Introduction

Adipose tissue is already considered as a metabolic active endocrine organ secreting numerous substances called adipokines. A growing body of evidence links two of these adipokines- chemerin and resistin, to the pathogenesis of rheumatoid arthritis (RA) based on their effect on vascular function and creating an environment of low grade inflammation. Nevertheless, the exact mechanism of how these molecules act on the target cells of joint elements are not fully understood.

Objective

The aim of this pilot study is to examine the association of the serum concentrations of chemerin and resistin with clinical markers of inflammation and disease activity in patients with rheumatoid arthritis. The aim of this pilot study is to examine the possible interaction between serum concentrations of the two secreted adipokines- chemerin and resistin and some well known markers of inflammation and disease activity in patients with rheumatoid arthritis.

Methods

Serum was collected from 20 patients (17 women, 3 men) and another 31 cases with no joint diseases were included as controls (21 women, 10 men). The levels of chemerin and resistin were measured by enzyme-linked immunosorbent assay (ELISA). Antropometric parameters were evaluated with standart procedures in a fasting status (0800 h) in the entire cohort. Rheumatoid factor (RF), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), serum level of uric acid (UA) were evaluated in the subgroup of 20 patients. Disease activity score was determined using the Disease Activity Score-28 for Rheumatoid Arthritis with ESR (DAS28-ESR).

Result

The serum concentration of resistin was significantly higher in RA patients (13.28 ± 6.18 ng/ml) than in the healthy controls (7.04 ± 2.09 ng/ml, $P < 0.001$). In contrast, there was no significant difference in chemerin levels between the patient and the control groups [247.0 (226.5–314.6) ng/ml vs. 228.8 (203.1–276.0) ng/ml, $P > 0.05$, respectively]. However, the serum chemerin concentration correlated positively with ESR ($r = 0.649$, $P = 0.002$), CRP ($r = 0.546$, $P = 0.013$), RF ($r = 0.465$, $P = 0.039$), and DAS28-ESR ($r = 0.807$, $P < 0.001$). In comparison, the serum level of resistin correlated positively only with CRP ($r = 0.537$, p 0.015), and DAS28-ESR index ($r = 0.470$, $P = 0.037$).

Conclusion

Taken together, these findings suggest that both chemerin and resistin might contribute to the inflammatory changes associated with RA, performing

pro-inflammatory activity. The two adipokines might also serve as novel biomarkers for reflecting disease activity.

Importance
There remains uncertainty about the impact of menopausal hormone therapy (MHT) on women's health. A systematic, comprehensive assessment of the effects on multiple outcomes is lacking.
Objective
To comprehensively summarize evidence on the benefits and harms of MHT across diverse health outcomes in women.
Data sources
MEDLINE, EMBASE and 10 other databases from inception to November 26, 2017, updated December 17, 2020.
Study selection
Systematic reviews or meta-analyses of randomized controlled trials (RCTs) and observational studies investigating effects of MHT, including estrogen-alone therapy (ET) and estrogen plus progestin therapy (EPT), on any health outcome or indicator in perimenopausal or postmenopausal women in all countries and settings.
Data extraction and synthesis
Two investigators independently extracted data and assessed study quality. Random-effects robust variance estimation was used to combine effect estimates.
Main outcomes and measures
All health outcomes included in previous systematic reviews, including menopausal symptoms, surrogate endpoints, biomarkers, various morbidity outcomes, and mortality.
Results
Sixty systematic reviews were included, involving 102 meta-analyses of RCTs and 38 of observational studies, with 121 unique outcomes. The overall quality of included systematic reviews was moderate to poor. In meta-analyses of RCTs, MHT was beneficial for vasomotor symptoms (risk ratio [RR] 0.29, 95% confidence interval [CI] 0.17–0.50) and vaginal atrophy (intravaginal ET: RR 0.31, 95% CI 0.12–0.81), as well as sexual function, all fracture, vertebral and non-vertebral fracture, diabetes mellitus, cardiovascular mortality (ET) and colorectal cancer (EPT), but harmful for stroke (RR 1.17, 95% CI 1.05–1.29) and venous thromboembolism (RR 1.60, 95% CI 0.99–2.58), as well as cardiovascular disease, cerebrovascular disease, non-fatal stroke, deep vein thrombosis, gallbladder disease, and lung cancer mortality (EPT). In meta-analyses of observational studies, MHT was associated with decreased risks of cataract, glioma, and esophageal, gastric and colorectal cancer, but increased risks of pulmonary embolism, cholelithiasis, asthma, meningioma, and thyroid and ovarian cancer. ET and EPT had opposite effects for breast and endometrial cancer, endometrial hyperplasia and Alzheimer's disease. Importantly, current evidence supporting the beneficial effects on coronary heart disease and all-cause mortality in young women (known as 'timing hypothesis') is only tentative.
Conclusions and relevance
MHT has a complex balance of benefits and harms on multiple health outcomes. Some effects differ qualitatively between ET and EPT. Clinicians should evaluate the credibility of the methods of systematic reviews prior to considering applying their results in clinical practice. A re-examination of current practice guidelines may be needed.

Cushing's syndrome: Do Cushing's patients have similar diagnostic and treatment journeys and outcomes to mine?

Margaret McBride
University of Lancaster, Faculty of Health and Medicine, Near Cupar, United Kingdom

Background
Having experienced Cushing's syndrome and disease, this author is now a Doctor of Philosophy student studying these medical conditions with the main aim of finding out if others diagnosed with these illnesses have experienced similar diagnostic and treatment journeys with similar outcomes.
Method
An online 2020 survey was conducted on 86 Cushing's members of the Pituitary Foundation, (Females = 71, Males = 15). The questionnaire contained 40 questions and the results analysed and reported quantitively and qualitatively.
Main Results:
The mean age of the females was 44, the males 39, (Ages 19–70 years). The mean length of time for a diagnosis of CS was 4.9 years, and for CD, 3.2 years. The male results were 2.5 years and 1.3 years respectively. The mean number of physicians consulted prior to diagnosis was 3. All members had blood tests prior to their diagnosis (Mean = 4). A range of diagnostic medical imaging examinations/procedures were named by 81% of the members. A collective total of 170 diagnostic imaging examinations/procedures were conducted prior to diagnosis. 49% had pituitary surgery, 55% had adrenal surgery and 36% of the members had been advised that they would always require to take steroid medicines. 22% had radiotherapy and 5% had chemotherapy. 81% found that their Cushing's illness had impacted on their work status, social life, personal and family relationships. 45% of the members found their endocrine team did not involve their family, while 52% found the team to be very supportive. 44% of the members were given advice to join a support group. 90% of them agreed that there is insufficient public awareness, 44% also agreed that there was a lack of knowledge/awareness by health professionals and suggested a range of educational training methods and promotional material. The QoL was measured using a Likert 5-point scale. The results showed slightly higher QoL scores at the time of completing the questionnaire than prior to diagnosis and during treatment. On examining the differences between the responses to these questions, no significant difference was found, (P =.406), I e there was no evidence of an improvement in their health status.
Conclusion
The many factors which combine to reduce QoL in those who are diagnosed with Cushing's illnesses were identified. Despite medical interventions the comorbidities, both physical and psychological create long-term detrimental effects, and in many cases cannot be reversed. The management of this disease can be improved by raising awareness in health professionals.

DOI: 10.1530/endoabs.73.AEP415

A single-center observational study of patients with ectopic ACTH syndrome

Olga Golounina[1], Liudmila Rozhinskaya[2], Svetlana Arapova[2], Michael Pikunov[3], Patimat Khandaeva[2], Larisa Dzeranova[2], Evgenia Marova[2] & Zhanna Belaya[2]

[1]I.M. Sechenov First Moscow State Medical University of the Ministry of Health of the Russian Federation (Sechenov University), Clinical Medicine, Moscow, Russian Federation; [2]National Medical Research Center for Endocrinology of the Ministry of Health of the Russian Federation, Neuroendocrinology and Osteopathy, Moscow, Russian Federation; [3]National Medical Research Center for Surgery named after A.V. Vishnevsky of the Ministry of Health of the Russian Federation, Moscow, Russian Federation

Background
Ectopic ACTH syndrome (EAS) is a rare cause of endogenous hypercortisolism.
Objective
To analyze clinical, biochemical features and treatment outcomes of patients with EAS.
Materials and methods
Retrospective, observational study on 129 patients (79 women, 50 men) with EAS diagnosed between 1990 and 2020. Plasma levels of ACTH (reference range: morning 7.2–63.3 pg/ml), late-night serum cortisol (64–327 nmol/l), late-night salivary cortisol (LNSC) (0.5–9.6 nmol/l) were measured by ECLIA Cobas 601; 24-h urinary free cortisol (24 hUFC) (100–379 nmol/l) – on Vitros ECi. Various imaging studies were performed in all patients to find the source of ACTH.
Results
The median age at diagnosis was 40 years [28;54]. 80 patients (62%) had bronchopulmonary neuroendocrine tumor (NET), 7 – thymic carcinoid, 7 – pancreatic NET, 5 – pheochromocytoma, 1– cecum NET, 1– appendix carcinoid tumor, 1 – medullary thyroid cancer and 27 (21%) patients had an occult source of ACTH. Mean time to diagnosis for patients with EAS was 32.5 months, 11 patients (8.5%) had cyclic course of the disease. Median basal plasma ACTH level at the time of the diagnosis was 141.1 pg/ml [101.9;202], median 24 hUFC was 2821.0 nmol/l [1691;6534.6], median late-night serum cortisol at 23:00 h and LNSC were 1228 nmol/l [959.1;1431.3] and 71.8 nmol/l [40.5;121], respectively. The most common complications in the active stage of the disease were type 2 diabetes mellitus (55%), cardiovascular disease (55%), arterial hypertension (84.5%), osteoporosis with low-energy fractures (60.5%). The median follow-up period of the patients was 27 months [10.5;61.0] with a maximum follow-up of 372 months. Currently, primary tumor was removed in 82 (63.6%) patients. Regional and distant metastases were revealed in 22 patients (17%). At the time of the last observation 58 patients (45%) were exhibited a full recovery, 12 (9%) – had relapse of the disease and received treatment with octreotide (20–50 mg/4 weeks) or ketoconazole (400 mg/day) to control severe hypercortisolism and 26 patients (20%) died from multiple organ failure ($n = 21$), pulmonary embolism ($n = 4$) or COVID-19 ($n = 1$). Bilateral adrenalectomy was performed in 23 patients (18%), in 16 of them there was an occult source of ACTH-producing tumor and in 7 patients – in order to control hypercortisolism at incurable stage of the disease.
Conclusion
In our study EAS was most commonly associated with intrathoracic tumors such as bronchopulmonary and thymic carcinoid. Surgical treatment of patients with the established source of the disease leads to remission of hypercortisolism in most cases.

