66;1.0] mmol/l, P = 0.001 and 18.6 [12.8;21.9] vs 24.5 [19.5;42.2] pg/ml, P = 0.018 respectively). However the clamp showed a significant lower M-index in PHPT group (5.48 [4.3; 7.47] vs 7.5 [6.45; 10.99], P = 0.005), insulin resistance was detected in 52.6% patients. We found significant correlations between PTH and triglycerides (r = 0.43) and total cholesterol levels (r = –0.44), P < 0.05 as well as Ca_{adj} and fasting plasma glucose (r = 0.36) and triglycerides (r = 0.60), P < 0.05 in general group. M-index correlated with serum phosphorous level (r = 0.46), triglycerides (r = –0.53), BMI (r = –0.43), %-total fat mass (r = –0.4) and visceral fat area (r = –0.45) in general group, P < 0.05 for all. But these data were not confirmed in the PHPT group except a correlation of M-index with triglycerides level (r = –0.59, P < 0.05).
Conclusion
Our results demonstrated the potential effect of PHPT on metabolic parameters, but further studies are required to clarify these links.

Parathyroid crisis – a conspicuous case of hypercalcemia

Asma Syeda[1,2], Nickolas coombs[1,2], Turab Mohammed[1,2] & Madhuri Manne[2]
[1]UConn Health, Farmington, United States; [2]Saint Francis Hospital, Hartford, United States

Introduction
Parathyroid crisis (PC) is a very rare yet fatal clinical condition which mandates urgent intervention. We present a case of parathyroid crisis with severe symptomatic hypercalcemia and multi-organ involvement.
Case description
A 63-year-old male presented with three days of generalized fatigue, abdominal pain and vomiting. Review of systems revealed constipation and symptoms suggestive of depression over the past 6 months. Vital signs were notable for tachycardia with a heart rate of 120 beats/minute. On physical examination, the patient was in mild distress and looked dehydrated. Laboratory investigations revealed hypercalcemia with a total calcium of 19.9 mg/dl, ionized calcium of 1.83 mmol/l, phosphorus of 3.2 mg/dl, creatinine of 2.7 mg/dl. Hypercalcemia workup revealed a PTH level of 2472 pg/ml and a normal urine calcium, vitamin D level and serum protein electrophoresis. Acute kidney injury, depression and gastrointestinal symptoms were explained by severe hypercalcemia. He was promptly treated with aggression fluid resuscitation, pamidronate and calcitonin. A Technetium 99m sestamibi scan demonstrated two large bilateral parathyroid masses which correlated with the findings on the ultrasound. The patient underwent bilateral parathyroidectomy and left thyroid lobectomy as the left sided mass was adherent to the thyroid gland. Parathyroid carcinoma was ruled out on biopsy and was consistent with hyperplastic parathyroid tissue. The PTH level decreased to 125 pg/ml intraoperatively and subsequently normalized. Post-operatively the patient developed hungry bone syndrome requiring IV calcium therapy and large-dose vitamin D supplementation.
Discussion
PC is a rare phenomenon where PHPT manifests as a hypercalcemic crisis (serum calcium > 14 mg/dl and multi-organ involvement) requiring urgent therapeutic intervention to prevent life-threatening complications from severely elevated calcium levels. PHPT can be due to parathyroid hyperplasia, adenoma or carcinoma. It is difficult to distinguish the etiology of PHPT clinically but when PTH levels are greater than 5 times the upper limit of

normal, it usually suggests parathyroid carcinoma. However, in our case, the inordinate levels of PTH were due to parathyroid hyperplasia. Imaging modalities are helpful in localizing the disease but cannot assess malignancy potential and fine needle aspiration cytology (FNAC) is contraindicated due to the risk of seeding. Hence, early surgery is the ultimate diagnostic and curative modality.

Aggressive hypercalcaemia with recurrent giant parathyroid adenoma following three parathyroidectomies

Ayaz Hussain, Ashwin Suri, Hassan Ibrahim, Christo Albor, Solat Hasnain & Jawad Bashir
Basildon University Hospital, Basildon, United Kingdom

The incidence of recurrent primary hyperparathyroidism (PHPTH) (> 6 months from initial exploration) has been reported to be between 1–10%. Repeated neck explorations could be challenging for surgeons and ensuring normalised biochemistry is vital for peri-operative safety. Recurrent parathyroid adenomas can present with aggressive hypercalcaemia which can be challenging to control prior to surgery. We report a similar case below. A 72 year old lady had her first presentation of PHPTH in 2008 (Corrected Calcium = 3.23 mmol/l, PTH = 29.3 pmol/l). Parathyroid imaging showed a right inferior adenoma (1.5 × 0.6 cm^3) reflecting a possible right parathyroid adenoma. The first surgery for parathyroidectomy needed to be abandoned in view of severe bradyarrhythmia (heart rate 37 due to complete heart block requiring pacemaker insertion). The second surgery was successful with removal of 3 parathyroid glands which confirmed two parathyroid adenomas and one hyperplastic parathyroid gland. Post-operative biochemistry normalised (Corrected Calcium = 2.51 mmol/l, PTH = 8.9 pmol/l). 10 years later the patient was referred to the endocrine team for symptomatic severe hypercalcaemia of 3.5 mmol/l. it was biochemically confirmed recurrent PHPTH with very high PTH levels (PTH = 65 pmol/l). Parathyroid imaging showed a left inferior giant parathyroid mass (4 × 2 × 2.7 cm) with mediastinal extension with displacement of oesophagus and possible infiltration into it. Given the high PTH levels, the size of the mass and refractory hypercalcaemia, it was discussed in MDT with suspicion of parathyroid carcinoma. Patient had significant cardiac history and hence normalization of calcium levels was mandatory for peri-operative safety. Despite repeated admissions for IV hydration and bisphosphonate infusions her calcium remained in range of 3–3.5 mmol/l. due to refractory hypercalcemia unresponsive to hydration and bisphosphonates, she was admitted to hospital 10 days prior to surgery. Her calcium was normalised by use of calcitonin subcutaneous injections along with conventional treatment. During surgery a large mass about 8 cm in size (7.8 × 2.6 × 0.6 cm^3) was removed which was confirmed to be parathyroid adenoma with no evidence of malignancy. This case highlights the aggressive nature of recurrent parathyroid adenomas. Perioperative refractory hypercalcaemia can be effectively controlled by use of calcitonin. Patients with multi-gland disease should also be screened for genetic causes of primary hyperparathyroidism like multiple endocrine neoplasia (MEN).

Height loss is almost 3 times more correlated with trabecular bone score than with bone mineral density

Dan Peretianu[1], Adrian Sarbu[2], Catalin Gavrila[2], Serban Motoiu[1], Mihaela Stanciu[3], Aurelian Ranetti[4] & Denis Paduraru[5]
[1]Medical Center Povernei, Endocrinology, Bucharest, Romania; [2]Medical Center 'Sana', DEXA, Bucharest, Romania; [3]Faculty of Medicine 'Victor Papilian', Endocrinology, Sibiu, Romania; [4]Central Military Hospital 'Carol Davila', Endocrinology, Bucharest, Romania; [5]Institute of Sportive Medicine, Laboratory of Physiology, Bucharest, Romania

Aim
To show that height loss is more correlated with vetebral micoarchitecture than with Bone Mineral Density (BMD).
Material and method
A. DEXA. Made with a GE-Lunar Prodigy Pro # 50 0074. Vertebral microarchitecture was investigated by Trabecular Bone Score (TBS). TBS software: TBS iNsight, version 3.0.2.0. B. Patients. 784 patients, 737 (94%) women, 47 men. Only 38 under 50 years. Age average: 66.04 years. Women: 65.8 years, men 69.89 years. C. Height measurement. At the time of DEXA analysis, each patient's height was measured (centimeters). Patients were asked to appreciate the difference in height compared to a previous age to which they can relate. D. Statistical analysis. Student t́test was used for differences. Linear correlation test (r) was used for correlations.
Results
1. Diagnosis of osteoporosis. BMD scores led to the classic diagnosis of osteoporosis in only 28.2% of patients. TBS T scores suggested the diagnosis of osteoporosis in 71.56% of patients (Table).

		BMD-T score			
		Normal	Osteopenia	Osteopo-rosis	Total
TBS-T score	Normal	33	11	5	49
		4.2%	1.4%	0.6%	6.3%
	Partial degraded -1 – 2.5 (osteopenia)	63	81	30	174
		8.0%	10.3%	3.8%	22.2%
	Degraded <-2.5 (osteoporosis)	121	254	186	561
		15.43%	32.40%	23.72%	71.56%
	Total	217	346	221	784
		27.7%	44.1%	28.2%	100.0%

The concordant diagnosis of osteoporosis by the intersection of BMD and TBS scores occurred in only 23.72% of patients. 2. Decreasing height. a. Average: 3.49 cm. Women loss height = 3.49 cm, Men loss height = 3.404 cm. Maximum average loss was recorded at over 85 years = 7.4 cm. The minimum mean loss was found at < 45 years = 0.8 cm. b. Correlations between height decrease and DEXA values. The correlation of the decrease in height with the T score of the BMD was $r = 0.1409$. The correlation of height decrease with TBS was 'r' = 0.4019. Both correlations generate $P < 0.001$. However, the value 'r' for the correlation with TBS was 2.85 times higher.
Conclusions
1. Vertebral compression is correlated with age, higher in women than in men. 2. Patients lose up to 7.4 cm in the 8th decade of life. 3. TBS is more correlated with vertebral microarchitecture and decrease in height with age compared to BMD, since the correlation 'r' between TBS values and height decrease and the correlation between height decrease and BMD is almost 3 times higher.

Postsurgical hungry bone syndrome in unrecognized severe primary hyperparathyroidism: A case report

Cvetanka Volkanovska Ilijevska[1], Marija Zivkovic[1], Aleksandra Stevchevska[1], Natasha Eftimovska Otovikj[2], Taner Hasan[2] & Sasha Jovanovska Mishevska[1]
[1]University Clinic of Endocrinology, Diabetes and Metabolic Disorders, Skopje, Macedonia; [2]City General Hospital '8th September', Skopje, Republic of North Macedonia, Skopje, Macedonia

Parathyroidectomy for hyperparathyroidism can be complicated with development of Hungry Bone Syndrome (HBS), a constellation of profound hypocalcemia with hypomagnesemia and hypophosphatemia. The severity of this potential life-threatening condition is related to the extent of the parathyroid-mediated high-turnover bone disease. We present a case of a 59-year-old woman developing post-surgical HBS as a result of longstanding severe unrecognized primary hyperparathyroidism (PHPT) and improper perioperative management. Our patient had a six-year history of upper gastrointestinal pain, progressive weight loss, recurrent bilateral nephrolithiasis with advanced chronic kidney disease (CKD) and chronic normocytic anemia. Due to fall related subtrochanteric fracture the patient was admitted in the local surgical hospital. Computed tomography evaluation revealed multiple osteolytic lesions in the axial and appendicular skeleton. The finding of elevated parathyroid hormone (PTH) (1355 pg/ml), hypercalcemia (3.54 mmol/l) and elevated alkaline phosphatase (ALP) led to the diagnosis of PHPT with brown tumours. 99mTc-sestamibi scan confirmed presence of left parathyroid adenoma

and notable tracer uptake in the affected bones. The patient was scheduled for parathyroidectomy. Comprehensive preoperative and postoperative care was not performed, and the occurrence of HBS was not considered. Early postoperative laboratory assessment showed normocalcemia and the patient was discharged. Two months later the patient presented to our clinic with laryngeal stridor, paraesthesia of the hands, muscle weakness and confusion. Laboratory assessment revealed severe hypocalcemia (0.65 mmol/l), hypomagnesemia (0.49 mmol/l), hypophosphatemia (0.94 mmol/l), elevated PTH (406 pg/ml) and profound vitamin D deficiency (7.39 ng/ml). Diagnosis of HBS was supported by the presence of parameters reflecting diminished osteoclast activity as demonstrated by the normalisation of ALP and significant osteoblast activity denoted by 5 times normal value of osteocalcin. Moreover, preoperative risk factors for HBS were also present such as brown tumours, depleted Vitamin D and most notably, missed opportunity for preoperative prevention of HBS. Our case shows that CKD associated secondary hyperparathyroidism does not protect from HBS in longstanding and neglected PHPT with extensive bone disease. Duration of HBS is determined by the time needed for skeleton remineralization, normalisation of markers of bone turnover, withdrawal of radiological features of brown tumors and significant gain in bone mass after initiation of calcium, magnesium and calcitriol supplementation. As COVID pandemic situation ensued, our patient refused radiological assessment for bone lesion remineralization, but the presence of clinical improvement, correction of anemia and normalization of bone markers turnover allowed us to conclude that resolution of HBS occurred.

Quality of life changes in patients with primary hyperparathyroidism after parathyroidectomy: The usefulness of PHPQoL questionnaire in clinical practice

Inna Gladkova[1], Vladimir Rusakov[1], Roman Chernikov[1], Yulia Karelina[1], Tatiana Nikitina[2], Sergey Efremov[3] & Tatiana Ionova[2]
[1]Saint Petersburg State University Hospital, Department of Endocrine Surgery, Saint Petersburg, Russian Federation; [2]Saint Petersburg State University Hospital, b. Quality of Life and Monitoring Unit, Saint Petersburg, Russian Federation; [3]Saint Petersburg State University Hospital, a. Department of Anesthesiology and Intensive Care, Saint Petersburg, Russian Federation

Primary hyperparathyroidism (PHPT) is a complex endoctinopathy that involves parathyroid glands which secreting too much parathyroid hormone and due to causes hypercalcemia effecting different organs and leading to significant quality of life (QoL) impairment. QoL assessment before and after surgery in patients with PHTP may be useful for comprehensive evaluation of the treatment effect, as well as for monitoring of the patient' condition after surgery, including in real clinical practice. The aim of the study was to evaluate changes in QoL of PHPT patients after parathyroidectomy (PTX) and to test applicability of the disease-specific QoL questionnaire – PHPQoL for its further implementing in clinical practice and research in this patients group. The PHPQoL includes 16 items; the total PHPQoL score is standardized from 0 (worst QoL) to 100 (best QoL). The linguistic and cultural adaptation of the PHPQoL questionnaire was carried out in accordance with international guidelines. Adult patients with PHPT who were referred to PTX filled out the PHPQoL twice: before and 3 mos after PTX. Psychometric properties of PHPQoL were tested – its reliability, validity and sensitivity. Statistical analysis of QoL data included assessment of Spearman correlations and Student's paired test. In the whole, 65 patients with PHPT were involved into the study (mean age – 52.3 ± 10.5 years, 97% – women): 67.7% patients were symptomatic, 35.4% patients had moderate or severe hypercalcemia. Satisfactory external and content validity of the PHPQoL were demonstrated; the tool was easy to understand and informative to capture specific concerns of PHPT patients. Reliability of PHPQoL was confirmed by the high Cronbach's alpha coefficient ($\alpha = 0.87$). Clinical validity of PHPQoL was shown: symptomatic patients had worse QoL than asymptomatic (PHPQoL total score 47.4 vs 64.7, $P = 0.01$); the more symptoms of PHPT the worse QoL ($r = –0.46$; $P < 0.001$). The positive effect of the surgery on QoL in PHPT patients was demonstrated: PHPQoL total score before PTX 46.7 vs 55.7 after PTX ($P < 0.05$), these results may testify sensitivity of the tool. Clinically meaningful QoL increase (MID for PHPQoL total score ≥ 9 points) was demonstrated in 44% patients after PTX; PHPQoL total score range 51–100 was revealed in 76% patients after surgery. PTX leads to noticeable QoL improvement in PHPT patients. PHPQoL is a feasible and practical PHPT specific tool with satisfactory reliability, validity and sensitivity for QoL assessment in PHPT patients undergoing surgery.

Adjuvant endocrine therapy impact on bone health in premenopausal women with hormone receptor-positive breast cancer: Results of a case series

Diana Lambrinoc[1], Roxana Duşceac[1,2], Alexandru Morea[1] & Cătălina Poiană[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Pituitary and Neuroendocrine Disease, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology Department, Bucureşti, Romania

Introduction
Adjuvant endocrine therapy has an important role in the management of hormone receptor-positive (expressing oestrogen/progesterone receptors) early-stage breast cancer, reducing the risk of recurrence and improving associated mortality. The estradiol depletion produced by hormone therapy has detrimental effects on skeletal health, which can lead to low bone mineral density (BMD), altered bone microarchitecture and increased risk of fracture.
Methods
7 premenopausal patients with histologically proven hormone receptor-positive breast cancer, treated with luteinising hormone releasing hormone (LHRH) analogue goserelin were evaluated in our clinic. 6 of them were treated also with selective oestrogen receptor modulator tamoxifen and one patient was receiving aromatase inhibitor letrozole. All of the patients received adjuvant chemotherapy and all had secondary amenorrhea. Lumbar spine, total hip and femoral neck BMD and Z-scores along with lumbar spine trabecular bone score (TBS) were measured using dual energy x-ray absorptiometry (DXA GE Lunar). Bone turnover was assessed by measuring C-terminal telopeptide of type I collagen (CTx), osteocalcin (OC) and N-terminal propeptide of type I procollagen (P1NP).
Results
The mean age was 43.8 ± 3.5 years old and the mean duration of endocrine therapy was 2.3 ± 1.6 years. The mean lumbar spine and femoral neck BMD were 1.025 ± 0.13 g/cm^2 and 0.895 ± 0.15 g/cm^2, respectively. The mean Z-scores were –1.08 ± 5 SD at lumbar spine and –0.51 ± 0.4 SD at femoral neck region. 2 patients had a Z-score at lumbar spine below –2 SD and one of the patients was diagnosed with a vertebral fragility fracture using radiography. Therefore, the treatment with bisphosphonates, calcium and vitamin D was initiated. All other patients also received calcium and vitamin D supplementation. The mean TBS was 1.324 ± 0.08, 4 patients having a TBS < 1.350, suggesting a degraded bone microarchitecture. The mean P1NP, OC and CTx were 65.7 ± 28.4 ng/ml, 19.54 ± 5.95 ng/ml and 0.49 ± 0.25 ng/ml, respectively, indicating an increased bone turnover, demonstrated by the elevated serum CTx and P1NP levels (mean values). There was no significant difference regarding BMD and bone biomarkers in letrozole-treated patient compared to tamoxifen group.
Conclusion
This study emphasizes the importance of assessing bone health and regular follow-up in women undergoing hormone therapy for breast cancer, as it can lead to bone loss and degraded bone microarchitecture. Furthermore, prevention of fragility fractures can be obtained by calcium and vitamin D supplementation or antiresorptive therapy, whenever it's necessary.

Parathyroid elastography—elastography evaluation algorithm

Laura Cotoi[1], Borlea Andreea[1], Cristina Mihaela Cepeha[1], Pop Nicusor[2], Daniela-Georgiana Amzar[3] & Stoian Dana[3]
[1]Victor Babeş University of Medicine and Pharmacy, PHD School, Timisoara, Romania; [2]Victor Babeş University of Medicine and Pharmacy, Biostatistics, Timisoara, Romania; [3]Victor Babeş University of Medicine and Pharmacy, Endocrinology, Timisoara, Romania

Introduction
Primary hyperparathyroidism is a common disorder of the parathyroid glands and the third most frequent endocrinopathy, especially among elderly women. Secondary hyperparathyroidism is a common complication of chronic kidney disease, associated with high cardiovascular morbidity and mortality. In both

primary and secondary hyperparathyroidism, the need to correctly identify the parathyroid glands is mandatory for a better outcome. Elastography can be an effective tool in the diagnosis of parathyroid lesions, by differentiating possible parathyroid lesions from thyroid disease, cervical lymph nodes, and other anatomical structures. There are currently no guidelines or recommendations and no established values on the elasticity of parathyroid lesions.
Materials and Methods
We have evaluated using shear wave elastography (SWE), both primary and secondary hyperparathyroidism, determining that parathyroid glands have a higher elasticity index than both thyroid tissue and muscle tissue. We evaluated two parathyroid lots, the first lot of patients diagnosed with primary hyperparathyroidism, clinically, biochemically and confirmed by pathological evaluation of parathyroid glands and the second lot of renal secondary hyperparathyroidism, confirmed clinically, biochemically and either by scintigraphy or MRI.
Results
For primary hyperparathyroidism, we have determined, using 2D-SWE, the parathyroid adenoma tissue (mean elasticity index (EI) measured by SWE 4.74 ± 2.74 kPa) with the thyroid tissue (11.718 ± 4.206 kPa) and with the surrounding muscle tissue (16.362 ± 3.829 kPa). For secondary hyperparathyroidism, by SWE elastographic evaluation, we have found that the mean EI in the parathyroid gland was 7.83 kPa, a median value in the thyroid parenchyma of 13.76 kPa, and a mean muscle EI value at 15.78 kPa.
Conclusion
Elastography can be a useful tool in localizing parathyroid disease, whether primary or secondary, by correctly identifying the parathyroid tissue. We have determined that an EI below 7 kPa in SWE elastography correctly identifies parathyroid tissue in primary hyperparathyroidism, and that a cut-off value of 9.98 kPa can be used in 2D-SWE to accurately diagnose parathyroid disease in secondary hyperparathyroidism.

Topographic diagnosis of primary hyperparathyroidism

Aicha Bouzid[1], Azzouz malha[2] & Djamila Meskine[1]
[1]Medical university of Algiers, Endocrinology & Metabolism laboratory Algiers 1, EPH Bologhine, Algiers, Algeria; [2]Medical university of Algiers. EPH Bologhine, Algiers, Algeria

Introduction
The diagnosis of primary hyperparathyroidism (PHP) is essentially biological. Current imaging techniques (ultrasound and scintigraphy) make it possible to locate an adenoma in the majority of cases. The objective of this study is to clarify the place of imaging in the topographic diagnosis of hyperparathyroidism.
Patients and methods
This is a retrospective study including 40 patients with PHP who have undergone cervical ultrasound and parathyroid scintigraphy, CT scan and MRI are performed as a second line when the latter are negative.
Results
40 patients are identified with a sex ratio of 4/1, the average age was 51 years (range from 18 to 70 years). HPP has been confirmed biologically in all patients. Cervical ultrasound revealed a single adenoma in 30 patients and hyperplasia in 2 cases. Parathyroid scintigraphy was performed in 37 patients, it demonstrated an adenoma in 59.5% of cases. The CT and MRI were negative.
Discussion
Imaging for parathyroid localization should be performed only after the diagnosis of PHP has been confirmed and the decision has been made to proceed with surgery. Localization is not to be used for diagnosis and should not be used to decide if a patient should proceed with surgery.
Conclusion
Through this study, cervical ultrasound appears to be more sensitive than parathyroid scintigraphy in the topographic diagnosis of PHP. Additional CT or MRI is indicated in the event of discordance or ectopic locations.

Paraplegia: a serious consequence of treatment delay in hyperparathyroidism During the COVID-19 pandemic

Sara Campos Lopes[1], Renata Carvalho[2], Sofia Marques[2], Sofia Rocha[2], Charlene Viana[3], Helena Marques[3], José Pedro Pinto[3], Mário Reis[3], Sofia Cavadas[3], Ricardo S. Pereira[3] & Ana Margarida Monteiro[1]
[1]Hospital de Braga, Endocrinology, Portugal; [2]Hospital de Braga, Nefrology, Portugal; [3]Hospital de Braga, General Surgery, Portugal

Background
Currently, serious complications of secondary hyperparathyroidism (sHPT) are rare due to early diagnosis and more effective treatments. These complications include osteitis fibrosa cystica, which is characterized by bone resorption and brown tumors. Depending on the location, they can cause pain or compressive symptoms.
Case report
We report a case of a 41-year-old black woman with a past medical history of arterial hypertension diagnosed at 25 years-old and chronic kidney disease (CKD) diagnosed at 35 years old, undergoing hemodialysis treatment. sHPT was present since the diagnosis of CKD, with PTH values consistently > 1000 pg/ml despite the use of cinacalcet and paricalcitol thrice-weekly during hemodialysis. In March 2020, during a visit to relatives in Angola, the patient had an intense and sudden dorsal pain. She developed progressive paraparesis and hypoesthesia of the lower limbs and fecal and urinary incontinence. Due to limited health care assistance and a travel ban due to the COVID-19 pandemic, medical evaluation was only possible six months later in Portugal. At hospital admission in September 2020, she presented with paraplegia and hypoesthesia of the lower limbs and fecal and urinary incontinence. CT-scan revealed bone lesions in three ribs, ischiopubic ramus, left acetabulum, and D7 and D11 vertebral bodies, with spinal canal invasion. A pathologic fracture in D11 and multiple millimetric lesions in some vertebral bodies and iliac bones were also detected. The lesions presented with a dominant blastic component. Serum levels of PTH were 1310 pg/ml (18.5–88.0 pg/ml) with normal total corrected calcium, vitamin D and phosphate levels. Bone biopsy was performed in one of the affected ribs, reporting histological abnormalities consistent with brown tumors. The 99m Tc-sestamibi scintigraphy detected increased metabolic activity in the inferior left lobe of the thyroid gland and in the bone lesion of the first costal arch. A subtotal parathyroidectomy was performed. On the first day post-surgery, PTH levels normalized (56.73 pg/ml). The histopathology report confirmed hyperplasia of the parathyroid glands. Currently, the patient is under motor rehabilitation and medicated with calcium, cholecalciferol, and alfacalcidol.
Conclusion
Despite being rare and benign, brown tumors can cause severe morbidity and should be considered in the differential diagnosis of bone lesions. Persistent sHPT unresponsive to medical therapy with calcimimetics and vitamin D derivates is a significant risk factor and should prompt a timely referral to parathyroidectomy. Unfortunately, the COVID-19 pandemic caused delays in consultations and surgeries reducing the possibility of early interventions.

Brown tumours resulting of secondary hyperparathyroidism in patients with chronic renal insufficiency

Mohamed Masmoudi, Rihab Guizani, Thabet Wadii, Lamghari Nora, Mehdi Hasnaoui & Mighri Khalifa
Tahar Sfar Hospital mahdia, ENT department, mahdia, Tunisia

Objectif
Brown tumour is a rare focal bone lesion encountered in patients with uncontrolled hyperparathyroidism (HPT). This disease affects only 1.5% of patients with secondary HPT. This bone lesion can affect any part of the skeleton. The treatment is mainly medical based on reducing the rates of parathyroid hormone (PTH). Surgery is reserved for severe form of brown tumour or in case of uncontrolled level of PTH. The aim of our work is to illustrate the clinical and therapeutic features of these rare tumour.
Patients and methods
This is a retrospective study of 5 chronic hemodialysis patients who developed a brown tumour due to secondary hyperparathyroidism. This study was carried out over a period of 10 years from 2008 to 2018.
Results
The average age of our patients was 38 years old with a sex ratio of 1.5. The average time to diagnosis brown tumours was 5 years. These tumours were located in the mandible in two cases, sternum bone in 1 case and femora in 2cases. The Mean serum calcium level was 1.90 mmol/l, the mean phosphoremia level was 2.20 mmol/l and the mean PTH level was 1500 pg/l. All patients had subtotal parathyroidectomy. Histologic examination of the gland showed parathyroid hyperplasia in all cases. No patient underwent intervention on the tumour. The outcome was favorable in all patients with clinical and radiological stabilization of bone lesions in 2 cases and spontaneous regression after parathyroidectomy in 3 patients without any recurrence.

Conclusion
Patients with chronic renal insufficiency may develop brown tumours in advanced stages of the disease as a result of uncontrolled hyperparathyroidism. Treatment is based on reducing the levels of PTH, either through medical management, or parathyroidectomy. The patient's prognosis is favourable, but the possibility of kidney transplantation to prevent relapse and the development of further brown tumours will have to be considered.

Symptomatic mastoidian brown tumor in a dialysed child

Miruna Anisia[1], Teodora Dumitru[1], Maria Christina Ungureanu[1,2], Cristina Preda[1,2], Starcea Magdalena[2,3] & Letitia Leustean[1,2]
[1]'Sf. Spiridon' Emergency Clinical Hospital, Endocrinology, Iaşi, Romania; [2]'Gr. T. Popa' University of Medicine and Pharmacy, Iasi, Romania; [3]'Sf. Maria' Emergency Clinical Hospital for Children, Pediatric Nephrology, Iasi, Romania

Brown tumors (BT) consist of focal bone lesions, caused by increased osteoclastic activity and fibroblastic proliferation. They appear in chronic kidney disease (CKD) as a result of renal osteodystrophy with high bone turnover, due to secondary hyperparathyroidism. BT are composed of mononuclear stromal cells mixed with multinucleated giant cells and hemosiderin deposits, which give the characteristic brown colour. We present the case of a 13-year-old girl, with end-stage CKD on peritoneal dialysis for 3 years, who accused important retroauricular pain with right hemifacial oedema and right retroauricular tumefaction. The cranio-cerebral CT shows a 3.6/2.4/1.6cm polylobate mastoidian tumor. The cervical US shows two homogenous hypoechoic nodules at the lower poles of the thyroid gland. Biologically there was severe vitamin D deficiency 4.7 ng/ml, mildly elevated parathormone levels 180 pg/ml, hypercalcemia and hyperphosphoremia, sugesstive of tertiary hyperparathyroidism. Total parathyroidectomy with subsequent parathyroid tissue transplantation in the left sternocleidomastoidian muscle was performed. Two months following surgery, a significant reduction in tumor volume was observed, the retroauricular region having a quasi-normal normal appearance. Clinically significant brown tumors in the pediatric population are uncommon and may mimic malignant lesions of the bone. Choosing between medical and surgical management may be challenging, due to the rarity of the tumor and lack of existing data. The effective control of hyperparathyroidism will often lead to tumor regression and calcification.

Phosphaturic mesenchymal tumour – diagnostic and therapeutic challenges

Ewa Zalewska[1], Monika Płoszaj-Neń[1], Bartosz Barćik[2], Arkadiusz Szarmach[2], Lucjan Samson[3], Piotr Łuczkiewicz[4], Katarzyna Gołąbek-Dropiewska[4], Joanna Chmiel[3], Ewelina Kardel-Reszkiewicz[5], Sonia Kaniuka-Jakubowska[1] & Krzysztof Sworczak[1]
[1]Medical University of Gdansk, Department of Endocrinology and Internal Medicine, Gdańsk, Poland; [2]Medical University of Gdansk, 2nd Department of Radiology, Gdańsk, Poland; [3]Medical University of Gdansk, Department of Orthopaedics and Kinetic Organ Traumatology, Gdańsk, Poland; [4]Medical University of Gdansk, Department of Emergency Medicine, Gdańsk, Poland; [5]Medical University of Gdansk, Department of Anesthesiology and Intensive Care Medicine, Gdańsk, Poland

Introduction
Tumour-induced osteomalacia (TIO) is a rare paraneoplastic syndrome caused mainly by a phosphaturic mesenchymal tumour (PMT) as a consequence of fibroblast growth factor 23 (FGF23) overproduction. The manifestation of TIO is mostly musculoskeletal. Locating the PMT is usually challenging and a successful surgical resection of the tumour leads to complete recovery.
Case presentation
A 42-year-old, Caucasian male patient, moving with the help of crutches, was admitted to our Clinic in August 2018, for exacerbating muscle and joint pain, and waddling gait. The pain of the lumbar spine and both feet was noticed for the first time in May 2014. The neurological treatment with pregabalin, venlafaxine, methylprednisolone, physiotherapy, and high doses of antibiotics due to suspicion of borrelia infection were not helpful in pain relief. Laboratory results revealed hypophosphatemia, hyperphosphaturia, and a high level of alkaline phosphatase. A chest CT showed multiple fractures of spinous processes both sides of the rib cage. Based on the clinical manifestation and the additional examinations, including 68GaDOTA-TATE PET/CT performed in March 2018, PMT of the right femur was suspected. In May 2018, the tumour resection was performed and the histopathological examination of the lesion confirmed the diagnosis. However, the patient's condition and post-surgical laboratory parameters had not improved. A second 68GaDOTA-TATE PET/CT scan revealed two lesions: in previously operated femoral bone and in jaw. After a systemic venous sampling of FGF23, performed to decide which foci should be treated, we focused on the right thigh. In January 2019, we carried out transarterial embolization (TAE) of the vessels supplying blood to the PMT to facilitate subsequent radiofrequency ablation (RFA) of the tumour remnants. After TAE and RFA, a profound improvement of the patient's condition was observed and he was able to walk without the aid of crutches, and the waddling gait withdrew. However, despite FGF-23 normalization, he presented with severe hypophosphatemia, and a year after the RFA a fatigue fracture of the left tibia occurred. A third 68GaDOTA-TATE PET/CT, performed in July 2020, showed an increased expression of somatostatin receptors of the tumour remnants. Treatment with somatostatin analogs turned out to be ineffective. In December 2020, a successful surgical resection of the PMT combined with prophylactic intramedullary nailing of the femur resulted in phosphates normalization and complete recovery.
Conclusion
By presenting this case we would like to encourage clinicians to persist in locating PMT and therefore resection, which may require innovative diagnostic tools and treatment.

The relevance of the problem of osteoporosis for medical professionals working in the field of physical and rehabilitation medicine

Larisa Marchenkova
National Medical Research Center for Rehabilitation and Balneology of Ministry of Health of Russian Federation, Somatic rehabilitation, anti-aging and reproductive health department, Moscow, Russian Federation

Background
There is a high prevalence of osteoporosis (OP) among patients of the older age undergoing rehabilitation. Therefore, it is obvious that physicians working in the field of physical and rehabilitative medicine should be well oriented in this medical problem.
Objectives
to study the relevance of the problem of osteoporosis (OP) for physicians working in the field of physical and rehabilitation medicine, their awareness of the main methods of diagnosis, treatment and prevention of this disease, as well as the frequency of their use in daily clinical activitie.
Methods
A cross-type study was carried out using a questionnaire survey. The study included 157 doctors (M-34, F-123) of 8 medical specialties working in 27 specialized medical institutions on the profile of 'medical rehabilitation. The questionnaire for doctors consisted of 21 items of special questions.
Results
90.45% of the surveyed doctors believed that the problem of OP is relevant for their clinical activities, 100% of the respondents indicated that the presence of OP significantly affects the rehabilitation prognosis and 95.54% – on the degree of effectiveness of medical rehabilitation. According to the respondents, patients with OP make up on average 30.0% [20.0; 50.0] (0–90) of the total flow of patients. 92.36% (145/157) of doctors indicated that they know the risk factors for OP, 98.73% (155/157) – methods for diagnosing OP, 68.79% (108/157) – methods for treating OP, 80.25% (126/157) – methods of preventing OP, 47.13% (74/157) – what is FRAX. However, 35.01% (55/157) of the respondents considered their level of awareness of the problem sufficient for managing patients with OP. Diagnostic procedures for OP are recommended by the all endocrinologists (100%) and the majority of traumatologists (72.73%), gynecologists (66.67) and cardiologists (64.28%), as well as on average half (50%) neurologists and therapists. Endocrinologists (100%), gynecologists (66.67%) and therapists (60%) are mainly involved in the treatment of OP. 32.48% (51/157) of physicians have ever referred their patients to a bone mineral density assessment.

Conclusion
The problem of OP is relevant for the clinical activities of specialists in physical and rehabilitation medicine, and there is the need for advanced training on the problem of OP among these specialists.

Unexpected association of severe hypercalcemia and hypophosphatemia in a patient with chronic hypoparathyroidism: A case report

Giulia Vandi, Guido Zavatta, Andrea Repaci, Paola Altieri & Uberto Pagotto
IRCCS Azienda Ospedaliero-Universitaria di Bologna, Division of Endocrinology and Diabetes Prevention and Care, Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna, Italy

Clinical vignette
A 65-year-old woman was hospitalized due to severe hypercalcemia (albumin-corrected calcium 16.9 mg/dl) associated with severe renal failure (creatinine 3.48 mg/ml), normal phosphate levels (3.9 mg/dl) and PTH < 5 pg/ml. Her past medical history included total thyroidectomy complicated by chronic hypoparathyroidism, for which she was followed by her primary care physician. One year before hospital admission, renal function was normal. The patient was on L-thyroxine at 75 mg/day, calcitriol at 1 mg/day and calcium carbonate at 1 g/day and hydrochlorothiazide at 25 mg/day. Hydrochlorothiazide had recently been added to control her blood pressure. Calcium and calcitriol were promptly stopped, and hydration and intravenous furosemide were given. We noticed that her initial phosphate levels were normal and apparently not consistent with vitamin D intoxication or her history of hypoparathyroidism. Her lab tests were checked over the following days and we observed a progressive reduction of her calcium levels (15.0–12.0–10.7–8.6 mg/dl) and creatinine (3.55–3.43–3.21–2.37 mg/dl). Unexpectedly, at the same time, her phosphate levels dropped (3.9–2.3–1.9–1.7 mg/dl). 24 h-urinary calcium (475 mg/day, normal range 50–400 mg/day) and urinary proteins were increased (19 mg/dl, normal range < 15 mg/dl), urinary phosphate reduced (0.2 g/day) but inappropriately high for her hypophosphatemia; 25(OH) vitamin D (15 ng/ml) and 1.25(OH)2 vitamin D were low (14.3 ng/ml, measured once calcitriol was stopped), CTX and bone alkaline phosphatase were within normal limits. After six days, the patient was discharged with low doses of calcitriol (0.25 mg/day) and addressed to the outpatient clinic. After fourteen days, renal function improved (creatinine 1.61 mg/dl), her calcium and phosphate levels were normal (9.5 and 2.8 mg/dl, respectively).
Discussion
Since her biochemistries improved within days, the most likely diagnosis was an overdose of calcitriol and calcium. However, this hypothesis did not explain her low phosphate levels. We believe that her hypophosphatemia might have been caused by a massive increase in her FGF-23 levels driven by calcitriol intoxication and hypercalcemia-induced acute tubular necrosis. Hypophosphatemia was unmasked soon after calcitriol was stopped. Our hypothesis could also explain the lower-than-expected tubular phosphate reabsorption in a patient with hypoparathyroidism and progressive improvement of her labs within a short time.
Final diagnosis
Calcitriol-intoxication associated with acute tubular necrosis and renal phosphate loss in a patient with chronic hypoparathyroidism.

Male osteoporosis

Aicha Bouzid[1], Djamila Meskine[1] & Azzouz malha[2]
[1]Medical university of Algiers,, Algiers, Algeria; [2]Medical university of Algiers. EPH BOLOGHINE, Algiers, Algeria

Introduction
Osteoporosis has generally been considered a female disease; this may explain why this pathology has focused less attention on men. While osteoporosis has been underestimated and poorly treated in female patients, the situation is even worse in male patients, despite the fact that up to one third of hip fractures are suffered by men.
Goal
To assess the characteristics and risk factors associated with male osteoporosis.
Patients and methods
This is a retrospective study conducted at the endocrinology department of EPH Bologhine, which included 100 patients referred for a measurement of bone mineral density. 23 patients had a Tscore<- 2.5.
Results
The mean age of the patients was 45.26 years with extremes of 20 to 82 years. A history of fracture was noted in 4 patients. Long-term corticosteroid therapy was found in 6 patients, 2 patients had cushing's disease. Hypogonadism is found in 4 patients, 2 patients were followed for digestive pathology (celiac disease and RCUH). Discussion Osteoporosis in men is a public health problem and puts you at risk of fractures. In fact, 15% of men over the age of 50 will have an osteoporotic fracture during their lifetime. One in two cases of male osteoporosis is a result of illness, treatment or exposure to a risk factor. There are multiple factors that influence the risk of fracture, beyond the simple decrease in bone mineral density and the risk of falls.
Conclusion
Male osteoporosis has a number of peculiarities that must be taken into account in diagnostic and therapeutic procedures.

AEP155

8 cases of parathyroid cancer: One-center experience

Nataliya Druzhkova & Zinaida Afanasieva
Republican clinical oncological dispensary of the Ministry of Health of the Republic of Tatarstan, Kazan, Russian Federation

Introduction
Parathyroid carcinoma (PC) occurs in 0.5–5% of cases among patients with primary hyperparathyroidism (pHPT). The prognosis for patients with PC is variable and depends on the presence of local or distant metastases and the completeness of the initial surgery. About 50% of patients become recurrence of the disease and require palliative surgery and/or drug therapy aimed at correcting severe hypercalcemia.
Objective
To assess the experience of diagnosis and management of PC in the Republican clinical oncological dispensary (RCOD) of the Ministry of Health of the Republic of Tatarstan (Kazan, Russia) in the period from 2008 to 2020.
Subjects and methods
Medical records of 8 patients with PC treated in RCOD from 2008 to 2020 were analysed.
Results
2 men aged 35 and 50 years and 6 women aged 29–76 years included in this review. 6 patients had symptomatic HPT with bone and visceral involvement, 2 had a pre-diagnosis of a thyroid tumor with mass-effect symptoms. Parathyroid hormone (PTH) varied from 350 to 3227 pg/ml (15–65), serum calcium (Ca) – from 2.77 to 3.35 mmol/l (2.0–2.57). According to ultrasound imaging, MIBI-scintigraphy, neck and chest CT PC was located on the neck in 6 patients, retrosternal – in 1 patient, in the upper mediastinum – in 1 patient. All patients received surgical treatment: 5 patients underwent hemithyroidectomy with PC removal; 1 – thyroidectomy with PC removal and central lymph node dissection; 1 – cervicotomy, sternotomy, PC removal; 1 – videothoracoscopic PC removal. Histologically and immunohistochemically PC was verified in all cases. 7 of 8 patients are alive. Recurrences of PC manifested with an increase of PTH and Ca, occurred in 2 patients. Paratracheal lymph nodes metastases were detected in male patient 5 years after the initial surgery. Multiple bones and lung metastases were diagnosed in female patient 1.5 years after first surgery. Both patients underwent palliative surgery. The persisting severe hypercalcemia after surgery in the female patient was successfully corrected with cinacalcet and denosumab for 9 months. Female patient died 3 years after the initial surgery due to hypercalcemic crisis and multiple organ failure. The male patient is alive, has mild hypercalcemia and continues treatment with bisphosphonates and calcimimetics.
Conclusion
Diagnosis of PC and its recurrence is a difficult task for the practitioner. The main method of treatment remains surgical. Hypercalcemia, which develops during the dissemination of the process, requires long-term medical correction with antiresorptive drugs and calcimimetics.

The association of vitamin D with peripheral neuropathy among prediabetic individuals and the effect of vitamin D supplementation

Mohamed Reda Halawa[1], Iman Ahmed[1], Nahla Fawzy Abouelezz[3], Laila Mohamed Hendawy[1], Naira Hany Abdelaziz[3] & Nagwa Roshdy Mohamed[1]
[1]Faculty of Medicine, Ain Shams University, Internal Medicine and Endocrinology Departement, Cairo, Egypt; [2]Faculty of Medicine, Ain Shams University, Community, Environmental and Occupational Medicine Departement, Cairo, Egypt; [3]National Institute of Diabetes and Endocrinology, Endocrinology and Diabetes Departement, Cairo, Egypt

Background
Vitamin D deficiency seems to be more prevalent among diabetic patients with distal symmetrical polyneuropathy. Besides, those patients have a lower pain threshold; there is a shortage of data concerning pre-diabetic individuals with peripheral neuropathy (PN).
Aim
First,to study the association of vitamin D deficiency with PN severity. Second, to determine the effect of vitamin D supplementation on PN in pre-diabetics.
Methods
178 pre-diabetic individuals aged18–60 years were recruited from outpatient department of the National Institute of Diabetes and Endocrinology, Cairo, Egypt; 89 patients with and 89 patients without PN (group A and group B, respectively).All patients werescreened for PN using 10 g monofilament, tuning fork, ankle reflex and pinprick test.In the first visit, baselineneuropathic total pain score and severity were assessed for group A, by Douleur Neuropathic 4 diagnostic questionnaire (DN4) and Short-form McGill Pain Questionnaire(SF-MPQ), respectively.In addition, serum 25- hydroxyvitamin D, ionized calcium, phosphorus, PTH, HbA1c, fasting blood glucose (FBG), 2hrs post 75 g glucose (2hr PPBG), creatinine, thyroid function test and lipid profile were measured for both groups. Prediabetic patients with PN were given vitamin D3 200.000IU IM monthly for 3 months. They were assessed clinically in 3 subsequent visits,one month apart. In the last visit all the laboratory measures, DN4 and (SF-MPQ) were repeated.
Results
None of the patients in both groups had sufficient vitamin D status.Vitamin D deficiency was highly prevalent among both groups, where 79.8% and 89.9% were deficient; 20.2% and 10.1% were insufficient among group A and group B respectively, *P* value 0.001.Nonetheless, there was insignificant difference in vitamin D levels between group A and group B (14 ± 6.4 and 14.6 ± 4, $P = 0.4$).Vitamin D level was negatively correlated with peripheral neuropathic total pain score and severity ($r = –0.65$, –0.47 respectively, $P < 0.001$) among group A. Moreover, vitamin D level was an independent predictor of neuropathic pain severity (odds ratio –0.18, 95% CI –0.33 –0.03, $P = 0.018$) after adjustment for age, BMI, FBG, 2hr PPBG, HbA1c, lipid profile, serum ionized calcium, phosphorus, PTH and TSH. Supplementation of vitamin D resulted in a highly significant improvement in FBG, 2hr PPBG, HbA1cand lipid profile, $P < 0.001$. Interestingly, total pain scoreand severity before vitamin D supplementation was (6.4 ± 1.6 and 28.3 ± 7.2, respectively) and after was(2.5 ± 0.9 and 17 ± 6.3, respectively, $P < 0.001$).
Conclusion
Vitamin D deficiency is prevalent among prediabetics and can be considered an independent risk factor for painful PN in those patients. Correction of vitamin D deficiency improves glycemic parameters and severity of peripheral neuropathy.

Lipid accumulation product can accurately rule out, but not rule in non-alcoholic fatty liver disease in type 1 diabetes

Jonathan Mertens[1,2,3], Eveline Dirinck[1,3], Luisa Vonghia[2,3], Sven Francque[2,3] & Christophe De Block[1,3]
[1]Antwerp University Hospital, Endocrinology, Diabetology and Metabolism; [2]Antwerp University Hospital, Gastroenterology and Hepatology; [3]University of Antwerp, Laboratory of Experimental Medicine and Paediatrics

Introduction
Lipid accumulation product (LAP), an index based on waist circumference (WC) and serum triglyceride levels, is associated with the presence and severity of non-alcoholic fatty liver disease (NAFLD). However, its potential as a risk marker of NAFLD in subjects with type 1 diabetes (T1D) has not been studied yet.
Aims
This study evaluated the ability of LAP to estimate the presence of NAFLD in adults with T1D.
Methods
Four hundred and seven adult T1D patients (age 18–88, 56.8% males) were included. Anthropometric, biochemical and imaging data were acquired during the screening visit. LAP was calculated as [WC (cm) – 58] × triglycerides (mmol/l) in females; [WC – 65] × triglycerides (mmol/l) in males. NAFLD was assessed using ultrasound, controlled attenuation parameter (CAP) and fatty liver index (FLI), ultrasound was set as the reference method.
Results
NAFLD prevalence according to ultrasound was 20.4%. LAP was positively correlated with FLI ($r = 0.728$, $P < 0.001$), CAP ($r = 0.433$, $P < 0.001$), the number of elements of the metabolic syndrome ($r = 0.659$, $P < 0.001$), age ($r = 0.115$, $P = 0.020$), insulin dose/kg ($r = 0.236$, $P < 0.001$), liver stiffness ($r = 0.110$, $P = 0.027$), HbA1c ($r = 0.188$, $P < 0.001$) and uric acid ($r = 0.324$, $P < 0.001$). LAP was negatively correlated with estimated glucose disposal as a measure of insulin sensitivity ($r = –0.478$, $P < 0.001$) and HDL-c ($r = –0.326$, $P < 0.001$). LAP values could be used to diagnose NAFLD in the total cohort (AUC = 0.767 [0.708–0.827], $P < 0.001$). The AUC to indicate NALFD was 0.790 [0.715–0.865] in males and 0.732 [0.635–0.828] in females ($P < 0.001$ for both), indicating a slight difference between genders. The ideal gender-specific cut-off value was 32.6, with a sensitivity and specificity of 70% vs . 78% for males, and 27.0 (72% vs . 75%) for females. Dichotomised based on the optimal cut-off, the prevalence of NAFLD according to LAP was 32.9%. This was significantly higher compared to ultrasound (χ^2, $P < 0.001$). True positive rate was 58/133 subjects (44%), false negative rate was 25/271 (9%), false positive rate was 56%, while true negative rate was 91%. LAP ≥ 32.6 (males) or ≥ 27 (females) was associated with ultrasound-based NAFLD (OR = 4.120 [1.954–8.690], $P < 0.001$) in a multivariate regression model including BMI (OR = 1.146 [1.043–1.260], $P = 0.005$), insulin dose/kg (OR = 4.838 [1.672–13.995], $P = 0.064$) and liver stiffness (OR = 1.410 [1.114–1.784], $P = 0.004$).
Conclusion
We are the first to demonstrate that LAP is an easily available risk marker of NAFLD in T1D, with high accuracy to rule out. If LAP is ≥ 32.6 (males) or ≥ 27 (females), NAFLD should be suspected but other tools are needed to confirm the diagnosis.

AEP158

Assessment of serum adiponectin levels in patients with type 1 diabetes and chronic kidney disease

Alena Sazonava[1,2], Tatsiana Mokhort[1] & Natalia Karlovich[1,2]
[1]Belarusian State Medical University, Endocrinology, Minsk, Belarus; [2]Republican Center for Medical Rehabilitation and Balneotherapy, Endocrinology, Minsk, Belarus

Aims
Diabetic nephropathy (DN) is a leading cause of chronic kidney disease (CKD). Renal impairment may affect not only glycemic control, but also metabolism of biologically active cytokines such as adiponectin. Taking into account multiple effects of adiponectin the purpose of the study was to assess its changes in patients with type 1 diabetes (T1D) and comorbid CKD.
Materials and methods
We recruited 129 patients with T1D and 39 healthy controls. T1D patients were divided into 2 groups according to GFR. The group 1 comprised 67 patients with GFR > 60 ml/min, group 2–62 patients with GFR < 60 ml/min. Biochemical parameters, lipid profile, HbA1c, NGAL, serum adiponectin levels were measured. Nonparametric statistical methods were used. A P-value < 0.05 was considered significant.
Results
Comparison groups were matched by age, gender, BMI, duration of T1D, HbA1c levels. Comparative analysis of patients in the subgroups according to GFR revealed reliable differences in basal adiponectin levels. Mediana of adiponectin levels in patients with GFR > 60 ml/min (15.65 [9.34; 32.58]) were lower than those in GFR < 60 ml/min (28.21 [16.73; 45.34]), control group had 37.58 [27.38; 42.86]). Then we divided T1D patients according CKD stages. Adiponectin level was 15.65 [9.34; 32.58] in CKD 1–2 ($n = 67$), in CKD 3 ($n = 32$) was 25.36 [14.02; 39.40], in CKD 4 ($n = 14$) was 27.46 [12.83; 69.31], in CKD 5 ($n = 16$) was 32.76 [23.54; 57.34]. It was found that the values of the median adiponectin levels progressively increase with deterioration of renal function towards end-stage CKD ($P = 0.002$), which suggests the possibility of considering this parameter as an indirect marker of decreased renal function. In both comparison groups, correlations

of adiponectin levels with marker of renal damage NGAL were obtained (ρ^1 =–0.413 and ρ^2 =–0.427, resp.). Patients with T1D and GFR < 60 ml/min had relationship between adiponectin and serum creatinine (ρ = 0.302) and eGFR (ρ =–0.298), which indicates the sensitivity of this parameter to decrease in renal function. The increase in adiponectin levels is most likely due to the non-absolute content of adiponectin in the serum, but the relative increase in the amount due to the decrease in renal clearance. We didn't observed relationship of adiponectin and BMI, gender, HbA1c.
Conclusion
In patients with T1D and diabetic nephropathy decline of GFR is accompanied by an increase of serum adiponectin levels due to decrease in renal clearance. Correlation of adiponectin and renal impairment markers suggests the possibility of considering this parameter as an indirect marker of decreased renal function.

Pharmacogenetics of metformin in polycystic ovary syndrome and type 2 diabetes mellitus

Moritz Strasser[1,2], Natascha Schweighofer[1,3], Anna Obermayer[3], Valentin Borzan[1,3], Christoph Haudum[1,3], Elisabeth Lerchbaum[3], Christian Trummer[3], Hans Dimai[3], Caren Sourij[3], Harald Sourij[3], Thomas Pieber[1,3] & Barbara Obermayer-Pietsch[3]
[1]CBMed Center for Biomarker Research in Medicine, Graz, Austria; [2]FH Joanneum, Graz, Austria; [3]Medical University Graz, Department of Internal Medicine, Division of Endocrinology and Diabetology, Graz, Austria

Background
Metformin is a widely used and effective agent in type 2 diabetes mellitus (T2DM) and polycystic ovary syndrome (PCOS). Yet, the mechanisms of action and the occurrence of side effects (e.g. abdominal bloating and pain), are still poorly understood. Since organic cation transporters (OCTs) are responsible for the hepatic and renal transport of metformin, we investigated a series of short nucleotide polymorphisms (SNPs) in the OCT genes in PCOS and in T2DM patient samples from either our PCOS patient registry or the Graz Diabetes Registry for Biomarker Research (GIRO).
Methods
After DNA isolation from plasma in 181 PCOS samples and 44 T2DM samples followed by a subsequent polymerase chain reaction (PCR) with a combined TaqMan assay, we compared 17 SNPs (rs456598, rs461473, rs3798174, rs7766568, rs316007, rs3798167, rs662301, rs2048327, rs376563, rs622591, rs9295125, rs3798172, rs2197296, rs12208357, rs34059508, rs628031 and rs3777392) from OCT1 and OCT3 transporters.
Results
Data of the study participants were analyzed according to the presence or absence of documented metformin-induced side effects. The distributions of different genotypes of the rs2197296 locus in the SLC22A1 gene, the rs376563 locus in the SLC22A2 gene and the rs3798167 locus in the SLC22A3 gene were statistically significant between the two groups. The effect was shown by a higher minor allele frequency in the group with documented metformin associated side effects ($\chi^{(2)}$ = 3.953, P = 0.047, $\chi^{(2)}$ = 7.342, P = 0.025 and $\chi^{(2)}$ = 12.251, P = 0.002 respectively).
Conclusion
In conclusion, we found three specific allelic variants in OCT candidate genes with distinct associations for side effects in metformin users either in PCOS or in T2DM. Therefore, those variants can be further investigated to better understand the metformin-associated side effects.

Background
Therapeutic experience with SGLT2i is limited in the elderly. Its initiation is not recommended in patients over 85 years based on volume depletion risk. The aim of this study is to analyze clinical efficacy and safety of SGLT2i in elder T2DM patients.
Methods
This observational retrospective study included 544 T2DM subjects who initiated SGLT2i as add-on treatment between February 2018–2019 and were monitored until February 2020. Two groups were performed: youngest-old = aged 60–74 years (N = 282) and old = 75 years and older (N = 111), patients < 60 were excluded. Clinical and biochemical outcomes were studied at baseline and at the end of monitoring.
Results
Mean age for the youngest-old was 62.3 and 79.7 for the old (maximum age 92 and N = 55 were ≥ 80). Most used SGLT2i was Empagliflozin (75.5% vs 79.28%, p 0.483). In 15.95% of the youngest SGLT2i adjustment was made facing 6.3% of the old (p 0.011). Both groups were fairly homogeneous in male percentage, renal function, HbA1c, stablished CVE, preexisting heart failure (HF) and use of loop diuretics (see table1). In the old group, patients had longer duration of T2DM, more concomitant insulin users and lower BMI.

Table 1.

	Youngest-old 60–75 (N = 282)	Old ≥75 (N = 111)	p
Male (N;%)	176 (62.4)	57 (51.3)	NS
BMI (kg/m² ± SD)	31.3 ± 6.27	29.57 ± 4.05	0.002
eGFR (ml/min ± SD)	83.3 ± 19.6	74.15 ± 17.90	NS
HbA1c (mean% ± SD)	7.85 ± 1.20	8.16 ± 1.27	NS
DM duration (years ± SD)	13.28 ± 7.46	16.97 ± 7.56	< 0.001
Insulin treatm ent (N;%)	83 (29.43)	49 (44.14)	0.005
Loop diuretic (N:%)	34 (12)	17 (15.31)	NS
Stablished CV disease (N;%)	77 (27.3)	33 (29.7)	NS
Pre-existing HF (N:%)	33 (11.7)	16(14.4)	NS
CVE follow-up (N:%)	12 (4.2)	6 (5.4)	NS
SGLT2i discontinuation (N;%)	45 (15.9)	27 (24.32)	NS
HF follow-up (N;%)	13 (4.6)	9 (8.10)	NS
Death	7 (2.4)	5 (4.5)	NS

Final %HBA1c was lower in the youngest: 6.9% (–0.88) vs 7.5% (–0.67), (p 0.136). CVE were infrequent: peripheral vascular disease was the main event in the youngest (6/12) whereas stroke prevailed in the elderly (4/6). There was a tendency to more SGLT2i discontinuation, HF in follow-up and death in the elderly although it was not statistically significant. The most frequent side effects in youngest and oldest were eGFR drops < 30, genital and urinary tract infection (31.8 vs 37%, 28.8% vs 22%; and 15.5% vs 25%). Oncological disease (6/7) was the main death cause in the youngest group while CVE and HF were in old group.
Conclusions
Initiation of SGLT2i seems to be safe and effective regardless of age.

An analysis of flash glucose monitoring (FGM) data on insulin-treated patients with diabetes: Effects of COVID-19 lockdown

Tanveer Ashraf, Radwa Helal, Maria Majeed & Nader Lessan
Imperial College London Diabetes Centre, Research, Abu Dhabi, United Arab Emirates

Introduction
Following the WHO declaration of COVID-19 as a pandemic and as many countries around the world, the United Arab Emirates government introduced gradual measures to stop the spread of the virus placing the country in a state of almost complete-lockdown. We report the impact of these restrictions on glucose control in patients with type 1 diabetes (T1D) and type 2 diabetes (T2D) on insulin therapy.
Methods
Data were retrieved on 21 individuals who were monitoring their glucose levels using FreeStyle Libre flash glucose monitoring (FGM) and were remotely connected to the diabetes clinic at Imperial College London Diabetes Centre (ICLDC), Abu Dhabi, UAE. Fourteen (8 females and 6 males) individuals had viable data (> 3 scans per day; consecutive 3 days) using international consensus on use of continuous glucose monitoring guidelines (Danne, Nimri *et al*. 2017). Non-parametric analyses of the data were performed on average glucose, percentage time in range (3.9–10.0 mmol/l) and percentage time in hyperglycaemia (> 10.0 mmol/l) using the Wilcoxon signed-rank test in STATA 15.0. These variables were calculated for each of the following periods: 30 days before the announcement of lockdown (period 1); and 30 days into lockdown (period 2) using MATLAB.
Results
Overall glycaemic control improved during lockdown as compared to the weeks before the spread of SARS-CoV-2. The 24-hour glycemic patterns were divided into 3-hour time slots for review and analyses; thus, identifying precise spikes contributing to hyperglycaemia. The highest glycaemic peaks were observed between 2 pm-5 pm (period 1) and between 7 pm-9 pm (period 2). Average glucose median (IQR) declined significantly from 7.5 (6.1, 10.8; period 1) to 6.9 (6.2, 9.9; period 2; $P = 0.005$) mmol/l. There was a modest, but statistically significant improvement in percentage of time in range (TIR) (3.9–10.0 mmol/l) from 88.5% to 90.6% ($P = 0.07$); glucose management indicator (GMI) also improved modestly and in a similar way from 6.5 (5.9, 8.0) % in period 1 to 6.3 (6.0, 7.6) % in period 2 ($P = 0.041$).
Conclusion
Despite the limited possibility to exercise and the incumbent psychologic stress of the COVID-related lockdown period, our study indicates an improvement in FGM-derived markers of glycaemic control. This suggests that slowing down routine daily activities can have beneficial effects on diabetes management.

Effects of long-term testosterone therapy on anthropometric parameters in men with functional hypogonadism and obesity: 12-year observational data from a controlled registry study in a urological setting

Farid Saad[1], Karim Sultan Haider[2] & Ahmad Haider[3]
[1]Bayer Ag, Medical Affairs Andrology, Berlin, Germany; [2]Private Urology Practice, Bremerhaven, Germany

Background
While almost all studies consistently show reduction of waist circumference as a result of testosterone therapy (TTh), effects on body weight are inconsistent and may depend on treatment duration, route of administration, and adherence.
Material and methods
After excluding men with primary hypogonadism, 476 men with functional, symptomatic hypogonadism were obese. 281 men received testosterone undecanoate injections 1000 mg/12 weeks following an initial 6-week interval (T-group), 195 men opted against TTh and served as controls (CTRL). Anthropometric measurements were performed at every visit for approximately 4.367 patient-years. 12-year data are reported. Changes over time between groups were compared and adjusted for age, weight, waist circumference, fasting glucose, blood pressure, lipids and quality of life to account for baseline differences between the two groups.
Results
Mean baseline age (years): 59.9 ± 5.5 (T-group), 62.9 ± 5.0 (CTRL) ($P < 0.0001$). Mean (median) follow-up: 9.4 ± 3.0 (11) years (T-group), 8.9 ± 3.0 (10) years (CTRL). Anthropometric parameters at 12 years, mean ± SE: Waist circumference (cm) decreased by 13.7 ± 0.3 (T-group) and increased by 8.1 ± 0.4 (CTRL), estimated adjusted difference between groups: –21.8 [95% CI: –22.9; –20.7] ($P < 0.0001$ for all). Weight (kg) decreased by 23.7 ± 0.4 (T-group) and increased by 7.3 ± 0.5 (CTRL), between-group difference: 31.0 [95% CI: –32.5; –29.6] ($P < 0.0001$ for all). Weight loss was 20.9 ± 0.3% (T-group), weight gain 7.8 ± 0.4% (CTRL), between-group difference: –28.7% [95% CI: –29.8; –27.5] ($P < 0.0001$ for all). BMI (kg/m^2) decreased by 7.8 ± 0.2 (T-group) and increased by 2.5 ± 0.3 in CTRL, between-group difference: –10.2 [95% CI: –11.0; –9.5] ($P < 0.0001$ for all). Waist:height ratio decreased by 0.08 ± 0.00 (T-group) ($P < 0.0001$) and increased by 0.05 ± 0.00 (CTRL) ($P = 0.05$), between-group difference: –0.12 [95% CI: –0.13; –0.12] ($P < 0.0001$). The visceral adiposity index (VAI) decreased by 2.8 ± 0.1 (T-group) and increased by 3.8 ± 0.2 (CTRL), between-group difference: –6.6 [95% CI: –7.2; –6.1] ($P < 0.0001$). 25 patients (8.9%) died in the T-group and 77 (39.5%) in CTRL ($P < 0.0001$). Medication adherence to testosterone was 100% as all injections were administered in the medical office and documented.
Conclusion
In men with hypogonadism and obesity, long-term TTh improves anthropometric parameters which may be a contributing factor to the observed reduction in mortality.

Semaglutide reduces fat accumulation in the tongue of obese women with polycystic ovary syndrome: A randomized, placebo-controlled prospective study

Mojca Jensterle[1,2], Simona Ferjan[1,2], Andrej Vovk[2], Tadej Battelino[3], Manfredi Rizzo[4,5] & Andrej Janez[1,2]
[1]University Medical Centre Ljubljana, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia; [2]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, Zaloška cesta 7,1000 Ljubljana, Slovenia; [3]Department of Pediatrics, Faculty of Medicine, University of Ljubljana, Bohoričeva 20, SI-1000 Ljubljana, Slovenia; [4]Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, University of Palermo, Italy; [5]Division of Endocrinology, Diabetes and Metabolism, Department of Medicine, University of South Carolina, Columbia, SC, USA

Objective
Fat depot in the tongue that represents 25–30% of the total tongue mass is largely unaddressed. It correlates with body mass index. The response to weight reduction induced by different anti-obesity modalities may vary between body fat compartments. Semaglutide, a long acting GLP-1 receptor agonist (GLP-1 RA), has the potential to reduce body mass with at least 2 to 3 times greater weight reduction than other studied GLP-1 RAs. This is the first study that assessed the effect of semaglutide on fat storage in the tongue in obese women with PCOS over 16 weeks.
Research design and methods
We conducted a single-blind, randomized, placebo-controlled prospective study comparing the effects of semaglutide versus placebo. 30 women (aged 33.7 ± 5.3 years, BMI 36.1 ± 3.9 kg/m^2, mean ± SD) diagnosed with PCOS by Rotterdam criteria, phenotype A, were randomized in a 1:1 ratio to semaglutide 1.0 mg (SEMA) or placebo group. Quantification of the tongue volume, fat and proportion of fat were obtained by MRI analysis. Total tongue volume was inferred via summation of the tongue mask voxels over all slices and multiplied by single voxel volume. Number of voxels defining the fat tissue was extracted with AFNI.
Results
25 patients concluded the study, 5 were excluded due to protocol violation associated with limitations due the COVID-19 pandemic. Weight reduction was significantly greater in SEMA when compared to placebo group (–5.2 ± 4.0 kg vs + 1.9 ± 5.6 kg, $P = 0.001$). BMI decreased by 1.9 ± 1.5 kg/m^2 in SEMA and increased by 0.7 ± 1.9 kg/m^2 in placebo group. The tongue fat reduction and reduction in tongue fat proportion were significantly greater in SEMA than in placebo (–1944 ± 5510 mm^3 in SEMA vs + 3116 ± 4868 mm^3 in placebo, $P = 0.022$ and –2% ± 7% in SEMA vs + 4% ± 6% in placebo, $P = 0.01$, respectively). Change in the total tongue volume did not significantly differ between the two groups. In SEMA, the tongue fat and tongue fat proportion were significantly reduced in 47% of patients whereas in the placebo group the tongue fat was reduced in only 17% of subjects. By correlation analysis we also found that the reduction of the tongue fat was associated with the reduction of body mass.
Conclusion
Compared with placebo, semaglutide treated patients lost significantly more fat in the tongue. Future studies are needed to assess the clinical

importance of the observed composition change in this unique therapeutic target, particularly in populations with obesity related sleep apnea, including PCOS.

The short-term effect of surgical and pharmacological intervention in obesity caused by MC4R deficiency: A single centre experience

Saradalekshmi Koramannil Radha[1], Esphie Grace Fojas[1], Tomader Ali[1], Sara GI Suliman[2] & Nader Lessan[1]
[1]Imperial College London Diabetes Centre, Research Department, Abu Dhabi, United Arab Emirates; [2]Imperial College London Diabetes Centre, Abu Dhabi, United Arab Emirates

Introduction
Melanocortin-4-receptor (MC4R) deficiency is the commonest of the rare monogenic forms of obesity. Bariatric surgery (BS) is the most efficacious treatment modality in the more 'common' polygenic obesity. Effect of surgical and drug treatment in obesity due to MC4R deficiency is not well-established.
Aim
We aimed to explore the effects of BS and drug treatment among the confirmed cases of obesity due to MC4R deficiency and compare the short term weight loss was control group who were tested negative for MC4R mutations.
Methods
Based on a strong family history and phenotypic characteristics, genetic screening for MC4R mutation(s) was conducted in 27 morbidly obese ICLDC patients. Data on pharmacotherapy and surgical treatment, including treatment dates, and duration was retrieved from electronic patient records. Weight loss percentage at a median of 6 months post-intervention was compared between age- and sex-matched MC4R-deficient and wild-type controls.
Results
Of the 27 patients, 8 were confirmed to have MC4R mutations. Three specific mutations were identified: Val103Ile, Ile170Val and Thr162Ile (most common). Six MC4R deficient patients and eight MC4R normal patients underwent sleeve gastrectomy. Weight loss at median 6 months post bariatric surgery was not significantly different between MC4R deficient and MC4R normal patients (P = 0.065). However the weight loss post BS in MC4R deficient patients showed variation depending on the type of mutation [17.99(6.1–22.54)%]. Homozygous Thr162Ile did not benefit from BS in terms of weight loss compared to their age and sex matched controls. Heterozygous Thr162Ile and homozygous Ile170Val benefited similarly from BS compared to the controls. Response to Liraglutide treatment was comparable in MC4R Thr162Ile heterozygous patient and control.
Conclusion
Observations from our study suggest that efficacy of surgical and medical intervention in MC4R deficient patients might depend on the mutation type and zygosity. Thr162Ile homozygous individuals might require multiple surgeries or continued pharmacological intervention to maintain weight loss over longer period of time.

Table 1. Comparison of weight loss following surgical and pharmacological interventions between MCR4 deficient and age and sex- matched MC4R normal individuals

Type of intervention	Age	Sex	Mutation	Zygosity	Weight loss %	
					MC4R deficient	MC4R Wild type
Sleeve gastrectomy	33.5/32.2	F	Thr162Ile	Heterozygous	19.05	15.24
	23/18	M	Ile170Val	Homozygous	22.54	29.9
	18/17.8	M	Thr162Ile	Homozygous	8.08	35.27
	14/18	F	Thr162Ile	Homozygous	6.91	23.75
	24.5/18	F	Thr162Ile	Heterozygous	20.81	23.75
Liraglutide	22.9/18.2	F	Thr162Ile	Heterozygous	4.89	5.61
Orlistat	20.5/19.5	M	Ile170Val	Homozygous	–0.91	10.29
	12/14.5	M	Thr162Ile	Homozygous	–4.62	–4.1

Circulating microRNAs as predictive tool of the effectiveness of lifestyle intervention for weight loss

Mercedes Clemente-Postigo[1,2], Leticia Coin-Araguez[2], Jose Carlos Fernández-García[2], Juan A Alcaide-Torres[2,3], Rajaa El Bekay[4], Maria Rosa Bernal-Lopez[3,5], Manuel Macias-Gonzalez[2,3] & Francisco J Tinahones[2,3]
[1]Department of Cell Biology, Physiology, and Immunology; Maimónides Biomedical Research Institute of Córdoba (IMIBIC)/University of Córdoba/Reina Sofia University Hospital; Córdoba, Spain, Cordoba, Spain; [2]Instituto de Investigación Biomédica de Málaga (IBIMA). UGC Endocrinología y Nutrición (Hospital Universitario Virgen de la Victoria), Universidad de Málaga, Malaga, Spain; [3]Centro de Investigación Biomédica en Red (CIBER) Fisiopatología de la Obesidad y Nutrición (CIBEROBN), Instituto de Salud Carlos III (ISCIII), Spain; [4]UGC Endocrinología y Nutrición (Hospital Universitario Regional de Málaga), Instituto de Investigación Biomédica de Málaga (IBIMA), Universidad de Málaga, Spain; [5]Internal Medicine Department, Regional University Hospital., Instituto de Investigación Biomedica de Malaga (IBIMA)., Spain

Background and aims
Lifestyle modifications based on diet and exercise are common strategies for the treatment and prevention of obesity and related comorbidities. However, not all patients respond equally to similar weight loss intervention which compromise patient adherence. Strategies for predicting the individual response are required for improving intervention efficiency by personalized recommendations. microRNAs (miRNAs), small RNA particles which regulates gene expression, has been detected in the circulation and proposed as biomarkers for disease and treatment response. However, there are few studies analyzing the usefulness of circulating miRNAs (c-miRNAs) as predictive biomarkers for the response to lifestyle modifications. Furthermore, c-miRNAs has not been specifically analyzed regarding interventions based on Mediterranean diet, which has been associated with higher health-related quality of life. Thus, the aim of this study was to analyze the relationship of the response to hypocaloric Mediterranean diet and promotion of physical activity with c-miRNAs previously associated with Type 2 Diabetes (T2D) and obesity.
Material and methods
Obese subjects (BMI > 30 kg/m^2; n = 60) underwent a hypocaloric Mediterranean diet together with increased physical activity during 1 year and c-miRNA levels as well as biochemical and anthropometric parameters were determined before and at year 1. Participants were classified according to their 1-year weight loss in low-responders (LR) and high-responders (HR).
Results
There was a significant improvement in anthropometric and biochemical variables after intervention, together with significant modification in miR-150 levels. HR subjects had lower baseline miR-130a and miR-150 levels than LR group (P < 0.05). There were positive and significant (P < 0.05) correlations between baseline miR-130a levels and weight at year 1; baseline miR-150 levels and HbA1c and triglyceride levels at year 1; baseline miR-142–3p and weight, BMI and glucose levels at year 1. In a lineal regression model baseline miR-150 levels were independently associated with weight loss at year 1. Notably, In silico enrichment analyses of miRNA target genes showed an involvement in adiposity-related and metabolic pathways.
Conclusion
c-miRNAs might be predictive biomarkers for the interindividual response to dietary intervention based on Mediterranean lifestyle.

The ecology of the microbiome in children with obesity is associated to insulin resistance anddiet composition

Roberta Ricotti[1], Francesca Archero[1], Valentina Landoni[1], Valentina Mancioppi[1], Marina Caputo[2], Simonetta Bellone[1], Arianna Solito[1], Valentina Antoniotti[1], Elisa Gamalero[3], Nadia Massa[3], Flavio Mignone[3,4,5], Maria Cavaletto[3], Emanuela Agosti[6], Elisa Bona[3,5] & Flavia Prodam[2,6]
[1]Università del Piemonte Orientale, SCDU Pediatrics, Department of Health Sciences, Novara, Italy; [2]Università del Piemonte Orientale, Endocrinology Unit, Department of Translational Medicine, Novara, Italy; [3]Università del Piemonte Orientale, Department of Sciences and Technological Innovation, Vercelli, Italy; [4]SmartSeq S.R.L., spin-off of the Università del Piemonte Orientale, Novara, Italy; [5]UPO-CAAD- Center of Translational Research on Autoimmune and Allergic Disease, Novara, Italy; [6]Università del Piemonte Orientale, Department of Health Sciences, Novara, Italy

Introduction
In the pediatric population, the progression of obesity-related diseases can be delayed or prevented through lifestyle changes, including the promotion of a Mediterranean-like dietary (MD) pattern.
Objective
We aimed to evaluate the gut microbiome ecology in relation to dietary and clinical parameters in the pediatric subjects with obesity recruited at baseline in a protocol on an educational training to MD.
Methods
A total of 55 subjects (6 and 18 years) with obesity, diet naïve or with failure to a previous weight loss program were recruited. We collected auxological, metabolic, nutritional parameters (KIDMED score; IDEFICS food frequency questionnaire), and stool samples. DNA was extracted directly from 0.25 g of stool using the Power SoilKit. DNA was amplified with primers for the V3 and V6 regions of 16S rDNA tagged with Multiplex Identifier sequences using Microbiota Solution B Kit optimized for Illumina Miseq sequencing. Raw FastQ sequences were analyzed using MicrobAT Software. Statistical analyses were performed using R software.
Results
All the 55 subjects showed a Bacteroides enterotype: 38% Bacteroidetes, 34% Firmicutes, 22% Unclassified Bacteria, 4% Actinobacteria, 1% Proteobacteria. At baseline, clinical and metabolic characteristics were homogeneous among children while microbial communities associated with the different subjects showed statistically significant differences according to age, Tanner stage considering sex, fasting insulin levels, fasting insulin resistance (HOMA-IR 95° percentile), percentage of carbohydrates, and fiber intake with the diet. In particular, considering HOMA-IR, *Bifidobacterium pseudocatenulatum*, unclassified Faecalibacterium, Bifidobacterium sp., Unclassified Sutterella, and unclassified Blautia were correlated with higher insulin resistance while *Dialister invisus* and Barnesiella sp. were associated with lower insulin resistance. Moreover, we observed *Bacteroides dorei, Bacteroides vulgatus*, Unclassified Ruminococcaceae, and unclassified Faecalibaterium associated with a higher carbohydrate intake. Finally, with a greater daily intake of fibers (> 8.5 g/1000 Kcal) we observed a decrease in Unclassified Faecalibacterium and an increase in *Ruminococcus bromii, Gemmiger fomicilis*, and Prevotella sp.
Discussion
These preliminary results highlight as diet, insulin sensitivity, and microbiome are strictly related also in children with obesity. We identified several bacterial groups not previously described in obesity. These findings are of importance for clustering patients and studying tailored dietary programs.

Amniotic membrane treatment of an oxidative stress murine chronic diabetic wound model

Adriana Panayi[1], Mengfan Wu[1], Qinxin Liu[2], Mehran Karvar[1], Shimpo Aoki[1], Yori Endo[1], Chenhao Ma[3], Ryoko Hamaguchi[1] & Dennis Orgill[1]
[1]Harvard Medical School, Boston, United States; [2]Tongji Medical College of Huazhong University of Science and Technology College of Medicine and Health Management, Wuhan Shi, China; [3]Peking Union Medical College Hospital, China

Background
To date, available animal models have failed to replicate the complex pathophysiology of chronic diabetic wounds. In a recent study we administered a regimen of antioxidant enzyme inhibitors (AIE) to develop a reliable and effective murine model. Here we use this model to test the efficacy of an amniotic membrane (AM) scaffold.
Methods
30 db/db mice received a pre-established AIE regimen and a 1 × 1 cm^2 full thickness skin wound was excised on their dorsum. The wounds of 15 mice were covered with AM and occlusive dressing (AM group). The remaining 15 received only occlusive dressing (Blank group). The wounds were photographed on day 0, 10, 14, 21 and 28 and mice were sacrificed at various time points with the tissue harvested for analysis.
Results
Histologically, the mice in the AM group had higher wound bed thickness, collagen deposition and keratinocyte proliferation than the Blank mice. The amniotic membrane appeared to improve the vascularization of the wound, both in terms of density and maturity of the vessels. Leucocyte infiltration was comparable between the groups and the wound healing rate of the AM group was similar to the untreated mice.
Conclusions
The AIE regimen arrested the wounds in the inflammatory stage of healing while treatment with amniotic membrane offers promising potential. Although the wound healing rate between the two groups was comparable, the scaffold improved the overall quality of the wound elucidating the mechanisms of function of the scaffold on chronic wound healing. Better understanding of the mechanisms of healing of chronic wounds will be instrumental for the development of more effective treatments.

AEP168

Use of the thrombolysis in myocardial infarction risk score for heart failure in diabetes in a type 2 diabetes mellitus outpatient population

Diogo Ramalho, Sara Correia, Lucia Almeida, Helena Alves, Gustavo Melo & Maria João Oliveira
Centro Hospitalar Vila Nova de Gaia / Espinho – Unit 1, Endocrinology, V.N. Gaia, Portugal

Background
Type 2 Diabetes Mellitus (T2DM) and Heart Failure (HF) are two directly related diseases associated with considerable morbimortality. The prevalence of HF in T2DM populations is up to 20%, 4 times higher than the general population. Additionally, health-related quality of life, hospitalizations for HF (HHF) and mortality risk are more common when both are present. Hence, HHF risk assessment in T2DM patients may lead to prompt preventive interventions.
Aim
To assess the stratification accuracy of the Thrombolysis In Myocardial Infarction (TIMI) Risk Score for Heart Failure in Diabetes (TRS-HFDM) for predicting hospital admissions for HF in a T2DM adult outpatient population.
Material and methods
We conducted a cross-sectional study in T2DM adult outpatients between December 2015 and December 2020. The TRS-HFDM, a novel, practical and validated risk score, was applied for prediction of hospital admissions for HF. It comprises prior HF (yes = 1), history of atrial fibrillation (yes = 1), CAD (yes = 1), estimated glomerular filtration rate (yes = 1), and urine albumin-to-creatinine ratio (microalbuminuria [> 30 mg/g] = 1; macroalbuminuria [> 300 mg/g] = 2). The TRS-HFDM ranges from 0 to 7 points, where 0, 1, 2 and ≥ 3 points are graded as 'low risk', 'intermediate risk', 'high risk' and 'very high risk'. ROC curve analysis was used to find the most appropriate TRS-HFDM cutoff point for the highest possible combination of sensitivity and specificity in predicting the primary endpoints: emergency room (ER) visits and HHF. Mann-Whitney U test was performed to compare TRS-HDFM scores between patients with and without the aforementioned outcomes. Binary logistic regression was applied to characterize the relationship between these variables.
Results
This study encompassed 353 T2DM patients, 197 women (55.8%), with a mean age (SD) of 73 (9) years. HF was present in 109 (30.9%) patients. 48 (13.6%) individuals had ≥ 1 ED visits and 36 (10.2%) ≥ 1 HHF. A TRS-HFDM cutoff of ≥ 3 showed the best combination of sensitivity/specificity in predicting ER visits (97.9% and 76.1%, respectively) and HHF (100% and 73.5%, respectively). There was a statistically significant increase in scores between patients who had those outcomes and those who did not (ER visit: OR = 2.835, $P < 0.001$; HHF: OR = 2.886, $P < 0.001$).
Discussion and conclusions
Our analysis proposes a cutoff of ≥ 3 to identify T2DM outpatients at risk for hospital admissions for HF. Greater absolute reductions are expected if early patient-tailored protective interventions take place in higher scores. Therefore, this simple tool may help in diminishing morbimortality in T2DM outpatients.

Glycemic control and complication rate through pregnancy and thirteen-years post-partum in women with microalbuminuria (type 1 diabetes T1DM)

Natalia Asatiani, Ramaz Kurashvili, Ekaterine Inashvili, Elena Shelestova & Ana Kopaleishvili
Georgia, National Center for Diabetes Research, Diabetes in Pregnancy, Tbilisi, Georgia

The aim of the present work was to assess the degree of glycemic control and complications rate through pregnancy and thirteen-years post-partum in women with microalbuminuria (T1DM).