Design of an online platform to support young diabetics transitioning to adult care: an experiment at the endocrinology service of casablanca university hospital

Kenza Sekkat, Nassim Essabah Haraj, Siham El Aziz & Asmaa Chadli
Department of Endocrinology, Diabetology and Metabolic Diseases Ibn Rochd University Hospital, Casablanca, Morocco

Introduction
The quality of the transition process from pediatric care to adult care represents an important factor in ensuring uninterrupted follow-up of care for T1D adolescents. By avoiding the risks of poor adaptation, better organization of care would facilitate this transfer. New technologies, notably websites and mobile applications, have been adopted throughout the world to support young patients transitioning to adult care, and their families.
Goal
Our work revolves around the design and development of an online platform, enriched with informative content that is geared toward preparing young diabetics for the transition from pediatrics to the service of Endocrinology and Diabetology for adults at the Casablanca University Hospital.
Methodology
A questionnaire was developed to investigate the needs of young diabetics during transition and to identify their preferred online communication channels. A requirements specification document has been drafted to identify the objectives of the site. The web agency developed the website on the Wordpress platform using PHP as a programming language; a simplified administration interface has been implemented to facilitate the modification of the content by the service's team.
Results
50 T1D patients aged 15 to 18 responded to the questionnaires. The data collected was used to create a website that met their needs, including the accessibility of information about their illness via easily digestible content. Information about the Endocrinology service has been added to familiarize young patients with their next service.
Conclusion
Transition interventions based on technology as a modern means of communication are increasingly used to further involve young people in their health care. Hence www.jisr.info is a website that provides young T1D patients with the right tools to improve their experience during transition to adult care.

Designing a chatbot for young diabetics: Unprecedented experiment at the endocrinology service of the casablanca university hospital

Kenza Sekkat, Nassim Essabah Haraj, Siham El Aziz & Asmaa Chadli
Department of Endocrinology, Diabetology and Metabolic Diseases Ibn Rochd University Hospital, Casablanca, Morocco

Introduction
Technological progress, the quest for optimization and the evolution of artificial intelligence have given birth to Chatbots. Also called a conversational agent, a chatbot is an artificial intelligence capable of conducting interactive human conversations. The main advantages of Chatbots are their availability 24/7, their accessibility (a Chatbot can take the form of a contact on Facebook Messenger), and the ease of access to information thanks to the common language imitating human conversation. Our goal was to design a technological tool that involves adolescents in the management of their diabetes via a robotic personal assistant.
Methodology
In order to define the functionalities of the chatbot and to collect the needs of T1D patients in terms of support and continuous learning, a questionnaire was designed. We used Flow XO, a visual chatbot editor that can be deployed on a wide range of websites, applications and social networks. A button to subscribe to our chatbot via Facebook messenger has been added to our service's website www.jisr.info.
Results
50 young type 1 diabetic patients aged 15 to 18 responded to the questionnaires. The data collected was used to develop the functionalities of the Chatbot. By clicking on the 'Subscribe to our Chatbot' link, our Chatbot, Karim, is added as a 'Friend' on Facebook. Karim supports DT1s in interpreting their blood sugar levels, can tell them what to do in the event of hypoglycemia or diabetic ketosis, and can also set reminders and give quick access to relevant information such as emergency numbers.
Conclusion
This Chatbot is an innovative means of health intervention allowing young T1D patients to get more involved in the management of their disease. This is a pilot version which will be enriched with new functionalities over time.

Treatment approach of insulinoma

Elyes Kamoun[1,2], Sabrine Mekni[1,2], Imen Rojbi[1,2], Youssef Lakhoua[1], Nadia Mchirgui[1,2], Ibtissem Ben Nacef[1,2] & Karima Khiari[1,2]
[1]Hospital Charles Nicolle, Tunis, Tunisia; [2]Medical School of Tunis, Tunis, Tunisia

Introduction
Insulinoma is the most frequent pancreatic endocrine tumor and is confirmed in case of a hyperinsulinic hypoglycemia with elevated C-peptide and absence of sulfonylureas. Tomodensitometry, MRI, endoscopic ultrasound

are the imaging means used to assess localization before surgery as it is not always determined by one mean only, and in a few cases, all means may not determine localization.
Methods
This is a descriptive, retrospective study including 10 patients with confirmed insulinoma. We collected imaging results, medical treatment, surgical management and histologic finding.
Results
For the 8 patients receiving surgery, 2 didn't have a precise localization for the tumor. Intra-operative palpation found a lesion in 3 cases, and intra-operative ultrasonography was done in 7 cases and found a lesion in 6 cases (one of them was the patient with no confirmed pre-operative localization). All 5 cases of confirmed tumor in the head of the pancreas were precisely diagnosed pre-operatively, 4 had an enucleation and one had a cephalic duodenal pancreatectomy (CDP). After enucleation, histologic examination confirmed 3 were well differenciated insulinomas and one had an islet cells hyperplasia (ICH), with a persistant hypoglycemia. The patient treated with CDP had a well differenciated tumor. The 2 cases with a suspected lesion in the tail of the pancreas and the patient with no confirmed localization had a caudal pancreatectomy (CP) with ICH in histologic finding. Medical treatment was used either for preoperative management, for post-operative control of persistant hypoglycemia or in case where surgery couldn't be done. One patient had an inoperable malignant insulinoma, and was put on diazoxide and octreotide with a good tolerance and no hypoglycemia. One patient refused the surgery, and was put under corticosteroids with lessening of hypoglycemia. The patient with no confirmed localization had diazoxide and corticosteroids for preoperative and post-operative control with persistence of hypoglycemia. In the case of persistant hypoglycemia after enucleation, lanreotide, corticosteroids and CP were used with a good control of hypoglycemia.
Conclusion
In our serie, preoperative and intra-operative investigations were able to determine the precise localization in 7 out of 8 cases, allowing a guided surgery with a preferred enucleation if it was in the head and CP if it was in the tail. Localized tumors were definitively treated in all cases, and persistence of hypoglycemia occurred only if ICH was confirmed, a strict follow-up must then be done.

AEP420

Clinical characteristics of organic hypoglycemia

Elyes Kamoun[1,2], Sabrine Mekni[1,2], Imen Rojbi[1,2], Nadia Mchirgui[1,2], Youssef Lakhoua[1], Ibtissem Ben Nacef[1,2] & Karima Khiari[1,2]
[1]Hospital Charles Nicolle, Tunis, Tunisia; [2]Medical School of Tunis, Tunis, Tunisia

Introduction
Spontaneous hypoglycemia in non-diabetic adults represent a challenge in confirming the organic cause, requiring in that case specific medication or surgery, in a setting of a possible life-threatening disease.
Methods
We conducted a retrospective study of patients admitted in our department for spontaneous hypoglycemia. Functional and factitious etiology were excluded. Clinical and biologic features were collected and were compared for 2 groups: the patients with confirmed adrenal insufficiency (group 1) and the patients with endogenous hyperinsulinism (group 2).
Results
Fourteen patients were included with confirmed organic hypoglycemia, 4 patients in the group 1 and 10 patients in the group 2. Mean delay between beginning of the symptoms and the day the patient consulted was 7.27 months in the first group and 8 months in the second group. Fasting was impossible in all the cases it was documented. There were 4 women in the group 1 vs 7 women and 3 men in the group 2. The first group had a lower mean age (37 ± 13 years vs 41 ± 15 years), lower body mass index (normal in all patients in group 1, superior to 25 kg/m^2 in 4 cases over 10 in the second group). Three patients in the first group described a loss of weight, and one with no change, while 6 patients in the second group described a gain of weight and 4 with no change. The group 1 had more neurogenic symptoms than neuroglycopenic ones, while in group 2, all patients had neuroglycopenic symptoms. Group 1 had 3 cases of fasting hypoglycemia and 1 case of late postprandial hypoglycemia, while group 2 had 6 cases of fasting hypoglycemia, 1 case of hypoglycemia after physical activity and 3 cases with no precise moment. Mean glycemia was lower in the second group comparing to the first group (0.27 ± 0.08 g/l vs 0.39 ± 0.13 g/l, P = 0.07).
Conclusion
Our study found differences in gender ratio, age, body mass index, signs and symptoms between the two groups, with lower mean glycemia in the endogenous hyperinsulinism group. A larger study must be conducted to find higher significant results for these clinal parameters.

AEP421

Epidemiological aspects of adrenal insufficiency detected by the Synachten test and insulin hypoglycemia during withdrawal from prolonged corticosteroid therapy

Mohamed Aymane Loukili, Najat Draoui, Anouar Jamal, Siham Rouf & Hanane Latrech
Mohammed VI University Hospital Center, Endocrinology Diabetology, Oujda, Morocco

Introduction
Adrenal insufficiency is the most common complication after long-term corticosteroid therapy, to affirm or exclude the diagnosis of adrenal insufficiency several authors suggest basal cortisol testing as first-line, however, others prefer stimulating tests (insulin hypoglycemia (IGH) or synacthen testing). The aim of our work is to Analyze the frequency and determinant of the biological adrenal insufficiency detected by stimulating tests.
Material and methods
This is a retrospective study concerning 27 patients, who have taken long-term corticosteroid therapy at doses higher than 7.5 mg/day stopped and hydrocortisone relayed at variable doses, 49 tests were performed. over a 6-year time period.
Results
The mean age was 41.4 ± 14.6 years, mean duration of corticosteroid therapy was 27.7 ± 45 months, the cortisol limit for exploration by a dynamic test was reached after an average of 15 months in 45% of cases. 63% of patients did not respond to the test, with a mean cortisol level of 13.7 ng/l, and 37% responded to the stimulation test, with a mean cortisol level of 20.1 ng/l. Half of these responder patients were tested by Synacthen 250 mg immediate and half with IGH.
Discussion-conclusion
Follow-up of patients after prolonged corticosteroid therapy allows to predicts the ideal time to perform corticotropic axis stimulation tests and then to stop or maintain hydrocortisone substitution, it also prevents acute adrenal insufficiency.

The effect of COVİD-19 process on patients with endocrinological disease in a pandemic hospital: What Happened to the others?

Evin Bozkur[1], Seda Turgut[1], Naim Pamuk[1], Hamide Piskinpasa[2], Duygu Metin[3], Cem Dural[4], Nuri Alper Sahbaz[4], Omur Gunaldı[5], Nikay Cakir[1], Meral Mert[1] & Sema Ciftci Dogansen[2]
[1]University of Health Sciences, Bakirkoy Dr. Sadi Konuk Training and Research Hospital, Endocrinology and Metabolism, İstanbul, Turkey; [2]University of Health Sciences, Bakirkoy Dr. Sadi Konuk Training and Research Hospital, İstanbul, Turkey; [3]University of Health Sciences, Bakirkoy Dr. Sadi Konuk Training and Research Hospital, Radiology, İstanbul, Turkey; [4]University of Health Sciences, Bakirkoy Dr. Sadi Konuk Training and Research Hospital, Surgery, İstanbul, Turkey; [5]University of Health Sciences, Bakirkoy Prof. Dr. Mazhar Osman Training and Research Hospital for Neurology, Neurosurgery and Psychiatry, Department of Neurosurgery, İstanbul, Turkey

Objective
To evaluate the effects of the pandemic process on those with an endocrinological disease that will require close follow-up from the last visit before the pandemic.
Design
This was a retrospective study.
Methods
Patients of 3903 with thyroid, calcium-bone metabolism, adrenal gland, pituitary diseases, and neuroendocrine tumor (NET) were retrospectively scanned. The remaining 855 (656F/199M) patients with active disease or

still needed the multidisciplinary approaches were included in the study. How many patients who continued the disease-related medical procedures could complete these procedures on time in the pandemic period were determined, and the medical deprivation rate (MDR) was calculated.
Results
The pre-pandemic period of our patients with thyroid disease (n = 594), calcium-bone metabolism disorder (n = 130), adrenal disease (n = 85), pituitary disease and NET (n = 46), had MDR 85%, 56%, 81% and 89%, respectively. For each subgroup of the patients; the lowest MDR (67%) was in medullary thyroid carcinoma, the highest MDR (89%) was in differentiated thyroid carcinoma; the lowest MDR (6%) was in osteoporosis, the highest MDR (100%) was in the active Paget's disease; the lowest MDR (0%) was in primary adrenocortical insufficiency, the highest MDR (100%) was in hyperfunction adrenal adenomas; the lowest MDR (81%) was in the pituitary incidentaloma or non-functional adenomas, and the highest MDR (100%) was in Cushing's disease, active prolactinoma, TSHoma, and NET, respectively.
Conclusion
This study analyzed the medical deprivations experienced by patients with endocrinological diseases during the pandemic period and showed that these patients' follow-up and treatment should not be underestimated during the pandemic period.
Discussion
With the decrease in the number of COVID-19 cases in countries affected by the pandemic, the impact of patients with other diseases who experienced medical deprivation became more prominent.

AEP423

COVID-19: Is there an urgent need to further assess how Cushing syndrome patients have reacted to this pandemic and what mechanisms are in place to support them?

Margaret McBride
University of Lancaster, Faculty of Health and Medicine, Lancaster, United Kingdom

Background
Similar to other patients with life-threatening medical conditions, the fear of contracting COVID-19 for Cushing Syndrome (CS) patients is a natural reaction which has created a number of urgent questions, requiring answers. These questions include: how my body will react to the virus; will my current comorbidities increase; what will happen if I don't have my regular clinic appointments, surgery and chemotherapy treatments? What do I do if I am hospitalised and will my endocrinologist contact me to advise?
Methods
A Quality of Life (QoL) CS 2020 survey on 86 members of a support group during the onset of the pandemic accidently revealed in one of the QoL open questions, the thoughts and fears of contracting the virus. A thematic analysis was conducted on the 29 members who expressed their fears, to ascertain patterns of importance and interpret any challenges/issues which might be affecting their QoL and thus reduce their QoL scores.
Results
The analysis revealed that all 29 were fearful of contracting COVID-19 and recorded a lower QoL score than those of the other participants, (P <.001). The main reasons given were: that they may not be able to tolerate additional medications; 3 of them had been diagnosed with Addison's disease, 8 with pulmonary, cardiovascular and inflammatory conditions and 6 with diabetes. All 29 had cancelled outpatient appointments including 1 who was awaiting chemotherapy and 16 their radiology appointments. 9 were awaiting surgery which had been postponed. 11 were disappointed that their endocrinologist had not contacted them but were glad that they belonged to a support group. 26 were already experiencing depressive illnesses as a consequence of their CS, reported that lockdown measures had made them feel isolated, depressed and in 1 case suicidal.
Conclusion
Endocrine advice and support is even more crucial during a pandemic. The fears engendered cause further challenges for these patients and undoubtedly a reduction in their QoL. This survey had identified the breakdown of social life and personal relationships due to their illness and this had led to loneliness and depression. COVID-19 is suggested in this survey, to exacerbate these, with serious long-term consequences. If support and advice are not in place, then morbidity and mortality rates may increase exponentially. It is imperative that these patients must be able to continue their diagnostic and treatment journeys in order to save their lives and further save cost for healthcare services and improve long-term patient outcomes.

The association of Vitamin D deficiency with COVID-19 severity and mortality

Mitra Kazemijahromi[1], HamidReza Samimagham[2], Mehdi Hassani Azad[3], Mohsen Arabi[4] & Dariush Hooshyar[5]
[1]Endocrinology and Metabolism Research Center, Hormozgan University of Medical Sciences, Bandarabbas, Iran; [2]Clinical Research Development Center, Shahid Mohammadi Hospital, Hormozgan University of Medical Sciences, Bandar Abbas, Iran; [3]Infectious and Tropical Diseases Research Center,Hormozgan Health Institue,Hormozgan University of Medical Sciences, Bandar Abbas, Iran; [4]Department of Internal Medicine and Public Health Research Center, Family Medicine Department, Iran University of Medical Sciences,Tehran, Iran; [5]Student Research Committee, Faculty of Medicine, Hormozgan University of Medical Sciences, Bandar Abbas, Iran

Background and objective
There are few studies showing the association between vitamin D deficiency and COVID-19 severity and mortality. This study designed to investigate the relationship between vitamin D deficiency and the severity and mortality of COVID-19.
Methods
The present cross-sectional study was conducted on 48 COVID-19 patients with positive PCR test results. Patients were divided into three groups according to their serum 25-OH vitamin D3 levels: group 1 < 20 ng/ml, group 2. 20–50 ng/ml, and group 3, ≥ 50 ng/ml. The relationship of the levels of vitamin D3, as well as the history of diabetes, hypertension, Ischemic Heart Disease (IHD), Glomerular Filtration Rate(GFR) ≤ 60 ml/min, LDH ≥ 500 U/l, and Lymphocyte count ≤ 1500 with the severity of the disease and its mortality were investigated.
Results
A significant relationship was observed between vitamin D ≤ 20 ng/ml and the severity of the disease (P < 0.001) and mortality (P = 0.001, adjusted OR = 2.4) in COVID-19 patients. It was also shown that GFR ≤ 60 ml/min (P = 0.02, adjusted OR = 3.6), IHD (P = 0.04, adjusted OR = 2.8), LDH ≥ 500 U/l (P = 0.027, adjusted OR = 1.8) and lymphocyte count ≤ 1500 (P = 0.002, adjusted OR = 2.2) significantly affected the mortality.
Conclusion
The present study showed a significant relationship between vitamin D deficiency and the severity of the disease and mortality in COVID-19 patients. These results suggest the need for appropriate health policies during the COVID-19 pandemic.