Materials and methods
In total 191 patients with T1DM were enrolled in the study. Based on albuminuria levels in the 1st trimester women were separated into 2 groups (Gr.). Gr.1 – 116 women with normoalbuminuria, Gr.2 – 75 women with microalbuminuria. Preconception care was performed in 46.5%- Gr.1 and 57.3% -Gr.2. Strict metabolic control was maintained and fetal surveillance was performed throughout the pregnancy. Repeated examinations –13 years post-partum.
Results
At entry HbA1c(%) levels for Gr.1 and 2 were: 7.42 (0.15) and 7.25 (0.14); by the end of the pregnancies they statistically decreased in both groups (Gr.1- $P = 0.000$, Gr.2 – $P = 0.000$). At entry percent (%) of retinopathy for Gr.1- 8.6 and Gr.2–20.0; by term the percent has not increased. The percent of women with macroalbuminuria increased, together with the growth of gestational age. By term macroalbuminuria was observed in 2.5% (Gr.1) and in 14.6% (Gr.2) of patients ($P = 0.0094$, OR-5.67). In Gr.1 percent of pre-eclampsia and preterm deliveries before 37 weeks of gestation was lower, than in Gr.2 (pre-eclampsia – $P = 0.0064$, OR –4.64; preterm deliveries $P = 0.048$; OR –2.8). Perinatal mortality was observed in Gr.1 – 0.8% and in Gr.2 – 6.6% of women ($P – 0.006$, OR – 7.73). Repeated examinations 13 years post-partum showed that HbA1c levels were statistically higher, than at the end of pregnancy: Gr.1–7.7 (0.41) ($P = 0.0002$), Gr.2 – 8.05 (0.26) ($P = 0.000$). Repeated examinations showed that percent of retinopathy, micro and macroalbuminuria, increased in both groups. Besides, patients from Gr.2 had statistically higher complications rate, than patients from Gr.1 (retinopathy – $P = 0.0002$, OR – 3.45; microalbuminuria – $P < 0.0001$, OR – 10.2; macroalbuminuria – $P = 0.0032$, OR- 3.03). Chronic kidney disease (stage 3–6) were observed in 36 patents. Nine patients from Gr.2 are on regular hemodialysis, and in two patient kidney transplantation was performed.
Conclusion
If microalbuminuria was detected in the 1st trimester, the risk of preeclampsia increased 4.6 times, the risk of preterm delivery increased 2.8 times and risk of perinatal mortality increased 7.3 times, compared to patients with normoalbuminuria. In both groups glycemia control deterioration was observed thirteen years post-partum. The higher complication percent was found if pregnancy proceeded with microalbuminuria, the risk of retinopathy increased 3.4 times and the risk of CKD increased 3 times compared to patients with normoalbuminuria.

Impact of social isolation and quarantine on the course of diabetes mellitus and its complications during Covid 19 pandemic in Adjara Region Country of Georgia

Liana Jashi[1,2], Ketevan Dundua[2], Rusudan Kvanchakhadze[2] & Nino Nizharadze[3]
[1]Batumi Endocrinology Center, Endocrinology, Batumi, Georgia; [2]David Agmashenebeli University of Georgia, School of Medicine and Dentistry, T'bilisi, Georgia; [3]Ministry of Health and Social Affairs Autonomous Republic of Adjara, Minister, Batumi, Georgia

Background
SARS-CoV-2 infection produces greater morbidity and mortality in people with cardiovascular disease, diabetes, and obesity. Quarantine and social distancing are necessary measures to prevent the virus from spreading but also lead to elevated levels of loneliness and social isolation. The aim of the study was to research impact of Social isolation and quarantine on compensation of diabetes and on progression of its complications.
Methods
A specific questionnaire was developed by us and was launched on the Google platform. In this Survey was participated 16 endocrinologists and 22 family and general practice doctors.
Resalts:
In the clinics patients application decreased by 79.9%; in 64.8% patients for communication was used mobile phone and social media. New diabetes cases manifestation was in 58.4%; HbA1c 6% to 23.5%, 7%-26.5%, 8%–41.2% and up 8.8% ketoacidosis (DKA) –4%; Hypoclicemia-22% anxiety and fear were observed on 82% of patients . 11.5% of ambulatory patients was switched on insulin therapy; stable angina pectoris attack increased by 35.5%, hospitalization MI was needed in 41.5%; BP levels increased in 88.2% of patients, high blood pressure hospitalization was declared in 50% cases, HF –35.5%, Nephropathy was complicated –4.9%, deterioration of vision was in 55.9% of patients; weight gain in 97.1%; cigarette consumption has increased on 35.3%; alcohol- 29.4%; Physical activity decreased in 29.8%.
Conclusion
According to doctors survey, social isolation and quarantine in diabetes reduces the availability of medical care, increases the weight of the patient, blood pressure, causes bad cigarette habits, increases alcohol consumption, and also worsens the emotional background of patients, which leads to the development of pre-existing cardiovascular diseases and other complications risk. The issue requires additional large-scale research.

AEP171

Risk factors of cardiovascular autonomic neuropathy in patients with prediabetes and coronary artery disease

Olena Stepura[1,2], Nadiia Zherdova[1,2], Georgy Manko vs ky[3] & Borys Mankovsky[1,2]
[1]State Scientific Institution 'Center for Innovative Medical Technologies of the National Academy of Sciences of Ukraine', Department of diagnosis and treatment of metabolic diseases, Kyiv, Ukraine; [2]P.L. Shupyk National Medical Academy of Postgraduate Education, Department of Diabetology, Kyiv, Ukraine; [3]Scientific and Practical Medical Center of Pediatric Cardiology and Cardiac Surgery, Department for adults, Kyiv, Ukraine

Background
Cardiovascular autonomic neuropathy (CAN) is a chronic complication associated with high risk of cardiovascular morbidity and mortality either in patients with diabetes mellitus and prediabetes. However, risk factors of CAN in patients with prediabetes and coronary artery disease (CAD) was not fully investigated.
Aims
The aim of this study was to investigate risk factors of CAN in patients with prediabetes and CAD.
Materials and methods
We examined 32 patients with prediabetes and angiography confirmed stenosis of coronary arteries, 20 males and 12 females (aged 61.44 ± 1.92 years, HbA1c – 5.87 ± 0.1%) (data are presented everywhere as mean ± SEM). All patients were performed cardiovascular autonomic reflex tests (CARTs) by Ewing. The diagnosis of CAN was confirmed in patients with 2 and more positive tests. The statistical analysis was performed using SPSS statistical package version 25.0 for Windows.
Results
CAN detected by 2 abnormal tests of CARTs was diagnosed in 40.6% patients with prediabetes and CAD, by 3 abnormal tests – in 43.8%. We found positive correlation between the total score of CARTs: and levels of total cholesterol, ($r = 0.44$, $P < 0.05$), fasting insulin, ($r = 0.41$, $P < 0.05$), HOMA-IR ($r = 0.46$, $P < 0.01$), heart rate ($r = 0.4$, $P < 0.05$), and negative correlation with glomerular filtration rate, ($r = –0.39$, $P < 0.05$). We found that CAN diagnosed by 2 abnormal tests of CARTs had positive correlation with fasting glucose, ($r = 0.36$, $P < 0.05$) and HbA1c ($r = 0.4$, $P < 0.05$), but if there was no correlation of CAN detected by 3 abnormal tests of CARTs with these parameters.
Conclusion
CAN is the common complication of prediabetes and there are some risk factors for its development revealed in our study.

NaKATPase activity regulated by glycemia level in patients with DM

Zulaykho Shamansurova[1,2], Talat Saatov[3] & Arina Tsoy[3]
[1]Institute of Biophisics and Biochemistry at the Nuuz, Metabolomics, Tashkent, Uzbekistan; [2]Tashkent Pediatric Medical Institute, Endocrinology, Tashkent; [3]Diyor Medical Centre, Тошкент, Uzbekistan

Introduction
NaKATPase is membrane bound enzyme, necessary for maintenance of the cell potential and volume, ion flow, neuronal signal transduction. Previous studies showed decreasing of its activity in patients with diabetes mellitus (DM). Mechanisms regulated enzymes activity in DM is not clear yet. We proposed that glycemia is a main regulator of NaKATPase activity in erythrocytes at the DM.
Material and methods
In 76 patients with DM, 31 with DM type1 and 36 with DM type 2. In observed persons blood glycemia, HbA1c, blood plasma tryglycerides,

cholesterol level were measured. Erythrocytes separated from blood, washed out with buffer saline. NaKATPase activity measured by differences of the inorganic phosphorus level in media after incubation with ATP.
Results
Erythrocytes NKATPase activity were decreased by 25% in patients with DM1 and 29.9% ($P < 0.05$) in patients with DM2 ($P < 0.05$) compared with healthy subjects. Enzymes activity were not depends from age and gender in person younger than 40 years old. There were no any differences in enzymes activity between patients with DM type 1 and type 2. Blood glycemia, HbA1c, tryglycerides and cholesterol levels were significantly higher in patients with DM in compare with healthy subjects and suggest about metabolic disturbances. Erythrocytes NaKATPase activity shown negative correlation with glycemia and HbA1c level. Interestingly, NaKATPase activity significantly increased in those who achieved better glycemic control, whereas remain unchanged in those with poor glycemia.
Conclusion
Erythrocytes NaKATPase activity is decreased in patients with DM type 1 and 2, and negatively depends from glycemia and HbA1c level. Glycemia is an independent factor in regulation of erythrocytes NaKATPase activity.

Hirata's disease (Insulin autoimmune syndrome) in an Egyptian female patient: A case report

Salah El Halawany
Faculty of Medicine, Ain Shams University, Diabetes and endocrinology, Cairo, Egypt

Introduction
Insulin autoimmune syndrome (IAS), is rare cause of hyper-insulinemic hypoglycemia due to production of autoantibodies against the endogenous insulin in persons not formerly received insulin with no evidence of pancreatic lesions. Most described cases were in Asian peoples and this is the first case reported from Egypt.
Case report
A 64-year-old Egyptian female presented with repeated postprandial hypoglycemic attacks, approximately three hours after food ingestion, which improved on ingesting sweets. On one occasion, the patient lost her consciousness and was transferred to the nearest hospital where her plasma glucose was 26 mg/dl and she regained her consciousness after IV Dextrose 25%. Then, she was referred to our department for further assessment. She has no past history of chronic illness, nor family history of similar condition. She denied insulin or oral hypoglycemic drugs intake. Dietary history showed high intake of simple carbohydrates to overcome her frequent hypoglycemia. On physical examination: she was an obese female with BMI 38.9 kg/m^2, blood pressure 125/70 mmHg and heart rate 84/min with no signs of insulin resistance and her chest, abdomen, cardiac and neurological examination was unremarkable. Laboratory findings, including liver, kidney, adrenal, thyroid and glycemic profile were all normal except for elevated HbA1c (was 6.2%) and IGT (2-hpp glucose 186 mg/dl). She underwent prolonged (180-min) oral glucose tolerance test (OGTT) using 75 gm glucose. The patient began to develop hypoglycemic symptoms at 180-min of OGTT, during which her simultaneous plasma glucose was 49 mg/dl, serum Insulin > 1000 µiu/ml and C-peptide 17.22 ng/ml. These results were consistent with hyper-insulinemic hypoglycemia. Serum sulfonylurea drug screen was negative. Contrast-Enhanced triphasic CT abdomen was unremarkable with no evident of any pancreatic lesions. anti-insulin autoantibodies were found to be extremely high (> 100 u/ml). thus, the diagnosis of IAS was established. The patient was instructed to eat small frequent meals of low glycemic index. azathioprine 50 mg twice daily plus Prednisolone 60 mg were commenced. Her hypoglycemic attacks had completely subsided after two months of therapy, then the prednisolone dose was reduced gradually over the next three months with no recurrence of hypoglycemia, and repeated serum insulin and insulin antibodies showed a continual decline and her insulin autoantibodies became negative after 3 months of therapy.
Conclusion
IAS should be considered in any patient with hyperinsulinemic hypoglycemia, particularly if no detectable pancreatic or extrapancreatic neoplasm.

Severe postprandial hypoglycemia as a possible sequel of COVID-19

Ricardo de León Durango[1], Alba Hernández Lázaro[1], Paula Maria Fernandez-Trujillo-Comenge[1], Agnieszka Kuzior[2], Manuel Esteban Nivelo-Rivadeneira[1], Ana Delia Santana-Suarez[1], Carmen Acosta-Calero[3], Claudia Arnas-Leon[4], Paula Gonzalez-Diaz[5] & Francisco Javier Martinez-Martin[6]
[1]Hospital Universitario de Gran Canaria Dr. Negrín, Endocrinology and Nutrition, Las Palmas de Gran Canaria, Spain; [2]Hospitales San Roque Meloneras, Endocrinology and Nutrition, Las Palmas de Gran Canaria, Spain; [3]Hospitales San Roque Meloneras, Endocrinology and Nutrition, San Bartolome de Tirajana, Spain; [4]Hospitales San Roque Vegueta, Endocrinology and Nutrition, Las Palmas de Gran Canaria, Spain; [5]Centro de Salud de Arucas, Arucas, Spain; [6]Hospital Universitario de Gran Canaria Dr. Negrín, Outpatient Hypertension Clinic, Las Palmas de Gran Canaria, Spain

Introduction
COVID-19 is an evolving disease and its clinical picture is constantly being updated. Severe hypoglycemia has not been usually recognized as a COVID-19 symptom (except when caused by hydroxychloroquine toxicity) but in our patient it has been apparently triggered by the disease.
Methods
Review of the patient's records and the relevant literature.
Clinical case
A 55 year-old woman (a licensed nurse) was referred to our Endocrinology Clinic for severe, frequent, invalidating episodes of hypoglycemia. She had primary hypothyroidism, correctly substituted with levothyroxine, and a history of gastroesophageal reflux, treated with a Nissen fundoplication the previous year, and was asymptomatic. In April 2020 she was admitted in our Hospital for severe SARS-CoV-2 respiratory infection and was discharged with residual emphysema. Immediately after the discharge she had almost daily episodes of postprandial hypoglycemia, occasionally severe with loss of consciousness, and she was admitted to our Emergency Room, with plasma glucose 40 mg/dl but normal insulin and C-peptide (respectively 9.34 µ/u/ml and 3.22 ng/ml) in the lab tests. An abdominal CT scan did not suggest insulinoma or other abnormal mass. The 72-hour fasting test did not suggest insulinoma either, and the 24-hour Holter monitoring was near normal, not suggesting triggering of the symptoms by arrhythmia. A gastric emptying scintigraphy did not suggest dumping syndrome. In our Clinic the patient was trained in a fractionated diet with servings of 30–40 g of complex carbohydrates 4–5 times daily, and in the use of a flash glucose monitoring device with alarm capacity. She was able to resume work but still had frequent non severe hypoglycemia during the afternoon and evening, but rarely in the night. Acarbose 50 mg was added at lunchtime, initially with minor intolerance symptoms (occasional meteorism) but the variability of her glucose profile was largely improved and the episodes of hypoglycemia became milder and infrequent (less than 1/15 days). The follow-up lab tests (December 2020) were: Glycemia 82 mg/dl, HbA_{1C} 5.3%, plasma insulin 8.32 µ/u/ml, proinsulin 1.6 pmol/l, C-peptide 2.77 ng/ml, normal free T4 and TSH.
Conclusion
Although postprandial hypoglycemia is frequent after gastric surgery, including fundoplication, there was a clear-cut temporal coincidence in our patient between the COVID-19 disease and the triggering of the hypoglycemic episodes, suggesting a causative or unmasking relationship.

United Kingdom; [10]University Hospitals Birmingham NHS Foundation Trust, Department of Endocrinology, Queen Elizabeth Hospital, Birmingham, United Kingdom; [11]Birmingham Women's and Children's NHS Foundation Trust, Birmingham Women's Hospital, Birmingham, United Kingdom

Background
Polycystic Ovary Syndrome (PCOS) is a common reproductive, endocrine and metabolic disorder. The UK National Institute of Health and Care Excellence (NICE) recommends evaluating emotional wellbeing in women with PCOS. Therefore, we conducted a health service evaluation to assess emotional wellbeing.
Methods
We invited women with PCOS via social media to complete an online survey in September 2020, supported by PCOS support groups: PCOS Vitality and Verity. The survey included questions on demographics and validated questionnaires including the Hospital Anxiety and Depression Scale (HADS; score 8–10 borderline; score ≥ 11 cases of anxiety and depression, respectively), Body Image Concern Inventory (BICI; score ≥ 72 suggestive of body dysmorphic disorder, BDD) and Beliefs About Obese Persons Scale (BAOP; higher score suggestive of weight bias), and Female Sexual Function Index (FSFI; higher score suggestive of psychosexual dysfunction). The results are reported as median and interquartile ranges (IQR).
Results
A total of 502 participants with self-reported PCOS completed the survey (48.4% were between 26–35 years of age; 74.1% identified as White British). The prevalence of anxiety and depression was 55.4% and 22.5%, respectively (HADS anxiety 11(8–14); depression 7(4–10)). According to BICI scores, 49.6% (n = 249) of women with PCOS suffered from body dysmorphic disorder. Scores for BAOP and FSFI questionnaires were 32(27–35) and 19.8(8.0–25.2), respectively. As expected, women with self-reported mental health diagnosis had higher HADS scores for anxiety (12(10–15) vs 10(7–13); P < 0.001) and depression (8(5–12) vs 6(2.25–8); P < 0.001). They also had higher body image concerns (BICI 74(64–82) vs 68(55.25–77.75); P < 0.001) and probable BDD (152 (58.9%) vs 97 (40.4%); P < 0.001). Presence of mental health diagnosis did not have an impact on perceived weight stigma (BAOP 32(28–36) vs 31(27–35); P = 0.346) or psychosexual function (FSFI 19.3(6.5–24.4) vs 20.6(11.3–26.1); P = 0.143). Borderline depression was more common in white ethnic women compared to non-white (n = 108 (25.3%) vs 74 (98.7%); P = 0.049). Based on ethnic group, results showed no difference in anxiety, depression, impact on body image concern, weight stigma and psychosexual function. Women with BDD had higher anxiety (HADS 13(10–15) vs 10(7–12.5)); P < 0.001), depression (HADS 8(6–11) vs 6(3–8.5); P < 0.001) and weight bias (BAOP 32(28–36) vs 31(26–35); P = 0.016). BDD did not impact psychosexual function (FSFI 19.8(6.8–24.8) vs 19.85(9.7–25.7); P = 0.453).
Conclusion
The study showed a high prevalence of anxiety, depression and BDD in PCOS, which was more severe in women with mental health disorders. It is important to address mental health and wellbeing in women with PCOS as part of their clinical care.

COVID-19 and diabetes: Impact on emergency department demand by diabetic patients. experience from a portuguese center

Maria João Ferreira[1], Jorge Pedro[1], José Luis Castedo[1], Fernando Pereira[2], Davide Carvalho[1] & Tiago Guimarães[2]
[1]Centro Hospitalar Universitário de São João, E.P.E., Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]Centro Hospitalar Universitário de São João, E.P.E., Department of Clinical Pathology, Porto, Portugal

Introduction
COVID-19 is an emerging disease caused by the new coronavirus (SARS-CoV-2) that has overburdened healthcare worldwide. In Portugal, schedule appointments were cancelled, postponed or changed to tele-consultation. The objective of the study is to assess the impact of the pandemic on the use of Emergency Department (ED) by diabetic patients.
Material and methods
Retrospective monocentric study of the ED demand by diabetic patients from the 1st March to the 30th of June of 2020, compared to the same period in 2019. Data collection was performed using discharge diagnosis according to ICD-9, and divided in four different groups: 'decompensated diabetes', 'diabetes complications', 'severe diabetes complications'. Chi-Squared test was used to compare the ED demand by the different diagnosis.
Results
The demand for acute care by diabetic patients diminished by 36.3% in 2020 compared to 2019. Cases of hypoglycemia and decompensated diabetes mellitus decreased in 2020 compared to 2019 (41.2% vs 33.1%, P = 0.137; 25.5% vs 21.5% in 2020, P = 0.409). On the other hand, complications of diabetes and serious complications of diabetes increased in 2020 (25.5%% vs 36.2%, P = 0.037; 7.8% vs 9.2%, P = 0.655). 23.8% of patients were hospitalized in 2020 vs 18.6% in 2019 (P = 0.251).
Conclusion
There was a decrease in the demand for urgent care by diabetic patients. However, in 2020 patients had more severe complications and a greater need for hospitalization. This is in line with other published studies. Long-term follow-up is needed to conclude if interruption in healthcare assistance has resulted in worsening of diabetic patients' health.

ER stress and toxic soluble misfolded proteins are present in diabetes and diabetic ketoacidosis in a sex dependent-manner

Janara Furtado[1], Nicole R. Bearss[1], Cameron G Mccarthy[1], Munier Nazzal[2], William B. Hoffman[3] & Camilla F. Wenceslau[4]
[1]University of Toledo College of Medicine and Life Sciences, Department of Physiology and Pharmacology, Toledo, United States; [2]University of Toledo College of Medicine and Life Sciences, Division of Vascular and endovascular Surgery, United States; [3]Medical College of Georgia, Augusta University, Department of Pediatrics, Augusta, United States; [4]University of Toledo College of Medicine and Life Sciences, Department of Physiology and Pharmacology, United States

Introduction
Diabetes, a metabolic disease, is responsible for 1.6 million deaths each year. Type 2 diabetes (T2D) is the most common type (90%) that usually occurs in adults. Type 1 diabetes (T1D) an autoimmune disorder, affects more children and adolescents. Diabetic Ketoacidosis (DKA) is the most common acute cause of morbidity and mortality in youth with T1D. Soluble protein oligomers (SPOs), are a class of misfolded toxic proteins released during endoplasmic reticulum (ER) stress and unfold protein response (UPR). Hyperglycemia leads to ER stress and activate the UPR pathway. We hypothesized that SPOs are increased in the plasma from patients with DKA. Also, ER stress induce SPO release and/or vice versa.
Methods
By using the dot blotting, we measured SPOs in plasma from young (8–18 years old) male (n = 4) and female (n = 6) DKA patients in three different time points: 6–12 hours of treatment; 2–3 weeks; and 3 months post-DKA correction. Mechanistically, we evaluated if vascular smooth muscle cells (VS MCs) from the tibial artery of a 45-year-old male with T2D in normal glucose, or human aortic endothelial cells (HAEC), from a 33 year old health woman, submitted to high glucose concentrations (35 nmol/l) for 48 hours, presents with ER stress and/or SPOs in the media. Some VS MCs and HAEC were treated with ER stress inhibitor (4-PBA 2 mmol/l), SPOs inhibitor (K01–162, 10 μmol/l), or vehicle (DMSO) for 48 hours.
Results
SPOs were present in plasma from patients with DKA at all-time points. Interestingly, SPOs levels increased in a time-dependent manner in females, but not males. On the other hand, SPOs were not detected in the media of VS MCs or HAEC patients. However, the C/EBP Homologous Protein (CHOP), a marker for ER stress, was expressed in VS MC from patient with T2D, and the treatment with ER stress inhibitor, PBA, but not SPOs inhibitor, decreased its expression (A.U.: Vehicle: 55.3 ± 5 vs . PBA: 40.1 ± 5* vs . K01–162: 64.3 ± 9; *P = 0.04 vs . Vehicle). CHOP was not detected in HAEC after high glucose treatment.
Conclusion:
In diabetes there is an accumulation of SPOs that may contribute to the systemic inflammation observed in young patients with DKA. Although there was ER stress in VS MC from T2D, SPOs were not detected in the supernatant from these cells nor HAEC treated with high glucose. More studies are necessary to evaluate the relation between SPOs, ER stress and vascular dysfunction in diabetes.

High prevalence of 1st trimester gestational diabetes mellitus in polish women is accompanied by insulin resistance similar to pcos cohort

Krysztof Lewandowski[1,2], Monika Gluchowska[3], Karolina Garnysz[4], Wojciech Horzelski[5] & Andrzej Lewinski[1,2]
[1]The Medical University of Lodz, Department of Endocrinology and Metabolic Diseases, Łódź, Poland; [2]'Polish Mother's' Memorial Hospital Research Institute, Department of Endocrinology and Metabolic Diseases, Łódź, Poland; [3]The Medical University of Lodz, Department of Pathology of Pregnancy, 1st Chair of Gynaecology and Obstetrics, Lodz, Poland; [4]'Polish Mother's' Memorial Hospital Research Institute, Department of Perinatology, Obstetrics and Gynaecology, Łódź, Poland; [5]The University of Lodz, Faculty of Mathematics and Computer Science, Lodz, Poland

Back ground
Both pregnancy and polycystic ovary syndrome (PCOS) constitute insulin-resistant states, while gestational diabetes (GDM) is associated with adverse pregnancy outcomes. Though screening for GDM is typically performed later in pregnancy, some women demonstrate significant insulin resistance (IR) and develop GDM even in 1st trimester. We have endeavoured to compare surrogate IR indices in 1st trimester pregnant women and in women diagnosed with PCOS according to the Rotterdam consensus criteria.
Patients and methods
We performed 75 g Oral Glucose Tolerance Test (OGTT) with insulin measurements in 106 healthy 1st trimester pregnant women at 9.9 ± 2.6 weeks of gestation and in 418 women with PCOS. We also assessed the prevalence of GDM according to the IADPSG and WHO (1999) criteria.
Results
Despite lower BMI (24.93 ± 5.43 kg/m^2 versus 26.53 ± 6.83 kg/m^2, P = 0.027) pregnant women had either similar (QUICKI, Belfiore index, $Stumvoll_{0–120\_min}$) or greater IR than women with PCOS (e.g. HOMA-IR 3.85 ± 6.11 versus 2.64 ± 2.04, P = 0.002, and $Stumvoll_{demographics}$ 0.1054 ± 0.045 versus 0.085 ± 0.58, P = 0.003), while only Matsuda index demonstrated less IR in pregnant women. Though correlation between IR indices in pregnant women was highly significant, it showed marked variability ranging from r = 0.334 (HOMA-IR versus Belfiore index) to r = 1.0 (HOMA-IR versus QUICKI). This was accompanied by high prevalence of GDM (14.2% and 9.4%, IADPSG and WHO criteria, respectively). Women with GDM diagnosed according to IADPSG criteria demonstrated greater IR than pregnant women without GDM. In women with GDM diagnosed according to WHO (1999) criteria these differences were visible only for OGTT-derived IR indices (Belfiore, Matsuda and Stumvoll0–120 index).
Conclusions:
Depending on the choice of IR indices healthy 1st trimester pregnant women demonstrate either similar, or greater IR than women with PCOS and this is accompanied by high prevalence of early GDM. It remains to be established whether GDM screening should be performed in the 1st trimester.

AEP179

Mother's education with type 1 diabetes and the risk of some neonatal outcomes

Veranika Prylutskaya[1], Tatsiana Skryplionak[2], Anzhalika Solntsava[1] & Yuliya Shyshko[2]
[1]State Medical University, Minsk, Belarus; [2]Republic Research and Practical Center << Mother and child >>, Minsk, Belarus

Aim
To evaluate some neonatal outcomes, depending on the level of education of the mother with type 1 diabetes (T1DM).
Materials and methods
A retrospective single-center study was carried out among 430 children from mothers with T1DM, who were born in 2015-2020 years. Taking into account the level of education of mothers, newborns were divided into 3 observation groups. The first group (Gr1) consisted of 70 children from mothers with low education, the second (Gr2) - 204 from mothers with intermediate education, the third (Gr3) - 156 from women with high education. The experience of diabetes in mothers Gr1 was 11(6-16) years, Gr2 - 13(7-18) years, Gr3 - 11(6.5-17.5) years (P > 0.05). Physical development of newborns was assessed using the Intergrowth-21st.
Results
The body weight of newborns of Gr1 was 3320(2800–3730) g, Gr2 – 3550(3000–3945) g, Gr3 – 3585(3150–3885) g ($P_{1–2}$ = 0.02, $P_{1–3}$ = 0.01, $P_{2–3}$ = 0.74). Z-score body weigh – 1.65(1.08–2.41), 1.63(0.89–2.45), 1.61(0.90–2.49) (P > 0.05). There were 45.7% of preterm infants among newborns Gr1, which was statistically significantly higher than in Gr2 (27.0%) and Gr3 (24.4%). Large for gestational age (LGA) newborns among full-term newborns in Gr1 were 50.0%, Gr2 – 59.7%, Gr3 – 54.9% (P > 0.05), among premature babies 78.1%, 74.9% and 79.1% (P > 0.05). The newborns from mothers with T1DM and intermediate education, compared with children from women with low education, had lower chances of prematurity (OR = 2.28, 95% CI 1.62–3.21), chances of respiratory support as mechanical ventilation at the 5th minute of life due to the respiratory distress syndrome and a low Apgar score (OR = 1.55, 95% CI 1.00–2.32). Newborns from mothers with T1DM and high education, in comparison with children from women with low education, also had lower chances of preterm birth (OR = 2.61, 95% CI 1.79–3.81), mechanical ventilation at the 5th minute of life (OR = 1.52, 95% CI 0.98–2.36).
Conclusion
The influence of maternal education on the outcomes of newborns from mothers with T1DM in Belarus has been established. The low level of education of the mother with T1DM is an important factor associated with some adverse neonatal outcomes (prematurity, mechanical ventilation at the 5th minute of life). The mother's education level did not affect the birth rate of LGA newborns.

Vitamin B12 status and maternal-fetal outcomes among women with gestational diabetes

Olga Gutu, Natércia Candeias, António Afonso & Jose Silva-Nunes
Hospital Curry Cabral, Department of Endocrinology, Diabetes and Metabolism, Portugal

Introduction
Vitamin B12 (vB12) deficiency has been associated with a plethora of hematologic, neurologic and metabolic abnormalities. In pregnant women, several studies have demonstrated an association with a greater maternal body mass index (BMI), maternal and offspring insulin resistance, gestational diabetes mellitus (GDM) and even later type 2 diabetes.
Aim of the study
Evaluation of maternal and fetal outcomes of pregnant women with GDM with and without vB12 deficiency.
Material and methods
Retrospective study based on data from 200 pregnant women with GDM evaluated between 2018 and 2019 that had B12 levels measured at the initial observation. It was considered vB12 deficiency if levels < 188 pg/ml.
Results
We considered two groups: Group 1 (n = 132) with vB12 within normal range; Group 2 (n = 68) with vB12 deficiency. Serum samples were collected at 27.6 ± 8 weeks of pregnancy. Mean vB12 level in Group 2 was 134 ± 106.2 pg/ml. GDM was diagnosticated in 46% vs 36.5% during the first trimester and in 54% vs 63.5% during the 2nd trimester. There was no statistical difference between groups in terms of age (33.3 ± 5.4 vs 33.5 ± 4.7years), initial HbA1c (5.4 ± 0.8% vs 5.3 ± 0.6%), HOMA-IR (3.1 vs 3.3), hemoglobin level (11.6 ± 1.6 vs 11.5 ± 2.1 g/l), percentile of fetal abdominal circumference in 3rd trimester (58 ± 19.5 vs 55 ± 22), gestational hypertension (3.7% vs 4.4%), pre-eclampsia (2.2% vs 1.4%), hydramnios (8.3% vs 8.8%) and pre-term delivery (4.5% vs 5.8%). All patients were already medicated with iron plus folic acid whereby deficiencies were not detected. The mean gestational age of delivery was 38 weeks without differences between groups. Group 2 had higher pregestational BMI (28.1 ± 7 vs 30.8 ± 5 kg/m^2; P = 0.03), 3rd trimester BMI (32.1 ± 3 vs 34 ± 6 kg/m^2; P = 0.04), higher rate of infectious complications in the postpartum period (0.7% vs 6.3%; P = 0.04) and tendency for macrosomia (4.3% vs 7.3%; P = 0.06). Although the rate of cesarean section was similar between groups (40% vs 36.7%, P = ns) the need to perform emergent cesarean section was higher in Group 2 (13.6% vs 60%; P = 0.01). Regarding the neonatal morbidity, the incidence of phototherapy due to hyperbilirubinemia was similar. Concerning postpartum reclassification, no statistical significance was observed between groups (diabetes mellitus in 6% for Group 1 and 9.7% for Group 2).
Conclusions
Pregnant women with GDM and vB12 deficiency had higher prevalence of obesity, emergent cesarean section and maternal complications in the postpartum period. More studies with a larger number of participants are needed to validate these results and, eventually, to find new associations with vB12 deficiency.

Glucagon levels in women with Alzheimer's disease

Marketa Vankova, Josef Vcelak, Daniela Vejrazkova & Bela Bendlova
Institute of Endocrinology, Molecular Endocrinology, Prague, Czech Republic

Alzheimer's disease (AD) is a neurodegenerative disease that manifests itself in the gradual loss of cognitive and behavioral functions. In humans, glucagon is processed in pancreatic alpha cells located next to insulin-secreting beta cells, suggesting a local interaction. Glucagon is also produced in the intestinal L-cells and in small amounts in the hypothalamus. The main function of glucagon is to counteract the effects of insulin and thus maintain balanced blood glucose level. In addition, glucagon also has the same neuroprotective effect as insulin on lowering glutamate in the central nervous system in diabetic rats, although both hormones have the opposite effect on glucose levels. Glucagon reduces glutamate in the central nervous system, reduces neuronal cell damage and improves neurological scores in mice. This study focused on glucagon levels in non-diabetic women with AD compared to controls, as well as on the changes of glucagon levels after five years in controls.
Methods
We evaluated the fasting metabolic parameters and glucose tolerance in 70 controls (median of age 68.2 years) and 41 women with AD (median age 74.7 years), both groups without type 2 diabetes. A group of 37 controls was re-evaluated after 5 years. The data were processed by GLM ANOVA (Statgraphics 18 × 64).
Results
Women with AD and controls had a similar body composition (median BMI [kg/m^2]: 25.7 (22.6, 29.4) vs . 27.7 (24.3, 30.2); $P = 0.13$), insulin resistance (median HOMA R: 1.74 (1.44, 2.74) vs . 2.05 (1.4, 3.67), $P = 0.91$) and insulin secretion (median HOMA F: 114 (79.8, 173) vs . 103 (78.8, 149), $P = 0.1$). Women with AD and controls had the same fasting glucose (median glucose [mmol/l]: 5.1 (4.8, 5.3) vs 5.3 (5, 5.8); $P = 0.06$), but women with AD had lower levels of glycated hemoglobin (median HbA1c [%]: 37 (35.3, 38.8) vs . 38 (37, 40.3); $P < 0.01$). Compared to controls, women with AD had significantly higher glucagon levels (median glucagon [pmol/l]: 51.1 (46.1, 57.3) vs . 41.5 (38.8, 46.5); $P < 0.001$). Long-term follow-up (5 years) of controls showed a decrease in glucagon levels with increasing age ($P < 0.001$).
Conclusion
Glucagon levels in women with AD are not associated with glucose tolerance or diabetes. Patients with AD have the same fasting blood glucose as controls, and even lower glycated hemoglobin (a long-term indicator of glucose metabolism). Women with AD could be resistant to glucagon, or it is a consequence of the brain's protective mechanism. The grants: NV 18-01-00399, MH CZ-DRO (EU 00023761).

Glycemic control in patients with different types of diabetes mellitus in Ukraine

Eugenia Globa & Nataliya Zelinska
Ukrainian Center of Endocrine Surgery, Endocrine Organs and Tissue Transplantation, MoH of Ukraine, Ukraine

Introduction
The aim of this study, which was conducted for the first time in Ukraine, was to analyze a glycemic control in patients with different types of diabetes mellitus (DM), including neonatal (ND) and maturity onset diabetes of the young (MODY) and changing their treatment after the results of genetic testing.
Materials and methods
The Ukrainian Pediatric Diabetes Register was established in 2002 and included 9471 children with type 1 DM (a prevalence of 1 in 800 for the pediatric population), 47 children with type 2 DM (a prevalence of 1 in 161270), 65 patients with ND (a prevalence of 1 in 116610) and 48 patients with MODY (a prevalence of 1 in 157910) in 2019y. We analyzed the glycemic control in patients depending on the type of DM, namely: type 1 DM ($n = 9471$), type 2 DM ($n = 47$). HbA1c was analyzed also in patients with ND ($n = 16$) with KCNJ11 and *ABCC8* variants and MODY ($n = 16$) with *HNF1A*/*HNF4A* and *ABCC8* variants before genetic testing and after 3 and 12 months of sulfonylurea (SU) treatment. To confirm the nature of ND and MODY, targeting next-generation sequencing (tNGS) of all known neonatal and monogenic diabetes genes was performed.
Results
According to the Register in 2019, in Ukraine the average age of children with type 1 DM was 11.5 ± 1.4 years, and the level of HbA1c was unsatisfactory (8.8v2.01%). The proportion of children who had ideal or optimal glycemic control (HbA1c < 7.5%) was the smallest (28.15%). The Register included also 47 children with type 2 DM with an average age of 16.2 [15.5; 18] years old and HbA1c level 6.7 [5.7; 7.9]%. All patients with ND and MODY with confirmed mutations in *KCNJ11*, *ABCC8* and *HNF1A*/*HNF4A* genes and unsatisfactory glycemic control discontinued insulin therapy (or other inappropriate treatment) and were transferred to SU, which lead to the significant improvement in glycemic control (decreasing of HbA1c level) after 3 months and 12 months of SU treatment ($P < 0.05$).
Conclusions
The glycemic control in patients with type 1 DM in Ukraine was unsatisfactory compared to ND and MODY patients with mutations in *KCNJ11*, *ABCC8* and *HNF1A*/*HNF4A* genes, who received pathogenetically justified treatment with SU drugs, as well as in type 2 DM patients.

Increase in PUFA and in protein intake leads to reduction of liver fat independently of weight loss in 12 months: the NutriAct trial

Laura Pletsch-Borba[1], Charlotte Wernicke[1], Konstantina Apostoloupoulou[1], Dominik Spira[1], Anne Pohrt[1], Silke Hornemann[2], Christiana Gerbracht[2], Andreas Pfeiffer[1], Joachim Spranger[1] & Knut Mai[1]
[1]Endokrinologie Und Stoffwechsel, Berlin, Germany; [2]Human Study Center, German Institute of Human Nutrition Potsdam-Rehbrücke, Nuthetal, Germany

Background
Long-term effects of an increase in unsaturated fatty acids and protein on changes in intrahepatocellular lipids (IHL) are still unclear. We aimed to explore the impact of changes in individual macronutrients on IHL changes within the NutriAct intervention trial over 12 months in middle-aged and elderly subjects (50–80 yrs) at risk for age-related diseases.
Design
In the NutriAct randomized controlled trial, the effect of a high-protein and high-UFA diet was compared to the dietary recommendations of the German Nutrition Society. Individuals who completed 3-day food records and had IHL data both at baseline and at month 12 were included in this study. Intake (E%) of each macronutrient was calculated and IHL was measured by proton density fat fraction spectroscopy. Associations between changes in macronutrients intake and changes in IHL were analyzed, including mediation analysis to identify the role of weight loss as a mediator.
Results
248 participants were included in the analyses (34% male, median age 66y). BMI and IHL improved in both intervention groups in 12 months (both $P < 0.01$) and differed significantly between groups ($P < 0.05$). Participants with higher increase in protein and PUFA intake and a greater decrease in carbohydrate intake showed a stronger improvement in IHL ($P < 0.05$). Changes in protein, carbohydrate and PUFA, and IHL improvement are mediated by BMI changes. Increase in protein ($P = 0.05$) and in PUFA ($P = 0.01$) intake was also directly associated to IHL improvement (not BMI change-mediated).
Conclusions
Increase in intake of protein and PUFA, and decrease in carbohydrates intake led to IHL reduction after 12 months in middle-aged and elderly subjects. While these effects are partially mediated by weight loss, there is also a direct effect between increase in protein (trend) and in PUFA and IHL improvement. These results give insight into the understanding of a high-UFA diet on IHL changes in a long-term dietary intervention.

Introduction
In general, the risk to develop Parkinson's disease (PD) is higher in men compared to women. Besides male sex and genetics, research suggests diabetes mellitus (DM) is a risk factor for PD as well. In this population-level study, we aimed at investigating the sex-specific impact of DM on the risk of developing PD.
Research design and methods
Medical claims data were analyzed in a cross-sectional study in the Austrian population between 1997 and 2014. In the age group of 40–79 and 80+, 235.268 patients (46.6% females, 53.4% males) with DM were extracted and compared to 767.681 non-diabetic controls (51.9% females, 48.1% males) in terms of risk of developing PD.
Results
Men with DM had a 1.46 times increased odds ratio (OR) to be diagnosed with PD compared to non-diabetic men (95% CI 1.38–1.54, $P < 0.001$). The association of DM with newly diagnosed PD was significantly greater in women (OR = 1.71, 95% CI 1.60–1.82, $P < 0.001$) resulting in a relative risk increase of 1.17 (95% CI 1.11–1.30) in the age group 40 to 79 years. In 80 +-year-olds the relative risk increase is 1.09 (95% CI 1.01–1.18).
Conclusions
Although men are more prone to develop PD, women see a higher risk increase in PD than men amongst DM patients.

Anemia in diabetes and pre-diabetes with normal kidney function: Prevalence and long- term association with morbidity and mortality

Daniel Erez[1,2], Coral Shaefler[1,3], Eytan Roitman[4], Sigal Levy[5], Martin Ellis[1,6], Zamir Dovrish[1,2] & Orit Twito[1,7]
[1]Tel-Aviv University, Sackler Faculty of Medicine, Tel-Aviv, Israel; [2]Meir Medical Center, Internal Medicne D, Kefar Sava, Israel; [3]Meir Medical Center, internal Medicine A, Kefar Sava, Israel; [4]Clalit Health Services, Tel Aviv-Yafo, Israel; [5]The Academic College of Tel Aviv–Yaffo, Tel Aviv-Yafo, Israel; [6]Meir Medical Center, Hematology, Kefar Sava, Israel; [7]Meir Medical Center, Endocrinology, Kefar Sava, Israel

Background
Although anemia was previously described as a complication of diabetes mellitus (DM), it's prevalence and prognostic meaning in patients with DM and pre-DM with normal kidney function was not thoroughly investigated.
Methods
A retrospective analysis of patients with DM and pre-DM referred to the endocrine institute in Meir medical center during 2015. Patients with estimated glomerular filtration rate (eGFR) < 60 ml/min or any other recognized cause of anemia were excluded. Four-years outcome was assessed including development of microvascular complications, macrovascular complications and mortality.
Results
A total of 622 patients (408 with DM and 214 pre-DM) were included. Their mean age was 64 ± 10.6 years, and 69% women. Baseline HbA1 c was 7.1 ± 1.7% and eGFR was 86.1 ± 15.3 ml/min. The prevalence of anemia was 19% in DM and 11% in pre-DM. Multivariable analysis adjusting for several clinical and laboratory parameters demonstrated a negative correlation between baseline hemoglobin level (as a continuous variable) and mortality ($P = 0.035$), microvascular complications ($P = 0.003$) and eGFR decline ($P < 0.001$), but not with macrovascular complications($P = 0.567$).
Conclusions
Our study demonstrates a significant prevalence of anemia unrelated to renal failure, both in DM and pre-DM and its association with development of microvascular complications, eGFR decline and mortality. These results underscore the need for intensive lifestyle and pharmacological intervention in pattients with DM or pre-DM and anemia.

[1]Osakidetza Basque Health Service- Mendaro Hospital, Endocrinology and Nutrition, Mendaro, Spain; [2]Osakidetza Basque Health Service- Mendaro Hospital, Cardiology, Mendaro, Spain; [3]Osakidetza Basque Health Service, Ermua Health Centre, Primary Care, Spain; [4]Osakidetza Basque Health Service, Mutriku Health Centre, Primary Care, Spain; [5]Osakidetza Basque Health Service- Mendaro Hospital, Internal Medicine, Spain; [6]Osakidetza Basque Health Service, Eibar Health Centre, Primary Care, Spain; [7]Osakidetza Basque Health Service, Soraluze Health Centre, Primary Care, Spain; [8]Osakidetza Basque Health Service, Torrekua Health Centre, Primary Care, Spain

Introduction and objectives
SGT2i have changed the paradigm of T2DM management. Last guidelines insist on the importance of using newer glucose-lowering drugs with a demonstrated reduction in cardiovascular events (CVE). The aim of this study is twofold: to describe CVE, heart failure (HF) and renal function evolution; and to assess its efficacy in non-selected patients with T2DM initiating SGLT2i
Material and methods
Retrospective observational study that included T2DM patients with SGLT2i initiation (Empagliflozin, Dapagliflozin or Canagliflozin) between February 2018–2019 from 2 hospitals and 10 primary care centers for a 78.000 population area. We analyzed metabolic outcomes (changes in HBA1c, weight), renal function evolution and the development of CVE and HF at baseline and at the end of monitoring (February 2020).
Results
544 patients were included. 342 men (63%), with a mean age of 66 years (10.2% $N = 55 \geq 80$ years). The mean follow-up was 22.6 ± 6.3 months. Baseline HbA1c mean was 7.9 ± 1.3%, BMI 31.5 ± 5.8 kg/m^2, eGFR 83.6 ± 20.1 ml/min/1.73 m^2 (12% below < 60) and diabetes duration was 12.5 ± 7.7 years. 23.4% of patients had albuminuria and 10.7% was on loop diuretic. 38% of the sample had underwent a transthoracic echocardiogram (TTE) before the SGLT2i was prescribed: 63 (11.6%) had had previous HF and 23 of them a decompensation in the past year. TTE was available in 88.9% of them with a mean ejection fraction of 48% comparing to 60.6% observed in 31.4% of patients with no HF history ($P < 0.001$). 32.5% ($N = 177$) were on insulin and SGTL2i was added as second, third or fourth line of treatment in 33%, 26.2% and 26.9% respectively. 16%($N = 87$) of patients discontinued treatment due to side effects and they were older than those who continued the therapy (69.8 vs 65.3 years, $P < 0.001$). Nearly 50% were urinary tract and genital infections and in 31 subjects eGFR went < 30. CVE´s prevalence was 23.7% ($N = 127$) but new onset ones were infrequent and non-fatal ($N = 19$, 3.5%). HF occurred in 4.6% ($N = 25$) and 16 patients required hospitalization. During follow-up, there were 12 deaths (2.2%): 2 because of terminal HF (included in a palliative care program). At the end of monitoring, SGLT2i lowered HBA1c and BMI –0.9% and –1.3 kg/m^2 respectively ($P < 0.001$) whereas eGFR remained stable (79.4 ± 22.6 ml/min/1.73 m^2).
Conclusions
Our registry suggests that SGLT2i improve glycemic control and weight parameters while renal function was preserved with low rates of intolerance and/or adverse events such as heart failure, CVE and death.

Free T4 is associated with exenatide-related weight loss in patients with type 2 diabetes mellitus

Ömercan Topaloğlu[1] & Didem Yıldız Toksöz[2]
[1]Kocaeli Derince Training and Research Hospital, Endocrinology, Derince/Kocaeli, Turkey; [2]Kocaeli Derince Training and Research Hospital, Internal Medicine, Derince/Kocaeli, Turkey

Introduction
Exenatide may provide weight loss in type 2 diabetes mellitus (T2D) via agonistic effect on GLP1 receptor. There is no study showing associations between free T4(fT4) and exenatide-related weight loss in T2D. We aimed to reveal the association between fT4 and exenatide-related weight loss, and change in thyroid functions with exenatide in euthyroid adult patients with T2D and obesity.
Materials and Methods
We included euthyroid adult patients with T2D and obesity under metformin, SGLT2 inhibitor and/or insulin treatment, whom exenatide was indicated. We excluded those < 18-year-old, with contraindication to exenatide, or history of thyroid dysfunction, or under levothyroxine or

antithyroid medications. We analyzed baseline demographic features, chronic illnesses (hypertension, hyperlipidemia), AntiTPO and lipid parameters. We evaluated change (level at 6th month of exenatide – baseline level) in body weight, body mass index (BMI), TSH, fT4, fasting blood glucose (FBG), HbA1c. We grouped them as weight gain vs weight loss (absent vs < 10% vs ≥ 10% weight loss).
Results
TSH change and fT4 change were –0.077(1.10) and –0.0123(0.20) in total (n = 106), respectively (P = 0.229 and P = 0.908, respectively). TSH was increased in weight loss group, but decreased in weight gain group (P = 0.018). fT4 at baseline and at 6th month of treatment were higher in weight loss group than weight gain group (P = 0.010 and P = 0.004, respectively). The ratio of patients having fT4 in upper-range was higher in weight loss group (P = 0.042). Decrease in BMI was positively correlated with fT4 level at 6th month of exenatide (r = 0.234 and P = 0.016) but not with baseline fT4.
Conclusion
Higher fT4, even in normal range, was associated with higher weight loss in the patients with T2D after initiation of exenatide. Thyroid function seems not to be affected by exenatide. Baseline fT4 may be considered when selecting exenatide in T2D especially if weight loss is targeted.

Tablo 1. Comparison of the patient characteristics according to the presence of weight loss

	Weight loss		
Parameters	Absent (n = 15)	Present (n = 91)	p value
	n		
Gender(female/male)	9/6	67/24	0.278

Feasibility study of IoT telemonitoring for elderly patients with type 2 diabetes mellitus: Results of the Greek pilot of the ACTIVAGE multicenter randomised control trial

George Dafoulas[1], Christina Karaberi[2], Sofia Segkouli[3], George Dimakopoulos[4], Konstantinos Votis[3], Dimitrios Tzovaras[3] & Alexandra Bargiota[1]
[1]Department of Endocrinology and Metabolic Diseases, Faculty of Medicine, University of Thessaly, Larisa, Greece; [2]Cities Net, Digital Cities of Central Greece, Trikala, Greece; [3]Information Technologies Institute, Centre for Research and Technology – Hellas, Thessaloniki, Greece; [4]Medical Statistics, Epirus Science and Technology Park Campus of the University of Ioannina, Ioannina, Greece

Introduction
The aim of the present feasibility study was to examine the impact of an Internet of Things (IoT) telemonitoring program, for elderly patients with type 2 diabetes mellitus (DMT2) on glycemic control.
Methods
In this feasibility, prospective, randomized, single-blinded, multicenter study elderly patients with DMT2 capable to use the IoT telemonitoring device, with an HbA1c > 7.5 were followed-up for 6 months. They were randomly assigned in the telemonitoring group (IG, N = 24) and in the control group (CG, N = 20). The inclusion criteria of the study were: age ≥ 65 years old, no comorbidities or 1–2 diabetes chronic illnesses and no Activities of Daily Living (ADL) impairments and ≤ 1 Instrumental ADL impairment. The primary objective of the study was the reduction of the HbA1c from over 7.5 to 7. In the IG group patients' blood glucose profiles were collected weekly using an IoT Point of Care Testing (POCT) health platform. Allocated health professionals provided by phone the appropriate counseling on lifestyle and medication changes when required. Patients in CG group received usual care with face-to-face consultations.
Results
Baseline Hba1c in IG was 7.655 ± 0.7280 and in the CG 7.873 ± 0.7923 (P = 0.361). Glycemic control was improved statistically significantly in the IG within the first 3 months of the follow-up (IG HbA1c: 7.031 ± 0.4250 versus CG HbA1c:7.585 ± 0.7923, P = 0.026). At 6 months follow-up there was no statistical significant improvement of the glycemic control improvement (IG HbA1c: 6.882 ± 0.5879 versus CG HbA1c: 7.129 ± 0.2928, P = 0.321) . No severe hypoglycemia event was registered in either of the two groups.
Conclusion
IoT telemonitoring seems to have the potential for closer monitoring of the elderly patients with T2DM improving with safety the glycaemic control. These are only pleminary data and more patients are needed for safer an more accurate results.

Type 1 Diabetes and physical activity – which are the barriers to its practice and what is therole of therapeutic education?

Juliana Marques-Sá*, Sara Campos Lopes* & Maria Joana Santos
Hospital de Braga, Endocrinology, Portugal
*These authors contributed equally to this work.

Background
Regular physical activity has a crucial role in the control of Type 1 Diabetes (T1D). Insecurity in the management of insulin therapy and fear for dysglycemia are barriers to the practice of exercise in T1D.
Aim
To identify barriers to regular physical activity in adult patients with T1D; to evaluate the impact of two educational sessions about exercise and strategies to achieve better glycemic control in this setting.
Materials and Methods
We conducted an online prospective study with adult patients with T1D, treated with functional insulin therapy (multiple daily injections regimen, exclusively). The patients had to perform physical activity regularly. Two 45 minutes Zoom webinars were carried out, with a two-day interval between them. In the first session, different types of exercises and strategies to adopt to minimize hipo- and hyperglycemias were explained. The second session was more practical with the debate of clinical cases brought by the speakers and the participants. The impact of the webinars in the knowledge of the attendees was evaluated through 15 questions applied before and after the sessions. For the assessment of perceived barriers to physical activity, the BAPAD-1 scale was used.
Results
We invited 67 patients to participate; 19 (28.4%) accepted and answered the BAPAD-1 scale. The majority were men (57.9%). Average age was 34 ± 8.8 years and median disease duration was 12.3 ± 10.4 years. In BAPAD-1, the average global score was 30.3 ± 12.3 points [maximum score: 77 (seven points per question)]; women had a higher global score (38.0 vs 24.7, P = 0.015). Fear of hypoglycemia was the main barrier to the practice of exercise (median score 5.0), in particular for women (P = 0.015). Weather conditions and the location of the gym were also frequent barriers in our population. Thirteen patients answered the pre-sessions' test. The average classification was 71.8 ± 10.6%. Ten patients attended both sessions and answered the after-sessions' test. The global score improved (92.7 ± 8.0%, P < 0.001). After the webinars, 80% of patients reported feeling confident/very confident in the management of their T1D in this particular setting. All the patients reported being satisfied with the sessions.
Conclusions
Patients with T1D face various barriers to the practice of exercise, mainly fear of hypoglycemia. Therefore, therapeutic education should pay special attention to hypoglycemia management. The webinars showed to be effective in increasing confidence and additional strategies to minimize

exercise-induced dysglycemia. The low rate of participation was reported to be due to constraints associated with work and with the COVID-19 pandemic.

The effect of increasing soluble diatery fibre content of meals on postprandial glycaemic and c-peptide response

Muhammad Aliyu Idris[1], Anas Ahmad Sabir[2] & Augustine Efedaye Ohwovoriole[3]
[1]Diabetes and Endocrinology Centre, King Fahad Hospital., Saudi Arabia; [2]Usman Danfodiyo University Teaching Hospital, Nigeria; [3]Lagos University Teaching Hospital, Nigeria

Background
Medical nutrition therapy is often the initial step in the management of Prediabetes and diabetes mellitus. Postprandial glycaemia contributes significantly to the glycaemic control of patients with diabetes mellitus. The beneficial effects of soluble dietary fibre in reducing postprandial glycaemia have been established. The 2017 global burden of disease (GBD) report shows that 97.000 deaths result from low fibre intake. Despite the this, the intake of fibre is low in many countries including European countries as shown by the 2009 European Nutrition and Health (ENH) report. The objective of this study is to evaluate the impact of increasing soluble fibre content of meals on postprandial glycaemic and c-peptide responses.
Methodology
This experimental randomised, crossover study was conducted among 20 healthy subjects. Anhydrous glucose drink (G) which was the reference meal was consumed in the first week. The participants were then randomized by balloting to consume one of the two test meals per week namely white fonio (*Digitaria exilis*) and white fonio (*Digitaria exilis*) fortified with 3 g of B-CAN soluble fibre. i.e. Non fortified fonio meal (NFFM) and Fortified fonio meal (FFM) respectively. All meals were served after an overnight fast with a washout period of one week between the test meals. Fasting and postprandial plasma glucose, serum concentration of pancreatic c-peptide were measured at 0, 30, 60, 90, and 120 minutes. All data were entered using Microsoft Excel and analysis performed using the Statistical Package for Social Science (SPSS) version 22.0. P-value was set at < 0.05.
Results
Twenty participants were enrolled in the study, but one participant could not complete the study, giving a participant response rate of 95%. The mean peak plasma glucose (PPG) level of FFM was lower than that of NFFM (6.1 mmol/l and 6.35 mmol/l respectively) and were significantly lower than the PPG level of the reference glucose drink which was 7.01 mmol/l. $P < 0.05$. The glycaemic indexes of NFFM and FFM were 85.9 and 77. 5, respectively. The peak serum postprandial c-peptide (PPCP) response was also lower for FFM than NFFM (3.553 ng/ml and 3.814 ng/ml respectively) when compared with PPCP of G (4.333 ng/ml). $P > 0.05$.
Conclusion
The finding and potential impact of this study is that the diet can be modified by increasing soluble dietary fibre to improve the postprandial glycaemic response and c-peptide responses.

Erythrocytosis in a patient on sodium glucose cotransporter-2 inhibitor

Shane Byrne[1,2], Mohammad Aiman Nor[1,3], Gerard Crotty[4] & Ma Pyeh Kyithar[1]
[1]Midland Regional Hospital Portlaoise, Diabetes and Endocrinology Department, Portlaoise, Ireland; [2]University College Dublin Intern Network, Ireland; [3]Mid-Leinster Specialist Training Scheme in General Practice, Ireland; [4]Midland Regional Hospital Tullamore, Haematology Department, Tullamore, Ireland

Background
Sodium glucose cotransporter-2 (SGLT-2) inhibitors have proven valuable in the management of type 2 diabetes. These agents are particularly effective in reducing hospitalisations with heart failure and cardiovascular mortality. Adverse effects are primarily centred on urogenital infections and hypovolaemia. Here, we report the case of a patient who developed asymptomatic erythrocytosis while taking empagliflozin.
Case report
A 44-year-old male patient with type 2 diabetes for 12 years, presented to diabetes clinic for review of suboptimal glycaemic control. He was treated with sitagliptin/metformin (50/1000 mg) BD and empagliflozin 10 mg once daily. Nine months later, his blood work showed erythrocytosis with haemoglobin (Hb) 18.3 g/dl (13.5–17.5), red blood cells (RBC) 6.34×10^{12}/l (4.5–5.5), haematocrit (Hct) 0.53 (0.4–0.5), reticulocyte count 202×10^{9}/l (50–100), normal white cell count 7.2×10^{9}/l and normal platelet count 169×10^{9}/l. The patient was asymptomatic and had no history of smoking, sleep apnoea, malignancy, testosterone use or exposure to high altitudes. Oxygen saturation was 98% on room air and BMI was 26 kg/m^2. Subsequent investigations showed packed red cells and reactive lymphocytes on blood film, normal erythropoietin level, normal SPEP, normal Hb electrophoresis and negative JAK2 V617F mutation. In the meantime, the patient decided to stop all anti-hyperglycaemic medications and relied solely on lifestyle modification for diabetes control. Coincidentally, erythrocytosis resolved spontaneously (Hb 17.4 g/dl, Hct 0.49) six months after stopping anti-hyperglycaemic agents. Follow-up in diabetes clinic revealed worsening glycaemic control (HbA1c 75 mmol/mol). At this point, he was restarted on empagliflozin 10 mg once daily. 4 months later, investigations showed recurrence of erythrocytosis (Hb 18.9 g/dl, Hct 0.55, RBC 6.6×10^{12}/l). Empagliflozin was discontinued and 6 weeks later his blood work showed slight improvement in erythrocytosis (Hb 18.6 g/dl, Hct 0.53). CT thorax/abdomen/pelvis showed no evidence of hepatic, renal or adrenal masses. He is due to have repeat blood work.
Discussion
There are five reported cases of erythrocytosis during treatment with SGLT-2 inhibitors in the literature; two cases had no risk factors for increased haematocrit, two were associated with co-administration with testosterone and one was unmasking of polycythemia vera. Our patient did not have any risk factor for increased haematocrit and erythrocytosis appears to be coincidental with SGLT-2 inhibitor use. A degree of plasma volume depletion due to osmotic diuresis leading to a relative erythrocytosis would make mechanistic sense. As erythrocytosis may predispose to prothrombotic events such as myocardial infarction and stroke, our case highlights the importance of monitoring haematocrits in patients on SGLT-2 inhibitors.

Investigation of 5 alpha reductase-1 and aromatase enzyme levels, gene expressions and kisspeptin and nesfatin-1 levels in male patients with metabolic syndrome and hypogonadism

Halil Güner[1], Guzin Yaylali[2], Mücahit Seçme[3], İbrahim Açıkbaş[3] & Hande Şenol[4]
[1]Pamukkale University, Faculty of Medicine, Department of Internal Medicine, Denizli, Turkey; [2]Pamukkale University, Faculty of Medicine, Department of Endocrinology and Metabolism, Denizli, Turkey; [3]Pamukkale University, Faculty of Medicine, Department of Medical Biology, Denizli, Turkey; [4]Pamukkale University, Faculty of Medicine, Department of Biophysics, Denizli, Turkey

Metabolic syndrome-associated hypogonadism is an important problem in men and is thought to occur by complex pathogenetic pathways. 26 men with metabolic syndrome-related hypogonadism, 26 men with metabolic syndrome with normal testosterone levels, and 26 healthy men were included in this study to examine the factors that may affect these pathogenetic pathways. Plasma nesfatin-1, kisspeptin, 5 alpha reductase-1 and aromatase levels and plasma 5 alpha reductase-1 and aromatase gene expressions were examined. As a result, plasma nesfatin-1 and kisspeptin levels of men with metabolic syndrome-related hypogonadism and only metabolic syndrome were found to be lower than healthy men ($P = 0.001$). There was no statistically significant difference for plasma nesfatin-1 and kisspeptin levels between the two groups with metabolic syndrome, with and without hypogonadism. Plasma 5 alpha reductase-1 and aromatase levels were also lower in men with metabolic syndrome-associated hypogonadism than healthy men ($P = 0.006$ and $P = 0.0001$, respectively). Plasma 5 alpha reductase-1 levels were not statistically significant in the metabolic syndrome group compared to the control group or the hypogonadism group. The difference between the aromatase levels between the two groups with metabolic syndrome with and without hypogonadism was not statistically significant. There was no statistically significant difference between the groups for 5 alpha reductase-1 and aromatase gene expressions ($P = 0.8$ and $P = 0.5$, respectively). A positive correlation was found between kisspeptin, nesfatin-1, plasma 5 alpha reductase-1 and plasma aromatase levels in all groups ($P = 0.0001$). Considering these findings, it can be thought that nesfatin-1 is an important mediator in the pathogenesis of metabolic syndrome and indirectly affects the development of metabolic syndrome-related male

hypogonadism. Although it has been shown in studies that kisspeptin is a regulator of the Hypothalamic-Pituitary-Gonadal axis at the hypothalamus level, it can be considered to be an important marker for the development of metabolic syndrome, and when the metabolic syndrome is associated with male hypogonadism, it is not effective in the pathogenesis alone, but may have a role in this pathogenesis through metabolic syndrome. It can be said that plasma 5 alpha reductase-1 levels are one of the important points in the development of metabolic syndrome-associated male hypogonadism. For aromatase, contrary to the classical view, it would be more appropriate to say it is a parameter that is affected by the process rather than the cause of hypogonadism and to review what we know about it.

Comparative analysis of the methods for differential diagnosis of non-diabetic hypoglycemia (NDH): Beta-hydroxybutyrate and glucagon test

Marina Yukina, Nurana Nuralieva & Ekaterina Troshina
Endocrinology Research Centre, Moscow, Russian Federation

Introduction
some authors propose to conduct consistently two additional tests for differential diagnosis (DD) of NDH with the main purpose to confirm or exclude the autonomous hyperinsulinemia (AH; insulinoma): determination the capillary beta-hydroxybutyrate (BHB) during prolonged fasting test (FT), and glucagon test (GT) at the moment of hypoglycemia. GT is more labor-intensive, high-cost and lead to potential complications. Therefore, we assumed that the BHB determination alone is enough for NDH DD.
Objectives
To compare the efficiency of GT and BHB determination in AH diagnosis.
Methods
In 59 patients aged 44 (23, 74) years with suspected NDH we conducted FT (was interrupted if glycaemia ≤ 2.8 mmol/l with symptoms of neuroglycopenia or, if maintaining normoglycemia, after 72 h). At the end of FT BHB was determined, then GT was conducted: 1 mg of glucagon was administrated iv with venous blood sampling for glucose through 3, 5, 10, 15, 20, 30 min. BHB ≤ 2.7 mmol/l and increase in glycemia ≥ 1.4 mmol/l during GT confirmed AH, opposite results indicated hypoinsulinemia.
Results
63% (n = 37) of patients had hyperinsulinemia (group 1); 37% (n = 22) – hypoinsulinemia/not confirmed NDH (group 2). BHB was 0.2 [0.1; 0.3] mmol/l in group 1; 4.4 [2.3; 4.9] mmol/l in group 2, P < 0.001. Sensitivity, specificity, accuracy of method were: 97.3%, 72.7%, 88.1%, accordingly. ROC-analysis indicated the excellent quality of model: AUC 0.989 [0.967; 1.000]. All patients with false positive results (1.85 [1.60; 2.00] mmol/l; n = 6) had insulin resistance (HOMA-IR > 2.7), that likely blocked ketogenesis. False negative result (3.3 mmol/l) identified in one patient with exacerbation of pyelonephritis, associated with increased ketogenesis. Increase in glycemia after glucagon administration was 2.8 [2.0; 3.4] mmol/l in group 1; 0.8 [0.6; 1.1] mmol/l in group 2, P < 0.001. Sensitivity, specificity, accuracy of method were: 94.6%, 100%, 96.6%, accordingly. ROC-analysis indicated the excellent quality of model: AUC 0.974 [0.937; 1.000]. False negative results (1.03 and 0.68 mmol/l; n = 2), presumably, were due to the influence of any other hormones on the glucagon effect on liver. Results of BHB determination and GT were identical in 90% of cases.
Conclusion
BHB determination and GT are highly sensitive and highly specific methods DD of NDH at the laboratory stage, with a small advantage for GT. But GT is more labor-intensive, high-cost and lead to potential complications. We assume that BHB determination during FT (especially at the end) is mandatory; GT should be used in doubtful cases as an additional method.

Hedonic rating of sucrose is sub-regionally associated with striatal dopamine transporter in humans

Kyoungjune Pak[1], Seongho Seo[2], Myung Jun Lee[1], Keunyoung Kim[1], Sunghwan Suh[3], Jeehyun Lee[1] & Injoo Kim[1]
[1]Pusan National University, Korea, Rep. of South; [2]Pai Chai University, Korea, Rep. of South; [3]Dong-A University, Korea, Rep. of South

Eating behavior is determined by both homeostatic and hedonic values. We investigated the association of hedonic value with striatal dopamine transporter (DAT) availability sub-regionally. An intravenous bolus injection of ^{18}F-FP-CIT was administered after the infusion of glucose or placebo, and the emission data were acquired over 90 mins. DAT availability, binding potential (BP_{ND}), were measured via the simplified reference tissue method. Subjects were assessed with sensory taste test of sucrose solutions. The 'most liked' sucrose concentration (%) was determined as the hedonic rating for sucrose. Twenty healthy males with the mean age of 23.9 ± 1.7 years (range 22 ~ 28 years) were participated in this study. The 12% sucrose solution received the highest liking score. BMI was associated neither with the 'most liked' sucrose concentration (r = –0.1812; P = 0.4446). After glucose loading, BPNDs of putamen were significantly increased (P = 0.0195, mean percentage change of BP_{ND} ± standard deviation; + 33.7 ± 51.7%), and those of caudate nucleus showed the increasing trend (P = 0.0601, + 70.4 ± 113.6%), while those of ventral striatum were not significantly different (P = 0.3330, + 29.6 ± 94.0%) compared with those after placebo loading (Figure 1). The relationships between the 'most liked' sucrose concentration (%) and BPNDs were investigated both by VOI-based and voxel-based analysis. With a VOI-based analysis, after glucose loading, the 'most liked' sucrose concentration (%) was negatively associated with BPNDs of caudate nucleus (r = –0.5437, P = 0.0132) and showed the trend of positive association with those from ventral striatum (r = 0.4115, P = 0.0715). Slopes of regression lines were significantly different according to sub-regions of striatum (F = 6.150, P = 0.0039) (Figure 2A). After placebo loading, the 'most liked' sucrose concentration (%) was not associated with BPNDs of ventral striatum (r = –0.1285, P = 0.5893), caudate nucleus (r = –0.2331, P = 0.3227) and putamen (r = –0.2506, P = 0.2866) without the significant difference in slopes of regression lines (F = 0.1235, P = 0.8841) (Figure 2B). With a voxel-based analysis, the 'most liked' sucrose concentration (%) was not associated with DAT availabilities of brain regions except for left putamen (MNI coordinates; –24 12 8, k = 87, T = 3.51) and left caudate nucleus (MNI coordinates; –18 14 12; –16 –6 24, k = 104, T = 3.36; 3.07) negatively after glucose loading (Figure 3). In conclusion, we have highlighted that striatal DAT increased after glucose loading in dorsal striatum, not in ventral striatum. These changes of striatal DAT were sub-regionally associated with the hedonic rating of sucrose from each subject.

glycaemic control in patients with Gestational Diabetes requiring betamethasone – a quality improvement project with intravenous insulin infusion protocol

Ihtisham Malik
Midland Regional Hospital, Mullingar, Ireland

Administration of antenatal steroids for foetal lung maturity is considered for all women at risk for preterm birth before 37 weeks. Administration of two doses of betamethasone 12 mg intramuscularly, 24 hours apart may result in a deterioration of glycaemic control for 2–3 days in patients with gestational diabetes (GDM), thereby potentially affecting foetal wellbeing. Current practice was noted to be inconsistent, and a protocol was drawn up for variable rate insulin infusion for all GDM patients requiring betamethasone. We sought to review effectiveness of the protocol to achieve better glycaemic control in those requiring betamethasone injections. Retrospective data was collected from chart review of 17 GDM patient who were treated with VRIII after betamethasone injections and subsequently monitored for up to 24 hours after last dose of betamethasone and glycaemic control was compared with the data of 17 GDM patients from before implementation of VRIII protocol Hourly glucose was monitored. There was no difference in glucose values in the first 14 hours. From 14 to 32 hours, mean glucose ± SD mmol/l were 7.8 ± 1.0 pre protocol, and 6.2 ± 0.4 post implementation of protocol (P = 0.002), We conclude that VRIII in GDM patients requiring betamethasone is effective in maintaining target glucose of 4 to 7 mmol/l.

Combined vildagliptin + metformin therapy can increase telomerase activity in patients with type 2 diabetes

Ekaterina Dudinskaya, Lubov Matchekhina, Irina Strazhesko & Olga Tkacheva
Pirogov Russian National Medical University, Russian Gerontology Research and Clinical Centre, Moscow, Russian Federation

Introduction
Metformin and vildagliptin are the medications amongst first-line treatment options in type 2 diabetes patients. Few recent studies have explained positive pleotropic effects of metformin therapy by telomerase activation and telomeres length in leukocytes preservation. Knowing the primary role of insulin-signalling pathway in insulin resistance development and physiology of ageing, it is possible to suggest, that one of the protective mechanisms of metformin and vildagliptin therapy is their ability to increase telomerase activity and thus to prevent accelerated telomeres shortening.
Aim of the study
To investigate effects of combined therapy with vildagliptin and metformin and their influence on telomerase activity in patients with type 2 diabetes.
Materials and methods
Total of 50 patients with diabetes were included in the study. Mean age was 58.4 ± 7.90 years. Diabetes duration was 0.9 ± 0.09 years. The patients were randomized with 1:1 ratio to a group treated with metformin 2000 mg/day and a group, which was given vildagliptin + metformin 100/2000 mg/day combination therapy. There were no statistically significant differences in age, sex, blood pressure, main carbohydrate metabolism parameters and vessel wall state between two groups. All patients were given recommendations on lifestyle changes (diet and physical activity). In 12 months after the initiation of treatment we performed: pulse wave velocity measurement, carotid arteries duplex scan, telomerase activity investigation on monocyte fraction of blood cells and pre-prandial glucose and HbA1c measurements. Statistical analysis was performed using SPSS 23.0.
Results
Examination after 12 months of treatment demonstrated, that either metformin monotherapy or its combination with vildagliptin had led to a significant glycaemic control improvement. In group 1 (metformin only) HbA1c and glucose levels decrease was 8.28% and 3.2% respectively, and in group 2 (combination therapy) – 3.4% and 1.5% respectively, reaching the normal range. The number of patients, who reached HbA1c less than 7.5% goal was 87.6% in group 1 and 64.7% in group 2. In group 2 were revealed statisitically significant increase in telomerase activity from 0.87 to 1.15 (P < 0.01) in contrast with group 1, where we observed a significant decrease in telomerase activity from 0.89 to 0.64 (p=0.01). After comparing all the numbers between two groups, we found, that vildagliptin + metformin combination therapy had a positive effect on changes in pulse wave velocity (P < 0.001), body mass(P < 0.001) and telomerase activity (P < 0.001).
Conclusion
Based on the obtained results it is possible to suggest the finding of a new independent pleotropic effect of metformin + vildagliptin combination therapy – the modulation of telomerase activity.

Maternally inherited diabetes and deafness, associated with a novel mitochondrial mutation, complicated by sever hypertriglyceridemia: Case report

Nabila Rekik, Wiem Gherissi, Dhoha Ben salah, Ameni Salah, Mona Mnif, Fatma Mnif, Faten Hadjkacem, Nedia Charfi, Mona Elleuch & Mohamed Abid
Hedi Chaker Hospital, endocrinology, Sfax, Tunisia

Introduction
Mitochondrial diseases are a clinically heterogeneous group of disorders that arise as a result of dysfunction of the mitochondrial respiratory chain. it is genetically heterogeneous diseases characterized by multisystem involvement. Thus, its clinical description is incomplete. The aim of this case report is to highlight the association between mitochondrial diabetes and severe hypertriglyceridemia. In this study, we describe the case of a 22 year old Tunisian girl, with a strong familial history of diabetes, hypertension and kidney diseases. The patient was born to a non-consanguineous marriage, attaining developmental milestones appropriately. Her past medical history was remarkable for hearing impairment, congenital Pigmentary retinal dystrophy, congenital structural abnormalities of the urogenital system and Diabetes with severe insulin deficiency but without typical features of Type 1diabetes (such as autoimmunity, prompt insulin requirement, ketoacidosis). Mitochondrial disease was then suspected and confirmed, since the age of 11, when genetic analysis identified A novel MT-CO1 m.6498C > A variation associated with the m.7444G > A mutation in the mitochondrial COI/tRNASer(UCN) genes The follow up findings revealed a poorly controlled diabetes (HBA1c 10.8%) despite increasing insulin requirement up to 2 uI/Kg /day and severe hypertriglyceridemia up to (13 g/l).The patient weight was 52 kg and her body mass index was 24.4 kg/m^2. Physical examination and abdominal imaging didn't reveal any pancreatitis features, except the presence of Hepatosteatosis. Furthermore, cardiovascular examination was normal and there was no evidence of eruptive xanthoma. Serum sample was milky and turbid. Lipoprotein-electrophoresis of serum, under fasting conditions, showed high levels of plasma VLDL (33%) and the presence of a small amount of chylomicrons (8.1%) accompanied by decreased level of HDL .Metabolic syndrome was then concluded by association of diabetes, hypertriglyceridemia, hypoHDL and hepatosteatosis. Severe hypertriglyceridemia was successfully resolved by diet control fibrates insulin and hydration therapy. In the other side, the patient was suffering of spaniomenorrhea, hyperandrogenism with hirsutism (Ferriman Gallwey score of 8), and gradual weight gain. Biochemically, hyperoestrogenaemia was observed in association with raised serum luteinizing hormone (LH), follicle-stimulating hormone (FSH) and antimullerian hormone (AMH) concentrations in 2016. Moreover, pelvic ultrasound revealed polycystic ovarian disease.
Conclusion
To our knowledge, this is the first case report describing a severe hypertriglyceridemia and polycystic ovary syndrome in maternally inherited diabetes and deafness.

Elderly patients with Type 2 Diabetes and Covid-19: the impact of glycemic control on the outcomes

Cátia Andreia Araújo, Bárbara Filipa Araújo, Miguel Melo, Carla Baptista, Sandra Paiva & Isabel Paiva
Centro Hospitalar Universitário de Coimbra, Serviço de Endocrinologia, Diabetes e Metabolismo, Coimbra, Portugal

Introduction
Diabetes mellitus (DM) is one of the major comorbidities in patients with Coronavirus disease (COVID-19) leading to poorer outcomes. Previous evidence showed that poorly-controlled hyperglycemia increases the

severity and mortality of COVID-19. Nevertheless, there is limited data on the role of in-hospital glucose control on the outcomes of elderly patients with type 2 diabetes mellitus (T2DM).
Objective
To access the impact of blood glucose control, assessed by the derived time in range (dTIR) and glycemic variability, on the mortality of elderly patients with T2DM and COVID-19.
Methods
We selected consecutive patients with laboratory confirmed COVID-19 who had been hospitalized in a general ward of our hospital between 25 March and 25 May 2020. From a total of 97 patients, we identified and included 38 patients with DM, with a median age of 80 years (IQR, 76–87). To assess glycemic control, all capillary blood glucose levels were extracted for each diabetic patient in the first seven days (four glucose tests per day). Individual derived time in range (percentage of time with plasma glucose between 70–180 mg/dl) was derived as the proportion of values within range (dTIR). dTAR (derived time above range) was derived as the proportion of values above range.
Results
The dTIR for all diabetic patients was 49%, and the dTAR was 52%. TIR > 70% was 36.8% for all diabetic patients. Nonsurvivors were more likely to have a lower TIR (38% vs . 73%, $P = 0.020$) and a higher TAR (62% vs . 27%, $P = 0.020$). Survivors were more likely to have TIR > 70% (50% vs . 14.3%, $P = 0.030$). There were no differences between groups regarding data estimates of glycemic variability: coefficient of variation (CV) (23.26 [17.46–35.76] vs . 29.15 [19.63–37.84], $P = 0.526$); high blood glucose index (HBGI) (13.78 [7.09–21.89] vs . 9.73 [3.35–17.03], $P = 0.151$); measure of stability of glycemia in comparison with an arbitrary assigned 'ideal' glucose value, 'R,' set to 100 mg/dl (M-100 index) (297.41[194.23–386.75] vs . 216.94 [147.00–321.54], $P = 0.123$) or measure of quality of glycemic control calculated as 0.001 × [mean + Standard of deviation (SD)] (J-index) (73.20 [45.82–104.39] – 56.99 [31.05–88.34], $P = 0.221$).
Conclusion
A poorer glycemic control, assessed by lower dTIR during hospitalization, was associated with in-hospital mortality. Clinicians should maximize TIR even in elderly patients, using a basal-bolus or continuous insulin infusion whenever needed, with appropriate surveillance.

Diabetes mellitus and COVID-19 – The bidirectional impact

Inês Manique[1], Alexandra Abegão Matias[1], Teresa Rego[1], Teresa Sabino[1], Bruno Bouca[1], Ana Cláudia Martins[1], Claudia Mihon[2], António Panarra[2] & José Silva-Nunes[1]
[1]Hospital Curry Cabral, Endocrinology, Diabetes and Metabolism, Lisboa, Portugal; [2]Hospital Curry Cabral, Internal Medicine, Lisboa, Portugal

Introduction
SARS-CoV2 infection can worsen glycemic control regardless of history of Diabetes mellitus (DM) and may precipitate new-onset diabetes (NOD). DM is also a risk factor for a greater severity of COVID-19. At-admission hyperglycemia (AH) is a known predictor of critical illness in other diseases.
Aims
Assess the impact of AH, regardless of the presence of DM, on the severity of COVID-19 inpatients.
Methods
Retrospective observational study on COVID-19 patients admitted to the IMFU from 3rd March to 31st October 2020, in order to assess associations between AH and severity outcomes: respiratory support (oxygen therapy or invasive mechanical ventilation – IMV), admission to Intensive Care Unit (ICU), and mortality in inpatients with and without DM.
Results
In 374 patients, 209 (55.9%) were males. The average age was 68 ± 19.3 years. DM was present in 105 patients (28.1%) with a HbA1c of 7.2% [IQR 6.2–8.3]. NOD was diagnosed in 15 patients (4%) with a HbA1c of 7.6% [IQR 6.8–11.1] with 2 of them presenting with diabetic ketoacidosis (DK). Blood glucose at admission was evaluated in 360 patients. Considering diabetic patients with AH ($N = 68$; 64.8%) there was a statistically significant correlation with COVID-19 severity ($P = 0.03$), IMV ($P = 0.008$) and ICU admission ($P = 0.026$) but not with oxygen therapy or mortality. In diabetic patients without AH ($N = 33$; 31.4%), there wasn't a statistically significant correlation with any of severity outcomes. In nondiabetic patients with AH ($N = 51$; 17.5%) there was a statistically significant correlation with oxygen therapy ($P = 0.001$); IMV ($P = 0.01$) and ICU admission ($P = 0.03$) but not with mortality (P = NS). All 15 NOD patients had AH and 12 had severe/critical COVID-19, needing oxygen therapy. ICU admission occurred in one third of NOD patients ($N = 5$): 4 of them being submitted to IMV; the other admitted due to DK. Three NOD patients died. In NOD patients, no statistical significance was found between AH and severity outcomes (probably due to the small size of this group of patients).
Conclusion
The results support previous data regarding the impact of at-admission hyperglycemia on severity outcomes, and suggests a strong effect on short and long-term prognosis of COVID-19 inpatients, both with and without diabetes. We reinforce the importance to assess at-admission glycemia in all patients admitted with COVID-19.

IL-18 in the Glucose Continuum

Iveta Nedeva[1], Antoaneta Gateva[1], Yavor Assyov[1], Vera Karamfilova[1], Tsvetelina Velikova[2], Kyosuke Yamanishi[3], Zdravko Kamenov[1] & Haruki Okamura[3]
[1]Medical university Sofia, Internal Medicine, Sofia, Bulgaria; [2]Medical university Sofia, Sofia, Bulgaria; [3]Hyogo College, Japan

Background
Both obesity and diabetes are associated with chronic low-grade inflammation. IL-18 is a cytokine that stimulates various cell types and has pleiotropic functions. The aim of the present study was to investigate the circulating levels of IL-18 in different stages of glucose dysregulation from obesity through prediabetes to newly diagnosed diabetes
Methods
IL-18 levels were determined using a commercially available human enzyme-linked immune sorbent assay (ELISA) kit.
Results
The sample consisted of 388 subjects with mean age 53.3 ± 10.78 years, divided in three age and BMI matched groups-obesity, prediabetes and diabetes. The control group consisted of 42 healthy individuals. IL-18 levels were significantly higher in patients with obesity and/or prediabetes and newly diagnosed diabetes compared to the control group respectively (249.77 ± 89.96; 259.01 ± 95.70; 340.98 ± 127.65 vs. 219.47 ± 110.53, $P < 0.05$). Correlation analysis showed that the level of IL-18 positively correlated with BMI, waist, WSR, VAI, liver enzymes, fasting and post load plasma glucose and insulin, uric acid, TG and negatively with HDL. ROC analysis determined circulating IL-18 levels to be of value for differentiating subjects with carbohydrate disturbances and those with MS. The AUC for carbohydrate disturbances was 0.597 ($P = 0.001$; 95%CI 0.539–0.654) and for MS AUC was 0.581($P = 0.021$; 95% CI 0.516–0.647).
Conclusion
The levels of IL-18 were increased in patients with obesity and carbohydrate disturbances. Further studies will elucidate the role of this cytokine in development of type 2 diabetes and its complications.

Liraglutide for weight management in syndromic obesity: effects in overgrowth adult Beckwith–Wiedemann syndrome

Marina Caputo[1,2], Tommaso Daffara[1], Simonetta Bellone[3], Valentina Mancioppi[3], Paolo Marzullo[1], Gianluca Aimaretti[1] & Flavia Prodam[1,2]
[1]Università del Piemonte Orientale, Italy, Endocrinology, Department of Translational Medicine, Novara; [2]Università del Piemonte Orientale, Italy, Department of Health Sciences, Novara; [3]Università del Piemonte Orientale, Novara, Italy, Division of Pediatrics, Department of Health Sciences, Novara, Italy

Context
Genetic obesity, including syndromic and non-syndromic forms, represent a minority of cases but gene dysregulations make their management particularly difficult. Among them, Beckwith–Wiedemann syndrome (BWS) is a multisystem human genomic imprinting disorder characterized by overgrowth, macroglossia, abdominal wall defects, hemi hyperplasia, enlarged abdominal organs, and an increased risk of embryonal tumours. The syndrome is caused by genetic and epigenetic changes on the chromosome 11p15 region, that include genes such as cyclin-dependent kinase inhibitor 1C (CDKN1C) or insulin like growth factor 2 (IGF-2), strong related to fetal and postnatal growth. Genetic and epigenetic alterations are frequently mosaic and lead to different clinical phenotypes, including early onset

obesity, although BWS is often an underestimated cause of syndromic obesity. Thus, less is known about obesity treatment in this syndrome.
Case description
We describe the first case of liraglutide treatment in an 18-year-old boy patient affected by BWS (Imprinting Center 1 Gain of Methylation (GoM IC1) associated with IC1 microdeletion) complicated by macroglossia, cryptorchidism, nephroblastoma, organomegaly, microscopic lymphocytic colitis, pharmacologically treated arterial hypertension, obesity and obstructive sleep apnea syndrome. He presented a normal cognitive development. BMI at the time of first transition visit in the adult endocrinology department was 40.6 kg/m^2 without glucose metabolism impairment. Lifestyles interventions failed because of a poor compliance. During 20 months of 3.0 mg liraglutide treatment weight loss of 19 kg (–13.3%) and BMI reduction of 6.8 points were registered without side effect. Normal glycemic and metabolic pattern was recorded without hypoglycemic episodes. Better control of blood pressure values was documented hesitating in improvement of quality of life.
Conclusion
liraglutide was effective on obesity in 7 subjects with Prader Willy Syndrome and 14 with melanocortin-4 receptor mutations. The efficacy of liraglutide in BWS could be related to a cross talk among glucagon like peptide (GLP)-1 system, mechanisms related to CDKN1C and dopamine mesolimbic circuit. Moreover, the causative mutation of BWS could interest genes such as IGF-2, implicated in postnatal overgrowth, and expresses by adipose tissue together with GLP-1 receptors. Thus, considering that GLP-1 promotes preadipocyte differentiation, reduces the expression of adipogenic and lipogenic genes, and enhances the expression of lipolytic markers, these could be some mechanisms targeted by liraglutide in BWS. On the other hand, the risk of hypoglycemia, although low during liraglutide, should be taken into account considering the intrinsic predisposition in BWS patients. Clinical trials aiming a tailored medicine in genetic obesity are needed.

Role of circulating cell-free deoxyribonucleic acid in the management of obese patients with breast cancer: Diagnostic impact, prognosis and relationship with obesity

Marwa Chiboub[1], Fatma Mnif[1], Wafa Benothman[1], Chaaben Kais[2], Abid Mohamed[1] & Cherif Boutheina[3]
[1]University Hospital Hèdi Chaker, Department of Endocrinology, Sfax, Tunisia; [2]University Hospital Hèdi Chaker, Department of Gynecology, Sfax, Tunisia; [3]Center of Biotechnology of Sfax, Laboratory of Molecular and Cellular Screening, Sfax, Tunisia

Introduction
Circulating cell-free deoxyribonucleic acid (cfDNA) is a topical subject that has proven its place in oncology. However, its regular use is always compromised by the relatively high cost of the technique. The objective of our study is to determine the usefulness of cfDNA in the management of obese patients with breast cancer as well as its prognostic impact.
Methods
Using real-time multiplex polymerase chain reaction (PCR), we studied the levels of circulating free DNA, with three different methods: fluorometry, Bglobin gene and ALU115 sequences, in samples. plasma from 105 patients divided into 4 groups (G1: 23 healthy controls, G2: 33 obese women, G3: 23 non-obese breast cancer patients and G4: 26 obese patients). To assess the applicability of cDNA as a biomarker for distinguishing between different study groups, we performed a Receiver Operating Characteristic (ROC) curve analysis. We also studied the relationship of the levels of molecular markers as well as the values of DNA integrity in the cancer group with the various clinicopathological parameters.
Results
While the levels of cfDNA in the two cancer groups were higher compared to the control groups, this result was only significant using the fluorometric method ($P = 0.045$) and ALU115 sequences ($P = 0.039$). The level of cfDNA was also associated with lymph node involvement ($P = 0.01$). In fact, the level of cfDNA was found to be significantly higher in both groups of obese women ($P < 0.001$). However, we have not found significant results by studying the different correlations between DNA integrity and cancer on the one hand and obesity on the other. Using the ROC curve analysis, we were able to distinguish between breast cancer cases and healthy controls using cDNA as a marker (cutoff: 7.91 ng/ml; sensitivity: 67.3%; specificity: 64.3%; $P < 0.001$). This threshold was higher taking into account the metabolic profile of the patients with a value of 10.15 ng/ml in the obese groups and of 7.04 ng/ml in the non-obese groups.
Conclusion
cfDNA is a valuable tool in the diagnosis of breast cancer but remains modifiable with the metabolic profile of the patients. But, more studies with larger cohorts are needed to validate the use of DNA integrity in cancer diagnosis and prognosis.

Is there an association between sex steroids and biopsy-proven non-alcoholic fatty liver disease in obese men? A cross-sectional analysis of 134 men

Carlien De Herdt[1], Christophe De Block[1,2], Van Dessel Kristof[1], Verrijken An[1], Sven Francque[2,3] & Eveline Dirinck[1,2]
[1]Antwerp University Hospital, Endocrinology-Diabetology-Metabolism, Antwerp, Belgium; [2]university of Antwerp, Faculty of Medicine and Health Sciences, Antwerp, Belgium; [3]antwerp University Hospital, Gastro-Enterology and Hepatology, Antwerp, Belgium

Background and aims
Low levels of testosterone and non-alcoholic fatty liver disease (NAFLD) in obese men are both linked to the metabolic syndrome, but the independent association between testosterone and NAFLD needs to be elucidated. In this cross-sectional analysis the association between total testosterone (total T) and calculated free testosterone (cFT) on the one hand and NAFLD, non-alcoholic steatohepatitis (NASH) and fibrosis on the other hand was investigated in obese men.
Methods
Data of 134 men of 18 years or older and a body mass index of at least 25 kg/m^2 who underwent a liver biopsy after visiting the obesity clinic were collected. Liver biopsy was performed if there was suspicion of NAFLD. Individuals were classified into 4 categories: no NAFLD, NAFL, NASH (no fibrosis (F0) or F1) or NASH with advanced fibrosis (F2-F4). Because of an unequal distribution of fibrosis, the 5 stages were regrouped into F0–1 and F2–4.
Results
Mean age was 45 ± 12, median BMI was 39.6 kg/m^2 (range 25.0–64.9). Only 5.2% of the individuals had no NAFLD. Of the individuals with NAFLD, 15.7% had NAFL, 56.7% had NASH F0-F1 and 22.4% had NASH F2-F4. Fibrosis stage 0 to 4 were present in respectively 47.8, 26.9, 17.2, 7.5 and 0.7%. cFT and total T were below the limit of normal in respectively 63% and 23% of individuals. One-way ANOVA showed a tendency toward a difference in the level of cFT between the grades of NAFLD ($P = 0.053$) that did not persist after controlling for confounding variables. No significant difference was seen for total T. Ordinal regression analysis showed a decreasing level of cFT was associated with an increase in the grade of NAFLD ($P = 0.005$) that did not persist after controlling for confounding variables. No significant effect of total T on the grade of NAFLD was seen. When performing the same analyses for fibrosis and after controlling for confounding variables, no difference in the level of cFT or total T were seen between F0-F1 and F2-F4 and no effect of cFT or total T was seen on the stage of fibrosis.
Conclusion
To the best of our knowledge, this is until now the largest study investigating the association between sex steroid levels and biopsy-proven NAFLD. After controlling for confounding variables no association was found between the level of total T and cFT on the one hand and NAFLD, NASH or fibrosis on the other hand.

The role of vitamin D deficiency in the development of latent autoimmune diabetes in adults

Iryna Tsaryk & Nataliia Pashkovska
Bukovinian State Medical University, Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine

Introduction
Vitamin D deficiency is recognized as a global problem worldwide. Today, there is information about the relationship between vitamin D levels and the pathogenetic links in the development of classic forms of diabetes mellitus (DM). In particular, vitamin D deficiency has been shown to cause insulin

deficiency, progression of insulin resistance, and β-cell dysfunction. There is growing evidence that vitamin D deficiency may be a risk factor for diabetes. At the same time, the role of vitamin D deficiency in the development of latent adult autoimmune diabetes (LADA) needs further study. The aim of our study was to determine the relationship between the level of vitamin D with carbohydrate metabolism and the level of antibodies to glutamic acid decarboxylase in patients with LADA.
Materials and methods
A study of 90 patients with diabetes (26 patients with type 1 diabetes mellitus (T1DM),28-with type 2 diabetes mellitus (T2DM),36-with LADA),as well as 25 members of the control group. Evaluated complaints, history, objective examination, carbohydrate metabolism, levels of antibodies to glutamic acid decarboxylase (antiGAD) and vitamin D. Vitamin D < 10 ng/ml was regarded as a deficiency,10–30 ng/ml as a risk of insufficient consumption, > 30 ng/ml as the optimal level. Patients with LADA were divided into two groups depending on the level of antiGAD:LADA1 and LADA2.We studied the relationship between vitamin D levels and carbohydrate metabolism in the study groups.
Results
Vitamin D deficiency was found in most patients:T1DM-62%,T2DM-75%, LADA-67%, and 12% of healthy individuals. The indicator of the insufficient consumption was registered in 34% of patients with T1DM,25% of patients with T2DM,25% of patients with LADA and 40% of the control group. In the remaining patients of the experimental group and in 28% of the control, this indicator was registered at the lower limit of normal. 20% of the surveyed control groups had the optimal level of vitamin D. Patients with LADA have the highest frequency (71%) and the degree of deficiency of this vitamin in a subgroup with LADA2 phenotype (LADA1–63%). In patients with LADA, there was a negative correlation between vitamin D levels and antiGAD titres ($P < 0.05$), as well as HbA1C levels ($P < 0.05$), and a positive correlation between vitamin D and C-peptide levels ($P < 0.05$).
Conclusion
Most patients with LADA have vitamin D deficiency, which is associated with a higher degree of autoimmunity, loss of beta-cell function and poorer compensation of the disease, which may indicate its role in the development and progression of this variant of diabetes.

AEP205

Prevalence of erectile dysfunction among the subjects with type 2 diabetes mellitus in the indian state of punjab

Vipan Talwar & Gourav Talwar
Golden Hospital, Endocrinology, Jalandhar, India

Background
Erectile Dysfunction (ED) is one of the most common sexual dysfunction occurring in men with Type 2 diabetes mellitus (T2DM) but its evaluation is often neglected in routine clinical practice. There is hardly any data on the prevalence of ED among the males with Type 2 diabetes mellitus in the Indian state of Punjab.
Aims
This cross sectional study was conducted to find out the frequency and risk factors of ED in subjects with T2DM in the Indian state of Punjab.
Material and methods
Study was conducted on 520 male subjects with T2DM attending the outpatient department of an endocrinology speciality hospital. All participants underwent detailed clinical evaluation, anthropometric measurements and relevant lab investigations like fasting plasma glucose (FPG), HbA1c, creatinine, lipid profile,testosterone. The presence of ED by was determined by using the International Index of Erectile Function-5 (IIEF-5) questionnaire, which consists of 5 items; a sum score of 21 or less indicates the presence of ED. Statistical analysis was done using SPSS.
Results
The mean age of subjects was 53.4 ± 16.8 years. Out of the 520 subjects, 298 (56.4%) had ED. ED was mild in 14.8%, mild to moderate in 17.6%, moderate in 14.4% where as severe ED was present in 9.6% of the subjects. The subjects with ED had higher mean age, longer duration of DM, higher body mass index (BMI), higher HbA1c, higher FPG, higher serum creatinine and lower serum testosterone level than those without ED. Also the Subjects with hypertension, peripheral artery disease, dyslipidaemia had higher prevalence of ED.
Discussion
ED is defined as the persistent inability to achieve or maintain penile erection for successful sexual intercourse and it results from complex interplay between vascular, neurologic, hormonal and psychological factors. In our study a high prevalence of erectile dysfunction was observed in type 2 DM subjects in Indian state of Punjab. The IIEF-5 score showed significant negative correlation with age, duration of diabetes, HbA1c, fasting plasma glucose, serum creatinine and significant positive correlation with serum testosterone. Poor glycaemic control, testosterone deficiency, peripheral arterial disease were the modifiable risk factors for ED in diabetic subjects.
Conclusions
The prevalence of ED is high among T2 DM patients. ED is an important but often neglected complication of diabetes and its assessment should be included in the routine evaluation of all men with diabetes so as to ensure its early diagnosis and prompt treatment.

The effect of renin-angiotensin-aldosterone system inhibitors on binary and continuous renal outcomes in subgroups of patients with diabetes: an extensive meta-analysis

Noor Alsalemi[1], Naoual Elftouh[1], Maudeline Louis[1], Cheryl Sadowski[2] & Jean-Philippe Lafrance[1,3]
[1]Maisonneuve-Rosemont Hospital Research Center, Canada; [2]Faculty of Pharmacy and Pharmaceutical Sciences, University of Alberta, Canada; [3]Maisonneuve-Rosemont Hospital Research Center, Nephrology, Canada

Introduction
Diabetic nephropathy is the leading cause of end-stage-kidney disease (ESKD). Clinical practice guidelines recommend prescribing renin–angiotensin aldosterone system inhibitors (RAASi) to prevent diabetic nephropathy at any stage. We conducted this extensive meta-analysis to compare the effects of RAASi with placebo and other antihypertensives in adults with diabetes on binary and continuous renal outcomes to provide a comprehensive review of the class effect of RAASi on several subgroups of study participants.
Methods
A systematic search to identify randomized clinical trials of a duration of 12 months or more that recruited more than 50 adults participants with type 1 or 2 diabetes mellitus with any stage of chronic kidney disease and proteinuria was conducted. Electronic searches were conducted with the help of a librarian in MEDLINE, CINAHL, EMBASE, Cochrane library with no language or date restrictions. Studies were screened against the inclusion and exclusion criteria by two reviewers independently.
Results and discussion
In this meta-analysis, evidence was drawn from 26.609 patients with diabetes from 46 studies on the effect of RAASi on binary and continuous renal outcomes. Our analysis shows that RAASi were superior to placebo in reducing the risks of ESKD(OR:0.74; 95% CI: 0.56–0.97) and doubling of SrCr levels(OR:0.71; 95% CI: 0.55–0.91), but not in promoting the regression of albuminuria(OR:3.00; 95% CI: 0.96–9.37). RAAS inhibitors, however, were not superior to other antihypertensives in reducing the risks of these outcomes. RAASi were better than placebo in reducing SrCr (the raw mean difference (RMD) was −13.4umol/l (95% CI: −16.78; −10.01)) and albuminuria levels (standardized mean difference (SMD) −1(95% CI: −1.57; −0.44, I^2=96%)). Surprisingly, RAASi reduced GFR levels more than placebo (RMD:−0.82ml/min;95% CI: −5.54; 3.91), yet it was not a statistically significant finding. When compared to active treatments, RAAS inhibitors did not reduce SrCr levels (RMD:0.03 umol/l;95% CI: −6.4; 6.10, I^2=76%), caused a reduction of GFR levels (RMD: −1.12 ml/min; 95% CI: −4.51; 2.09, I^2=86%), and resulted in modest reduction of albuminuria levels (SMD:-0.55; 95% CI: −0.95;-0.16, I^2=90%). Patients with T2DM, macroalbuminuria and longer duration of DM had less risk to develop ESKD in placebo-controlled trials, while longer duration of DM, normal renal function, and hypertension increased the probability to achieve regression of albuminuria in active-controlled trials.
Conclusion
While our findings revealed the non-superiority of RAASi over other antihypertensives and portrayed class effect on several subgroups of study participants, it raised a challenging question on whether RAASi deserve their place as first-line therapy in managing diabetic nephropathy.

Correction of oxidative stress in experimental diabetes mellitus by means of natural antioxidants

Talat Saatov[1], Mukhammadjon Mustafakulov[1], Sanobarkhon Irgasheva[1], Zafar Ibragimov[1,2], Elvira Ibragimova[1], Tokhir Ishanhodjaev[1], Bakhodyr Zainutdinov[1], Nigora Samarkhodjaeva[1] & Nodira Abdullakhodjaeva[3]
[1]Institute of Biophysics and Biochemistry, Mirzo Ulugbek National University of Uzbekistan, Laboratory of Metabolomics, Tashkent, Uzbekistan; [2]Institute of Hematology, Uzbekistan Public Healthcare Ministry, Department of Molecular Genetics, Tashkent, Uzbekistan; [3]Institute of Bioorganic Chemistry, Uzbekistan Academy of Sciences, Tashkent, Uzbekistan

Associated with the increased generation of free radicals and reduced activity of antioxidant system, oxidative stress is a pathogenetic mechanism underlying the onset of diabetic complications. Antioxidants are known to facilitate normalization of lipid peroxidation, composition, structures and functions of biological membranes. Antioxidants are universal membrane-trophic agents protecting against damaging factors. Plant antioxidants play a significant role in treatment of diabetes mellitus (DM).
The work was initiated to study oxidative stress in experimental DM and its correction with natural antioxidants.
Materials and methods
Antioxidant properties of medications based on phenolic compounds isolated from the leaves of cotton *Gossypium hirsutum L.* (gossitan) and euphorbia *Euphorbia Fergansis* (euphorbin), as well as extract of safflower *Carthamus tinctorius* blossoms and quercetin were studied in the models of adrenaline autoxidation and ascorbate-dependent lipid peroxidation *in vitro*. Hypoglycemic effects of the medications were studied in the experimental model of alloxan diabetes in rats. Blood glucose reaching more than 9–11 mmol/l, the medications and gliclazide, a commercially available blood glucose lowering drug (Servier, France), as a control at the recommended dose *o.d.* for 10 days were administered to the animals by a gastric tube. The orthotoluidine test was used to measure blood glucose. Activity of the rat liver glucokinase was calculated by changes in concentrations of exogenous glucose in % to the control upon the 30-minute incubation with the liver homogenates from rat with alloxan diabetes before and after the 10-day administration of polyphenols.
Results
Demonstrating high antioxidant activity, gossitan, euphorbin, safflower extract and quercetin were found to cause reduction in blood glucose concentrations in animals with experimental diabetes, associated with a reduction in free-radical lipid oxidation and an increase in activity of enzymes involved in glucose utilization. The medications demonstrated significantly higher antidiabetic effect than gliclazide. The combination of antioxidative and hypoglycemic effects in the medications under study would make possible correction not only of glycemia, but also of the free-radical processes taking place in diabetes mellitus to decrease the risk of onset and progression of diabetic complications.

Introduction
Once thought to typify type 1 diabetes mellitus (T1DM), diabetic ketoacidosis (DKA) in people with type 2 diabetes mellitus (T2DM) is also now increasingly recognized. We explored the clinical and biochemical differences in DKA in the two types of diabetes.
Methods
This retrospective cohort study included all the DKA episodes from April 2014 to September 2020 at a large tertiary care centre in West Midlands, United Kingdom. People admitted with DKA were classified as having T1DM or T2DM based on previously established diagnosis, treatment history, autoantibody status, and/or phenotypic features. The two groups were compared for differences in precipitating factors, biochemical profiles at presentation, management, and outcomes of the admission with DKA.
Results
A total of 786 DKA episodes were identified. Eighteen were excluded due to unclear underlying type of diabetes. 75.9% (n = 583/768) had T1DM, and 24.1% (n = 185/768) had T2DM. The most common precipitating causes in both groups were intercurrent illness (total: n = 272/768, 35.42%; T1DM: n = 198/583, 33.96%; T2DM: n = 74/185, 40.00%) and suboptimal compliance to treatment (total: n = 206/768, 26.82%; T1DM: n = 176/583, 30.19%; T2DM: n = 30/185, 16.22%). There was no clear precipitant in 16.15% (n = 124/768) (T1DM: n = 95/583, 16.30%; T2DM: n = 29/185, 15.68%). There was no significant difference in biochemical profiles on admission [median(Q1-Q3) pH (T1DM: 7.22(7.09–7.29); T2DM: 7.24(7.11–7.30); P = 0.3266), bicarbonate (T1DM: 11.90(7.13–16.78); T2DM: 13.20(7.75–17.80); P = 0.2192), glucose (T1DM: 28.00(20.45–34.80); T2DM: 26.55(16.21–35.09); P = 0.4496), lactate (T1DM: 2.6(1.8–4.3); T2DM: 2.6(2.04–4.21); P = 0.6532), serum osmolality (T1DM: 310.07(300.61–320.90); T2DM: 312.13(300.11–328.79); P = 0.2787)] between the two groups, except for urea, which was higher in T2DM [T1DM 7.1(5.1–10.6); T2DM 8.9(6.4–16.8); P < 0.0001]. There was no difference in appropriateness of fixed rate intravenous insulin infusion administered [T1DM: 100.00%(93.53–104.48); T2DM: 99.48%(90.00–102.27); P = 0.0688], proportion of hourly glucose measurements [T1DM: 99.49%(61.71–131.95); T2DM: 92.78% (64.33–120.22); P = 0.2143], proportion of hourly ketone measurements [T1DM: 46.39% (24.30–71.43); T2DM: 44.43% (20.90–70.74); P = 0.6485], and fluids administered [T1DM: 80.00% (58.33–100.00) vs 80.00% (50.00–112.50); P = 0.4978]. People with T1DM had more episodes of hypoglycaemia [T1DM 0(0–1); T2DM 0(0–0); P = 0.0056] during DKA management. Although there was no difference in the total DKA duration between the two groups [T1DM: 13.92(9.11–21.92); T2DM: 13.90(7.73–21.12); P = 0.4638], people with T2DM had significantly longer hospital stay [T1DM: 2.95(1.68–6.05); T2DM: 11.02(4.99–23.11)]; P < 0.0001].
Conclusion
Both cohorts had similar DKA severity, management, complications, and duration. People with T2DM required longer hospital stay, suggesting a more complex need for care, and increased economic burden. Increased awareness of DKA in people with T2DM is needed for improved prediction and prevention.

Clinical and biochemical assessment of erectile dysfunction in men with type 1 diabetes

Ghofrane Hakiri, Kamilia Ounaissa, Achwek Mahrez, Manel Dridi, Imen Sebai, Haifa Abdessalam, Asma Ben Brahim, Rym Yahiaoui & Chiraz Amrouche
Institut De Nutrition, Tunis, Tunisia

Background
Erectile Dysfunction (ED) is a common complication of diabetes, but also one of the most underdiagnosed. ED is considered a vascular impairment that shares many risk factors with cardiovascular disease (CVD) and could be an early marker of systemic endothelial dysfunction. The aim of our study is to assess the prevalence and risk factors for ED by using the International Index of Erectile Function- 5 (IIEF-5) in type 1 diabetic men undergoing a health investigation.
Methods
This is a cross-sectional, prospective study including 50 type 1 diabetic men. All men underwent a detailed health examination including physical assessment, evaluation of various life-style factors, medical history and a blood analysis. IIEF-5's Arabic version was used to assess the prevalence and the degree of ED. A hormonal assessment was performed including testosterone, follicle-stimulating hormone (FSH), luteinizing hormone (LH), thyroid-stimulating hormone (TSH), free thyroxine (FT4) and Prolactin. Borderline hypogonadism was defined as the presence of total testosterone level < 3 ng/ml.
Results
The mean age the study group was 37.88 ± 9.31 years. According to the IIEF-5 score, 67% reported on any degree of ED, 25.7% had mild ED (IIEF-5 score 17–21), 18.9% mild to moderate ED (IIEF-5 score 12–16), 12.4% moderate ED (IIEF-5 score 8–11) and 10% severe ED (IIEF-5 score 5–7). The mean duration of diabetes in this group was 12.2 ± 7.9 years. The prevalence of comorbid conditions increased with ED severity (P < 0.05).

Risk factors for ED were microvascular complications of diabetes (OR: 1.02; 95% CI: 0.99–1.6), and hyperlipidemia (OR: 2.20; 95% CI: 1.55–3.5). Borderline hypogonadism was found in 10.5% of men with ED with mean testosterone level 2.2 ± 0.2 ng/ml. The prevalence of hypogonadism was higher in diabetics with diabetic nephropathy (32%) and diabetic retinopathy (28%).
Conclusions
ED is frequent in diabetic men; its frequency is correlated with the presence of microvascular complications and hyperlipidemia.

Diabetic bullosis: about 2 cases

Imen Chabchoub[1], Mouna Elleuch[2], Dhoha Ben Salah[2], Wajdi Safi[2], Nadia Charfi[2], Mouna Mnif[2], Hadj Kacem Faten[2], Nabila Mejdoub[2] & Abid Mohamed[2]
[1]Hedi Chaker Hospital, Internal Medicine, Sfax; [2]Hedi Chaker Hospital, Endocrinology And Diabetes, Sfax, Tunisia

Introduction
Dermatological manifestations associated with diabetes affect approximately 30% of patients. Diabetic Bullosis is a rare complication of diabetes. It is a rare bullous dermatosis charecterised by the occurrence of bubbles on healthy skin with variable levels of cleavage.
Objective
We propose to study the epidemiological, clinical and evolutionary characteristics of Diabetic Bullosis in diabetic patients who are followed up at the Endocrinology Department of Sfax, Tunisia.
Patients and methods
Descriptive, retrospective study of diabetic patients over a period of 15 years (2005–2019). The disease was retained clinically.
Results
Diabetic bullosis was found in 2 male patients aged 69 and 87 years respectively at the time of diagnosis of bullosis. One was type 1 diabetic and the other type 2 diabetic. The diabetes had been progressing for 10.5 years. The recommended therapy was empirical insulin therapy in 1 case, oral antidiabetic drugs relayed by insulin in 1 case. Diabetes was complicated by sensitive polyneuritis in gloves and socks in one case and diabetic nephropathy in another case. No other skin or osteo-articular complications were objectified. Clinically, the skin lesions presented as multiple bullous lesions, without inflammatory areola, with clear content, occurring on healthy skin sitting on the hands in one case and on the big toe in another case. Therapeutically, local care was recommended in both cases, combined with antibiotic therapy in one case due to bacterial superinfection. An improvement of the lesions occurred in 1 case.
Conclusion
The bullosis of diabetics is a characteristic skin complication of diabetes. Its etiology is still unknown. Its evolution is benign and its treatment remains essentially preventive.

AEP211

Selective sodium-glucose cotransporter inhibitors 2 (isglt2) in patients with high risk of amputation

Mª del Carmen Serrano Laguna[1], Verónica Ávila Rubio[2], Sara León Utrero[2] & Pablo José López-Ibarra Lozano[2]
[1]Hospital Universitario Reina Sofia, Córdoba, Spain; [2]Hospital Universitario Clínico San Cecilio, Granada, Spain

Introduction
The use of iSGLT2 remains controversial in diabetic patients with peripheral arterial disease.
Objectives
Assess metabolic effect and risk of amputations of iSGLT2 in diabetic patients treated in the Multidisciplinary Unit of Diabetic Foot (MUDF) comparatively with a control group.
Design and methods
Retrospective observational study in which the patients seen at the MUDF from December 2017 to January 2021 were recruited. A treatment group with iSGLT2 was selected and these data were compared with a control group. Clinical, metabolic, anthropometric variables and amputation rate were collected in both arms. Statistical analysis was performed using the SPSS program (SPSS, inc, v21.0).
Results
312 patients were recruited: 83 in treatment with iSGLT2 and 229 as a control group. The treatment group had a mean age of 65.99 ± 10.31 vs 68.14 ± 12.11 years of the control group ($P = 0.12$) and a disease evolution time of 17.33 ± 10.26 vs 18.10 ± 11.97 ($P = 0.52$). Weight of 86.88 ± 17.77 kg vs 82.65 ± 15.65 kg ($P = 0.57$) and a mean BMI of 31.07 ± 5.61 kg/m^2 vs 29.58 ± 4.91 kg/m^2 ($P = 0.03$). Basal HbA1c (iSGLT2 vs control group): 8.83 ± 1.67% vs 7.71 ± 1.72% ($P = 0.00$); mean reduction: 1.04 ± 1.32% vs 1.42 ± 2.34% ($P = 0.38$); Final HbA1c: 8.08 ± 1.37 vs7.42 ± 1.32% ($P = 0.05$). No statistical significant differences between the basal LDL values (96.29 ± 38.95 mg/dl vs 98.8 ± 40.93 mg/dl, $P = 0.67$)) or the reductions obtained in both arms (11, 28 ± 31.16vs12.25 ± 31.84, $P = 0.91$). Risk factors for amputation: higher proportion of hypertension (78.3% vs 72.2%), dyslipidemia (74.7 vs 71.1%), smokers (58.2 vs 49.8%) in the group with iSGLT2, as well as a greater history of chronic ischemia (41 vs 38.2%) and neuropathy (74.4 vs 70.9%). The rate of amputations after follow-up was 15.7% in the iSGLT2 group compared with the 12.3% control group ($P = 0.55$).
Conclusions
This study shows that treatment with iSGLT2 in a group of diabetic patients with a high risk of amputations is effective and safe, not increasing this rate comparing with control group of MUDF, despite presenting greater number of risk factors for it.

Influence of diabetes in heart failure with preserved ejection fraction

Marta Borges-Canha[1,2], Francisco Vasques-Nóvoa[1,3], Francisca Saraiva[1], Ana Rita Leite[1], Ana Cristina Oliveira[1], Joao Sergio Neves[1,2], Madalena von Hafe[1], Catarina Vale[1,3], Davide Carvalho[2] & Adelino F. Leite-Moreira[1]
[1]Departamento de Cirurgia e Fisiologia, Faculdade de Medicina da Universidade do Porto; [2]Serviço de Endocrinologia, Diabetes e Metabolismo, Centro Hospitalar Universitário de São João, Porto, Portugal; [3]Serviço de Medicina Interna, Centro Hospitalar Universitário de São João, Porto, Portugal

Introduction
Heart Failure with Preserved Ejection Fraction (HFpEF) denotes a growing challenge due to the population aging and the rising prevalence of cardiovascular risk factors.
Aim
We aimed to evaluate the influence of the diagnosis of diabetes mellitus (DM) on the signs and symptoms, comorbidities and echocardiographic and vascular evaluation of patients with HFpEF in a stable phase.
Methods
Cross-sectional study including 94 patients with HFpEF in stable phase, followed in our center. Signs, symptoms and comorbidities were obtained by anamnesis, physical examination and patient medical records. The cardiac function was evaluated by echocardiography performed by expert cardiologists. Endothelial function (Reactive Hyperemia Index) was evaluated with the EndoPATTM2000 device, and carotid-femoral pulse wave velocity. The associations between DM and previously defined outcomes were assessed through linear and logistic regression models, adjusted for sex, age, systolic blood pressure (SBP) and body mass index (BMI).
Results
The included population ($n = 94$) has an average age of 73.8 ± 8.8 years and 53.8% are males. Average BMI is 29.4 ± 5.3 kg/m^2 and 52.7% of the patients have DM. Concerning signs and symptoms, no differences were recorded regarding oedema, NYHA class, orthopnea or nocturnal paroxysmal dyspnea. About comorbidities, patients with DM have higher SBP (OR 14.2 [5.0 to 23.4] mmHg; $P < 0.01$), and higher prevalence of both peripheral arterial (OR 15.5 [2.6 to 92.7]; $P < 0.01$) and cardiovascular atherosclerotic (OR 6.4 [1.5 to 26.8]; $P = 0.011$) diseases. The echocardiographic evaluation showed that patients with DM have an inferior isovolumetric relaxation time (ms) comparing to patients without DM (ß = –11.4 [-22.4 to -0.36]; $P = 0.019$). Patients with DM have a higher pulse wave velocity (m/s), comparing to patients without DM (ß=2.13 [0.92 to 3.33]; $P < 0.01$).
Conclusion
In patients with HFpEF, the presence of DM associates not only to higher prevalence of comorbidities but also to deleterious cardiac structural and vascular changes.

Analysis of lipid profile in a sample of patients with type 1 diabetes (T1D)

Miguel Damas-Fuentes[1], Carmen Hernandez Garcia[2], Jose Ignacio Martinez Montoro[1], Andrea Fernandez Valero[1] & Francisco Tinahones Madueño[1]
[1]Virgen de la Victoria Hospital, Endocrinology and Nutrition, Málaga, Spain; [2]Torrecárdenas University Hospital, Endocrinology and Nutrition, Almería, Spain

Introduction
Dyslipidemia is a major cardiovascular risk factor, being its detection and control essential due to risk of serious complications. Numerous trials have demonstrated its relationship with T2D, but it has not been so well studied in T1D.
Objective
To obtain information about relationship between dyslipidemia and T1D and analyze its prevalence and control in a sample of patients.
Material and methods
Retrospective descriptive observational study that analyzes data from 235 patients with DM1 in Endocrinology Consultation at Virgen de la Victoria Hospital in Malaga.
Results
50.6% were women, with a mean age of 34.59 ± 12.6 years; BMI 25.47 ± 4.27 kg/m^2 and diabetes of 18.09 ± 10.15 years of evolution. From all of them, 93 (39.6%) had dyslipidemia with mean analytical parameters: glycemia 159 ± 74.4 mg/dl, HbA1c 8.6 ± 7.5%, total cholesterol 179.2 ± 7.5 mg/dl, HDL 59.9 ± 36.6 mg/dl, LDL 106.4 ± 76.9 mg/dl, triglycerides 104 ± 216.5 mg/dl. Only 74 (79.6%) received lipid-lowering treatment: 71 (76.3%) statins; 2 (2.2%) statins plus ezetimibe and 1 (1.1%) fenofibrate; with results at 6 months of: CT 163 ± 32 mg/dl, HDL 57 ± 16 mg/dl, LDL 88 ± 24 mg/dl, TG 90 ± 47 mg/dl. From them 17 (22.97%) achieved LDL < 70 mg/dl; 35 (47.29%) presented figures between 70–100 mg/dl and 22 (29.79%) LDL > 100 mg/dl. The sum of patients in treatment with LDL < 100 mg/dl was 52 (70.26%). In addition, they presented a higher percentage of comorbidities compared to non-dyslipidemic patients: hypertension 43 (18.3%) patients with dyslipidemia compared to 6.3% of non-dyslipidemic patients, smoker 29.8% vs 27.5%; taking antiaggregant 19.6% vs 8.5%; and complications: retinopathy 15.3% vs 9.2%; diabetic kidney diseases 13.2% vs 12.7%; neuropathy 3.8% vs 3.5% and a history of CVD 3% vs 0.7%.
Conclusion
There is a significant relationship between dyslipidemia and age, DM1 evolution time and BMI but not HbA1c. Furthermore, it is more frequent in those patients who present other cardiovascular risk factors.

Rare case of fluoroquinolone induced hypoglycaemia

Laju Etchie, Mehreen Anwar, Devaka Fernando, Ashok Poduval & Vakkat Muraleedharan
Kings Mill Hospital, Diabetes and Endocrinology, Nottinghamshire, United Kingdom

We would like to present an interesting unusual case of fluoroquinolone induced hypoglycaemia. As per FDA Adverse Event reporting System and medical literature published between 1987–2017, fluoroquinolones are said to have caused about 67 cases of life-threatening hypoglycaemic coma including 13 deaths and 9 permanent disabling injuries, most cases were associated with levofloxacin. Its hypoglycaemic effect is more common in elderly population who are on oral hypoglycaemic agents and insulin but can also happen in non diabetics. Our patient was a sixty seven year old woman who presented with an unwitnessed fall and decreased oral intake. She had a background of learning disability, hypertension, epilepsy, bronchial asthma, chronic iron deficiency anaemia, chronic mild lymphopenia, osteoporosis and previously treated uterine cancer. After clinical review an impression of hospital acquired pneumonia with possible aspiration pneumonia was made along with hyponatraemia secondary to dehydration. She was commenced on intravenous levofloxacin 500 mg twelve hourly and metronidazole 500 mg eight hourly. On first day of admission, venous plasma glucose was noted to be 7.1. She was not known to have diabetes. On third day of admission she was found unresponsive with an early warning score of four, capillary blood glucose was found to be 0.6 mmol/l, this improved with 10% glucose. Blood sugars continued to be low requiring further intravenous glucose. A medication review was undertaken and levofloxacin was discontinued. After 24 hrs of discontinuation of levofloxacin, the hypoglycaemic episodes resolved and her blood glucose later remained > 5 mmol/l throughout the admission.. A short synacthen test showed normal cortisol response (At 0 min – 262 nmol/l, 30 mins- 467 nmol/l). As the patient had no further hypoglycaemic episodes after stopping levofloxacin, a diagnosis of levofloxacin induced hypoglycaemia was made and no further investigation was deemed appropriate at that point. In experimental studies with rat islet cells exposed to quinolones, an increase in insulin secretion via blockade of adenosine triphosphate (ATP)–dependent potassium channels was observed. Thus, the possible mechanism could be increased insulin release via blockade of ATP-sensitive potassium channels in the beta-cells of the pancreas. Health professionals should be aware of the potential risk of severe hypoglycaemia with the use of Fluoroquinolones as it remains antibiotic of choice for many inflammatory conditions and blood glucose monitoring should be recommended if it is prescribed in elderly diabetic patients or in elderly patients who have poor oral intake or in those with other comorbidities to prevent life threatening hypoglycaemia.

Microvascular complications in type 1 diabetes diagnosed during adulthood: prevalence and predictive factors

Hadj Kacem Faten, Khouloud Boujelben, Allymamod Bibi Twaheerah, El Arbi Kawthar, Charfi Nadia, Mnif Fatma, Mnif Mouna, Rekik Nabila & Abid Mohamed
Hedi Chaker Hospital, Sfax, Tunisia, Department of Endocrinology, Diabetology

Introduction
Type 1 diabetes (T1D), also known as juvenile diabetes, commonly occurs in young individuals. However, autoimmune diabetes may be diagnosed in the elderly, with different clinical and biological aspects. The aim of our study is to identify the prevalence of and risk factors for microvascular complications related to T1D diagnosed during adulthood.
Patients and methods
A retrospective study, from 2010 to 2019, including 166 patients diagnosed with T1D occurred after the age of 20, with positive anti-pancreatic antibodies (Anti GAD, Anti ICA and/or Anti IA2). The incidence of microvascular complications and potential predictive factors were analyzed.
Results
Mean age was 31.81 years (95 males vs 71 females). Mean diabetes duration was 7.34 ± 6.73 years (2 months-44.5 years) and 57.8% of patients had diabetes that had progressed for at least 5 years. Microvascular complications occurred in 21.5% of patients. A total of 16 patients (9.6%) had diabetic retinopathy after a mean diabetes duration of 13.23–9.26 years (0.7–38 years). Diabetic kidney disease was observed in 6% of patients after an average duration of diabetes of 16.7 ± 6.68 years. The mean urea and creatinine level was 5.35 mmol/l and 75.8 umol/l,respectively. The prevalence of albuminuria was 7.2%. Seven patients underwent hemodialysis for *end-stage renal disease*. Peripheral neuropathy complicated diabetes in 18.1 % of patients after a mean duration of 9.66 ± 7.55 years (1–30 years). Only 15 patients had cardiovascular autonomic neuropathy: urogenital dysfunction in 14 patients, gastroparesis in 3 patients and orthostatic hypotension in 1 patient. Diabetic retinopathy and kidney disease were both significantly more common in men ($P < 0.05$).A higher prevalence of diabetic retinopathy was significantly observed in patients with longer diabetes duration ($P < 0.05$). Patients who developed diabetic kidney disease were significantly older ($P < 0.05$). Furthermore, there was a significant correlation between this complication and high blood pressure. Diabetic kidney disease was also significantly associated with an increased incidence of diabetic retinopathy, hypertension and macrovascular complications. Diabetic neuropathy was significantly related to diabetes duration, age, basal metabolic index (BMI) and creatinine clearance ($P < 0.05$).

Conclusion
Among adults who had been diagnosed with T1D, screening of microvascular complications remains a crucial step in T1D's management. Their early identification helps to reduce their adverse repercussions.

AEP217

In the context of acute disease does the same hyperlactatemia cut-off point hold similar meaning in patients with and without Diabetes mellitus? A retrospective study

Inês Vieira, Maja Petrova & José Moura
Coimbra Hospital and University Center, Endocrinology, Portugal

Introduction
Hyperlactatemia is defined by a lactate value > 2 mmol/l and a lactate value above > 4 mmol/l is commonly used to define more severe hyperlactatemia. It is a common disorder in critically ill patients, associated with adverse prognosis. Diabetes mellitus (DM), however, can also be associated with increased lactate levels at baseline.
Objectives
To document the development of severe hyperlactatemia in acute situations in patients with and without DM; to analyze potential contributors to lactate elevation and its impact on mortality; to analyze whether lactate values > 4 mmol/l have equal prognostic significance in patients with and without DM.
Materials and methods
A retrospective cross-sectional study was performed with patients admitted to internal medicine wards in the context of acute disease, displaying lactate values ≥ 2 mmol/l. Data was collected regarding age, sex, independence-index, highest lactate values, contributors to hyperlactatemia, DM and mortality.
Results
A sample of 151 patients with lactate ≥ 2 mmol/l was analyzed, median age of 83.00 ± 17.00 years, 55.00% female. DM was present in 55.60% and these patients had higher lactatemia (5.35 ± 4.84 vs 3.90 ± 3.56 mmol/l, $P = 0.003$), with the majority reaching values > 4 mmol/l (vs 34.8% in non-DM patients). The most frequently identified potential contributors to the development of severe hyperlactatemia (lactate > 4 mmol/l) in DM patients were metformin consumption concomitantly with factors potentiating its accumulation, sepsis/septic shock, ischemia and neoplasia. In non-DM patients the last three factors were the most frequently found. The 30-day mortality rate was 25.82% and deceased patients also displayed higher lactatemia during hospital stay (5.93 ± 5.19 vs 4.52 ± 4.21; $P = 0.037$). Lactate values > 4 mmol/l were more frequently associated with mortality and these values were observed more often in patients with DM. However, a tendency towards higher lactate values in DM patients was registered not only in those who died, but also in the patients who survived. In multivariate analysis, lactate values > 4 mmol/l were an independent predictor of mortality in the global sample and in the subgroup without DM, but not in DM patients.
Conclusion
In our sample, patients with DM reached higher lactate levels than non-DM patients. Our analysis, however, raises the possibility that the same lactate values may not have equal capacity to assess prognosis in acute situations in patients with and without DM, since a lactate value > 4 mmol/l was an independent predictor of mortality only in non-DM patients. Large-scale studies are needed to optimize cut-off points for lactatemia in patients with high baseline values, such as DM patients.

Utilisation of fibrosis-4 (fib-4 score) for screening non-alcoholic fatty liver disease (nafld) in women with type 2 diabetes (t2dm) in real world setting

Dakshata Padhye[1], Snehal Tanna[2], Aleyamma James[1] & Nithya Nair[1]
[1]Conquer Diabetes Clinic, Mumbai, India; [2]Jupiter Hospital, India

Introduction
Limited evidence exists for hepatic fibrosis in Type 2 Diabetes (T2DM). NAFLD is an independent risk factor for incident diabetes with trends towards increased risk in women.
Methods
We conducted a cross-sectional, retrospective analysis in 438 women with T2DM.FIB-4 score was used to estimate extent of incidental finding of liver fibrosis.
Results
Mean fibrosis 4 score (FIB-4) was 1 (SD ± 0.66, 95% CI 0.98 to 1.1), Vs (HbA1c <7%, $n = 117$, 1.11) and uncontrolled group of diabetes (HbA1c ≥ 7%, $n = 321$, 1.02); $P = 0.21$. Mean AST, ALT (u/l) and platelet (109/l) were 23, 24 and 301, respectively. Patients were grouped based on FIB-4 scores (group 1: < 1.45, group 2: ≥ 1.45 < 2.67, group 3: ≥ 2.67 < 3.25, group 4: ≥ 3.25) for HbA1c, duration of diabetes and age (Table 1). Difference in age groups was statistically significant ($P < 0.0001$) with youngest patients (56.8 years) lowest FIB-4 scores
Conclusion
FIB-4 score was a simple, cost effective tool to identify T2DM women who are at risk of hepatic outcomes without any apparent clinical symptoms of liver disease. Patients with FIB-4 score in the range 1.45–2.67 were provided lifestyle modification and managed by pharmacotherapy options of pioglitazone, vitamin E, SGLT2 inhibitors, GLP-1 agonists and saroglitazar and patients with higher scores (≥ 2.67) were timely referred to hepatologists

Table 1. Age, Duration of Diabetes and HbA1c by FIB-4 range (mean ± SD, 95% CI)

	Overall	Group 1 FIB-4 < 1.45	Group 2 FIB-4 ≥ 1.45 < 2.67	Group 3 FIB-4 ≥ 2.67 < 3.25	Group 4 FIB-4 ≥ 3.25	p value (comparison across FIB-4 range)
No. of patients	438	368	58	5	7	
Age	58 ± 10.0, 95% CI 57.0 to 59.0	56.8 ± 10.2, 95% CI 55.8 to 57.9	65.9 ± 7.0, 95% CI 64.0 to 67.7	64.8 ± 9.9, 95% CI 52.4 to 77.1	60.4 ± 6.9, 95% CI 54 to 66.8	< 0.0001
Duration of Diabetes	10 ± 7.3, 95% CI 9.3 to 11	9.7 ± 7.3, 95% CI 9.0 to 10.5	10.7 ± 6.9, 95% CI 8.8 to 12.5	7.62 ± 4.5, 95% CI 1.9 to 13.3	15.2 ± 5.6, 95% CI 10.0 to 20.4	0.16 (NS)
HbA1c	7.9 ± 1.5, 95% CI 7.8 to 8.1	7.8 ± 1.4, 95% CI 7.7 to 8.0	8.2 ± 1.8, 95% CI 7.7 to 8.7	7.5 ± 1.2, 95% CI 6.0 to 9.0	7.3 ± 1.0, 95% CI 6.4 to 8.3	0.30 (NS)

Comparative evaluation of dapagliflozin and empagliflozin influence on the biomarkers of fibrosis and inflammation in patients with type 2 diabetes and very-high risk of cardiovascular events

Denis Lebedev[1] & Alina Babenko[1,2]
[1]Almazov Medical Research Centre, Institute of Endocrinology, Saint-Peterburg, Russian Federation; [2]Almazov Medical research centre, Saint-Peterburg, Russian Federation

Recently, sodium-glucose cotransporter 2 inhibitors (SGLT2i) have demonstrated cardioprotective effects. However, findings for major adverse CV events (MACE) outcomes with dapagliflozin are not concordant with the empagliflozin studies and the possible mechanisms of cardioprotective effects are not fully understood. The aim of the study was to compare the two distinct SGLT2i, empagliflozin and dapagliflozin, in their influence on the biomarkers of fibrosis and inflammation.
Materials and methods
Sixty two patients with type 2 diabetes (T2DM) and 3 major risk factors for cardiovascular events were included in the study. Patients were randomized into either empagliflozin group (10 mg/day) or dapagliflozin group (10 mg/day). Duration of the study was 6 months. The outcome measures included changes in glycated hemoglobin (HbA1c), galectin-3, tissue inhibitor of metalloproteinase-1 inhibitor (TIMP-1), procollagen type I carboxy-terminal propeptide (P1CP), matrix metalloproteinase-9 (MMP-9), paraoxonase 1 (PON1), ST-2, C-reactive protein (CRP) and interleukin-6 (IL-6).
Results
Baseline characteristics were not different in the empagliflozin and dapagliflozin group. After 6 months of treatment, patients in both groups showed significant improvements in body mass index (BMI), fasting glucose (FG), and HbA1c levels. There were no significant differences in galectin-3, P1CP, MMP-9, ST-2, CRP, IL-6, TIMP-1 and PON1 concentrations between groups after 6 months of treatment.

Conclusion
Our study demonstrated that dapagliflozin and empagliflozin did not differ in their influence on biomarkers of fibrosis and inflammation. However, larger studies are needed to clarify exact cardioprotective mechanisms of SGLT2i.

Visceral adiposity index and atherogenic index of plasma: Simple markers of insulin resistance in type 2 diabetic patients

Asma Kardi[1], Ibtissem Oueslati[1], Meriem Yazidi[1], Bassem Hammami[2], Fatma Boukhayatia[1], Fatma Chaker[1], Moncef Feki[2] & Melika Chihaoui[1]
[1]La Rabta hospital, university of Tunis El Manar, Faculty of Medicine, Endocrinology, Tunis, Tunisia; [2]La Rabta Hospital, University of Tunis El Manar, Faculty of Medicine, Laboratory of Biochemistry, Tunis, Tunisia

Introduction
Homeostasis model assessment for insulin resistance (HOMA-IR) is widely used as a marker of insulin resistance. However, it reminds an expensive maker requiring insulin dosage. Several studies tried to found simple alternative predictors of insulin resistance such as triglycerides to HDL-C ratio with conflicting reported findings. The aim of our study was to investigate the usefulness of the atherogenic index of plasma (AIP) and the visceral adiposity index (VAI) as insulin resistance markers.
Methods
We conducted a transversal study in 55 patients with type 2 diabetes mellitus treated with oral antidiabetic drugs. All participants had physical examination and laboratory investigations. HOMA-IR index, AIP and VAI were calculated.
Results
The study population included 29 women and 26 men. Their mean age was 54.6 ± 10.1 years. Seventy seven percent of patients had well-controlled diabetes. The mean of fasting insulin levels was 9.7 ± 5.1 miu/l. Sixty two percent of patients had insulin resistance. The mean of VAI was 2.5 ± 1.7 with extremes of 0.46 and 8.75. According to VAI level, adipose tissue dysfunction was absent, mild, moderate, and severe in 46, 9, 25 and 20% of patients, respectively. The VAI was positively correlated with insulin level ($r = 0.557$; $P < 10^3$) and HOMA-IR index ($r = 0.569$; $P < 10^{-3}$). Patients with insulin resistance had significantly higher VAI than those without insulin resistance ($P = 0.033$). The AIP demonstrated a low risk in 47%, an intermediate risk in 15% and a high risk in 38% of patients. This index was positively correlated with insulin level ($r = 0.432$; $P = 0.001$) and HOMA-IR index ($r = 0.468$; $P < 10^{-3}$). However, no significant difference was found between patients with or without insulin resistance ($P = 0.069$).
Conclusion
AIP and VAI are commonly used as markers of atherosclerosis and cardiovascular risk. However, our results demonstrated that they could be used as simple and inexpensive markers of insulin resistance instead of insulin dosage and HOMA-IR index.

Plasma angiopoietin-like 4 protein: Long term evolution after 3 different techniques of bariatric surgery

Guillermo Velasco de Cos[1], Angela Gonzalez Diaz-Faes[2], Armando Guerra Ruiz[1], Ricardo Batanero Maguregui[2], Elena Gonzalez Lopez[3], Coral Montalbán Carrasco[2], Bernardo Alio Lavín Gómez[1], María Teresa García-Unzueta[1] & Luis Alberto Vázquez Salvi[2]
[1]Hospital Universitario Marqués de Valdecilla, Análisis clínicos, Santander, Spain; [2]Hospital Universitario Marqués de Valdecilla -Endocrinologia, Santander, Spain; [3]Hospital Universitario Marqués de Valdecilla, Inmunología, Santander, Spain

Introduction
Angiopoietin-like 4 protein (ANGPTL-4) is importantly produced in adipose tissue, mediates the inhibition of lipoprotein-lipase and has been recently related with the risk of atherosclerosis and type 2 diabetes (T2D). Bariatric surgery has demonstrated improvements in lipid profile, T2D and cardiovascular risk. But information about ANGPTL-4 circulating levels in severe obesity and after bariatric surgery is scarce.
Objective
To evaluate the evolution of circulating ANGPTL-4 seven years after 3 different techniques of bariatric surgery and its relationship with improvement in lipid profile.
Results
ANGPTL-4 circulating levels and lipid profile were analyzed in 23 non-diabetic women (age 37.7 + 9.3) with severe obesity (BMI 48.9 ± 6.5 kg/m^2) before and 6.9 ± 2.1 years after bariatric surgery: sleeve gastrectomy ($n = 8$), gastric bypass ($n = 8$) and biliopancreatic diversion ($n = 7$) (weight loss 42.0 ± 16.3 kg) as well as in 8 control lean women. ANGPTL -4 levels (ng/ml) decreased significantly (304.53 ± 48.75 pre vs 197.77 ± 64.10 post; $P < 0.001$; control 172.51 ± 28.01; $P < 0.001$ vs pre, and without differences with post-surgery levels ($P = 0.293$). There were no differences in ANGPTL-4 change among groups. Triglycerides and HDL-cholesterol, as expected, improved as well after surgery. Correlations were found between ANGPTL-4 and improvement in HDL-cholesterol ($r = –0.48$, $P = 0.028$).
Conclusion
Plasma ANGPTL-4 is markedly elevated in women with severe obesity and 7 years after bariatric surgery it decreases to levels comparable to control lean subjects, in parallel with triglycerides and HDL-cholesterol improvement. These findings suggest that ANGPTL-4, mainly derived from adipose tissue, could be an important mediator of lipid improvement after bariatric surgery.

Insulin resistance in association with cardiovascular risk factors and thyroid function

Nijole Kazukauskiene, Aurelija Podlipskyte, Giedrius Varoneckas & Narseta Mickuviene
Lithuanian University of Health Sciences, Laboratory of Behavioral Medicine, Neuroscience Institute, Palanga, Lithuania

Insulin resistance (IR) occurs as part of a cluster of cardiovascular-metabolic abnormalities. Given the seriousness of the cardiovascular diseases data there is the increasing burden of diabetes.
The aim of the study was to investigate insulin resistant in association with cardiovascular risk factors among 45–84-year-old citizens of Palanga.
Methods
A randomized epidemiological study was performed with 850 subjects. All participants were evaluated for sociodemographic, clinical, cardiovascular risk factors and biochemical analysis (including glucose, insulin, thyroid hormones (TH), total cholesterol, LDL and HDL and triglyceride). IR was evaluated by homeostasis model assessment of IR (HOMA-IR).
Results
All study participants were stratified into groups without IR (HOMA-IR≤2.7) 67% ($n = 557$) and with IR (HOMA-IR > 2.7) 33% ($n = 278$). Participants with IR were more likely to be older, female and have lower education. The analysis between two groups showed some significant relationships between IR and cardiovascular risks factors, e.g. triglyceride levels was significantly higher (respectively 1.7 and 1.2 mmol/l) and HDL significantly was lower (respectively 1.3 and 1.6 mmol/l) in group with IR compared with group without IR. The IR group had a statistically significant higher incidence of metabolic syndrome (MetS) and type 2 diabetes mellitus (T2DM) (51.4% and 16.2%, respectively) compared with group without IR (11.0% and 3.1%, respectively). There were no significant differences of TH between groups according to RI. However in groups according to MetS, concentrations of TSH, FT3 and FT3/FT4 ratio differed significantly. Significantly higher TSH and lower FT3 was in the group with MetS. The predictable accuracy was presented using receiver performance characteristics curves for HOMA-IR scores in women and man separate. If the HOMA-IR score is higher than 3.45, he or she is significant more likely to have T2DM. In men cut-off was higher (3.52), with higher sensitivity (94.1), but slightly lower specificity (79.9) compared with women (respectively 3.35, 65.0 and 84.4). These data demonstrated invariant relationship between HOMA-IR and presence of T2DM.
Conclusions
The results showed several significant associations between IR and cardiovascular risk factors, as well as between higher TSH, lower FT3, and MetS. HOMA-IR cut-offs can predict the presence of T2DM and HOMA-IR can be used not only for indicating the presence of IR.

Free T4 level may be associated with insulin requirement in gestational diabetes mellitus

Ömercan Topaloğlu[1] & Mehmet Uzun[2]
[1]Kocaeli Derince Training and Research Hospital, Endocrinology, Derince/Kocaeli, Turkey; [2]Dokuz Eylül University School of Medicine, Oncology, Turkey

Introduction
Gestational diabetes mellitus (GDM) may frequently be overcome by nutrition therapy alone, but insulin regimen may be necessary in about 30 % of the patients with GDM. It was known that thyroid hormones were associated with glucose metabolism. Therefore, we aimed to investigate the association of fT4 level with insulin requirement in euthyroid pregnant women with GDM.
Materials and methods
We consecutively included euthyroid patients with GDM, and excluded those with thyroid dysfunction or any previous history of use of levothyroxine or antithyroid drug. The diagnosis of GDM was based on ADA criteria. Demographic features, previous history of GDM, gestational hypertension, insulin requirement (absent vs present or basal vs intensive regimen) and dose, nutrition and exercise adherence, and HbA1c, TSH, fT4, fT3, 25(OH) vitamin D3 levels were analyzed. We grouped the patients according to fT4 levels: lower than mid-normal (group A) vs upper than mid-normal (group B), or lower than normal range vs in normal range. We assessed the patients in 3rd trimester after 34th weeks of the pregnancy.
Results
Of total (n = 228), insulin was necessary in 58 patients. Insulin use was more frequent in the patients with fT4 level lower than normal range than those with normal fT4 (P = 0.003, OR:5.69 (95% CI 1.60–20.24)). Number of insulin injections was higher in group A than group B (0.022). fT4 level was not associated with insulin dose, HbA1c level, previous history of GDM, or diet adherence.
Conclusion
Lower fT4 level even in normal range may worsely affect glucose metabolism in euthyroid pregnant women with GDM. Our findings suggest that euthyroid hypothyroxinemia in pregnancy may be associated with difficulty in control of hyperglycemia. GDM would be an indication for treatment with levothyroxine in euthyroid hypothyroxinemia.

Treatment transition in a recently described HNF4α-MODY variant: Better late than never?

Mariana Barbosa[1], Manuel C. Lemos[2] & Vera Fernandes[1]
[1]Hospital de Braga, Endocrinology, Portugal; [2]CICS-UBI, Health Sciences Research Centre, University of Beira Interior, Portugal

Introduction
Maturity Onset Diabetes of the Young (MODY) type 1 is characterized by mutations in hepatocyte nuclear factor 4ń (HNF4ń) gene, leading to progressive dysfunction of pancreatic beta-cells with optimal response to sulphonylurea treatment. However, most of these patients are initially misdiagnosed as having type 1 diabetes and inappropriately treated with insulin. Data on adequate transferring from insulin to sulphonylureas following genetic diagnosis in this setting is limited.
Case
We report the case of a 45 year-old male with a so-called type 1 diabetes, diagnosed at 10 years-old. He was under metformin and glibenclamide for twelve years, and then insulin therapy was initiated. He was not overweight and presented significant family history of diabetes: mother, grandmother, father and a 12 year-old daughter (diagnosed two years ago, under insulin regimen). Further investigation revealed negative pancreatic antibodies, low C-peptide and poor metabolic control throughout the years, with diabetic retinopathy. Given these data, genetic testing for MODY was performed and identified a heterozygous missense variant of HNF4ńgene (c.602A > C, p.His201Pro), recently described in the literature (also found in his daughter). In December/2020, he was under an intensive basal-bolus insulin regimen (insulin detemir 14 units twice daily and insulin glulisine before meals; total daily dose 34 units, body weight 75.4 kg). Laboratory workup showed glucose 274 mg/dl, C-peptide 0.37 ng/ml (0.81–3.85), HbA1c 8.5%. Flash glucose monitoring system revealed estimated A1c 9.1% and marked glycemic variability: 67% above target, 32% in target and 1% below. Transferring of treatment was performed under medical surveillance: we stopped rapid-acting insulin, maintained long-acting insulin dosage and started gliclazide 80 mg/day. Close patient monitoring was maintained and three weeks later he presented a much more stable glycemic pattern with estimated A1c 7.6% and glucose values 37% above target, 63% in target and 0% below. Basal insulin was reduced to 20 units/day and gliclazide dose increased to 120 mg, with continuous glycemic improvement (estimated A1c 7.0%), on ongoing monitoring.
Discussion
Recent data on HNF4ńMODY suggests that sulphonylurea should be added to existing insulin therapy, rather than replacing it, in subjects with longer duration of diabetes who are overweight and have high HbA1c at the time of genetic diagnosis, as found in our case. Nonetheless, this commonly forgotten diagnosis should be seeked, given that treatment change could have significant clinical impact, with improvement of glycemic control and patient quality of life (as a pill replaced three insulin injections per day).

The effect of obesity on the association between type 2 diabetes mellitus and polycystic ovary syndrome: a meta-analysis of observational studies

Panagiotis Anagnostis[1], Rodis Paparodis[2], Julia Bosdou[3], Christina Bothou[4], Djuro P. Macut[5], Dimitrios Goulis[1] & Sarantis Livadas[6]
[1]Unit of Reproductive Endocrinology, 1st Department of Obstetrics and Gynecology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece, Thessaloniki, Greece; [2]Center for Diabetes and Endocrine Research, University of Toledo College of Medicine and Life Sciences, Toledo, OH, USA; [3]Unit for Human Reproduction, 1st Department of Obstetrics and Gynecology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece; [4]Klinik für Endokrinologie, Diabetologie und Klinische Ernährung, Universitätsspital Zürich, Zürich, Switzerland; [5]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [6]Endocrine Unit, Metropolitan Hospital, Athens, Greece

Objective
The exact risk of type 2 diabetes in women with polycystic ovary syndrome (PCOS) is unknown. It is also unclear if obesity independently increases the risk in this population. The aim of this study was to systematically review and synthesize the best available evidence regarding the association between PCOS and type 2 diabetes, stratified according to obesity status.
Methods
A comprehensive search was conducted in PubMed, CENTRAL and Scopus databases up to October 31, 2020. Data are expressed as relative risk (RR) with 95% confidence interval (CI). The I^2 index was employed for heterogeneity. Research design and methods: The eligibility criteria were fulfilled by 23 studies (319.780 participants; 60.336 PCOS and 8847 type 2 diabetes cases). Women with PCOS demonstrated a higher risk of type 2 diabetes than those without PCOS (RR 3.45, 95% CI, 2.95–4.05, $P < 0.001$; I^2 81.6%). This risk remained significant both in studies matched or unmatched for participants' age. With regard to body mass index, the RR for developing type 2 diabetes in obese and non-obese PCOS women compared with their non-PCOS counterparts was 3.24 (95% CI 2.25–4.65; $P < 0.001$; I^2 30.9%) and 1.62 (95% CI 0.14–18.50; $P = 0.70$; I^2 89.9%), respectively. The RR in obese compared with non-obese women with PCOS was 3.85 (95% CI 1.99–7.43; $P < 0.001$; I^2 46.2%). This was also the case for overweight compared with normal-weight women with PCOS.
Conclusion
Women with PCOS present an increased risk of type 2 diabetes compared with non-PCOS women only if they are obese/overweight.

Features of bacterial metabolism of the colon in patients with type 2 diabetes mellitus (T2D) and non-alcoholic fatty liver disease (NAFLD)

Svetlana Silvestrova, Zvenigorodskaya Larissa & Petrakov Alexander
Moscow Clinical Research and Practice Center Named after Loginov, Moscow Department of Health, Moscow, Russian Federation

The key factor in the pathogenesis of both T2D and NAFLD is insulin resistance, which causes the lipids accumulation in hepatocytes and an increase of the lipid peroxidation, the production of reactive oxygen species and the development of inflammation. It has been shown that the main metabolic products of the saccharolytic microflora-short-chain fatty acids (SCFA), such as acetic (Ac), propionic (Pr) and butyric (Bu), can have an anti-inflammatory effect through their suppression of histone deacetylase (HDAC) activity (Arpaia N *et al*., 2013).
The aim
To study the features of bacterial metabolism in the colon in patients with T2D and NAFLD in comparison with the activity of the lipid peroxidation process.
Materials and methods
The study included 46 patients with T2D and NAFLD, mean age – 56.4 ± 7.2 y. The activity of lipid peroxidation process was assessed by conc. of malondialdehyde (MDA) in blood. The concentrations of fecal SCFA (Ac, Pr, Bu, valerian acid and their isoforms) were determined by GLC- method.
Results
It was shown that the average blood MDA level in T2D + NAFLD patients was increased by 70% and amounted to 17.4 ± 1.3 mmol/l vs norm (N) - 10.1 ± 0.8 mmol/l ($P < 0.001$). The value of total SCFA (TSCFA) was reduced and averaged 8.6 ± 2.8 mg/g vs N 10.6 ± 2.6 mg/g, $P < 0.01$. In the structure of the metabolites, there was a decrease in the proportion of butyrate (T2D + NAFLD 12.1 ± 0.8% vs N 16.0 ± 0.6%, $P < 0.001$) and an increase of propionate one (T2D + NAFLD 23.1 ± 0.5% vs N 20.0 ± 0.6%, $P < 0.001$). In T2D + NAFLD patients in stage of steatohepatitis, there was a more pronounced decrease in total metabolic activity due to a decrease in conc. of butyrate. In addition, there was an increase in the proportion of iso-acids, metabolites of the proteolytic microflora (9.4 ± 0.7% vs N 6.3 ± 0.04%, $P < 0.02$). In order to assess the degree of anti-inflammatory action of microbiota, a correlation analysis was performed between conc. MDA and SCFA. There were significant correlations between the TSCFA ($r = –0.437$; $P = 0.049$), acetate ($r = –0.4550$; $P = 0.024$), propionate ($r = –0.375$; $P = 0.037$) and conc. MDA.
Conclusion
Thus, a decrease in the total metabolic activity of the colon microflora in T2D + NAFLD occurs due to a decrease in the activity of Bu-producing and an increase in Pr – producing bacteria. Inverse correlation conc. SCFA and MDA indicate a pronounced effect of the luminal SCFA on the processes of inflammation in T2D with NAFLD patients.

Diabetes and cftr gene mutations: Prevalence and correlation in patients with cystic fibrosis

Mireia García-Ramírez[1], Ángel Rebollo-Román[1], Paloma Moreno-Moreno[1], Carlos-Manuel Alzás-Teomiro[1]; José-Manuel Vaquero-Barrios[2] & Alfonso Calañas-Continente[1]
[1]Unidad de Gestión Clínica de Endocrinología y Nutrición, Hospital Universitario Reina Sofía de Córdoba,Córdoba, Spain; [2]Unidad de Gestión Clínica de Neumología. Hospital Universitario Reina Sofía. Córdoba. Spain

Aim
To establish a relationship between the severity associated with cystic fibrosis transmembrane conductance regulator protein (CFTR) mutations and the prevalence of abnormal glucose tolerance and diabetes in patients diagnosed with cystic fibrosis (CF).
Methods
Observational, cross-sectional, clinical research in patients with CF evaluated at Hospital Universitario Reina Sofía (Córdoba).
Results
29 patients were selected for the study. Age: 34.41 ± 8.95 years, with a CF evolution time of 26.22 ± 10.43 years. 55% women. 72.41% of patients had two severe mutations (class I, II and III mutations) while the remaining 27.59% had at least one mild mutation (class IV and V mutations). After the oral 75g-glucose test (OGTT) 17.2 % patients were diagnosed with cystic-fibrosis related diabetes (CFRD), 41.4% with impaired glucose tolerance (IGT) and 41.4% showed a normal glucose tolerance. 66.7% of patients with two severe mutations were diagnosed with CFRD or IGT, compared to 37.5% of patients diagnosed with CFRD or IGT who had at least one mild mutation ($P < 0.001$).
Conclusions
In our series, there are statistically significant differences in the prevalence of CFRD and IGT depending on the type of mutations in the CFTR protein, with a higher prevalence in those patients with severe genotype.
Keywords: diabetes, cystic fibrosis, genotype, complications

AEP228

Association of IDO polymorphism with oxidative status, metabolic control and inflammation in patients with type 2 diabetes mellitus

Marta Neves[1], Manuel Bicho[2,3], Ana Carolina Santos[2,3], João F. Raposo[4] & Ana Valente[2,5]
[1]Faculdade de Medicina, Universidade de Lisboa;, Gabon; [2]Laboratório de Genética, Ecogenética e Saúde Humana, Instituto de Saúde Ambiental-ISAMB, Faculdade de Medicina, Universidade de Lisboa; [3]Instituto de Investigação Científica Bento da Rocha Cabral, Lisboa; [4]Associação Protectora dos Diabéticos de Portugal, Lisboa; [5]Atlântica - Escola Universitária de Ciências Empresariais, Saúde, Tecnologias e Engenharia, Barcarena, Oeiras

Introduction
The Indoleamine 2.3-dioxygenase (IDO) is an enzyme involved in tryptophan metabolism, encoded by the IDO1 gene in humans. In Caucasians, the rs9657182 polymorphism of IDO gene was found to be associated with neurobehavioral complications, especially depression. Several studies in Type 2 Diabetes Mellitus (T2DM) describe psychological factors as barriers to the successful implementation of a healthy eating plan. According to our knowledge there is a lack of data that relates the IDO polymorphism with oxidative status and inflammation in T2DM.
Aim
1) To evaluate the distribution of the genotypic and allelic isolated and combined frequencies of the IDO polymorphism; 2) To study a possible association of this polymorphism with biomarkers of oxidative status, diabetes metabolic control and inflammation.
Material and methods
Observational analytical epidemiological study in 150 Caucasian adults with T2DM aged 40–75 years. Two groups were formed: GI75 patients with angiopathy and GII75 patients without angiopathy. The IDO genotypes were identified using the endpoint analysis method. Blood levels of malondialdehyde, ascorbic acid (AA), homocystein (Hcy), Hemoglobin A1c, vitamins B6, B12 and B9 were measured by HPLC methods. Creactive protein (CRP) serum levels were achieved by ultrasensitive immunoturbidimetric assay. Statistical analysis was performed using SPSS, version 26.0. Statistical significance was considered for $P < 0.05$.
Results
CT genotype was the most prevalent (GI: 52.9%; GII: 38.5%) and the CC genotype was the least frequent (G: 13.7%; GII: 21.2%). There were no significant differences between groups in the distribution of genotypic and allele frequencies of the IDO polymorphism, but there were differences between sexes ($\alpha = 0.025$). The average blood concentrations of AA and vitamin B12 were significantly higher ($\alpha = 0.049$; $\alpha = 0.025$; respectively) in subjects with the TT genotype compared to the CC + TC genotypes. Mean value of CRP was statistically lower in TT genotype ($\alpha = 0.044$). Having the TT genotype seems to be associated with a decreased risk of having low AA blood levels (OR = 0.363 [0.155–0.850]; $\alpha = 0.020$) and higher CRP plasma levels (OR = 0.310 [0.126–0.762]; α=0.011). This genotype was also associated with an increased risk of having higher concentrations of Hcy (OR = 3.238 [1.340–7.824]; $\alpha = 0.009$).
Conclusion
The TT genotype of the IDO gene rs9657182 polymorphism seems to offer protection against inflammation (< CRP levels) and cardiovascular disease (< Hcys values), as well as, favoring the antioxidant capacity by association with higher vitamin C concentrations in patients with T2DM.

Treatment of psoriasis in patients with type 2 diabetes

Elena Brutskaya-Stempkovskaya[1], Alla Shepelkevich[1], Vadim Sushinski[1], Yuliya Dydyshka[1] & Anastasia Plotnikova[2]
[1]Belarusian State Medical University, Belarus; [2]Minsk Central City Policlinic N21

Skin diseases in patients with type 2 diabetes mellitus (T2DM) are increased. Patients with T2DM and psoriasis have an increased risk of psoriasis exacerbations.
Objective:
to study the influence of T2DM on the psoriasis treatment.
Materials and methods
We studied hospitalized patients with T2D and psoriasis in dermatological clinic during 5 years ($n = 47$) - the main group. Comparison group 1- patients with psoriasis without T2D ($n = 40$), comparison group 2 - patients with T2D without psoriasis ($n = 37$). Patients were excluded: with the psoriatic arthritis, GFR ≤ 45 ml/min/1.73 m^2.
Results
Patients of the main group (women-53.2%, men-46.8%, mean age 61.0 ± 7.7 years), comparison group 1 (women-55%, men- 45%, mean age 60.5 ± 7.5 years), comparison group 2 (women-54%, men-46%, mean age 62.0 ± 7.8 years) were same in clinical, anthropometric, anamnestic and laboratory data (AST, ALT, total cholesterol, creatinine, $p > 0.05$). Patients of the main group and comparison group 1 differed in serum glycaemia ($P = 0.005$), HbA1c ($P = 0.009$). Patients of the main group had an increase HbA1c (11.8 (7.9–12.3)) compared with the comparison group 2 (6.8(6.1–7.3), $P = 0.006$) in the exacerbation of psoriasis period.
Duration of inpatient treatment of psoriasis until remission in patients of the main group was significantly longer (16.1 ± 2.4 days) compared with the comparison group 1 (13.0 ± 2.1 days, $P = 0.041$). The number of patients who needed the use of systemic glucocorticosteroid was higher in patients of the main group (14.9 %) compared with the comparison group 1 (2.5 %), F=0.05, $P = 0.048$.
Conclusions
There is probably a correlation between psoriasis exacerbation and T2DM decompensation. T2DM in patients with psoriasis can lead to a more severe exacerbation of psoriasis, which increases the duration of treatment and the frequency of systemic glucocorticosteroid use, which can lead to a decrease in DM2 control.

Use of continuous glucose monitoring for control assessment in type 2 diabetes patients

Tzvetelina Totomirova, Mila Arnaudova & Maria Lazova
Military Medical Academy, Clinic of Endocrinology and Metabolic Diseases, Sofia, Bulgaria

Continuous Glucose Monitoring (CGM) is proved to be useful for dose adjustment in patients treated with multiple insulin injection regimens or with continuous subcutaneous insulin infusion. CGM give precise information about glucose variability in type 1 diabetes but are rarely used in type 2 patients. We assessed continuous glucose monitoring systems (CGMs) as control assessment tool in patients with type 2 diabetes receiving different treatment regimens. We studied 85 patients (50 men, 35 women; mean age 43.93 ± 10.87 years, mean disease duration 21.91 ± 6.07 years) with type 2 diabetes (31 receiving non-insulin therapy, 33 treated with pre-mixed insulin, 21 on multiple insulin injections. Continuous glucose monitoring by using iProTM was performed for seven days and HbA1c was measured at the end of this period. High positive correlation was found between HbA1c (7.46 ± 1.19%) and average glucose level during CGM period (7.45 ± 1.57 mmol/l) ($r = 0.73$), AUC above limit ($r = 0.75$) and percentage of time spent with glucose above 7.8 mmol/l (38.26 ± 26.38%, $P < 0.05$, $r = 0.69$). There was similar but negative correlation between HbA1c and percentage of time within the limit 3.9–7.8 mmol/l for all groups (56.07 ± 24.28%, $P < 0.05$, $r = –0.63$). Comparing CGM results in different treatment groups we found similar correlations of HbA1c and percentage of time spent within limit (non-insulin treated group 55.65 ± 25.99%, $phi_1 = –0.48$; premixed insulin treated group 54.33 ± 24.85%, $phi_2 = –0.67$; intensified insulin treatment group 59.62 ± 21.36%, $phi_2 = –0.58$). No correlations were found between HbA1c and number of all, positive and negative excursions. These results do not differ for age and gender. We conclude that performing CGM in patients with type 2 diabetes could give more precise information about the overall control nevertheless short time reflected and could present details about glucose deviations and hypoglycemic episodes and thus be useful for current treatment adjustment.

Factors influencing pregnancy planning of women with diabetes

Btissam Ouafidi, Fatiha El Miski, Moukhlis Sabah, Bouab Maryem, Amine Lamrissi, Karima Fichtali & Said Bouhiya
Ibn Rochd University Hospital of Casablanca, Morocco, Gynecology and Obstetrics Department, Casablanca, Morocco

Introduction
For diabetics, preparation for pregnancy is essential; it allows conception in the best conditions, in order to reduce the risk of fetal malformation and abortion. The objective of this study is to determine the factors involved in pregnancy planning.
Materials and methods
Descriptive retrospective study, including 200 patients with pre-gestational diabetes followed in the department of gynecology and obstetrics between October 2019 and October 2020.
Results
The study included 200 patients with an average age of 31.9 years (19–49). 31.2% had type 1 diabetes and 68.8% had type 2 diabetes. The mean presentational BMI was 23.36 kg/m (14–47). Glycemic control during

pregnancy was not achieved in 70.7% of patients. The average duration of diabetes was 6.5 years (1–20) with an HbA1c of 8.16%. Among the patients, 24.7% had planned their pregnancy (HbA1c less than 6.5%) compared to 75.3% who had not. In terms of motivation, pregnancy was highly desired in 75.2% of patients who had planned their pregnancy compared to 56.2% of other patients. Regarding the presence of previous obstetric complications, patients who had planned their pregnancy had a history of fetal death in utero in 19.51% vs 10.2%. In addition, there was no difference with respect to socio-economic level or the presence of social security coverage or the other obstetrical histories studied, or the type of diabetes.
Discussion
The occurrence of pregnancy in a woman with diabetes potentially carries many risks for both mother and child. Pregnancy programming involves therapeutic adaptation to achieve perfect glycemic control and screening for possible complications. All diabetic women of childbearing age should be educated in this regard.

Long-term testosterone therapy improves lipid profile in men with functional hypogonadism and overweight or obesity: 12-year observational data from a controlled registry study in a urological setting

Farid Saad[1], Karim Sultan Haider[2] & Ahmad Haider[3]
[1]Bayer AG, Medical Affairs Andrology, Berlin, Germany; [2]Private Urology Practice, Urology and Andrology, Bremerhaven, Germany; [3]Private Urology Practice, Bremerhaven, Germany

Background
Effects of testosterone therapy (TTh) on lipid parameters are inconsistent and may depend on treatment duration, route of administration, and adherence. While in short-term studies, testosterone usually lowers HDL, long-term studies seem to increase HDL. Total cholesterol, LDL and triglycerides are either reduced by TTh, or effects are neutral.
Material and methods
After excluding men with primary hypogonadism, 723 men with functional, symptomatic hypogonadism were either overweight or obese. 367 men received testosterone undecanoate injections 1000 mg/12 weeks following an initial 6-week interval (T-group), 356 men decided against TTh and served as controls (CTRL). Measurements were performed 1–4 times a year for approximately 6.913 patient-years. The lipid accumulation product (LAP) as an indicator of metabolic syndrome was calculated according to Kahn 2005. 12-year data are reported. Changes over time between groups were compared and adjusted for age, weight, waist circumference, fasting glucose, blood pressure, lipids and quality of life to account for baseline differences between the two groups.
Results
Mean baseline age (years): 58.8 ± 5.9 (T-group), 63.1 ± 4.9 (CTRL) (P < 0.0001). Mean (median) follow-up: 9.3 ± 3.0 (10) years (T-group), 9.8 ± 2.6 (11) years (CTRL). Lipids at 12 years (mmol/l), mean±SE: Total cholesterol decreased by 2.6 ± 0.1 (T-group) and increased by 1.4 ± 0.1 in CTRL, estimated adjusted difference between groups: -4.0 [95% CI: -4.1;-3.8] (P < 0.0001 for all). HDL increased by 0.5 ± 0.0 (T-group) and decreased by 0.4 ± 0.0 (CTRL), between-group difference: 0.9 [95% CI: -0.8;-0.9] (P < 0.0001 for all). LDL decreased by 1.7 ± 0.0 (T-group) and increased by 1.0 ± 0.0 (CTRL), between-group difference: -2.8 [95% CI: -2.9;-2.6] (P < 0.0001 for all). Triglycerides decreased by 1.0 ± 0.0 (T-group) and increased by 0.7 ± 0.0 in CTRL, between-group difference: -1.7 [95% CI: -1.7;-1.6] (P < 0.0001 for all). Non-HDL decreased by 3.0 ± 0.1 (T-group) and increased by 1.8 ± 0.1 (CTRL), between-group difference: -4.8 [95% CI: -5.0;-4.6] (P < 0.0001 for all). Remnant cholesterol decreased by 1.5 ± 0.1 in the T-group and increased by 0.6 ± 0.1 in CTRL, between-group difference: -2.1 [95% CI: -2.4;-1.8] (P < 0.0001 for all). LAP (cm*mmol/l) decreased by 90.3 ± 3.6 in the T-group and increased by 60.8 ± 3.6 in CTRL, between-group difference: -151.0 [95% CI: -162.9;-139.2] (P < 0.0001 for all). 27 patients (7.4%) died in the T-group and 98 (27.5%) in CTRL (P < 0.0001). Medication adherence to testosterone was 100% as all injections were administered in the medical office and documented.
Conclusion
In men with hypogonadism and overweight or obesity, long-term TTh improves the lipid profile which may be a contributing factor to the observed reduction in mortality.