Serum 25(OH)D level in patients with COVID-19

Alena Andreeva[1], Tatiana Karonova[1], Ksenia Golovatuk[1], Ekaterina Bykova[1], Maria Vashukova[2] & Elena Grineva[1]
[1]V.A.Almazov National Medical Research Centre, Institute of Endocrinology, Saint Petersburg, Russian Federation; [2]S.P. Botkin Clinical Infectious Hospital, Saint Petersburg, Russian Federation

Recently, vitamin D deficiency has been considered as a risk factor for the morbidity and the severity of acute respiratory infections. The aim of this study was to evaluate the interlinks between serum 25(OH)D level and severity of new coronavirus infection (COVID-19) in hospitalized patients.
Methods
We included 131 patients aged 21 to 93 y.o. (mean age 51.7 ± 13.8 years), 76 (57.1%) men, hospitalized following COVID-19 infection. We assessed serum 25(OH)D level for all of them using Abbott Architect i2000 with immunochemiluminescent assay.
Results
Twenty-five (19.1%) patients (15 males) had severe disease, and 108 subjects (80.9%) (61 males) had a moderate one. Fatal outcome was registered in 18 (13.7%) patients and 15 (83.3%) of them had severe course of disease. Half of the severely ill patients were obese. Also, obesity was seen in 64.0% of deceased patients, and was significantly more often than in the discharged ones – 21.3% (P < 0.001). Diabetes mellitus and cardiovascular diseases occurred with the same frequency, regardless of the disease severity. Serum 25(OH)D level ranged from 3.0 to 97.0 ng/ml (13.5 [9.6;23.3] ng/ml). Vitamin D deficiency was diagnosed in 90 (68.7%) patients including 37 with severe deficiency (25(OH)D level < 10 ng/ml). It was found that in patients with severe course, serum 25(OH)D level was significantly lower (9.7 [6.0;14.9] ng/ml) and vitamin D deficiency was more common than in patients with moderate course of the disease (14.6 [10.6;24.4] ng/ml,

P = 0.003). The same pattern was revealed in patients with fatal outcome, where 25(OH)D level was 9.6 [6.0;11.5] ng/ml, compared to levels seen in discharged patients (14.8 [10.1;24.3] ng/ml) (P = 0.001). We found that severe vitamin D deficiency was associated with increased risk of COVID-19 severity (OR = 3.79 [95% CI:1.53–9.39]; P = 0.005) and fatal outcome (OR = 4.07 [95% CI: 1.46–11.35], v0.009). The threshold for 25(OH)D level that was associated with an increased risk of severe course in this population was 11.7 ng/ml (AUCarea = 0.693; sensitivity 71.3% and specificity 68.0%, P = 0.003). Approximately the same 25(OH)D level was associated with an increased risk of mortality – 10.9 ng/ml (AUC_{area} = 0.746; sensitivity 73.9% and specificity 72.2%, P = 0.001).
Conclusions
COVID-19 patients have Vitamin D deficiency in most cases and severe vitamin D deficiency has been found to be associated with an increased risk of severity and fatal outcome of new coronavirus infection.

Telehealth experience of endocrinology research centre

Anna Gorbacheva, Oksana Logvinova & Natalia Mokrysheva
Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Telemedicine is a useful tool for improving the availability of medical care, especially in the era of COVID-19. It is required to study the needs of the Russian population for telemedicine services for each specific disease.
Methods
In Russian Federation telemedicine consultations (TMC) have been legally allowed since 2018. According to the law, if the patient has not previously attended a face-to-face consultation, the doctor has no right to make a diagnose and prescribe treatment. Remote consultations after a face-to-face visits have no restrictions. All TMC were conducted by physicians of Endocrinology Research Centre in Moscow with medical information system with the identification of the patient's and the doctor's personalities. All data is shown as median [Q1;Q3], unless otherwise indicated.
Results
The number of TMC increased from 104 in 2019 to 1548 in 2020. A sharp increase in patients' requests results from COVID-19 pandemic. Adults received 1200 TMC (M:F = 167:1033, i.e. 13.9% and 86.1%, respectively). 460 were conducted with videoconferencing (38.3%). With the exclusion of repeated TMC, 973 individual adult patients applied for TMC in 2020 (M: F = 143: 830, i.e. 14.7% and 85.3%, respectively). The median age of adult patients was 38.0 years [31.0; 53.0], among women – 37.5 years [30.0; 52.0], among men – 42.5 years [34.3; 54.0]. 348 consultations were provided to children (M: F = 130: 218, i.e. 37% and 63%, respectively). 106 were conducted with videoconferencing (30.4%). With the exclusion of repeated TMC, TMC was provided to 272 children (M:W = 102:170, i.e. 37.5% and 62.5%, respectively). The median age of children was 10.0 years [6.0;14.0], among girls – 11.0 years [6.3;14.0], among boys – 10.0 years [4.0;13.0]. All 1548 TMńwere performed for 201 diseases (indicated by the ICD-10 code). 38 conditions accounted for 65% of all consultations. Among adults, 880 unique cases were identified (1 patient with one certain disease). The most frequent cases were E05.0 (8.8%), E21.0 (4.6%), E66.0 (4.4%), E04.2 (4.3%) and E06.3 (4.2%). Among children, 267 unique cases were identified, the most frequent were E25.0 (12%), E34.3 (7.5%), E66.0 and E10.8 (6% each), E23.0 (5.2%).
Conclusion
The demand for TMC in 2020 increased dramatically. In Endocrinology Centre the demand for TMC didn't correlate with the prevalence of certain diseases. It is necessary to develop telehealth technologies for other conditions and conduct further research to determine the feasibility of including TMC in the national guidelines.

A case of severe erosive rheumatoid arthritis developed in an elderly male patient after bilateral adrenalectomy performed for ectopic Cushing's syndrome

Hunkar Aggul[1], Ece Baydar[1], Ogun Bilen[2] & Sayid Zuhur[2]
[1]Tekirdag Namik kemal University, Internal Medicine, Turkey; [2]Tekirdag Namik kemal University, Endocrinology and metabolism, Turkey

Introduction
Some, cases of autoimmune diseases were previously reported after surgical remission of CD. In most cases, autoimmune diseases have generally been reported in younger females. However, some cases of Hashimoto's thyroiditis, multiple sclerosis, vitiligo, and sarcoidosis in male patients, after the restoration of hypercortisolemia have been reported as well. Nevertheless, an immediate occurrence of severe erosive rheumatoid arthritis (RA) in an elderly male patient after bilateral adrenalectomy while taking glucocorticoid replacement therapy has not been reported so far.
Case
A 67-year-old male patient admitted to our outpatient clinic with classical signs and symptoms of CS. CS was diagnosed by a failure of suppression of cortisol on low and high dose dexamethasone suppression tests, high urinary free cortisol, and high plasma ACTH levels. A pituitary adenoma could not be found on magnetic resonance imaging, therefore, an IPSS (inferior petrosal sinus sampling) was performed and the result was compatible with an ectopic CS. However, an ectopic tumor could not be found on the neck, chest, and abdominal CT scans, as well as on 68Ga- DOTATATE PET-CT. Bilateral adrenalectomy was performed and treatment with hydrocortisone and fludrocortisone was started. Six months later, the patient was admitted with bilateral small joint arthritis of the hands and morning stiffness. The serum Anti – CCP (Cyclic Citrullinated Peptide, erythrocyte sedimentation rate, and C-reactive protein were 6.2 U/ml (< 5 U/ml), 38 mm/h (< 20 mm/h), and 26 mg/l (< 5 mg), respectively. A hand x-ray showed bilateral space narrowing of the proximal interphalangeal joints with marginal erosions of the proximal interphalangeal joints, soft tissue swelling with periarticular osteopenia, and ulnar deviation of the 2. phalanxes. The patient was diagnosed with erosive RA and treatment with methotrexate was started.
Discussion
The occurrence of autoimmune diseases after remission of CS has been reported in some cases. The restoration of the physiological production of cortisol may cause an immune reaction, leading to the onset of autoimmune disease. RA is an autoimmune disease that is generally seen in females between 40–50 years of age. Our case is the first to report an elderly male patient with erosive RA after bilateral adrenalectomy who was taking physiological doses of hydrocortisone. Therefore, all patients with CS, including elderly male patients, should be closely observed for the occurrence of autoimmune disease after successful restoration of hypercortisolemia.

Sonoelastographic characteristics of parathyroid tumors

Yuriy Aleksandrov & Ivan Belyakov
Yaroslavl State Medical University, Surgery, Yaroslavl, Russian Federation

In 2016–2020, 181 patients (mean age – 54.8; range 31–77 years) with tumors of parathyroid glands (PG) were operated. All patients had hyperparathyroidism. The diagnosis was confirmed by high levels of ionized calcium and parathyroid hormone (PTH) in the blood. Ultrasound was performed in all patients before surgery. The evaluation of ultrasound images of PG tumors was carried out according to the following parameters: echogenicity, echostructure, shape, clarity and evenness of contours, the presence of calcinates, features of vascularization. The PG sizes and localization were recorded.
Results
It was possible to accurately determine the localization of tumors in 92.4% of cases. In 14 cases, ultrasound was ineffective: in 5 cases, the PG tumor was mistakenly interpreted as a thyroid node, in 3 cases it was located behind the trachea, in 2 cases – in the mediastinum, in 4 cases-the PG tumor was not visualized. Most tumors were located in the projection of the right lobe of the thyroid – at 55.2% and 44.8% – on the left. In the projection of the lower poles of the thyroid was up 29.6% of the tumors, on the rear surface of the middle segments doll TG – 19.7%, and for the upper poles of the thyroid of 2.8%. When measuring the volume, most tumors were up to 1 cm^3 – 50.7%, from 1 cm^3 to 10 cm 3–40.9% of all adenomas, from 10 cm^3 and – 8.4%. The tumors had an oval or irregular shape on 87.3%. The majority of PG tumors (92.3%) had clear contours. Smooth contours had 61.5% of tumors, uneven contours – 38.5%. Tumors of PG were identified by ultrasound as hypoechoic focus (85.5%), as isoechoic (8%) and anechoic (2.8%) formations. PG tumors had a heterogeneous structure in 58.5%, homogeneous-41.5%. In 63.4%, PG tumors were hypervascular, while in 32.4%, the incoming vessel was clearly visualized, forming a 'vascular arc'. In 36.6%, the blood flow was hypovascular. The liquid component in PG tumors was rarely observed – in 12.7% of cases, and calcification elements were detected only in 4.2%.

Conclusion
The most likely ultrasound signs of PG tumors are: a single hypoechoic formation, with clear uneven contours, an irregular, elongated shape, located outside the thyroid gland, along its posterior surface, more often in the projection of its lower poles. An important criterion characteristic of a PG tumor is the hypervascular type of blood flow and the presence of an incoming feeding vessel.