Efficacy and safety of gp40081 (insulin aspart biphasic 30) compared to novomix 30 flexpen in type 2 diabetes mellitus patients

Julia Isaeva, Igor Makarenko, Galina Vinderskaya, Maksim Magruk & Roman Drai
Saint Petersburg, Geropharm, RnD, Saint Petersburg, Russian Federation

Introduction
A biosimilar is a biological medicinal product that shows high similarity to another already approved medicine product containing biotechnology-derived protein as active substance. The similarity depends on the biosimilar development program that includes comparative studies of physical and chemical properties, *in vitro* pharmacodynamics, pharmacokinetics and pharmacodynamics in humans. Insulin aspart biphasic 30 is one of the most convenient insulin formulations providing both prandial and basal insulin in a single injection. Russian biopharmaceutical company GEROPHARM has developed insulin aspart biphasic 30 that showed similarity to an originator NovoMix 30 FlexPen (NN-Asp30) in all abovementioned studies. The last stage of the biosimilar development program is comparative immunogenicity and efficacy study of insulin biosimilar and reference drug. Therefore, the aim of this study was to compare the immunogenicity and the efficacy of insulin aspart biphasic 30 (GP40081 (GP-Asp30)) with originator insulin NN-Asp30.
Methods
This was a multicenter, randomized, open-label, active-controlled, non-inferiority phase 3 clinical trial in parallel groups, conducted in order to compare safety (immunogenicity) and efficacy of GP-Asp30 with these parameters of NN-Asp30. This 26-week clinical trial enrolled 264 participants with type 2 diabetes mellitus (HbA1c 7.6–12.0%), randomized 1:1 to once-daily GP-Asp30 (n = 132) or NN-Asp30 (n = 132). The primary safety endpoint was immune response (development of anti-insulin antibodies (AIA)) at week 26. Secondary immunogenicity endpoints included the change of mean AIA concentration from baseline to weeks 12 and 26, the formation of neutralizing antibodies and clinically significant immune response at week 26. Efficiency endpoints included HbA1c change at week 26 from baseline, change of fasting plasma glucose (FPG) at week 26 from baseline and change in seven-point glucose profile (SPGP). Non-inferiority margin for HbA1c was 0.4 %.
Results
The frequency of immune response was similar in GP-Asp30 and NN-Asp30 (PP-population) both at week 12 (P = 0.107), and at week 26 (P = 1.000). The change of mean AIA concentration was not also significantly different in GP-Asp30 and NN-Asp30 (ITT-population) both at week 12 (P = 0.191), and at week 26 (P = 0.435). The frequency of clinically significant immune response was similar in GP-Asp30 and NN-Asp30 (P = 0.861 for ITT-population, P = 0.858 for PP-population). Inter-group difference of HbA1c change at week 26 was 0.12 (95% CI [-0.14, 0.38]). FPG, SPGP and insulin dose were similar between the groups.
Conclusions
GP-Asp30 and NN-Asp30 demonstrated similar safety (immunogenicity) and efficacy.

DOI: 10.1530/endoabs.73.AEP233

Vildagliptin is a safe and powerful oral antidiabetic drug for elderly adults with type 2 diabetes

Hariballav Mahapatra[1,2] Laxminarayan Mahapatra[1], Monalisa Khuntia[1], Abhay Kumar Sahoo[2] & Soumya Sucharita[1]
[1]Sevayan Diabetes Centre, Puri, India; [2]IMS and SUM Hospital, SOA University, Department of Endocrinology, Bhubaneswar, India

DPP4 inhibitors are special class of drugs that not only improve metabolism in a glucose dependant manner, but also suppress the glucagon axis. Due to its glucose dependant insulinotropic action, vildagliptin is thought to be relatively safe for people who are at risk of developing low glucose episodes. We studied the glucose lowering potential and hypoglycemic effects of vildagliptin among elderly diabetics who were uncontrolled with at least 2 oral antidiabetic medications. For this study, we recruited elderly adults (aged more than 60 years) with type 2 diabetes and elevated HbA1c (> 8%). All the participants were on at least 2 OADs at the time of enrollment, but not on insulin or GLP-1 agonists within 3 months. After due consent they were administered vildagliptin 50 mg twice daily in addition to their existing therapy and were evaluated 6 months later. Data of 386 elderly adults (Males/Females: 275/111) were available for analysis. The mean age of the sample was 62.7 ± 10.8 years and the duration of diabetes was 10.6 ± 6.6

years respectively. At the time of enrollment into the study, their mean FPG and PPG were 149.5 ± 47.1 mg/dl and 221.0 ± 61.8 mg/dl respectively, which declined to 128.5 ± 235.4 mg/dl and 186.8 ± 50.5 mg/dl in order after 6 months' treatment. During the same period, HbA1c was reduced in a statistically significant fashion. The change in HbA1c was 1.7 ± 1.6% from a baseline HbA1c of 9.8 ± 2.3%. Although overall incidences of hypoglycemia was not frequent, more number of cases occurred among individuals who were on sulfonylurea therapy ($P < 0.05$). There was no significant increase in the liver enzymes post treatment. The subjects did not experience any weight gain after the treatment. Our study showed that vildagliptin is a safe agent for the management of elderly diabetics and was found to reduce the glycemic parameters significantly. Addition of vildagliptin in elderly individuals improved the HbA1c by 1.7 ± 1.6% in 6months of treatment. Vildagliptin was also found to be weight neutral, which is important for the elderly population as they find it difficult to go for regular exercise due to the age related issues.

Introduction

Recently, cross-sectional studies report associations between long-term glucocorticoid levels in scalp hair (HairGC) and obesity. However, there is a wide variation in studied outcomes and associations, possibly caused by differences in population characteristics, e.g. age, sex, dispersion of adiposity, and used laboratory methods. The aim of this systematic review and meta-analysis was to investigate the relation between HairGC and anthropometrics and to explore possible moderators of this association.

Methods

We searched the Medline, Embase, Cochrane, Web of Science, Scopus, Cinahl, PsycInfo, and Google Scholar databases for articles that relate HairGC to measures of adiposity (date 11–16–2020). Primary outcomes were correlations between hair cortisol (HairF) and cortisone (HairE), and anthropometrics: BMI, waist circumference (WC) and waist-hip-ratio (WHR). Authors were contacted to provide missing outcome information. Pooled correlation coefficients were calculated using random effects models. Assessment of heterogeneity was performed using the I^2 statistic. Exploratory moderator analyses were performed with subgroup analyses and meta-regression. This systematic review was performed in accordance to the PRISMA guidelines.

Results

Our systematic search identified 150 cohorts, comprising a total of 37.107 unique individuals, of which 15.033 sampled from population-based cohorts. For BMI, the pooled correlation for HairF was 0.121 (95% CI 0.083–0.158, $n = 26.941$; I^2 94.2%, $P < 0.001$) and for HairE 0.108 (95% CI 0.047–0.167, $n = 7.250$; I^2 52%, $P < 0.01$). For WC, the pooled correlation for HairF was 0.111 (95% CI 0.058–0.164, $n = 10.290$; I^2 63%, $P < 0.01$) and for HairE 0.200 (95% CI 0.137–0.264, $n = 2.198$; I^2 0%, $P = 0.42$). For WHR, the pooled correlation for HairF was 0.102 (95% CI 0.040–0.163, $n = 6.865$; I^2 27%, $P = 0.14$) and for HairE 0.261 (95% CI 0.195–0.330, $n = 1.314$; I^2 0%, $P = 0.40$). A higher percentage of male participants was related to stronger correlations with WC ($P < 0.001$), but not with BMI and WHR. Mean age, mean BMI, and mean HairGC levels of the cohorts did not significantly moderate the pooled correlations, neither did the used laboratory techniques (immunoassays vs mass spectrometry-based assays).

Conclusion

This unique, large meta-analysis demonstrates that long-term endogenous glucocorticoids as assessed by HairGC show small but consistent correlations to measures of obesity, despite a large heterogeneity between the included cohorts. The strongest associations were found between HairE and WC and between HairE and WHR. This suggests that glucocorticoid levels in the high-normal range, especially cortisone, may contribute to or reflect the state of specifically central adiposity, even within the general population.

The intensity of menopausal hot flushes is associated with values of the hepatic steatosis index

Eleni Armeni[1], Areti Augoulea[1], Stavroula Paschou[1], Iliana Karagkouni[1], Nikoletta Mili[1], Lorena Kontou[2], Georgios Kaparos[2], Dimitrios Rizos[2], Theo Panoskaltsis[1] & Irene Lambrinoudaki[1]

[1]Second Department of Obstetrics and Gynecology, Aretaieio Hospital, National and Kapodistrian University of Athens, Athens, Greece; [2]Hormonal and Biochemical Laboratory, Aretaieio Hospital, National and Kapodistrian University of Athens, Athens, Greece

Introduction

Menopausal transition is associated with an increase in the cardiovascular risk, possibly related with the sharp decrease of estrogen levels. Menopausal symptoms and more specifically hot flushes have been previously linked with an increase in cardiovascular risk. On the other hand, non-alcoholic fatty liver disease is considered as another presentation of the metabolic syndrome, conferring additional cardiovascular risk to the affected individual. This study aimed to evaluate any possible link between the severity of menopausal hot flushes and indicators of liver steatosis or fibrosis, expressed indirectly by the Fibrosis 4 score (Fib4) and the hepatic steatosis index (HSI).

Methods

This was a cross sectional study, consisting of 5.995 non-obese postmenopausal women, retrieved from the Menopause Clinic of the Aretaieio Hospital, Athens, Greece. All participants underwent hormonal and biochemical assessment and the HSI as well as Fibrosis 4 score (Fib4) were calculated, according to the biographically available algorithm. The intensity of hot flushes was evaluated as none, mild or moderate-to-severe.

Results

Our women were aged 56.7 ± 7.5years, with a menopausal age 8.9 ± 6.7years and body mass index 25.0 ± 2.7 kg/m^2. HSI values were 34.8 ± 4.2 (range 23.7–62.3), Fib4 values were 1.15 ± 0.4 (range 0.11–4.70), Fib4 values < 1.45 were found in 20.1% of women, while Fib4 values > 3.25 were found in 0.3% of women. HSI > 36, implying likely NAFLD, was evident in 75.5% of the sample. Moderate to severe hot flushes were evident in 18.3% of our women (993/5438). We observed a gradient linear increase in mean values of HSI and linear decrease in mean values of Fib4, according to increasing severity of hot flushes (none vs mild vs moderate-to-severe: HSI, 34.6 ± 4.1 vs 34.7 ± 4.1 vs 35.6 ± 4.4; Fib4, 1.17 ± 0.45 vs 1.14 ± 0.43 vs 1.08 ± 0.41 P-value < 0.001 ANOVA for linear trend, univariate). Multivariable logistic regression analysis showed that presence of moderate to severe hot flushes was associated with mean values of HIS (OR=1.060, P-value=0.002) and menopausal age (OR=0.884, P -value < 0.001) in a stepwise model that also included age, BMI, triglycerides, HDL, HOMA-IR, smoking alcohol, physical activity. No linear or dichotomous associations were observed between Fib4 values and the severity of hot flushes.

Conclusion

Mean levels of HIS were associated with the severity of menopausal hot flushes, in this large sample of postmenopausal women. We did not observe any associations between mean values of the Fib4 index and the severity of hot flushes.

Elevated circulating cell-free deoxyribonucleic acid in obese individuals

Marwa Chiboub[1], Fatma Mnif[1], Imen Gargouri[1], Kais Chaaben[2], Abid Mohamed[1] & Cherif Boutheina[3]

[1]University Hospital Hèdi Chaker, Department of endocrinology, Sfax, Tunisia; [2]University Hospital Hèdi Chaker, Department of Gynecology, Sfax, Tunisia; [3]Center of Biotechnology of Sfax, Laboratory of Molecular and Cellular Screening, Sfax, Tunisia

Introduction

Altered levels of circulating cell-free deoxyribonucleic acid (ccf DNA) have been found in several pathologies and might have a diagnostic value. With the steadily growing number of studies in the issues related to obesity

research, it is proven, that obesity might be related to wide number of body disorders. In the current opinion, we hypothesized that there is a correlation between obesity and elevated cfDNA levels in the circulation.
Methods
This is a prospective analytic study about 56 cases. The sample included individuals who have no medical or surgical history. They were categorized according to their body mass index (BMI) groups: Group 1: normal group with BMI: [18.5–24.9 kg/m^2] and Group 2: obese group with BMI > 30 kg/m^2. Using Beta Globin 110, we investigated the levels of ccf DNA in plasma samples from obese women (n = 33) and from controls (n = 23). We also studied the relationship of the levels of this molecular marker with the various clinicopathological parameters of obesity.
Results
The study population included 56 females with a mean age of 31 ± 10.6 years. The average body mass index (BMI) was 22.5 kg/m^2 in group 1 and 39 kg/m^2 in group 2. In the serum, the mean concentration of ccf DNA was significantly higher in the obese patients as compared to the controls (P < 0.001). There were positive correlations between cfDNA levels and different parameters of obesity, with the weight (P = 0.001), the BMI (P < 0.001) and the waist circumference (P = 0.002).
Conclusion
There is a correlation between the obesity and elevated cfDNA levels. This correlation based on free radicals and oxidative stress hypothesis of cellular molecules damage and cell injury which in turn leads to a disorder in the whole body, but it still needs to more study and investigation.

Effect of a 16-week physical activity program on body composition and aerobic capacity parameters in a population of obese youth

Wajdi Safi[1], Nabila Rekik Mejdoub[1], Mohamed Abdellahi Mohamed Ahmed[1], S. Regaieg[2], M. Kamoun[1], H. Elleuch[3], H. Rebai[4], M. Mnif Feki[1], N. Charfi[1] & Mohamed Abid[1]
[1]Department of Endocrinology and Diabetology CHU Hedi Chaker Sfax, Tunisia; [2]Faculty of Sciences Bizerte, Tunisia; [3]Department of Physical Medicine and Rehabilitation CHU Habib Bourguiba, Sfax Tunisia; [4]Higher Institute of Sport and Physical Education Sfax, Tunisia

Introduction
The prevalence of childhood obesity continues to increase nowadays but also its long-term complications, particularly metabolic and cardiovascular, and this is due in large part to all the current modern conditions and means that promote sedentary lifestyle and lack of 'physical activity
Material and methods
We developed a 16-week aerobic exercise program (four 60-minute sessions per week at 70–85% FCM), in addition to school physical education and without dietary intervention; including Twenty-eight obese children divided into 2 groups with the same characteristics at inclusion (G1: exercise group; G2: control group) in order to be able to study the beneficial effects of this program on the body composition and aerobic capacity of obese children.
Results
After the training program, only G1 showed a significant reduction in BMI and waist circumference compared to baseline (P < 0.001). A signi fi cant decrease in fat mass was observed only in G1 while a significant increase in lean mass was observed in both groups but more marked in G1. There was a significant increase in the maximal metabolic equivalent of the METmax task (P < 0.05) in G1, and no significant change in this parameter was observed in G2.
Conclusion
This training program has beneficial effects on body composition and aerobic capacity parameters in obese children. Our intervention has the advantage of offering a sustainable and reproducible school and community approach to the management of childhood obesity.

The efficacy of complex kinesiotherapy in weight loss and improving of carbohydrate metabolism in obesity patients

Valeriia Vasileva, Larisa Marchenkova & Mikchail Eryomushkin
National Medical Research Center of Rehabilitation and Balneology, Department of Somatic Rehabilitation, Reproductive Health and Active Longevity, Moscow, Russian Federation

Aim of the study was to estimate the effect of complex with 4 kinesiotherapy methods on body weight loss and carbohydrate metabolism in patients with obesity.
Material and meth
ods. 80 people were enrolled in the study. 40 people in the first group (G1) -54–63 years old with obesity (mean age 57 [54;63] years, weight 100.5 [89.5;114.8]kg, BMI 35.6 [32.8;43.2] kg/m^2, waist circumference WC 105.5 [100.3;118.3] cm, hip circumference HC 117.5[108.5;127.3] cm. 40 people in the second group (G2) 58 [53;66] years old with obesity (weight 107[94.3;127] kg, BMI 41.7[34.2;46.9] kg/m^2, WC 109[105;125.8] cm, HC 127[112.3;139.8] cm. Complex kinesiotherapy administrered daily for 3 weeks included interactive sensorimotor training on double platform,complex of physical exercises in the gym and ergocycle. In addition, in G2. patients included kinesitherapy in a pool. Weight, WC, HC, carbohydrate tolerance test (TT HC), insulin last 3 weeks was measured at baseline and after the treatment was completed.
Results
There was a significant improve in body weight in G1 (100.5 [89.5;114.8]kg vs 98[87.5;111.3] kg in 3 weeks; P = 0.000), BMI (35.6 [32.8;43.2] vs 34.6 [32;42.1]kg/m^2; P = 0.000), WC (105.5 [100.3;118.3] vs 103.5[97;114.3]cm; P = 0.000), HC (117.5[108.5;127.3] vs 115.5[107;122.8]; P = 0.000). Body weight in G2 (107[94.3;127] kg vs 104.5[93.3;123.5] kg; P = 0.000), BMI (41.7[34.2;46.9] vs 39.3 [33.9;45.4]kg/m^2; P = 0.000), WC (109[105;125.8] vs 107[98.8;120]cm; P = 0.000), HC (127[112.3;139.8] vs 121[109.5;133.5] cm; P = 0.000). We registered statistically significant elevation in insulin levels of G2 vs to G1. With Z=2.63 in G1, P = 0.003 and Z=1.96, P = 0.002 in G2, and Z=2.87 when assessing the significance elevation between G1 and G2, P = 0.023. Significantly improved performance of TT HC in G1. Z=2.02, P = 0.04, in G2. Z=3.004, P = 0.002. When assessing the significance of differences between G1 and G2 after treatment, Z=2.3, P = 0.017.
Conclusions. Complex treatment with 4 methods of kinesiotherapy helps to reduce body weight, WC, HC, insulin, TT HC in obesity. Intensification training using kinesitherapy in a pool showed more significant improvements in carbohydrate metabolism.

Impact of sleeve gastrectomy on uric acid metabolism in a Tunisian obese group

Hedfi Imene, Faten Mahjoub, Nadia Ben Amor, Ramla Mizouri, Berriche Olfa & Jamoussi Henda
National Institute of Nutrition, Tunis, TUNISIA., Obesity Unit UR18ES01, Tunis, Tunisia

Introduction
Facing the repeated failures of the medical management of obesity, bariatric surgery offers a promising therapeutic option in terms of achieving weight loss and metabolic benefits. Our study aimed to assess the impact of sleeve gastrectomy on uric acid metabolism in obese subjects.
Methods
This was a repeated retrospective cross-sectional study including 40 obese patients who were followed up at the Research Unit on Obesity at the National Institute of Nutrition and Food Technology in Tunis up to 12 months after sleeve gastrectomy. The preoperative clinical and biological data and those checked at six and 12 months after surgery were collected from the patients' medical records.
Results
The mean patients' age was 34.65 ± 8.17 years and the sex-ratio was 0.21. The mean body mass index (BMI) was 50.23 ± 8.3 kg/m^2. The average uricemia was 325.3 91.6 µmol/l. The frequency of hyperuricemia in our population was 7%. After sleeve gastrectomy, the mean excess weight loss was 55.8% at 12 months. Uric acid levels decreased in patients with initial hyperuricemia. The hyperuricemia remission was observed in two out of three patients. However, we noted an improvement of the uric acid level in the patient who retained this abnormality. For patients who did not initially suffer from hyperuricemia, we saw an insignificant increase in uricemia, six months after the sleeve gastrectomy. Indeed, three patients developed this abnormality at six months post-operative. This was followed by a significant decrease in uric acid levels one year after the intervention.
Discussion
After bariatric surgery, weight loss would decrease uric acid levels, on the one hand, by reducing the production of urate and on the other hand, by increasing urate renal excretion following insulin sensibility enhancement since urate renal clearance has an inverse relationship to insulin resistance [1]. Referencet

AEP241

GLP-1 receptor agonists and bariatric surgery in nonalcoholic steatohepatitis

Soraya León[1], María Dolores Alcántara-Laguna[2], Maria José Molina[1], Alfonso Jesús Calañas Continente[1], Concepción Muñoz[1], Maria Angeles Galvez Moreno[1] & Aura D. Herrera-Martínez[1]
[1]Hospital Universitario Reina Sofia, Endocrinología, Córdoba, Spain; [2]Hospital Reina Sofía, Endocrinología, Spain

Rationale
Obesity is associated with multiple comorbidities including nonalcoholic steatohepatitis (NASH). Despite its association with increased morbidity and mortality, treatment options are limited. Some studies have suggested that glucagon-like peptide-1 receptor agonists (aGLP-1) are associated with NASH resolution. Additionally, the effects of bariatric surgery on NASH-associated liver fibrosis are controversial.
Methods
Clinical and biochemical variables of 399 patients with obesity were recorded. Different treatment-groups were analyzed: aGLP-1 in monotherapy, bariatric surgery (BS) or the combination of both. Intrahepatic fibrosis was assessed by non-invasive liver index Fib-4 before and after 6 months of treatment.
Results
The whole cohort included 62.4% females (mean age 48-y old); 37.3% had T2DM, 82% underwent BS. Mild fibrosis degree (F0-F1) was observed in 68.7% of patients, without differences among treatments groups. Serum transaminases significantly improved in patients with T2DM compared with patients without T2DM that underwent BS ($P < 0.05$). Patients treated with aGL1 before surgery had increased weight loss 6 months after BS than patients that were not treated with aGLP-1. Improvement of Fib-4 score was observed in 4.3% of patients that received aGLP-1 (3.5% of weight loss); in 2.11% of patients that underwent BS (26% of weight loss); and in 21.7% of patients that received both treatment options (23.5% of weight loss).
Conclusions
aGLP-1 in combination with BS represents a valuable therapeutic option for NASH in patients with obesity. Further studies in patients without T2DM and/or obesity are still required.

AEP242

Post hip-fracture rehabilitation outcomes of diabetic and non-diabetic elderly patients

Ronen Ben-Joseph[1], Barak luboshitz[2], Rachel Heffez-Ayzenfeld[1,2] & Orit Twito[2,3]
[1]Meir Medical Center, Geriatric Medicine, Kfar-Sava, Israel; [2]Tel-Aviv University, Sackler Faculty of Medicine, Tel-Aviv, Israel; [3]Meir Medical Center, Endocrinology, kfar-Sava, Israel

Background
Although patients with diabetes mellitus (DM) are at higher risk of hip fracture, data regarding the effect of DM on rehabilitation outcomes is limited.
Methods
A retrospective population-based study was conducted comparing diabetic and non-diabetic elderly patients with a recent hip fracture who were admitted to a geriatric rehabilitation facility during 2014–2019. The Functional Independence Measure (FIM) was used to assess physical and cognitive function. Delta-FIM was calculated by subtracting admission FIM from discharge FIM. One-year mortality, hospitalizations and fractures were assessed.
Results
Six hundred and thirty post hip-fracture elderly patients were included, mean age 83 ± 7 years, 70.48%(444) females. Of them 30.63% (193) had DM. The diabetic patients were younger (81.41 vs. 84.28 years, p value < 0.01) and had higher rates of co-morbidities including hypertension, chronic kidney disease, ischemic heart disease and cerebrovascular diseases. Baseline cognitive and motor scores were similar between groups. Delta motor-FIM was similar in diabetics and non-diabetics (15.56 ± 8.95 and 14.78 ± 8.79, respectively, $P = 0.35$). Similar rates of patients were discharged to nursing care facilities. on Multivariate regression analysis motor FIM improvement was positively correlated with higher BMI, male gender and younger age but not with DM. Cognitive FIM did not change significantly during rehabilitation in both groups, and there was no difference in 1-year hospitalizations or fractures rates. One-year all-cause mortality was higher in diabetic patients (10.9% and 6.6%, respectively, $P = 0.07$). After adjusting for covariates, DM was associated with higher mortality risk (OR = 2.78, CI[1.28, 6.04], $P = 0.01$).
Conclusions
Diabetic patients have similar post-hip fracture rehabilitation potential compared with non-diabetics, in spite of higher prevalence of co-morbidity. These results support resource allocation for post-hip fracture rehabilitation in patients with DM. The higher 1-year all-cause mortality in patients with DM reinforces the need for close follow-up and control of co-morbidities in this population.

AEP243

Impact of supervised physical activity on cardiovascular autonomic status in type 2 diabetes patients

Laura Stirane[1,2], Karlis Stirans[2,3], Leonora Pahirko[1], Janis Mednieks[2] & Jelizaveta Sokolovska[1]
[1]University of Latvia, Riga, Latvia; [2]Pauls Stradins Clinical University Hospital, Riga, Latvia; [3]Rezekne hospital, Rezekne, Latvia

Background
Cardiac autonomic neuropathy (CAN) is a serious complication of diabetes mellitus (DM) that is strongly associated with increased risk of cardiovascular mortality. The significance of CAN has not been fully appreciated. Treatment of CAN includes physical activity.
Aim
To detect CAN status and measure the influence of physical activity on the autonomic nervous system using cardiovascular autonomic reflex tests (CARTs).
Methods
The study included 51 patients with type 2 diabetes: 30 were allocated to the control group (Con, $n = 30$) and the rest to the interval training (IT, $n = 21$) group. IT group exercised 3 times a week for 60 minutes for 4 month using a mobile device application. CAN was assessed on tilt table testing using 5 CARTs proposed by Ewing *et al.* (1985): parasympathetic function: heart rate (HR) response to the Valsalva manoeuvre (Valsalva ratio), HR response to deep breathing (E/I ratio) and HR response to standing (30 s/15 s ratio). Sympathetic function was measured by blood pressure (BP) responses to lying and standing as well as BP response to a sustained handgrip. Each test was assessed with a score of 0 for normal, 0.5 for borderline, and 1 for an abnormal result. Patients who had Ewing score ≥ 2 were classified as CAN positive.
Results
At baseline, CAN was detected in 33 (65%) patients. Ewing score in the CAN positive patients was 2.61 ± 0.74 and in CAN negative patients 1.08 ± 0.58. Probability of CAN before and after the intervention was 0.65 (95% CI - 0.38, 0.85) and 0.48 (0.22, 0.76) in the control group and 0.80 (0.48, 0.94) and 0.58 (0.27, 0.84) in the IT group. After the intervention between group (Con vs IT) change in CARTs and Ewing score was: Valsalva ratio 1.13 to 1.17 mm vs 1.12 to 1.25 mm (*P*-0.091); E/l ratio 12.85 to 12.51 mm vs 13.09 to 12.88 mm (p-0.902); 30s/15s ratio 1.04 to 1.06 mm vs 1.03 to 1.09 mm (p-0.233); BP response to lying and standing 8.69 to 9.45 mmHg vs 11.91 to 15.54 mmHg (*P*-0.420); BP response to handgrip 25.03 to 26.30 mmHg vs 26.76 to 22.70 mmHg (*P*-0.268); Ewing score 1.94 to 1.69 vs 2.04 to 1.74 (*P*-0.885).
Conclusions
CAN is a common complication of diabetes that often goes unrecognized. Physical activities can improve autonomic status.

DOI: 10.1530/endoabs.73.AEP243

AEP244

Optimization of surgical treatment of patients with diabetic foot syndrome

Andrew Burak
Ternopil State Medical University, Department of Surgery No1, Ukraine

Background
The development of purulent-necrotic complications of the lower extremities is one of the most dangerous complications of diabetes. According to the Internationale Diabetes Federation, the number of hospitalized patients with foot lesions due to diabetes is 25–47%, and subsequently causing high amputations in 12% of such patients. That is why the comprehensive approach of the surgeon and endocrinologist is the key to successful treatment of such patients. The purpose of the study is to improve the quality of surgical treatment of patients with diabetic foot syndrome by improving the method of surgical treatment of the stump and fixation of the skin after phalangeal amputation.
Materials and methods
The analysis of the results of treatment of 88 patients, age from 46 to 72 years treated in the surgical department with purulent-necrotic complications lesions of toes with type II diabetes mellitus was done.
Results
The methods of surgical treatment of the foot and the fixation of the skin flap proposed by us improve the existing other methods, where the execution of amputation of the dead part of the phalanx of the finger or even the heads of the metatarsals is carried out using a cut-off metal disk rotating at a speed of 20.000 rpm (revolutions per minute), followed by gradual polishing of the cutoff point of healthy bone tissue. The fixation of the skin flap is carried out by seamless method after preliminary treatment with certain aqueous solutions of antiseptics and an even distribution of the amorphous component, which is formed as a result of mechanical treatment of the stump with a corundum grinding nozzle up to 10 mm in diameter in the form of a layer for 1–2 minutes at a speed of 10.000 rpm.
Conclusions
The proposed method of amputation of the phalanx of the finger is characterized by rapid and qualitative cut off of the dead part of the phalanx, absence of additional traumatization of the stump of the bone and surrounding tissues. This approach to treatment of purulent-necrotic wounds in patients with diabetic foot syndrome provides significant acceleration of wound healing, reduces the risk of implantation infection, eliminates additional tissue injuries during overlaying and sewing, and, accordingly, reduces the patient's stay in hospital treatment to 5 to10 days.

AEP245

Necrotizing external otitis in diabetic patients: Role of imaging

Mohamed Masmoudi, Mehdi Hasnaoui, Lazid Sara, Thabet Wadii & Mighri Khalifa
Tahar Sfar Hospital Mahdia, ENT Department, Mahdia, Tunisia

Purpose
To describe the role of imaging in diagnosis and detection of complications of necrotising external otitis in diabetic patients.
Material and methods
Our retrospective study included 43 diabetic patients who suffered from necrotising external otitis, from 1992 to 2020. All our patients had CT scan of the temporal bones and the brain. MRI was performed in 4 cases.
Results
The mean age was 69.4 years with female predominance. The average duration of diabetes follow up was over 10 years. In 33 cases, the causative agent was bacteria; fungal pathogens were found in 11 cases. In all cases, CT scan showed thickening soft tissue and cortical bone erosion of the external auditory canal. In 31 cases, it revealed opacification of the mastoid air cells and middle ear (erosion of the ossicular chain in 8 cases). Periauricular soft tissues inflammatory changes was noted in 10 cases. In the complicated cases, CT scan revealed: an anterior extension of the infection to the temporomandibular joint (5 cases), a bone destruction of the intratympanic facial canal (2 cases), an erosion of the tegmen tympani (2 cases), a parapharyngeal (2 cases) and parotid (1 case) involvement, a retropharyngeal abscess (1 case), an extension to the nasopharynx (2 case), a skull base extension (4 cases), an extension to the cervical vertebra (1 case) and an extension to the petrous apex (1 case). The CT angiography revealed venous obstruction of the sigmoid sinus (1 case), cavernous sinus (1 case) and internal jugular vein (3 cases), an osteolysis of the carotid canal (2 cases) and the jugular bulb with thrombosis of this latter and the petrous part of the internal carotid artery (1 case). MRI, performed in 4 cases, showed: a retropharyngeal abscess with skull base extension (1 case), cervical vertebra extension with epidural abscess (1 case) and thrombosis of the sigmoid sinus and the internal jugular vein (1 case).
Conclusion
Necrotizing external otitis remains a serious invasive infection which must be highly suspected mainly in diabetic patients. Imaging is necessary to establish the diagnosis and to detect complications.

Risk factors associated with diabetic foot amputation among patients hospitalized for diabetic foot ulcer in a public hospital

Olga Gutu[1], Miguel Vasques[1], Inês Manique[1], Sara Amaral[1], Bruno Bouça[1], Joanna Prokop[1], Ana Cláudia Martins[1], António Afonso[1], José Neves[2] & Jose Silva-Nunes[1]
[1]Hospital Curry Cabral, Centro Hospitalar Universitário Lisboa Central, Department of Endocrinology, Diabetes and Metabolism, Portugal;
[2]Hospital Curry Cabral, Centro Hospitalar Universitário Lisboa Central, Department of Surgery

Introduction
Diabetic foot is one of the most devastating of chronic complications of diabetes mellitus (DM) and is responsible for about 25% of hospitalizations. Worldwide, the diabetic foot represents the main cause of non-traumatic lower limb amputation.
Aim of the study
Identification of risk factors for foot amputation among in patients hospitalized for diabetic foot in a tertiary public hospital in Portugal.
Material and methods
Retrospective observational study of data collected from April 2017 to April 2020.
Results
There were 279 admissions involving 233 patients;161(69%) were males. Mean age was 68 ± 11.5 years and 219 (94%)] presented type 2 DM. The mean diabetes duration was 18.4 ± 10.5 years. Patients were divided into two groups: Group 1 (n = 140) patients not submitted to amputation; Group 2 (n = 93) patients submitted to amputation. There was no statistical difference between groups in terms of age (68.4 ± 11.6 vs. 67.5 ± 11.4 years), mean DM duration (18.1 ± 9.8 vs 18.8 ± 10.5 years), history of previous foot amputation (21.7% vs 30.1%), documentation of microvascular complications [retinopathy (50.4% vs 46.8%), neuropathy (75.8% vs 74.4%) and nephropathy (47% vs 52.2%)], smoking (26% vs 28.7%), high blood pression (84% vs 85%) and neuroischemic foot lesions (71.7% vs 78.5%). However, Group 2 presented higher HbA1c (8.1% vs 9.4%; P = 0.03), higher prevalence of osteomyelitis (28% vs 47%, P = 0.02) and higher prevalence of macrovascular complications: peripheral arterial disease (21.7% vs. 91.3%; P < 0.001) and ischemic heart disease (30% vs. 45%; P = 0.02). Regarding Grade 4 Wagner foot ulcer classification (localized gangrene) it was predominant in Group 2 (40% vs 10.8%; P = 0.01); all five patients with Grade 5 (extensive gangrene) were submitted to foot amputation. The global rate of mortality during hospitalization was 6.8% (n = 16) without significant differences between groups (5.8% vs 8.6%). The cause of death was sepsis in 7 cases, stroke in 2, sudden cardiac death in 3, acute myocardial infarction in 1, subdural hemorrhage in 1, and unknown cause in 2 cases.
Conclusions
Worse metabolic control and presence of peripheral arterial disease, ischemic heart disease or osteomyelitis as well as higher degrees in the classification of foot ulcers were risk factors for lower limb amputation among patients with DM. These results point to the need for an aggressive approach in this population, through preventive strategies, careful monitoring and management by multidisciplinary teams.

Clinical characteristics and outcomes of elderly type 2 diabetic patients with SARS-COV2 infection: a retrospective single centre study

Bárbara Filipa Araújo[1], Cátia Andreia Araújo[1], Miguel Melo[1], Mariana Lavrador[1], Ana Rita Elvas[2], Diana Alexandra Festas Silva[1], Joana Reis Guiomar[1], Sandra Paiva[1] & Isabel PAIVA[1]
[1]Coimbra University Hospital, Endocrinology Department, Portugal;
[2]Portuguese Institute of Oncology, Coimbra, Endocrinology Department, Portugal

Introduction
Diabetes mellitus (DM) and older age are frequent comorbidities as well as factors associated with poorer outcomes in patients with Coronavirus disease (COVID-19). The reason for worse prognosis in patients with diabetes is likely to be multifactorial.
Objectives
We aimed to evaluate clinical characteristics and their impact on the outcomes of elderly patients with and without DM hospitalized with COVID-19.
Methods
In this retrospective study, we included 97 hospitalized patients (38 with DM, 59 without DM). We compared demographic characteristics, comorbidities, chronic medications, admission findings and outcomes between patients with and without DM.
Results
The mean age was 80 (± 9) and 75 (± 15) years in the group with DM and without DM, respectively. A higher prevalence of arterial hypertension (92.1% vs. 59.3%, P = 0.001), previous medication with RAAS inhibitors (64.9% vs. 44.1%, P = 0.047), chronic heart failure (55.3% vs. 32.2%, P = 0.024) and chronic pulmonary disease (28.9% vs. 11.9%, P = 0.035) was observed in patients with diabetes. There were no differences between groups regarding laboratorial and radiological findings at admission or fatality rate (36.8% DM vs 27.1% non-DM, P = 0.312). Among DM patients, nonsurvivors presented with higher Pneumonia Severity Index (PSI) score (159 ± 36 vs. 109 ± 30, P = 0.001), a higher NT-proBNP (5521 [4256–15280] vs. 1541 [288–2349] pg/ml, P = 0.047), a lower PaO2/FiO2 ratio (214 [181–259] vs. 300 [248–347], P = 0.033) and were more likely to have bilateral lung involvement at admission (78.6% vs. 29.2%, P = 0.013). Rates of acute kidney injury (85.7% vs. 33.3%, P = 0.003), acute heart failure (57.1% vs. 25.0%, P = 0.048) and secondary bacterial infection (64.3 vs. 26.1%, P = 0.022) were higher in deceased patients. When comparing deceased patients with survivors, there were no differences on the likelihood of being previously treated with insulin (60% vs 37.5%, P = 0.269), metformin (50% vs. 41%, P = 0.730), or DDP4i (40 vs. 33.3%, P = 0.775).
Conclusions
Elderly diabetic COVID-19 had a striking high risk of mortality. A more severe disease at presentation correlates with mortality. Organ disfunction reflects a rapid disease progression, significantly influencing the risk of death. These findings emphasize the frailty of diabetic and elderly patients with comorbidities, that should be regarded as high risk patients.

Effect of coronavirus disease on the clinical course of diabeticketoacidosis (DKA) in people with type 1 and type 2 diabetes

Eka Melson[1,2], Punith Kempegowda[2,3], Agnes Johnson[4], Lucy Wallett[3], Lucretia Thomas[4], Dengyi Zhou[4], Catherine Holmes[3], Agata Juszczak[3], Muhammad Karamat[3], Sandip Ghosh[3], Wasim Hanif[3], Parth Narendran[3,5] & Srikanth Bellary[3,6]
[1]Ninewells Hospital, NHS Tayside, United Kingdom; [2]Institute of Metabolism and Systems Research, University of Birmingham, United Kingdom; [3]University Hospitals Birmingham NHS Foundation Trust, United Kingdom; [4]College of Medical and Dental Sciences, University of Birmingham, United Kingdom; [5]Institute of Immunology and Immunotherapy, University of Birmingham, United Kingdom; [6]School of Life and Health Sciences, Aston University, United Kingdom

Introduction
Coronavirus disease (COVID-19) in people with diabetes is associated with a disproportionately worse prognosis. DKA is an acute complication of diabetes with a mortality rate of approximately 0.67%. Little is known about natural history of DKA in the presence of COVID-19 infection. This study aimed to explore the effects of COVID-19 infection on presentation, clinical course and outcome in patients presenting with DKA.
Methods
We undertook a retrospective cohort study of all people admitted with DKA in our institution from 01 March 2020 to 30 May 2020. Based on the SARS-Coronavirus-PCR test results, they were categorised into COVID-positive and COVID-negative groups. A pre-COVID group was established using data from 01 March 2019 to 30 May 2019 as an additional control. DKA was diagnosed as per Joint British Diabetes Society guidelines in the UK. For all patients, we recorded demographic data, diabetes type, various biochemical measurements at the time of admission, time to resolution of acidosis, time to resolution of ketosis, need for admission to ITU, length of stay and final outcome. The data were analysed using GraphPad Prism Version 6.07. One-way ANOVA was used to compare the differences between groups. P-values provided are two-tailed, and value of < 0.05 was considered as statistically significant.
Results
A total of 88 DKA episodes were included in this study. There was no significant difference in the severity or duration of DKA between the three groups (12.5 hours vs 14.9 hours vs 17.9 hours for COVID-positive, COVID-negative and pre-COVID groups respectively; COVID-positive vs. negative, $P > 0.99$; COVID-positive vs. pre-COVID, P = 0.8772; COVID-negative vs. pre-COVID $P > 0.99$). COVID-positive T1DM ([60 mmol/l (35.9–60.0)] were more hyperglycaemic on admission compared to COVID-negative ([31.4 mmol/l (28.0–39.1)] and pre-COVID groups ([24 mmol/l (20.2–33.75)]. There was an over representation of T2DM in COVID-positive group with DKA (n = 15/20) than in pre-COVID (n = 8/37) or COVID-negative groups (n = 2/31). Six people with COVID and four people without COVID required intensive care. Five (1/31 COVID-negative and 4/20 COVID-positive) died. In patients with T2DM, all deaths occurred in COVID-positive group.
Conclusion
COVID infection appears to influence the natural history of DKA differently in T1DM and T2DM. Patients with T1DM and COVID-19 presented with more hyperglycaemia. Patients with T2DM were unusually presenting in DKA when infected with COVID with more ITU need and higher mortality rates.

Efficacy of liraglutide in weight reduction in a patient with HAIR-AN syndrome - case report

Weronika Wasyluk[1,2], Joanna Świrska[1], Beata Matyjaszek-Matuszek[3] & Agnieszka Zwolak[1]
[1]Medical University of Lublin, Chair of Internal Medicine and Department of Internal Medicine in Nursing, Lublin, Poland; [2]Medical University of Lublin, Doctoral School, Lublin, Poland; [3]Medical University of Lublin, Chair and Department of Endocrinology, Lublin, Poland

HAIR-AN is a rarely recognized syndrome which is characterized by hyperandrogenism (HA), insulin resistance (IR) and acanthosis nigricans (AN). In the course of the syndrome, anovulation and metabolic disorders can develop, too. It is therefore suggested by some authors that HAIR-AN is an extreme phenotype of the polycystic ovary syndrome (PCOS). Generally, considering wide spectrum of metabolic and endocrine disorders which can be associated with the syndrome, it still remains therapeutic challenge. We present a case of a 32-year-old woman with HAIR-AN syndrome in whom introduced treatment regimen including liraglutide therapy improved her metabolic and procreative status. The patient was admitted to the Endocrinology Clinic because of 3rd degree obesity (BMI 50.22 kg/m^2), severe hirsutism, acanthosis nigricans and secondary amenorrhea. At that moment the patient was already treated with metformin which was prescribed by gynaecologist a few months prior to the hospitalization. In the laboratory tests, severe hyperandrogenemia, impaired glucose tolerance with hyperinsulinemia and atherogenic dyslipidemia were stated Hypercortisolemia, congenital adrenal hyperplasia or high prolactin level were ruled out. Eventually, the diagnosis of HAIR-AN syndrome was proposed. The treatment with metformin was continued. Low-calorie diet and systematic physical activity were recommended – the patient has undergone education in this field. Furthermore, as the therapy with only metformin did not improve patient's health status, liraglutide (1.2 mg/day) was added to the treatment. After six month therapy, a 33 kg reduction in body weight was achieved with BMI decline to 33.2 kg/m^2. The patient started to menstruate again. She also observed hirsutism reduction. Clinical amelioration was accompanied by metabolic and hormonal profile improvement – decline in insulin glucose and androgens' level; improved lipids' profile. The presented case shows the importance of body loss in the treatment protocol for HAIR-AN syndrome and the role of liraglutide in the therapy. Liraglutide, a drug from the group of GLP-1 analogues, ameliorates the symptoms related to HAIR-AN most probably not only due to its potential in body mass reduction. Several small studies confirmed already improve in insulin resistance, decline in androgen levels and normalization of menstrual cycle in PCOS patients who received liraglutide. Based on the case presented, it seems that HAIR-AN patients would also profit from liraglutide therapy and thus such a therapy deserves attention.

Evaluation of the results of weight loss at 1 year after bariatric surgery at the regional university hospital of malaga

Silvia Patricia Alonso Gallardo, Viyey Kishore Doulatram Gamgaram, José Abuín Fernández, Montserrat Gonzalo Marin & Sergio Valdés Hernández
Hospital Regional Universitario de Málaga, Endocrinología y Nutrición, Spain

Introduction
Morbid obesity is a very prevalent disease, bariatric surgery being a fundamental pillar in its treatment.
Objective
To analyze the results of weight loss at 1 year in patients operated on gastric bypass and sleeve at the Regional University Hospital (HRU) of Malaga.
Methods
Retrospective observational study, with a follow-up period of 1 year, of 215 patients with morbid obesity who underwent bariatric surgery at the HRU of Malaga with systematic data collection and complete follow-up. 90 subjects had undergone gastric bypass surgery (between May 2003 and November 2018) and 125 by gastric sleeve (between January 2009 and July 2019).
Results
Of the total number of patients, the mean age at the date of the intervention was 44 years, 30.5% were men. The mean BMI before surgery was 50.15 kg/m^2 and the mean weight 136 kg. One year after surgery, the mean weight loss achieved in the case of gastric bypass was 46.94 kg (range 4.60–111.60 kg) with a mean percentage of excess weight loss of 72.59% (range 14–137%); while with the sleeve technique, there was a mean weight loss of 48.21 kg (range 20–109 kg) with a mean percentage of excess weight loss of 70.09% (range 29–113%). Regarding the global results, the percentage of patients with excess weight loss above 50% was 87.9%, while 70% achieved the double objective of excess weight loss above 50% + BMI below 35 kg/m^2.
Conclusions
Satisfactory weight results are observed in the short term, with no significant differences between the 2 techniques used in terms of the mean weight loss and the percentage of excess weight loss.

*These authors contributed equally to this work
Introduction
The prevalence of obesity has risen dramatically worldwide in the last three decades. Due to this obesity pandemic, a growing demand for weight-loss drugs has emerged. The increased use of these drugs has consequently lead to an increase in the report of adverse reactions.
Case report
A 45-year-old woman with past medical history of class I obesity and psoriatic arthritis, presented with an itchy rash, developing one day after starting a weight-loss drug, naltrexone/bupropion. Physical examination revealed an erythematous maculopapular rash on the trunk and upper limbs, without mucosa involvement. Seeing as a drug reaction was suspected, naltrexone/bupropion was discontinued and prednisolone 0.5 mg/kg/day was initiated. Two days later, the rash progressed to form multiple, non-follicular, pinhead-sized pustules, on an edematous disseminated erythema, extending to the face and lower limbs. The patient was admitted to the hospital, and cyclosporine 3 mg/kg/day and prednisolone 0.5 mg/kg/day were administered, with good response. Nevertheless, cyclosporine had to be suspended after one week due to hepatotoxicity. Histological assessment of a skin biopsy was consistent with pustular psoriasis. After two weeks, the patient was discharged with a slow tapering plan of prednisolone. She later relapsed with classic psoriatic plaques, occasionally studded with pustules, on the limbs. Treatment with adalimumab was subsequently initiated. Patch tests were performed on the upper back six months later with naltrexone/bupropion, naltrexone, and bupropion (each 30% pet.). Readings on day (D) 3 showed positive reactions to naltrexone/bupropion and bupropion. A biopsy of this reaction confirmed an allergic dermatitis.
Conclusion
Psoriasis can be triggered or exacerbated up by certain drugs. Several cases of severe bupropion-associated skin drug reactions and psoriasis have been reported, including one case of psoriasis related to the anti-obesity drug naltrexone/bupropion. Nonetheless, the exact mechanism by which bupropion triggers psoriasis is unknown. In our case, the positive patch test to bupropion suggests that an initial acute generalized exanthematous pustulosis caused by bupropion might have elicited psoriasis as a result of the Koebner phenomenon. To the best of our knowledge, this is the first report on a type IV hypersensitivity reaction to bupropion documented through patch testing. There is a known association between psoriasis and metabolic syndrome, a frequent diagnosis in obese patients. Hence, special precautions should be taken when prescribing naltrexone/bupropion to patients with a known history of psoriasis.

Background and aims
Nonalcoholic fatty liver disease (NAFLD) is a major health threat in both developed and developing countries and is a precursor of the more advanced liver diseases including nonalcoholic steatohepatitis (NASH), liver cirrhosis and liver cancer. One of the numerous molecules participating in the development of liver steatosis is p63. Although p63 is mainly known for its roles as a tumor suppressor and cell maintenance and renewal, we have recently reported that it is also relevant in the control of lipid metabolism. More specifically, TAp63α isoform is elevated in the liver of animal models of NAFLD as well as in liver biopsies from obese NAFLD patients. Furthermore, downregulation of p63α in the liver attenuates liver steatosis in diet-induced obese (DIO) mice. Autophagy is a critical intracellular pathway that targets cytoplasmatic components to the lysosome for degradation. A specialized form of autophagy that degrades lipid droplets, is known to be a major pathway of lipid mobilization in hepatocytes. Its impairment has been associated with the development of fatty liver and insulin resistance. Thus, it is established that autophagy acts as a protective mechanism in the pathogenesis of NAFLD. Autophagy-related gene 3 (ATG3) is an enzyme mainly known for its actions in the LC3 lipidation process, which is essential for autophagy. Despite it is implicated in different biological functions, its role in lipid metabolism and its contribution to NAFLD remains unknown.
Results
We found that autophagy-related gene 3 (ATG3) was modified by TAp63α activation and downregulated after p63α inhibition. Further *in vitro* and *in vivo* experiments demonstrated that ATG3 is elevated in several animal models of NAFLD and in the liver of patients with NAFLD, who also show a positive correlation between ATG3 and steatosis grade and NAS score. Genetic overexpression of ATG3 increased the lipid load in hepatocytes, while its repression alleviated TAp63α- and diet-induced steatosis. Unexpectedly, ATG3 exerted its role in lipid metabolism by regulating SIRT1 independent of an autophagic action.

Conclusion
Our findings indicate that ATG3 is a novel gene implicated in the development of NAFLD.

Association between obesity and anxiety: A cross-sectional study in Sfax, Southern Tunisia

Yosra Mejdoub[1], Hanen Maamri[1], Dhoha Ben Salah[2], Nouha Ketata[1], Kassis Mondher[1], Kammoun Sourour[1], Mouna Elleuch[2], Jamel Dammak[1], Jihen Jdidi[1] & Abid Mohamed[2]
[1]Hedi Chaker University Hospital, Department of Community Health and Epidemiology, sfax, Tunisia; [2]Hedi Chaker University Hospital, Departement of endocrinology, sfax, Tunisia

Introduction
Obesity is recognized to be one of the greatest public health problems worldwide. In addition to physical health problems, obesity is also linked to an increased risk of mental health disorders such as anxiety. The objective of this study was to determine the prevalence of anxiety in obese adults and the factors associated with anxiety in this population.
Methods
We conducted a cross-sectional study on June and July 2020. We included all obese adults aged 19 to 64 years consulting at the basic health centre of Sfax and having a BMI greater than or equal to 30 kg/m^2. We excluded pregnant and nursing women and patients with severe decompensated organic disease and psychiatric disorder. We used the Hospital Anxiety and Depression scale (HAD) to evaluate anxiety.
Results
One hundred and fifty patients were included in our study. The sex ratio (male/female) was 0.3. The median age of patients was 50 years (IQR 37–58 years). Among the study population, we noted 40 diabetic patients (27.2%), 58 hypertensive patients (38.7%) and 12 smoking patients (8.0%). Thirty-four (22.7%) subjects had a heavy workload. Out of the 150 patients, 44(29.3%) had an extreme preoccupation of the body, 88(58.7%) had a low to moderate preoccupation of the body and 18 (12.0%) did not have a preoccupation of the body. The average anxiety score was 13.05 ± 3.3. We found that 113 (75.3%) of obese adults had definite anxiety symptoms and 26 (17.3%) had depression. We found that certain anxiety was more common among patients with extreme preoccupation to the body (88.6% vs 73.9% vs 50%, P = 0.003) and among those who have a heavy workload (88.2% vs 71.6%, P = 0.047). Nevertheless, there was no significant association between certain anxiety and depression (84.6% vs 73.4%, P = 0.2).
Conclusion
Anxiety was relatively high among people with obesity. Our study confirms the data from the literature, and underlines the need to set up a program to detect and act early on psychiatric disorders of obese.

AEP254

Characterization of glycemic profile and glucose-lowering treatment in hospitalized patients of a central hospital by main diagnosis and length of stay

Patrícia Rosinha[1], Sofia Teixeira[2], Cláudia Amaral[2] & Helena Cardoso[2]
[1]Centro Hospitalar Baixo Vouga, Endocrinology Department, Aveiro, Portugal; [2]Centro Hospitalar Universitário do Porto, Endocrinology Department, Porto, Portugal

Introduction
Glycemic control during hospitalization has an impact on the length of hospital stay (LOS) and infection rates. This knowledge has led to a growing concern with hyperglycemia and its repercussions.
Objectives
This study aims to evaluate the glycemic profile and diabetes mellitus (DM) treatment paradigm of hospitalized patients in a central hospital by main diagnosis and LOS.
Methods
We performed an observational cross-sectional study on the 9th October 2020 that included non-critical adult patients admitted to Centro Hospitalar Universitário do Porto (except pregnant/puerperal women), with DM and a minimum of 24 hours of hospitalization. The diagnosis of DM was made by consulting the clinical file and glycemic control was assessed using capillary blood glucose (CBG) values in the previous 24 hours. The main diagnosis of hospitalization was categorized as infection/non-infection and the LOS as A (1–3 days), B (4–7 days), C (8–14 days), D (15–30 days) and E (> 30 days). Statistical analysis: SPSS version 20.0.
Results
A total of 128 patients (57.8% male, mean age 73.7 ± 11.6 years) were included, with medians of LOS of 11.0 (19.0) days and mean CBG of 166.2 (69.4) mg/dl (95.5–392.0). Regarding the diagnosis, 51 (39.8%) had infection and 7 (5.5%) were hospitalized for DM or its complications. The median mean CBG was higher in the group of patients diagnosed with infection [183.7 (65.2) vs 160.1 (75.1) mg/dl, P = 0.099]. A larger proportion of patients without a diagnosis of infection was being treated exclusively with glucose-lowering drugs (6.5% vs 3.9%, P = 0.702) and a lower percentage was insulin-treated (26.0% vs 37.3%, P = 0.239) compared to infected patients. There were also considerable percentages of patients only under sliding scale regimen, especially in the group without infection (44.2% vs 37.3%, P = 0.468). By LOS, the median maximum CBG was higher in groups B to D (P = 0.025) and there were no significant differences in terms of median minimum/mean CBG. The percentage of insulin-treated patients was minimal in group A (9.1%) and maximum in group D (43.3%, P = 0.133).
Conclusion
The diagnosis of infection is common in hospitalized diabetic patients and tends to be associated with higher median CBG values. The rates of exclusive use of the sliding scale regimen are still higher than desirable, particularly in infected patients. LOS between 4 and 30 days also seem to be associated with higher CBG values and there appears to be an increased insulin therapy use as hospitalization time increases.

AEP255

Audit on GLP-1 mimetics monitoring in East Kent university hospitals UK

Abdelmajid Musa & Alamin Alkundi
William Harvey Hospital, Endocrinology and diabetes, Ashford, Kent, United Kingdom

Aims/objectives
The aims of the audit were to assess the monitoring of GLP-1 analogues if they were in accordance in monitoring to National institute of clinical excellence guidelines and appropriate in continuation and 6 months review with these guidelines.
Methods
A retrospective audit of 81 patients with Type 2 diabetes who were taking GLP-1 analogues between January 2010 and July 2019 at East Kent university hospitals was performed across both hospital sites in August 2019. The review time from initiation of the drugs varies between 10 years and 8 months. The data was collected from the hospital software systems and hard copy notes.
Results
The collected data demonstrated that 34.5%[28 patients] of patient's continue to take the drugs despite that they were not meeting the criteria's [reduction of at least 1% of HbA1c and 3% reduction of body Wight after 6 months] 51.% [[41 patients] of the patients met the criteria at assessment time but none reviewed in appropriate time, 13.58% [11 patients] never reviewed since initiation of treatment however only one patient stopped from taking these drugs.[because of side effects]. The audit demonstrates significant failure of our trust to be adherent to nice guidelines in monitoring of these drugs [reviewing after 6 months and continuation if reduction of at least 1% in HbA1c and 3% of body Wight reduction was achieved]. Conclusions: The audit demonstrated that standards for initiation were met but significant failure in reviewing and continuation criteria's. We recommended GLP-1 mimetics monitoring form to be kept with patients of type2 DM notes and to be assessed by physician with each visit Were audit in July 2020 and the re audit data showed considerable improvement as 35% of the reviewed patient [28 patients] stopped from taking these drugs because they were not meeting the nice guidelines criteria's for continuation.

Real-world experience of Evolocumab for treatment of hyperlipidemia in an outpatient population

Sajid Iqbal, Alia Al Tikriti & Adam Buckley
Imperial College London Diabetes Centre, Research, Abu Dhabi, United Arab Emirates

Background
Use of Evolocumab as a monotherapy or in combination with other lipid lowering drugs reduces LDL-C by up to 60% in patients with or without familial hypercholesterolemia (FH), diabetes mellitus (DM), or coronary artery disease (CAD). Data regarding the efficacy of PCSK9 inhibitors in MENA populations is lacking.
Method
Retrospective case review of all patients initiated on Evolocumab treatment at Imperial College London Diabetes Centre, Abu Dhabi, between 2017 and 2020.
Results
A total of 183 individuals were identified, of which six (3.3%) were diagnosed with FH (four heterozygous, two homozygous), 141 (77.0%) primary hyperlipidemia and 36 (19.7%) mixed hyperlipidemia. Mean + SD age 51.5 + 12.4 years, 51.4% (n = 94) male, 129 (70.5%) Diabetes Mellitus (DM), of which 125 (96.9%) Type 2 and four (3.1%) Type 1. The most commonly stated indication for use was statin intolerance in patients with primary hyperlipidemia (n = 59, 32.3%). Baseline median (IQR) LDL-C was 4.03(3.01–5.08), HDL-C 1.18(1.02–1.40), total cholesterol (TC) 5.70(4.45–6.86), and triglycerides (TG) 1.93(1.34–2.70). Significant reductions in median LDL-C (48.3%, P < .001), TG (16.1%, P < .001) and TC (34.7%, P < .001) occurred in the first 90 days of administration together with an increase in HDL-C of (8.3% P < 0.001). A total of 165 (90.2%) patients achieved a ≥ 30% reduction in LDL-C on initial 90 days of treatment; of these 158 (86.3%) maintained this reduction at each follow-up visit over a follow-up period of at least 1.5 years. However, 25 (13.7%) patents did not maintain this reduction on at least two occasions during their follow-up. This was attributed to unavailability of medication in nine (36%) individuals, non-concordance in ten (40%) or withdrawal of treatment in six (24%) cases.
Conclusion
Clinically meaningful, statistically significant and sustained reductions in LDL, TG and TC levels were observed, affirming the role of PCSK9 inhibitors in management of hyperlipidemia in the Emirati population.

AEP257

The optimal HbA1c threshold for predicting diabetes mellitus defined by OGTT in a high-risk population in Algiers about 500 cases

Samira Belkacem
Endocrinology, Pierre Marie Curie Center, of Medecine, Algiers, Algeria

Introduction
Type 2 diabetes mellitus chronic hyperglycemia resulting from a defect in the secretion of insulin or the action of insulin or from these two associated abnormalities.
Aim of the study
To try to establish an optimal threshold of HbA1C to predict diabetes mellitus on a sample of Algiers population not known to be diabetic but at high risk compared to the gold standard OGPO.
Method
500 patients (345 women, 155 men) aged ≥ 40 years consulting at the level of primary care structures, volunteers, but at high risk of diabetes, are subjected to a questionnaire, then to screening by carrying out a hyperglycemia caused by oral route (OGTT), HbA1c (HPLC TOSOH G8 method), SNSF, and ophthalmologic examination (fundus). The sensitivity and specificity of HbA1c at different thresholds for the diagnosis of diabetes and pre-diabetes were studied by ROC curve. The diagnostic performance of HbA1c was assessed by the areas under the ROC curve (AUC) estimated by the DeLong method.
Results
53.2% of patients present with dysglycemia: 23.8% with diabetes mellitus, 29.4% with pre-diabetes: 6.8% with moderate fasting hyperglycemia (HMJ). 22.6% ITG glucose intolerance. The optimal HbA1c threshold for the diagnosis of diabetes mellitus is 6.27% with a sensitivity of 78% CI (0.9134–0.924) and a specificity of 88%, PPV: 67.88%, NPV: 92.83%. For the diagnosis of pre-diabetes, the optimal HbA1c threshold is 5.83%, with a sensitivity of 71% CI (0.6221–0.8016) and a specificity of 81% (0.7268 - 0.8950), PPV: 80.6%, NPV: 72 %. The HbA1c at the threshold ≥ 5.7% of ADA seems more interesting for screening the maximum number of diabetics (98%) than that of prediabetes (67%). Our HbA1c threshold ≥ 5.83% being less sensitive to detect dysglycemia compared to that of ADA (92% of type 2 diabetes mellitus and 54% of prediabetes).

Seuil d'HbA1c %		Normal	Pré diabète	Diabète
ADA American Diabetes Association	< 5.7	156(65%)	47(33%)	2(1.6%)
	5.7–6.4	76(32%)	79(55%)	36(30%)
	≥ 6.5	6(2.5%)	17(12%)	81(68%)
Algiers Belkacem	< 5.83	192(80.6%)	66(46%)	9(7.5%)
	5.83–6.26	33(14%)	46(32%)	17(14%)
	≥ 6.27	13(5.5%)	31(22%)	93(78%)
	total	238(100%)	143(100%)	119(100%)

Conclusion
The use of HbA1c by the standardized method may be a means of screening in high-risk subjects. This HbA1C screening strategy must be verified at the level of the general Algerian population and involves periodic evaluation.

HbA1c threshold to predict prediabetes in a non-diabetic population but high risk of diabetes

Samira Belkacem
Endocrinology, Pierre Marie Curie Center, of Medecine, Algiers, Algeria

Introduction
When we talk about the prevalence of diabetes on a planetary scale, we can speak of a global epidemic or even a pandemic. Its prevalence continues to increase and the detection of individuals at risk of developing this disease remains a major concern.
Aim of the study
To attempt to establish standards for HbA1c by assessing the validity of this test in the diagnosis of pre-diabetic conditions and in normal subjects. This test has not yet been validated by Algerian national studies.
Material and methods
345 women, 155 men consultants at the level of primary care structures, volunteers, but at high risk of diabetes, are subjected to a questionnaire (specifying all the anthropometric parameters and the risk factors of diabetes: family and personal history of Type 2 diabetes mellitus (Type 2 DM), hypertension obesity, dyslipidemia.), then screening by performing an OGTT/HbA1c (HPLC), blood count and ophthalmologic examination. The correlation between 2 qualitative variables was analyzed by the Pearson correlation coefficient. The significance level of the tests was $P \leq 0.05$ (5%). The sensitivity and specificity of HbA1c at different thresholds for the diagnosis of diabetes and pre-diabetes were studied by ROC curve. The diagnostic performance of HbA1c was assessed by the areas under the ROC curve (AUC) estimated by the DeLong method.
Results
For the diagnosis of pre-diabetes, the optimal HbA1c threshold is 5.83%, with a sensitivity of 71%) and a specificity of 81%, PPV: 80.6%, NPV: 72%. The HbA1c at the threshold ≥ 5.7% of the ADA seems more interesting for screening the maximum number of diabetics (98%) than that of prediabetes (67%). Our HbA1c threshold ≥ 5.83% being less sensitive to detect dysglycaemia compared to that of ADA (92% of (Type 2DM) and 54% prediabetes).
Conclusion
The use of HbA1c by the standardized method may be a means of screening in high-risk subjects. This HbA1C screening strategy must be verified at the level of the general Algerian population and involves periodic evaluation.

Clinical and immunological profile of newly diagnosed diabetic patients in a cohort of young adults of national hepatitis C Virus survey in Egypt

Laila Hendawy[1], Mohamed Halawa[1,2], Yara Eid[2], Salah Elhalawany[1] & Ahmed Hegab[3]
[1]Ain Shams University, internal medicine and endocrinology, Cairo, Egypt; [2]Ain Shams University, Cairo, Egypt; [3]National institute of diabetes and endocrinology, internal medicine and endocrinology, Cairo, Egypt

Background
Type 2 diabetes has traditionally been considered a disease affecting older age groups. In recent years, however, Type 2 diabetes has become increasingly common in children, adolescents and young adults.
Aim of the work
To estimate the prevalence of T2D among a sample of Egyptian youth aged (18–30) and to highlight the challenges in differentiating T1D from T2D in early onset diabetes depending on clinical and laboratory characteristics.
Methodology
Our cross sectional study was performed on two hundred newly diagnosed diabetic patients aged (18–30) years. All patients were subjected to full medical history and thorough clinical examination. Laboratory investigations included FBS, HbA1C, fasting C peptide and GADA. Patients with Medical disorders that would potentially confound results or patients receiving drugs that may affect blood glucose level as steroids were excluded from the study.
Results
About 59% (118) of our patients were T2D while (82) 41% were T1D. T1DM was more dominant than T2DM in age group less than 25 years (T1DM 79% vs T2DM 21%, $P < 0.001$), while T2DM was more than T1DM in age group more than 25 years (T2DM 93% vs T1DM 17%, $P < 0.001$). GADA was detected in 74 % of T1DM patient and it was high titer while GADA was detected in only 8% of T2DM with low titer, in addition GADA positive patients were significantly younger than negative patients, age (20.9 ± 2.5 years vs 26.4 ± 3.5 years respectively) ($P < 0.001$). C peptide was predominantly higher in T2D than T1D (1.4 ± 0.5 ng/ml T2D vs 0.7 ± 0.3 ng/ml T1D $P < 0.001$), but there was no difference in C peptide between GADA positive and negative neither T1DM nor T2DM patients. DKA was higher in T1DM than T2DM in both the GADA positive and GADA negative patients (92.7% in T1D, vs 5.1% in T2DM), but surprisingly higher in GADA negative than GADA positive in both T1DM and T2DM patients ($P < 0.001$). Also, family history of diabetes was more common in T2DM (T2DM 70.3% vs T1DM 26.8%, $P < 0.001$), history of autoimmune diseases was more common in T1DM (T1DM 18.3% vs T2DM 2.5%, $P < 0.001$).
Conclusion
The prevalence of diabetes mellitus especially T2D is increasing among youth may be due to changing lifestyle and genetic background, collection of detailed clinical and laboratory data has become fundamental to correctly evaluate diabetes trends in youth and to describe optimal treatment to different cases.

AEP260

The role of bile acids in the pathogenesis of non-alcoholic fatty liver disease and type 2 diabetes mellitus

Zvenigorodskaya Larissa, Petrakov Alexander, Nilova Tamara & Shinkin Mikhail
Moscow Clinical Research and Practice Center Named after Loginov, Moscow Department of Health, Moscow, Russian Federation

Bile acids (BA) regulate glucose and lipid metabolism, provide bile flow, increase lipase activity by 10–15 times. With the development of inflammation, violations occur in the membrane proteins of glucose transporters.
Aim
Determine the total pool of bile acids in NAFLD with diabetes mellitus (DM) and impaired glucose tolerance (IGT). Determine the content of inflammation markers lipoprotein-associated phospholipase (Lp-PLA2), endotoxin (ET) in the blood serum of NAFLD patients.
Material and methods
On a biochemical analyzer 'Olympus' using test systems * Randox * (England), the total content of BA was determined by the enzymatic method. 80 patients with NAFLD with type 2 diabetes and ITG were examined. BMI 36–40 kg/m^2. During ultrasound, fatty hepatosis or diffuse liver damage was detected. Analysis of biochemical parameters showed a significant increase in aminotransferases in 90% of cases. Lp-PLA2 was determined by the enzyme immunoassay using the PLAC TEST diagnostic kits (USA), and the LAL test (USA) was used to determine ET.
Research results
In 59 NAFLD patients with diabetes, there was a significant decrease in the fatty acid content by 45% compared to the control, the level of bile acids in the blood serum was 2.97 ± 1.02 μmol/l, and with ITG 8.88 ± 4.94 μmol/l and a high content of PLA2 median 605 (504–826) ng/ml. In patients with NTG, PLA2 was significantly lower and amounted to a median of 430 (324–497) ng/ml. The content of Et in patients with diabetes is increased 12-fold. This activates Ca2 + channels on the membrane of smooth muscle cells, which leads to the activation of PLA2.
Conclusions
In NAFLD patients with diabetes, biliary insufficiency develops, the PLA2 and ET indices are significantly increased, which indicates the presence of inflammation and a high risk of cardiovascular complications, including coronary atherosclerosis, myocardial infarction and stroke. An increase in the content of inflammatory markers leads to a decrease in the activity of nuclear receptors for the synthesis and conjugation of BA.

Self-Management Behavior of the Patients with Type 2 Diabetes: A Cross-Sectional Survey in the Eastern European population (Belarus)

Andrei Yaroma[1], Larissa I. Danilova[2]
[1]Belarusian Medical Academy of Postgraduate Education, Department of Psychotherapy and Medical Psychology, Minsk, Belarus; [2]Belarusian Medical Academy of Postgraduate Education, Department of Endocrinology, Minsk, Belarus

Background
The prevention of complications and improvement of metabolic control and state of health in diabetes cannot be effective only with medications. And now we need to develop different approaches – not only up to date pharmacological treatment of diabetes, but change the Self-Management Behavior among patients with Type 2 Diabetes.
Aims
To assess the current status of diabetic self-management behavior and the factors responsible for such knowledge among type 2 diabetes patients in Minsk, Belarus.
Methods
A correlational, exploratory, quantitative research design was utilized. We used the Diabetes Self-Management Questionnaire (DSMQ) and a questionnaire with free questions related to diabetes to investigate patients with T2DM from August to December 2020 in Minsk, Belarus.
Results
We enrolled a total of 206 patients in the present study. The median score of self-management behavior was 5.48 (10 maximum point), the interquartile range was 4.64–6.04 points. An analysis of subscale was: 'Glucose Management' was 7.33 (6.00; 8.00) (P-value: < 0.001); 'Dietary Control' 5.00 (3.33; 5.83) (P-value: < 0.001); 'Physical Activity' 4.44 (2.22; 5.56) (P-value: < 0.001); 'Health-Care Use' 5.56 (3.33; 6.67) (P-value: < 0.001). Answers for the 16 th item 'My diabetes self-care is poor' were: 'Applies to me very much' 27.20%; 'Applies to me to a consider-able degree' 4.76%; 'Applies to me to some degree' 33.80%; 'Does not apply to me' 34.27%. Further, a correlation was made between the onset of the disease, the patient's age, the degree of cognitive impairment, the average mean of hemoglobin A1c and DSMQ subscales.
Discussion
Self-Management Behavior in Patients with Type 2 Diabetes was negatively correlated with: the duration of the course of diabetes; the patient's age; the degree of cognitive impairment; the existing disorders of carbohydrate metabolism.
Conclusion
There are a number of reasons that could affect on changes in Self-Management behavior. It is likely that the maximum Self-Management behavior changes are available to the patient in the early stages of the onset of type 2 diabetes. Given the limited capacity of any national health care system, it is worth paying attention to the possibility of making maximum efforts to change Self-Management behavior among patients in whom the period of diagnosis of diabetes mellitus is from 1 to 2 years.

AEP262

Retinol-binding protein in the diagnosis nafld and type 2 diabets

Zvenigorodskaya Larissa, Nilova Tamara, Petrakov Alexander, Galina Varvanina & Shinkin Mikhail
Moscow Clinical research and practice center named after Loginov, Moscow Department of Health, Moscow, Russian Federation

Retinol binding protein (RBP) is an adipokine, related to insulin resistance (IR). Excess free fat acid reduces the binding of insulin by hepatocyte receptors and leads to hyperinsulinemia. RBP transport protein synthesized in hepatocytes and adipocytes. The level of RBP increases in patients with obesity, diabetes andnon-alcoholic fatty liver disease (NAFLD). It is positively correlated with the degree of severity of the inflammatory process and fibrosis. The RBP regulates the activity ofinsulin in tissues, skeletal muscles, and the liver.

Purpose of research

Determine RBP in patients with NAFLD and type 2 diabetes. Compare the results of RBP with markers of lipoprotein-associated inflammation phospholipase (FLA2) and nitrogen oxide (NO), which inhibits the proliferation of collagen and regulates hepatic blood flow.

Material and methods

208 patients with NAFLD and type 2 diabetes were examined. The average age is 57.3 ± 5.2. There were 76 patients with type 2 diabetes and 132 with impaired glucose tolerance (NTG). BMI more than 30 kg/m^2 (34.85 ± 1.79). Clinical, biochemical, and instrumental research methods were performed. RBP was determined in 89 patients with type 2 diabetes using the immunoassay method in blood serum. The control group consisted of 15 practically healthy person. FLA was determined by immunoenzyme method. NO metabolites were determined by Express method.

Research result

The RBP content in the control group was 26.15 ± 1.31 mg/l. The RBP content in patients with type 2 diabetes without NAFLD (group 1) was reduced by 12.8 % and amounted to 30.54 ± 0.87 mg/l. The RBP content in 49 patients with NAFLD and2 diabetes (group 2) wassignificantly increased by 48.9 % and amounted to 55.83 ± 2.92 mg/l. The FLA2 content wasincreased by 4.78 times in relation to the control in group 2. The content level stable nitric oxide metabolites wasincreased in parallel with liver activity enzymes. There is a direct positive correlation between FLA2 and NO. The correlation coefficient was $r = 0.625$ $P = 0.001$

Conclusion

The level of RBP was significantly increased in patients with type 2 diabetes and NAFLD compared with control and group 1. Increase in the content of inflammatory markers accompanied by an inflammatory process in the liver with increased activity liver enzymes and the severity of morphological changes.

Study on INS gene rs689 polymorphism in patients with diabetes mellitus genetic burden

Talat Saatov[1], Elvira Ibragimova[1], Zafar Ibragimov[1,2], Nasiba Alimova[3], Tokhir Ishanhodjaev[1], Bakhodyr Zainutdinov[1], Abdunabi Tashtemirov[1], Kudrat Babaev[2] & Zulaykho Shamansurova[1,4]
[1]Institute of Biophysics and Biochemistry, Mirzo Ulugbek National University of Uzbekistan, Laboratory of Metabolomics, Tashkent, Uzbekistan; [2]Institute of Hematology, Uzbekistan Public Healthcare Ministry, Department of Molecular Genetics, Tashkent, Uzbekistan; [3]Center for the Scientific and Clinical Study of Endocrinology, Uzbekistan Public Healthcare Ministry, Tashkent, Uzbekistan; [4]Tashkent Pediatric Medical Institute, Uzbekistan Higher Education Ministry, Tashkent, Uzbekistan

Testing for genetic markers is a promising approach in early diagnosis of type 1 diabetes mellitus (DM1). Of all DM1-associated genes and genetic loci, after HLA class II, insulin promoter gene confers the highest risk for the onset of disease with the burdened familial history for diabetes mellitus.

Materials and methods

Genealogical analysis was used to identify the hereditary nature of the disease. DNA samples from 94 Uzbek patients with DM1 with the burdened familial history and from 66 apparently healthy persons included into the control group were analyzed. Original designs for primers to perform standard polymerase chain reaction (PCR) were made by bioinformatics analysis of data from NCBI Genome Data Viewer (GDV) by means of BioEdit program. INS (rs689) gene polymorphic region was amplified by PCR using allele-specific PCR methods.

Results

The findings from the genotyping of rs689 polymorphism of INS gene demonstrated that the frequencies of INS gene wild A allele were 76.1% and 90.1% in patients and controls, respectively. In the population sample, the T deleterious allele could be seen less frequently than in the 1st group patients (9.9 and 23.9%, respectively). Among patients with DM1, the AT genotype was 2.3 times more frequent than in the non-diabetics (39.3 vs 16.7%, respectively). The findings from the study on association between INS gene polymorphism and DM1 risk demonstrated statistically significant association of the T allele (χ^2=9.4; P< 0.05; OR = 2.88; 95%CI 1.84–5.59) and the AT heterozygous genotype (χ^2=9.2; P< 0.05; OR = 3.42; 95%CI 1.58–7.42) with the increased DM1 risk. The differences with the control group by the A allele (OR = 0.34; 95% CI: 0.18–0.67; χ^2 = 9.4) of INS gene can be the evidence for its negative association with the disease, that is, the A allele carriership reduces DM1 onset risk being of a protective character. In other studies, next to significantly lower incidence of DM1 the Asian populations were established to have higher frequency of the A allele of INS gene rs689. Thus, the findings from genotyping of INS gene rs689 polymorphism in patients with the familial burden for diabetes mellitus demonstrated association of the T allele and the AT heterozygous genotype with the DM onset risk.

Introduction

Dapagliflozin is sub-optimally utilised in the real world. There is a lack of a comprehensive collaborative guidance for a practical approach to manage patients with cardiometabolic, renometabolic and viscerometabolic disorders. Patients across the CRV-M continuum includes patients with varied clinical profiles.

Methods

Two round Delphi study was conducted using a virtual online-digital connect approach with 35 clinicians with cumulative clinical experience of 1050 man years of experience across different specialties. This was preceded by contemporary evidence-based discussion on therapeutic approaches, through multidisciplinary modules for six hours covering cardiometabolic, renometabolic and viscerometabolic disorders, with focus on dapagliflozin. A consensus was reached on the clinical aspects that were endorsed by 50% or more of the experts

Results

Of the total 33 questions, seven were unanimously (100%) rated with the same response and 12 received the same response by > 50% of the participants. The mean man years of experience of the respondents with unanimous response was 175.7 years (± 43.92, minimum 120, maximum 240, 95% CI 135.1 to 216.3) significantly higher as compared to respondents > 50% similar response 122.5 years (± 10.74, minimum 60, maximum 180, 95% CI 98.86 to 146.1) (P = 0.0118). The index weighted impact score based on the man years of experience was higher for the

unanimous responses group (1.43). There was a unanimous consensus, with absolute agreement for the cardiometabolic based chronic disease (CMBCD) approach, SGLT2 inhibitors as emerging approach to address the residual risk, and reduction of single-nephron glomerular filtration rate as a mechanism for renoprotection. 88% participants attributed insulin resistance as an important reason for autonomic dysfunction in patients with T2DM. The DAPA-CKD and DAPA-HF trials appears to have a potential scientific impact in the real-world utilisation of Dapagliflozin in patients with DKD and HFrEF.
Conclusion
The results of this study suggest that irrespective of presence of diabetes, dapagliflozin has a potential to optimise the management of patients. Dapagliflozin, beyond the ability to increase glycosuria, with relatively higher level of evidence, across the CRV-M continuum, appears to be a promising agent.

Acute fatty liver of pregnancy masquerading as diabetic ketoacidosis

Mehreen Anwar, Yamin thant, Sardar Muhammad Shoaib Khan & Muhammad Athar Iqbal Khan
Kings Mill Hospital, Diabetes and Endocrinology, Nottinghamshire, United Kingdom

Acute fatty liver of pregnancy (AFLP) is a rare obstetric metabolic emergency (UK incidence 1/20.000 maternities) which typically presents in 3rd trimester or postpartum and has a high maternal and foetal mortality and morbidity (UK Maternal mortality 1.8%, perinatal mortality 104/1000 births). Diagnosis can be delayed due to lack of set diagnostic criteria, rarity and overlapping clinical presentation with many other obstetric metabolic pathologies. Urgent delivery and supportive care are the mainstay of treatment. We would like to present an interesting case of AFLP which was initially managed as diabetic ketoacidosis (DKA). A 20-year-old lady with a background of gestational diabetes on insulin presented at 32 weeks' gestation in her second pregnancy with general malaise, reduced foetal movements, and anorexia and was found to be icteric with hyperglycaemia, severe metabolic acidosis and ketosis and deranged liver functions. She was started on fixed rate intravenous insulin infusion (FRII) and IV fluids with a diagnosis of DKA. She was transferred to ITU due to lack of response to treatment where intravenous bicarbonate was given with only transient improvement in her acidosis. Liver ultrasound showed uncomplicated gallstones with normal liver. Rest of the non-invasive liver screen was unremarkable. Foetus was being regularly monitored through cardiotocography with no concerns. She was being managed with inputs from obstetrics, diabetologists, gastroenterologists and intensivists in ITU for five days but despite appropriate management of DKA, there was no resolution of her metabolic abnormalities, at which point, expert opinion was sorted from maternal medicine department of the tertiary care centre who suggested a diagnosis of AFLP and advised urgent delivery. She underwent emergency caesarean section at 33 weeks' gestation and all her biochemical abnormalities started to improve post-partum with complete resolution of acidosis in 48 hours and normalisation of LFTs in two weeks. The baby was admitted to NICU for two weeks and intubated and NG fed for first week and later on discharged with no complications. Both mother and baby are now healthy. AFLP is a rare obstetric emergency which requires a high index of suspicion for diagnosis. This case was especially challenging given the hyperglycaemia and ketosis at presentation; these are not widely recognized metabolic abnormalities in AFLP. Diabetologists would rarely be involved in the care of AFLP however this case shows the importance of suspecting an alternate diagnosis when a 'diabetic emergency' does not respond to otherwise highly effective treatment modalities.

To assess the glucose metabolism using the flash glucose monitoring system (FGMS) in patients with hormone replacement therapy for hypopituitarism

Jiaxin Zhang1, Qiong He1, Minmin Han1, Jie Li1, Dan Yang1, Xintong Hou1, Guimei Yang1, Jing Yang1, Yunfeng Liu1 & Yi Zhang2
[1]First Hospital of Shanxi Medical University, Department of Endocrinology, Taiyuan, China; [2]Department of Pharmacology, Shanxi Medical University, Taiyuan, China

Background
Hormone replacement therapy is often used for hypopituitarism, which leads to dysglycemia. This study is conducted to assess the glucose metabolism conditions using the flash glucose monitoring system (FGMS) in patients with hormone replacement therapy.
Method
Seven patients who were diagnosed as hypopituitarism and treated with glucocorticoids and L-Thyroxine were qualified to participate in this study. These patients' blood pressure, blood sugar, sodium ions and FT3, FT4 were normal after hormone replacement therapy. We also recruited five healthy volunteers responsible for normal controls. FGMS data were disposed from two perspectives. Firstly, parameters consist of 24-hour mean blood glucose (24 h MBG), standard deviation of blood glucose (SDBG), coefficient of variance (CV), mean of daily differences (MODD), time in range (TIR). Secondly, several time periods were analyzed specifically, including the whole day, nocturnal, fasting, and postprandial periods. All of these indexes were analyzed by a t-test or Mann-Whitney test.
Results
Compere with HCs, the indexes including 24hMBG (P = 0. 956), SDBG (P = 0. 056), CV (P = 0. 610), MODD (P = 0. 416) and TIR (P = 0. 59) had normal outcomes. There was no significantly different AUC was identified at the whole day (P = 0. 360); significantly different AUC was found at nocturnal period (3. 93 ± 0. 50vs4. 0 ± 0. 41, P = 0. 009), fasting period (4. 05 ± 0. 62vs4. 28 ± 0. 38, P = 0. 003), after breakfast (4. 77 ± 0. 64vs4. 80, 5. 95, P < 0. 001), after lunch (6. 11 ± 0. 93vs5. 86 ± 0. 42, P < 0. 001) and after dinner (5. 95 ± 0. 66vs4. 58, 6. 33, P = 0. 09).
Conclusion
Patients with hormone therapy had higher postprandial blood glucose than HCs. Because exogenous hormones cannot simulate the secretion rhythm of endogenous hormones. In addition, patient's nocturnal blood glucose was low. Exogenous hormones had a short acting time, which can not maintain nocturnal blood glucose. On the other hand, exogenous hormones inhibited adrenal glands' function, leading to the further lack of endogenous hormones and the low blood sugar level at night.

p53 family controls several metabolic and cellular functions. The p63 member regulates lipid metabolism in hepatocytes and contributes to the development of liver steatosis. Here we show that p63 plays an important role in liver fibrosis. P63 is upregulated in patients with NASH, correlating positively with fibrosis score and collagen 1a1 expression. P63 expression is also increased in different animal models of diet-induced NASH and chemically induced liver fibrosis. Mice with hepatic downregulation of p63 fed a high fat diet or choline deficient and high fat diet (CDHFD) for 52 weeks display reduced collagen deposition, hydroxyproline levels and expression of collagen markers. Similar results were found when these mice were challenged to methionine and choline deficient diet. Consistent with this, the hepatic overexpression of TAp63α isoform accelerates the fibrosis induced by CDHFD. Our findings indicate an unexpected role of p63 in the metabolic and profibrotic action in liver disease.