Case report: The spectrum of autoimmune thyroid disease in association with chromosome 18p deletion syndrome

Sorana Vasilescu[1], Natalia Raluca Mitru[1], Alberto Massarella[1], Anca Andrei[1], Diana Preda[1,2] & Alexandra Mirica[1,2]
[1]Emergency Hospital for Children Grigore Alexandrescu; [2]Carol Davila University of Medicine and Pharmacy

Introduction
Chromosome 18p deletion syndrome is a rare chromosomal abnormality caused by the complete or partial delation of the short arm of chromosome 18, represented by facial dysmorphic features, hypodontia, microcephaly, short webbed neck, intellectual disability, reproductive system dysplasia, rarely with autoimmune disorders and IgA, IgG or IgM deficiency. A small subset of patients, approximately 9–10% have cardiac/brain disorders. Circa 150 cases were reported in literature, since it was first described by de Grouchy et al in 1963. Incidence is estimated to be roughly 1:50.000 live births.
Case report
We report the case of a 7 years and 2 months old girl with facial dysmorphism, who was referred to us after being reported symptoms of hyperthyroidism such as palpitations, dysphagia and episodes of diaphoresis. She was the first child born to a non-consanguinous young couple, with a normal gestational period. The parents denied any significant pathological history. She was born full term by caesarean section, Apgar score 8 and birth weight of 3.1 kg. Her height was 47 cm. Karyotyping revealed a deletion of the short arm of chromosome 18 (Cz18p11), causing defective neuropsychomotor development. Our physical examination revealed short statured 95 cm [–3.29 standard deviation score (SDS)], weight 13.5 kg (44% percentile), microcephaly, short neck, hypertelorism and epicanthal folds, enlargement of the thyroid gland. Her vital signs were: heart rate 145 beats/min, blood pressure 100/60 mmHg. Pubertal development B2P1A1. Ecocardiography revealed perimembranous ventricular septal defect and aneurysm of the membranous intraventricular septum. Transthoracic ultrasound showed ventriculomegaly. Thyroid ultrasonography revealed thyroid enlargement, heterogenous with slightly increased vascularity. Blood tests results showed hyposideremia and low ferritin levels. Gonadal hormones levels showed prepubertal status. PTH, ACTH, basal cortisol levels were normal. Initial thyroid function test showed TSH: 0.03 IU/ml, free T4 (fT4): 22.04 pg/ml (8.9–17.2), anti-TPO: 707 IU/ml(n < 35) and TRAb 36.96 IU/m(< 1.75) confirming the clinical diagnosis of Graves's disease. We started treatment with 10 mg/per day Thiamazol reaching euthyroidism. Five months later thyroid test were TSH 69 IU/ml, free T4 (fT4): 2.35 pg/ml (8.9–17.2), anti-TPO: 695 IU/ml(n < 35). Based on such findings we started Levothyroxine with titration of the dose until hormonal levels were normal.
Conclusion
We report a rare case of Graves's disease as a initial manifestation of thyroid autoimmune disease in association with 18p deletion syndrome. It is worth mentioning that autoimmune disorders are especially linked with the deletion of the long arm chromosome 18 leading us to the particularity of this case.

Sulfamethoxazole/Trimethoprim associated hypoglycaemia in a patient with renal transplantation history

Mariana Lavrador, Diana Catarino, Cátia Andreia Araújo, Luísa Barros & Isabel Paiva
Centro Hospitalar e Universitário de Coimbra, Endocrinology Department, Coimbra, Portugal

Background
Although rare, hypoglycaemia in patients without history of diabetes should be recognized and studied, in order to reduce associated morbidity. Cotrimoxazole (TMP/SMX) is commonly used in clinical practice and hypoglycaemia is a rare side effect associated with its use. Literature advocates that this effect is due to the fact that SMX has the same sulphanilamide structural group of sulfonylurea, mimicking the hypoglycaemic effect by stimulating pancreatic insulin secretion.
Clinical case
A 62-year-old black woman, admitted in infectious diseases ward, with a diagnosis of cerebral toxoplasmosis. Previous history of bilateral nephrectomy and kidney transplantation 8 years ago, under treatment with tacrolimus 4 mg id and prednisolone 5 mg id, with 25.4 ml/min/1.73 m^2 eGFR. She started pyrimethamine 75 mg od and sulfadiazine 1500 mg 4 times a day, which were discontinued due to vomiting at day 21. A switch to TMP/SMX (1920 mg 3/day) was performed, with good tolerance. On 6th day after starting this drug, the patient showed generalized tonic-clonic seizure and a blood glucose level of 21 mg/dl. Evaluation by endocrinology was requested for severe hypoglycaemia in a patient without diabetes. A 10% glucose infusion was initiated, but the patient maintained hypoglycaemia (capillary blood glucose ~ 30–41 mg/dl), requiring administration of an intravenous bolus of hypertonic glucose solution and also glucagon. The hypothesis of acute adrenal insufficiency and pituitary apoplexy were excluded. Retrospectively, an episode of hypoglycaemia was detected in routine analytical study, on the 3rd day after the beginning of TMP/SMX. Insulin and C-peptide levels were measured, with values of 99 uUI/ml (< 30) and 20 ng/ml (1–7.6), respectively, which were compatible with endogenous hyperinsulinism. TMP/SMX was suspended by the suspicion of iatrogenic hypoglycaemia. Glucose infusion was maintained for 2 days, without any further hypoglycaemic episodes. Ten days after the suspension of TMP/SMX, insulin (8.5 uUI/ml) and C-peptide (5.8 ng/ml) levels were back to normal.
Conclusion
High levels of C-peptide during the episode of hypoglycaemia confirm endogenous insulin secretion. TMP/SMX associated hypoglycaemia can occur in the presence of risk factors, such as high dosage and compromised renal function. Renal dysfunction can lead to decreased drug clearance, leading to gradual accumulation and manifestation of symptoms after a few days. After suspension, difficulty in reversing the hypoglycaemia was not only due to the half-life extension but also because of dose-dependent side effect.

A giant GIST of the greater omentum in a female transsexual patient, hopefully not a side effect of hormonal therapy

Paula Gonzalez-Diaz[1], Ricardo de Leon-Durango[2], Alba Hernandez-Lazaro[2], Paula Maria Fernandez-Trujillo-Comenge[2], Agnieszka Kuzior[3], Carmen Acosta-Calero[3], Yanina Elizabeth Velazquez[2], Esther Hernandez-Felipe[5], Maria del Pino Perez-Garcia[6] & Francisco Javier Martinez-Martin[7]
[1]Centro de Salud de Arucas; [2]Hospital Universitario de Gran Canaria Dr. Negrín, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [3]Hospitales San Roque Meloneras, San Bartolome de Tirajana, Spain; [4]Centro de Salud Cueva Torres, Las Palmas de Gran Canaria, Spain; [5]Centro de Salud Guanarteme, Las Palmas de Gran Canaria, Spain; [6]Universidad de Las Palmas de Gran Canaria, Facultad de Ciencias de la Salud, Las Palmas de Gran Canaria, Spain; [7]Hospital Universitario de Gran Canaria Dr. Negrín, Outpatient Hypertension Clinic, Las Palmas de Gran Canaria, Spain

Introduction
Many transsexual patients are concerned about the risk of cancer associated with hormonal gender-affirming therapy. However, the general risk seems to be very low. We hereby report the case of a strikingly large gastrointestinal stromal tumor (GIST) in a male-to-female transsexual patient, after 25 years of hormonal therapy.
Methods
Review of the patient's clinical records and the relevant literature.
Background
GISTs are mesenchymal tumors arising from the smooth muscle pacemaker interstitial cell of Cajal. Most are gastric, but GISTs occurring elsewhere in the gastrointestinal tract have a higher malignant potential. About 85% derive for mutations in the KIT gene (encoding a receptor tyrosine kinase protein). They may present as intramural smooth muscle cell tumors, similar to uterine leiomyomas. However, these last tumors express estrogen and progesterone receptors and are hormone-dependent. On the other hand,

GISTs have nor been shown to express these receptors and are generally not considered as hormone-dependent. The mainstay of GIST therapy is surgery, but tirosin-kinase inhibitors such as imatinib are useful as adjuvants.
Case report
A 46 year-old female transsexual patient had been on estrogen plus antiandrogen since she was 20 years old; currently on 4.59 mg of estradiol (transdermal aerosol) and 75 mg of cyproterone acetate (oral) daily, maintaining suppressed LH and FSH, and testosterone and estradiol within the normal fertile female range. She had undergone bilateral augmentation mammoplasty but not genital reassignment surgery. Last year, she presented a large indolent abdominal mass, and the FDG PET-CT scan showed a giant GIST (size 196 mm transverse × 92 mm posteroanterior × 124 mm craniocaudal), centered in the greater omentum but contacting non-invasively also the stomach, the left liver lobe, the pancreas and the transverse colon. The affinity for FDG was low (SUVmax 3.04), similar to that of the hepatic parenchyma, suggesting a low grade of malignancy. There were no pathological FDG deposits outside the tumoral mass, with no suspicious adenopathies and no signs of liver, lung, adrenal or bone metastases. The patient underwent surgery and is currently being treated with imatinib. The tumor tested negative for estrogen and progesterone receptors, and following the patient's wishes the hormonal therapy has not been withdrawn.
Conclusion
A GIST has never to our knowledge been reported in a transsexual patient. Although the unusual size of our patient's tumor might raise concerns about the possible implication of the hormone therapy, there is no clear rationale for them.

Endocrine function in centenarians

Hassan Heshmati
Endocrinology Metabolism Consulting, LLC, Anthem, AZ, United States

Introduction
Centenarians are subjects living 100 years or older. They represent a model of successful aging. In 2020, the number of centenarians in the world was approximately 573.000. Multiple endocrine changes occur with normal aging. Most centenarians have managed to avoid, postpone, or overcome the important age-related and life-threatening diseases. The purpose of this review is to present the endocrine function in centenarians with special emphasis on two relevant endocrine glands in this population, the thyroid and the adipose tissue.
Methods
A systematic search of literature was conducted using the search terms centenarians, endocrine function, thyroid, thyroid hormones, thyroid-stimulating hormone (TSH), adipose tissue, and adipokines.
Results
According to most studies, free triiodothyronine (T3) levels decrease while reverse T3 and TSH levels increase with aging. There is also an increase in the levels of most adipokines produced by the adipose tissue (e.g., leptin, resistin, interleukin 6, tumor necrosis factor alpha, and adiponectin). Thyroid hormones play an important role in aging and lifespan. Lower thyroid hormone levels and higher TSH levels have been reported to be associated with increased longevity. Centenarians have higher TSH levels compared to controls, partly due to a genetic background. The elevated levels of pro-inflammatory adipokines (e.g., interleukin 6 and tumor necrosis factor alpha) can negatively impact aging and lifespan by promoting chronic diseases (e.g., obesity, type 2 diabetes, and ischemic heart disease). In contrast, elevated levels of adiponectin (anti-inflammatory adipokine) can be beneficial for lifespan. High adiponectin levels may represent a compensatory response to limit oxidative stress and inflammation. Adiponectin levels are elevated in centenarians and may explain the favorable metabolic phenotype of these individuals.
Conclusion
Hormones influence the aging process and longevity. Centenarians have higher TSH and adiponectin levels compared to controls. High TSH is likely related to a favorable outcome in centenarians regardless of its underlying mechanism. High adiponectin may contribute to extended longevity of centenarians.