Challenges in availability of insulin in Malwa region of Madhya Pradesh, INDIA during COVID-19 lockdown and its impact on perceived stress in patients

Bharat Saboo[1,2]
[1]Prayas Diabetes Center, Diabetology, Indore, India; [2]Prayas for Care of Diabetes Society, Diabetology, Indore, India

Title:
Challenges in availability of insulin in Malwa region of Madhya Pradesh, INDIA during COVID-19 lockdown and its impact on perceived stress in patients
Introduction
There are large number of patients of diabetes who require insulin to control their blood sugar. During the covid 19 lockdown, many medicines were not easily available and insulin being a life-saving and necessary medicines requires smooth availability. Non availability of insulin causes sugar fluctuations and anxiety in minds of patients and attendants and can affect well-being.
Methods
We surveyed 140 patients on insulin for their insulin availability and stress level were recorded using perceived stress score questionnaire during the period of COVID-19 Lockdown-1 from 5th to 10th april 2020.
Result
There was a difficulty in procuring insulin in the region surveyed which was reported by 73 % of respondents. The difficulty was more with analogues 88% as compared with regular insulins. Was more in rural areas 53 % as compared to urban areas. Almost 88 % of respondents had higher perceived stress scores due to this reason.
Discussion
There is pressing need to establish supply chains in a proper manner so that a patient need not face difficulty in procuring a lifesaving drug such as insulin. The need is more in Rural areas, and more with analogues so that the stress associated with scarcity of insulin can be alleviated.
Keywords: Insulin, analogue, nonavailability, perceived- stress, lockdown, covid-19.

Factors predictive of glycemic control of pregnant diabetic women

Fatiha El Miski, Btissam Ouafidi, Moukhlis Sabah, Bouab Maryem, Amine lamrissi, Karima Fichtali & Said Bouhiya
IBN Rochd University Hospital of Casablanca, Morocco., Gynecology and Obstetrics Department, Casablanca, Morocco

Introduction
Diabetic pregnancy is an at-risk pregnancy, hence the importance of perfect glycemic control. The objective of this study is to evaluate glycemic control of pregnant women and these intervening factors.
Materials and methods
Our study is prospective observational and analytical, including 300 patients with diabetic pregnancy followed in the obstetric gynecology department of Ibn Rochd hospital in Casablanca-morocco between November 2019 and November 2020.
Results
The study included 300 patients with an average age of 32.6 years (18–42). 45% had gestational diabetes and 55% had pre-gestational diabetes, of which 5% had planned their pregnancy. The mean pre-conceptional HbA1c was 8%. For treatment, 78% of the patients were on insulin and 22% were following hygienic and dietary rules. All patients were on a basal bolus regimen, 37% of whom were on analogues. Regular self-monitoring was ensured in 32% of patients. Physical activity was practiced in 27% of patients. 90% of the patients ate three meals a day and 66% of the patients ate one to two snacks a day. 40% abused slow sugars and 36% consumed fast sugars. Glycemic control was perfect in 64% of the patients and insufficient in 36%. A significant relationship was found between glycemic control and slow sugar abuse ($P < 0.05$) as well as type of diabetes ($P < 0.02$) (better control for pre-gestational diabetes).
Discussion
It is established that an optimized management, in particular a perfect glycemic balance, reduces the risks related to pregnancy. Several factors intervene as demonstrated in our study, namely: eating habits and type of diabetes.

Correlation between cystatin C and cardiovascular risk factor in patients with type 2 diabetes mellitus without kidney disease

Ivona Risovic[1], Vlastimir Vlatkovic2[1], Snjezana Popovic Pejicic[1], Aleksandra Grbic[1] & Gabrijela Malesevic[1]
[1]University Clinical Center of the Republic of Srpska, University of Banja Luka, Faculty of Medicine, Endocrinology, Banja Luka, Bosnia and Herzegovina; [2]University Clinical Center of the Republic of Srpska, University of Banja Luka, Faculty of Medicine, Nephrology, Banja Luka, Bosnia and Herzegovina

Introduction
Diabetes mellitus (DM) is considered as equivalent to cardiovascular disease (CVD), so the intensive control of all risk factors for CVD in patients with DM is recommended. Risk factors for CVD include: dyslipidemia, hypertension, smoking, family history of CVD and albuminuria. In addition to being a sensitive and reliable marker for evaluation of kidney function, research suggests that cystatin C may be a useful predictor for the detection and prediction of CVD. The aim of the study was to investigate the correlation between serum cystatin C and the risk factors for CVD in patients with type 2 DM without kidney disease.
Methods
The cross- sectional study included 90 patients with type 2 DM who were divided in two groups: group I 50 patients with type 2 diabetes mellitus without kidney disease and 40 patients with diabetes mellitus with kidney disease. Patients with DM did not have presence of CVD (ischemic heart disease, previous myocardial infarction and stroke). Patients without kidney disease were noralbuminuric and have normal glomerular filtration rate calculated using Chronic Kidney Disease Epidemiology Collaboration equation. We examined the correlation between serum cystatin C and risk factors for CVD dyslipidemia, hypertension, smoking, albuminuria, and a family history of CVD.
Results
The analysis showed that group II had more risk factors for CVD. Patients without kidney disease had LDL and triglycerids without reference range for DM, 15 were smokers and positive family history of CVD was found in 7 patients. The mean serum levels of LDL and triglycerides were higher in group II (LDL 3.34 ± 1.09 vs. 2.78 ± 1.15, $P < 0.05$, triglycerides 2.26 ± 1.22 vs. 2.11 ± 1.09, $P > 0.05$). In group I, cystatin C values showed a statistically significant direct correlation with serum triglycerides ($r = 0.42$, $P < 0.05$) and and systolic blood pressure ($r = 0.33$, $P < 0.05$) and inverse correlation with serum HDL cholesterol level. In group II cystatin C also showed significant correlation with triglycerides ($r = 0.36$, $P < 0.05$), inverse correlation with serum HDL ($r = –0.40$, $P < 0.05$).
Conclusion
The study showed correlation between cystatin C and CV risk factors as lipid parameters and systolic blood pressure in patients with type 2 DM without kidney disease.
Key words: diabetes mellitus, cystatin C, cardiovascular disease, kidney function

AEP271

Role of diabetic autonomic neuropathy in development of diabetic cardiomyopathy in patients with diabetes

Snjezana Popovic Pejicic[1,2], Nina Pejicic[1], Gabrijela Malesevic[1], Valentina Soldat Stankovic[1] & Ivona Risovic[1]
[1]University Clinical Centre of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina; [2]University of Banja Luka, Faculty of Medicine Banja Luka, Banja Luka, Bosnia and Herzegovina

Aim
Diabetic cardiomyopathy (DC) is congestive heart failure developed in diabetic patients, without coronary, hypertensive, valvular nor myocardial alcoholic disease. Aim of this stady was to confirm if presence of diabetic autonomic neuropathy (DAN) is correlating with development of DC in patients with diabetes.
Methods
We have evaluated 90 examinees: 30 of them with diabetes type 1(T1D), 30 with diabetes type 2 (T2D) and 30 healthy examinees that were in control group. With all examinees we have performed cardiovascular dynamic tests and echocardiography – one-dimensional, two-dimensional and doppler on Aloca 830 machine. Parasympathetic function was tested with 3 cardiovascular reflexes tests (Valsalve maneuver, deep breathing test, stand-up after lying position test), and sympathetic function with 2 tests (orthostatic hypotension test, and hand grip test).
Results
Results have showed that systolic function of left chamber (LC) in T1D patients with DAN was normal in 90.5%, and pathological in 9.5% ($P < 0.01$), and in T2D patients with DAN was normal in 76.7%, and

pathological in 23.3% ($P < 0.01$). LC diastolic function in T1D patients with DAN was normal in 46.7%, and pathological in 52.4% ($P > 0.05$). In T2D patients with DAN, diastolic function of LC was impaired in 83.3% ($P < 0.01$).
Conclusion
DAN is significantly increased in patients with T2D. Within those patients, diastolic function of LC was impaired significantly more frequent, until systolic function was non-affected in both of these diabetes types. Correlation between LC diastolic function impairment and DAN could signify its possible spot in diabetic cardiomyopathy etiopathogenesis.

Influence of nutritional status on clinical outcomes among hospitalized patients with covid-19

Keyla María Dotres Fallat[1], Joana Nicolau[1,2], Luisa Ayala Corao[1], Pilar Sanchís Cortés[2], Irene Rodríguez Rodríguez[1,2], Ana Gloria Soler Beunza[1], Andrea Pompeo Romano[1] & Lluís Masmiquel Comas[1,2]
[1]Hospital Universitari Son Llàtzer, Endocrinología y Nutrición, Palma, Spain; [2]Fundació Institut d'Investigació Sanitària Illes Balears (IdISBa), Palma, Spain

Background and aims
Several factors that worsen the prognosis of the new coronavirus SARS-CoV-2 have been identified, such as obesity or diabetes. However, despite that nutrition may change in a lockdown situation, little is known about the influence of malnutrition among subjects hospitalized due to COVID-19. Our study aimed to assess whether the presence of malnutrition among patients admitted due to COVID-19 had any impact on clinical outcomes compared with patients with the same condition but well nourished.
Methods
75 patients admitted to hospital due to COVID-19 were analyzed cross-sectionally. Subjective Global Assessment (SGA) was completed by phone interview. Clinical parameters included were extracted from the electronic medical record.
Results
According to the SGA, 27 admitted due to a COVID-19 infection had malnutrition. Patients not well nourished were older than patients with a SGA grade A (65 ± 14.1 vs 49 ± 15.1 years; $P < 0.0001$). Length of hospital stay among poorly nourished patients was significantly higher (18.4 ± 15.6 vs 8.5 ± 7.7 days; $P = 0.001$). Mortality rates and admission to ICU were greater among subjects with any degree of malnutrition compared with well-nourished patients (7.4% vs 0%; $P = 0.05$ and 44.4% vs 6.3%; $P < 0.0001$). CRP (120.9 ± 106.2 vs 60.8 ± 62.9 mg/l; $P = 0.03$), D-dimer (1516.9 ± 1466.9 vs 461.1 ± 353.7 ng/ml; $P < 0.0001$) and ferritin (847.8 ± 741.1 vs 617.8 ± 598.7mg/l; $P = 0.03$) were higher in the group with malnutrition. Haemoglobin (11.6 ± 2.1 vs 13.6 ± 1.5 g/dl; $P < 0.0001$) and albumin 3.2 ± 0.7 vs 4.1 ± 0.5 g/dl; $P < 0.0001$) were lower in patients with any degree of malnutrition.
Conclusions
The presence of a poor nutritional status is related to a longer stay in hospital, a greater admission in the ICU and a higher mortality.

Acute hyperglycemic emergencies during lockdown: COVID-19 collateral damage

Bárbara Filipa Araújo[1], Cátia Andreia Araújo[1], Mariana Lavrador[1], Ana Rita Elvas[2], Sandra Paiva[1] & Isabel PAIVA[1]
[1]Coimbra University Hospital, Endocrinology Department; [2]Portuguese Institute of Oncology, Coimbra, Endocrinology Department

Introduction
In march 2020, the COVID-19 pandemic registered its first cases in Portugal, leading the government to impose lockdown, in order to prevent the spread of cases. With social isolation and outpatient activity being ceased, there was an increase in mortality of non-COVID patients. The lockdown recommendations are in contradiction with comprehensive diabetes care and reflected in less regular patient-provider interactions, which in some cases contributed to the worsening of glycemic control and presentation with acute complications of diabetes.
Aim
To evaluate the impact of lockdown in the severity and characteristics of hyperglycemic emergencies (diabetic ketoacidosis [DKA] and hyperosmolar hyperglicemic state [HHS]).
Methods
Retrospective single center study. We included patients with a diagnosis of DKA or HHS admitted in the lockdown months (march to may 2020). The control group were patients admitted with DKA or HHS in the homologous period of 2019.
Results
18 patients were admitted in 2020 and 12 in 2019. The mean age was 48 (± 24) years in 2019 and 60 (± 26) in 2020 ($P = 0.192$). HHS represented 50% of cases in 2020 and 25% in 2019 ($P = 0.171$). In the lockdown period patients were more likely to have type 2 diabetes (55.6% vs 33.3%, $P = 0.232$), had a higher number of comorbidities (2.4 ± 1.4 vs 1 ± 0.9, $P = 0.009$), more microvascular complications (50% vs 8.3%, $P = 0.049$), and usual attendance at primary care services (61.1% vs 16.7%, $P = 0.008$). At admission, lockdown patients were more likely to present with dehydration (55.6 vs. 9.1%, $P = 0.009$) and altered mental status (61.1 vs 25%, $P = 0.048$). There were more cases of severe DKA in 2020 (45.5% vs 0%, $P = 0.038$). Although with statistically not significant difference, patients had tendentially higher urea (39.5 vs 30.5 mg/dl, $P = 0.391$), creatinine levels (1.85 vs 1.42 mg/dl, $P = 0.051$) and osmolarity (310 vs 293 mOsm/kg, $P = 0.172$); more complications during in-hospital stay (38.9 vs 8.3%, $P = 0.064$) and higher mortality (16.7 vs 0%, $P = 0.136$). The cases of initial presentation of diabetes did not differ between periods (16.7%).
Conclusion
During lockdown there were more admissions with acute hyperglycemic emergencies, those with more severe presentations, resulting in a higher fatality rate. Reduced access to primary care and hospital services for diabetes, combined with fear of exposure to the virus in these settings drive to delayed care-seeking. Telehealth or telephonic consultations should be encouraged to prevent complications and ensure access to therapy. Download of records from insulin pumps/CGM should be used whenever possible to optimize glucose control.

Sex-specific variations in lipid concentrations following a low-fat diet are mediated by vitamin D status: a 12-week prospective dietary intervention study among Christian Orthodox fasters

Spyridon Karras[1], Theocharis Koufakis[1], Lilian Adamidou[2], Georgios Dimakopoulos[3], Paraskevi Karalazou[4], Katerina Thisiadou[4], Alkiviadis Bais[5], Themistoklis Tzotzas[6], Kali Makedou[4], Eleni Manthou[1] & Kalliopi Kotsa[1]
[1]Aristotle University of Thessaloniki, Division of Endocrinology and Metabolism, First Department of Internal Medicine, Medical School, Thessaloniki, Greece; [2]AHEPA Hospital, Department of Dietetics and Nutrition, Thessaloniki, Greece; [3]University of Ioannina, Medical Statistics, Epirus Science and Technology Park Campus, Ioannina, Greece; [4]Aristotle University of Thessaloniki, Laboratory of Biological Chemistry, Medical School, Thessaloniki, Greece; [5]Aristotle University of Thessaloniki, Laboratory of Atmospheric Physics, Thessaloniki, Greece; [6]Saint Luke's Hospital, Department of Endocrinology, Thessaloniki, Greece

Background
Orthodox religious fasting (OF) is a variation of the classical Mediterranean Diet during which meat and other animal products are restricted, whereas fish are occasionally and sea food are always allowed. The aim of this prospective study was to assess sex-specific differences in changes of lipid concentrations in a cohort of metabolically healthy adults following OF and investigate a potential role of vitamin D status in mediating these variations.
Methods
45 individuals (24 females, 53.3%) with mean age 48.3 ± 9.1 years and mean Body Mass Index 28.7 ± 5.8 kg/m^2 were followed for 12 weeks. Anthropometrical, dietary and biochemical data (serum lipids and vitamin D concentrations) were collected at baseline, 7 weeks after the implementation of OF and 5 weeks after participants returned to their standard eating habits (12 weeks from baseline). According to 25-hydroxy-vitamin D [25(OH) D] measurements, fasters were classified into two groups: those with concentrations above and below the median of values.
Results
Female participants with 25(OH)D concentrations below the median demonstrated a non-significant reduction by 15% in total and low-density

lipoprotein cholesterol during the fasting period, followed by a significant increase (170.74 vs. 197.50 and 99.63 vs. 121.06 mg/dl respectively, $P < 0.001$) 5 weeks after OF cessation. On the other hand, male participants with 25(OH)D levels below the median manifested an inverse, non-significant trend of increase in serum lipids during the entire study period.
Conclusions
Our findings indicate sex-specific variation in lipid concentrations following a low-fat dietary pattern, modulated by vitamin D status. Further studies are required in order to unravel the underlying mechanisms and evaluate the association of these inter-gender differences with cardiovascular risk and benefit of vitamin D supplementation.

Low-density lipoprotein cholesterol target achievement in patients with diabetes

Ghofrane Hakiri, Yosra Htira, Manel Dridi, Zohra Hadj Ali & Faika Ben Mami
Institut De Nutrition, Tunis, Tunisia

Background
Diabetes is often associated with other cardiovascular (CV) risk factors such as dyslipidemia, wich increases the risk of degenerative disease and contributes to elevate morbi-mortality in these patients. The aim of this study was to assess the CV risk level of diabetic patients and to determine the rate of lipid targets achievement.
Methods
it was a descriptive cross-sectional study including 100 diabetic. CV risk levels and low- density lipoprotein cholesterol (LDL-C) goal achievements were performed according to ESC's guidelines updated in 2019.
Results
The mean age was 50 ± 10.6 years with a predominance of females (52.8%). All patients had dyslipidemia associated with type 1 (72.8%) or type 2 (27.8%) diabetes. The most common type was mixed dyslipidemia (47.2%), followed by pure hypertriglyceridemia (38.9%) and only 13.9% had pure hypercholesterolemia. According to new guidelines, 37.8% and 62.2% were considered as very high and high CV risk, respectively. Most patients at very high cardiovascular risk (82%) had complicated diabetes. These complications were represented by diabetic retinopathy (65.4%) and diabetic kidney disease (34.6%). The other patients had cardiovascular disease established clinically or by imaging (18%), namely coronary artery disease (6%), stroke or transient ischemic attack (1.2%) and arterial occlusive disease of the lower limbs (10.8%). Less than half of the patients achieved their recommended LDL-c goals (38.3%). According to the CV risk level, only 12.1% and 26.2% met their goals for very high risk and high risk, respectively. Non-achievement of LDL-c goals was significantly associated with discontinuation of treatment ($P < 0.001$). In 2/3 of cases, it was explained by the non-availability of lipid-lowering treatment in dispensaries. Among the patients who did not reach their LDL-c goals, poorly adapted dosage and treatment were observed in 48.3% and 32.3% of cases respectively ($P = 0.04$).
Conclusions
Despite of high CV risk levels, most of patients didn't achieve recommended goals. This is likely to be due to either discontinuation of medications or therapeutic inertia.

Heterozygous familial hypercholesterolemia with intolerance to PCSK9 inhibitors

Miguel Saraiva[1], Pedro Palma[2], José Alexandre Queirós[3] & Isabel Palma[1]
[1]Centro Hospitalar e Universitário do Porto, Endocrinology, Diabetes and Metabolism, Portugal; [2]Unidade Local de Saúde de Matosinhos, Portugal; [3]Centro Hospitalar e Universitário do Porto, Nephrology, Portugal

Introduction
Heterozygous familial hypercholesterolemia is one of the most common genetic disorders and it is associated with an at least ten times higher risk of coronary heart disease. Frequently, it is necessary to medicate the patients with PCSK9 inhibitors (PCSK9i) so they can reach LDL-c target values. In Portugal, the only evolocumab is available and the most commonly reported adverse effects are local pruritus and upper airway symptoms.
Case report
A 42-year-old woman was referred to our department because of a poorly controlled hypercholesterolemia despite being on maximal doses of statin and ezetimibe. She had a family history of premature coronary disease and had a serum total cholesterol level of 415 mg/dl and an LDL-c level of 327 mg/dl. Her Dutch Lipid Clinical Network score was above 8 points. As so, she underwent genetic testing which revealed a pathogenic mutation in heterozygosity. She started evolocumab and responded well to the first dose (LDL-c reduction of 53%) but reported transient headaches, nausea and myalgia. After the second dose, she developed self-limited headaches, dizziness, myalgia and an acute confusional state with spatial disorientation and horizontal binocular diplopia. Both a brain CT scan and an MRI were performed and showed no relevant findings. The patient also underwent neurological, psychiatric and otorhinolaryngological assessments which excluded other etiologies. Thus, evolocumab was suspended. 6 months later, her cholesterol levels had risen to alarmingly high levels and the PCSK9i was reintroduced – the patient once again developed a worrisome confusional syndrome and evolocumab was permanently suspended. As an alternative, she started lipoprotein apheresis and responded well to this treatment (LDL-c reduced by 57%). Since then, she has an apheresis session every two weeks and no adverse effects have been reported.
Discussion
This case report demonstrates an association between evolocumab and the development of neurocognitive symptoms. Other potential explanations would be the induced hypocholesterolemia or the abrupt cholesterol reduction. However, it has already been proved that LDL-c reductions to values below 25 mg/dl due to the action of PCSK9i occur safely. Furthermore, a similar LDL-c reduction was achieved with the lipoprotein apheresis without any adverse effects. In fact, although extremely rare, the association between PCSK9i and neurocognitive symptoms has been described in some clinical trials. As so, the authors intend to raise awareness on the need to monitor neurocognitive symptoms in patients taking evolocumab.

Frequency of obesity among individuals with spondylarthritis

Ben Ali Khaoula[1], Maroua Slouma[2], Chadia Zouaoui[1] & Imen Gharsallah[2]
[1]Military Hospital of instruction of tunis, Endocrinology and Nutrition, Tunisia; [2]Military Hospital of instruction of tunis, Rheumatology, Tunisia

Background
Spondylarthritis may be associated with substantial burden of comorbidities, which can increase the cardiovascular risk. Obesity if associated with spondylarthritis not only can rise the risk of a possible heart disease but it may also deteriorate their functional prognosis.
Objectives
The main target of this study was to evaluate the frequency of obesity in spondylarthritis patients.
Materials
We performed a cross-sectional study including 96 patients with spondylarthritis(SA) diagnosed according to ASAS criteria, the disease activity were assessed using ASDAS, for each patient we mesured height in meter and weight in kg and we calculated the body mass index(BMI) using the metric formula Weight(kg)/Height(m)^2.
Results
The mean average was 41.45 + 12.52 years, sex ratio was 3. Clinical phenotypes of SA were: ankylosing spondylarthritis (62.4%),psoriatic arthritis(20.8%), arthritis associated with inflammatory bowel disease (12%). The mean duration of the disease was 110.9 + 106.16 months. The mean C-reactive protein and erythrocyte sedimentation rate were 31.48 and 37.19 respectively. The mean ASDAS-CRP,BASMI and BASFI were 3.63 + 2.26 and 2.45 + 2.44, 4.61 + 2.67. The mean BMI was 25.38 + 4.61. Underweight percentage was 0.2%, patients in the normal range were 50%, patients with overweight percentage was 45.8%(33.33% were pre-obese and 14.58 % obese).54.34 % of patients with overweight have ankylosing spondylarthritis and 26% of them have psoriatic arthritis. There were no correlation between BMI and ASDAS-CRP, BASMI and BASFI.
Conclusion
Spondylarthritis with obesity may increase mortality in our population by increasing the cardiovascular risk, that is why a healthy eating and if possible a regular physical activity may improve the prognosis of the disease.

Response to direct antiviral agents in chronic hepatitis C in patients with metabolic syndrome

Mrabet Soumaya, harbi raida, Imen Akkari & Ben Jazia Elhem
Farhat Hached University Hospital, Gastroenterology, Sousse, Tunisia

Introduction
Direct antiviral agents (DAAs) are a real revolution in the treatment of chronic hepatitis c (CHC). It is a short-term treatment with few side effects. Insulin resistance in patients with metabolic syndrome, causes the onset of steatosis, contributes to the progression to cirrhosis and decreases the chances of a response to treatment. The aim of our study was to evaluate the response to DAAs in patients with metablic syndrome.
Methods
This is a retrospective study including all patients with hepatitis C treated with DAAs, between January 2018 and December 2020.
Results
Fifty paients were included in our study, divided into 31 women and 19 men, with an average age of 52 years (between 16 and 82 years). Twenty three patients (46%) had a metabolic syndrome. Thirteen patients had arterial hypertension and 7 patients were diabetic. HCC was discovered during screening in 40% of cases. The other circumstances of discovery were: blood donation (15%), asthenia (15%), arthralgia (15%), cytolysis (10%) and thrombocytopenia (5%). Genotype 1b was predominant (76%). The mean pretreatment viral load was 1.457.542 IU/ml. Abdominal ultrasound revealed hepatic steatosis in 8 cases. Twelve patients had F0-F1 Fibrosis measured by Fibroscan. The viral load at the end of anti-viral treatment and the viral load 6 months after the end of treatment were undetectable.
Conclusion
In our study, metabolic syndrome was present in 46% of patients. Sustained virological response was obtained in all patients. Thus the metabolic syndrome did not influence the response to DAAs.

The gut microbiota phylotypes in obese patients with arterial hypertension and pre-diabetes

Sergiy Koval, Iryna Snihurska & Kostiantyn Yushko
L.T. Malaya Therapy National Institute of the National Academy of Medical Sciences of Ukraine, Department of Arterial Hypertension and Prevention of Its Complications, Kharkiv, Ukraine

Gut microbiota, its phylotypes, the Firmicutes/Bacteroidetes ratio can play important role in the pathogenesis of arterial hypertension, obesity and metabolic disorders.
The aim of the study was to evaluate the content of the main phylotypes of the gut microbiota (Firmicutes, Bacteroidetes and Actinobacteria), the Firmicutes/Bacteroidetes ratio in patients with arterial hypertension, abdominal obesity and pre-diabetes.
Materials and methods
The study involved 46 patients with arterial hypertension 2–3 degrees and abdominal obesity (30 men and 16 women), mean age 54.9 ± 6.2 years old with pre-diabetes (main group, $n = 17$) or without disorders of carbohydrate metabolism (comparison group, $n = 29$). The main and the comparison groups were comparable in age, gender composition and duration of hypertension. The control group consisted of 20 healthy individuals without cardiovascular diseases, obesity and severe chronic diseases. The investigation included standard clinical, laboratory and instrumental methods. The content of the main gut microbiota phylotypes was determined by identifying the total bacterial DNA and DNA of Firmicutes, Bacteroidetes, and Actinobacteria using the method of quantitative real-time polymerase chain reaction. The Firmicutes/Bacteroidetes ratio was calculated additionally.
Results
In patients with arterial hypertension and abdominal obesity (total group) significant increasing of the relative content of Firmicutes compared with the control group was observed (45.42 [33.24; 55.07] % vs 29.18 [22.45; 38.14] %, $P < 0.01$), in the absence of a significant difference with the relative content of Bacteroidetes and Actinobacteria. The Firmicutes/Bacteroidetes ratio was significant higher in total group in comparison with control group (1.59 [1.04; 5.17] vs 0.92 [0.64; 2.37], $P < 0.01$). In patients with arterial hypertension and abdominal obesity with pre-diabetes in comparison with those without disorders of carbohydrate metabolism found significant increasing of the relative content of Firmicutes (51.12 [29.78; 68.51] % vs 40.73 [21.53; 57.14] %, $P < 0.01$) and the Firmicutes/Bacteroidetes ratio (1.84 [1.24; 5.68] vs 1.35 [0.96; 4.64], $P < 0.01$). The relative contents of Bacteroidetes and Actinobacteria were not significant differ in main and comparison groups ($P > 0.05$).
Conclusion.
The results of the study may indicate a significant role of the gut microbiota in the development of initial disorders of carbohydrate metabolism in patients with arterial hypertension and abdominal obesity. The relative content of the Firmicutes and the Firmicutes/Bacteroidetes ratio can be considered as important markers of pre-diabetes in indicated patients.

Effects of Glucagon-Like-Peptide-1 analogue treatment in genetic obesity

Mila Welling[1,2,3], Cornelis de Groot[1,3,4], Lotte Kleinendorst[5], Bibian van der Voorn[1,2,3], Jansteven Burgerhart[6], Eline van der Valk[1,2], Mieke van Haelst[5,7], Erica van den Akker[1,3] & Elisabeth van Rossum[1,2]
[1]Erasmus MC, University Medical Center Rotterdam, Obesity Centre CGG; [2]Erasmus MC, University Medical Center Rotterdam, Department of Internal Medicine, division of Endocrinology; [3]Erasmus MC, University Medical Center Rotterdam, Department of Pediatrics, division of Endocrinology; [4]Willem-Alexander Children's Hospital, Leiden University Medical Center, Department of Pediatrics division of Endocrinology; [5]Amsterdam UMC, University of Amsterdam, Department of Clinical Genetics; [6]Sint Jansdal Hospital, Department of Internal Medicine; [7]Amsterdam UMC, Vrije Universiteit Amsterdam, Department of Clinical Genetics

Introduction
Obesity is highly prevalent, comes with serious health burden and is difficult to treat. In a minority, there is a genetic cause for the obesity. In these patients, therapy-resistant obesity is often observed despite intensive lifestyle treatment. Moreover, it is still unclear whether bariatric surgery is less successful in genetic obesity. Liraglutide is a Glucagon-Like-Peptide-1 (GLP-1) receptor agonist or GLP-1 analogue, showing positive effects on metabolic parameters, satiety and weight loss in lifestyle-induced obesity. We present our experiences of GLP-1 analogue treatment in patients with genetic obesity disorders.
Methods
Adults with overweight or severe obesity and a molecularly proven genetic cause were treated with liraglutide 3.0 mg daily, in addition to ongoing intensive supportive lifestyle treatment. Anthropometrics, metabolic parameters, resting energy expenditure (REE), side effects, and subjectively reported satiety and quality of life were assessed.
Results
Two patients with a heterozygous pathogenic melanocortin 4 recepter variant and two patients with 16p11.2 deletion syndrome, ranging in age between 21 and 32 years and in BMI between 28.1 and 55.7 kg/m^2 at baseline, were treated. At end of follow-up, ranging between 33 weeks and 12 years, a mean change in BMI and waist circumference was observed of –5.7 ± 3.8 kg/m^2 and –15.2 ± 21.1 cm, respectively. All patients reported better quality of life, three of them also reported improved satiety. Moreover, improvement of metabolic parameters was seen. No clear effect on REE was observed. Two patients experienced mild side effects, e.g. nausea and stomach pain, for a brief period.
Conclusion
We here show beneficial effects of GLP-1 analogues on weight, metabolic parameters, and quality of life in four patients with genetic obesity. Satiety improved in three of the four patients. All patient achieved at least the clinically relevant 5–10% weight loss. Our findings suggest that GLP-1 analogue treatment might be an effective treatment option, in addition to a healthy lifestyle, for patients with genetic obesity.

Effect of elevated hemoglobin A1c on complication rates after bariatric surgery: a retrospective cohort study

Willy Theel, Janneke Wiebolt, Silvia Eskes & Francoise Klessens
Franciscus Gasthuis & Vlietland, Internal Medicine, Rotterdam, Netherlands

Objective
The aim of this study is to evaluate whether an increased preoperative hemoglobin A1c (HbA1c) is a risk factor for postoperative complications.
Methods
We retrospectively reviewed a database of patients who underwent a laparoscopic sleeve gastrectomy or a laparoscopic gastric bypass. The database was split into two cohort according to the preoperative HbA1c (> or ≤ 7 mmol/l).
Results
We included 250 patients in both groups. There were 31 complications (12.4%) in the group with a preoperative HbA1c ≤ 7 mmol/l and 50 (20%) in the group with a preoperative HbA1c > 7 mmol/l (P = 0.057). The preoperative HbA1c is a predictive risk factor for patients younger than 52 (OR = 1.031, 95%CI (1.009–1.053)/P = 0.005) but not for those older than 52 (OR = 1.009, 95%CI (0.985–1.033)/P = 0.48).
Conclusions
In this study an increased preoperative HbA1c (> 7 mmol/l) was associated with a greater risk for postoperative complications in bariatric patients younger than 52 years old, although the magnitude of this risk may be clinically less relevant.

AEP282

Role of sarcopenia in cognitive function in patients with morbid obesity before bariatric surgery

Andreu Simó-Servat[1], Montserrat Ibarra[1], Mireia Libran[1], Maite Valverde[1], Veronica Perea[1], Luis García-Pascual[1], Aida Orois[1], Carmen Quirós[1], Laura Casas[2] & Maria Jose Barahona Constanzo[1]
[1]Universitari Mutua de Terrassa, Endocrinology, Terrassa, Spain; [2]Hospital Universitari Mutua de Terrassa, Neurology, Terrassa, Spain

Aim
Obesity was shown to be related to global cognitive decline, being especially altered the executive function and the information processing speed. Additionally, sarcopenic obesity (SO) was associated independently with a deterioration in global cognition, executive function, information processing speed, global memory and cerebral atrophy in patients > 65 years. However, at present there is no data regarding the role of sarcopenia in the cognitive function in patients with morbid obesity (MO) < 65 years.
Material and methods
Cross-sectional study. Forty-three patients that will undergo Y-de- Roux gastric by-pass were selected from those attended at the MO Unit of our hospital. Body composition by bioimpedance analysis (BIA) and Neurocognitive Test Battery (NTB) were assesed in all patients 1 month prior bariatric surgery (BS). For identifying subjects with SO by BIA, we used the skeletal muscle mass index (SMI) (SM/height^2). We set that obese subjects from the lowest tertile of SMI were sarcopenic whereas those from the two highest tertiles were not.
Results
Thirteen patients were allocated in the SO group and 26 in the non-SO group. All patients in the SO group were female (100% vs 58%), older (59 ± 5 vs 51 ± 8 years), with lower BMI (41 ± 1.3 vs 45 ± 5 kg/m^2), higher fat mass (%) (50 ± 4 vs 43 ± 8) and lower claw force by hand dynamometer (21 ± 4.5 vs 31.5 ± 10) (P < 0.005). SO group had worse performance (raw score) in inverse visual span [3(2–5) vs 4(3–7)], Trail Making Test A [47(32–99) vs 38(15–98)], Trail Making Test B [133(74–300) vs 86(36–300)] and Symbol Digit Test (31 ± 13 vs 42 ± 13) (P < 0.005). No differences were observed in educational level between both groups. The 4 cognitive tests correlated with age (P < 0.005). After regression analysis, age and the presence of SO significantly correlated with Trail Making Test B and Symbol Digit Test, but only was the inverse visual span test that correlated with SO (ń0.459, P < 0.05), losing the correlation with age.
Conclusions
Sarcopenia could play a role in impaired executive function and information processing speed in a cohort of patients with MO < 65 years. Larger series are needed in order to confirm this preliminary results.

AEP283

Diabetic nephropathy in absence of diabetic retinopathy in type 2 diabetes mellitus patients

Rahma Khalaf, Zohra Hadj Ali, Yosra Htira & Faika Ben Mami
National Institute of Nutrition, Tunis, Tunisia

Background
There is a well-recognized association between diabetic retinopathy (DN) and diabetic nephropathy (DN), in which nephropathy without retinopathy is rare but retinopathy without nephropathy is common.
Aim
To highlight the discordance between retinopathy and nephropathy and describe a series of patients with diabetic nephropathy who had no evidence of diabetic retinopathy.
Methods
110 type 2 diabetes patients with diabetic nephropathy were studied retrospectively. Patients with clinical suspicion of non diabetic nephropathy were excluded. The patient's age, gender, body mass index, duration of diabetes, glycosylated hemoglobin (HbA1c), low density lipoprotein cholesterol and presence of diabetic peripheral neuropathy were determined.
Results
Of the study population, 31 patients (28.18%) had no evidence of diabetic retinopathy. 51.61% were male. Median age was 56 ± 15 years. The mean duration of diabetes was 12 ± 5 years, mean body mass index was 28.72 ± 4.3 kg/m^2 (overweight), mean low density lipoprotein cholesterol was 1.25 ± 0.3 g/l. All patients had poor glycemic control with a mean HbA1c of 10.3%, 51.61% had treated hypertension, 32.26% had diabetic peripheral neuropathy. 58.06% had albuminuria without renal failure, 41.92% had renal failure without albuminuria: mean estimated glomerular filtration rate (eGFR) was 50 lm/min/1.73 m^2.
Conclusion
We have identified a subset of patients with diabetic nephropathy but who are protected from retinopathy. It is possible that there is an extreme phenotype of diabetic patients with unaffected eyes who carry genes protecting against DR.

Management of emphysematous pyelonephritis: Report of Two Cases

Bel Hadj Sliman Chayma, Sabrina Ayari, Bchir Najla, Zouaoui Chadia & Ouertani Haroun
Military Hospital of Tunis, Endocrinology-Nutrition, Tunis, Tunisia

Introduction
Emphysematous pyelonephritis (EPN) is a necrotizing infection of the renal parenchyma which occurs preferentially in diabetics and is fraught with heavy mortality. Adequate therapeutic management is controversial: medical or surgical, conservative or radical. We report two observations of emphysematous pyelonephritis in two female diabetic patients, aged 58 and 50 years old, respectively.
Observation
The symptoms were similar for both patients: fever, lower back pain, renal angle tenderness, dysuria, hyperglycemia and ketonuria. Blood tests indicated an inflammatory syndrome, acute renal failure and diabetic ketoacidosis. The urinalysis revealed pyuria, leukocyturia and a varied bacterial flora. The urine's culture of the first patient yielded a growth of Candida whereas E.coli was isolated in the second patient. In both cases, renal ultrasound showed uretero-pelvic dilation upstream of a stone embedded in the meatus and CT-scan confirmed the diagnosis of EPN. The outcome of conservative management was different for both patients. The first patient was successfully treated with conservative management using broad-spectrum antibiotic and percutaneous drainage. However, despite percutaneous drainage and antibiotic therapy, subsequent nephrectomy was required for the second patient as she presented a septic shock. The outcome was favorable in both cases after conservative management in the first case and radical management in the second case.
Conclusion
EPN is a life-threatening infection that should be suspected in any diabetic with severe acute pyelonephritis resistant to medical treatment. In case of failure of conservative treatment, nephrectomy should be considered.

AEP285

Association of metabolic syndrome and hepatic steatosis in type 2 diabetics

Abdessamad Malki, Messaoudi Najoua, Imane Assarrar, Siham Rouf & Hanane Latrech
Mohamed VI University Hospital Center, Oujda, Department of Endocrinology and Diabetology, Oujda, Morocco

Introduction
Metabolic steatopathy or non-alcoholic fatty liver disease (NAFLD) and type 2 diabetes (T2DM) are common diseases that regularly coexist and can act in synergy by increasing the risk of metabolic complications and cardiovascular events. NAFLD seems to be frequently associated with metabolic risk factors reflecting the metabolic syndrome. The aim of this study is to analyse the characteristics of this association in type 2 diabetics.
Materials and methods
This is a retrospective and descriptive study, including 190 type 2 diabetic patients, hospitalised in an Endocrinology-Diabetology department over a period of 6 years. All the patients benefited from an abdominal ultrasound with NAFLD search, and were monitored by our centre's hepato-gastroenterology department as part of a multidisciplinary care programme. The data were exploited by SPSS-V21.
Results
Among the 190 participants in the study, NAFLD was found in 51% patients. The mean age of our patients was 59.7 ± 11.6 years, with a female predominance of 73.2%. The mean initial HbA1c was 10.1 ± 2.1%, with a mean duration of diabetes of 9.8 ± 7.9 years. Patients had hypertension (57.7%), obesity (55%), abdominal obesity (78%) and metabolic syndrome in 88.7% of cases. 89.6% had dyslipidemia, hypertriglyceridemia in 45.4% and hypoHDLemia in 75.8%. Macroangiopathic complications were present in 25.8% of patients and microangiopathic complications in 36.1%. The management of NAFLD consisted of optimal glycemic control through lifestyle modification alone (56.7%), with metformin (16.5%). 5.2% of patients were treated with liraglutide.
Discussion-conclusion
NAFLD is a common comorbidity during diabetes type 2. It is frequently associated with the metabolic syndrome. Thus, early screnning of NAFLD in type 2 diabetes is recommended, with multidisciplinary management by reducing the modifiable metabolic risk, optimal glycemic control and optimisation of weight loss to limit the progression of the disease.

Brain perfusion in patients with type 1 diabetes and cognitive dysfunction

Mariia Matveeva[1], Julia Samoilova[2] & Olga Tonkih[3]
[1]Siberian State Medical University, Departments of General Practise and outpatient therapy, Tomsk, Russian Federation; [2]Siberian State Medical University, Department of of Therapy with a Course in Clinical Pharmacology, Tomsk; [3]Siberian State Medical University, Department of tomographic research methods, Tomsk, Russian Federation

Purpose of the study
Evaluation of cerebral microcirculation using contrast and non-contrast magnetic resonance perfusion in patients with type 1 diabetes and cognitive dysfunction.
Material and methods
The study complied with generally accepted ethical rules. The study included 45 patients with type 1 diabetes mellitus with cognitive dysfunction and 20 patients without. All patients were continuously monitored glycemia. Magnetic resonance imaging was performed on a Signa Creator 'E' magnetic resonance imaging machine, GE Healthcare, 1.5 Tesla, China: the techniques were dynamic contrast ('Gadovist', IV, bolus, 5 ml) and arterial spin labels.
Results
We found decreased blood flow velocity in patients with type 1 diabetes and cognitive dysfunction in the white and gray matter areas of the frontal, occipital and temporal lobes $P \leq 0.05$). Hyperglycemia and the following glycemic variability indices - index of long-term glycemic increase, risk of hyperglycemia and hypoglycemia, rate of glycemic change, indicator of glycemic control quality - have the greatest effect on cortical structures according to perfusion data, and in case of uncontrasted glycemic control quality and rate of change, risks of hypo and hyperglycemia. The main factors of cerebral microcirculatory changes are history of severe hypoglycemia episodes, duration of disease, arterial hypertension and elevated cholesterol levels.
Conclusion
The level of glycated hemoglobin and glycemic variability, as well as acute complications, duration of DM, and associated conditions (arterial hypertension and hypercholesterolemia) underlie microcirculatory impairment of the brain in type 1 diabetes. The most significant data were obtained with contrast perfusion.

Predictive factors associated with diabetic kidney disease in adult-onset Type 1 Diabetes

Hadj Kacem Faten, Khouloud Boujelben, Allymamod Bibi Twaheerah, Safi Wajdi, Mnif Fatma, Mnif Mouna, Charfi Nadia, Rekik Nabila & Abid Mohamed
Hedi Chaker Hospital, Sfax, Tunisia, Department of Endocrinology, Diabetology

Introduction
Uncontrolled hyperglycemia of diabetes is a common cause of renal failure and diabetic nephropathy, which is also called diabetic kidney disease (DKD). Despite improvements in the management of type 1 diabetes (T1D), progression of diabetic nephropathy remains unpredictable and associated with high morbidity and mortality. The objective of this study is to assess the prevalence and risk factors for diabetic kidney disease among adults-onset T1D.
Patients and methods
A retrospective study, from 2010 to 2019, including 166 patients diagnosed with T1D, occurred after the age of 20, with positive anti-pancreatic antibodies (Anti GAD,Anti ICA and /or Anti IA2). The incidence of DKD and its potential predictive factors were analyzed.
Results
Our study includes 71 women and 95 men, with mean diabetes duration of 7.34 ± 6.73 years (2 months-44.5 years).The mean age was 31.81 years. DKD was observed in 6% of patients after a mean diabetes duration of 23 ± 8.3 years.By the time of diagnosis of DKD, mean age was 41.7 ± 7.2 years. Approximately 80% of patients who had been diagnosed with DKD were hypertensive. The mean systolic and diastolic BP were 139.01 ± 24.55 mm Hg and 77 ± 11.6mmHg,respectively. The mean urea and creatinine levels were 16 ± 9.12 mmol/l and 241.6 ± 160.2 umol/l,respectively. Seven patients underwent hemodialysis for end-stage renal disease. Diabetes duration was a significant predictor of incident DKD ($P < 0.05$). T1D adults with diabetic nephropathy were older than those with normal renal function (41.7 ± 7.92 vs 31.18 ± 31.18 years; $P < 0.05$). Significant linear trends were observed for hig systolic and diastolic blood with increasing creatinine level ($P < 0.05$). Adults with diabetic retinopathy have a significant high prevalence of DKD (90%) ($P < 0.05$). DKD is significantly more prevalent among T1D adults who have been diagnosed with macrovascular compared to those without macrovascular damage (90% vs 2.6%; $P < 0.05$). High triglycerides and total cholesterol levels have also been associated with a heightened risk of DKD ($P < 0.05$).
Conclusion
Identification of predictive factors of DKD is a crucial step in the management of patients diagnosed with T1D during adulthood. Linear relationship of diabetic nephropathy was found with diabetes duration, age, macrovascular complications and perturbed lipid profile. Then, further studies are needed to better identify these factors and facilitate monitoring of T1D patients.

The impact of printed educational materials on knowledge in women with gestational diabetes mellitus

Radiana Staynova[1] & Emanuela Vasileva[2,3]
[1]Medical University - Plovdiv, Department of Pharmaceutical Sciences, Plovdiv, Bulgaria; [2]Medical University - Plovdiv, Propedeutics of Internal Diseases, Plovdiv, Bulgaria; [3]UMHAT Kaspela, Clinic of Endocrinology and Metabolic Diseases, Plovdiv, Bulgaria

Aim
To evaluate the impact of printed educational materials on knowledge in women with gestational diabetes mellitus (GDM).
Materials and methods
A randomized controlled trial was performed among women with GDM. A total of 135 pregnant women with GDM who attended antenatal clinic were randomly assigned to either an intervention (45 pregnant women) or a control group (90 pregnant women). The women from intervention group received additional printed educational materials about GDM management, while patients from control group received standard care. A self-administrated questionnaire was used for evaluation of women's knowledge about GDM management. Data was statistically processed using SPSS ver. 17.
Results
Demographic and maternal characteristics were similar in both groups. The overall mean age was 32.3±4.9 years ranging from 24 to 45. The correct

answers about knowledge of diabetes complications were reported in more than 50% of women in both groups. There was a significant difference in knowledge about the risk factors for GDM (85% in intervention group vs 44% in control group, $P < 0.01$). The number of correct answers were higher in the intervention group in regard of GDM treatment (92% compared with 79% in control group, $P < 0.01$), self-monitoring of blood glucose and outcomes of GDM ($P < 0.01$). The differences in nutritional knowledge were not statistically significant.
Conclusion:
The results from the study show that printed educational materials can improve patients' knowedge about GDM management as well as their health literacy and motivation.

AEP289

The effect of empagliflozin on main cardiovascular risk factors in patients with type 2 diabetes with normal and excessive body weight

Oksana Didushko & Olena Kobrynska
Ivano-Frankivsk National Medical University, Endocrinology, Ivano-Frankivsk, Ukraine

Aim
Study the efficacy of empagliflozin effects on main cardiovascular risk factors in non-insulin-dependent diabetic patients with normal and excessive body weight.
Objectives
60 patients with type 2 diabetes who have been taking metformin for at least 6 months but haven't reached the target level of glycated haemoglobin (HbA1c), as well as 10 healthy individuals were examined. Depending on the prescribed treatment patients with type 2 diabetes were randomly split into 4 groups: IA and IIA – patients with normal body weight, IB and IIB – overweight patients. IA and IIA patients took individual doses of metformin, IB and IIB patients took empagliflozin at a dose of 10 mg/day in addition to metformin.
Results
After a 6-month course of treatment, the dynamics of blood pressure (BP) has become more pronounced due to the complex treatment as compared with basic therapy. Systolic BP has decreased by 11.82% ($P < 0.05$) in IB group and by 12.4% ($P < 0.05$) – in IIB group, diastolic BP has decreased by 8.15% ($P < 0.05$) and 8.3% ($P < 0.05$) respectively. The treatment has resulted in a positive dynamics of carbohydrate metabolism, which was statistically more significant in patients of IB and IIB groups than in IA and IIA groups: fasting glycaemia in patients of IB group has decreased by 27.19% ($P < 0.05$), the level of HbA1c – by 10.13% ($P < 0.05$), in patients of IIB group – by 16.28% ($P < 0.05$) and 11.1% ($P < 0.05$), respectively. In our opinion, a statistically significant ($P < 0.05$) decrease of HOMA IR index by 41.9% in patients of IIB group is of great importance, in other groups no statistically significant changes have been found. During treatment no statistically significant decrease in body mass index (BMI) was observed in patients of IA, IIA and IB groups, while in patients of IIB group this index has decreased significantly ($P < 0.05$) from 27.82 ± 0.35 up to 25.1 ± 0.50 kg/m^2. Statistically significant effect of empagliflozin on leptin levels has been revealed. It has decreased by 29% ($P < 0.05$) in patients with normal BMI in IB group, and by 39.5% ($P < 0.05$) – in the group of overweight patients (IIB). Patients not taking empagliflozin haven't presented any statistically significant dynamics of leptin levels.
Conclusions
Empagliflozin has a significant effect on the main cardiovascular risk factors: it helps to reduce body weight, waist circumference, BP, leptin levels, carbohydrate metabolism and insulin resistance.

Gestational diabetes:predicting factors for switch to insulin

Zeineb Bargaoui, Zohra Haj Ali, Amal Salem, Yosra Htira & Faika Ben Mami
National Nutrition Institute, Tunisia

Introduction
Insulin therapy in gestational diabetes (GD) is the second line of therapy after failure of diet rules (DR). The aim of our study was to determine the predictive factors for switching to insulin in gestational diabetes.
Method
This is a descriptive cross-sectional retrospective study, including 82 patient files followed at the gestational diabetes unit of the National nutrition institute.
We analysed
Age, term of pregnancy at first consult, initial blood sugar level, family history of diabetes cases, pre-conceptional Body Mass Index (BMI), weight gain during pregnancy and obstetric history.
Results
The average age of our population was 33.5 years (19–44 years). The average pre-conceptional BMI was 29 kg/m^2 (18–47.2 kg/m^2).The average GD discovery term was 28 weeks. A family history of diabetes cases was found in 46.3% of the cases. The average gestity was 3 and the average parity was 2. The history of GD was found in 13.4% of cases, a fetal death was found in 11% of cases and fetal macrosomia in 12.2% of cases. The diet rule lead to achieve glycemic targets in 77.5% of patients and a switch to insulin therapy was imperative in 22.5% of cases. The average of HBa1c was 5.2%. No significant relationship was found between age, preconceptionl BMI, weight gain during pregnancy, and use of insulin therapy during GD. The use of insulin was more frequent when there is a history of foetal macrosomia ($P = 0.022$), when the term of discovery of GD is early (less than 24 weeks) ($P = 0.045$), when initial blood sugar level > 1 g/l ($P = 0.045$) and increased pregnancy ($P = 0.042$).
Conclusion
In our study, history of macrosomia, early discovery term of GD, baseline blood glucose > 1 g/l and numerous pregnancies are predictors of insulin use during GD. In the presence of these factors, an intensification of DR and closer monitoring should be implemented for better management.

Clinical research out of insulin glargine u300 in type 1 diabetes mellitus patients with frequent hypoglycemia: a real world experience

Savas Volkan Kisioglu[1,2], Ahmet Suat Demir[2], Damla Tufekci[3], Yasemin Emur Gunay[2], Hulya Coskun[2], Ozge Ucuncu[2], Irfan Nuhoglu[2], Mustafa Kocak[2], Serdar Karakullukcu[3] & Halil Onder Ersoz[2]
[1]Health Sciences University Kanuni Training and Research Hospital, Department of Endocrinology; [2]Karadeniz Technical University, Department of Endocrinology, trabzon, Turkey; [3]Bayburt Community Health Center, Community Health Center, Turkey

Aims/Introduction
We aimed to see whether Insulin Glargine U300 can provide better blood glucose control while reducing hypoglycemia in a more homogeneous population compared to previous studies.
Materials and methods
For evaluation of FBG, HbA1c and weight at 6 months and all variables final, observation windows of 120–240 days (4–8 months) and 240–480 days (9–16 months) after Insulin Glargine U300 initiation, respectively, were permitted. Hypoglycemia was defined as blood glucose level < 70 mg/dl, either symptomatic or asymptomatic, or measured in hospital or at home.
Results
The 35 patients comprised, 20 (57.1%) female and 15 (42.9%) men with a mean age of 24.1 ± 6.6 years. Mean BMI was 24.4 ± 7.4 kg/m^2. Pre-study treatment regimens were given Table 1. A significant decrease was not found between baseline and HbA1C values in 6 month ($P = 0.199$) but in follow-up period (between 9–16 month) significant decrease was found ($P = 0.025$) (Table 2.). Hypoglycemic events occurred in all patients (100%) before using Insulin Glargine U300, while the incidence of hypoglycemic events gradually decreased to 74.3%, 68.6% and 68.6% between months 1–3, 3–6 and 6–9 respectively. Of the 26 patients that declared their satisfaction, 23 (88.5%) of them were satisfied, 2 (7.7%) of them indicated that there was no significant difference, and 1 (3.8%) patient was unsatisfied.
Conclusions
Over 9 – 16 month follow up period, Insulin Glargine U300 led to a significant reduction not only in HbA1c levels but also in the frequency of hypoglycemia, and also yielded high satisfaction rates.

Table 1. Pre-study treatment regimens

Treatment	n (%)
Basal insulin + bolus insulin	35 (100)
IGlar U100	28 (80)
Insulin Detemir	7 (20)
Insulin Aspart	23 (65.7)
Insulin Lispro	8 (22.2)
Insulin Glulisin	4 (11.1)

A survey of nutritional issues in type 2 diabetes among patients in khorezm region of uzbekistan

Malika Rakhmetova
Urgench Branch of Tashkent Medical Academy, Nursing Education, Urgench, Uzbekistan

Purpose of the study
In Uzbekistan, more than 80% of patients with type 2 diabetes mellitus have uncompensated diabetes, including those receiving adequate free drug therapy. This is mainly due to the neglect of non-drug measures and unhealthy diets. The purpose of the study was to establish the reasons for patients' non-compliance with nutritional rationalization prescriptions, on the example of the Diabetes School at Khorezm Regional Endocrinology Center.
Methodology
An examination of 54 patients with type 2 diabetes mellitus, including a comparison of fasting and prandial blood sugar levels, of HbA1c, combined with an adherence survey. The survey had a question on digital literacy (capacity to use IT for remote consultations).
Results
Only 3 patients in the sample registered target levels of carbohydrate metabolism (HbA1c less than 7%, fasting sugar less than 7 mmol/l, prandial glycemia less than 10 mmol/l). Based on levels of compliance with nutritional rationalization, patients were divided into three categories: 22 (40.7%) patients with a negative attitude to any dietary restrictions, 26 (48.2%) patients wishing but lacking knowledge about correct nutrition, and 6 (11.1%) patients who were compliant and knowledgeable about nutritional rationalization. But only 3 of them had compensated diabetes. The respondents believed that the reasons for the ineffectiveness of the diet therapy are outdated nutritional traditions, the impact of food advertising, aggressive advertising of dietary supplements and the consumption of excessive amounts of processed foods, as well as the high salt, sugar and fat content in locally popular foods (e.g. bread and biscuits). Of 54 patients, only 6 (9.3%) were capable to use IT for remote consultation.
Conclusions
Regular workshops at the Diabetes Schools are not effective since they don't offer tailored approach sensitive to the stage of the disease, its complications, age, gender, diabetes treatment, dietary habits, marital status, financial security and employment. Remote observation will not work for the elderly and digitally illiterate patients and will be limited to better educated patients active in the workforce. For sufficient glycemic control, the efforts of the endocrinologist and patients is to be combined with relevant policies at the level of the medical practice and research communities, the food industry and government agencies.

AEP293

Effectiveness of semaglutide in obese patients with type 2 diabetes. a six-month clinical experience

Andrea Fernández Valero, José Ignacio Martínez Montoro, Ana María Gómez Pérez, Miguel Damas-Fuentes & Francisco José Tinahones Madueño
Hospital Universitario Virgen de la Victoria, Endocrinology and Nutrition, Málaga, Spain

Introduction
Semaglutide is a glucagon-like peptide-1 receptor agonist which has shown important benefits in patients with type 2 diabetes mellitus (T2DM) in randomized clinical trials. Its commercialization in Spain began in May of 2019. The main purpose of this study was to analyze the effectiveness of this drug into routine clinical practice in patients with T2DM with a body-mass index above 30 kg/m^2.
Matherial and methods
Retrospective observational study including demographic, analytical and clinical features of 27 patients in whom semaglutide was started. The beginning dose was 0.25 mg once-weekly during the first month, and after this period of time it was increased to 0.5 mg once-weekly. A second follow-up visit was performed 6 months after the drug was started, with the aim of evaluating the impact of its use.
Results
Data of 27 patients (14 men and 13 women) with TD2M were analyzed. The overall mean age was 60.1 ± 11 years, with a mean time of evolution of the disease of 8.7 ± 6.5 years. The 18.5% of them had established cardiovascular disease (coronary heart disease). Basal characteristics of the population at the beginning: BMI 42.3 ± 8.3 kg/m^2; weight 116.8 ± 30.3 kg; HbAa1c 8.2 ± 1.6%; fasting blood glucose 166.7 ± 55.6 mg/dl; blood pressure 149.5 ± 22.2/84.8 ± 12.6 mm Hg. The number of antidiabetic drugs was 1.44 ± 0.75 before starting semgalutide (85% of the patients were receiving metformin, 26% SGLT-2 inhibitors, 26% GLP-1 RA, 11% sulfonylurea and 7% DPP-4 inhibitors). 37% of the patients were treated with insulin therapy. At six-months follow-up visit, significant mean reductions of BMI (39.9 ± 7.1 kg/m^2), weight (110.7 ± 25.9 kg), HbA1c (6.6 ± 1.1%) and fasting blood glucose (116.4 ± 24.9 mg/dl) were obtained. After this, 85% of the patients treated with metformine and 48% with SGLT-2 inhibitors. Sulfonilureas were discontinued in all patients. The DPP4 inhibitors were discontinued when semaglutide was started. The percentage of patients with insulin therapy did not change.
Conclusions
Semaglutide is an effective pharmacologic agent for the treatment of T2DM in terms of metabolic control (HbA1c reduction) and weight reduction.

Serum ferritin levels correlate with ultrasonography-determined liver steatosis severity in type 2 diabetes patients with NAFLD

Bojan Mitrovic[1], Vladimir Samardzic[2], Zoran Gluvic[1], Ratko Tomasevic[3], Milan Obradovic[4], Emina Sudar-Milovanovic[4] & Esma R. Isenovic[4]

[1]Zemun Clinical Hospital, Department of Endocrinology, Diabetes and Medicine ITU, Zemun, Serbia; [2]Zemun Clinical Hospital, Department of Endocrinology and Diabetes, Zemun, Serbia; [3]Zemun Clinical Hospital, Department of Gastroenterology, Zemun, Serbia; [1]'VINńA' Institute of Nuclear Sciences- National Institute of the Republic of Serbia, Laboratory for radiobiology and molecular genetics, Belgrade, Serbia

Introduction
Non-alcoholic fatty liver disease (NAFLD) is a component of metabolic syndrome (MetS). Hence, it is frequently associated with type 2 diabetes mellitus (T2DM). The low-grade inflammation associated with NAFLD usually explained the changes in serum iron metabolism. This study aims to assess the link between liver steatosis severity and serum iron, ferritin, and transferrin levels.
Material and methods
A case-control study involved 30 non-obese subjects (BMI 18.5–30 kg/m^2), who suffered from T2DM for less than 5 years. Such subjects are regularly under treatment by metformin (M) and sulphonylurea (SU) derivates. Liver steatosis severity is determined by ultrasonography and presented as grades 1, 2, and 3 (initial, moderate, and advanced liver steatosis), respectively, according to Singh *et al*. criteria (Singh *et al*. Indian J Endocr Metab 2013;17: 990–5).
Results
In the observed population, 14 (47%), 11 (36%), and 5 (17%) subjects are determined to grade 1, 2, and 3 liver steatosis severity groups, respectively. The mean values of iron homeostasis markers have not differed from normal values. Liver steatosis severity grades positively correlated with serum ferritin levels, and this correlation is not revealed in the cases with serum iron and transferrin levels.
Conclusion
The low grade of liver steatosis has predominated in non-obese T2DM subjects under treatment with M and SU, irrespective of glycemic control quality. An increase in liver steatosis severity follows the ascending trend of ferritin levels. Further studies are needed to elucidate the impact of the quality of T2DM control on liver steatosis severity and iron metabolism markers.

Risk factors for diabetes mellitus in a high-risk population: About 500 cases

Samira Belkacem
Endocrinology, Pierre Marie Curie Center, of Medecine, Algiers, Algeria

Introduction
The prevalence of diabetes and pre-diabetes is steadily increasing. It affects 3 new cases every 10 seconds and more than 6 million per year. Objective: to determine the risk factors associated with diabetes in an Algiers population not known to be diabetic but at high risk.
Methods
500 patients aged 40 and over consulting at the level of primary care structures, volunteers but at high risk of diabetes, are subjected to a questionnaire, then to screening by carrying out an OGTT, an HbA1c (HPLC), an SNSF. The sensitivity and specificity of HbA1c at different thresholds for the diagnosis of diabetes and pre-diabetes were studied by ROC curve. The diagnostic performance of HbA1c was assessed by the areas under the ROC curve (AUC) estimated by the DeLong method.
Result
Among the 500 patients studied 69% are women and 31% are men with a sex ratio of 2.22. Of which half of the cases aged between 45–54 years. 53.2% of patients present with dysglycemia: including 29.4% pre-diabetes: (6.8% moderate fasting hyperglycemia (HMJ), 22.6% (Glucose intolerance) and 23.8% diabetes mellitus. The risk factors associated with diabetes in our population in descending order are:
• Excess weight (BMI ≥ 25 kg/m^2) (P < 0.001).
• Male sex. (p: 0.025).
• Age ≥ 45 years (p: 0.033).
• Maternal family history of diabetes mellitus. (P: 0.042)
• waist/hip ratio ≥ 0.85 (android type) in women (P: 0.043)
• high blood pressure (P: 0.045).
Conclusion
Diabetes mellitus is a major public health problem around the world. It is unfortunately associated with the development of serious complications, which have a significant impact on morbidity and mortality. Early diagnosis could reduce and delay these complications, so it is important to identify pre-diabetic conditions early so that prevention efforts can be implemented by targeting these populations, and thus help prevent or slow down. the progression of this condition to overt diabetes.

Newly diagnosed diabetes in pregnancy among bulgarian pregnant women - national screening in 2019

Boyana Trifonova[1], Anna-Maria Borissova[1], Lilia Dakovska[2], Eugenia Michaylova[3] & Mircho Vukov[2]
[1]University Hospital Sofiamed, Medical Faculty, Sofia University St Kliment Ohridski, Clinic of Endocrinology and Metabolic diseases, Medical Faculty, Sofia, Bulgaria; [2]UMHAT Sofiamed, Clinic of Endocrinology and Metabolic diseases, Sofia, Bulgaria; [3]MLD Bodimed, Sofia, Bulgaria

According to the FIGO (2015) and later WHO (2019) classifications, hyperglycaemia detected for the first time during pregnancy may be associated with Diabetes In Pregnancy (DIP) or Gestational Diabetes mellitus (GDM).
Aim
To specify the frequency and type of newly diagnosed diabetes during pregnancy in the Bulgarian population of women.
Material
We studied 547 pregnant women with a mean age of 30 ± 5 years, through a cross-sectional multicenter population-based study in 84 settlements in Bulgaria.
Methods
A two-hour, 75 g oral glucose tolerance test (OGTT) was performed in one Central laboratory on the day of the blood sampling. The statistical analysis was performed using standard SPSS 13.0 for Windows.
Results
Hyperglycaemia was observed in 14.4% (79/547) pregnant women after fasting state or in the course of classic OGTT, according to the criteria of WHO'2019, FIGO'2015, NICE'2015. It turned out that the number and frequency of pregnant women with Hyperglycemia in the period up to 24 gestational week (g.w.) is 7.5% (29/386) and increases in the period after 24 g.w. reaching 31% (50/161), P < 0.01. Only 8.9% (7/79) of the pregnant women were newly diagnosed with Diabetes mellitus according to the criteria for the general non-pregnant population, ie. Diabetes in Pregnancy (DIP), while the remaining cases met the criteria for GDM - 91.1%.
Conclusion
As soon as pregnancy occurs, it is necessary to perform OGTT to detect undiagnosed Diabetes mellitus (DIP). In the case of a negative result, OGTT is repeated in 24–28 g.w, when the risk of GDM increases.

Effect of yog nidra on the self-estimated levels of stress and epworth sleep score in t2dm patient.

Bharat Saboo[1,2], Shweta Saboo[3] & Hemant Sharma[3]
[1]Prayas Diabetes Center, Diabetology, Indore, India; [2]Prayas for Care of Diabetes Society, Diabetology, Indore, India; [3]Choithram College Indore, Yoga, Shri Ram Talawali, India

Introduction
Stress and anxiety have become major killers in our developed and devloping countries both. Literature has shown reluction in stress results in better owerall well being. lack of sleep is also a contibutor to stress.In T2DM patients this becomes even more important as the have higher oxidative stress, Yoga Nidra is already prescribed by scholars in several countries because of its potential to activate the parasympathetic nervous system and positively influence stress-related parameters such as skin conductivity and cortisol level, which is beneficial for reducing stress related illness and further complications.
Aim
Effect of Yog Nidra on the self-estimated levels of stress and Epworth Sleep Score in T2DM Patient.

Method
The meditation was provided as audio file and carried out during a period of 30 days by the participants of the meditation group.
Method
This study is the first to examine the effects of of Yoga Nidra that was independently conducted by each of the participants using an audio file. Instructions and data collections were carried out via online Survey; the audio file with the Yoga Nidra meditation was provided via download link. No eligibility or exclusion criteria for selection of participants. All subjects participated anonymously and voluntarily. The study was conducted in a pre-post-follow-up design with two measurement points. The intervention period between pre-test and post-test was 30 days;To measure the self-estimated levels of stress and any changes in the course of the study Percieved Stress Score was used.
Result
The meditation group (N = 41) showed Reduction in percieved stress score, Better Epworth Sleep Score (ESS) after the intervention compared with a control group (N = 43).
Discussion
The present study showed the effectiveness of Yoga Nidra and seated meditation in reducing anxiety and stress levels of T2DM Patients when compared to the control group.Yoga nidra is easy to administer, relatively safe and does improve sleep.The model developed for yoga nidra intervention can be used in chronic insomnia patients as an adjunct in management of chronic insomnia. However, more studies, with different groups of all ages and occupations, are necessary to better elucidate the mechanisms through which Yoga Nidra works.

Microbiota disorders in type 2 diabetes and obese patients

Zvenigorodskaya Larissa, Shinkin Mikhail, Anna Akopova & Svetlana Silvestrova
Moscow Clinical research and practice center named after Loginov, Moscow Department of Health, Moscow, Russian Federation

Aim
To assess the effect of Zakofalk in complex therapy in patients with type 2 diabetes and obesity.
Materials and methods
We examined 68 patients with type 2 diabetes and 28 with obesity (body mass index over 30 kg/m^2). The control group consisted of 20 people. The groups were comparable in terms of age, sex, and antihyperglycemic therapy. In addition to a thorough clinical examination of all study participants, the content of short-chain fatty acids (SCFA)took place. SCFA before and after four weeks of Zakofalk therapy. In 45 patients with type 2 diabetes during examination, including capsule endoscopy, endoscopic and histological changes in the lining of the colon were diagnosed, their own previously not diagnosed microischemic colitis. Some patients with type 2 diabetes and obesity have a concomitant disease with irritable bowel syndrome. The results of the study of the SCFA content are presented below. According to the structure of aspen bacterial metabolites of the colon in the study groups, P < 0.05: Butyrate: type 2 diabetes + NAFLD at 19%, the norm at 16% Propionate: type 2 diabetes + NAFLD at 23%, the norm at 20% Acetate: Type 2 DM + NAFLD at 58%, normal at 64% The total concentration of SCFA in patients with type 2 diabetes, P < 0.02: Obesity group: 11.4 ± 4.1 mg/g Type 2 diabetes group: 4.9 ± 1.0 mg/g Norm: 10.6 ± 3.1 mg/g
Conclusions
Thus, the appointment of butyrate seems to be a promising approach to improve the effectiveness of treatment of patients with type 2 diabetes and obesity. The use of butyrate (Zakofalk) in complex therapy leads to a decrease in systemic and local inflammation, regulation of the production of glucagon-like peptide-1 and glucagon-like peptide-2, PYY, reprofiling of the microbiota from lactate to butyrate, a decrease in insulin resistance, an improvement in the glycemic profile, restoration of the visceral barrier intestine, stimulation of its own butyrate-producing microbiota. In the treatment of microischemic colitis, the drug helps to reduce flatulence, abdominal pain, normalize stool, and modify eating behavior.

Evaluation of international experience in the management of patients with diabetes mellitus after liver transplantation

Shinkin Mikhail, Zvenigorodskaya Larissa, Anna Akopova & Ashot Mkrtumyan
Moscow Clinical research and Practice Center Named after Loginov, Moscow Department of Health, Moscow, Russian Federation

Aim
Analyze a number of foreign sources to assess the risks of developing post-transplant diabetes mellitus (PTSD).
Materials and methods
In total, we analyzed more than 70 sources from Western Europe, East Asia and South Africa. Pancreatic ńcell dysfunction, impaired insulin secretion associated with the use of calcineurin inhibitors and inhibitors of the mammalian target of rapamycin complex 1 (mTORC1), postoperative weight gain, and hepatitis C associated with insulin resistance. According to Lv C., Zhang Y and all; Song J.L., Gao W and all; Xue M., Lv C. and all - a quarter of patients without diabetes mellitus developed PTSD at the time of liver transplantation, which corresponded to the previously presented data - from 19 to 35% However, studies by Liu F.C., Lin J.R. and all; Abe T., Onoe T and all reported lower incidence rates of 6 to 8%. According to Aravinthan A.D., Fateen W., Doyle A.C. *et al*., the incidence of PTDM was significantly higher in the early post-transplant period. According to the results of a retrospective study by E.J. Carey *et al*., A 2-fold increase in the risk of developing PTSD is associated with an excess of plasma glucose for every 10 mg/dl before liver transplantation. It has been suggested that a wide range of factors in the recipient and donor, the causes and severity of liver disease, as well as the characteristics and duration of surgery and treatment in the post-transplant period play an important role in the development of PTSD. A meta-analysis of 19 retrospective studies of over 4.500 patients by D.W. Li *et al*., Identified independent risk factors for PTSD. These included male sex, body mass index, etiology of hepatitis C, impaired fasting plasma glucose levels before liver transplantation, and tacrolimus use.
Conclusions
General approaches to the treatment of PTSD have not yet been developed. Patients require individual drug correction under the supervision of an endocrinologist and hepatologist. Of course, it will be more difficult for liver cells burdened with pathologically altered metabolism in diabetes mellitus to cope with toxic effects, because this organ is characterized by a reduced functional reserve. Therefore, when prescribing therapy, preference should be given to drugs that are least metabolized in the liver. In patients with diabetes after liver transplantation, it is necessary to carry out not only adequate immunosuppressive therapy, but also hypoglycemic therapy. Insulin is currently the drug of choice.

Nutritional status of Tunisian women followed for gestational diabetes

Amal Salem, Zohra Haj Ali, zeineb Bargaoui, Yosra Htira & Faika Ben Mami
National Nutrition Institute, Section C, Tunis, Tunisia

Introduction
The respect of dietetic rules constitutes the cornerstone of the management of gestational diabetes (GD). The aim of our study was to describe the spontaneous food intake in Tunisian women followed for GD.
Methods
This is a descriptive and retrospective study, including 82 patients followed at the gestational diabetes unit of the National Institute of Nutrition. We analyzed: age, pre-conceptional body mass index (BMI), weight gain during pregnancy and food survey.
Results
The average age of our population was 33.5 years (19–44 years). The average preconception BMI was 29 kg/m^2(18–47.2 kg/m^2). The average weight gain during pregnancy was 6 kg (–14 to + 37 kg) Pregnant women followed for gestational diabetes were investigated at the average term of

28 weeks. The food survey had found an average intake of carbohydrates, proteins and lipids respectively of 52.5%, 32% and 15.7%. Regarding the food survey, 39.7% of the women had an excessive intake of carbohydrates, 46% had an excessive intake of lipids and 30.2% had a reduced intake of proteins. Daily fiber intake was decreased in 55.6% of women participating in the survey. An iron deficiency was found in the daily food intake in 92% of women. Vitamin D intake was decreased in 96.8% of the population surveyed with calcium intake decreased in 52.4% of cases. The w6/w3 ratio was increased in 79.4% of the women and 84% of the participants had a decreased zinc intake.
Conclusion
Nutritional education targeting the general population should be established in order to limit the consequences of these multiple nutritional deficiencies.

The role of diabetes in the clinical presentation and prognosis of bell palsy

Mohamed Masmoudi[1], Mehdi Hasnaoui[2], Rihab Lahmar[1], Sara Lazid[1] & Mighri Khalifa[1]
[1]Tahar Sfar Hospital Mahdia, ENT Department, Mahdia, Tunisia; [2]Tahar Sfar Hospital Mahdia, ENT Department, Sfax, Tunisia

Objective
to analyze the clinical presentation and prognosis of Bell's palsy in diabetic patients.
Materiel and methods
This retrospective study included 76 diabetic patients with Bell 's palsy in the ENT department of Tahar Sfar Mahdia; Tunisia from January 1988 to December 2018. The system of House-Brackmann was used for assessing the severity of nerve damage.
Results
a total of 76 diabetic patients with Bell's palsy were included in this study. The average age was 46 years (range: 26 and 82 years). In terms of their sex distribution, we found a male dominance (41 men, 35 women). According to the House-Brackmann (H-B) grading system, four patients were diagnosed with grade III, 41 with grade IV, 15 with grade V and 16 with grade VI. All 76 patients received the same therapeutic protocol, which included intravenous administration of prednisolone and acyclovir 500 mg intravenous thrice daily. Serum glucose was monitored thrice daily with finger prick testing and appropriatr treatement was administered according to the instructions of their physician. After a 6-months follow-up, complete recovery was achieved in 60 patients. Three patients presented a grade IV, five patients a grade III and 10 patients a grade II paresis. Recurrence episodes were noted in four patients.
Conclusion
a relationship between the severity of Bell palsy and diabetes seems to be demonstrated. We highlight the importance of glycemic control for prevention as well as the treatment of Bell palsy in diabetic patients.

Poor glycemic control in type 2 diabetes: From eating behavior to therapeutic inertia

Najat Draoui, Abir Tahri, Imane Assarrar, Siham Rouf & Hanane Latrech
CHU Mohammed VI, Oujda, Morocco

Introduction
Adherence to therapy is a common problem, predominating mainly in patients with chronic diseases like diabetes, and it is often associated with inappropriate eating behavior, both of these factors can lead to a poor glycemic control, and of cause a high levels glycated hemoglobin.
Objectives
Evaluate the impact of various parameters (age, gender, duration of diabetes, socio-economic status, polymedication, analphabetism, family situation, etc.) on therapeutic adherence, dietetics and physical activity in poor glycemic control in type two diabetic patients.
Methods
This is a transversal study of one hundred twenty-seven patients that they have poorly controlled diabetes, who were hospitalized in the Endocrinology Department between two thousand sixteen and two thousand nineteen for management.
Results
Our study included one hundred twenty-seven patients, hospitalized for poorly controlled diabetes. Seventy percent of patients are female, the average age is sixty-four years, the average glycohemoglobin is ten and a half pourcent. The average duration of diabetes is eleven years, fifty-nine pourcent of cases have a poor socio-economic level, forty-eight pourcent live in rural areas, sixty-six pourcent are illiterate, ninety-nine pourcent lives with family and thirty-four pourcent are in polymedication. sixty-two pourcent of these patients report poor adherence to treatment, and the dietary assessement found inappropriate eating behavior in eighty-three pourcent of patients, and that thirteen pourcent of these patients practice regular physical activity.
Conclusion
Treatment adherence, diet and physical activity are important parameters in the management of type two diabetes, which explains the poor glycemic control in many patients despite an adapted antidiabetic treatment.

Impact of diabetes mellitus on survival in upper aerodigestive tract squamous cell carcinoma

Mohamed Masmoudi, Mehdi Hasnaoui, Mighri Khalifa, Thabet Wadii & Rihab Guizani
Tahar Sfar Hospital Mahdia, ENT Department, Mahdia, Tunisia

Introduction
Association between diabetes mellitus and cancer outcomes has been demonstrated in several cancer sites. Data for upper aerodigestive tract carcinoma are limited. Our aim is to study the impact of diabetes mellitus on survival in upper aerodigestive tract squamous cell carcinoma.
Material and methods
A retrospective study of 130 patients treated for upper aerodigestive tract squamous cell carcinoma, between 1992 and 2019. Nasopharyngeal, nasal cavity and paranasal sinus carcinomas are excluded. We used the Kaplan–Meier method to calculate the cumulative proportion surviving. Survival curves were compared by log-rank test (P < 00.05 for statistical significance). We used the Cox regression model for multivariate analysis.
Results
Our study included 117 men and 13 women. The mean age was 59.8 years. The tumour sites were: larynx (100 cases), hypopharynx (20 cases), tongue (9 cases) and lip (1 case). Twenty-nine patients (22.3%) had type 2 diabetes mellitus. No patient had type 1 diabetes mellitus. Five-year overall survival was 62.1% for nondiabetic group compared with 55.4% for diabetic group. There was no statistically significant difference between the 2 groups (P = 0.77). Five-year disease-free survival was 60.8% for nondiabetic group compared with 54.7% for diabetic group, without significant difference (P = 0.63). Multivariate analysis of overall and disease-free survival did not demonstrate a statistically significant difference between the diabetic and nondiabetic groups (P = 0.2 for overall survival and P = 0.7 for disease-free survival).
Conclusion
The impact of diabetes on survival in upper aerodigestive tract squamous cell carcinoma is controversial in the literature. Our results demonstrate that there was not significantly poorer overall or disease-free survival in type 2 diabetes mellitus patients. This may provide guidance for the multidisciplinary team that treats diabetic patients with head and neck cancer.

Comparing impact of SGLT2 inhibitors and GLP-1 agonists on lipid profile among the patients with diabetes mellitus Type 2. Results of a prospective 18-week observational study

Nestan Bostoganashvili[1], Rusudan Kvanchakhadze[2], Ketevan Mikadze[3] & Manoni Panchulidze[4]
[1]Tbilisi Heart and Vascular Clinic, Tblisi, Gerogia; [2]National institute of Endocrinology, Tblisi, Georgia; [3]Clinic 'ENMEDIC', Tblisi, Georgia; [4]'Family Doctor', Tblisi, Georgia

Background
In Georgia, significantly huge number of patients with Diabetes Mellitus Type 2 (DMT2) suffer from cardiovascular diseases (CVD) and obesity. Since, dyslipidemia is one of major factors, leading to cardiovascular

(CV) mortality, it is crucial to investigate the effects of relatively novel hypoglycemic agents- Sodium Glucose Cotransporter 2 (SGLT2) inhibitors (Dapagliflozin) or Glucagon like peptide 1 (GLP-1) agonists (Liraglutide) on lipid profile.
Aim
The aim of our short-term observational study was to assess and compare impact of SGLT2 inhibitor and GLP-1 agonist on lipid profile in patients with DMT2 and dyslipidemia.
Methods
A total of 48 patients with DMT2, (Mean age 51.8 yrs. ± 6.1. Mean duration of DMT2 ± 8.3 yrs., n = 30 male, n = 28 female) were recruited in the observational study. All of them had been treated with GLP1 agonists or SGLT2 inhibitors, (25 patients treated with SGLT2 inhibitors, 23 patients treated with GLP1 agonists) as add-on therapy to Metformin, at least for 6 months. On based of that, we divided the patients respectively into two groups and compared the effects of GLP-1 agonists and SGLT2 inhibitors on lipid profile at baseline and on 18th week of the study. All the patients were instructed to keep healthy diet and physical activity
Results
42 patients completed the follow-up. After 18 weeks of the treatment, the study showed the upward trend of HDL-Cholesterol (HDL-C) and downward trends of Total Cholesterol (TC) and LDL-Cholesterol (LDL-C) among patients treated with SGLT2 inhibitors (mean LDL-C –0.2 mmol/l, mean TC –0.2 mmol/l and mean HDL-C + 0.3 mmol/l). Mean reduction in LDL-C by 0.4 mmol/l was seen among the patients treated with GLP-1 agonists. However, there was no significant effect shown on mean HDL-C or TC values. Mean levels of Triglycerides (TG) remained unchanged in both groups.
Discussion
We think, that different impacts of hypoglycemic medications on lipid profile seen in our patients should be taken into concern. Mean LDL-C was reduced in both groups, but more effectively in GLP-1 treated patients, On the other hand mean HDL-C was increased only in SGLT-2 inhibitor-treated patients. Thus, these hypoglycemic agents have mildly different beneficial effects on dyslipidemia, However these are the 18-week study results and we do hope to investigate accurately the whole lipid profile among our patients for following months.

Nutritional impact of tobacco in diabetic patients

Mouna Elleuch[1], Gorchene Asma[1], Dhoha Ben Salah[1], Khouloud Boujelben[1], Nour Moalla[1,2], Fatma Mnif[1], Nadia Charfi[1], Nabila Rekik Majdoub[1], Mouna Mnif[1], Hadj Kacem Faten[1] & Abid Mohamed[1]
[1]Tunisia; [2]Family Medicine

Background
It's well known that smoking and diabetes are direct causes for serious health problems such as cancer, and atherosclerosis. It is suggested that smoking indirectly leads to atherosclerosis by influencing nutrient intakes as smokers tend to eat more fat and carbohydrates and less mono unsaturated fats and fiber than non-smokers. But no studies assessed the impact of tobacco on nutrition in diabetic patients.
Aim
The aim of this study was to compare the nutrient intake in smokers and non-smokers in people suffering from diabetes.
Methods
We compared the food survey of smokers and non-smokers in diabetic patients. Sixty male diabetic patients were divided in two groups, 30 of whom were current-smokers and 30 were non-smokers.
Results
The main age of the participants was 51 years old. The average tobacco consumption among smokers was 26.41 pack-year. The average BMI was 26.74 and 23 kg/m^2 in non-smoking and smoking diabetics respectively. Loss of appetite was reported in two smoking diabetics. The average caloric intake in non-smoking diabetic patients was 2670 kcal versus 2984 kcal in smoking patients (P = 0.189). The average fat intake in smokers was 111 g versus 108 g in non-smokers (P = 0.533).The average consumption of saturated fats was 10.16 in non-smokers and 7.6 in smokers (P = 0.300). The average consumption of polyunsaturated fats was 17.4 g and 10.4 g in non-smokers and smokers respectively (P = 0.329). Monounsaturated fat were 21 g in non-smokers versus 15 g in smokers (P = 0.240). The average intake of carbohydrates in non-smokers was 353 g versus 409 g in smokers (P = 0.098). Fiber intake was 20.7 g and 17.2 for non smokers and smokers respectively (P = 0.371).
Conclusion
Unlike data in literature, no significant difference was found regarding carbohydrate, proteins, fat and fiber intake, as well as the intake of mono and polyunsaturated fats between smokers and non-smokers.

Characteristics and Prevalence of diagnosed type 1 diabetes among Tunisian adults

Hadj Kacem Faten, Khouloud Boujelben, Allymamod Bibi Twaheerah, Ben Salah Dhouha, Charfi Nadia, Mnif Fatma, Mnif Mouna, Rekik Nabila, Elleuch Mouna & Abid Mohamed
Hedi Chaker Hospital, Department of Endocrinology, Diabetology, Sfax, Tunisia

Introduction
Diabetes mellitus is a serious metabolic disease, described by the World Health Organization as a global epidemic. An alarming increase in its prevalence among adults is observed in Tunisia as everywhere else in the world. Because type 2 diabetes preponderates among adults, few epidemiological studies focused on type 1 diabetes (T1D) that occurs during the adulthood. The aim of this study is to determine the prevalence of DT1 among Tunisian adults and identify their clinical and biological features.
Patients and methods
This study was carried out on adults who had diabetes diagnosed after the age of 20 years (n = 280), in Sfax (the south west of Tunisia) during the period from January 2011 to December 2019. Various clinical and biochemical parameters were evaluated.
Results
Among the 280 included adults, 166 (59%) were diagnosed with type 1 diabetes. An average of 9 patients per year was newly diagnosed with T1D after the age of 20 years. In our study, 22.9% of patients were ethylic and 44% were smokers. The mean age at onset was 31.81 years old ± 9.39 (range, 20–64 years) with significant male predominance (P = 0.01) and a sex ratio of 1.34. Approximately 71% of patients had a family history of diabetes. High blood pressure (56%), obesity (26.5%) and ischemic heart disease (12.7%) were the most common family histories. Only 46 patients (27.7%) had an autoimmune disease besides diabetes. The association of another autoimmune disease with diabetes was significantly more common in women (P < 0.05).Furthermore, adults presenting with another autoimmune disease were significantly older than those without (P < 0.05). The mean of basal metabolic index (BMI) was 21.05 kg/m^2. Underweight was found in 23.5% of cases and 63.9% of patients had normal BMI. Overweight and obesity were observed in 9% and 3.6% of patients, respectively. Ketosis were observed in 50.6% of cases, with beta cell decline ranging from 1 week to 24 months, preceded by oral therapy in 24.1% of cases. Mean blood glucose was 21.01 ± 7 mmol/l and mean glycated hemoglobin (HbA1c) was 11.88 ± 2.51% Glutamic acid decarboxylase (GAD) autoantibodies were positive in 97.6% of cases with a mean average of 485.31 ± 431.5 UI. Protein tyrosine phosphate (IA2) and islet cell (ICA) autoantibodies were positive in 13.3 and 17.4% of cases,respectively.
Conclusion
This study provided an estimate of incidence of diagnosed T1D among Tunisian adults and highlights the importance of its screening even during adulthood.

Screening for dyslipidemia in diabetic patients in a town in the Moroccan desert: the town of Es-Smara. Screening for dyslipidemia in diabetic patients in a town in the Moroccan desert: The town of Es-Smara

Sara Ijdda, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
University Hospital Center Mohamed VI, Departement of Endocrinology, Diabetes, Metabolic Disease and Nutrition, Marrakech, Morocco

Introduction
In diabetes, lipid abnormalities are frequent and pronounced and are an important factor in increased cardiovascular risk, especially in type 2 diabetics, mostly in combination with other risk factors. The aim of this work is to highlight the prevalence of dyslipidemia in a considerable population of diabetics in Es-Smara.

Patients and methods
As part of a multidisciplinary medical caravan carried out in the Moroccan desert, a diabetology consultation was conducted for the benefit of diabetic patients in the Es-Smara region. The biological analyzes were carried out in the same laboratory; they included the determination of triglycerides and cholesterol with its HDL and LDL fractions, serum creatinine and glycated hemoglobin.
Outcomes
During 3 days of consultation, we have identified 116 patients with type 2 diabetes, the average age of the patients was 57 years, with a female predominance. Hypertension was noted in 26% of patients. Waist circumference was high in 113 patients (97%) with an estimated mean of 92.7 cm and a female predominance of 77%. Sedentary lifestyle was found in 111 patients (95%). The mean duration of diabetes was 6.4 years, poor glycemic control was observed in 54 patients (46.5%) with an average HbA1c of 8.67%. In our study, 87 patients presented with dyslipidemia (75%). It was dominated by hypertriglyceridemia in 47.4% of cases, LDL hypercholesterolemia represented 31%, HDL hypocholesterolemia 17% and mixed dyslipidemia 39%. Dyslipidemia was more common in women (65%) than in men. We noted a considerable consumption of fenofibrates in 35% of cases.
Discussion/Conclusion
These dyslipidemic diabetics are patients at very high cardiovascular risk with potential damage to target organs. It is therefore incumbent on them to significantly improve their care through an adequate health policy, the aim of which is to improve access to care and extend social coverage. Earlier screening, appropriate and vigorous treatment of the associated cardiovascular risk factors is also required in order to control this dyslipidemia.

AEP309

Achieving target values for measures for peripheral arterial disease, nephropathy and dyslipidemia in type 2 diabetes- two year assessment

Ragini Rohatgi, Sonali Ghodke & Daisy Alfred
Rohit Diabetes Centre, Mumbai, India

Objective
T2DM is a major risk factor of peripheral artery disease, leading to increased morbidity and mortality as well as an accelerated disease course. Microalbuminuria is an indicator for overt nephropathy and early cardiovascular disease
Methods
We analysed data from outpatients attending a comprehensive diabetes care centre (n = 202), from 2019 till 2020, who had any of values beyond normal targets, for either of HbA1c, LDL-C, Ankle Brachial Index (ABI), Toe Brachial Index (TBI) or Albumin Creatinine Ratio (ACR). Percentage of patients achieving target values were classified as ATV (Achievers for the Target Value)
Results
Total of 202 patients (95 males, 107 females) were evaluated for glycemic and non – glycemic parameters (lipid profile, ABI, TBI, UACR). Mean age was 53 (± 13 years (95% CI 51 to 55). Mean duration of diabetes was 7.7 (± 6.5 minimum 1, maximum 36, 95% CI 6.8 to 8.6). The mean HbA1c was 8.5% (± 2 minimum 5.3, maximum 15, 95% CI 8.2 to 8.8). 4 patients reported macroalbuminuria (ACR > 300) and 49 patients had microalbuminuria (ACR 30–300). HbA1c and non glycemic measures as a marker for comprehensive diabetes care (table)

Table 1. HbA1c and Non Glycemic Measures as a Marker for Comprehensive Diabetes Care

	Mean	± SD	95% CI	n (%) within target
HbA1c (< 7%)	8.7	2.1	8.3 to 9.1	54 (26.7)
LDL-C (target < 100 mg/dl) (n = 102)	73	18	69 to 76	102 (50.4)
ABI- Right (target 1–1.29)	1.2	0.07	1.2 to 1.2	146 (72.2)
ABI- Left (target 1–1.29)	1.2	0.08	1.2 to 1.2	141 (69.8)
TBI- Right (target 0.5–0.75)	0.65	0.066	0.62 to 0.68	25 (12.3)
TBI- Left (target 0.5–0.75)	0.63	0.077	0.60 to 0.67	22 (10.8)
Albumin Creatinine Ratio (ACR) (Normal < 30)	12	6.7	11 to 14	92 (45.5)

Discussion/Conclusion
Achievement of TBI (left side) was most compromised with just 10.8% of the patients demonstrating desired values, followed by TBI (right side) within normal values in 12.3% of patients and HbA1c of < 7 was not achieved by 73.3% of patients. Highest proportion of ATV were for the ABI value-right (72.2%). Results from our study provide indicators for formulation of patient outcome improvement plan. Evidence from our comprehensive care approach complements the clinical decision-making tool to allocate resources to intervene early to minimise the complications of diabetes and improve outcome

Vitamin D levels in a cohort of patients with SARS-CoV-2 infection and relationship with disease outcome

Kostoglou Athanasiou Ifigenia[1], Nikolakopoulou Sofia[2], Alexandra Konstantinou[2], Lambros Athanassiou[2], Alexandros Spyrantis[2], Olga-Maria Spyropoulou[2], Olga Mascha[3], Charilaos Samaras[2], Ioannis Bliziotis[2] & Panagiotis Athanassiou[4]
[1]Asclepeion Hospital, Voula, Department of Endocrinology, Athens, Greece; [2]Asclepeion Hospital, Voula, Covid Department, Greece; [3]Asclepeion Hospital, Voula, Department of Biochemistry, Athens, Greece; [4]Saint Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece

Infection with the new SARS-CoV-2 or Covid-19 virus has a variable course. It may run as a mild disease or may cause severe pneumonia necessitating hospitalization. Vitamin D has immunostimulatory action and causes the release of substances necessary for combating an infection. Therefore, the relationship of vitamin D with the SARS-CoV-2 virus is under scientific evaluation. The aim was to measure vitamin D levels in a cohort of patients hospitalized with SARS-CoV-2 infection. In a cohort of 43 patients, 20 male and 23 female, hospitalized with the SARS-CoV-2 infection 25(OH)D_3 levels were measured. 25(OH)D_3 levels were also measured in a group of control subjects. The patients were classified in 4 groups, a group with uncompromised respiratory function (n = 17 patients), a group with mild respiratory insufficiency (n = 12), a group with severe respiratory insufficiency (n = 5) and a group with severe respiratory insufficiency requiring intubation (n = 8). For the evaluation of the results of the present study 25(OH)D_3 levels were classified as deficiency (0–10 ng/ml), insufficiency (10–20 ng/ml) and sufficiency > 20 ng/ml. 25(OH)D_3 levels in the SARS-CoV-2 patients were 16.16 ± 1.55 ng/ml (mean ± SEM) as compared to those in the control group, 27.28 ± 1.94 ng/ml (P < 0.001, Student's t test). Within the group 37 patients finally survived the infection while 6 died either during hospitalization or immediately thereafter. The outcome of the infection, i.e. respiratory insufficiency or need for intubation was found to be related to the levels of 25(OH)D_3 (P = 0.003, chi-square test). It appears that vitamin D deficiency as assessed by the measurement of 25(OH)D_3 levels is prevalent in patients with severe SARS-CoV-2 infection requiring hospitalization. Vitamin D levels appear also to be related to the outcome of the infection. This result is in accordance with the immunostimulatory action of vitamin D, an action known since the very early years of its discovery.

Impact of the COVID pandemic and lockdown in the glycemic and weight control of patients with type 1 and type 2 diabetes – data from a Portuguese hospital

Sara Franco, Filipa C. Bastos, Ana Gonçalves Ferreira, David Barbosa, Ricardo Capitão, Maria Manuel Costa, Henrique Vara Luiz, Isabel Manita, Maria Carlos Cordeiro, Luísa Raimundo & Jorge Portugal
Hospital Garcia de Orta, Almada, Portugal

Introduction
Due to the COVID pandemic, Portugal was forced to start lockdown on March 18 th that lasted until June 1st. Lockdown caused a lot of changes in the daily activities of the Portuguese people, such as eating habits, exercise, time spent at home and stress management. After the lockdown people noticed difficult access to healthcare.
Objective
Our aim was to evaluate if these changes had an impact in the glycemic and weight control of patients with diabetes.

Material and methods
We performed a retrospective study and included patients with type 1 and type 2 diabetes followed in our hospital. We checked hemoglobin A1c (%) between December 2020-February 2021 (before lockdown), between June-August 2021 (during lockdown) and after September 2021 (after lockdown), and we evaluated weight (Kg) before and after lockdown. In the group of type 1 diabetes we also analyzed TIR (time in range (%)) and TBR (time below range (%)) before lockdown (January-February), during lockdown (April-June) and after lockdown (July-September).
Results
We included data from 233 patients, 119 with type 1 diabetes, (43.9 ± 1.2 years; 51% women and 49% men) and 114 with type 2 diabetes (65.4 ± 1.2 years; 52% men and 48% women). Our analysis showed no significant changes in any of these variables, but showed a trend for improvement in the glycemic control in type 2 diabetes (A1c before lockdown 8.1 ± 0.14 vs during 7.8 ± 0.18 vs after 7.8 ± 0.2; $P = 0.323$). In patients with type 1 diabetes we noticed a trend for glycemic improvement during lockdown but not after (A1c 8 ± 0.1 vs 7.7 ± 0.1 vs 8 ± 0.2; $P = 0.2$), and also better TIR during lockdown (45.5 ± 1.8 vs 51.7 ± 2.1 vs 48.2 ± 1.8; $P = 0.08$). However, our analysis showed an elevation of the time spent in hypoglycemia after lockdown (TBR 5.2 ± 0.6 vs 5.3 ± 0.7 vs 6.5 ± 0.6; $P = 0.3$). There was a trend for reduction in weight in type 2 diabetes after lockdown (82.47 ± 2.4 vs 80.44 ± 2.7; $P = 0.576$).
Conclusion
Glycemic control can improve during lockdown maybe because people can more easily manage diabetes at home. At the long term, the pandemic can worsen the glycemic control, because of the lack or difficult access to healthcare and increased stress. The new diabetes technologies can help us managing these patients, especially during the pandemic.

AEP312

An unusual case of hypoglycaemia

Sadia Nasir, Syed Kashif Kazmi, Sidrah Khan & Singhan Krishnan
Hinchingbrooke Hospital, United Kingdom

We report a 77 year old male who presented to the respiratory clinic with episodes of periodic sweating. These episodes were associated nausea. They came on with exercise and always occurred before meals. The resolving factor noted by the patient was food intake and no features suggestive of reactive hypoglycaemia were noted. His past medical history was significant for hypertension, mild bronchiectasis, mild to moderate obstructive sleep apnea requiring CPAP therapy and ischemic heart disease. He was previously taking Ramipril for his blood pressure control but was switched to Losartan two months back due to cough. He was not known to have diabetes. The patient was reviewed in the cardiology clinic as well and the possibility of a cardiac arrhythmia was ruled out. Blood insulin and C-peptide levels were sent off which came back raised. On the basis of this the patient was referred to the Endocrinology clinic to rule out the possibility of an Insulinoma and for further workup. The patient was provided with a glucometer and was checking his blood glucose levels when he was symptomatic and three times a day. Blood glucose readings as low as 2.5 mmol coinciding with symptoms of sweating and nausea were recorded. Physical examination was unremarkable with the exception of some mild respiratory crackles at the right base which were stable from previous examination. He had a BMI of 32. A 72 hour fasting test and short Synacthen test was done, both of which were normal, and the possibility of insulinoma was ruled out. The patient's Losartan was stopped and the hypoglycaemic episodes were resolved. ACE inhibitors and ARBs are the first line treatment for hypertension as recommended by NICE. Several studies have reported ACE inhibitors and ARBs improve insulin sensitivity and is favoured in patients with impaired glucose tolerance. Due to this, ACE inhibitors can lead to approximately three to four fold increase in hypoglycaemic episodes in in diabetics and rarely in non-diabetics. However no cases of hypoglycaemia in non-diabetics have been reported with ARBs so far.

Features of the course of metabolic syndrome in latent autoimmune diabetes in adults

Nataliia Pashkovska, Iryna Tsaryk, Galina Koval, Ivan Pankiv, Antonina Piddubna, Yuliya Marchuk & Nataliia Abramova
Bukovinian State Medical University, Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine

Introduction
Latent autoimmune diabetes in adults (LADA) is a specific type of diabetes mellitus (DM), the prevalence of which varies from 4% to 14%. Although LADA combines the pathogenetic and clinical features of both type 1 (T1DM) and type 2 diabetes mellitus (T2DM), the latest recommendations of the American Diabetes Association refer it to T1DM (ADA, 2021). Given that this variant of diabetes is also similar to T2DM, the risk of metabolic syndrome (MS) in this category of patients is particularly relevant. At the same time, the existing results of research in this area are quite contradictory. The aim of this study was to determine the prevalence of metabolic syndrome and its components in LADA depending on the phenotype of the underlying disease.
Materials and methods
54 patients with LADA were examined, the comparison group consisted of patients with T1DM (30 patients) and T2DM (45 patients). The average age was 54.7 years. Patients with LADA according to the main phenotypes were divided into 2 groups: LADA 1 (28 individuals) with high antibody titres (□180 U/ml) to glutamic acid decarboxylase (antiGAD) and LADA 2 (26 individuals) with low antibody titres (18 -180 U/ml). The phenotypic features of the prevalence of MS and its components in LADA were studied in accordance with the criteria of the International Diabetes Federation (IDF, 2009). In establishing LADA, we were guided by the recommendations of the Immunology of Diabetes Society (IDS, 2005).
Results
The prevalence of MS in LADA was 55.6% and exceeded that in T1DM (19%), but was lower compared with T2DM (71.4%). In addition to hyperglycemia, abdominal obesity (62.2% of patients), hypertension (77.8%), and dyslipidemia (55.6%) were the most common components of MS in LADA. The highest prevalence of MS was found in patients with LADA 2 phenotype (69.2%), which was close to that in T2DM. At the same time, it was lower (40.9%) in LADA 1, but twice as high as in T1DM. Negative correlations were found between body mass index, waist circumference and antiGAD titers in patients with LADA ($P < 0.05$).
Conclusion
Metabolic syndrome was found in 55.6% of patients with LADA. The prevalence of metabolic syndrome depends on the phenotype of the disease and was highest in LADA 2 (69.2%), which indicates that patients with this phenotype belong to the group of high cardiovascular risk.

Evolution of the parameters of liver function after sleeve gastrectomy

Hedfi Imene, Olfa Lajili, Faten Mahjoub, Nadia Ben Amor, Ramla Mizouri, Berriche Olfa & Jamoussi Henda
National Institute of Nutrition, Tunis, Tunisia., Obesity Unit UR18ES01, Tunis, Tunisia

Introduction
Obesity is an undeniable global health problem that has taken on epidemic proportions in both developed and developing countries. Bariatric surgery offers a promising therapeutic option mostly in the face of frequent failures of dietary management of obesity. Our study aimed to describe the evolution of parameters of liver function after sleeve gastrectomy.
Methods
It was a retrospective study including 40 obese patients who were followed up at the Research Unit on Obesity at the National Institute of Nutrition and Food Technology in Tunis up to 12 months after sleeve gastrectomy. In preoperative, all patients underwent an abdominal ultrasound and a liver bioassessment. The preoperative clinical and biological data and those checked at six and 12 months after surgery were collected from the patients' medical records.
Results
The mean patients' age was 34.65 ± 8.17 years and the sex-ratio was 0.21. The mean body mass index (BMI) was 50.23 ± 8.3 kg/m^2. Fifteen percent of our patients had hepatic cytolysis and 12% had anicteric cholestasis. Fatty liver disease was noted in 62% of patients. After sleeve gastrectomy, blood levels in transaminases decreased significantly ($P < 0.01$). No patients had hepatic cytolysis one year after the intervention. Also, blood levels of gamma-glutamyl transferase decreased significantly ($P < 0.05$). Only one patient retained anicteric cholestasis one year after surgery. Of the 25 patients with hepatic steatosis initially, four had had an abdominal ultrasound control which confirmed the absence of this abnormality. The mean excess weight loss was 40.2 ± 14% [4.1–74.6] at six months and 55.8 ± 20.5% [7.3–90.1] at one year. More than half of our patients lost more than 50% of their excess weight one year after sleeve gastrectomy.

Conclusion
Results of our study testify to the effectiveness of sleeve gastrectomy in improving parameters of liver function. This would be explained not only by the significant weight loss induced by this surgical technique but also by the metabolic changes such as increased levels of incretin thus improving insulin sensibility of patients and their metabolic parameters.

Diabetic peripheral neuropathy: Predictive factors and management

Abdessamad Malki, Mohamed Aymane Loukili, Anouar Jamal, Siham Rouf & Hanane Latrech
Mohamed VI University Hospital Center, Oujda, Department of Endocrinology and Diabetology, Oujda, Morocco

Introduction
Diabetic peripheral neuropathy is a common degenerative complication of diabetes. The aim of our work is to focus on the prevalence of this complication in relation to the imbalance of diabetes in type 2 diabetics (T2DM).
Materials and methods
This is a retrospective study, including 202 type 2 diabetic patients hospitalized in an Endocrinology-Diabetology department, over a 6-year time period. All patients have benefited for a neurological examination with calculating of the DN4 score, the data were exploited by SPSS-V21.
Results
The mean age of our patients was 57.1 ± 13.1 years, with a sex ratio M/F of 0.25. The prevalence of diabetic neuropathy was 22.27% with an average duration of diabetes of 14.37 ± 8.85 years and an average HbA1c of 10.7 ± 1.6%. The DN4 score is positively correlated with the level of HbA1C (P = 0.04). Other microangiopathies were present in 53.33%, including nephropathy (24.44%) and retinopathy (35.55%). Macrovascular complications were present in 62.22%, including coronaropathy (42.22%), ischemic stroke (20%), peripheral arteriopathy (6.66%). The therapeutic management consisted of an optimal glycemic control, leading to an HbA1c level of 8.2 ± 2.2% on average after 3 months. 4.4% of patients were treated for neuropathic pain with an antidepressant.
Conclusion
The prevalence of diabetic neuropathy is high in T2DM, uncontrolled diabetes is the most common factor which is frequently associated with other degenerative complications. The preventive and curative treatment consists of an optimal glycemic control.

Chronic diabetic kidney disease, senescenceand cardiovascular disease

Beatriz Ugalde Abiega[1], Iciar Martin Timon[1], Inmaculada Moreno-Ruiz[1], Elena Corchete Prats[2], Isabel Huguet[1], Susana Bacete Cebrián[1], Javier Modamio[1] & Cristina Sevillano-Collantes[1]
[1]Hospital Infanta Leonor, Endocrinology, Madrid, Spain; [2]Hospital Infanta Leonor, Nephrology, Madrid, Spain

Cardiovascular disease (CVD) is more prevalent in patients with chronic kidney disease (CKD) and *Diabetes mellitus (DM)* than in the general population. Microparticles (MPs) released during cell activation and/or apoptosis could be biomarkers of CVD. These MPs, which show vascular damage, are named according to the injured cell, as endothelial (EMPs) or platelet (PMPs).
Aim
Assess the MPs plasma concentration in diabetic patients with or without nephropathy, and evaluate its correlation with the occurrence of CVD.
Patients and methods
A prospective, observational, transversal study in 46 diabetic patients from Infanta Leonor University Hospital. Total MPs, endothelial and platelet, were measured in all cases. The Chi-square test was used to compare qualitative variables, and a linear regression analysis with the MPs as a dependent variable. A $P < 0.05$ was considered significant.
Results
Out of the 46 patients, 27 (58.7%) were men, and 23 (50%) were on hemodialysis (HD). The average age was 64.9 (11.7) years old, patients on HD being older ($P < 0.01$). They also had a higher frequency of atrial fibrillation ($P < 0.035$), retinopathy, neuropathy, heart failure, peripheral artery disease and high blood pressure (HBP) ($P < 0.01$for all), than patients with normal glomerular filtration rate. They showed, as well, a higher number of total MPs ($P < 0.01$) and endothelial MPs ($P < 0.01$), with no difference of PMPs. The linear regression analysis to establish if the difference was a consequence of age or HD, showed that only HD was a determining factor for total MPs, but not for EMPs.
Conclusions
The increase in total MPs and EMPs observed in patients on HD with a higher number of CVD non-thrombogenic episodes in the diabetic population studied, could be related to the lack of MPs difference observed.

	Diabetic patients on HD (n = 23)	Diabetic patients with normal RR (n = 20)	Total DS o%	P

Peculiarities of type 2 diabetes in men with androgenic deficiency

Daria Skuridina & Tatyana Demidova
Pirogov Medical University, Department of Endocrinology, Russian Federation

Relevance
Androgenic deficiency is an important pathogenetic element in the development of metabolic syndrome and cardiovascular diseases in men. It has been proven that in male patients with type 2 diabetes, hypogonadism develops much more often.
Objective
To study the features of the course of type 2 diabetes mellitus (T2DM) in men with androgen deficiency. Research objectives: 1. To estimate the incidence of hypogonadism in men 35–65 years old with type 2 diabetes. 2. To compare the incidence of non-fatal myocardial infarction and history of stroke in the group of patients with T2DM and hypogonadism with the group of patients with T2DM without hypogonadism. 3. To study the spectrum of late complications of T2DM in these groups. 4. Compare the parameters of carbohydrate and lipid metabolism, the degree of insulin resistance in these groups.
Materials and methods of the research
The study included 84 men with type 2 diabetes. To diagnose hypogonadism, the levels of total testosterone (T), sex hormone binding globulin (SHBG), albumin and luteinizing hormone (LH) were measured. Free testosterone (free T) levels were calculated using a calculator from Ghent University Hospital, Belgium. 43 patients underwent a retrospective analysis of case histories (spectrum of late complications, the presence of heart attacks and strokes, laboratory data – total cholesterol (CS), triglycerides (TG), fasting blood plasma glucose, basal insulin level, glycated hemoglobin (HbA1c)). The HOMA-IR index was used to determine the degree of insulin resistance.
Research results
The average age of men was 56.21 ± 6.26 years. The incidence of laboratory-confirmed hypogonadism is 42.9%. An average positive

correlation was found between androgen deficiency and the incidence of non-fatal cardiovascular events ($r = 0.45$ $P < 0.05$). There was no statistically significant relationship between the presence of hypogonadism and the incidence and degree of late complications of T2DM. Patients with low T levels tended to have higher HOMA-IR values compared to patients with normal T levels ($P < 0.05$). At the same time, the indicators of carbohydrate and lipid metabolism did not differ significantly in these groups ($P > 0.05$).
Conclusions
The revealed incidence of hypogonadism in men with T2DM corresponds to the data of international studies. The presence of a significant correlation between low testosterone levels and cardiovascular events in patients with T2DM suggests that hypogonadism can be used as an additional criterion for cardiovascular risk. Testosterone deficiency exacerbates insulin resistance, which can lead to weight gain and impair carbohydrate metabolism.

Influence of depression on glycemic control in patients with typ1 diabetes

Snjezana Popovic Pejicic[1,2], Nina Pejicic[1], Gabrijela Malesevic[1], Valentina Soldat Stankovic[1] & Tamara Dojcinovic[1]
[1]University Clinical Centre of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina; [2]University of Banja Luka, Faculty of Medicine Banja Luka, Banja Luka, Bosnia and Herzegovina

Aim
Depression in diabetic patients is related to low quality of life, inadequate abiding by diabetes diet, physical activity and drug therapy.Aim of the stady is determine the presence of depression and its impact on the level of metabolic control of the disease; impact of structured education on the level of knowledge and HbA1c in patient with diabetes type 1 (T1D)
Methods
The study included 38 patients with T1D, median age of 32.7 years, 27 women and 11 men. For assessment of the level of depression the Zung Self-Rating Depression Scale was used, as well as questionnaire on socio-demographic information. Interactive education program-structured therapy and study program 'Düsseldorf model' of 5 day duration was applied. All patients had HbA1c measured in the beginning of the education and at 3, 6, 9 and 12 month follow-ups.
Results
Based on the Zung Self-Rating Depression Scale 52.6% patients had clinically significant level of depression, 42.1%showed mild symptoms of depression and5,.2% patients showed no symptoms of depression. In the group of depressive diabetics 65% had unsatisfactory level of glycoregulation. After structured education program HbA1c levels decreased by 1.8% after 6 months and 1.2% after 12 months compared to initial levels ($P < 0.005$).
Conclusion
It could be concluded that the presence of depression has a tendency to predict poor metabolic control of diabetes. Structured education program is efficient in improving glycaemic control in patients with type 1 diabetes. It motivates patients in achieving better glycaemia control.

Angiotensin-converting enzyme gene (i/d) polymorphism in association with the diabetic nephropathy

Taner Hasan[1], Ivana Trajkovska[1], Natasha Nedeska[1], Cvetanka Volkanovska Ilijevska[2] & Slavica Josifovska[3]
[1]City General Hospital, Endocrinology, Diabetes and Metabolism, Skopje, Macedonia; [2]University Clinic of Endocrinology, Diabetes and Metabolic Disorders, Endocrinology, Diabetes and Metabolism, Skopje, Macedonia; [3]Laboratory of Molecular Biology, Institute of Biology, Faculty of Natural Sciences, Ss. Cyril and Methodius University, Molecular Biology, Skopje, Macedonia

Polymorphisms in the Angiotensin-converting enzyme (ACE) gene have been associated with development of diabetic nephropathy (DN), a major microvascular complication of the type 2 diabetes mellitus (T2DM). Since the genetic predisposition plays an important role in development of DN in patients with T2DM, genetic testing might largely contribute to better assessment of the risk of DN in such patients. The aim of this study is to investigate the association of the ACE gene I/D polymorphism with DN in T2DM patients. The study is designed as a case-control genetic association study. The samples from 88 patients with T2DM were analyzed, including 57 patients with DN and 31 without DN. The study includes also 26 healthy controls. The demographic, clinical and laboratory data are analyzed in addition to the genetic profiling of the patients for the ACE gene. Genotyping of the ACE gene I/D polymorphism resulted in determination of the patient's genotype: D/D, I/D or I/I. The results revealed a statistically significant association of genotypes D/D and I/D with the occurrence of nephropathy compared to the I/I genotype. In the group of patients with T2DM, the carriers of the D/D or I/D genotypes have 6.46 folds higher odds and 1.7 folds higher relative risk for developing nephropathy than the carriers of I/I genotype. The results confirmed the correlation of the genetic polymorphism and the development of the DN in patients with T2DM indicating its potential predictive use in terms of the clinical follow-up, treatment selection and prognosis of DN.

Bruns–garland syndrome as the first presentation of type 2 diabetes – a report of two cases from Sri Lanka

Piyumi Wijewickrama[1], Sathyajith Ambawatte[2], Kamal Gunarathne[3] & Noel P Somasundaram[1]
[1]NHSL, Endocrinology, Colombo, Sri Lanka; [2]Ministry of Health, Neurology, Colombo, Sri Lanka; [3]NHSL, Neuro-electrophysiology, Colombo, Sri Lanka

Introduction
Diabetes mellitus (DM) is a global health issue. Sri Lanka has the second highest diabetes prevalence at 20–79 years in South-East-Asia (1). Diabetic-radiculoplexus-neuropathy is a rare entity causing significant disability, also known as diabetic amyotrophy and Bruns-Garland syndrome, occurring due to immune mediated microvasculitis (2). Although Diabetic-lumbo-sacral-radiculoplexes-neuropathy (DLRPN) is well described, Diabetic-cervical-radiculoplexus-neuropathy (DCRPN) is rare. We report two cases of DLRPN and DCRPN as the first presentation of DM.
Case-description
Case-1: A previously healthy 49-year-old Sri Lankan hotel chef presented with painful weakness and wasting of left arm for 3 months with weight loss. Left shoulder-girdle muscles were wasted with diminished power and reflexes. He had high Erythrocyte-sedimentation-rate (ESR) at 60 mm/hr, with normal C-Reactive protein (CRP). His cerebrospinal fluid (CSF) showed albumino-cytological-dissociation with high CSF protein at 70 mg/dl and unremarkable high volume cytospin. His magnetic resonance imaging (MRI) of cervico-thoracic spine with brachial plexus was normal. His Fasting blood glucose (FBG) was198 mg/dl, and HbA1C was 9%, confirming newly diagnosed DM. Nerve conduction study (NCS) showed comparative amplitude reduction. Electromyogram revealed positive sharp waves, frequent fibrillations and high amplitude polyphasic motor unit potentials with reduced recruitment in proximal muscles of left upper limb. Case-2: A previously healthy 47-year-old carpenter presented with asymmetrical painful weakness of thighs for 5 months with weight loss and fatigue. Lower limb proximal muscles were asymmetrically wasted with reduced power and knee jerks. He had high ESR of 72 mm/hr with normal CRP and CSF showing albumino-cytological-dissociation with unremarkable high volume cytospin. He was diagnosed with DM on admission, with FBG of 208 mg/dl and HbA1C of 9.4%. MRI and NCS were normal. Electromyogram showed similar changes in both quadratus femoris, more on left side. Both had no trauma history, infection or osmotic symptoms. Screening for an alternative aetiology was unremarkable. Patient1 was diagnosed with DCRPN while patient2 with DLRPN. Both showed significant improvement following optimization of glycemic control, with symptomatic treatment and physiotherapy.
Conclusion
DCRPN and DLRPN were never reported as the first presentation of diabetes in Sri Lanka. DCRPN is rare and can lead to misdiagnosis. This is an eye opener to consider a new diagnosis of diabetes mellitus even in previously healthy patients presenting with radiculo-plexus neuropathies to the Neurology department.

Immune thrombocytopenia presenting with celiac disease and Hashimoto's Thyroiditis in type 2 diabetes patient: A case report

Rahma Khalaf, Zohra Hadj Ali, Yosra Htira & Faika Ben Mami
National Institute of Nutrition, Tunisia

Introduction
The combination of at least three autoimmune diseases in the same patient is defined as multiple autoimmune syndrome. Recent studies demonstrated a higher prevalence of celiac disease in patients with immune thrombocytopenia when compared to the general population. Here we report the occurrence of celiac disease, Hashimoto's disease and immune thrombocytopenia in type 2 diabetes patient.
Case report
A 64 years old man was referred for a recently diagnosed corticosteroid induced type 2 diabetes mellitus treated by oral anti diabetic drugs (metformin 2000 mg/j + glimepiride 2 mg/j). Past medical history was significant: immune thrombocytopenia diagnosed at the age of 30 years old treated by corticotherapy in 1986, 2017 and 2019, celiac disease diagnosed at the age of 44 years old treated by gluten free diet, benign stenosis of the common bile duct, hypertension controlled by two antihypertensive drugs (bisoprolol 5 mg/j + loop diuretics 40 mg/j) and atrial fibrillation anticoagulated with Vitamin K antagonists. The physical examination was strictly normal. The biochemical report was: Hb1Ac = 10.3%, triglycerides = 2.45 mmol/l, total cholesterol = 4.03 mmol/l, HDL = 1.05 mmol/l, LDL = 1.86 mmol/l, ASAT = 25 UI/l, ALAT = 54 UI/l, eGE = 116.3 ml/min/1.73 m^2, white blood cell count = 8000/mm3, hemoglobi *n* = 14 g/dl and a platelet count = 24 0000/mm^{33}. The corticosteroid tapering protocol has been started. The patient refused insulintherapy. Medical decision was to intensify the treatment: glimepiride 4 mg/j + metformin 2000 mg/j. Four months later, the biochemical report was HbA1c = 6.5%, fasting blood glucose = 8 mmol/l, elevated TSH (38µUI/ml) and decreased FT4 (8.57 pmol/l). Primary hypothyroidism was diagnosed on routine screening. The patient did not report any hypothyroidism symptoms. Since the main etiology is autoimmune, an access protocol was complemented with antibodies, highlighting the elevation of antiperoxidase antibodies (455.9 UI/ml) concluding diagnosis of Hashimoto's Thyroiditis. Interconsultation with the cardiology service was initiated, starting treatment with Levothyroxine 12.5 µg/day. Appropriate adjustment of the Levothyroxine therapy is needed to determine the proper dosage.
Conclusion
Patients with autoimmune history should be screened regularly in order to detect the outbreak of new autoimmune diseases, since they have common mechanisms and a shared genetic background.

A retrospective analysis of clinical manifestations of patients with acute intermittent porphyria: three case reports and literature review

Qingyang Li[1], Yi Ren[2] & Jing Yang[2]
[1]Shanxi Medical University, Taiyuan, China; [2]The First Hospital of Shanxi Medical University, Department of Endocrinology, Taiyuan, China

Background
Acute intermittent porphyria (AIP), a rare autosomal-dominant inherited disorder, caused by pathogenic mutations in the gene encoding porphobilinogen deaminase (PBGD). To explore its clinical characteristics, we investigated three patients with AIP admitted to our hospital.
Methods
In this study, patients successfully diagnosed with AIP and treated at the First Hospital of Shanxi Medical University since January 1, 2016, were enrolled. Information regarding the medical history, symptoms, treatments, prognoses, and gene mutations of these patients was collected and analysed.
Results
Three patients, all young women, were included in the study. Their main symptoms were abdominal pain, accompanied by abdominal distension, nausea, vomiting, hypertension, tachycardia, etc. Laboratory results from all three subjects showed severe hyponatremia and hyperuricemia. At the same time, patients A and B suffered from epileptic seizures when their serum sodium levels sharply decreased. After carbohydrate loading therapy, the symptoms of all three patients were alleviated. And the earlier carbohydrate loading was administered, the faster the symptoms were relieved and the better the prognosis would be. However, high-doses of glucose intravenously administered may exacerbate hyponatremia. During the treatment, their uric acid levels firstly dropped and then rose again as their conditions improved. There were different mutations in the PBGD gene that had been detected in the three patients: Patient A with the heterozygous deletion frameshift mutation (c.730_731del), Patient B with c.1078_1132del, Patient C with the intronic mutation c.160 + 5G > C.
Conclusion
The clinical manifestations of AIP are complex and variable. In patients with unexplained abdominal pain, hyponatraemia, and neuropsychiatric symptoms, acute episodes of AIP should be considered. Our study indicated that seizures in patients with AIP might be associated with hyponatremia. Gene sequencing can identify possible pathogenic mutations and improve the accuracy of diagnosis. Carbohydrate loading is the main treatment to alleviate the symptoms of AIP. Meanwhile, patients' serum sodium levels should be monitored and corrected in time during glucose therapy.

Identification of a novel mutation of the abcc8 gene in a greek subject with mody12

Georgia Kanti[1], Labrini Papanastasiou[1], Amalia Sertedaki[2], Spyridoula Glikofridi[1], Christina Kanaka Gantenbein[2] & Theodora Kounadi[1]
[1]General Hospital of Athens 'G. Gennimatas', Endocrinology Unit, Athens, Greece; [2]'Agia Sophia' Children's Hospital, Division of Endocrinology, Diabetes and Metabolism, First Department of Pediatrics, National and Kapodistrian University of Athens School of Medicine, Athens, Greece

Introduction
'Maturity-onset diabetes of the young' (MODY) constitutes a group of clinically and genetically heterogeneous monogenic forms of diabetes, characterized by beta-cell dysfunction. It describes an autosomal dominantly inherited disorder, caused by mutations in different genes, characterized by noninsulin-dependent diabetes commonly diagnosed at a young age. Fourteen MODY subtypes have been reported, often misdiagnosed as type 1 or 2 diabetes.
Aim
To present a male suspected for MODY, who was tested molecularly using the Next Generation Sequencing (NGS) for 7 MODY genes (GCK, HNF1A, HNF4A, HNF1B, INS, ABCC8 and KCNJ11).
Case description
A 17-year-old male presented after laboratory investigation indicating hyperglycemia (glucose: 281 mg/dl). He complained for polyuria, polydipsia and weight loss (~ 4 kg) in the last month. On admission, he had glucose: 391 mg/dl without acidosis, HbA1c: 10.4%, normal BMI (18.7 kg/m^2) and negative pancreatic auto-antibodies. Urinary protein excretion was elevated (205 mg/day). There was no family history of diabetes. He was initially treated with insulin, which was gradually decreased and finally discontinued within a month. Three months later his HbA1c was 7.2% and insulin treatment was implemented again due to poor glycemic control. Genetic analysis revealed that he was heterozygous for a novel p.V21F variant of the ABCC8 gene (exon 1, c.61G > T, of paternal origin) and for the p.A98V variant of the HNF1A gene (exon 1, c.293C > T, of maternal origin). p.V21F variant is reported for the first time and is classified as likely pathogenic, while p.A98V is classified as likely benign. Once the mutation was identified, the patient switched to gliclazide, which was eventually replaced by insulin as hyperglycemia was not successfully controlled with sulfonylurea alone (HbA1c after 3 months of treatment increased to 7.6%). Genetic investigation in both parents revealed that the father was heterozygous for the same ABCC8 p.V21F likely pathogenic variant, but asymptomatic. The HNF1A variant was inherited from the mother.
Conclusions
Given the different therapeutic approach and the complications risk depending on the diabetes form, a correct diagnosis and optimal treatment is essential for a good prognosis and appropriate genetic counseling. This case emphasizes the need of considering molecular analysis, even in the absence of a family history of diabetes if clinical suspicion for MODY is high. A novel likely pathogenic variant of the ABCC8 gene is described, which refers to subtype MODY 12 and cannot be successfully treated with sulfonylurea monotherapy, as generally suggested (1).

Diabetes, a harbinger of pancreatic tumor

Amal Mehrzi[1], Manel Jemel[2], Meriem Madhbouh[1], Hiba Chatti[1], Wiem Madhi[1] & Ines Kammoun[2]
[1]National Institute of Nutrition and Food Technology, Department of Endocrinology, Tunis, Tunisia; [2]National Institute of Nutrition and Food Technology El Manar University, Department of Endocrinology, Tunis, Tunisia

Introduction
Pancreatic cancer is one of the cancers of the digestive tract for which the prognosis has not been improved in terms of early diagnosis. Recent diabetes can be indicative of this pathology.
Observation
A 56-year-old man with no notable pathological history who has presented for 04 months a deterioration in general condition with weight loss. On clinical examination: BMI: 17 kg/m^2. In biology: Venous glycemia: 32 mmol/l/l, HbA1c: 8.9%. Transaminases: normal, total bilirubin: 317 mmol/l (60N). GGT: 92 IU/l (5N), PAL: 537 IU/l, albuminemia normal, serum calcium. No degenerative complications of diabetes have been noted. An abdominal ultrasound revealed dilation of the intra and extra hepatic bile ducts without any detectable obstacle. Bili-MRI showed a poorly limited 17 × 18 mm pancreatic head mass responsible for dilation of the Wirsung's duct with upstream parenchyma. The patient was put on insulin therapy and underwent a corporeal-caudal pancretectomy surgery followed by hormone therapy. The evolution was marked by glycemic instability with severe hypoglycaemia despite a drop in insulin-like doses of 0.1 u/kg. Is this an improvement in his diabetic pathology?
Conclusion
Diabetes can be concomitant with the diagnosis of pancreatic cancer in 40% or during the two years preceding the diagnosis of this neoplasia in 16% of cases. Diabetes can get better 57–89% of the time. Experimental studies have well established the diabetogenic effect of pancreatic neoplastic cells which are metabolically active. They alter carbohydrate metabolism, lowering the release of insulin.

Association of glucocorticoid receptor gene polymorphism A3669G (9β) with lower glucose concentration 2 hours after OGTT in patients during chronic glucocorticoid treatment

Karolina Nowak[1], Marta Sobalska-Kwapis[2], Wojciech Zgliczynski[1] & Lucyna Papierska[1]
[1]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland; [2]University of Lodz, Biobank Lab, Department of Molecular Biophysics, Lodz, Poland

Background
2–3% of the general population is chronically treated with glucocorticoids (GCs). Modification of the structure and/or function of the glucocorticoid receptor (GR) due to its polymorphisms may result in increased (GC – S – bclI, N363S) or decreased (GC – I – A3669G, ER22/23EK) sensitivity to GCs. To date, whether such modulation of cell's response to GCs can be associated with presence or absence of the side effects of GCs treatment has not been studied.
Objective
The aim of the study was to investigate the association between GR polymorphisms (bclI, N363S, A3669G and ER22/23EK) and adverse events of GC treatment in patients diagnosed with rheumatic disease during chronic glucocorticoid treatment.
Material and methods
150 patients were enrolled into the study. Based on five-point (0'–120') oral glucose tolerance test (OGTT) glucose and insulin areas under the curve (AUC) as well as indicators of insulin resistance were calculated. Data regarding BMI and waist circumference were gathered and body composition was measured using dual energy X-ray absorptiometry. High Resolution Melting method was used for genotyping.
Results
OGTT was performed in 125 females and 25 males of mean age of 56.8 years. Mean current dose of GCs was 7 mg. 21 carriers of GC – I variants (excluding GC – S carriers) had lower glucose concentrations 2 h after OGTT compared to 55 carriers of the 'wild type' of all four polymorphisms (98.9 mg/dl vs 128.4 mg/dl, $P = 0.01$). There was also a trend towards higher cumulative dose of GCs (31.9 g vs 12.55 g, $P = 0.06$) and longer treatment duration in GC – I carriers (139.1 months vs 80 months, $P = 0.09$). There was no difference between groups in age, current dose of GCs, cholesterol concentrations, BMI, waist circumference, body or trunk fat percentage, HOMA-IR, HbA1c, Matsuda Index, AUCs, glucose or insulin concentrations in other time points of OGTT. 53 carriers of N363S and/or heterozygous bclI variants (excluding GC – I carriers) were compared to 50 'wild type' carriers. There was no difference between groups in age, current, cumulative dose of GCs, treatment duration, cholesterol concentrations, BMI, waist circumference, body or trunk fat percentage, HOMA-IR, HbA1c, Matsuda Index, AUCs, glucose or insulin concentrations in OGTT.
Conclusion
Polymorphisms of GR that decrease sensitivity to GCs (A3669G and ER22/23EK) are associated with lower glucose concentrations after 2 h of OGTT. Whether this could lead to decrease risk of diabetes in carriers is open for future studies.

A case of hypertriglyceridemia after the use of tamoxifen

Yasemin Emur Gunay, Damla Tufekci, Ahmet suat Demır, Muhammet Cuneyt Bilginer, Hulya Coskun, Irfan Nuhoglu, Ozge Ucuncu & Mustafa Kocak
Karadeniz Technical University Faculty of Medicine, Department of Endocrinology and Metabolism, Trabzon, Turkey

Introduction
Tamoxifen is a selective estrogen receptor modulator used in the treatment of estrogen/progesterone receptor-positive breast cancer. Due to the increased frequency of breast cancer in the premenopausal period, the use of tamoxifen is quite common in patients with hormone receptor positivity. Although it is a commonly-used drug, the number of cases with elevated triglyceride levels is very few. Here, we present a case with severe hypertriglyceridemia due to the use of tamoxifen admitting with the acute pancreatitis-like clinic.
The Case
A 44-year-old female patient diagnosed with breast cancer two years ago had undergone neoadjuvant chemotherapy. Tamoxifen treatment was started 1.5 years ago when a positive estrogen receptor has detected a result of pathology. The patient, who presented with complaints of abdominal pain and nausea, was hospitalized with the diagnosis of severe hypertriglyceridemia when the triglyceride level measured was 1560 mg/dl (N 50–150). There was no other disease in the patient's history that could be the cause of secondary hypertriglyceridemia (diabetes, family history, alcohol use…). Body Mass Index was 26 kg/m^2. She did not have sensitivity, defense, and rebound in the abdomen in physical examination. Amylase, lipase values, and thyroid function tests were normal in the biochemical examinations of the patient. Since the amylase-lipase values may be normal in pancreatitis with hypertriglyceridemia, abdominal tomography was performed to rule-out possible diagnosis of pancreatitis in the etiology of abdominal pain. In the tomography, the gall bladder, biliary tracts, and pancreas were reported to be normal. Gemfibrozil 1200 mg/day and Omega-3 capsule 3000 mg/day treatment was initiated for the patient. The intravenous fluid replacement was also performed. It was considered that the elevated triglyceride levels of the patient might be due to the use of tamoxifen. After consultation with medical oncology, the patient's tamoxifen treatment was changed to anastrozole. In the follow-up of the patient, here complaints regressed. The patient, who had triglyceride levels of 480 mg/dl, was discharged.
Conclusion
Clinicians must be careful in terms of hypertriglyceridemia that may be associated with tamoxifen and pancreatitis that may develop in this respect. Screening for dyslipidemia before starting tamoxifen is recommended, especially in people with a family history. Patients' lipid levels should be followed. In the presence of symptoms, the drug should be discontinued and not retried because of the risk of inducing acute pancreatitis. Even if the amylase and lipase values are normal, caution should be exercised in patients with high triglyceride levels.

The impact of violated production of vascular endothelial growth factor expression on thyroid hormones metabolism in obese patients

Nataliia Abramova, Nataliia Pashkovska, Yuliya Marchuk, Ivan Pankiv, Antonina Piddubna, Galina Koval & Iryna Tsaryk
Bukovinian State Medical University, Clinical Immunology Allergology and Endocrinology, Chernivtsi, Ukraine

Introduction
Obesity is an important medical and social problem of our time, because its prevalence is growing rapidly and affects about 30% of the adult population of the planet. Obesity is characterized by an increase in the expression of cytokines that cause endothelial damage. It is known that prohormone thyroxine (T_4) is converted into 5 times more active triiodothyronine (T_3) in peripheral organs (such as liver kidneys) and tissues with the help of deiodinases. Hyperproduction of cytokines by adipose tissue impairs this conversion of thyroid hormones with the development of 'low T_3' syndrome. Besides adequate blood supply is important in the process of deiodination of T_4. Therefore, it is important to study the relationship between endothelial function and thyroid hormones metabolism.
The aim of the study
To study the dependence of thyroid hormones metabolism on the level of vascular endothelial growth factor in the serum of venous blood in obese patients.
Materials and methods
52 obese patients and 20 practically healthy persons were enrolled into the study. Obesity was established in the case of an increase in body mass index above 30 kg/m^2. Free triiodothyronine (fT_3) and free thyroxine (fT_4) levels were determined. To assess the violation of peripheral conversion of thyroid hormones, the ratio of fT_3/fT_4 was calculated. The level of vascular endothelial growth factor (VEGF) was determined.
Results
In obese persons, a decrease in fT_3 by 31.4%, an increase in fT_4 by 22.6% and decrease in fT_3/fT_4 ratio by 39.1% ($P < 0.05$) were found. An increase in VEGF expression by 37.3% on the background of obesity compared with control ($P < 0.05$) were revealed. Negative correlations between VEGF expression and fT_3 ($r = –0.438$, $P < 0.05$), fT_3/fT_4 ($r = –0.522$, $P < 0.05$) were obtained.
Conclusions
1. Metabolism of thyroid hormones is decreased with the development of the syndrome of 'low triiodothyronine syndrome' in obese patients. 2. Endothelial function is impaired with increasing expression of vascular endothelial growth factor against the background of obesity, 3. Indicators of thyroid hormone metabolism depend on the level of vascular endothelial growth factor.

Non alcoholic steatohepatitis related cirrhosis and hepatocellulair carcinoma: A ten years rerospective study

Mrabet Soumaya, Harbi Raida, Imen Akkari & Ben Jazia Elhem
Farhat Hached University Hospital, Gastroenterology, Sousse, Tunisia

Introduction
Currently, the incidence of metabolic steatopathies is clearly increasing. Unlike simple fatty liver disease, non-alcoholic steatohepatitis (NASH) can progress to cirrhosis and hepatocellular carcinoma (HCC). The aim of our study was to determine the factors associated with these complications in patients with NASH.
Methods
This is a retrospective study including all cirrhotic patients followed between January 2011 and December 2020. The severity of the cirrhosis was assessed by the CHILD-Pugh score. Six-monthly abdominal ultrasound monitoring was performed in all patients for the detection of HCC.
Results
One hundred and sixty six patients; 92 women (55.4%) and 74 men (44.6%) were included. The average age was 57.2 years (between 17 and 88 years). NASH was retained in 27 patients (16.3%) as the etiology of the cirrhosis. Cirrhosis was classified as CHILD A in 8 cases (29.6%), CHILD B in 13 cases (48.2%) and CHILD C in 6 cases (22.2%). Twenty two patients presented with edemato-ascitic decompensation (81.5%). Four patients (14.8%) developed hepatic encephalopathy. Esophageal varices were present on upper gastrointestinal fibroscopy in 26 patients (96.2%): grade 1 (11 cases), grade 2 (12 cases) and grade 3 (3 cases). Two patients (7.4%) developed hepatocellular carcinoma after 5 years and 6 years of progression respectively. Death occurred in 4 patients (14.8%) with a mean delay of 37 months.
Conclusion
In our study, non-alcoholic steatohepatitis related cirrhosis was found in 16.3% of all cirrhotic patients, of which 7.4% developed HCC.

The role of obesity management in the reversal of type 2 diabetes mellitus

Tahir Omer
University of South Wales, Cardiff Campus, United Kingdom

The prevalence of Type 2 Diabetes Mellitus (T2DM) is drastically rising globally. It is projected to rise to close to 600 million in 2 decades. This rise parallels the increased prevalence of obesity which is estimated to rise to over 1 billion obese individuals by the year 2025. The association between the Body Mass Index (BMI) and type 2 Diabetes is well recognised. Raised BMI is a major predictor of the risk of T2DM. T2DM is associated with multiple complications and it wields huge negative impact on the economy due to its financial burden. Preventing Type 2 Diabetes, therefore, has become a public health priority. Many published randomized controlled trials (RCTs) have demonstrated that implementing lifestyle measures in terms of dietary modifications and/or increasing the level of physical activity can successfully prevent or delay the onset of T2DM. This integrative review utilises evidence from different randomised trials obtained through a literature search on the database of PubMed and Google Scholar to examine the evidence behind the idea that T2DM is preventable by lifestyle modification. 12 RCTs carried out on individuals with impaired glucose tolerance and reviewed the effect of lifestyle interventions on the onset of type 2 Diabetes were identified and analysed. Most of the studies yielded consistent results in keeping with those of other diabetes prevention trials. There is clear evidence in literature that T2DM can be prevented or its onset delayed by intensive lifestyle changes including dietary measures and increased level of physical activity. There is, however, limited evidence that implementing lifestyle changes might alter the overall macro or microvascular outcome. There is wide variability in the applied lifestyle changes in these trials. Future research should focus on establishing standardised dietary and physical activity recommendations that are tailored to the needs of different ages and ethnic subgroups in the community as per NICE guidance.

Study on oxidative stress parameters in obesity associated insulin resistance and diabetes mellitus

Talat Saatov[1], Sanobarkhon Irgasheva[1], Zafar Ibragimov[1,2], Elvira Ibragimova[1], Tokhir Ishanhodjaev[1], Bakhodyr Zainutdinov[1], Mukhammadjon Mustafakulov[1], Timur Alimov[1,2], Nigora Maksutova[3] & Zulaykho Shamansurova[1,4]
[1]Institute of Biophysics and Biochemistry, Mirzo Ulugbek National University of Uzbekistan, Laboratory of Metabolomics, Tashkent, Uzbekistan; [2]Institute of Hematology, Uzbekistan Public Healthcare Ministry, Department of Molecular Genetics, Tashkent, Uzbekistan; [3]Center for the Scientific and Clinical Study of Endocrinology, Uzbekistan Public Healthcare Ministry, Tashkent, Uzbekistan; [4]Tashkent Pediatric Medical Institute, Uzbekistan Higher Education Ministry, Tashkent, Uzbekistan

Obesity of varying severities can be seen in the vast majority of patients with type 2 diabetes mellitus (DM2). Oxidative stress is considered as a key pathogenetic link in the formation of metabolic disorders in obesity. The work was initiated to assess intensity of oxidative stress in obese patients with DM2.
Materials and methods
The patients were divided into 3 groups. Patients with DM2 and BMI > 30 kg/m^2 were included into the 1st group. The 2nd group consisted of obese non-diabetic persons with BMI > 30 kg/m^2. Apparently healthy persons with BMI < 30 kg/m^2 were included into the 3rd group. Concentrations of malondialdehyde (MDA), a lipid peroxidation (LPO) end product, were

used to assess LPO in blood of patients with diabetes mellitus. Activity of catalase, an antioxidant system (AOS) enzyme, was used to assess AOS. Serum concentrations of TNF-α, a proinflammatory cytokine, were measured by EIA with the test systems (Vector-Best, Russian Federation).
Results
As compared to apparently healthy persons, HOMA-IR index was found higher in obese non-diabetics by 1.8 times ($P < 0.05$) and in obese patients with DM2 by 2.6 times ($P < 0.01$). Lipid profile parameters typical of atherogenic disorders, to name elevated triglycerides, as well as LDL, VLDL and cholesterol, were found in obese patients in these two groups. Our study on blood LPO and AOS demonstrated significant impairments in peroxidation and weakening of antioxidant mechanisms both in obese diabetics and non-diabetics. As compared to apparently healthy persons, serum concentrations of MDA, a toxic product of lipid peroxidation, were observed higher in obese diabetics (by 40.3%, $P < 0.01$) and obese non-diabetics (by 14.3%, $P < 0.05$). In these patients, blood catalase activity was found declined to be the evidence for reduction of AOS activity. Of interest, as compared to apparently healthy persons, serum TNF-α levels were found significantly higher by 5 times ($P < 0.01$) in obese diabetics and by 4.5 times ($P < 0.05$) in obese non-diabetics, demonstrating direct correlation to HOMA-IR index.
Conclusion
Associated with obesity, insulin resistance and diabetes mellitus facilitate intensification of oxidative stress in the organism. Significant elevations in serum TNF-α concentrations is the risk factor for insulin resistance and DM2.

Do metabolic syndrome and diabetes affect skin autofluorescence in patients with morbid obesity?

Tugce Apaydin & Dilek Gogas Yavuz
Marmara University School of Medicine, Endocrinology and Metabolism, Istanbul, Turkey

Purpose
Obesity, diabetes mellitus, and metabolic syndrome (MetS) have been known to be associated with increased skin autofluorescence (SAF). In patients with MetS, higher SAF measurements were found to be associated with an increased number of the components of MetS. In this cross-sectional study, we aimed to evaluate the association of MetS and its' components with skin autofluorescence in severely obese patients and to examine whether diabetes or metabolic syndrome contributed to the increase in skin AGE in obese patients.
Methods
We included 801 patients with morbid obesity who were followed up at Marmara University Medical School Endocrinology and Metabolism Department outpatient clinic between 2017 and 2020. Cross-sectionally, advanced glycation end products (AGEs) were measured using SAF in the forearm approximately 10 cm below the elbow fold, with an AGE Reader (DiagnOptics Technologies, Groningen, The Netherlands). Laboratory data [fasting plasma glucose, HbA1c, LDL-c, HDL-c, triglyceride, total cholesterol] were obtained retrospectively from the medical records.
Results
In this cross-sectional study, the prevalence of MetS in morbidly obese patients was 65.5% (n = 525). Diabetes mellitus and hypertension were present in 40.9% (n = 328) and 43.7% (n = 357) of the patients. Morbid obese patients and patients with MetS had higher SAF measurements compared to the control group, 1.85 ± 0.44 AU and 1.86 ± 0.43 AU versus 1.72 ± 0.30 AU, respectively ($P = 0.016$). SAF measurements of MetS negative patients were not statistically different from the control group ($P = 0.076$). Patients with five MetS criteria had higher SAF measurements compared to patients with less number of the MetS components ($P = 0.019$). There was no difference between SAF levels between diabetic patients, patients with impaired glucose metabolism and patients with normal glucose metabolism ($P = 0.513$). In multiple regression analysis, HDL level was found to be an independently associated parameter with SAF (R2 = 6.06%, $P = 0.033$).
Conclusion
We found that obesity itself rather than concurrent diabetes and metabolic syndrome contribute to an increase in SAF. Although MetS, diabetes mellitus are known as factors related to increased SAF, obesity can cause elevated SAF measurements in different ways independently of concomitant comorbid diseases, larger studies with longer follow-up are needed to enlighten the underlying mechanism.

Prevalence of obesity and its association with metabolic diseases in women from low-and-middle income countries (LMICs): A systematic review and meta-analysis

Thais Rocha[1], Eka Melson[1,2], Javier Zamora[1,3], Borja M. Fernandez-Felix[3], Soha Soby[4], Ana Pilar Betran[5], Wiebke Arlt[1] & Shakila Thangaratinam[1]
[1]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom; [2]Ninewells Hospital, NHS Tayside, Dundee, United Kingdom; [3]Instituto Ramón y Cajal de Investigación Sanitaria – IRYCIS, Clinical Biostatistics Unit, CIBER Epidemiología y Salud Pública (CIBERESP), Madrid, Spain; [4]Queen Mary University of London, Women's Health Research Unit, Barts and The London School of Medicine and Dentistry, London, United Kingdom; [5]World Health Organization, Department of Reproductive Health and Research, Genève, Switzerland

Introduction
Obesity is a global health challenge, with more than 50% of the world´s obese population residing in LMICs. Although adiposity is a well-known major risk factor for noncommunicable diseases (NCDs) such as hypertension, and diabetes mellitus, the delivery of effective NCDs interventions is still a challenge to health systems. About 85% of the NCDs premature deaths occur in LMICs. Obesity is more prevalent in women than men, however the burden of obesity and its association with NCDs in women from LMICs is unknown. We performed a systematic review and meta-analysis to assess the prevalence of obesity and metabolic complications in adult women from LMICs.
Methods
MEDLINE, EMBASE and Cochrane were searched from inception to February 2020. Cross-sectional and cohort studies that reported prevalence of obesity from LMICs were included. Prevalence (95%CI) of obesity and metabolic outcomes were assessed and stratified according to World Bank Region, country´s income status, setting, and year of the study. Meta-regression was performed for the association between the risk of obesity, hypertension, and T2 diabetes and age.
Results
From the 11.189 citations identified, 218 studies were eligible for analysis (376.405 women in 63 countries). Overall prevalence of obesity, hypertension, and type 2 diabetes in women were 22% (95% CI 20–24%), 26% (95% CI 23–30%), and 7% (95% CI 6–9%), respectively. Prevalence varied according to World Bank Region ($P < 0.001$), country´s income status ($P < 0.001$) and setting ($P < 0.001$). Higher rates of obesity, hypertension, and type 2 diabetes were found in upper-middle countries and urban setting. Obesity increased the risk of hypertension [OR: 2.43 (95% CI 2.19–2.80)] and type 2 diabetes [OR: 2.84 (95% CI 2.16–3.74)] in women. Overall, women presented almost a 3-fold increase of the risk of obesity [OR: 2.75 (95% CI 2.50–3.02)] as compared to men. Meta-regression suggests a positive association between women´s age and the prevalence of obesity [1.045 (95% CI:1.03–1.06, $P < 0.001$)], hypertension [1.085 (95% CI:1.07–1.10, $P < 0.001$)] and T2 diabetes [1.076 (95% CI:1.03–1.12, $P < 0.001$)]. Same association was found for the risk of obesity in women, irrespective of age difference between women and men [1.019 (95% CI:0.99–1.05, $P < 0.232$)].
Conclusion
Women are disproportionately affected with obesity compared to men in LMICs. It is therefore essential for decision-makers to develop appropriate strategies to tackle obesity and its complications in the female population in LMICs.

Adherence to the mediterranean diet and metabolic syndrome: Potential relationship in patients candidates for bariatric surgery

Sara León Utrero, Mª del Carmen Andreo López, Enrique Redondo Torres, Mª del Carmen Serrano Laguna & Mª Luisa Fernández Soto
Hospital Universitario San Cecilio, Servicio de Endocrinología y Nutrición, Granada, Spain

Objective
To study the possible relationship between adherence to the Mediterranean diet and the metabolic syndrome.
Material and methods:
Retrospective observational study of patients evaluated in a prebariatric surgery consultation between November 2017 and November 2019,

who were given a questionnaire of adherence to a Mediterranean diet. Anthropometric and analytical parameters related to the metabolic syndrome are evaluated. The statistical study was carried out with the SPSS15 program
Results
Total of 135 patients (60% women) with a mean age of 44.53 ± 13.03 years. Average weight of 124.00 ± 25.84 kg and BMI of 43.68 ± 7.28 kg/m^2. When carrying out the adherence questionnaire to the Mediterranean diet, 61% obtained a score of less than 7 points (low adherence). Analytically, mean basal glycemia of 100.98 ± 25.59 mg/dl, HbA1c of 5.99 ± 0.99%, HOMA index of 5.99 ± 4.63, insulinemia of 25.97 ± 15.85 mg/dl. dl, total cholesterol 187.84 ± 36.58 mg/dl, HDL 47.78 ± 9.79 mg/dl, LDL 114.6 ± 30.15 mg/dl and triglycerides 164.88 ± 128.09 mg/dl. They had 25-hydroxyvitamin D levels of 18.4 ± 7.15 and C-reactive protein of 12.56 ± 23.05. When performing the Student's T test for independent samples, we found that the group with low adherence presented statistically significant differences (–10.16 ± 4.42 mg/dl, P = 0.02) in the levels of insulinemia; without differences in the rest of the variables analyzed.
Conclusion
Good adherence to the Mediterranean diet can contribute to a lower situation of hyperinsulinism, which in turn would lead to a lower risk of developing type 2 diabetes mellitus, which as we know is a fundamental element of the metabolic syndrome.

Antipsychotic induced obesity in schizophrenia and GLP-1 analog treatment? – A case-report

Iva Jakubíková & Martin Haluzík, MD, DSc
Institute for Clinical and Experimental Medicine, Diabetes Centre, Prague, Czech Republic

Introduction
Schizophrenia is one of the seven most disabling diseases according to World Health Organization. The most potent antipsychotic drugs clozapine and olanzapine are associated with excessive weight gain. Premature deaths in schizophrenia and shorter life expectancy are mainly caused by obesity-related cardiovascular diseases. Obesity itself is associated with brain deterioration, cognitive decline and overall worse quality of life. GLP-1 receptor analogs may be a potent drugs in schizophrenia addressing metabolic disturbances with potential central effects through GLP-1 receptors leading to neuroprotection, plasticity and learning. Studies in this specific field are scarce, so I present here a case-report.
Case-report
A 49 years-old male was referred to our obesity clinic. He has suffered from schizophrenia since the age of 24, type 2 diabetes since the age 34. The weight gain caused by psychiatric disease was poteantiated by psychiatric medication, currently a long term treatment by risperidone 4 mg daily and olanzapine 5 mg daily. At the initial visit, the patient was very passive in communication, but he filled all questionnaires including 10 days dietary monitoring, where the food was stated precisely with timing, location and in grams. After nutritionist consultation (diet 150 g saccharides, 50 g lipids, 80 g protein, 6000kJ) and physicians´ recommendations done emphasizing the need for physical activity -walking instructions, buying watch for daily step monitoring etc the patient lost 9 kilos in 3 months. He felt generally better, was surprisingly quite talkative, reached every day walk of about 8000 steps. The diabetes control improved from 70 mmol/mol to 57 mmol/l also due to newly prescribed weight-lowering GLP-1 analog semaglutide after 2 months of usage currently on dose 0.5 mg weekly, plus from previous metformin 2 g/day. After 3 months the BMI decreased from 37.6 kg/m^2 to 34.8 kg/m^2 and waist circumference from 125 cm to 120 cm, respectively.
Conclusion
From my clinical point of view I was a bit sceptic to the adherence of this schizophrenic patient to the weight-reducing programme. On the other hand the primary and secondary obesity prevention in psychiatric patients must be addressed. These patients need deeper clinical focus from all specialists and obesity centers shall meet the needs. Many schizophrenic patients are underestimated in obesity interventions and most of them never get a chance. GLP-1 analogs build new effective perspectives in the treatment of obese schizophrenic patients including potential neuroprotective effects.

Trends in dietary food groups and DASH score among adults: A longitudinal study from tehran lipid and glucose study, 2006–2017

Maryam Aghayan, Somayeh Hossainpour & Parvin mirmiran
Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Nutrition and Endocrine Research Center, Tehran, Iran

Background
To examine the secular trends of dietary food groups and diet quality among adults, overall and by sex, education, and occupation status.
Methods
This study was conducted within the framework of the Tehran Lipid and Glucose Study (TLGS). Demographic and anthropometric measurements were gathered using standard questionnaires. In terms of socioeconomic information, participants were divided into two groups according to their education and occupation levels. Regular dietary intakes of participants were gathered by a validated and reliable food frequency questionnaire over the previous year and the DASH scores were computed to evaluate the diet quality. Generalized Estimating Equations were used to assess secular trends in food groups within the four phases.
Results
From 2006 to 2017, the intakes of whole grains, legumes, and nuts and seeds increased, and the intakes of refined grains, dairy products, and solid fats decreased significantly (P for trend < 0.001). Dietary fruits, vegetables, meats, and soft drinks intakes did not change significantly. According to socioeconomic groups, meats intake decreased significantly among men, non-educated, and non-occupied participants, and fruits intake increased in both women and educated participants. Based on a 40-point scale, the DASH score increased from 18.1 ± 0.0 in phase1 to 22.7 ± 0.1 in phase 4 of the TLGS (P for trend < 0.001).
Conclusions
Over a decade, in addition to improvements in intakes of a number of dietary food groups, the estimated overall diet quality of the study population showed a modest improvement. These findings may determine areas for more attention to improve the overall dietary intake of the population.
Keywords: Food groups; DASH score; Trend; socioeconomic status; Adults; TLGS

AEP336

A case of post-partum diabetic ketoacidosis in a patient with gestational diabetes mellitus

Nauman Jadoon
Queen Elizabeth University Hospital, United Kingdom

Background
There is ample data linking GDM to risk of type 2 diabetes mellitus postpartum, however, development of type 1 diabetes mellitus and presentation with DKA is rare especially few weeks postpartum.
Case
A 28 year old female 4 month postpartum was admitted to hospital with rapid weight loss and osmotic symptoms. She did not have any past medical history of note, with history of T2DM in both mother and father. She had gestational diabetes during her pregnancy which required insulin to control. Her weight dropped from 72 kg post-natally to 55 kg on presentation with significant weight loss in the 2 weeks prior to admission. Her HbA1c in her third trimester was 42 which jumped to 98 mmol/mol. She was admitted with a glucose 20.5 mmol/l, H + 63 nmol/l, HCO3 10 mmol/l and was started on treatment for DKA at that point. Because of the history of Hb D Punjabi trait, fructosamine was checked which was also elevated at 600 umol/l. Her c-peptide was 0.11 nmol/l and GAD antibodies were negative. The patient was discharged 2 days later on Levemir and novorapid and followed up by the diabetes team.
Discussion
Previous case reports have shown that T1DM either presents early on in the first few days after delivery or few months afterwards, while our patient presented with DKA 4 months postpartum with DKA. The case presented here highlights that patients treated for GDM can present with T1DM postpartum and this should be considered.

A challenging presentation of Catamenial DKA

Nabeel Ahmed
Leighton Hospital, Endocrinology, United Kingdom

A 34-year-old T1DM nurse was admitted with a history of recurrent episodes of DKA. In the current admission at our hospital, on detailed history she reported of getting DKA almost every month when her menses would start. She would be following the sick day rules of DKA but it wouldn't help prevent her going into DKA. No other precipitating factors were found. She was diagnosed as a case of Catamenial DKA and was started on OCP's to see how what effect it would have on her DKA the next month. She unfortunately was re admitted with DKA warranting ITU admission around the time of withdrawal bleeding of OCP's. A joint Endocrine- Gynaecology MDT was dine and she evaluated by Gynaecology team to rule out endometriosis with USS Pelvis and CT-TAP. She was then started on GnRH analogue to cease her menses and started on HRT with all the risks and benefits explained of the same. She has been regularly followed up at Diabetic and Gynaecology clinics and hasn't had an episode of DKA in the past 6 months now with excellent BM control. Points for discussion with the audience: 1. Catamenial DKA and its management. Your experience? 2. Guidelines for managing this rare type of DKA? 3. OCP vs GnRH + HRT ; your experience and alternatives?

Management of cervicofacial odontogenic cellulitis in diabetics

Mohamed Masmoudi, Mehdi Hasnaoui, Lazid Sara, Rihab Lahmar & Mighri Khalifa
Tahar Sfar Hospital Mahdia, ENT Department, Mahdia, Tunisia

Objective
To summarize the characteristics and treatment experience of cervicofacial odontogenic cellulitis in diabetic patients and to provide clinical basis for the diagnosis and treatment.
Material and method
Retrospectively analysed 50 cases of cervicofacial cellulitis in diabetics in the ENT department of Taher Sfar Mahdia, Tunisia from from january 2015 to december 2018.
Results
A total of 50 diabetic patients were included in this study. The average age was 40 years (Range: 7 and 71 years). In terms of their sex distribution, we found a male dominance. The level of hygiene of the patients was poor: 80% did not brush their teeth. 15 patients were cigarette smokers and 3 were alcohol consumers. The waiting period before consultation varied between 1 and 30 days. 30% of patients said they had taken a no steroidal anti-inflammatory drug. 50% of patients were under antibiotic treatment the time of the consultation. The clinical sign was mainly an exo-buccal tumefaction in 40 patients. The results showed that 35 of cases were located under the chin. As for the clinical form, 60% of the patients presented a serous acute cellulitis, 30% a suppurative acute cellulitis and 10% a chronic cellulitis. The main etiology was in 90% dental pulp necrosis. The treatment consisted in prescription of antibiotic and intensified insulin therapy in all of cases, a surgical drainage in 30% of cases and an extraction of the affected tooth in 70% of the cases. The treatment allowed to achieve a favorable evolution in 98% of the cases. One patient died due to mediastinitis.
Conclusion
the inadequate treatment or chronic dental infection, associated with immunodepression and some cofactors (tobacco, alcohol.) can lead to severe case of cellulitis. Medical and surgical management should be carried out as soon as possible to prevent serious complications.

Predictors of masked hypertension in type 2 diabetics

Safi Wajdi[1], Hadj Kacem Faten[1], Hana Charfi[1], Ghorbel Dorra[2], Elleuch Mouna[1], Boujelben Khouloud[1], Triki Faten[2], Mnif Fatma[1], Charfi Nadia[1], Mnif Feki Mouna[1], Rekik Nabila[1], Kammoun Samir[2] & Abid Mohamed[1]
[1]Hedi Cheker, Endocrinology, Tunisia; [2]Hedi Cheker, Cardiology, Tunisia

Introduction
Masked arterial hypertension (HTAM) is a relatively recently described entity which gives patients with it the same cardiovascular risk as permanent hypertension. In this context, we report a prospective study including 53 patients in order to determine the prevalence and predictive factors of HTAM in diabetics.
Methods
Descriptive prospective study of 53 patients treated in the endocrinology Diabetology departement of hedi ckeker university hospital sfax, Tunisia. These patients had no history of hypertension and did not take any treatment for high blood pressure. Medical follow up showed normal blood pressure (lower than 140/90) for the last 2 years.
Results
The average age of our patients was 55.3 years (range 35–75 years) with a sex ratio (M/F) equal to 0.89. The duration of diabetes was on average 8.7 years (range 2–17 years). The prevalence of HTAM was 64%, occurring in predominantly non-dipper subjects (58.5%) Regarding the predective factors of HTAM, we were able to collect in univariate analysis the following factors: duration of diabetes, fasting blood sugar, weight and microalbuminuria. In multivariate analysis, the predictive factors that emerged in our study are poor glycemic control (HbA1c > 7%), high body mass index (BMI) and duration of diabetes with an OR of (15.8; $P = 0.04$) (1.2; $P = 0.02$) and (1.3; $P = 0.009$). Our results are consistent with those of the literature which shows that diabetes imbalance, BMI and duration of diabetes are predictive factors of AMTH. Other risk situations for HTAM, not isolated in our work, have been found and mentioned by some authors: advanced age, male sex, metabolic syndrome as well as normal high blood pressure in the office.
Conclusion
It seems essential to carry out ambulatory screening for HTAM in diabetic patients. The induced morbidity and mortality and the cardiovascular risk would be significant and fully justify it.

Management of carpal tunnel syndrome in diabetic patients

Soumaya Elarem, Aymen Haj Salah, Ikram Haddada, Hajer Kerkeni, Wafa Said, Mouna Sghir & Wassia Kessomtini
Tahar Sfar Hospital, Mahdia, Tunisia

Introduction
Carpal tunnel syndrome (CTS) is the most common compressive neuropathy in upper limb. Although most causes are idiopathic, CTS may be associated with some systemic conditions such as diabetes mellitus (DM). The aim of this study was to describe conservative procedures used in physical medicine and rehabilitation in the management of CTS.
Patients and methods
We carried out a descriptive retrospective study of cases of diabetic carpal tunnel syndrome treated in PMR department over a period of 1 year.
Results
Thirty-five cases of CTS were included in the study, 27 women and 8 men. The mean age was 46.68 ± 10.69 years. CTS was bilateral in 88% of cases. Acroparesthesias was the major symptom described in 56% of cases. An electro neuromyography (ENMG) was performed in 80% of patients revealing moderate impairment in 52% of cases. Rehabilitation techniques included transcutaneous electrical nerve stimulation (TENS) and therapeutic ultrasound (US) as well as manual therapy for the median nerve and its surrounding structures were prescribed to 62% of the patients. Half of the patients received vitamin therapy and 35.5% pregabalin. Theses therapeutic measures were efficient in 67.5% of the cases and local corticosteroid infiltration was required in 42.5% of the cases. Surgery was required in 12% of cases for whom conservative treatment wasn't efficient.
Conclusion
Conservative treatment including physiotherapy modalities and manual therapy occupies an important place in the management of CTS in PMR.

Prevention of cardiovascular risk in the elderly with diabetes

Tlili Abir, Najoua Lassoued, Rebai Senda, Alaya Wafa, Zantour Baha & Sfar Mohamed Habib
Taher Sfar University Hospital, Endocrinology Department, Mahdia, Tunisia

Introduction
Cardiovascular disease is the leading cause of death ahead of infectious diseases and cancers. The frequency of morbidity and mortality associated with cardiovascular diseases increases in the elderly and their management becomes more difficult. Hence an early and adequate management of cardiovascular risk factors is needed. The objective of this work was to determine the cardiovascular risk factors in elderly diabetics and to assess the quality of cardiovascular risk management in these patients.
Patients and methods
Retrospective study of 94 diabetic patients aged over 65 years who were hospitalized in the endocrinology department of Mahdia or followed up at the outpatient clinic between November and December 2020.
Results
The mean age was 71 ± 5 years with extremes of 65 and 90. The female predominance was remarkable. Almost all of our patients had type 2 diabetes. The mean duration of diabetes was 12 ± 8 years. Cardiovascular disease was present in 26.6% of patients. The level of cardiovascular risk was high in 39.4% of patients and very high in 41.5% of patients. The cardiovascular risk factors observed were: hypertension (73.4%), android distribution of fat (7.44%), dyslipidemia (55.3%), microalbiminuria (7.44%), obesity (29.8%), smoking (7.4%) and a family history of cardiovascular disease at an early age (3.2%). The prevention of cardiovascular risk was primary for 37.2% of our patients and secondary for 30.9% of cases. Antiplatelet drugs were prescribed in 33% of patients. The subjects who required statin treatment as recommended represented 57% of patients, of whom 92.6% were treated.
Conclusion
Our study confirmed that the management of the cardiovascular risk in the elderly diabetic patients was satisfactory and in accordance with the recommendations of 'learned societies'.

[1]Ankara University, Endocrinology and Metabolism, Ankara, Turkey; [2]Ibn Sina University Hospital, Turkey

Aims
During April and May 2020 in Turkey, changing priorities in the health system and some restrictions on daily life in order to prevent the spread of SARS-CoV-2 infection may worsen metabolic control of people with diabetes. We aimed to investigate whether glycemic dysregulation or disturbance of lipid metabolism occur in people with diabetes during the lockdown period.
Methods
This retrospective study included 132 participants with type 2 diabetes mellitus and 6 participants with type 1 diabetes mellitus. We compared some metabolic parameters [HbA1c (Glycated haemoglobin), LDL (Low density lipoprotein), HDL (High density lipoprotein), Triglyceride, Body weight] of these people in pre-lockdown and post-lockdownperiod.
Results
HbA1c levels of the participants were higher in post-lockdown period when compared with pre-lockdown period (mean HbA1c 8.1% (65 mmol/mol) and 7.7% (60.7 mmol/mol) respectively, $P = 0.001$). In people with uncontrolled diabetes whose HbA1c > 7% (53 mmol/mol) in pre-lockdown period, higher triglyceride levels were detected in post-lockdown period ($P = 0.036$). There was no significant change in LDL, HDL levels and bodyweight.
Discussion
There are few studies analyzing real-life data specific to the metabolic control of people with diabetes during the pandemic period. In a Chinese study of 135 participants aged older than 65, HbA1c change between January and March in 2020 was statistically significant compared with the same period last year. In a study from India with 52 people with type 1 diabetes, it was observed that the average HbA1c values, which were 72.7 mmol/mol (8.8%) before COVID-19 lockdown period, increased to 85.8 mmol/mol (10%) after lockdown period. Our findings replicated the main outcomes of these two studies. In contrast with the Indian study, the majority of our sample was diagnosed with type 2 diabetes. Our study showed that triglyceride levels increased statistically significant in individuals with uncontrolled diabetes. The lockdown period may cause metabolic dysregulation due to physical inactivity, increased carbohydrate intake, weight gain, sarcopenia, and emotional stress.
Conclusion
Our results reflect the real-world experience of metabolic dysregulation of people with diabetes during lockdown. Considering these results; special measures like home exercise programs, telemedicine consultations, and the spread of technologies for diabetes should be taken for follow-up of individuals with diabetes during the pandemic lockdown.