Potential endocrine markers of severity and outcomes in critical patients with COVID-19

Volha Isachkina[1] & Larissa I. Danilova[2]
[1]10th City Hospital, Endocrinological, Minsk, Belarus; [2]Belarusian Medical Academy of Postgraduate Education, Endocrinological, Minsk, Belarus

Background
The current COVID-19 pandemic is the worst from world infection outbreaks have occurred frequently in the last two decades, and it has led to significant mortality. Although the respiratory system is the most prominent target of SARS-CoV-2, extrapulmonary involvement are important contributors of its morbidity and mortality. A number of symptoms occur in these patients due to the involvement of various endocrine glands. The nervous, endocrine, and immune systems contribute to the response and dynamic adaption to various stresses. Activation of the hypothalamic-pituitary-adrenal axis has been demonstrated in various active critical illnesses. Looking for potential endocrine markers appears to be useful for obtaining information of severity and outcomes in critical patients with COVID-19.
Materials and methods
Prospective descriptive study of critical patients with COVID-19 admitted to the ICU of the hospital from October, 2020, to January, 2021, including hormonal markers and mortality.
Results
In this study, a total 82 of critical patients with COVID-19 in the ICU were enrolled. Dehydroepiandrosterone Sulfate (DHEA-S), total testosterone, SHBG levels were measured in serum of patients. The mean age was 60.4 (standard deviation (SD) 8.7) years, the number of men was 63.4% percent. Regarding outcomes, 46.3% patients with COVID-19 died in the ICU. Mortality consists 38.4% vs 60% in men and women respectively. There are no significant differences in DHEA-S and SHBG levels in died and recovered women with COVID-19. As to men with COVID-19 there are no significant differencse in SHBG levels (21.29 (SD 12.59) nmol/l vs 34.45 (SD 24.53 nmol/l) and in DHEA-S levels (59.06 (SD 37.32) mkg/dl vs 62.03 (SD 33.34) mkg/dl) in died and recovered patients respectively. The mean levels of total testosterone were 2.41(SD 1.83) nmol/l in died patients vs 9.87(SD 6.88) nmol/l in recovered ones ($P < 0.001$).
Conclusion
We expect that the total testosterone may be a useful endocrine marker for poor prognostic outcomes for men with COVID-19 because of its strong association with risk of death.

Drinking only when thirsty or when eating solids can normalize serum sodium levels in most patients with SIADH and a high fluid intake, regardless of Urine Osmolarity

Mario Pazos, Jorge Gabriel Ruiz Sánchez, Xavier Pérez Candel, Martín Cuesta Hernández, Celia Lopez Nevado, Raquel Pallarés, PATRICIA ESPINOSA DE LOS MONTEROS, Fernando Hernández Olmeda, Alfonso Calle & Isabel Runkle
Hospital Clínico San Carlos, Endocrinology and Nutrition, Madrid, Spain

Introduction
Institutional campaigns, and some health care professionals, encourage the elderly to drink large quantities of fluids, regardless of their level of thirst. Furthermore, SIADH-inducing medications can often cause dryness of mouth. Thus, patients when diagnosed with SIADH can have a high fluid intake (FI), drinking in the absence of thirst. However, fluid restriction, considered the first step in therapy of mild/moderate SIADH hyponatremia, has a poor evidence base, shows an irregular response, can interfere with the intake of protein in solid foods, and should not be used in intense heat. We studied the response of SIADH patients with a history of drinking large volumes of fluids without thirst (HHFI) to simple 'hygienic' fluid intake (HFI) measures.
Methods
Retrospective study of 34 patients diagnosed with SIADH and HHFI in a monographic hyponatremia outpatient clinic of a University hospital in Madrid, Spain. HFI: patients were instructed to drink only when thirsty, unless eating solids, and rinse without swallowing when dryness of the mouth and not thirst was present. Those attaining eunatremia were classified by Urine Osmolality (UOsm). Patients with Primary Polydipsia

(UOsm ≤ 100 mOSm/kg) were excluded. Serum Sodium (SNa) in mmol/l. UOsm in mOsm/kg. Eunatremia was defined as a SNa 135–145. SPSS 25.
Results
Mean age 72 (SD: 15) years, 20/34 (58.2%) women. Nadir SNa: 123 (SD: 6.7). The initial daily fluid Intake ranged from 2.5–10 l, median: 3.2 l [IQR 2.99–4.00]. Mean SNa at the start of HFI: 130 (SD: 5). Following HFI, 26/34 (76.5%) attained eunatremia: mean SNa 138.7 (SD: 3) $P < 0.01$. When classified by UOsm at diagnosis, eunatremia was achevied by 8/10 (80%) with UOsm 101–200; by 5/9 (56%) with UOsm 201–280; by 8/10 (80%) with UOsm 281–600, and 3/5 (60%) with UOsm > 600. When a UOsm cut-off point of 280 was used, 14/19 (73.6%) with UOsm 101–280 reached eunatremia, and 11/15 (73.3%) with UOsm > 280. In no patient was nutritional status worsened. 8/10 non-responders were treated with tolvaptan, achieving eunatremia. 2/10 non-responders were lost to follow-up.
Conclusions
Some SIADH patients at diagnosis have a history of drinking large volumes of liquids in the absence of thirst. Instruction directed towards limiting fluid intake to drinking when thirsty and at meals, as well as distinguishing between thirst and dryness of mouth, can permit attainment of eunatremia in a majority of these subjects, regardless of UOsm at diagnosis.

Congenital adrenal hyperplasia due to 3 beta hydroxysteroid dehydrogenase deficiency About two cases

Samira Belkacem
Endocrinology, Pierre Marie Curie Center, of Medecine, Algiers, Algeria

Introduction
3ßeta Hydroxysteroid Dehydrogenase (3ß HSD) deficiency is a very rare autosomal recessive disorder affecting the synthetic pathways of all active steroids in the adrenals and gonads.
Observation
The 4-year-old child M.A and his 8-year-old sister M.M, from a consanguineous marriage, with a family history of sexual ambiguity. The clinical examination found a sexual ambiguity in the boy: – micro penis; scrotal hypospadias with a single orifice; – scrotum bifid normally wrinkled and pigmented; – absence of palpable gonads in the bursae Concept of salt loss syndrome at the age of 1 month associated with hypomasculinization of the external genitalia. Hormonal exploration: high ACTH levels, low cortisol and testosterone, high SDHEA.

	Before treatment	After treatment
ACTH (pg/ml)	27 165	215
Cortisol 8 h nmol/l	158	3.12
17OHP (ng/ml)	22.8	0.65
SDHEA (ug/dl)	78.20	4.89
Testo (nmol/l)	7.83	0.06

Genitography
Mullerian residue of 18 mm ending in the bulbar urethra.
Barr test
Barr corpuscles: 0%; test in favor of a genetically male sex. Karyotype: 46XY. – Patient put on 10 mg of hydrocortisone and 9 alpha fludrocortisone. – He is referred for childhood surgery for the treatment of hypospadias. For sister Manel: a salt loss syndrome which appeared at birth without sexual ambiguity, treated with hydrocortisone and at 5 years old, onset of precocious pseudo puberty with acceleration of bone age, pubertal stage S2P2, Genitography: female urethra, karyotype: 46 XX. High ACTH (1122 pg/ml), low cortisol (4.64 nmol/l), 17OHP (0.33 ng/ml), SDHEA (8.21 mg/dl); testo (0.26 nmol/l). Put on hydrocortisone 20 mg/day and 9 alpha fludrocortisone.
Discussion
(3ß HSD) deficiency is a very rare form of congenital adrenal hyperplasia encompassing the forms with loss of salt and without loss of salt with a broad clinical spectrum including glucocorticoid deficiency and under-virilization in men manifested by micropenis and severe perineo-scrotal hypospadias. The prevalence is unknown due to the great rarity of the disease. Boys have different levels of under-virilization at birth. In both sexes, the salt loss forms lead to symptoms of dehydration and hypotension in the first weeks of life which can be fatal.The disease is caused by mutations in the HSD3B2 gene located on chromosome1p13.1.
Conclusion
The deficit of 3B HSD has benefited from advances in biochemistry and molecular biology which have opened up new perspectives in the field of pathophysiology, genetic determinism, diagnosis and antenatal treatment.

Analysis of glycemic variability in patients with diabetes mellitus type 2

Elena Makhlina & Yana Navmenova
SI << The Republican Research Center for Radiation Medicine and Human Ecology >>, Endocrinology, Gomel, Belarus

Objective
To identify risk factors affecting the severity of glycemic variability indicators in patients with diabetes mellitus type 2.
Materials and methods
The study included 92 patients with diabetes mellitus type 2 and an average age of 62.25 ± 9.52 years. A biochemical blood test was performed on an automated Cobas 6000 system. To assess the glycemic variability, the standard deviation (SD, mmol/l), the coefficient of variation (CV,%) and the mean amplitude of glycemic excursion (MAGE, mmol/l) were determined. Statistical processing of the data array was performed using the statistical program MedCalc v.11.6.0.0. (MedCalc Software Inc.). The level $P < 0.05$ is considered as a criterion for the statistical confidence of the results.
Results
According to the results of logistic regression, BMI has a greater effect on CV (RR = 0.83; 95% CI 0.75–0.32 $P = 0.002$), SD (RR = 0.90; 95% CI 0.83–0.97, $P = 0.009$), MAGE (RR = 0.89; 95% CI 0.81–0.97, $P = 0.014$) than the experience of type 2 diabetes mellitus on CV (RR = 1.10; 95% CI 0, 99–1.21 $P = 0.053$), SD (RR = 1.09; 95% CI 0.99–1.19, $P = 0.05$), MAGE (RR = 1.06; 95% CI 0, 97–1.16, $P = 0.136$) and the level of TG on CV (RR = 0.53; 95% CI 0.27–1.05 $P = 0.070$), SD (RR = 0.80; 95% CI 0, 57–1.10, $P = 0.176$), MAGE (RR = 0.83; 95% CI 0.57–1.20, $P = 0.335$). A decrease in BMI increases the degree of manifestation of GV indicators by an average of 1.1 times. The threshold value of BMI was 28.6 kg/m^2 for CV AUC = 0.77 (sensitivity 64.0% [95% CI 42.5; 82.0], specificity 88.0% [95% CI 77.8; 94.7], $P = 0.002$), for SD AUC = 0.69 (sensitivity 41.67% [95% CI 27.6; 56.8], specificity 90.9% [95% CI 78.3; 97.5], $P = 0.0003$), for MAGE AUC = 0.68 (sensitivity 46.8% [95% CI 29.1; 65.3], specificity 86.4% [95% CI 75, 0; 94.0], $P = 0.0021$).
Conclusions
A risk factor that increases glycemic variability is a BMI less than 28.6 kg/m^2. A decrease in BMI increases the degree of manifestation of GV indicators by an average of 1.1 times.

Insulinoma during pregnancy: A case report

Elyes Kamoun[1,2], Sabrine Mekni[1,2], Chayma Besrour[1,2], Imen Rojbi[1,2], Nadia Mchirgui[1,2], Youssef Lakhoua[1], Ibtissem Ben Nacef[1,2], Ouertani Haroun[2,3] & Karima Khiari[1,2]
[1]Hospital Charles Nicolle, Tunis, Tunisia; [2]Medical School of Tunis, Tunis, Tunisia; [3]The Military Hospital of Tunis, Tunis, Tunisia

Introduction
Insulinoma is a rare neuroendocrine tumor with an incidence of 1 to 4 per million person-years. It is the most frequent endocrine tumor of the pancreas and is revealed by a spontaneous hypoglycemia in the absence of insulin or any antidiabetic medication.Only few cases of confirmed insulinoma with pregnancy have been described in the literature. We describe a case of insulinoma discovered early in pregnancy.
Case report
A 24-year-old woman was admitted in our department at 12 weeks of gestation for morning asthenia and loss of conscience, with glycemia inferior to 0.5 g/l. Endogenous hyperinsulinic hypoglycemia was confirmed with a spontaneous hypoglycemia and laboratory blood glucose at 0.41 g/l, a concomitant insulinemia at 6.4 µUI/ml (≥ 3), C-peptide levels at 2.01 ng/ml (≥ 0.6) and absence of sulfonylurea. Localization was assessed by a pancreatic MRI concluding to a 10 mm tumor in the head of the pancreas, with low-signal intensity on T1-weighted images and high-signal intensity

on T2-weighted images. A complementary investigation by an endoscopic ultrasound identified 11 * 13 * 8 mm tumor in the head of the pancreas. The patient was operated on at 17 weeks of gestation. The tumor was removed by enucleation during an open surgery. Histologic and immunohistochemical reports concluded to a 15 mm well differenciated neuroendocrine tumor with no angioinvasion. Immediate post-operative follow up was marked by a pancreatic fistula persistent during 5 weeks, treated by drainage. In long-term follow-up, she no longer had hypoglycemia and gave birth at 40 weeks of gestation to a healthy girl weighting 4 kg.
Conclusion
This case highlights a rare clinical presentation of an insulinoma. The confirmation of the diagnosis is through the same biologic investigations than the non-pregnant population. The delay between diagnosis and treatment should be short in order to prevent foetal hypoglycemia.

Insulinoma: a challenge for a diagnosis

Elyes Kamoun[1,2], Sabrine Mekni[1,2], Chayma Besrour[1,2], Imen Rojbi[1,2], Nadia Mchirgui[1,2], Youssef Lakhoua[1], Ibtissem Ben Nacef[1,2] & Karima Khiari[1,2]
[1]Hospital Charles Nicolle, Tunis, Tunisia; [2]Medical School of Tunis, Tunis, Tunisia

Introduction
Insulinoma is the most frequent endocrine tumor of the pancreas and a diagnosis challenge in all cases of spontaneous hypoglycemia. The confirmation of hypoglycemia is the first step of the diagnosis before initiating the complementary investigations to confirm the insulinoma and determine its localization. The aim of this study was to investigate the diagnosis of insulinoma in a setting of organic hypoglycemia.
Methods
We performed a retrospective study of 38 adults in patients presenting with spontaneous hypoglycemia over a 19-year period. Hypoglycemia was confirmed when blood glucose levels were inferior to 0.45 g/l, insulinemia and C-peptide were elevated if respectively superior to 3 µUI/ml and 0.6 ng/ml.
Results
Ten patients were included with a confirmed hyperinsulinic hypoglycemia, with a sex ratio of 3/7. The mean age was 41 ± 15 years. Neurogenic and neuroglycopenic symptoms were present respectively in 9 and all cases. Fasting hypoglycemia was present in 6 cases, after physical activity in one case and at any time in 3 cases. Hypoglycemia was obtained spontaneously in 6 cases with mean hypoglycemia at 0.27 g/l, mean insulinemia at 118.6 µUI/ml and mean C-peptide at 32.01 ng/ml. Hypoglycemia was obtained after a supervised fast test in 4 cases, with hypoglycemia obtained after a mean of 3 hours. Mean hypoglycemia was 0.28 g/l, mean insulinemia was 29.8 µUI/ml and mean C-peptide was 5.13 ng/ml. Sulfonylureas weren't detected in all patients. In imaging investigations, abdominal ultrasonography was normal in the 6 patients it was performed on. Abdominal CT scan was performed in 8 patients and found a tumor in 3 cases. Abdominal MRI was performed in 7 patients, was normal in 3 cases and found a tumor in 4 cases. Endoscopic ultrasound was performed in 8 patients, was normal in 3 cases and found a tumor in 5 cases. It found a tumor in the 4 patients with a tumor in the MRI with a patient whose tumor was only diagnosed with endoscopic ultrasound. The tumors confirmed by CT scan weren't found by other imaging means. CT scan and endoscopic ultrasound were enough to found the localization in the 8 patients with confirmed localization before surgery.
Conclusion
The diagnosis of insulinoma is easily confirmed when the hypoglycemia is confirmed and allowing all biology investigations. The challenge remains in the localization as no imaging procedure was enough on its own to confirm localization, and even with all procedures, localization wasn't found in 2 cases, confirming therefore the difficulty of pre-operative investigations.

A case report of cerebral salt wasting incorrectly diagnosed as the syndrome of inappropriate antidiuretic hormone secretion

Mohammed Qayum[1], Tavlene Banwaith[1], Ghulam Nawaz[1], Jayashekara Acharya[1] & Veena Sudarshan[2]
[1]Hereford County Hospital, Hereford, United Kingdom; [2]University of Buckingham Medical School, Buckingham, United Kingdom

Cerebral salt wasting (CSW) occurs as the result of injury to the central nervous system and is most commonly found among those who have experienced a traumatic brain injury (TBI). Although incidence is varied, it has been reported to be as high as 30% within the patient population presenting to hospital with a TBI. CSW causes hyponatremia with concurrent hypovolemia and increased sodium within urine despite normal renal function. Because of its rare nature, CSW is often misdiagnosed as the syndrome of inappropriate antidiuretic hormone secretion (SIADH). Misdiagnosis of CSW occurs at increased rates within healthcare setting wherein the condition is rarely encountered – as with the current case who presented to a district general hospital. This can have a deleterious impact upon patient outcomes, as the conditions require the introduction of treatment regimens that are the opposite of each other. SIADH calls for fluid restriction, while CSW and its accompanying hypovolemia require sodium and fluid repletion. The following case report details an 81-year-old male patient who presented to a district general hospital following a fall that included trauma to the head and subsequent cerebral haematoma. Incorrectly diagnosed with SIADH, his condition continued to decline (including sodium levels as low as 124 mmol/l and a postural hypotension-induced syncopal episode) despite receiving appropriate treatment for his initial diagnosis. Following a consultation with an endocrinologist, his diagnosis was changed from SIADH to CSW and treatment with > 3 l/day with IV normal saline (0.9% solution) was administered. The patient was also advised to eat and drink as normal. After two days on this regimen, his sodium levels increased to 131 mmol/l and an increase in blood pressure alleviated his postural hypotension. After 27 days in the hospital, the patient achieved normal sodium levels and was discharged with advice to monitor his sodium levels via monthly monitoring with his general practitioner. At follow-up, the patient had maintained healthy sodium levels and an MRI of his head revealed resolution of the cerebral haematoma. Despite CSW and SIADH both causing hyponatremia, their etiologies hold important differences and, consequentially, their treatment requirements should be considered mirror images of each other. In order to effectively diagnose and treat patients with either CSW or SIADH, the awareness of both conditions must be increased among healthcare professionals.