The effect of Covid-19 pandemic lockdown on the blood glucose regulation of diabetic patients; one center experience

Yasemin Emur Gunay[1], Hulya Coskun[1], Egemen Unal[2], Damla Tufekci[1], Ahmet Suat Demir[1], Muhammet Cuneyt Bilginer[1], Ozge Ucuncu[1], Irfan Nuhoglu[1] & Mustafa Kocak[1]
[1]Karadeniz Technical University Faculty of Medicine, Department of Endocrinology and Metabolism, Trabzon, Turkey; [2]Yildirim Beyazit University Faculty of Medicine, Department of Public Health, Ankara, Turkey

Aim
The COVID-19 pandemic has affected the whole world, reducing hospital admissions of patients with chronic diseases. This study aims to evaluate the effects of difficulties experienced by diabetic patients in diabetes management on blood glucose regulation during the COVID-19 pandemic lockdown.
Methods
This study included 93 diabetic patients followed up in Endocrinology and Metabolic Diseases Clinic of Karadeniz Technical University. Biochemical parameters (glucose, HbA1c, lipid profile), diet and exercise status were compared between patients' first admission to the hospital after June 2020, the date that pandemic course started to slow down and their last admission before 11 March 2020, the date of the first case seen in Turkey. The frequency of blood glucose monitoring, compliance to diabetic treatment, hypoglycemia and hyperglycemia frequency, hospital admission requirements of patients and whether they had any infection were questioned.
Findings
89.2% of the participants were Type 2 Diabetes Mellitus (DM) and 10.8% were Type 1 DM. We found that 78.5% of them had dietary compliance, 41.9% did exercise at home, 53.8% used their medicines regularly, and 43.0% monitored their blood glucose every day. More than one hypoglycemia per week was observed in 15.1% of the patients, while hyperglycemia was observed more than once a week in 4.9%. When biochemical values before and after the lockdown were compared, a statistically significant decrease was found in fasting glucose level ($P = 0.026$) and body mass index ($P = 0.008$). No statistically significant difference was observed in terms of HbA1c and lipid levels before and after the lockdown. When the HbA1c change was evaluated; it was observed that the frequency of HbA1c increase was higher in those who did not comply to their diet and who did their blood glucose follow-up 'less than once a week or not at all' ($P = 0.001$; $P = 0.015$, respectively). When non-HDL-K change was evaluated; it was observed that non-HDL-C increase was higher in those who did not comply to diet regularly and did not exercise at home ($P = 0.047$; $P = 0.037$, respectively).
Discussion
This study has shown that patients who did not have COVID infection and did not apply to the hospital for treatment and follow-up of diabetes during the COVID-19 pandemic lockdown, can continue their diabetes management, compliance and follow-up on their own. It once again pointed out the importance of diabetes education, diet, exercise, frequency of blood sugar monitoring and compliance to the treatment.

Hypoglycemia in non-diabetic patients

Messaoudi Najoua, Nisrine Bouichrat, Nada Derkaoui, Marouan Karrou, Rami Imane, Siham Rouf & Hanane Latrech
Mohammed VI University Hospital Center, Oujda, Department of Endocrinology-Diabetology and Nutrition, Oujda, Morocco

Keywords: Hypoglycemia- non-diabetic patients

Introduction

Hypoglycemia in non-diabetic patients is a rare entity, diagnosed by the presence of Whipple's triad (plasma glucose concentration less than 50 mg/dl, neuroglycopenic-symptoms, and resolution of symptoms after the correction of hypoglycemia). It may be secondary to several etiologies, including tumors that may be malignant. Prolonged supervised fasting is frequently used to diagnose and orientate the etiological investigations. The aim of our study is to describe the initial symptoms, the evaluation and management of hypoglycemia in patients without diabetes mellitus.

Patients-methods

This is a retrospective and descriptive study including non-diabetic patients admitted in the Endocrinology-Diabetology and Nutrition Department of the Mohammed-VI University-Hospital-Center of Oujda-Morrocco, for the exploration and management of hypoglycemia. All patients have benefited from a clinical examination, biological and radiological exploration.

Results

We have collected 07patients admitted to our department for hypoglycemia. No history of diabetes was noted in these patients. The mean age at admission was 29.8 ± 22.2 years, ranging from 17 months to 54 years. The sex-ratio (M/F) was 4/3. All patients showed neuroglycopenic signs. A prolonged supervised fast was performed in 5 patients, confirmed the presence of hypoglycemia. Eiologies were various: the diagnosis of adrenal insufficiency was established in 2 patients (17-month-old infant and 4-year-old child). A benign insulinoma was noted in one patient and a malignant insulinoma with extensive liver metastases in one patient with persistent hypoglycemia after surgery, motivating the use of everolimus at a dose of 10 mg/day. The diagnosis of functional hypoglycemia was concluded in 3 patients, secondary to somatostatin-analogues treatment in one acromegalic patient, one case of prediabetes, and in one patient an abnormal-regulation of carbohydrate metabolism was observed.

Discussion and conclusion

Recently, Non-diabetic hypoglycemia are classified according to the clinical condition of the patient: well or ill appearing individual. Biological exploration should be done at the time of spontaneous development of symptoms. If this is not possible, it can be done during a prolonged supervised fast test (up to 72 hours), which constitute the gold standard for diagnosis and etiological orientation. The etiological investigation includes searching for an insulinoma, the most frequent tumor responsible for hypoglycemia in adults, which requires an echo-endoscopy and pancreatic CT-scan.The treatment is initially based on the correction of acute hypoglycemia according to the patient's state of consciousness. Either by 15 to 20 g of glucose orally if patient is conscious or by intravenous administration of glucose serum if patient is unconscious. after correction, the treatment is etiologic.

The functional status of the thyroid gland in pregnant women with gestational diabetes mellitus

Fatima Ushanova & Tatyana Demidova
Pirogov Russian National Research Medical University, Department of Endocrinology, Moscow, Russian Federation

Background and aims

Gestational diabetes mellitus (GDM) is a disease manifested by hyperglycemia, first diagnosed during pregnancy, which usually resolves after delivery. In GDM, there is a risk of adverse effects in both a mother and a fetus. Thyroid hormones (TG) play a huge role in the proper development of the child. Given the high prevalence of thyroid pathology and disorders of carbohydrate metabolism during pregnancy, the study of the relationship between these diseases and the prevalence of hypothyroidism in this group of pregnant women is relevant to improve the effectiveness of treatment and prevent complications.

Materials and methods

Retrospective analysis of individual pregnancy cards for 2019 based on the antenatal clinics of the Moscow Department of Health V.P. Demikhov Hospital. All women underwent a study of fasting blood plasma glucose, TSH, free T3, free T4, antibodies to thyroid peroxidase (TPO), an oral glucose tolerance test was performed at 24–28 weeks of gestation.

Results

Outpatient records of 779 pregnant women aged 19 to 46 years were evaluated, of which 599 patients were diagnosed with GDM. The average age of pregnant women with GDM was 33 years. Diet therapy was prescribed in 100% of cases. 349 (58.26%) pregnant women with GDM had no concomitant pathology. In 114 (19.03%) cases of GDM manifest hypothyroidism was revealed; in 19 (3.17%) cases, there was subclinical hypothyroidism as a result of autoimmune thyroiditis (AIT); 46 patients showed carriage of antibodies to TPO with a normal TSH level. The average values of hormonal parameters in the study group were: FT3 – 3.44 (0.36–15.8) pmol/l, FT4 – 2.33 (0.099–19.4) pmol/l, TSH – 3.15 (0.02–8.72) mIU/l. 74% of pregnant women with GDM had a BMI of 25 to 30 kg/m^2, with a mean of 27.3 kg/m^2. In 92 (15.35%) pregnant women, GDM developed against the background of obesity (BMI over 30 kg/m^2); 19 (3.17%) patients with GDM had hypothyroidism and obesity.

Conclusions

According to the conducted statistical analysis, it follows that GDM occurs more often in women with overweight at the time of gestation. GDM in this group of pregnant women is often combined with hypothyroidism and the carriage of antibodies to TPO. In this connection, further study of the relationship between these pathologies is required.

Use and effectiveness of dapagliflozin in type 1 diabetes: Clinical experience data of six months

José Ignacio Martínez Montoro, Andrea Fernández Valero, Miguel Damas Fuentes, José Luis Pinzón Martín & Francisco J Tinahones
Hospital Universitario Virgen de la Victoria, Endocrinology and Nutrition Department, Málaga, Spain

Introduction

Sodium-glucose cotransporter-2 inhibitors (SGLT2i) are a new class of oral antidiabetic drugs used for the treatment of type 2 diabetes mellitus. Recently, the SGLT2i dapagliflozin was approved for use in type 1 diabetes (T1DM) as an add-on to insulin therapy.

Material and methods

We conducted a retrospective observational study which included demographic and clinical-analytical data from 16 patients with T1DM that started dapagliflozin at a dosage of 10 mg/day. Our purpose was to assess the effect of dapagliflozin six months after its initiation.

Resultados

Data were analyzed from 16 patients with T1DM, 10 women and 6 men, 41.2 ± 14.8 years old, 22.7 ± 14.7 years of diabetes duration. 3 of the participants presented high blood pressure. With regard to diabetic complications, 4 patients had retinopathy, 1 nephropathy, 1 neuropathy, 1 ischemic cardiomyopathy. Basal characteristics of the participants: BMI 32.4 ± 6 kg/m^2; weight 91.1 ± 16.7 kg; HbA1c 8.1 ± 0.8%; blood pressure 129.8 ± 23.1/77.8 ± 11.12 mm Hg; basal insulin dose 46.7 ± 24.2 IU, prandrial insulin dose 34.8 ± 16 IU. 5 of the participants were on treatment with metformin. Six months after the initiation of dapagliflozin, significant reductions in BMI (30.7 ± 6.4 kg/m^2), weight (86.9 ± 18.2 kg), HbA1c (7.5 ± 0.7%), basal insulin requirements (44.3 ± 25 IU) and prandrial insulin requirements ((29.6 ± 15.2 IU) were observed. There were no significant differences with respect to blood pressure. Two patients discontinued dapagliflozin because of recurrent urinary tract infections.

Conclusion

The use of dapagliflozin in patients with T1DM was associated with an improvement of metabolic control, weight loss and reduction of insulin requirements, without severe side effects.

Growth factors in trophic disorders in diabetics

Henricia Laurinda Pangui, Mjabber Amal, Nassim Essabah Haraj &, Siham El Aziz & Asmaa Chadli
Ibn Rochd, Endocrinology, Casablanca, Morocco

Introduction

Epidermal growth factors accelerate healing in lesions of trophic disorders.

Methods

This is a prospective study carried out between February and June 2019 in the endocrinology and metabolic diseases department, involving 6 patients admitted for diabetic foot progressing for more than 3 months without

healing after conventional treatment. Having received the injections of growth factors of the EGF type.
Results
the sex ratio is 2, with an average age of 53 years (39–73), T2D is more representative at 67% with an average seniority of 16.5 years, all patients were unbalanced with an average HbA1c at 8.45%, degenerative complications are found in all our patients with an IRCT patient on dialysis. Foot lesions are mainly located on the sole of the foot with a type of plantar perforating disease complicated in 3 cases by osteitis, with an evolution ranging from 3 months to 2 years, on arteriopathic feet, classified stage IIIB and IIIC of the 'UT. The pre-treatment management consisted of a discharge and dressing adapted for each patient, a sorting of antibiotics and glycemic control. The patients received an average of 6 injections of EGF at the rate of 2 sessions per week, the average length of stay in hospital is 21 days. There was a case of over granulation causing treatment to be stopped. Complete granulation was obtained in 4 patients, with a mean total healing time of 80 days.
Conclusion
Growth factor injections considerably improved the healing and healing time of foot lesions in our patients and thus appears to be an asset in the management of diabetic foot.

The impact of functional insulin therapy on the psychological aspect of type 1 diabetics

Sanaa Bammou, Ait Yahya Abderrahmane, Rafi Sana, El Mghari Ghizlane & El Ansari Nawal
Mohamed VI University Hospital Center, Department of Endocrinology, Diabetology, Metabolic Diseases Nutrition, Marrakech, Morocco

Introduction
Functional insulin therapy is an educational method that is part of a strategy to intensify type 1 diabetes in order to optimize the balance of diabetes while improving the psychological aspect of the patient. The aim of this study is to assess the impact of functional insulin therapy on the psychological aspect of type 1 diabetics.
Patients and method
This is a retrospective and analytical descriptive study, conducted from March 2019 to August 2019, we included 20 type 1 diabetic patients who benefited from a functional insulin therapy education program and an evaluation of the psychological impact made by a questionnaire and a psychological interview.
Results
The average age of the patients was 20 years, with a sex M/F ratio of 4/16, and the duration of diabetes was on average 8 years. Functional insulin therapy is used exclusively in all patients. The psychological evaluation shows an improvement in the perception of the impact of diabetes in (66%), there is a decrease in anxiety in (75%), With (80%) of the patients declared a satisfaction with the method, (60%) declared acceptance of the treatment, 14 patients (70%) reported more autonomy and self-management and only (40%) reported an improvement in their socio-professional relationships, The doctor-patient relationship improved in (90%) patients. According to the open questions, functional insulin therapy provides better diabetes control and food freedom. The difficulties mainly felt are the calculation of the quantities of carbohydrates, the economic constraint and the multiple injections for treatment and monitoring.
Conclusion
The results suggest that learning functional insulin therapy improves the psychological aspect of type 1 diabetics through better control of the disease.

Implementation of flash glucose monitoring system in a regional hospital in the province of Cordoba

Ana Barrera Martín[1,2], Mª del Carmen Serrano Laguna[1,2], Rocío Domínguez Rabadán[1,2] & María Ángeles Gálvez Moreno[1]
[1]Hospital Universitario Reina Sofia, Endocrinología y Nutrición, Córdoba, Spain; [2]Hospital Público De Montilla, Endocrinología y Nutrición, Montilla, Spain

Introduction
The development of flash glucose monitoring system (FGM) has led to a change in the paradigm of diabetes control, beyond the evaluation of glycosylated hemoglobin (HbA1c). FGM allows to improve control of type 1 diabetes mellitus (T1DM) and the quality of life of patients.
Objective
Describe the baseline characteristics of patients with T1DM in a regional hospital in the southern area of the province of Cordoba and study changes after the start of FGM.
Design and methods
A retrospective observational study of patients we implant FGM, from the opening of the consultation (June 2020) to the present. Statistical analysis was performed using the SPSS program (SPSS, inc, v21.0) (Student's t-test for related samples).
Results
We evaluated 36 patients, a mean age of 36 ± 14.11 years, 58.3% women, BMI 26.46 ± 4.77 kg/m^2, 13.9% with thyroid pathology. Cardiovascular risk factors: 6.9% smokers, 11.1% hypertensive, 19.4% dyslipidemic. Previous follow-up of T1DM: 88.9% Endocrinology, 8.3% Internal Medicine and 2.8% Primary Care.
Baseline characteristics
20.83 ± 12.11 years of evolution, 38.9% performed between 4–6 daily blood capillary glucose, 30.6% diet by rations, basal insulin: 80.6% insulin Glargine U300; prandial insulin: 55.6% insulin Aspart; total daily insulin dose 0.70 ± 0.22IU/kg/day, 8.3% treatment with metformin. Microvascular complications: 19.44% (retinopathy); Macrovascular complications: 2.78% (ischemic heart disease). 5.6% of the patients required recycling of diabetes education. 94.4% had not used FGM and were referred to start it (86.1% in the first visit, 5.9% in the second). Biochemical and ambulatory glucosa profile (AGP) comparison from FGM implantation to successive revisions (first vs second, both with FGM): HbA1c 7.51 ± 0.72% vs 7.65 ± 0.65%, glucose 142.50 ± 36.65 vs 183.08 ± 63.88 mg/dl, P = NS both; no positive microalbuminuria data at follow-up. Coefficient of variation (CV) 38.54 ± 8.26 vs 36.55 ± 6.09%, GMI 7.06 ± 0.94 vs 7.36 ± 1.19%, time in hyperglycemia 31.09 ± 21.9 vs 35.18 ± 24.54%, time in hypoglycemia 6.73 ± 4.92 vs 9.91 ± 15.04%, time in range 62.18 ± 20.82 vs 5 4.91 ± 28.13%, P = NS in all. Average glucose 154.55 ± 35.64 vs 164.27 ± 45.83 mg/dl, P = 0.039.
Conclusions
In this cohort, the use of FGM has allowed a decrease in CV (although not significantly). However, the biochemical control and the glucometric data don't show an improvement trend, despite the increase in progressive use, possibly due to the low availability of data at present (more than half of patients have not yet undergone review after start FGM). In this regard, adequate diabetes education is essential, which we must emphasize more in our patients, increasing the rate of referral to nursing.

Dietary beliefs and behavior of pregnant women with diabetes

Bouab Maryem, Moukhlis Sabah, Btissam Ouafidi, Fatiha El Miski, Amine Lamrissi, Karima Fichtali & Said Bouhiya
Ibn Rochd University Hospital of Casablanca, Morocco., Gynecology And Obstetrics Department, Casablanca, Morocco

Introduction
Pregnant women with diabetes are prone to overeating and decreased physical activity, both sources of glycemic disorder. The objective of our study is to evaluate these dietary beliefs in order to improve the management of diabetes.
Materials and methods
Prospective observational study, including 100 patients with diabetic pregnancy followed in the department of gynecology and obstetrics of the ibn rochd university hospital center in Casablanca between January 2020 and November 2020.
Results
The study included 100 patients with an average age of 30 years, 40.5% had gestational diabetes and 59.5% had pre-gestational diabetes. 78.9% of the patients were on insulin and 21.1% were undergoing hygienic and dietary rules. Glycemic control was perfect in 56.4% of patients. For eating behavior: an abuse of slow sugars was found in 64% of patients with fat abuse in 64.6% and a consumption of fast sugars in 24.6%. 70.8% ate at fixed times while 18% skipped at least one meal. Regarding dietary beliefs, 70% of the patients thought they should eat less to be healthy, 39% thought

they could eat the food they wanted, 40% thought they should eat for two and 35% thought that weight gain should not be limite. As for physical activity, it is practiced by 28% of patients, 72% think it helps glycemic control while 20% think it can harm their pregnancy.
Conclusion
Our study shows the dietary beliefs and behavior of pregnant diabetic patients and highlights the need for better information and improved dietary education of these patients.

AEP351

Seasonal changes of 25(OH) vitamin D among elderly patients

Justyna Nowak[1], Marzena Jabczyk[2] & Barbara Zubelewicz-Szkodzińska[3]
[1]Medical University of Silesia, Faculty of Health Sciences in Bytom, Bytom, Poland; [2]Medical University of Silesia, Department of Nutrition Related Prevention; Faculty of Health Sciences in Bytom, Bytom, Poland; [3]Medical University of Silesia, Department of Nutrition Related Prevention; Faculty of Health Sciences in Bytom, Bytom, Poland

Introduction
Vitamin D plays an important role in human physiology. It is synthesis mainly by the skin during sun exposure. Elderly population are at risk to develop vitamin D deficiency caused by many factors (reduced sunlight exposure, impaired skin synthesis and hydroxylation in the liver and kidney as well as decreased dietary intake and impaired intestinal absorption).
Aim
The purpose of the study was to assess the status of vitamin D across the different seasons among elderly population.
Material and methods
The study group comprised 152 patients above 60 years, hospitalized in the geriatric department. The samples was collected between 2013–2015. Each individual provided consent before included to the study. Blood samples were collected after overnight fasting. The serum level of 25-hydroxyvitamin D (ng/ml) was measured by enzyme-linked immunosorbent assay (ELISA). The study group was divided into four seasons (spring, summer, autumn, winter).
Results
Mean age of participant were 76.24 ± 7.47 years. The mean 25(OH)D level among study group was 14.61 ± 5.96 ng/ml. The mean serum of vitamin D during particular seasons was: 15.54 ± 5.31 ng/ml (spring), 16.33 ± 7.40 ng/ml (summer), 14.14 ± 5.08 ng/ml (autumn) and 14.03 ± 4.28 ng/ml (winter). There was no statistically differences (P = 0.3450). Most of the patients had vitamin D deficiency – 83.20%. 16.80% study group had suboptimal vitamin D level. In the spring, autumn and winter, vitamin D deficiency was observed among 87.50%, 86.40% and 86.70% group. The proportion of suboptimal vitamin D level was higher in the summer (25.0%) as compared with the other seasons. We observed also that the mean serum of 25(OH)D level among respective months was not statistically significant differences (P = 0.2655).
Conclusion
Vitamin D deficiency was observed in examined study group, in spite of the seasons. There is no significant differences in mean serum vitamin D concentration among patients across the seasons. Anyway, a proper vitamin D supplementation should be recommended and implemented alongside any elderly person's daily diet.

Bullosis diabeticorum

Dayssem Khelifi, Takwa Bacha, Meriem Jones, Noureddine Litaiem & Faten Zeglaoui
Department of Dermatology, Charles Nicolle Hospital, Tunisia

Introduction
Skin damage is common in diabetes. They can be classified into three groups: dermatoses associated with diabetes, acute and chronic skin complications of diabetes and dermatoses associated with antidiabetic treatments. Bullosis in diabetics, also called Bullosis diabeticorum, is one of the cutaneous complications of diabetes. It is a rare bullous dermatosis particular by its exclusive occurrence in diabetics.
Observation
We report the case of a 73-year-old patient. In his history, there was high blood pressure and type 2 diabetes for 26 years complicated by peripheral neuropathy. He had complained of tense blisters which had started suddenly and spontaneously for 05 days. These lesions were non-painful and non-itchy. There was no history of photosensitivity and the patient could not recall any new drug intake. Clinical examination revealed multiple tense bubbles of serous content on a nonerythematous base was ween on the anterior surface of both legs. Complete blood count and electrolyte test were within normal limits. Serum creatinine was 71 µmol/l, CRP 9 mg/l, and HbA1c 7.1%. Histopathology of the lesional skin showed a subepidermal bulla without any inflammatory infiltrate. A direct immunofluorescence test was negative. Local care after removal of bubbles was indicated. The bubbles healed spontaneously after three weeks, without recurrence with a follow-up of 11 months.
Discussion-conclusion
Diabetic bullosis is characterized by the sudden onset of large, tight bubbles with clear or hemorrhagic content, in healthy skin, without pain, pruritus, inflammation or mucosal damage. It predominates on the soles and the toes. The pathophysiology is poorly understood and would involve vascular alterations, mechanical and /or trophic abnormalities related to the underlying neuropathy. The main differential diagnosis is bullous pemphigoid. The treatment is symptomatic with a spontaneously favorable outcome over a few weeks. This evolution constitutes a key element for the diagnosis.

Screening for obstructive sleep apnoea in type 2 diabetes subjects using STOP-BANG questionnaire

Vipan Talwar & Gourav Talwar
Golden Hospital, Endocrinology, Jalandhar, India

Introduction
The association between Obstructive sleep apnoea (OSA) and type 2 diabetes mellitus (T2DM) is well known and this combination imposes a higher risk of complications in the affected indvidual. Polysomnography which is a gold standard for diagnosing OSA is not universally available, so many of the patients with OSA remain undiagnosed. A questionnaire-based OSA screening for risk stratification can help early detection of OSA in T2DM.
Methods
This was a cross-sectional study done in an endocrine speciality hospital in the Indian state of Punjab. The participants were 486 adult subjects with T2DM who all underwent clinical evaluation, anthropometry, investigations and were administered STOP-BANG questionnaire, which is an eight items tool with four symptoms and four signs to stratify the OSA risk. The scoring scale is categorized into three risk groups; low risk (0–2), intermediate risk (3–4) and high risk (5–8) respectively.
Results
Out of all the participants 57.3% were males. Mean age of the participants was 56.7 ± 12.8 years. STOP-BANG score of ≥ 3 was present in 43.6% of the participants with moderate risk score (3–4) in 26.2% and high risk score (5–8) in 17.4% of the participants. The score showed positive correlation with age, male sex, duration of diabetes, BMI, hypertension and CAD. It was not correlated with Hba1c, use of insulin.
Discussion and conclusions
Various studies have shown high prevalence of OSA in subjects with T2DM and the presence of OSA being associated with an increased likelihood of hypertension, cardiovascular disease, diminished quality of life and increased mortality justifies the importance of screening for OSA in diabetic patients. In the present study by using a clinical tool STOP-BANG questionnaire we have found high prevalence (43.6%) of OSA in T2DM subjects and its significant correlation with age, duration of diabetes, BMI, H/T and CAD. STOP-BANG is a simple screening tool having high sensitivity and can be conveniently used in primary care setting to identify the subjects at risk of OSA. These sub-set of patients can be then subjected to polysomnography for confirmation and appropriate timely management, so as to reduce the morbidity and mortality associated with untreated OSA.

AEP354

Predictors of the development of androgen deficiency in men with type 2 diabetes mellitus

Elena Vaschenko
The Republican Research Centre for Radiation Medicine and Human Ecology, Endocrinology, Gomel, Belarus

The aim of the study is the search of predictors of the development of androgen deficiency in men with 1 diabetes mellitus type 2. The study included 243 men with type 2 diabetes mellitus aged 35–55 years. The median age of men was 39.00 [30.00; 45.00] years, the median duration of diabetes mellitus type 2 was 12.00 [7.00; 22.00] years. As a result of the research, it was found that an increase in the patient's age significantly increased the risk of developing androgen deficiency (b = 0.07, Exp (b) = 1.08 (1.00 ÷ 1.16), P < 0.05). The age of smoking experience also had a significant effect on the risk of developing androgen deficiency (b = 0.06; Exp (b) = 1.07 (1.10 to 1.13), P < 0, 04). The relative risk of developing (RR) androgen deficiency in men with a smoking experience of more than 7 years was 3.76 and was statistically significant (95% CI = 1.07 ÷ 13.25). With an increase in the level of glycated hemoglobin, the risk of developing androgen deficiency also increased significantly (b = 0.08; Exp (b) = 1.01 (1.00 ÷ 1.02), P < 0.04). The exceeding of the glycated hemoglobin level above 7.5% demonstrated a statistically significant RR = 6.71 (95% CI = 1.19 ÷ 37.86). The reduction of LDL decreased the risk of developing androgen deficiency in the men surveyed at the level of a stable trend (b = –0.45; Exp (b) = 0.64 (0.35 ÷ 1.18), P < 0.10). At an LDL level of less than 3.50 mmol/l, the RR of androgen deficiency was 0.29 and was statistically significant (95% CI = 0.09 to 0.97). The rise in VLDL significantly increased the risk of androgen deficiency (b = 0.71; Exp (b) = 2.04 (1.11 ÷ 3.76), P < 0.02). At a VLDL level of 0.42 mmol/l, the RR was 2.58 (95% CI=1.38 to 3.29). As can be seen from the data provided, unsatisfactory compensation of type 2 diabetes mellitus increases the risk of developing androgen deficiency in men.

Mucormycosis of the ENT sphere in diabetic subjects: About 4 observations

Mouna Bellakhdhar[1], Takwa Belaid[1], Ghammam Monia[1], Ben Abdelkarim A[2], Yaakoub A[3], Mahrezi Abir[1], kermani Wassim[1], El Euch Koussay[2], Fathallah A[3] & Abdelkafi Mohamed[1]
[1]Department of Otolaryngology and Head and Neck Surgery, Farhat Hached Sousse Hospital, Tunisia; [2]Endocrinology Department, Farhat hached Sousse Hospital, Tunisial; [3]Parasitology mycology laboratory, Farhat Hached Sousse Hospital, Tunisia

Introduction
Mucormycosis is a rare and often fatal fungal infection which is caused by a group of molds called mucormycetes.It usually occurs in immunocompromised subjects and especially diabetics. The aim of our work is to specify the epidemiological, clinical and therapeutic characteristics of ENT mucormycosis in diabetic subjects.
Material and methods
A retrospective study included 4 diabetic patients with ENT mucormycosis diagnosed over 18-year period, from January 2000 to December 2017.
Results
The study involved two men and two women, aged between 40 and 77. All patients were diabetic. There were 2 cases of sinonasal mucormycosis, 1 case of rhinocerebral mucormycosis and 1 case of otologic involvement with cerebral extension. The diagnosis was based on anatomopathologic and mycologic examination. Culture isolated Rhizopus oryzae in 4 cases. The four patients were put on Amphotericin B associated with surgical curettage. One patient presented with an allergy to Amphotricin B, hence the use of its liposomal form. The evolution was good in 2 patients, one of whom retained a sequellar facial paralysis. A fatal issue occurred in 2 cases with otocerebral and rhinocerebral involvement.
Conclusion
Otorhinolaryngologic mucormycosis is a rare fungal infection. Rhinocerebral involvement is the most common clinical form and otological involvement is exceptional. The prognosis remains severe, depending mainly on the early diagnosis and treatment.

Obesity before and during pregnancy-a powerful risk factor for hyperglycemia in pregnant Bulgarian women

Boyana Trifonova
University Hospital Sofiamed, Medical Faculty, Sofia University St Kliment Ohridski, Clinic of Endocrinology and Metabolic diseases, Medical Faculty, Sofia, Bulgaria

The epidemic of obesity, as well as the reduced physical activity are a complex of reasons for the increase in the frequency of Glucose tolerance disorders. The aim was to analyze the frequency and role of Obesity/ Overweight for the development of Hyperglycemia in the Bulgarian population of pregnant women.
Material
We screened 547 pregnant women, mean age 30.49 ± 5.12 years, divided into two groups: with Hyperglycemia (n-79) and with Normoglycemia (n-468).
Methods
Body mass index (BMI) before pregnancy and the current one at the time of the study were calculated. A two-hour, 75 g oral glucose tolerance test (oGTT) was performed.
Results
Obesity was found for the whole group before pregnancy in 10.2% (56/547) resp. overweight in 20.1% (110/547). With regard to BMI before pregnancy, this relationship proved to be significant when comparing the mean ranks for Hyperglycemia (Mean Rank 260.42 vs 354.44, P < 0.001), when compared with Normoglycemia in the respective group. We obtained the same significant results in the analysis of the impact of obesity during pregnancy. The mean ranks for Hyperglycemia (Mean Rank 257.24 vs 373.28, P < 0.0001), when compared with the respective group with Normoglycemia. Therefore, women with a higher BMI before and during pregnancy are significantly at risk of developing glucose intolerance during pregnancy.
Conclusion
Obesity affects a large number of young people, but this factor is subject to modification. Young women who are obese/overweight should be consulted prenatally, and if they become pregnant, they should be tested for glucose tolerance disorders as early as possible.

Isolation of nerve growth factor in blood specimens from patients with type 1 diabetes mellitus

Talat Saatov, Gulnora Artykbaeva, Ilmira Yalalova & Akhmadjon Mamadjanov
Institute of Biophysics and Biochemistry, Mirzo Ulugbek National University of Uzbekistan, Laboratory of Metabolomics, Tashkent, Uzbekistan

Physiological role of nerve growth factor (NGF) was characterized for the sensory and vegetative nervous systems, as well as for the central, endocrine and immune systems. The growth simulator and a cytokine, NGF is known to be involved in the metabolism of various pathological conditions. Recent clinical and academic studies among patients with diabetes mellitus, insulin resistance and Alzheimer's disease have brought to light previously unreported cell and pathological conditions. Relevant epidemiological data can serve as the evidence for close association between cognitive deterioration and diabetes mellitus due to the defective glucose uptake in the neurons for energy generation. Insulin is known to control the synaptic plasticity due to internalization of neuroreceptors. Accordingly, it is of significant interest to find out if there is any association of diabetes mellitus, the body's failure to produce enough insulin, with the compromised function of neurotrophins. The work was initiated to isolate NGF in blood specimens from patients with type 1 diabetes mellitus.
Materials and methods
Successively, adsorption chromatography on silica glass, gel filtration by means of Toyopearl HW55 resin (Tosoh Bioscience GmbH, Germany), carboxymethylcellulose chromatography and preparative PAGE were used to isolate the NGF fraction from blood serum of diabetics (n = 7) and non-diabetics (n = 7).
Results and discussion
By means of a method for generation of fractions, we compared blood sera from diabetic and non-diabetic donors for neurogrowth activity. The product we isolated is a high molecular weight complex of NGF and protein carrier

of globulin nature with disulfide bond and neurite-stimulating activity of 2×10^2 BU/mg of protein, molecular mass of 160 kDa and pI 9.1–9.7. After treatment with dithiothreitol, we got a protein with molecular mass of 15–30 kDa and activity of 6×10^2 BU/mg of protein. All the properties indicated pertinence of the protein to NGF. Major complications, to name the dysfunction and degeneration of various peripheral neurons among them are typical of diabetes mellitus. Sensory impairments prevail; degeneration of small diameter sensory fibers results in major symptoms. Our findings demonstrated that blood serum NGF concentrations in the diabetics were 2.5 times lower than those in the non-diabetics. In diabetes mellitus, key components of the NGF signal pathway are found deregulated, the same goes to production of the NGF-controlled neuromodulators. Insulin therapy facilitated elevation of the regulator's concentrations, but they did not reach the standard one. This seems to confirm the hypothesis that in diabetes both neuronal and peripheral insulin sensitivity is impaired.

Impact of diabetes on liver fibrosis in chronic hepatitis C

Mrabet Soumaya, Harbi Raida, Imen Akkari & Ben Jazia Elhem
Farhat Hached University Hospital, Gastroenterology, Sousse, Tunisia

Introduction
Chronic hepatitis C (CHC) is associated with an increased incidence of insulin resistance and diabetes mellitus. Obesity and insulin resistance are associated with faster progression of fibrosis in these patients. The aim of our study was to assess the impact of diabetes on the severity of hepatic fibrosis in patients followed for CHC.
Methods
This is a retrospective study conducted between January 2017 and December 2020 including all patients followed for CHC. The evaluation of hepatic fibrosis was performed by measuring hepatic elasticity by the Fibroscan. Significant fibrosis was defined by a fibrosis score ≥ F2. Advanced fibrosis was defined by a score F3-F4.
Results
44 patients were included; 28 women (63.6%) and 16 men (36.4%) with an average age of 49 years (16–81 years). Diabetes was present in 13 patients (29.5%). Metabolic syndrome was associated to diabetes in all patients. Nine patients were treated by oral anti-diabetics. Others were treated by insulin injections. The level of glycated hemoglobin was < 7% in all patients. Significant fibrosis ≥ F2 was found in 7 patients (53.8%). Advanced fibrosis F3-F4 was observed in 3 patients (23.1%). And three patients had a score of fibrosis F0-F1. The analytical study did not show a significant difference in hepatic elasticity between diabetic patients (mean elasticity of 9.15 Kpa) and non-diabetic patients (mean elasticity of 8.18 Kpa); $P = 0.630$.
Conclusion
In our study, diabetes was found in a third of patients with chronic hepatitis C without an impact on the severity of the hepatic fibrosis.

Type 2 diabetes in young people About 30 cases preliminary results

Ornella Marline Yvonne Dinghat, Nassim Essabah Haraj, Siham El Aziz & Asmaa Chadli
Faculty of Medicine and pharmacy of the University Hassan II Casablanca, Department of Endocrinology, Diabetology and Metabolic Diseases. UHC Ibn Rochd, Casablanca, Morocco Laboratory of Neuroscience and Mental Health, Casablanca, Morocco

Introduction
Type 2 diabetes has long been considered a disease of overweight adults. However, its incidence is increasing rapidly in children and adolescents along with that of overweight and obesity. The aim of this study was to assess the prevalence and clinical profile of type 2 diabetes in young subjects.
Materials and methods
Descriptive prospective study from January 2019 to August 2020 including 30 diabetic patients aged 15 to less than 35 years hospitalized in our department and in whom the diagnosis of type 2 diabetes was evoked according to the criteria of the ADA 2020.
Results
The mean age of our patients was 24.02 ± 6.23 years, with a female predominance of 73.3%. Forty percent of our patients were already known to have diabetes with an average length of 1.67 years ± 2.70 and 60% had just been diagnosed. Type 2 diabetes was discovered after revealing ketosis in 14 patients, incidentally in 12 patients, after ketoacidosis in 2 patients, and after gestational diabetes in 2 patients. The cardiovascular risk factors found were obesity in 26.7% of cases and the syndrome metabolic in 20% of cases. The complications found were diabetic retinopathy in 13.3% of cases and diabetic neuropathy in 33.3% of cases. Acanthosis nigricans was present in 66.6% of our patients.
Conclusion
Type 2 diabetes is common in young people, hence the importance of its prevention in this category of the population which must be focused on lifestyle changes.

Dunnigan syndrome in Central South Africa: A case report

Thabiso Rafaki Petrus Mofokeng & Nontsikelelo Poswa
University of the Free State, Internal Medicine, Bloemfontein, South Africa

Introduction
Familial partial lipodystrophy type 2 is caused by several pathogenic variants of lamin LMN gene. Males and females are equally affected by the autosomal recessive condition which manifests before age 2. They gradually loose fat in the upper and lower extremities as well as the gluteal area.
Case
We present a 31 year old female athlete who presented with oligomenorrhoea, diabetes mellitus, and severe fasting hypertriglyceridemia in 2007, followed by tuberous xanthoma fat deposition in 2009, hypertension and Asthma in 2019. Examination revealed a lean body habitus and evidence of severe insulin resistance (IR) i.e. hirsutism and diffuse acanthosis nigricans. The complications came early and were difficult to manage with tools available in our public setting. She used private health care until her return in 2019. She has two unaffected siblings. She received the following treatment: Pioglitazone 15 mg, Novomix 30: 54 u & 46 u, Metformin 1 g bd, Bezalip 400 mg/d + Atorvastatin 40 mg/d, Losartan 50 mg bd.
Investigations
Bloods: (2007) TC 27.5, TG 280, HbA1c 12.5%, AST 16, ALT 14, FPG 29 (2020) TC 4.3, TG 6.64, HbA1c 10.7%, HDL 0.76.
Molecular genetic analysis

Gene	Exon	cDNA	Amino acid	Classification	Zygosity
LMNA	8	C.1444 > T	p.Arg482Trp	Pathogenic	Heterozygous

Conclusion
Although this is a rare condition, early diagnosis and counselling is critical in order to minimize metabolic and systemic complications, including cardiovascular death by screening the family and treating everyone affected.

Syndromic mitochondrial diabetes: About three Tunisian families

Wajdi Safi[1], Mouna Tabbebi[2], Faten Hadj Kacem[1], Hana Charfi[1], Chiraz Zayani2, Dhouha Ben Salah[1], Mouna Mnif Feki[1], Faiza Fakhfakh[2] & Mohamed Abid[1]
[1]Hedi Chaker hospital, Sfax; TUNISIA, Sfax, Tunisia, Department of Endocrinology, Sfax, Tunisia; [2]Faculty of Sciences of Sfax, TUNISIA, Laboratory of Molecular and Functional Genetics, Sfax, Tunisia

Introduction
Mitochondrial diabetes (DM) is characterized by a broad spectrum of phenotypic and genotypic involvement. Among 86 patients with DM, we chose to study the peculiarities of syndromic DM diagnosed in three families in order to be able to establish a correlation between this diversity of phenotypic expression and the biomolecular substratum of the mitochondrial genome.
Results
These are four patients (index case) belonging to 3 families with an average age of onset at 22 years (3–32), sex ratio 3 F/1H. Maternal transmission of diabetes in half of cases with a phenotype reminiscent of type 1 diabetes (MIDD1) in all patients. The sequencing of the mitochondrial genome

using the candidate gene and mitochondrial genome approach approach allowed us to highlight the mitochondrial biomolecular peculiarities within our population, in fact the two patients presenting a phenotype suggestive of Wolfram syndrome presenting a central diabetes insipidus. and bilateral optic atrophy had a mutation in the gene encoding ND1 (mitochondrial complex I enzyme). Concerning the patient presenting phenotypic traits suggestive of a MELAS syndrome associating pyramidal syndrome, epilepsy and lactic acidosis, an m.1640A > G mutation of the tRNA gene Val in the homoplasmic state was found underlining the genotypic heterogeneity of this syndrome. Finally, we report for the first time the coexistence of a primary amyloidosis and a MIDD1 by mutation m3243A > G (tRNA Leu) in the fourth patient who had presented extra pancreatic manifestations common to the type hypertrophic cardiomyopathy, glomerular nephropathy and neuropathy. peripheral.
Conclusion
Certainly, progress in molecular biology and a better understanding of the signaling lines of intracellular proteins will make it possible to clarify the etiopathogenic link and to establish a correlation between the clinical phenotype and the spectrum of mitochondrial genetic damage.

Clinical features of patients with diabetic ketoacidosis and acute pancreatitis

Dhouha Ben Salah, Asma Zargni, Mouna Elleuch, Wiem Gherissi, Fatma Mnif, Nedia Charfi, Mouna Mnif, Nabila Rekik Majdoub, Hadj Kacem Faten & Abid Mohamed
Hedi Chaker Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction
Acute pancreatitis (AP) is the most common affection of the pancreas, it often leads to glycemic disorders. On the other hand, diabetic ketoacidosis (DKA) is associated with nonspecific increase in serum amylase levels. The aim of this study was to evaluate the clinical characteristics of acute AP concomitant with DKA.
Methods
We conducted a retrospective and descriptive analysis of clinical records of patients diagnosed with DKA and AP, between 2000 and 2020 in endocrinology department. All patients fulfilled the current diagnostic criteria of both, DKA and AP. Clinical, biological and radiological data were collected.
Results
A total of 18 patients (7 males and 11 females) were enrolled in the study. The mean age was 40 years, ranging from 16 to 70 years. Of 18 patients, 11 had prior history of diabetes and five had hyperlipidemia. Two patients had a history of alcohol use. All the patients presented nausea and vomiting at time of admission. Abdominal pain was absent in five patients and four were comatose on admission. The mean BMI was 26.6 kg/m^2. Both serum amylase and lipase levels were elevated in all patients with a mean value of 324 (NR: 10–45 UI/l) and 272 UI/l (NR:10–60 UI/l) respectively. AP confirmed by an abdominal computed tomography (CT) scan finding was occurred in 16 patients. The etiology of acute pancreatitis was gallstone in five, hypertriglyceridemia in two, and idiopathic in eleven patients.
Conclusions
Although DKA can be associated with elevated amylase and lipase in 16–25% of cases, acute pancreatitis may co-exist with DKA in at least 10–15% of DKA patients [1]. The pathogenesis of AP in DKA varies, but at least in some transient and profound hyperlipidemia is an identifiable factor. AP is more likely in severe DKA with significant acidosis and hyperglycemia.

Solid pseudopapillarytumor of the pancreas: Report of a special case

Faten Haj Kacem, Ameni Salah, Sidina Med Elmokhtar, Mouna Elleuch, Dhouha Ben Salah, Fatma Mnif, Mouna Mnif, Nabila Rekik, Nadia Charfi & Mohamed Abid
UHC Hedi Chaker, Endocrinology, Sax, Tunisia

Introduction
Solid pseudopapillary tumors (SPT) of the pancreas area rare exocrine pancreatic tumor behaving in a low-grade fashion, with limited local invasion risk and a rare metastatic evolution. They mainly affect young women. Their etiopathogenesis remains uncertain. We report the case of a 15-year-old boy,having congenital anomalies, who presented a solid and pseudopapillarytumour of the pancreas.
Case report
A fifteen-year old boy with a familial history of diabetes, infertility andepilepsia was known to have a polymalformative syndrome made up of a single left kidney and bone malformations (dorsal scoliosis and a butterfly vertebral defect at the L4 lumbar spinal level). He was admitted in October 2019 on the general surgery department of the UHC Habib BourguibaSfax for acute abdominal pain and an epigastric mass. Biological assessment was correct, whereas MRI showed a 10 cm cystic tumor lesion of the pancreas with a thick wall significantly enhanced especially on late sequences without obvious invasion of neighboring structures suggesting SPT of the pancreas. A caudal spleno-pancreatectomy with a high segmental resection removing the tumor as a single piecewas then done. The anatomopathological examination confirmed the diagnosis of SPT without lymph node metastases or local invasion. A prediabetes was revealed after surgery with a fasting plasma glucose (FPG) level of 5.8 mmol/l and a glycated hemoglobin(A1C) level of 6.17%. One year later, the patient was admitted in the endocrinology department of the UHC HediChakerSfax for an inaugural ketosis-prone diabetes. He reported an important weight loss in the last two months and a flu a week before his admission. The rest of the somatic exam was normal as well as the biological assessment except an A1clevel at 16.9%.An abdominal CT scan revealed a remaining pancreas (cephalic) of homogeneous density and enhancement. The pancreatic and thyroid antibodies were negative.A detailed physical examination, ophthalmologic examination and cardiac ultrasound did not find other associated malformations. Although a diabetes secondary to pancreatectomy seemed the most probable, we completed with a DNA sample in search of monogenic diabetes.
Discussion-Conclusion
TPS is extremely rare in men. Also, the association of TPS with a single congenital kidney or bone malformations had not been reported in the literature to our knowledge.

Characteristics of the metabolic syndrome in the elderly with diabetes

Tlili Abir, Najoua Lassoued, Rebai Senda, Alaya Wafa, Zantour Baha & Sfar Mohamed Habib
Taher Sfar University Hospital, Endocrinology Department, Mahdia, Tunisia

Introduction
The metabolic syndrome (MS) presents a major public health problem, especially in elderly diabetics. The objective of this study is to assess the frequency and characteristics of MS in elderly diabetics.
Patients and methods
Retrospective study of 94 diabetic subjects over the age of 65 years who were hospitalized in the endocrinology department of Mahdia or followed at the outpatient clinic between November and December 2020.
Results
The mean age was 71 ± 5 years with extremes of 65 and 90. The female predominance was remarkable. Almost all of our patients had type 2 diabetes. The mean duration of diabetes was 12 ± 8 years. MS was present in 74.6% of patients. In these patients, elements of MS other than diabetes were: hypertension in 24% of cases, hypoHDLemia in 18% of cases, hypertriglyceridemia in 42% of cases and android obesity in 54% of cases. One third of these patients presented with cardiovascular disease: myocardial infarction (18%), stroke (6%), arteritis of the lower limbs (10%) and significant carotid stenosis (1%).
Conclusion
Through our study, we found that MS is very common among elderly diabetics. Adequate management of these patients appears to be necessary in order to avoid cardiovascular morbidity and mortality.

Diabetic retinopathy: prevalence and risk factors in a type 2 diabetic population

Eya Safi, Yosra Htira, Manel Dridi, Mehrez Achwak, Ghofrane Hakiri, Zribi Sabrine, Zohra Hadj Ali & Feika Ben Mami
National Nutrition Institute, C, Tunisia

Introduction
One of the major complications of diabetes that can lead to blindness is diabetic retinopathy. The objective of our work is to determine the prevalence of this complication in a type 2 diabetic population as well as its various risk factors.
Methods:
This is a retrospective study including 100 type 2 diabetic patients followed up in the 'C' department of nutrition and diabetology at the National Institute of Nutrition in Tunis.
Results
The average age was 56.8 years old. A female predominance was noted in two-thirds of cases (66%). The mean duration of diabetes was 11.28 years. The mean HbA1c was 10.69 ± 2.51%. The average BMI was 29.8 ± 5.59 kg/m^2. Diabetic retinopathy was present in 46% of patients. The frequency of this complication was significantly correlated with the age (P = 0.022) and the duration of progression of diabetes (P = 0.005). Diabetic retinopathy was linked to higher HbA1c and BMI levels but this was not significant. It was more frequent in hypertensive patients (P = 0.07) who represented more than half of the population. The mean systolic blood pressure was higher in the presence of diabetic retinopathy but this was not significant. This complication was more frequently noted in dyslipidemia (N = 82) without this being significant. The triglyceride level was higher in patients with diabetic retinopathy (2.04 ± 1.11 g/l vs 1.78 ± 0.76 g/l). The latter also had a significantly higher LDL cholesterol level (P = 0.01). Active smoking was reported by 20% of the population with no statistical relation to the occurrence of retinopathy.
Conclusion
Diabetic retinopathy was a frequent complication in our population. As risk factors, we noted the age, duration of progression of diabetes, poor glycemic control, presence of overweight, hypertension and dyslipidemia. As one of the leading causes of blindness worldwide, screening for risk factors for diabetic retinopathy and their control is imperative.

Diabetes-related knowledge among type 2 diabetic patients in Sfax, south Tunisia

Yosra Mejdoub[1], Kawthar Ayedi[2], Dhoha Ben Salah[3], Mouna Elleuch[3], Hanen Maamri[1], Jamel Dammak[1], Jihen Jdidi[1] & Abid Mohamed[3]
[1]Community Health and Epidemiology Department, Hedi Chaker University Hospital, University of Sfax, Sfax, Tunisia; [2]Faculty of medicine of Sfax, Sfax, Tunisia; [3]Department of Endocrinology, Hedi Chaker Hospital, Sfax, Tunisia

Introduction
Type 2 diabetes mellitus is a major non communicable disease which needs continuous and improved interventions. Knowledge assessment studies are useful for providing baselines for healthcare policies and educational programs.
Aim of this study
To evaluate diabetes-related knowledge among type 2 diabetes patients.
Methods
A cross sectional study was conducted on adult patients with type 2 diabetes who had been diagnosed since at least 6 months and taking medical treatment. Data were collected from November 2019 to February 2020, through a designed questionnaire. We used SPSS version 20 for data analysis.
Results
In total, 233 type 2 diabetic patients were surveyed, including 142 (60.1%) females. The mean age was 58.8 (SD = 10.8). One hundred seventy-five (75.4%) of cases were living in urban area. Forty-seven patients (20.3%) were non-educated, and 118 patients (50.9%) had primary education level. One hundred fourteen participants had low socioeconomic status. Overall, 78.5% of patients had a family history of diabetes. The mean duration of diabetes was 11.8 (SD = 9.1) years. Of all respondents, 132 (56.9%) were on oral diabetic tablets only, and 33 (14.2%) were on insulin only. The mean BMI was 30.6 (SD = 6.6).The mean glycated haemoglobin was 8.78 (SD = 1.98). About 57% of patients had confirmed diabetes complications. Of all interviewed, 157 (67.4%) confirmed receiving diabetes information. Overall, 78.1% of patients knew that polyuria and polydipsia are frequent symptoms of hyperglycaemia. Forty patients (17.2%) were knowledgeable about causes of hypoglycaemia. Regarding, diabetes risk factor, 85% of patients were knowledgeable about the genetic factor, while 76.4% and 65.7% of patients were knowledgeable about obesity and sedentary lifestyle, respectively. About 85.4% of patients knew that poor control of diabetes could increase the risk of complications. Regarding the management of diabetes, 93.6% and 91.4% of patients knew the importance of individualized diet plan and regular physical activity, respectively.
Conclusion
This study showed that diabetic patients had limited level of diabetes-related knowledge, which could negatively affect their diabetes control and quality of life. Accordingly, there is an urgent need for improving educational program based on patients' needs and characteristics.

Quality improvement project on pilot joint diabetes-renal clinics in a district general hospital in United Kingdom

Kasi Subbiah[1], Aizzah Mahmood[2], Samundeeshwari Perumal[3], Nihil Chitalia[4] & Cynthia Mohandas[1]
[1]Darent Valley Hospital, Diabetes and Endocrinology, Dartford, United Kingdom; [2]Darent Valley Hospital, Internal Medicine, Dartford, United Kingdom; [3]UMF Iasi, General Medicine, Iasi, Romania; [4]Darent Valley Hospital, Renal Medicine, Dartford, United Kingdom

Diabetes is the leading cause of end stage renal failure. So, identifying patients at risk and intensifying management of blood pressure, lipids and glycaemic control can reduce and delay progression to organ replacement therapy. The aim of our study was to determine whether our pilot 3 monthly joint diabetes-renal clinics set up in April 2018 was able to achieve targets outlined by national guidelines and whether patient satisfaction and improved outcomes could lead to further service expansion. We collected retrospective data using electronic records for all 48 patients attending the pilot joint diabetes-renal clinic over a 2-year period. Patient satisfaction was assessed through a self-reported questionnaire. 40 patients had type 2 and 8 patients had type 1 diabetes. The number of hospital visits had significantly decreased from a mean 4.5 to 1.25 visits per year; mean age 68.3 years; mean current eGFR was 27.4 ml/min/1.73 m^2 (median 26.5) from a mean baseline of 30.2 ml/min/1.73 m^2 (median 29). The rate of decline of eGFR was 0.11 ml/min/month during this period; mean current blood pressure 154/75 mmHg with 33.3% of patients meeting the target < 130/80 mmHg; current HbA1c 68 mmol/mol vs 77 mmol/mol at baseline; LDL cholesterol 2.03 mmol/l vs 2.7 mmol/l at baseline. 91.6% patients who had no identified contraindication were on lipid lowering drugs. 37.5% patients were not on ACE inhibitors, the top 3 reasons being troublesome hyperkalaemia, significant eGFR drop on initiation and allergic reactions. All 32 patients assessed through a self-reported questionnaire found having both specialties at the clinic appointment to be beneficial as they attended fewer hospital appointments, and they needed less duplication of blood tests as a result of the joint clinic. 21.8% and 18.7% patients felt that it would be beneficial for a diabetes specialist nurse and a dietician to be available at the appointment, respectively. All patients felt that there was clear communication about any changes made to their medication and treatment plan at the appointments. Our findings suggest that the rate of deterioration of renal function can be slowed by aggressive risk factor management. More importantly patient satisfaction considerably improved by attending the joint clinics and will also lead to savings in health care. This will lead to a business case to expand this service further and develop joint diabetes-cardio-renal service to improve the care of patients with complex long-term conditions.

Type 1 diabetes and Klinfelter syndrome: A case report

Ajili Rihab, Yosra Hasni, Ben Abdelkarim Asma, Saad Ghada, Kacem Maha, Maaroufi Amal, Chaieb Molka & Ach Koussay
Farhat Hached Sousse, Endocrinology, Tunisia

Introduction
Klinfelter syndrome (SK) is the most common sex chromosome disorder. Affected males carry an additional × chromosome, which results in male hypogonadism, obesity and an insulin resistance field explaining the frequent association of KS and type 2 diabetes. However, cases of type 1 diabetes (T1D) in KS are rarely reported in the literature. We report a case.
Observation
This is a 31-year-old patient admitted with newly discovered diabetes associated with weight loss. The diagnosis of autoimmune T1D was made based on positive T1D antibodies and the patient was put on insulin. The examination objectified a skinny man with tall stature, small testes and gynecomastia. Hypogonadism was suspected due to the absence of secondary sexual characteristics with a Tanner at G1P2A1. Hormonal assays confirmed hypergonadotropic hypogonadism. SK was then evoked clinically and confirmed by a karyotype showing a chromosomal mosaic 47, XXY/46, XX.
Discussion and conclusion
The association of T1D and KS is still unclear, but studies suggest that patients with KS have a higher susceptibility to autoimmune diseases. This is because low levels of testosterone and high estrogen in KS may predispose hypogonadal males to develop defects in T cell activity that lead to autoimmune disorders, in particular destruction of Langerhans β cells.

Seasonal variation of diagnosis of Type 1 diabetes mellitus: A real phenomenon-Preliminary results

Salma Ben Yakhlef, Messaoudi Najoua, Nada Derkaoui, Siham Rouf & Hanane Latrech
Mohammed VI University Hospital, Mohammed I University, Oujda, Morocco, Department of Endocrinology-Diabetology, Oujda, Morocco

Introduction
Diabetes is a growing health concern, considered as a worldwilde multifactorial public health challenge especially in developping countries. The concept of seasonality in T1DM diagnosis, has been suggested by different studies, implying the existence of several environmental factors as triggers and potentiators of β-cell destruction. The purpose of this study is to elucidate epidemiological profile and the seasonal variation of type 1 diabetes mellitus (T1DM) diagnosis in our center.
Patients and methods
This is a retrospective and prospective data analysis of 115 patients at T1DM onset, followed up in in the endocrinology department of Oujda's Mohammed VI university hospital. For all statistical tests, P value below 0.05 was pictured as statistically significant.
Results
A total of 115 patients admitted at the onset of T1DM were involved in the study. The overall mean age at diagnosis was 17.3 years ± 8.8. Diabetic ketoacidosis at initial presentation was diagnosed in 54% of patients including 75% cases with pulmonary infection. Classic b-cell autoimmune markers were surveyed ; and 64% were found positive for antiglutamic acid decarboxylase antibodies (GADA).The average of initial hemoglobin A1c value was 11.95 ± 2.15%, and the average serum 25OHD concentration was 14.64 ng/ml ± 6.38. More children were diagnosed with T1DM during the cold months as opposed to the warm months, with non significantly difference between boys and girls ($P = 0.54$). Patients were majoritary born during automne: 24.8% with and the correlation was statistically significant ($P < 0.05$). The number of patients diagnosed with type 1 diabetes was higher during the cooler months of the year compared to the warmer ones. The increase of Vitamin D deficiency during cold months was not statistically significant ($P = 0.17$)
Conclusion
The number of patients diagnosed with type 1 diabetes was higher during the cold months of the year compared to the warmer ones; just as the international reports; implying seasonal viral infections in the progression of the autoimmune process. The global pattern of seasonality of onset of T1DM, puts the local individual studies into a globalc ontext and provides a springboard for further research into aetiological aspects of childhood Type 1 diabetes.

The peculiarities of diabetes in the elderly

Anouar Jamal, Mohamed Aymane Loukili, Abdessamad Malki, Siham Rouf & Hanane Latrech
Mohamed Vi University Hospital Center, Oujda, Endocrinology Diabetology and Nutrition, Oujda, Morocco

Introduction
The number of elderly diabetics continues to increase and represent a large and great fraction of the elderly and diabetics. Thus the objective of our study is to show the particularities in this population.
Materials and Methods
This is a retrospective study included 107 type 2 diabetic patients aged 65 years and older hospitalized in an Endocrinology-Diabetology and Nutrition department of Mohamd VI university hospital center oujda, over a period of 6 years. The data collection and analysis performed by SPSS V21.
Results
The average age of our patients is 72.5 ± 14% years, with a sex ratio of 0.55. The average duration of evolution is 10 ± 14% years. The reason for hospitalization was dominated by diabetic imbalance in 60% followed by simple ketotic decompensation in 20% of cases. Hypertension and dyslipidemia were present in 67% and 21% of patients respectively. Overweight and obesity were the most frequent abnormalities on clinical examination: 28% and 15% respectively. Mean HbA1c at admission was 10.3 ± 2.3%. Dyslipidemia in 35% of cases. 64% had macroangiopathy: Ischemic heart disease (35%), ischemic STROKE (12.3%), arteriopathy (5%), stroke (13%), 46% had microangiopathy: nephropathy (31%), retinopathy (20%), neuropathy (10%). Therapeutically, the majority of our patients were put on insulin: 65%, Hb1aC in 3 months was on average 8.2 ± 2%.
Discussion-Conclusion
The prevalence of diabetes in the elderly is steadily increasing, and management must be tailored to each patient's individual profile, given the frequency of complications, co-morbidities, and high risk of hypoglycemia.

Epidemiological aspects and therapeutic conduct necrosant fungal ear infections: about 20 cases

Monia Ghammem, Lobna Chouchane, Mouna Bellakhdher, Rihab Lahmar, Wassim Kermani & Mohamed Abdelkafi
ENT and Neck Surgery Department, Farhat Hached Hospital, Susa, Tunisia

Aims
Necrotizing external otitis (NEO) is osteomyelitis of the base of the skull. Previously Pseudomonas Aeruginosa was incriminated in 90% of cases. However, fungal NEO have been emerging in recent years. It is a pathology that occurs primarily in immunocompromised terrain such as diabetic and may affect the patient's functional and vital prognosis.
Materials and methods
A retrospective study of 20 cases of fungal NEO conducted at Sousse ENT department over an 11-year period (2006–2016).
Results
The average age of the patients was 67 years (3 to 90 years). The sex ratio was 1.7. 80% of our patients were diabetic. The average time to diagnosis was of 27 days. The most common clinical signs were intense and sleepless otalgia resistant to medical treatment present in all our patients and otorrhea in 45% of cases. A peripheral facial palsy was present in 5 cases. An infectious biological check-up has been requested in all our patients and has objectified breeding of VS and CRP. A brain and temporal ct scan was performed in all of our patients and showed osteolysis signs in all our patients: endocrine extension was present in 15% of cases, mastoiditis in 25% of cases, extension to deep spaces in 5% of cases and to the parotid lodge in 5% of cases. All our patients have had bacteriological and mycological samplings at admission with initial probabilistic antibiotherapy anti pyocyanic, diabetes balance

and local care. Mycosic origin was confirmed in 19 cases following of mycological samples or histological examination. The sample was negative in one case. The germs found were Candida (47%), Aspergillus sp (47%), and rhizopusoryzae (6%). Pseudomonas aeruginosa was associated in one case. The lack of improvement under antibiotic treatment, the negativity of bacteriological samples as well as mycological results led us to implement an antifungal treatment. The evolution was favorable in 14 patients, 2 were referred for hyperbaric oxygen therapy, 2 were lost of sight and 2 were patients died during treatment.
Conclusion
Diagnosis of mycosic origin of fungal SDO difficult to isolate agent response. The negativity of bacteriological samples and the lack of response to treatment encourages us to take mycological samples. Despite the negativity of these, we are always able to prescribe antifungals as early as possible to preserve the functional and vital prognosis of patients with debilitated terrain.

Atypical presentation of Type 1 diabetes mellitus

Mark Niven[1], Esther Kafri[1], Elizabeth Nissim[2] & Ina Dubin[2]
[1]Laniado Hospital, Endocrine and Diabetes Unit, Netanya, Israel; [2]Laniado Hospital, Internal Medicine A, Netanya, Israel

Introduction
Diabetic ketoacidosis (DKA) is associated with Type 1 diabetes mellitus (T1DM), whilst hyperglycemic hyperosmolar state (HHS) with Type 2 (T2DM). HHS has been well described as a presentation of T1DM in children, but not in adults. We present present a case of T1DM presenting in a young adult as HHS, with severe hyperglycemia but without acidosis.
Case report
A 21 year old male presented with a 4 5 day history of weakness, thirst, polydipsia and polyuria. He had vomited once. He was previously well but had received Growth Hormone for idiopathic short stature between the ages 15 18. He has a cousin with T1DM. On examination he was afebrile, pulse 62, BP 125/57, BMI 22. Blood glucose was 993 mg/dl, Na^+ 131 mM, K^+ 5.2 mM, creatinine 1.2 mg/dl, pH 7.353, bicarbonate 23.5 mM, serum osmolality 319 mOsm/kg. Anion gap not measured. Urine ketones 15. HbA1c 10.2%. In view of his age he was treated as for DKA with intravenous fluids and insulin. He displayed substantial insulin resistance and at discharge required a total of 82U daily, about 1.4 U/kg/day, . Subsequently his insulin requirement fell and was 24U daily two months after discharge. Serological studies showed positive anti-GAD and anti-islet cell antibodies at over 2000 [< 5] and over 900 [< 30] respectively. He is now well controlled on treatment with an insulin pump and continuous monitoring system, most recent HbA1c 6.6%. However, his younger sister age 9 has recently been diagnosed with celiac disease. Previous serological testing of our patient for celiac disease was negative but we are now repeating this as well as checking diabetes antibodies in the sister.
Discussion
This patient presented with a picture typical for HHS in T2DM, with severe hyperglycemia but without metabolic acidosis. Urine ketone testing showed minimal ketones, as a result of this case we have introduced blood ketone (betahydroxybutyrate) into the hospital. In spite of his normal weight he exhibited severe insulin resistance presumably as a result of glucotoxicity, but with sufficient residual insulin secretion to prevent ketoacidosis. Whether there is an association with his previous GH treatment is unclear. The recent diagnosis of celiac disease in his sister strengthens the implication of immunogenetic factors.

Diabetic ketoacidosis precipitated by COVID-19 in patient without respiratory symptoms: 2 case reports

Najoua Lassoued[1], Ajili Rihab[1], Rebai Senda[1], Chelli Jihen[2], Zantour Baha[1] & Sfar Mohamed Habib[1]
[1]Taher Sfar University Hospital, Endocrinology Department, Mahdia, Tunisia; [2]Taher Sfar University Hospital, Department of Infectious Diseases, Mahdia, Tunisia

Introduction
Diabetes mellitus (DM) is one of the risk factors associated with severe illness in Coronavirus disease 2019 (COVID-19) leading to increased hospital admissions and mortality. COVID-19 can precipitate hyperglycemic emergencies like diabetic ketoacidosis (DKA) in patients with DM. We report 2 cases of diabetic ketoacidosis (DKA) secondary to COVID-19 with an atypical clinical picture mainly made up of neurological disorders without respiratory signs.
Observations
Case 1: A 67-year-old patient, Type 1 diabetic for 34 years, is admitted for DKA. The symptoms go back 10 days made of asthenia and disorders of consciousness without respiratory signs. On admission the patient was drowsy and afebrile. Hemoglobin A1c was 11%. There was lymphopenia, mild cytolysis, and increased c-reactive protein (CRP). The chest x-ray showed an interstitial syndrome with no obvious pulmonary opacity. The lumbar puncture was normal as well as the cerebral CT scan. In view of the absence of evident factor that precipitated DKA, we performed a SARS-CoV-2 RT-PCR test which had returned positive. The patient was transferred to the COVID unit. The course was marked by repetitive episodes of hypoglycemia with significant reduction in daily insulin doses. The patient improved with PCR negative after 12 days. Case 2: A 57-year-old patient, type 2 diabetic for 23 years on oral antidiabetics, is admitted for DKA. Symptoms can be traced back to a week marked by the onset of asthenia and vomiting without coughing or dyspnea. On admission the patient was subfebrile and drowsy. He even fell from his bed because of the neurological disorders. He had lymphopenia, mild hepatic cytolysis and a slight increase in CRP. On the chest x-ray there was an alveolar-interstitial syndrome. The respiratory condition worsened on the 3rd day of his hospitalization requiring the use of Oxygen therapy. SARS-CoV-2 RT-PCR test returned positive and the patient was transferred to the COVID unit with good evolution after 10 days.
Conclusion
These case reports highlight important issues in DM patients with DKA. First, we documented the variability of the clinical picture of COVID-19. We have recognized patients without respiratory symptoms, with severe metabolic complication. Second, SARS-CoV-2 must be considered as a cause of metabolic decompensation even in patients without respiratory symptoms. In this regard, adequate use of personal protective equipment should be considered in the attention of these patients until SARS-CoV-2 is ruled out.

Wolfram syndrome: A diagnostic challenge

Dayssem Khelifi, Wided Debbabi, Issam Kharrat & Slim Samet
Ibn Jazzar Hospital, Tunisia

Introduction
Wolfram syndrome (also known as DIDMOAD syndrome) is a rare, genetic, endocrine disorder characterized by the early onset of diabetes mellitus and optic atrophy. It is frequently associated with diabetes insipidus, deafness and neurological signs.
Observation
A 26-year-old woman was burn out of a consanguineous marriage. Diabetes mellitus was revealed at the age of 6 by ketoacidosis, treated from the outset with insulin therapy. Antiglutamic acid decarboxylase and anti-islet cell antibodies were negative.Three years later, a decline in visual acuity was reported. On ophthalmology evaluation, bilateral optic atrophy associated with pigmentary damage to the peripheral retina were reported. At the age of 12, she presented two episods of generalized tonic clonic seizures (negative etiologic investigation) and was started on antiepileptics. At the age of 15, secondary enuresis was installed and a water deprivation test revealed diabetes insipidus which responds well to desmopressin. Wolfram's diagnosis was brought up. Through audiometry and imitanciometry, moderate hypoacusis was detected with bilateral neurosensory auditory loss. Renal ultrasonography revealed a struggling bladder and dilation of the urinary tract.
Discussion-conclusion
Wolfram syndrome is a rare diffuse neurodegenerative disease, predominantly in the central nervous system and the endocrine abnormalities, causing a complex and disabling syndromic. It constitutes a diagnostic challenge for the diabetologist since diabetes is confused at its onset with type 1 diabetes and is often its first manifestation

Iatrogenic hypercalcemia and depression. A case report

Marjeta Kermaj, Edlira Elezi, Marsela Xhindi & Agron Ylli
UHC 'Mother Tereza', Endocrinology, Tirana, Albania

Introduction
Calcium is an important metabolite. Abnormal blood calcium levels can affect brain function resulting in clinical signs. Iatrogenic hypercalcemia is a disorder rarely described in literature and there are few reported cases of association with neuropsychiatric manifestations. Psychiatric symptoms and abnormal physical symptoms are usually observed with a serum calcium level above 12 mg/dl. Our case report findings suggest the importance of control of serum calcium in patients treated with active vitamin D preparations or calcium supplements.
Case report
We present a clinical case of a 64 years old woman with no significant past medical, psychiatric or substance use history. She was presented at the emergency unit with mental confusion, disorientation, headaches, significant physical weakness, difficulty moving her body, loss of appetite, nausea and vomiting, abdominal pain and constipation. These signs had started last years but were worsened the last months. Medical history: She was diagnosed with primary hypoparathyroidism 40 years ago and was treated with calcium supplements and vitamin D analogs. Last 10 years, she did not have medical control but continued the same dose of drugs by herself. Laboratory tests: calcemia 12.4 mg/dl, PTH 0.6 (8 76 pg/ml) 25OH vitamin D 10.1 ng/ml (> 30). TSH 2.3 (0.4 4.2 mIU/ml). Blood tests, liver and kidney function resulted normal. Head-CT scan resulted normal. Firstly, she was treated with liquids i/v, diuretics and oxygen therapy with discontinuation of calcium supplements and vitamin D analogs. Then she was transferred to Endocrinology Department for further treatment. After no other medical cause was found, depression due to iatrogenic hypercalcemia was diagnosed. During her hospital stay she followed psychotherapy sessions with the psychologist, onwards the psychiatrist started the treatment with antidepressants. After calcium correction, her neurological and psychiatric manifestations were improved. She discharged the hospital in improved condition, under treatment with vitamin D analogs, calcium supplements, vitamin D3, and antidepressants. One and two weeks later she resulted with normal levels of calcium and improvement of physical and mental condition. She continues to be in a stable condition, followed by endocrinologist and psychiatrist.
Conclusion
All physicians must be aware about hypercalcemia and long-term consequences especially depression and mental health, to prevent the lack of diagnosis or misdiagnosis. It is very important periodic monitoring of calcium levels in patients under treatment with calcium supplements and vitamin D.

AEP376

Pancreatic cancer masquerading as uncontrolled diabetes

Nyein Ei Phyo, Praneshan Moodley & Geraldine Quintero Platt
Derriford Hospital, General Internal Medicine, Plymouth, United Kingdom

We describe the case of a 77 year old male admitted with acute confusion. He had a background of Type 2 Diabetes Mellitus, alcohol excess, hypertension, and was a heavy smoker. A venous blood gas showed a high anion gap metabolic acidosis (pH 7.327, a modestly elevated lactate at 1.3), a glucose level of > 27.8 mmol/l, with a capillary ketone level of 5.0 mmol/l. His calculated serum osmolality was 276 mmol/kg, although account was not taken of the possibility of concomitant alcohol intoxication which might have led to a higher calculated osmolality. Unfortunately, a measured serum osmolality was not included in the initial blood tests in the emergency department. He was approaching diabetic ketoacidosis, and was likely in a hyperosmolar hyperglycaemic state. A fixed rate insulin infusion was started. Biochemical parameters improved within hours of initiating Insulin, and were accompanied by improvement in symptoms. A urinary tract infection, manifested by urinary retention, was treated. Subsequent history taking revealed significant weight loss and epigastric discomfort in the context of a new Iron Deficiency Anemia. CT imaging revealed a 5.2 cm mass in the tail of the pancreas. CA 19–9 level was 5855 kU/l. His diabetes was reasonably controlled with an HbA1c of 57 mmol/mol one year before admission. Subsequent months saw an alarming rise in his HbA1c, reaching a level of 146 mmol/mol one month prior to admission. Non-compliance was suspected. In our patient the precipitant of HHS may have been a urinary tract infection. He had two well-established risk factors for pancreatic cancer, namely, smoking and Type 2 Diabetes. There are conflicting data regarding the significance of alcohol as a risk factor for pancreatic cancer. Two pooled analyses suggested that, if there is an effect of alcohol, it is small and limited to heavy drinkers. There are suggestions that Diabetes may be a consequence rather than a cause of pancreatic cancer. A recent onset of Diabetes may be an indicator of underlying pancreatic cancer or herald its onset. Here, rapidly worsening glycaemic control, culminating in HHS may have been a harbinger of the pancreatic cancer diagnosis. It is unfeasible to screen every older asymptomatic adult with new onset Diabetes or unexplained deterioration in glycaemic control with cross-sectional imaging. However, healthcare professionals must be alert to the possibility of an underlying pancreatic cancer given its poor prognosis at all stages, especially when there are risk factors and symptoms.

AEP377

The estimation of comorbid endocrine and metabolic disorders based on CIRS score in emergency workers of the Chernobyl accident having cardiovascular diseases

David Belyi[1], Olena Nastina[1], Gennadyi Sydorenko[1], Zhanna Gabulavichene[1], Nataly Kursina[1], Victoriya Bilaya[2], Olexander Bazyka[1] & Olexander Kovaliov[1]
[1]National Research Center for Radiation Medicine, Cardiology Department, Kiev, Ukraine; [2]National Research Center for Radiation Medicine, Department of Radiation Induced Somatic Pathology, Kiev, Ukraine

Objective was to analyze the place of endocrine and metabolic disorders among other comorbid diseases in the Chernobyl accident emergency workers (EW) who had cardiovascular diseases as main pathology.
Materials and methods
The health state was analyzed in 420 male EW, who worked at the Chernobyl NPP at 1986–1987 yrs, and 188 males not exposed to ionizing radiation (the control group, CG). Patients of both groups had a hospital treatment due to cardiovascular pathology during 2011–2019 yrs. For estimation of comorbid diseases the Cumulative Illness Rating Scale (CIRS) was used.
Results
The CIRS total score was significantly higher in EW comparing with CG (10.3 ± 2.9 vs 8.8 ± 3.0 units, $P = 0.000$). According to relative number of patient with revealed pathology of different CIRS categories, 'Endocrine/ metabolic and breast' ranks 5 following 'Heart' (1), 'Neurological' (2),'Vascular' (3) and 'Musculoskeletal and skin' (4) systems. The rest 7 categories (we did not analyze 'Psychiatric illness') had less patients with corresponding organ systems diseases. In 'Endocrine…' category mild problems (score 1) was revealed in 34.8% EW, moderate problems (score 2) in 15% and severe/extremely severe (score 3–4) in 6.2% EW. Regardless of score number EW did not differ from CG patients (29.8, 13.8 and 5.9% correspondingly). For comparison in CIRS category 'Heart' patients with score 1 was 43.6% EW vs 45.7% CG ($P > 0.05$), score 2–19.5% vs 22.3% ($P > 0.05$) and score 3–4 – 35.2% vs 26.6% ($P < 0.05$). By mean score calculated for every category 'Endocrine…' ranks 4 (0.8 ± 0.9 in both EW and CG, $P = 0.293$) following 'Vascular' (2.5 ± 0.8 in EW and 2.3 ± 1.0 in CG, $P = 0.06$), 'Heart' (1.9 ± 0.9 in EW and 1.7 ± 0.9 in CG, $P = 0.024$) and 'Neurological' (1.6 ± 0.8 in EW and 1.1 ± 1.0 in CG, $P = 0$). Amongst endocrine and metabolic disorders diabetes mellitus, thyroid gland goiters and obesity govern score presence but the score value was determined by diabetes mellitus severity course and body mass index. Thyroid gland goiters were frequent pathology as well but with mild course.
Conclusions
In patients with cardiovascular diseases as main pathology comorbid endocrine and metabolic disorders met sufficiently frequently in EW and non-irradiated patients and had high score value skipping ahead only cardiovascular, neurological and musculoskeletal diseases.
Keywords: emergency workers of the Chernobyl, cardiovascular disease, comorbidity, Cumulative Illness Rating Scale, endocrine and metabolic disorders.

Prescription of Statins in the elderly with diabetes

Tlili Abir, Najoua Lassoued, Ajili Rihab, Alaya Wafa, Zantour Baha & Sfar Mohamed Habib
Taher Sfar University Hospital, Endocrinology Department, Mahdia, Tunisia

Introduction
The prevalence of cardiovascular disease in the elderly is very important. The prevention of cardiovascular risk is essential in order to avoid the morbidity and mortality associated with these diseases. The objective of this study was therefore to assess the frequency of prescription of statins in elderly with diabetes and to analyze the benefit risk ratio of this prescription.
Patients and methods
Retrospective study which involved 94 diabetic subjects aged over 65 years who were hospitalized in the endocrinology department of Mahdia or followed at the outpatient clinic between the month of November and the month of December 2020.
Results
The mean age was 71 ± 5 years with extremes of 65 and 90. All of our patients had type 2 diabetes. The mean duration of diabetes was 12 years ± 8. A quarter of the patients had chronic renal failure (24.46%). Hypothyroidism was found in 14.9% of our patients. The subjects who required treatment with statins according to the recommendations represented 57% of patients, of whom 92.6% were treated. Of these patients, 26.7% achieved the therapeutic goal of LDL-cholesterol according to the level of cardiovascular risk. Patients over 80 years of age accounted for 7.4% of all elderly subjects. None of these patients was prescribed with statins. For patients treated with statins, no adverse effects have been reported despite advanced age and associated comorbidities. No cardiovascular events were noted after the prescription of statins in this cohort. A statin withdrawal was observed in two patients with no obvious medical cause. It would be related to non-adherence to therapy in these patients.
Conclusion
Through this study, we observed good tolerance after taking a statin in diabetic patients despite advanced age with an obvious benefit given the absence of cardiovascular events and the absence of side effects.

Ectopic cushing's syndrome due to an acinic type parotid carcinoma

Dimitra Zerva, Dimitra Pappa, Eleftheria Mparmpa, Anastasia –fonstantina Sakali, Pinelopi Thoda, Eleni Georgiou, Ioannis Gountios & Alexandra Bargiota
University Hospital of Larissa, Department of Endocrinology and Metabolic Diseases, Larissa, Greece

Introduction
Ectopic Cushing's syndrome(ECS) is responsible for 15–20% of all cases of ACTH dependent Cushing's syndrome. We present here a very rare case of ECS due to an acinic parotid carcinoma (ACC).
Presentation
A 44 year old woman with a medical history of metastatic ACC parotid carcinoma and type 1 diabetes mellitus (T1DM), referred to our department, due to cushingoid features, progressive fatigue, inability to walk and severe hypokalcemia (serum potassium (P) 2.4 mEq /l) refractory to replacement. The last four months she gained weight, had difficulties to control her diabetes, inability to climb stairs and became hypertensive. Physical examination revealed a cushingoid appearance, with centripetal obesity, moon face, enlarged supraclavular fat pads, proximal muscle weakness, mild pigmentention and thinning of the skin and pheripheral oedema. Her blood tests revealed hypercortisolemia with loss of diurnal rhythm [cortisol 8pm 64 μg/dl, (< 18 μg/dl), salivary cortisol 8pm 23.2 μg/dl (< 0.783, μg/dl), 24 h UFC 3468 μg (< 120 μg/dl)], high ACTH levels [ACTH 439 pg/ml, (< 60 pg/ml)] and hypokaliemic metabolic alcalosis.(*P* 2.4 mEq/l, ABG's: *ph* = 7.47, PCO_2 = 31 mm/Hg, PO_2 = 105 mm/Hg, HCO_3 = 22.6 mmol/l). Recent imaging revealed extended metastatic disease, with no pathology of pituitary or adrenal glands. The diagnosis of ECS was made and due to the severity of her clinical picture and her rapid deterioration, no further confirmatory test were done and the patient started on fluconazole 400 mg iv/d, metyrapone 3 gr/d, spironolactone 100 mg/d and potassium replacement. Due to the extensive metastatic disease, resection of the tumor was not possible. Eight days later the patient had a remarkable clinical improvement and laboratory findings showed serum and salivary cortisol within the normal range. Five months after the diagnosis of ECS, her hypercortisolemia remained controlled but the patient had bone marrow infiltration and passed away.
Conclusions
Acinic cell parotid carcinoma, an aggressive tumor, is a very rare cause of ECS, with only six more cases to be reported so far. All patients presented with severe weakness and hypokaliemia. Due to the scarcity and the aggressiveness of these tumors, earlier diagnosis and treatment can be still a changeling issue but may affect the outcome.

Multiple metastases of parathyroid carcinoma and papillary thyroid carcinoma in a female patient treated with long-term hemodialysis

Julia Krupinova, Anna Eremkina, Ekaterina Dobreva, Iya Voronkova & Natalia Mokrysheva
Endocrinology research center, Moscow, Russian Federation

The combination of thyroid and parathyroid carcinoma (PC) are extremely rare. We present a case with metastases of both tumors to the lymph nodes of the neck in a woman who received renal replacement therapy with long-term hemodialysis.
Case report
In 1984, when she was 24 years old, the patient began working at a nuclear power plant as a chemical water treatment operator. The total length of service was 25 years. In 2009 (at the age of 49) the patient presented decreased renal filtration (creatinine 110 μmol/l, GFR 51 ml/min/1.73 m^2) as well as increased PTH (2500 pg/ml (15–65)) and total calcium (3.36 mmol/l (2.15–2.55)). In 2010, the left lower parathyroid gland (PG) was removed, and the left thyroid lobe resected. A histological examination revealed PC (ñT2Nx). Immunohistochemical (IHC) examination revealed the PTH staining, the tumor cell nuclei was immunopositive for parafibromin; the Ki-67 proliferation index was 5%. Over the next 3 years, the PC was in remission. The hemodialysis therapy was started. After 12 months PC progression was diagnosed and a final thyroidectomy was performed along with total parathyroidectomy and central lymph node dissection using intraoperative navigation methods (single-channel gamma detection probe, Gamma Probe 2, and fluorescence angiography with indocyanine green (ICG). During the surgery, the lesion in the thyroid bed on the left showing significant uptake of the isotope (^{99m}Tc-MIBI) and ICG was exposed. Microscopic examination showed a focus of PC in the fatty tissue, and two lymph nodes with subtotal metastases of papillary thyroid cancer (follicular variant). The morphological features of the PC are similar to the histological picture of the PC removed in 2010. IHC examination of the PC revealed diffuse expression of PTH and parafibromin. The Ki-67 proliferation index was 7%. This treatment led to achievement of laboratory targets: PTH 160 pg/ml, albumin-corrected calcium 2.53 mmol/l, Ca^{++} 1.23 mmol/l. Ultrasound, CT with contrast, SPECT/CT, needle washing liquid PTH (more than 5000 pg/ml) demonstrated an ongoing relapse of the disease with multiple metastases of PC to the neck lymph nodes. However, the dimensions of the lesions are not 'target' ones and, in view of the absence of uncontrolled hypercalcemia, follow-up was continued.
Conclusion
We believe it is important to publish different variants of PC and its combinations with other conditions in order to summarize available data and subsequently create clear recommendations for the prediction, treatment and monitoring in this complex group of patients.

Case report: Secondary adrenal insufficiency and primary hypothyroidism following Nivolumab therapy in a patient with metastatic melanoma

Paloma González Lázaro, Antonio Moreno Tirado, Cristina Contreras Pascual, Cristina Montalban Mendez, María Zhao Montero Benítez & Inés Gómez García
La Mancha Centro Hospital Center, Alcázar de San Juan, Spain

Introduction
In recent years, we have observed significant progress in cancer treatment associated with the development of immunotherapy. Nivolumab, an anti-PD-1 antibody, blocks the interaction between PD-1 and its ligands and inhibits the signaling pathway by preventing the tumor-derived PD-L1 from blocking T lymphocytes. In patients with metastatic melanoma, it is used either in monotherapy or in combination with other drugs. Immunotherapy is associated with the possibility of immune-related adverse effects (irAE) including endocrinopathies (3–23%). Thyroid disorders are the most common. Hypophysitis, adrenal insufficiency and diabetes are possible complications which require immediate treatment. We report the case of

a patient with metastatic melanoma following Nivolumab therapy who developed adrenal insufficiency and primary hypothyroidism.
Case report
63-year-old male with personal history of melanoma metastatic to lymph nodes, liver and spleen has received treatment with nivolumab every 15 days for 5 months. He was referred to our department for fatigue, appetite loss and weight loss of 10 kg in the last 2 months and relative hypotension. Laboratory data revealed elevated thyroid-stimulating hormone and low free thyroxine and positive TPO antibodies; low morning cortisol without correspondence increase of ACTH. Other pituitary hormones were normal. No enlargement of the pituitary gland was apparent by magnetic resonance imaging. The patient was diagnosed with nivolumab induced secondary adrenal insufficiency and primary hypothyroidism. Hormone replacement with levothyroxine (100 mg/day) and oral hydrocortisone (20 mg/day) was started. Nivolumab was discontinued, resulting in amelioration of his symptoms and hydrocortisone was successfully tapered. Nowadays, the patient is on treatment with levothyroxine replacement and has restarted nivolumab every 15 days, metastatic lesions gradually have decreased in size without any additional treatment. During follow-up, the patient presented normal cortisol response to the Short Synacthen Test.
Conclusions
In the management of patients receiving immunotherapy, awareness of the possibility of irAE is crucial. Many of the irAE are linked to the endocrine system. Before anti-PD-1 treatment introduction, an evaluation of the patient for autoimmune diseases should be performed. Thyroid antibodies and type 1 diabetes-related antibodies are considered risk factors and therefore—when detected—organ-specific immune complications should be expected. We suggest routine monitoring of fasting blood-glucose, blood pressure and serum sodium and thyroid function during nivolumab and other cancer immunotherapies. When unexpected fatigue, hypoglycemia, hypotension or hyponatremia appeared, adrenal deficiency should be taken into consideration.

Nutritional assessment and Ghrelin system as predictors of clinical evolution in gastro-enteropancreatic neuroendocrine neoplasms

Carlos Manuel Alzás Teomiro[1], Soraya León-Idougourram[1], María Dolores Alcántara-Laguna[1], Manuel D. Gahete[2], María José Molina-Puertas[1], Justo P. Castaño[2], Raúl M. Luque[2], María Ángeles Gálvez Moreno[1] & Aura D. Herrera-Martínez[1]
[1]Reina Sofía University Hospital, Endocrinology and Nutrition, Córdoba, Spain; [2]Maimonides Institute for Biomedical Research of Cordoba (IMIBIC), Córdoba, Spain

Background
Patients with neuroendocrine neoplasms (NENs) might present with malnutrition due to the tumor itself and/or its treatment. Poor nutritional status and weight loss can lead to poor outcomes, including decreased quality of life, increased complication rates and mortality. Ghrelin is an orexigenic hormone, which is implicated in appetite regulation, body weight, inflammation and immune cell activation. Its gastric secretion mainly depends on the nutritional status of the body, consequently, it may affect the clinical evolution and prognosis of these patients.
Objective
To evaluate nutritional parameters of patients with gastroenteropancreatic (GEP)-NENs and to explore the influence of the mRNA expression of some ghrelin system components in the nutritional status of GEP-NENs patients and their clinical outcomes.
Methods
Clinical data of 104 patients was collected. The mRNA expression of some ghrelin system components was determined using qPCR in 64 tumor samples. Statistical analysis was performed with SSPS v.24.
Results
In our cohort, decreased BMI was associated with relapsed disease and decreased albumin with increased mortality($P < 0.05$). Patients who currently remain disease-free had increased BMI at diagnosis compared with patients with active disease ($P < 0.05$); the survival rate in our cohort was 95 months. The presence of metastasis at diagnosis tended to related with BMI and serum LDL levels. Almost one third of patients (27.8%) presented altered nutritional parameters at diagnosis. Patients with gastric NENs tended to present with lower levels of serum ferritin, lymphocites and total cholesterol compared with other locations. The molecular tumor expression of ghrelin tended to correlate with some nutritional parameters including weight at diagnosis, serum ferritin, total cholesterol and LDL levels.
Conclusions
BMI, serum nutritional parameters and the molecular expression of some ghrelin system components might be related with the clinical evolution of GEP-NENs patients. Routine nutritional evaluation and early nutrition intervention should be implemented to improve the outcome in these patients. Further studies are still required.

Paraganglioma of the basis cranii due to somatic mutations ind SDHB and PTEN genes

Ailsa Maria Main[1], Marianne Klose[1], Krogh Rasmussen[1], Anand Chainsukh Loya[2], Caroline Maria Rossing[3], Thomas Kistorp[4], Kaare Fugleholm Buch[5], Christine Soelling[6], Lars Poulsgaard[5], Goetz Benndorf[7] & Ulla Feldt-Rasmussen[1]
[1]Rigshospitalet, Endocrinology, Copenhagen, Denmark; [2]Rigshospitalet, Pathology, Copenhagen, Denmark; [3]Rigshospitalet, Genomic Medicine, Copenhagen, Denmark; [4]Rigshospitalet, Anesthesia, Copenhagen, Denmark; [5]Rigshospitalet, Neurological Surgery, Copenhagen, Denmark; [6]Rigshospitalet, Neurosurgical Anesthesia, Copenhagen, Denmark; [7]Rigshospitalet, Radiology, Copenhagen, Denmark

Head and neck paragangliomas (HNPGLs) are a type of neuroendocrine tumour. They arise from the sympathetic ganglia and can be either sporadic or due to hereditary syndromes (up to 40%). Most HNPGLs do not produce significant amounts of catecholamines[1]. Often, HNPGLs are detected in late stages due to compression or infiltration of cranial structures[1]. We report a case of a paraganglioma of the basis cranii due to somatic variants of SDHB (succinate dehydrogenase gene B) and PTEN (phosphatase and tensin homolog) with both an unusually serious presentation and a surprisingly good outcome. A 39-year-old Caucasian woman with no prior medical history was found unconscious and emaciated in her home. In the intensive care unit (ICU) the patient was treated for multi-organ failure with multiple complications and difficulties in stabilizing her blood pressure with values up to 246/146. She spent a total of 72 days in the ICU and on the 31st day clinical assessment revealed foramen jugulare syndrome and paralysis of the right n. facialis. A CT cerebrum, MRI, PET-CT, MIBG-scintigraphy and a Ga-Dotatoc PET confirmed a right-sided tumour of the basis cranii of 6.5 × 4.5 cm. A urine test showed high amounts of norepinephrine (35.1–45.4 nmol/l, ref < 1.09 nmol/l) and a tumour biopsy confirmed the diagnosis of a paraganglioma. Phenoxybenzamine and Labetalol was used to stabilize blood pressure. She underwent two tumour embolization treatments before total tumour resection on day 243. Plasma norepinephrine normalised after surgery (0.77 nmol/l, ref: < 1.09 nmol/l) as did her blood pressure (approx. 130/80). The damage to the cranial nerves was permanent. The patient has made a remarkable recovery and will need rehabilitation to improve her physical performance. Next generation sequencing (NGS) of tumour tissue revealed somatic mutations of SDHB (c.565T > G, p.C189G) and PTEN (c.834C > G, p.F278L). The NGS genome panel showed no germline variants and whole genome sequencing was negative. An SNP-array of tumour DNA showed loss of heterozygosity of p.1 (including SDHB) and p.11. It is very rare that a patient with a somatic variant in the SDHB gene does not hold a germline variant. SDHB variants are often associated with malignancy and future follow-up with scans and clinical assessments will show whether this is a case of a benign or malignant paraganglioma.

Introduction
Alternative splicing allows the generation of multiple RNA isoforms from a single pre-RNA molecule, and thereby contributes to a multitude of physiological processes, but can also be involved in many diseases, including cancer. Indeed, disruption of alternative splicing has been linked to key cancer features, such as tumor growth, metastasis and hormone responsiveness and is increasingly regarded as a novel and transversal cancer hallmark. The dysregulation of the splicing machinery could constitute the underlying cause in many of these alterations and, consequently, is an attractive target of study. In this context, it has been previously described that a member of SR splicing factor family, SRSF2, play a relevant role of as an oncodriver in various cancers like hepatocellular carcinoma and myelodysplastic syndromes.
Objective
We aimed to investigate the presence, relevance and potential role as diagnostic/prognostic biomarker and therapeutic target of SRSF2/SC35 in two tumoral pathologies strongly influenced by the patient endocrine-metabolic status: 1) prostate cancer (PCa), the most diagnosed tumors among men worldwide; and 2) pancreatic ductal adenocarcinoma (PDAC), one of the most lethal cancers.
Methods
The expression of SRSF2 was measured in tumor vs. non-tumor adjacent tissue in a set of 79 PDAC and 45 PCa human samples. The results were validated using publicly available external cohorts. The role of this splicing factor was assessed *in vitro* by analyzing a set of functional parameters in response to siRNA-induced SRSF2-silencing in various PDAC and PCa cell lines.
Results
Our data revealed that SRSF2 was overexpressed in both tumors and its expression was associated to poor prognosis and relevant malignancy features, including tumor stage, presence of lymph node invasion and/or metastasis, which was confirmed using independent cohorts of patients. SRSF2-silencing significantly reduced cell migration, proliferation, invasion, and colony formation in PDAC and PCa cell lines in comparison with control cells through the alteration of key oncogenic signaling-pathways and the modulation of the expression of relevant genes.
Conclusions
These results suggest a role of the splicing factor SRSF2 in both pancreatic and prostate adenocarcinoma oncogenesis and aggressiveness, thus paving the way to explore its possible value as a biomarker and therapeutic target in both types of cancers.

Ectopic ACTH secretion from a metastatic gastric carcinoma with neuroendocrine component

Annalisa Montebello, Darryl Portelli & Mark Gruppetta
Mater Dei Hospital, Diabetes and Endocrinology, Msida, Malta

Background
Ectopic ACTH secretion accounts for 9–18% of ACTH dependent Cushing's' syndrome. The most common causes are intrathoracic neuroendocrine tumours. Gastric tumours as a cause of ectopic ACTH secretion are remarkably rare.
Case report
A seventy-five-year-old gentleman complained of a four month's history of epigastric discomfort, anorexia, and weight loss. He was a known diabetic and hypertensive. A computed tomography (CT) scan showed diffuse enhancement and thickening of the pylorus up to the pyloric antrum for a length of eight centimetres with large hepatic and coeliac lymph node metastases. An oesopho-gastro-duodenoscopy showed an ulcerating mitotic lesion on posterior antral wall, extending from the antrum through the pylorus and into the first part of the duodenum. Within two weeks he developed recurrent vomiting, new onset lower limb oedema and orthopnoea. His diabetes and hypertension had suddenly become difficult to control. Blood results showed severe new onset hypokalaemia of 1.75 mmol/l with metabolic alkalosis. ECG showed global T wave inversions and U waves. The combination of hypokalemia, metabolic alkalosis and a stomach lesion triggered a series of investigations to assess if severe hypercortisolaemia could be the underlying diagnosis. A 9am cortisol level was 3325 (145–619 nmol/l), overnight dexamethasone suppression test 2602 (< 50 nmol/l), 24 hr urinary cortisol 4316 (57.7–806 nmol/24 hrs) and ACTH levels 358 (10 48 pg/ml). Gastric biopsies showed a moderately to poorly differentiated intestinal-type adenocarcinoma with neuroendocrine differentiation. The poorly differentiated component expressed neuroendocrine markers CD56, synaptophysin and chromogranin, the latter being weakly expressed. Ki 67 index was 70%. It was concluded that the patient had a non-neuroendocrine neoplasm with a focal neuroendocrine component secreting ACTH. The hypokalaemia was managed with aggressive central and peripheral potassium replacement and spironolactone. Metyrapone was started to block adrenal cortisol synthesis with doses being cautiously titrated according to his 24 hour urinary cortisol results. These decreased to 1254 and 1822 nmol/24hrs. Insulin was started. He was unfit for surgery and was planned for six cycles of a combination of Carboplatin/Etoposide chemotherapy once every 3 weeks. He received three cycles of Carboplatin but his health deteriorated. Repeat CT scan showed an increase in liver metastases and adrenal hypertrophy. He was given adequate pain relief, fluids and he died a few days later.
Conclusion
This case highlights the accelerated presentation, rapid malignant progression and poor prognosis of hypercortisolism due to ectopic ACTH secretion.

Testosterone replacement therapy(TRT) and prostate cancer

Olena Mitrofanova[1], Sheenam A[1], Yagoub Abdelgader[2] & Vikram G Aarella[2]
[1]Pilgrim Hospital, Boston, United Kingdom; [2]Pilgrim Hospital, Diabetes and Endocrinology, Boston, United Kingdom

Title – Testosterone replacement Therapy (TRT) and prostate cancer
Hypogonadism is a condition with low serum testosterone level, which can manifest as depression, lack of libido, decreased bone mineral density and muscle weakness In patients with hypogonadism returning serum testosterone to normal levels results in improvement in cognition, mood, sexual function, physical performance, normalises bone density and erythropoiesis.
Case
We describe the case of 64-year-old man who was diagnosed with primary testosterone deficiency in the year 2008. His past medical history also includes essential hypertension, asthma, obesity and fatty liver. He does not have a family history of malignancy. He started on Testosterone replacement Therapy (TRT) in the form of Testogel and it was titrated to achieve and maintain optimum testosterone level. In October 2019, we noticed PSA (Prostate specific Antigen) raise to 5.2 mg/l and patient was referred to urology team. At that time, he did not have lower urinary tract symptoms; he had good erectile function on testosterone supplement, in urology he had a MRI of prostate and Trans perineal biopsy which came back as prostate adenocarcinoma which was of intermediate risk. Testosterone replacement was stopped; Following a Multidisciplinary team meeting Oncologists managed him for his Prostate cancer. He received Brachytherapy and Radiotherapy with good response. Oncologists suggested to us that testosterone replacement therapy can be restarted not earlier than 18 months and only if PSA level will remain within the normal range.
Key learning
There is no proven correlation between normal or high serum testosterone levels and prostate cancer. However, regular checking of PSA level helps to diagnose prostate cancer early. In this case, the patient was referred to urology department immediately after the abnormal test result and had a good outcome Some studies showed that ~ 15% of hypogonadial men with PSA lower than 4.0 mg/l will have prostate biopsy showing cancer. Men with low testosterone levels have also shown to have worse prognoses in prostate cancer with higher grade, more aggressive cancer while men with normal or higher testosterone level would more likely to have less advanced forms of cancer. The possible explanation is that lower levels of testosterone would not activate the androgen response elements in the PSA promoter, so these patients will be diagnosed much later. PSA can raise shortly after initiation of TRT but overall there is no proven increased risk of developing prostate cancer while on TRT.

Introduction
Inadequately managed papillary thyroid carcinoma (PTC) patients result in potentially higher fatal outcomes due to a lack of sufficient prognostic data/markers, inadequate periodic individualized follow-up risk assessments and/or insufficient initial treatment. MiR-146b, -21, -221, -222, -181b are potential biomarkers for risk stratification of PTC.
Aim
The aim of our study was to analyze expression of five miRNA molecules (miR-21; miR-221; miR-222; miR-146b; miR-181b) in PTC formaline fixed paraffin embedded (FFPE) tissue samples and evaluate the relation to clinicopathological parameters.
Methods
We analyzed expression of miR-221, miR-222, miR-146b, miR-21, miR-181b in the 312 patients FFPE PTC tissue samples and evaluated their expression relationship with clinicopathological parameters.
Results
MiR-221, miR-222 expression was higher in the PTC tissue samples with extrathyroidal extension (P = 0.049, 0.003, respectively). Higher expression of miR-21 was related to unifocal lesions (P < 0.011), and concomitant autoimmune thyroiditis (0.007). In a group of PTC patients with T1a and T1b sized tumors, the expression of miR-146b, miR-21, miR-221, miR-222 in PTC tissue samples was lower than in patients with T2, T3, T4(P = 0.032; 0.0044; 0.003; 0.001, respectively). Patients with lymph node metastases had higher expression of miR-21, -221, -222 and -181b (P < 0.05). High expression of miR-146b, miR-221, miR-21 panel is associated with decreased overall survival (Log rank P = 0.19).
Conclusion
5 analyzed miRNA's expression have significant relations to clinicopathologic parameters so further investigations of these molecules are necessary while searching for prognostic PTC biomarkers.

Clinical, genetic & imaging characteristics of mediastinal paraganglioma – a case series

Mark Quinn, Carroll Paul, Barbara McGowan, Mamta Joshi, Louise Izatt & Anand Velusamy
Guy's and St Thomas' NHS Foundation Trust, United Kingdom

Introduction
Paragangliomas (PGLs) are neuroendocrine tumours that arise from neural crest-derived chromaffin cells. They can develop anywhere these cells exist from the base of the skull to the pelvis. All PGLs have neuro-secretory potential and can produce symptoms due to catecholamine excess. While the majority are benign they do have malignant potential. Mediastinal PGLs are rare and often have a strong genetic predisposition. A higher proportion of these tumours can be secretory when comparted to head and neck PGLs. Novel functional imaging modalities have increased tumour detection rates. Surgical resection is often challenging due to their proximity to vital structures. Here we present our experience of 8 patients with mediastinal PGLs with a median of 5.5 years follow up (range 2–16 years).
Case descriptions
We report 8 cases (3 female, 5 male) of mediastinal PGLs in patients aged 19–81 years (median age 58). 5 presented with a solitary mediastinal PGL, 2 with multiple lesions and 1 with metastatic spread. 4/8 were diagnosed as a result of cascade screening. These all had a heterozygous pathogenic SDHB variant and were asymptomatic. Genetic analysis of the remaining 4 patients revealed no genetic abnormality in 3/8 and an SDHA variant of uncertain significance in 1/8. 3/8 were diagnosed incidentally and the remaining 1 patient was diagnosed due to symptomatic catecholamine excess. Serum or urinary samples demonstrated catecholamine excess in 37.5% of cases. The functional imaging modalities utilised included FDG PET (2/8), DOTATATE PET (3/8) and MIBG scintigraphy (7/8). Gallium DOTATE and FDG PET CT demonstrated 100% sensitivity in identifying these tumours. MIBG scanning demonstrated 57% sensitivity. 6/8 underwent surgery. 2 patients were diagnosed with ischaemic heart disease pre-operatively and underwent a simultaneous coronary artery bypass graft. Post-operative follow up ranges from 1 to 16 years. No recurrent or metastatic disease has been identified in these 6 cases. 1/8 was managed conservatively. Peptide receptor radionuclide therapy was used to treat 1 patient with metastatic disease. Latest imaging demonstrates stable disease in these 2 cases
Conclusion
Mediastinal PGLs are rare but carry a strong genetic predisposition. More are being identified due to improved functional imaging techniques. Interpretation of these imaging modalities requires careful consideration. A high proportion of mediastinal PGLs can be secretory. Surgical intervention should be performed in a specialist cardiothoracic centre and a multidisciplinary approach is needed for risk stratification, pre- and post-operative management. With this approach excellent outcomes can be achieved.

Levels of Pro-inflammatory biomarkers in Papillary thyroid cancer

Ramesh Bangariahgari[1], Ramakanth Bhargav Panchangam[2], Rajesh Bangaraiahgari[3], Rafi Md[1] & Rajkiran Reddy Banala[4]
[1]Surabhi Medical College, Biochemistry, India; [2]Endocare Hospital, Vijayawada, Endocrine and Metabolic Surgery, Vijayawada, India; [3]Surabhi Medical College, Anatomy, India; [4]Sunrise Hospitals, Genetics, India

Introduction
Papillary thyroid carcinoma (PTC) is the most common endocrine malignancy. Apart from genetics, autoimmunity has been implicated in its pathogenesis. But, reports have been conflicting ranging from causative, protective and

neutral role of immunomodulation. In this context, we set out study the role of Pro- inflammatory cytokines in PTC in South Indian population.
Material and methods
This pilot prospective case-control study was conducted on surgically managed PTC patients. Institutional ethical committee approval was obtained. Diagnosis of PTC was based on imaging, fine needle aspiration cytology and later confirmed by histopathology. Exclusion criteria were subjects with any systemic or chronic inflammatory disease or any medication which interferes with the normal function of the hypothalamic-pituitary-gonadal axis. Serum samples were collected from 45 PTC subjects and 43 age matched healthy controls. Interleukin-6 (IL-6), Tumour necrosis factor-alpha (TNF-α) and high sensitive C reactive protein (hsCRP), leptin levels were measured in all serum samples. Statistical analysis was performed by one way ANOVA with Dunnet's test and Pearson correlation tests.
Results
The mean hSCRP level in PTC and controls were 18.4 ± 3.1 mg/ml and 5.3 ± 1.2 mg/ml respectively. The mean TNF-α level, IL-6 level and Leptin levels were 294 ± 31 pg/ml, 13.5 ± 4.5 pg/ml and 1.96 ± 0.7 ng/ml respectively. Serum leptin level in controls was 3.6 ± 1.7 ng/ml. There was statistically significant difference of all the pro-inflammatory cytokines compared to controls (P value < 0.05) with negative correlation for leptin levels.
Conclusions
Our study shows raised titers of pro-inflammatory markers – IL-6, TNF-ń and hsCRP, while reduced leptin levels correlated with PTC suggesting a contributory role. But, the exact immuno-modulatory role of these markers in thyroid cancer needs more research.
Keywords: Papillary thyroid cancer; Tumour necrosis factor; Interleukin-6; Goiter; Auto-immunity; Leptin.

Assessment of different markers of ovarian reserve in women with differentiated thyroid cancer treated with radioactive iodine

Agnieszka Adamska[1], Paulina Tomczuk-Bobik[1], Anna Popławska-Kita[1], Katarzyna Siewko[1], Angelika Buczyńska[1], Piotr Szumowski[2], Łukasz Żukowski[2], Janusz Myśliwiec[2], Monika Zbucka-Krętowska[3] & Adam Krętowski[1]
[1]Medical University of Białystok, Department of Endocrinology, Diabetology and Internal Medicine, Białystok, Poland; [2]Medical University of Białystok, Department of Nuclear Medicine, Białystok, Poland; [3]Medical University of Bialystok, Department of Gynecological Endocrinology and Adolescent Gynecology, Białystok, Poland

Objective
It has been shown that treatment with radioactive iodine (RAI) of women with differentiated thyroid cancer (DTC) is connected with decreased serum concentration of anti-Müllerian hormone (AMH). To date, others markers connected with ovarian reserve have not been investigated yet. Therefore, the aim of the present study was to evaluate the effect of RAI on serum concentration of inhibin B, follicle stimulating hormone (FSH), AMH and antral follicle count (AFC) in women with DTC treated with RAI.
Materials and methods
We examined 25 women at the median age of 33, who were treated with single dose of RAI. Serum concentrations of inhibin B, FSH, AMH and AFC were assed at baseline and one year after RAI treatment.
Results
We found decreased serum levels of AMH (P = 0.02), inhibin B (P = 0.03) and AFC (P = 0.03) but not FSH (P = 0.23) one year after RAI treatment in comparison to the baseline.
Conclusions
We concluded that RAI treatment have signifficant impact on serum concentrations of AMH, inhibin B and AFC in premenopausal women with DCT, therefore this markers are usefull for assesment of ovarian reserve. Additionally, an assesment of ovarian reserve markers and the protection of oocytes, prior to treatment with RAI, should be considered in premenopausal women.

A rare cause of postmenopausal hirsutism – granulosa cell tumor of the ovary

Himamshu Acharya N[1], Chitra Selvan[1] & Sujani BK[2]
[1]Ramaiah Medical College, Endocrinology, Bengaluru, India; [2]Ramaiah Medical College, Obstetrics and Gynaecology, Bengaluru, India

Androgen excess in post-menopausal women usually results from ovarian or adrenal pathology. Identifying pathology is significant as many ovarian tumors can be malignant in nature. We report a case of granulosa cell tumor which presented with virilizing signs. A 66-year-old postmenopausal lady presented with temporal hair loss and weight gain. She had to drop out of her church choir as she had a change in her voice. She was concerned about her facial hair growth which was significantly affecting her social life. She had no known comorbidities and her past medical and family histories were noncontributory. She was on over the counter herb-based nutritional supplements. On examination, she appeared muscular, had temporal recession of hair, had a deep low-pitched voice. Modified Ferriman – Gallwey score was 3/36; involved mainly face. Biochemical evaluation revealed FSH – 44 mIU/ml, LH- 14.71 mIU/ml, Total testosterone – 530.3 ng/dl, Free testosterone – 14.43 ng/dl, bioavailable testosterone – 368 ng/dl, SHBG – 17 nmol/l, DHEA-S – 329.03 ng/ml, androstenedione – 1.72 ng/ml, TSH – 3.06 mIU/l. Renal and liver functions were normal. Ovaries and adrenals were normal on abdominal MRI; there were multiple uterine fibroids. A re-evaluation after a month of discontinuing the nutritional supplements revealed persistently high testosterone of 517 ng/dl, free testosterone – 10.9 ng/dl, bioavailable testosterone – 279 ng/dl, and a free androgen index of 59.2%. 8 am cortisol was 6 mg/dl. GnRH suppression with GnRH analogue was conducted. A reduced level of testosterone (150 ng/dl) post GnRH suppression suggested an ovarian source of testosterone. She was suggested to undergo bilateral salpingo-oophorectomy along with hysterectomy. Pathologists were requested for careful inspection of ovaries. Histopathology revealed granulosa cell tumor of the ovary measuring 1.2 cm × 1 cm with no significant nuclear atypia along with uterine leiomyoma and adenomyosis. The tumor was limited to one ovary. On follow-up, after a month, her voice improved and there was a decrease in hair-fall and change in body habitus. Androgen secreting tumors form about 1% of all ovarian tumors. Granulosa cell tumors belong to sex cord-stromal tumors. Generally, they secrete estrogen but rarely may secrete androgens. Due to the malignant behavior of the tumors, early diagnosis plays an important role.

Malignant pheochromocytomas and paragangliomas: clinical and pathological characteristics of a tertiary hospital' cohort

Joana Reis Guiomar[1], Carolina Moreno[1,2], Adriana Lages[2], Lúcia Fadiga[1], Diana Alexandra Festas Silva[1] & Isabel Paiva[1]
[1]Coimbra Hospital and University Center, EPE., Endocrinology, Diabetes and Metabolism Department, Coimbra, Portugal; [2]University of Coimbra, Faculty of Medicine

Introduction
Pheochromocytomas (PHEO) and paragangliomas (PGL) are neuroendocrine tumors arising from the chromaffin cells of the adrenal medulla and extra-adrenal autonomic paraganglia, respectively. They are rare and generally benign neuroendocrine tumors. However, malignancy (defined as the evidence of metastases in nonchromaffin sites distant from the primary tumor) occurs in 2 to 26%. Malignant PHEO and PGL are very challenging malignancies associated with poor prognosis.
Objective
Descriptive analysis of the clinical and pathological characteristics of patients with malignant PHEO and PGL followed since 1987 at the Endocrinology Department of a tertiary hospital.
Material and methods
Retrospective cohort study based on the clinical files with clinical, biochemical, imaging, histologic examination, genetic and overall survival characterization.
Results
13 patients, mean age at diagnosis 40.77 ± 16.80 years, 53.8% female. At diagnosis: 10 (76.9%) patients with PHEO(2 of them with bone metastasis), 2 (15.4%) with PGL and 1 (7.7%) patient with PHEO and PGL. Diagnosis made by: hypertension difficult to control in 7 (58.3%) patients, symptoms related to the mass in 3 (25%) and incidentaloma in 2 (16.6%). 5 (50%) patients presented elevated urinary and plasma metanephrines, 3 (30%) elevated plasma metanephrines (with normal urinary metanephrines) and 2 (20%) increased urinary metanephrines (without plasma metanephrines results). On CT only one patient had tumor size < 4 cm, 4 (50%) had heterogeneous enhancement and 2 (25%) had necrosis suggestive areas. All patients underwent surgical treatment. In histologic examination, the mean PASS score was 6.50 ± 2.77 and only 1 (12.5%) patient had a PASS score < 4. Metastasis occurred 8.00 ± 6.15 years after diagnosis: bone (n = 3), pulmonary (n = 2), peritoneal (n = 2), kidney (n = 1), pancreas (n = 1), liver (n = 1) and contralateral adrenal

gland (n = 1). A genetic study was carried out in 9 patients (MAX, RET, SDHAF2-B-C-D, TMEM127, VHL, NF1) and only 1 was positive for NF1. 2 (15.4%) patients died from complications of the disease, 1 (7.7%) died from pneumonia and 10 (76.9%) are being followed, only one of them without active disease. Mean survival was 13.46 ± 11.98 years.
Conclusion
PHEO/PGL are neuroendocrine tumors with aggressive potential that is very difficult to predict. In this cohort, regarding malignant PHEO/PGL, 83% had symptoms, 88.9% tumors > 4 cm and 87.5% PASS score ≥ 4, characteristics that seem to be more frequently associated with malignancy. Long-term follow-up is essential, as metastases can occur several years after diagnosis. In our data, metastases occurred up to 18 years after diagnosis.

Severe hypoglycemia: First manifestation of an advanced hepatocellular carcinoma

Wiem Ben Elhaj, Imen Rojbi, Meriem Adel, Nadia Mchirgui, Youssef Lakhoua, Ibtissem Ben Nacef & Karima Khiari
Charles Nicolle Hospital, Department of Endocrinology, Tunisia

Background
Hypoglycemia is a well-established as a serious paraneoplastic complication of hepatocellular carcinoma (HCC). However, hypoglycemia presenting the first presentation of HCC is not frequent. In this regard, we present the case of a patient who had hypoglycemia as first manifestation of HCC.
Observation
A 55yearold man presented to the Emergency Department with loss of consciousness preceded by dizziness, weakness and blurred vision due to severe hypoglycemia (20 mg/dl), from which he recovered after treatment with intravenous glucose. Then, he was admitted to our department. This symptomatology occurred for one month twice a week. He denied any recent alcohol consumption or the use of other drugs. Past medical history included only schizophrenia treated with Haloperidol and Trihexyphenidyl since 25 years. The patient was lethargic and his BMI was 18 kg/m^2. Clinical examination noted a hard and irregular hepatomegaly with collateral venous circulation. No splenomegaly was found. His cardiovascular and respiratory system findings were within normal limits. Laboratory testing revealed hypoglycemia as documented by a very low serum glucose 1.04 mmol/l, serum creatinine 52 µmol/l, serum glutamic oxaloacetic transaminase level of 243 IU/l and serum glutamic pyruvic transaminase level of 71 IU/l. The patient's insulin level was < 0.1 IU/ml and the blood cortisol level was elevated, thus excluding respectively the diagnosis of insulinoma and adrenal *insufficiency*. The hepatitis B surface antigen level and the test for the hepatitis C virus antibody were negative. Abdominal ultrasound revealed enlarged dysmorphic liver, seat of multiple nodules saving no segment. Computed tomography revealed multiple hepatic lesions consistent with multifocal multicentric HCC and multiple pulmonary metastases. Subsequent investigations showed serum α-fetoprotein more than 4000 UI/ml (normal range < 4 UI/ml), IGF1 = 0.001 ng/ml, and IGF2 = 561 ng/ml. Therefore, the diagnosis of HCC and non-islet cell tumor hypoglycemia (NICTH) was considered. Initially, the patient was treated with continuous 10% dextrose infusion and due to the advanced disease stage, he was not a candidate for surgical or palliative cytoreductive therapies. He received only palliative treatment, including oral prednisolone 30 mg once daily in addition to frequent high complex carbohydrate meals with some improvement in the severity of hypoglycemia.
Conclusion
Hypoglycemia due to NICTH is an established paraneoplastic complication of HCC. The prognosis for metastatic or unresectable HCC is poor. The use of frequent, high complex carbohydrate meals and oral steroids are options for management of this condition.

Untreated phaeochromocytoma and co-existing severe pulmonary hypertension: Friend or foe?

Su Tee[1], May Rui Loo[2], Azmi Mohammed[2], Ahmed Al-Sharefi[1], James Lordan[3], Peter Truran[4], Yaasir Mamoojee[1] & M Shafie Kamaruddin[2]
[1]Royal Victoria Infirmary, Newcastle upon Tyne Hospitals NHS Foundation Trust, Department of Endocrinology, United Kingdom; [2]Darlington Memorial Hospital, County Durham and Darlington NHS Foundation Trust, Department of Diabetes and Endocrinology, United Kingdom; [3]Freeman Hospital, Newcastle upon Tyne Hospitals NHS Foundation Trust, Department of Respiratory Medicine, United Kingdom; [4]Royal Victoria Infirmary, Newcastle upon Tyne Hospitals NHS Foundation Trust, Department of Endocrine Surgery, United Kingdom

Phaeochromocytomas are neuroendocrine neoplasms originating from chromaffin cells of the adrenal medulla, causing 0.1–0.2% cases of hypertension. Although rare, phaeochromocytoma is potentially life-threatening, leading to hypertensive crises if unrecognised or mismanaged. Chronic thromboembolic pulmonary hypertension (CTEPH) is a potential complication of thromboembolic disease, usually resulting from ongoing vascular obstruction following pulmonary emboli. We report a complex case of a patient with phaeochromocytoma and CTEPH and discuss unique management challenges. A 56-year-old lady was referred to Endocrinology in July 2017 following an incidental finding of a 2.9 cm right adrenal nodule on CT pulmonary angiogram. She was diagnosed with a pulmonary embolism in 2016, and also had a diagnosis of dilated cardiomyopathy, attributed to excess alcohol intake. She had no symptoms suggestive of catecholamine excess (palpitations, chest pain, episodic pallor), and was taking Ramipril, Bisoprolol, Ivabradine and Rivaroxaban. Examination revealed multiple cutaneous neurofibromas, blood pressure was 115/70 mmHg. Biochemical investigations showed elevated plasma metadrenalines (1431 pmol/l, range 80–510 pmol/l), normetadrenalines (3452 pmol/l, range 120–1180 pmol/l) and 3-methoxytyramine (205 pmol/l, range 0–180 pmol/l), consistent with a diagnosis of phaeochromocytoma. Testosterone, dehydroepiandrosterone sulphate and androstenedione levels were within normal range. A MIBG scan showed solitary uptake in the region of the right adrenal gland, with no extra-adrenal lesions. Bisoprolol was stopped, and phenoxybenzamine was up-titrated to 20 mg twice daily. She was referred for adrenalectomy but declined surgery despite extensive counselling about the risks of untreated phaeochromocytoma. In May 2020, she was referred to the regional pulmonary hypertension service due to deteriorating respiratory status and syncope with hypotension. Escalation of therapy with systemic vasodilators was pursued, and potential lung transplantation was discussed. She remained significantly hypotensive despite stopping all anti-hypertensives and having ongoing catecholamine excess from untreated phaeochromocytoma. Following multidisciplinary discussions between endocrinologists, respiratory physicians, endocrine surgeons and anaesthetists, the difficult decision was reached that due to poor physiological reserve, simultaneous lung transplantation and adrenalectomy would carry significant mortality risk and was therefore not performed. This is a fascinating case of unique dual pathology and underlying physiological paradox. Treatment of CTEPH creates vasodilatation and anti-sympathetic effects, thereby ameliorating symptoms of increased right ventricular pressure. In this patient, the presence of catecholamine excess leading to alpha-adrenergic overstimulation and subsequent vasoconstriction was probably a life-sustaining mechanism, allowing maintenance of some cardiac output following intensification of pharmacological treatments for CTEPH. This case also adds to growing evidence justifying biochemical screening for phaeochromocytoma in asymptomatic patients with neurofibromatosis, despite it not being recommended in existing guidelines.

131I-MIBG treatment in malignant pheochromocytoma: A case report

Lucia Almeida[1], Helena Alves[1] & Hugo Duarte[2]
[1]Centro Hospitalar de Vila Nova de Gaia/Espinho, Endocrinology, Vila Nova de Gaia, Portugal; [2]Instituto Português de Oncologia do Porto, Nuclear Medcine, Porto, Portugal

Introduction
A pheochromocytoma is a tumor arising from adrenomedullary chromaffin cells that commonly produces one or more catecholamines. About 80 to 85% of chromaffin-cell tumors are pheochromocytomas. It is recommended that initial biochemical testing should include measurements of plasma free metanephrines or urinary fractionated metanephrines. ^{123}I-metaiodobenzylguanidine (MIBG) scintigraphy is a functional imaging modality, in patients with increased risk of metastatic disease.[1] Radiolabelled MIBG treatment is indicated in tumours showing adequate uptake and retention of the radionuclide and these include pheochromocytomas, paragangliomas and medullary thyroid cancer.[2]
Clinical case
In 2015, a 50 year-old woman, with hypertension was sent to Endocrinology practice in the setting of palpitations, headache, flushing

and uncontrolled blood pressure values for 3 months, over an incidental discover (from an abdominal computed tomography – TC) of an adrenal nodule (33 × 36 × 40 mm) with extensive central necrosis suggestive of pheochromocytoma. Laboratory workup revealed normal plasma fractionated metanephrines and 24-hour urine fractionated metanephrines and catecholamines . ^{123}I-MIBG scintigraphy showed high uptake in the right adrenal gland, confirming pheochromocytoma diagnosis. The patient started α-blockade with phenoxybenzamine 10 mg bid and was submitted to right adrenalectomy. Histology was compatible with pheochromocytoma (Pass score: 3). In 2019, routine surveillance laboratory workup showed increased urinary metanephrine and normetanephrine levels: 545 mg/24H (< 320) and 408 mg/24H (< 390), respectively. Scintigraphy revealed new foci of ^{123}I-MIBG uptake on the sternum body and on the diaphysis of the left femur, highly suggestive of metastatic disease. ^{68}Ga-DOTANOC-PET/CT showed metastatic lesions with high expression of somatostatin receptors in the axial skeleton: L4 and 9th left rib, along with the lesions found with ^{131}I-MIBG scan. The patient was proposed to ^{131}I I-MIBG treatment (6400 MBq). Post-treatment ^{131}I-MIBG scintigraphy still reveals uptake on the 9th left rib and left femur diaphysis but the other lesions showed no uptake. The patient is now asymptomatic and under tight clinical and imagiological surveillance.

Conclusion

This case reveals the importance close, active surveillance of these patients. 131I-MIBG can be very effective as a treatment of malignant pheochromocytoma, with great safety profile and no significant side effects.

Parathyroid carcinoma: A case report

Jose Antonio Ariza Jimenez, Eyvee Arturo Cuellar Lloclla & Jose Alvaro Romero Porcel

Hospital Universitario Virgen de Valme, Endocrinology and Nutrition, Sevilla, Spain

Introduction

Parathyroid carcinoma is a rare endocrine carcinoma, which represents less than 1% of all cases of primary hyperparathyroidism. It usually affects people between 44–55 years old without differences between sexes. Sometimes it is related to HRPT2 gene mutations and it has a variable prognosis.

Presentation of case

A 56-year-old man was referred to our centre to complete an hypercalcemia study. He had an unremarkable past medical history and he did not take any regular medications. He presented a few months history of asthenia and weight loss. Serum investigations: Calcium 12.8 mg/dl (Albumin corrected), P: 2.14 mg/dl, PTH 578 pg/ml, 25-OH vitamin D: 33 nmol/l, Glomerular filtration rate: 53.45 ml/min. On examination he had a firm, well defined right thyroid nodule. Neck ultrasound revealed a 46.2 mm (TI-RADS 5) nodule in right thyroid lobe and a 18.6 mm (TI-RADS 4) nodule on left thyroid lobe. On the first nodule the fine needle aspiration citology (FNAC) showed a probably parathyroid carcinoma meanwhile on the second nodule FNAC showed an atypia of undetermined significance (Bethesda III). 99 mTc thyroid scintigraphy demonstrated an hypermetabolic mass on right lower parathyroid gland. CT scan showed an heterogeneous hypodense mass with lobulated margins, and inner calcifications, which displaced the trachea and contacted the lower pole of the right thyroid lobe and esophagus. Until surgery treatment with cinacalcet at progressive doses was started achieving lower calcium values (10.9 mg/dl). Intraoperatory biopsy informed about nodule with marked nuclear atypia cell proliferation and solid growth pattern; undergoing total thyroidectomy and lower right radical parathyroidectomy. Pathologist confirmed parathyroid carcinoma with marked nuclear atypia, inflammatory component and signs of focal vascular invasion. The other nodule was described as hyperplasic. After surgery PTH was 49.5 pg/ml and calcium levels were 9.4 mg/dl 24 hours later. In the follow up the patient presented hypocalcemia and needed high calcium doses and vitamin D supplies. This prolonged requirement despite of calcium supplies in addition to a bone densitometry which informed of osteoporosis leaded us to a postsurgical hungry bone syndrome. At present the patient keeps stable and pending of genetic study result.

Conclusion

– Parathyroid carcinoma should be considerated in the differential diagnosis of hypercalcemia. – An early diagnosis and surgical resection is essential to reduce morbidity and mortality. – Genetic study can help to detect this pathology in relatives.

Prostate cancer (PCa) is the second most diagnosed cancer type and the sixth cause of cancer death among men worldwide. Due to the usual slow course of the progression of this disease, there is a growing interest in finding chemopreventive therapeutics with a low risk of side effects. In line with this, recent studies have shown that hydroxytyrosol (HT), one of the main extra virgin olive oil phenolic compounds, exerts a protective role against different cancer types. Moreover, semisynthetic derivatives of HT could improve its bioavailability and pharmacological activities. Thus, in this study we aimed to compare the *in vitro* anticancer effects of HT and five semisynthetic derivatives, including alkyl ethers, esters, and nitro-derivatives against different PCa cell lines. Antiproliferative effects of HT and two lipophilic derivatives [hydroxytyrosyl acetate (HT-Ac) and ethyl hydroxytyrosyl ether (HT-Et)] were significantly higher in cancerous PC-3 and 22Rv1 cells than in non-malignant RWPE-1 cells, whereas the nitro-derivatives were more cytotoxic in RWPE-1. In addition, HT, HT-Ac and HT-Et significantly reduced migration capacity in RWPE-1 and PC-3 as well as prostatosphere size and colony formation in 22Rv1 cells. Nevertheless, HT-Ac and HT-Et, but not HT, were able to decrease phospho-AKT/AKT levels and colony and prostatosphere formation in PC-3. In sum, our results together with previous studies showing the antioxidant capacity of HT and its lipophilic derivatives suggest that they could be considered as potential therapeutic tools in PCa.

Introduction

Pheochromocytomas are rare catecholamine-producing neuroendocrine tumours arising from chromaffin cells of the adrenal medulla or extra-adrenal sympathetic paraganglia(paragangliomas).

Aim

To characterise demographic, clinical, and biochemical/genetic features of a cohort of patients with pheochromocytoma and paraganglioma (PPGL), assessing for differences between two-time periods over a three-decade span.

Methods

A retrospective, cross-sectional study was performed on patients with histologically proven PPGL diagnosed between 1988 and 2020 at our center. Demographic,clinical, biochemical and imagiological data at presentation, genetic testing and clinical outcomes at the last follow-up were retrieved. To investigate potential differences over the past 30 years, we divided the cohort into two groups based on the year of diagnosis and a previous published

analysis. Group 1 was comprised of patients diagnosed between 1988–2010 (n = 25) and group 2 between 20102020 (n = 24).
Results
Forty-nine patients(53.1% male) were included; mean age at diagnosis was 46.0 ± 17.0 years with a median follow-up time of 5.6 (2.3–9.6) years. Pheochromocytoma was diagnosed in 85.7% (n = 42);bilateral in 3 patients; the remainder were paragangliomas. One individual presented a simultaneous bilateral pheochromocytoma and abdominal paraganglioma. Most patients presented with de novo or refractory hypertension(53.1%),typical spells(34.7%) or an incidentally found lesion on imaging(30.6%).Urinary fractionated metanephrines were measured in all patients,89.8%(n = 44) had evidence of increased catecholamine secretion(3 were paragangliomas). Noradrenergic phenotype was found on 27.3% with adrenergic co-secretion on the remainder. Conventional and functional imaging(mostly MIBG scan) was performed in most. At diagnosis, median PPGL dimension was 40 (29–64) mm and 10.2% were metastatic. Genetic testing was performed in 36.7%(n = 18) with a germline variant on a PPGL susceptibility gene found in half of them(MAX, VHL and SDHB).On group comparison, there is a trend for lower age at diagnosis with a statistically significant increased($P < 0.05$) antihypertensive treatment use with lower systolic blood pressure at diagnosis. We also found an increased use of genetic testing and lower use of MIBG as functional imaging modality in more recent years, reaching statistical significance.
Conclusion
We detail the presentation and work-up of a cohort of PPGL; over a 30-year period the proportion of patients submitted to genetic testing increased significantly(from 21% to 54%).Our work identifies currently followed patients to be referred for genetic testing.

Heterogeneity of the clinical presentation of the MEN1 LRG_509t1 c.781C > T (p.Leu261Phe) variant within a three-generation family

Aleksandra Gilis-Januszewska[1], Anna Bogusławska[1], Magdalena Godlewska[1], Kornelia Hasse-Lazar[2], Beata Jurecka-Lubieniecka[2], Barbara Jarzab[2], Anna Sowa-Staszczak[1], Anna Skalniak[1] & Alicja Hubalewska-Dydejczyk[1]
[1]Jagiellonian University Medical College, Department of Endocrinology, Kraków, Poland; [2]M. Sklodowska-Curie Memorial Institute — Cancer Centre, Gliwice Branch, Department of Nuclear Medicine and Endocrine Oncology, Gliwice, Poland

Background
Multiple neuroendocrine neoplasia type 1 is a rare, heterogeneous genetic disorder with an autosomal dominant inheritance, predisposing to benign and malignant tumors. The phenotype of MEN1 syndrome varies between patients in terms of tumor localisation, age of onset and clinical aggressiveness, even between affected members of the same family. We report a heterogenic phenotype of the MEN1 variant c.[781C > T] (LRG_509t1) previously reported only once in a family with isolated hyperparathyroidism.
Methods
A large Polish kindred with suspicion of MEN1 syndrome underwent clinical evaluation and genetic testing.
Results
A heterozygous missense variant in exon 4 of the gene was identified in the sequence of the MEN1 gene (LRG_509t1), i.e. c.781C > T, leading at protein level to the amino acid change p.Leu261Phe in three-generation family. In the screened family, 5/6 affected members already developed hyperparathyroidism. In the index patient and two other family members, aggressive course of the disease, with dissemination of pancreatic-neuroendocrine tumor (insulinoma and non-functioning neuroendocrine tumors) was observed. In the index patient, late diagnosis and slow progression of the dissemination process was observed during 24 years of follow-up.
Conclusion
The very rare variant of MEN1, LRG_509t1 c.781C > T /p.Leu261Phe (LRG_509t1) diagnosed within a three -generation family has heterogenic clinical presentation. Further follow-up of the family members should be performed to confirm the spectrum and exact time of clinical presentation of this alteration.

CGMS-monitored preoperative diazoxide therapy of a pancreatic insulinoma: A case report

Anna Vágvölgyi[1], Rea Ágnes Nagy[1], Szabolcs Nyiraty[1], Krisztian Sepp[1], József Kocsis[2], Attila Oláh[3] & Zsuzsanna Valkusz[1]
[1]University of Szeged, Faculty of Medicine, Department of Internal Medicine, Szeged, Hungary; [2]Petz Aladár University Teaching Hospital – Gyń, Department of Pathology, Gyń, Hungary; [3]Petz Aladár University Teaching Hospital – Gyń, Department of General Surgery, Gyń, Hungary

Insulinomas are predominantly benign pancreatic neuroendocrine tumors presenting with hyperinsulinemic hypoglycemia. Surgical resection is currently the standard treatment for pancreatic insulinoma, but other treatment options, such as oral medication with diazoxide may be necessary for symptomatic patients who are not candidates for surgical resolution or for those who need bridging therapy till the surgical intervention. We present the case of a 54-year-old man who was admitted to our Endocrinology Department with a 2-year history of epileptic seizures of unknown origin. The seizures occurred, when he was on a weight loss diet. Neurological workup (including a negative MRI of the head and EEG) could not define the etiology of the seizures. Laboratory studies showed hypoglycemia with hyperinsulinemia almost every 3 hours. An endosonographic investigation was planned to identify the suspected insulinoma, but this got delayed because the patient was diagnosed with SARS-CoV-2 infection. He became subfebrile, developed lethargy and cough, but did not require oxygen supplementation. Chest CT showed pneumonia and abdominal CT revealed a 17 × 17 mm lesion in the pancreatic tail, which was believed to be consistent with the radiological manifestation of an insulinoma. Surgical removal of the tumor was planned following recovery from COVID-19. In the meantime, for symptomatic treatment he was started on diazoxide therapy. To reveal asymptomatic hypoglycemia and to take advantage of the hypoglycemia alert function of the device, the tissue glucose level of the patient was real-time monitored with continuous glucose monitoring system (CGMS). CGMS was started 1.5 days before the introduction of diazoxide therapy and was continued for a total of 6 days. The patient was discharged with diazoxide to be used during recovery from COVID-19. After his recovery the surgical resection was successfully performed. The patient was discharged without diazoxide therapy and did not show hypoglycemic tendency. Hypoglycemia increases cardiovascular mortality, therefore avoidance or prompt treatment of hypoglycemic episodes is imperative in patients with insulinomas, until definitive surgical intervention can be performed. Our case highlights that CGMS can be successfully used to detect asymptomatic hypoglycemia in patients with insulinoma, and can also confirm the response to medical therapy.

Association of gastric GIST and Cushing syndrome

Laura Teodoriu[1], Gabriel Dimofte[2,3], Natalia Velenciuc[2,3], Bianca Ioan[4], Letitia Leustean[1,4], Christina Ungureanu[1,4] & Cristina Preda[1,4]
[1]University of Medicine and Pharmacy Gr. T Popa, Endocrinology, Iasi, Romania; [2]University of Medicine and Pharmacy Gr. T Popa, Surgery, Iasi, Romania; [3]Regional Institute of Oncology, Surgery, Iasi, Romania; [4]Emergency Clinical Hospital of Saint Spiridon, Endocrinology, Iasi, Romania

Gastrointestinal stromal tumors (GIST) are in high risk of developing additional malignancies, hereditary and also nonhereditary kind. Genetic changes are involved in the formation of GIST, about 80% are associated with KIT gene mutation and 10% of cases are associated with PDGFRA gene. These two mutations are found in both familial and sporadic GIST. We report a 65 years old female patient with a history of surgery for gastric GIST (T2N0). During the follow-up, after 4 years, she was diagnosed with left adrenal incidentaloma (35 mm). The endocrine exam revealed multiple thyroid nodules with large calcifications on ultrasound. Calcitonin was slightly increased with possible interference from proton pump inhibitors medication that she was using at the time. Vitamin D was low 15 ng/ml (N > 30 ng/ml) with a slightly increased PTH and normal serum calcium. Adrenal hormonal tests concluded: 8 a.m Cortisol: 25 μg/dl (N.V. 4.5–23 μg/dl), ACTH: 7 pg/ml (N.V. 7–63 pg/ml), CLU: 400 μg/24 h (N.V. 36–137 μg/24 h). The negative dexamethasone test (1 mg overnight, 2 mg for two days and 8 mg at midnight) along with the presence of adrenal tumor were suggestive for ACTH independent Cushing syndrome. The patient was referred to surgical department for curative treatment of the adrenal tumor. GIST and other endocrine neoplasias may occur in Carney triad and Neurofibromatosis type

1. This case is in accordance with other patients reported in the literature with same cancer association: GIST and Cushing syndrome, our goal being to determine sporadic occurrence or genetic affiliation between these two.

Gonadal dysfunction in male patients with neuroendocrine tumors

Bojana Popovic, Ivana Bozic Antic, Tatjana Isailovic, Tamara Bogavac, Dusan Ilic, Valentina Elezovic Kovacevic, Milica Opalic, Sanja Ognjanovic & Djuro Macut
Clinic for Endocrinology, Diabetes, and Metabolic Diseases, University Clinical Centre of Serbia, Department for Endocrine Tumors and Hereditary Cancer Syndromes, Belgrade, Serbia

Introduction
Hypogonadism is a potential manifestation of many chronic diseases including cancer, presumably related to their severity. Since novel anti-cancer treatments have significantly increased survival rates of affected patients, issue of hypogonadism becomes more significant, given the importance of issues like quality of life and potential for reproduction. The aim of our study was to analyze gonadal axis function in male patients with neuroendocrine tumors.
Subjects and methods
We retrospectively analyzed 43 male patients aged 57.7 ± 13.5 years (15–76) with diagnosed neuroendocrine tumor and available hormonal data, prior to initiation of specific anti-cancer treatment. None of the patients had concomitant pituitary adenoma. All patients underwent standard oncological evaluation, with tumor staging and grading. Blood samples were taken for determination of testosterone, FSH (follicule-stimulating hormone) and LH (luteinizing hormone), as well as routine biochemical analyses. Basic antropometric parameters were measured. Statistical analysis was performed by SPSS software.
Results
Minority of patients in our group were younger than 50 years of age (8, 18.6%). All, but 2 had metastatic disease, with unknown primary in 39.5% (17), pancreatic in 30.2% (13), lung in 20.9% (9), small intestinal in 7.0% (3), and pharyngeal tumor in 2.3% (1) of cases. Three patients had grade 1 tumor (7.0%), 14 grade 2 (32.6%), and 26 grade 3 (60.5%). Low testosterone level was diagnosed in 4 patients (9.3%). After exclusion of one patient with ectopic Cushing's syndrome, malignant disease could be atributed as a cause in remaining cases (6.97%), hypogonadotropic in 2 cases, and hypergonadotropic in 1. Overall 6 patients had elevated LH levels (5.9 ± 3.4, 1–15), suggesting a certain degree of subclinical primary hypogonadism in 14.0% of our patients. There was no correlation between testosterone levels and any of biochemical and antropometric parameters ($P > 0.05$). There was no significant difference in testosterone levels between patients with different tumor grades ($P = 0.579$). Elevated FSH level was observed in 32.6% (14) patients, suggesting spermatogenesis failure. Only one patient younger than 50 had elevated FSH (15.9 ± 19.5, 0.5–102.0), and none had elevated LH, while there was no significant difference in tumor grades between two age groups ($P = 0.711$). Afore mentioned differences in FSH, LH and testosterone did not affect survival in our group of patients ($P > 0.05$ for all).
Conclusion
Based on preliminary data, presence of neuroendocrine tumor doesn't seem to have a significant impact on gonadal function, at least in younger patients. Risk for spermatogenesis failure should be explored further).

Neuroendocrine neoplasms of the larynx: About 4 cases

Ghammmam Monia, Lobna Chouchane, Mouna Bellakhdhar, Rihab Lahmar, Kermani Wassim & Abdelkefi Mohamed
Farhat Hached Hospital, ENT, Sousse, Tunisia

Objectives
studying the clinical and evolutionary characteristics of neuroendocrine laryngeal tumors and their management modalities.
Materials and methods
A retrospective study with 4 cases of neuroendocrine tumors (NET) of the larynx ENT service of the Farhat Hached hospital of Sousse.
Results
Our series consisted of 3 men and a woman. The average age was 49 years [35–63 years]. Alcohol and tobacco poisoning was reported in 3 cases. The two main signs were chronic dysphonia associated with dyspnea. The average time of evolution was 8 months. The cervical examination had objectified metastatic lymphadenopathy in 1 patient. The indirect laryngoscopy objectified a tumor lesion of the epiglottic left fold in one case, a tumor lesion taking the 3 stages of the larynx with a fixed hemilarynx in 3 cases. There was no distant metastasis in all cases. Anatomopathological study of biopsies with immunohistochemical analysis supported a well-differentiated carcinoid tumor in 1 case, small cell NET in 2 cases, and low-differentiated high-grade NET in 1 case. Therapeutic management consisted of radiation chemotherapy in 2 cases, in total laryngectomy with curage functional lymph node in 2 cases. The evolution was marked by tumor recurrence in one case indicating surgery correction. Cerebral and spinal metastases were observed during follow-up in 2 patients.
Conclusion
Neuroendocrine tumors are exceptional tumors of the larynx. The diagnosis is on anatomopathological and immunohistochemical examination. Management treatment depends on the histological subtype. Surgery is the treatment of choice for typical carcinoid tumors, atypical carcinoid tumors and paragangliomas. The treatment of small cell NET is based on radiation chemotherapy.

Cadmium levels in human breast tissue and estradiol serum levels: Dose-response data analyses

Aleksandra Buha[1], Milena Andjelkovic[2], Dragana Javorac[1], Katarina Baralić[1], Elena Kacavenda[1], Evica Antonijevic[1], Stefan Mandic Rajcevic[3], Miroslav Granic[3,4], Danijela Djukic-Cosic[1] & Zorica Bulat[1]
[1]University of Belgrade – Faculty of Pharmacy, Department of Toxicology, Belgrade, Serbia; [2]Health Center Kosovska Mitrovica, Kosovska Mitrovica, Serbia; [3]Faculty of Medicine University of Belgrade, Belgrade, Serbia; [4]University Hospital Medical Center Bezanijska kosa, Belgrade, Serbia

Cadmium (Cd) is a ubiquitously present toxic metal with an established ability to induce endocrine disruption, in literature often referred to as metalloestrogen. Some of the major uncertainties connected with endocrine disrupting chemicals (EDCs) in general, are low-dose exposure and the presence of nonmonotonic dose-response curves. This study aims to elucidate the presence of a dose-response relationship between the measured Cd levels in the tissue (internal dose) and estrogen levels in serum (hormonal response). The study was conducted at the Clinic for Oncology of the Clinical Hospital Center 'Bežanijska kosa', Belgrade, Serbia in the period between January and September 2019 and included 55 patients diagnosed with breast cancer and 41 women with benign breast changes. All participants were further classified based on their menopausal status. Prior to surgery, venous blood samples were obtained from the anterior cubital vein after a 12 h fasting period and estradiol levels were determined in serum. After surgical tissue removal, Cd levels were determined in the tumor and the surrounding healthy breast tissue. Tissue samples were mineralized using wet digestion and Cd levels were determined using atomic absorption spectrometry. Dose-response modeling was performed using PROAST software version 67.0 (the Dutch National Institute for Public Health and the Environment, RIVM). Data on estradiol and Cd levels were analyzed as continuous individual data using menopausal status the presence of malignant/benign change as variable factors. Benchmark response was set to 10% and the averaging method was used to calculate the Benchmark dose (BMD) interval. Akaike information criterion was used to evaluate the model. The mathematical relationships between the concentration of Cd in the surrounding healthy/tumor tissue and the levels of estradiol in the serum of the subjects has been shown and BMD values were calculated. Rather low calculated BMD values indicate that even levels lower than 1 ng Cd/g breast tissue can lead to a 10% change in measured estrogen serum levels. These results implicate the presence of the dose-response behavior of EDCs and propose this method for investigating the possible presence of nonmonotonic dose-response curves, as well. Moreover, the obtained results testify that the BMD concept can be used as an approach to analyze human data. Further research on this topic is necessary so that the extrapolation of data from animals to humans can be, at least partly, replaced by the process applied in this study, thus facilitating risk assessment, especially for EDCs.

Development of *in vitro* rat, dog and human deiodinase inhibition assays with LC-MS/MS analysis for the identification of endocrine disruptors

Dongtao Lee[1], Kenneth Macleod[2], Larry Higgins[3], Rachel McBrinn[4], Robin Dickinson[1] & Claudia McGinnis[1]
[1]Concept Life Sciences, Endocrine Toxicology, Dundee, United Kingdom; [2]University of Dundee, School of Life Sciences, Dundee, United Kingdom; [3]H-Toxicology Consulting, Cupar, United Kingdom; [4]University of Dundee School of Medicine, Systems Medicine, Dundee, United Kingdom

Thyroid hormones are important regulators of metabolism and development. Iodothyronine selenodeiodinases can both activate and inactivate thyroid hormones (Bianco *et al*. 2002) thus *in vitro* assays to quantify deiodinase inhibition are considered to be a valuable tool for studying effects on thyroid hormone metabolism by potential endocrine disruptors. The prohormone thyroxine (T4) is converted to 3,5,3'-triiodothyronine (T3) by outer-ring deiodination, or to 3,3',5'-triiodothyronine (reverse T3/rT3) by inner ring deiodination. These compounds can then be further de-iodinated to diiodothyronine (T2). This work describes the development of screening *in vitro* methodology for the analysis of thyroid hormone metabolism by LC-MS/MS. Recombinant deiodinase enzymes D1, D2 and D3 for rat, dog and human were ectopically expressed in HEK293 cells and used to set up species-specific and isoform -specific incubation conditions to determine optimal protein and incubation kinetics for each enzyme. The conversion of T4 or rT3 by each respective recombinant deiodinase was assessed, and reactions were monitored by LC-MS/MS assay for formation of T2 or T3 for D1, T3 for D2 and rT3 for D3. Using known inhibitors of deiodinases, 6-propyl-2-thiouracil (PTU) for D1 and aurothioglucose (ATG) for D2 and D3, we demonstrate that the rat, dog and human deiodinase assays generate robust and reproducible data. These deiodinase assays are now routinely performed to assess the potential endocrine disrupting properties of small molecules.

Thoracic trauma associated gynecomastia

Nádia Mourinho Bala, Nuno Raposo, Sílvia Guerra & Cristina Valadas
Hospital Beatriz Ângelo, Endocrinology, Portugal

Introduction
Gynecomastia is characterized by the abnormal enlargement of one or both male breasts due to proliferation of the glandular tissue, with many possible underlying causes. A documented rare cause of gynecomastia is chest trauma.
Case report
We present a case of a 53-year-old male patient, with a personal history of arterial hypertension and depressive disorder, medicated with fluoxetine, perindopril, amlodipine and indapamide. The patient had a documented history of a three-story fall six months before, with associated chest trauma and rib fracture, which required admission in an intensive care unit. The patient was referred to an endocrinology consult following a slightly painful, progressive increase in volume of the right breast, with no associated nodules or masses, which started after the fall. The blood analysis were in the normal range, including alpha-fetoprotein < 1.3 ng/ml, FSH 7.1 mUI/l (RV 1.4–18.1), LH 6.3 mUI/l (RV 1.5–9.3), prolactin 7.7 ng/ml (RV 2.1–17.7), beta-HCG < 0.1UI/l, total testosterone 270 ng/dl (RV 193–740). The patient underwent a breast ultrasound scan that confirmed bilateral, asymmetrical gynecomastia, with a right breast gland of 22 mm and left gland with 12 mm. Due to the presence of a hypoechogenic retroareolar area on the right gland the patient underwent an ultrasound-guided micro biopsy. The histological result was benign. After one year of follow-up the patient still presents with gynecomastia, although in slight regression.
Discussion
We report a case of gynecomastia where the only identified trigger was the acute chest trauma. The underlying pathophysiological mechanisms remain unclear, but some authors propose that the local release of growth factors plays a role, leading to the differentiation and proliferation of precursor cells, resulting in mature glandular enlargement.

Arrhythmias and cardiac conduction disorders in patients with acromegaly

Elena Przhiyalkovskaya, Konstantin Melkozerov, Alina Almaskhanova, Natalya Tarbaeva, Maria Kuklina, Polina Alferova, Irina Gomova, Leonid Belousov, Zhanna Belaya, Alexander Vorontsov & Victor Kalashnikov
Endocrinology Research Centre, Ministry of Health of Russia, Moscow, Russian Federation

Cardiovascular complications including arrhythmias and cardiac conduction disorders (ACCDs) are leading risk factors for high mortality rate in acromegaly. ACCDs are the main cause of sudden cardiac death in patients with acromegaly. These disorders are detected in up to 40% of patients. Different pathogenetic mechanisms contribute to the development of concentric biventricular myocardium hypertrophy which leads to electrophysiological myocardium feature changes. The goal of the study is to evaluate the prevalence of heart complications in patients with acromegaly.
Materials and methods
A single-center cross-sectional study, which included 461 patients (151 men and 310 women) with acromegaly, was conducted. All patients underwent a standard medical examination including hormonal blood tests, electrocardiogram, echocardiography and electrocardiogram daily monitoring. Eighteen patients with arrhythmias (11 men and 7 women) had cardiac magnetic resonance imaging (MRI) with gadolinium-based contrast.
Results
The prevalence of ACCDs in patients with acromegaly was 42%. The most common types of ACCDs were sinus bradycardia – 19.1% of cases and conduction disorders of bundle branch blocks – 14.5%. Men were more likely to suffer from arrhythmias and cardiac conduction disorders than women (54.2% and 37.4%, respectively, $P = 0.0005$). Patients with ACCDs had a longer medical history of acromegaly (average duration 10 vs 7 years, respectively, $P = 0.04$). Cardiac conduction disorders were commonly observed in patients who were treated with somatostatin analogs comparing to patients who didn't undergo this therapy (50% and 38.6% respectively, $P = 0.004$). Pacemakers were implanted in 3 patients, and an implantable cardioverter defibrillator was used in one patient due to susteined ventricular tachycardia. Sixty one percent of patients with acromegaly and ACCDs who underwent MRI had signs of myocardial fibrosis.
Conclusion
ACCDs are common in patients with acromegaly, predominantly males, increasing in prevalence with a longer history of the disease or somatostatin analog therapy. Myocardial fibrosis is supposed as one of the most likely cause of ACCDs in patients with acromegaly.

A new cause of endogenous hyperinsulinism?

Manuel J Caballero, José Ignacio Fernández Peña & Eyvee Arturo Cuellar Lloclla
Hospital Universitario Virgen de Valme, Endocrinology and Nutrition Unit, Sevilla, Spain

We present the case of a patient who started having repeated episodes of symptomatic hypoglycemia at the age of 50.
Medical history
Father had type 2 diabetes. Former smoker, moderate alcohol consumption. Chronic otitis media with cholesteatoma, surgically removed. Congenital cataract operated at the age of 3.
Clinical course
At around the age of 50, the patient started having sporadic episodes of sympathoadrenal and neuroglycopenic symptoms, with plasma glucose levels of 60 mg/dl, that ceased after the intake of sugars. The episodes occurred more frequently in the early morning fasting state, but also before meals during daytime. His general practitioner detected a fasting glucose level of 42 mg/dl and HbA1c of 3.3%, refering the patient to Endocrinology. During the following years, a fasting evaluation evidenced hypoglycemia with inappropriately elevated levels of insulin and C-peptide (insuline/glucose ratio 0.61). A CT and an abdominal arteriography didn't show pancreatic lesions. The patient was diagnosed with endogenous hyperinsulinism without detection of insulinoma. At age 56, the episodes of hypoglycemia became more frequent and treatment with diazoxide was initiated, with dose titration up to 250 mg/day and partial response with a decrease in the number of episodes. Further testing was performed: glicazide was detected in HPLC of a sample obtained during hypoglycemia, but this could not be confirmed in three subsequent analyses;

proinsulin levels were elevated; no insulin antibodies were present. Localizing studies were repeated: CT, echo-endoscopy and abdominal arteriography were carried out without findings; and MRI revealed slight contrast enhancement in the head of the pancreas. That same year, another MRI did not confirm such abnormality. During the follow-up, the dose of diazoxide was progressively reduced to 100 mg/day, and remained well-tolerated. Between the ages of 63 and 68, there was a gradual increase in the frequency of episodes of hypoglycemia and a decrease in the associated symptoms. At age 68, the case was reevaluated with a new sulfonylureas analysis that was performed during hospitalization with a negative result, a new localizing study (CT, MRI and echo-endoscopy) without findings and a MODY panel genetic test, which revealed a mutation in GLIS3 gene. This gene can function both as an activator and a repressor of transcription in pancreatic beta cells, which could explain the endogenous hyperinsulinism in our patient.

Characterization of neuroinflammatory makers and related-genetic variants in athletes from a long duration ultramarathon mountain cycling race and endurance exercises

Andreia Matos[1,2,3,4,5], Miguel Matinho[1,6], Miguel Fontes[1,6], Ana Carolina Santos[1,2], Ângela Gil[1,2], Carlos Cardoso[7], Manuel Bicho[1,2] & Isanete Alonso[1,8,9]
[1]Faculty of Medicine, University of Lisbon, Lisbon, Portugal, Laboratory of Genetics and Environmental Health Institute, Portugal; [2]Instituto de Investigação Cientifica Bento da Rocha Cabral, Lisbon, Portugal; [3]i3S, Institute for Research and Innovation in Health, University of Porto, Porto, Portugal; [4]INEB, Institute of Biomedical Engineering, University of Porto, Porto, Porto, Portugal; [5]ICBAS-Institute of Biomedical Sciences Abel Salazar, University of Porto, Porto, Portugal; [6]Faculdade de Ciências da Universidade de Lisboa, Departamento de Biologia Animal, Lisbon, Portugal; [7]Clinical Chemistry Laboratory, Joaquim Chaves Group, Miraflores; [8]Saint Louis Hospital, Lisbon, Portugal; [9]Escola Superior de Saúde do Instituto Politécnico de Leiria

Introduction
Exercise induces changes in the inflammatory profile that can comprehend changes during and immediately after exercise with long-term effects. This inflammatory profile could impact the cognitive function and so, the performance.
Objectives
Compare the inflammatory status from long duration and endurance exercises and correlate it with an immune and neuroendocrine genetic profile.
Material and methods
Fifty-five non-professional athletes (mean age 44.8 ± 7.1 years) participating in a 9-day mountain cycling ultramarathon (TransPortugal) and 27 endurance athletes participating in 1-year of competition: 17 amateurs (mean age 43 ± 7.0 years) and 10 Professional (mean age 20 ± 1.6 years) were evaluated. Before and after race/season, were determined metabolic parameters by standard methods; IL6, TNF-alpha, BDNF and cortisol determined by ELISAs. Functional genetic polymorphisms IL-6 (rs 10 08 795), IL-1ß (rs 16 944), TNF-alpha (rs 18 00 629), IDO1 (rs 96 57 182) and 5HTTVNTR (VNTR-17bp) were determined by endpoint-analysis and PCR/RFLP.
Results and conclusions
Before the competitions, TransPortugal athletes had lower levels of inflammation (PCR and TNFα) than endurance athletes. TransPortugal athletes presented higher levels of insulin ($P < 0.001$) and HOMA-IR ($P < 0.001$), contrarily to endurance athletes that presented higher levels of glucose ($P < 0.0001$) and HOMA-ß ($P = 0.006$). The impact of a 9-days long duration exercise were reflected on inflammatory profile with an extensive increase of IL-6 and PCR ($P < 0.0001$) and uric acid ($P = 0.027$). The TNF-α levels continued to be higher in endurance athletes in relation to TransPortugal athletes ($P < 0.0001$). The IDO1-TT ($P = 0.002$), 5HTTVNTR-12/12 and IL-1ß-GG ($P = 0.038$) genotypes were more associated to TransPortugal athletes in relation to endurance athletes. This profile could contribute to a better performance. TransPortugal athletes with IDO1-TT genotype presented higher levels of TNF-alpha post-race ($P = 0.046$) and haptoglobin pre-race ($P = 0.029$); IL-1ß-GG genotype higher levels of IL-6 post-race ($P = 0.048$); and the 5HTTVNTR-12/12 genotype higher levels of haptoglobin post-race ($P = 0.039$) and lower levels of glucose ($P = 0.055$) and PCR post-race ($P = 0.059$). For endurance athletes, we only found merely modulation of IDO1 and IL-1ß associated to glucose and HOMA-ß pre-race ($P < 0.05$) and 5HTTVNTR-12/12 genotype presented higher levels of TNF-alpha pre-race ($P = 0.033$). In conclusion, accordingly to the inflammatory status, seems that TransPortugal athletes are more prepared for competition that endurance athletes and with a genetic profile that could explain some interindividual variations leading to modulation of inflammatory process and neuromodulation.

Successful treatment of nesidioblastosis during the time of pandemic: A case report

Sándor Halmi[1], Eszter Berta[1], Inez Lengyel[1], Judit Toth[2], Zsolt Kanyari[3], David Hutkai[4], V Endre Nagy[1] & Miklos Bodor[1]
[1]Faculty of Medicine, University of Debrecen, Division of Endocrinology, Department of Internal Medicine, Debrecen, Hungary; [2]Faculty of Medicine, University of Debrecen, Department of Oncology, Debrecen, Hungary; [3]Faculty of Medicine, University of Debrecen, Department of Surgery, Debrecen, Hungary; [1]Faculty of Medicine, University of Debrecen, Department of Internal Medicine, Debrecen, Hungary

Introduction
In the background of persistent hyperinsulinemic hypoglycemia the insulinomas of the pancreatic beta cells may be present, but in some rare cases we fail to identify a well-defined lesion and the insulin hypersecretion is caused by nesidioblastosis, a diffuse proliferation of the pancreatic islet cells. However, the localization of the lesion is necessary for proper treatment, in certain cases finding the insulinoma is difficult and can only be helped by special examination techniques, like selective intraarterial calcium stimulation.
Case report
We report the case of a 36-year-old man who has acoustic neurinoma in his previous history. His present symptoms started one and a half year ago. In the background of collapses, dizziness, agitation, somnolence, hypoglycemia was found caused by hyperinsulinemia. The Whipple triad during the fasting test confirmed the diagnosis of the hormone producing lesion. The careful non-invasive examinations (abdominal ultrasound, CT and MRI) could not identify the insulinoma. In November 2020 he was admitted to our hospital with severe symptoms of hypoglycemia. Despite the iv. glucose substitution, calcium antagonist and octreotide therapy the hypoglycemia persisted, so calcium stimulation was performed, which showed significant elevation of C-peptide and insulin levels of the middle third of the pancreas, but also an elevation could be found in the tail region. Partial pancreatectomy was scheduled, which needed to be postponed because the patient acquired SARS-Covid 19 infection. Later the partial pancreatectomy was performed, and the histology showed nesidioblastosis. The patient was released from the hospital on calcium-antagonist and diazoxide therapy with good clinical response.
Conclusion
The differential diagnosis of insulinoma and diffuse nesidioblastosis from the clinical and biochemical perspective is challenging when no imaging technique could localize the lesion, but in the perioperative diagnosis the highly sensitive and specific selective intraarterial calcium stimulation can be helpful. The final diagnosis is based on histopathological findings, which determines the further therapeutic steps. In our case, despite the delays and inconveniences caused by the SARS-Covid 19 pandemic, we could achieve a good clinical response with partial pancreatectomy and chemical suppression.

Post-menopausal virilizing tumor of the ovary

Nádia Mourinho Bala[1], Nuno Raposo[1], José Maria Aragüés[1], Sílvia Guerra[1], Delfina Brito[2] & Cristina Valadas[1]
[1]Hospital Beatriz Ângelo, Endocrinology, Portugal; [2]Hospital Beatriz Ângelo, Pathology, Portugal

Introduction
Leydig cell tumors are rare entities, representing less 0.1% of all ovarian tumors. Generally these tumors are benign and unilateral. Most originate from the hilus cells and, less frequently, from the ovarian cortical stroma. Leydig cell tumors are functioning tumors, frequently associated with virilization symptoms in post-menopausal women.
Case report
We report the case of a 77 year-old female patient, caucasian, with personal history of autoimmune hepatitis, type 2 diabetes, dyslipidemia and Hashimoto thyroiditis. The patient had a history of 4 pregnancies,

with no complications, and menopause at 42 years old with no hormone replacement therapy. The patient presented with a 4 years history of virilization symptoms, namely hirsutism (Ferriman Gallwey Score 11). The blood analysis showed a total testosterone 290 ng/dl (RV < 41), free testosterone 5.60 ng/ml (RV 0.10–4.70), delta-4 androstenedione 2.9 ng/ml (RV 0.4–3.7), 17-hydroxyprogesterone 1.80 ng/ml, dehydroepiandrosterone sulfate 72 mg/dl (VR 26–460). A transvaginal ultrasound was ordered, which showed enlarged ovaries when adjusted to age, but with normal echostructure and no other findings. A pelvic magnetic resonance imaging exam was performed, revealing only a 16 mm uterine nodule, in favor of a submucous leiomyoma. After excluding adrenal causes of virilization, it was decided to underwent laparoscopic bilateral oophorectomy and hysterectomy. The histopathology revealed a 8 mm ovary tumor, with foci of luteinized cells, and reinke crystals, positive for inhibin and calretinin and negative for estrogen and progesterone receptors, findings that supported the diagnosis of nonhilar Leydig cell tumor. Following the surgery, the testosterone and free testosterone levels returned to normal. It is important to point out that a patient's sister presented with the same symptoms and blood analysis findings around the same age as our patient, but she refused further medical investigation.

Discussion

Accurate diagnosis of virilizing tumors of the ovary is often challenging, due to the fact these tumors might be too small to be detected in imaging exams. In this case, after excluding adrenal production of androgens, the main diagnostic hypothesis was a virilizing tumor of the ovary. For this reason the favored approach was surgery. The histopathological result confirmed the hypothesis and the patient symptoms and abnormal laboratory findings resolved. Since the patient's sister had the same symptoms in the same age group, we suspect the existence of a possible familial genetic syndrome. However no genetic investigation was completed for cost-effectiveness reasons.

Psychological Impact of COVID-19 national lockdown meAsures on tRansgenDer people in Italy: The PICARD study

Rosario Ferrigno[1], Mariagrazia Fattoruso[1], Alessandra Delli Veneri[1,2], Alessia Cuccurullo[2], Daniela Lourdes Falanga[2], Anna Lisa Amodeo[2,3], Cristina De Angelis[1], Francesco Garifalos[1], Davide Menafra[1], Stefano Zarrilli[1], Felice Iasevoli[4], Roberto Vitelli[5], Annamaria Colao[1] & Rosario Pivonello[1]

[1]Università 'Federico II' di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Napoli, Italy; [2]ASL Napoli 3 Sud, Consultorio InConTra, Portici (NA), Italy; [3]Università 'Federico II' di Napoli, Dipartimento di Studi Umanistici, Sezione di Psicologia Clinica, Napoli, Italy; [4]Università 'Federico II' di Napoli, Dipartimento di Neuroscienze, Scienze Riproduttive ed Odontostomatologiche, Sezione di Psichiatria, Napoli, Italy; [5]Università 'Federico II' di Napoli, Dipartimento di Neuroscienze, Scienze Riproduttive ed Odontostomatologiche, Sezione di Psicologia Clinica, Napoli, Italy

During 2020 spring, national lockdown was adopted in Italy to prevent COVID-19 pandemic spread. Restrictive measures, including lockdowns, were associated with impaired psychological outcome, mainly increased perceived stress and anxiety, in general population. As transgender people (T*) are associated with higher prevalence of perceived stress, anxiety, and depression, higher psychological vulnerability during lockdowns cannot be excluded. The aim of the PICARD study was the evaluation of psychological impairment in T* during the COVID-19-related Italian national lockdown, as compared with healthy subjects. The study enrolled 112 T* (41 T* women, 71 T* men; age: 18–55 yrs) and 224 age- and gender-matched cisgender controls. General Anxiety Disorder-7 (GAD7), Perceived Stress Scale (PSS), and Patient Health Questionnaire 9 (PHQ9) questionnaires (higher scores indicated higher psychological impairment) were telematically and anonymously administered to study participants during the last three weeks of national lockdown to screen their general anxiety, perceived stress, and depression status levels. Demographic, social, and clinical information were also collected. Compared with cisgender controls, T* experienced significantly higher scores in GAD7, PSS, and PHQ9 questionnaires ($P < 0.001$). In particular, T* men experienced significantly higher scores in all questionnaires ($P < 0.001$), whereas no significant differences were observed between T* and cisgender women. In the T* population, higher GAD7, PSS, and PHQ9 scores were contemporary observed in T* < 25 vs > 35 yrs ($P < 0.001$), T* without name change vs ongoing ($P < 0.01$), T* with no gender-affirming surgeries versus reconstructive surgeries ($P < 0.02$), and T* suffering from lockdown-related domestic violence vs who did not ($P < 0.04$). Higher GAD7 and PSS scores were contemporary observed in unemployed vs employed T*($P \leq 0.05$), whereas higher PSS and PHQ9 scores were contemporary observed in T* living with their parents vs alone ($P < 0.02$) and with partner ($P < 0.03$). Isolated higher PSS scores were observed in T* not performing vs performing hormonal treatments ($P < 0.001$). In conclusion, compared with cisgender controls, T* suffered increased psychological morbidity, namely general anxiety, stress perception, and depressive status, during Italian national lockdown. In particular, younger T*, unemployed T*, T* still living with their parents, and T* in the earliest stage of their transitional process (i.e. without birth name change, hormonal treatments, or gender-affirming surgeries) were more psychologically vulnerable. Therefore, empowerment of psychological counseling for T* during COVID-19 pandemic should be considered by health care services.