Myasthenia during multiple autoimmune syndrome: About two observations

Mouna Elleuch[1], Dhoha Ben Salah[2], Nadia Charfi[3] & Abid Mohamed[2,3]
[1]Hedi Chaker Hospital, Internal Medicine, Sfax, Tunisia; [2]Hedi Chaker Hospital, Endocrinology and Diabetes, Sfax, Tunisia; [3]Hedi Chaker Hospital, Endocrinology Department, Sfax, Tunisia

Introduction
Multiple autoimmune syndrome (MASI) is a rare entity, defined by the presence of at least three autoimmune diseases in the same person. We report two specific observations of myasthenia gravis in the context of an SAIM3.
Observation 1
A 58-year-old man initially presented bilateral ptosis, difficulty chewing and swallowing, dysphonia and fatigability. Myasthenia gravis was suspected due to the aggravation of this complaints with effort and confirmed by prostigmine test and EMG which showed a post-synaptic block in the neuromuscular junction. The diagnosis of hypothyroidism was suggested by mucocutaneous infiltration and constipation and confirmed by a TSH elevated to 100IU/ml with a low FT4 of 5 pmol/l. It was hypothyroidism secondary to Hashimoto's thyroiditis with highly positive antithyroglobulin and Anti thyroperoxydase antibodies. The onset of melanoderma and hypotension suggested adrenal insufficiency, confirmed by low basal cortisolemia at 53 ng/ml and insufficient response to synactene 250g to 150 ng/ml after optimal thyroid hormone substitution. Anti-adrenal Antibodies were negative. The cervico-thoracic CT scan ruled out the presence of a thymoma. The diagnosis of SAIM type 3 was retained. The patient was trated by Mestinon, Cortef and Levothyroxine. The evolution was favorable.
Observation 2
A 14 year old patient, initially hospitalized for ptosis, asthenia and thermophobia. Clinical examination showed bilateral ptosis, ophthalmoplegia with limitation of lateral and vertical movements. The diagnosis of myasthenia gravis was made by a positive prostigmine test: correction of the deficiency within a few minutes after VILI injection of an ampoule of prostigmine. The electro-neuro-myogram was in favor of the diagnosis of myasthenia gravis. Anti-acetylcholine receptor antibodies were positive. Clinical examination of the patient also showed weight loss, fine tremors of the extremities, tachycardia and glare. The diagnosis of hyperthyroidism was confirmed

by an elevated FT4 of 27.8 pmol/l (8.6–25 pmol/l) and a braked TSH of 0.001 mU/l. This hyperthyroidism was related to Hashimotoxicosis guiven the positivity of anti thyroglobulin and anti thyroperoxydase antibodies. Signs of hypocorticism such as asthenia, weight loss, melanoderma and hypotension were objectified. Addison's disease was confirmed by low baseline cortisolemia at 37.4 ng/ml and positive adrenal antibodies. The patient was treated with prostigmine 240 mg/dr, cortef 15 mg/dr and radioactive iodine for her hyperthyroidism with good evolution.
Conclusion
The association of the different autoimmune diseases reflects the presence of a common genetic ground on which environmental factors determining clinical aspects are grafted.

Association of Hadju Cheney syndrome with adrenal insufficiency in a diabetic patient: A rare association

Najoua Lassoued[1], Ajili Rihab[1], Rebai Senda[1], Arfa Sondos[2], Zantour Baha[1] & Sfar Mohamed Habib[1]
[1]Taher Sfar University Hospital, Endocrinology Department, Mahdia, Tunisia; [2]Taher Sfar University Hospital, Internal Medecine Department, Mahdia, Tunisia

Introduction
Hadju Cheney syndrome (HCS) is a rare progressive and debilitating genetic disorder that is characterized by a high degree of phenotypical pleiotropy. We report the first clinical case of a 44-year-old patient with HCS, diabetes and adrenal insufficiency (AI).
Observation
A 44-year-old patient with a history of myocardial infarction at the age of 33 and diabetes for 2 years on oral antidiabetic drugs is admitted for switching to insulin therapy. On examination, he had short stature, facial dysmorphism, early tooth loss with diffuse acroosteolysis on standard radiograph. The biological assessment showed a normal phosphocalcic balance. Bone densitometry showed diffuse osteoporosis. The renal ultrasound and the cardiac ultrasound were without abnormalities. Faced with the characteristic polymalformative syndrome, the diagnosis of HCS has been made and the genetic study looking for a mutation in the NOTCH2 gene is underway. In addition, the patient presented repeated episodes of hypoglycemia during his hospitalization with an inappropriate cortisolemia at the time of the hypoglycaemia, which allowed us to retain the diagnosis of AI very probably of central origin. The patient was put on hydrocortisone.
Discussion
HCS is a rare genetic skeletal syndrome. The diagnosis of this syndrome was made in our patient based on the characteristic clinical features and imaging findings in hands, feet and skull. Recently it has been shown that restricted range of mutations in the terminal exon of NOTCH 2 causes this syndrome. There has been no report about the linking of HCS and DM, although several studies addressed the pancreas and Notch signaling. Discussing the type of diabetes in our patient was therefore a bit difficult, we ruled out type 1 diabetes as well as mitochondrial diabetes. Type 2 remains the most likely with rapid recourse to insulin therapy. In addition, cranial dysplasia can be the cause of pituitary insufficiency which could explain the adrenal insufficiency in our patient. However, there was no other pituitary insufficiency.
Conclusion
Until this case, there has been no reported case of HCS with DM and AI. The present case indicates that there may be a link between HCS and DM in regard to the mutation of NOTCH2. Confirmation awaits further studies of the relationship between insulin secretion and NOTCH2 signaling.

AEP442

Corticosteroids – 70 years of balancing between good and bad

Sanja Borozan & Snezana Vujosevic
Clinical Centre of Montenegro, Department of Endocrinology, Podgorica, Montenegro

When in September 1948 the 'Compound E' was first synthesized and successfully administered as intramuscular injection to a woman with rheumatoid arthritis, hardly that anyone could imagine what profound impact it will have on medical research and practice. In a span of just two years, in 1950, the fascinate drug was renamed to Cortisone and brought from laboratory to broad clinical use. Seventy years later, it is still hard to find a medical field where corticosteroids are not present due to several roles they play in the human body. Corticosteroids are the cornerstone of therapeutical approach in wide spectrum of antinflammatory and autoimmune-based diseases and one among ten most commonly prescribed and over-the-counter drugs. However, from the very beginning to nowadays, the limiting factor regarding their use are side effects. Back to 1948, the reports are saying that after a couple months of continuous therapy with cortisone, the first patient was admitted to psychiatry clinic for comprehensive assessment and treatment of psychotic episodes. Description of side effects along with development of new cortisone derivates in order to minimise toxicity and improve potency shaped the next decades in corticosteroid timeline. The occurrence and magnitude of corticosteroid side effects is time and dose-dependent, following either linear or threshold dose-response pattern. Their extensive use in chronic conditions along with awareness about disadvantages triggered highly innovative research and expansion of new preparations for local administration. Prescribing corticosteroids via inhaled, topical dermal, intra-articular, epidural, intranasal or periocular route, particularly when used at high doses, allows us to target specific problem, diminish system resorption and consequently side effects, ranging from mild suppression of hypothalamic-pituitary axis to life-threatening infections. Corticosteroids inspire and teach. While search for corticosteroid preparations with even better risk-benefit profile continues, their use in chronic inflammatory and autoimmune diseases requires rationality in determining the optimal therapeutical regimen, convenient tapering schedule and often a skilled balancing between desired and side effects.

Monitoring of patients on high-dose long-term steroids in a rheumatology outpatient service

Sinead Cadogan & Sharon Cowley
The Mater Misericordiae University Hospital, Ireland

Introduction
Corticosteroids play an essential role in the management of many rheumatic diseases. However, corticosteroids are associated with many adverse effects, including hyperglycaemia, dyslipidaemia, and osteoporosis. These adverse effects are dose related and patients on high dose, long term steroids (defined as > 5 mg oral prednisolone and treatment duration > 3 weeks) are at greatest risk. NICE guidelines on corticosteroids recommend monitoring of HbA1c, triglycerides, and potassium for all patients on long term steroids1. Regarding osteoporosis risk, it is recommended that all adults who are expected to be on prednisolone ≥ 5 mg/day (or equivalent) for over 3 months have bone mineral density assessed three-yearly[2].
Aims
To examine whether Hba1C, potassium, and lipid profile are monitored amongst rheumatological patients on steroids, and to assess whether these patients have had bone mineral density assessed within the previous 3 years by means of dual energy X-ray absorptiometry (DEXA).
Materials and methods
This retrospective audit examined the records of 442 patients attending rheumatology clinics in Mater Misericordiae University Hospital, Dublin, Ireland over a 4-week period in November 2020.
Methods and results
Fourteen percent (n = 62) of patients were on high dose long term steroids. Seventy-one percent (n = 44) were female, 29% male (n = 18), with a median age of 63 years. The most common conditions encountered were rheumatoid arthritis (22% n = 14), giant cell arteritis (21% n = 13), polymyalgia rheumatica (18%, n = 11), systemic lupus erythematous (6% n = 4), large vessel vasculitis (5% n = 3), mixed connective tissue disease (5% n = 3) Bechet's (5% n = 3) and others (18% n = 11). All patients were on prednisolone and the mean dose was 8.7 mg. The median duration of treatment was 24 months. Ninety seven percent of patients (n = 60) had potassium checked within the preceding 12 months. Fifty percent (n = 31) had triglycerides checked, 52% (n = 32) had Hba1C checked. The average Hba1C level was 42.4 mmol/mol. Forty three percent (n = 14) had Hba1c in the range of 42–47, while 16% (n = 5) had a Hba1c ≥ 48. The majority of patients (69%, n = 43) had undergone DEXA scanning, with an average recorded T score of –1.47.
Conclusions
Corticosteroids have a significant role to play in the management of many rheumatic conditions. Prescribers need to be aware of the many associated adverse effects and monitor for the presence of these effects accordingly.

Vitamin D deficiency in young adults and the question of the need for early replacement for the primary prevention of osteoporosis

Tatjana Bačun[1,2], Ivan Lekić[1], Jelena Šarić[1], Barbara Bačun[3], Željko Debeljak[1,4], Dunja Degmečić[1,5] & Vatroslav Šerić[1,4]
[1]Josip Juraj Strossmayer University of Osijek, Faculty of Medicine, Osijek, Croatia; [2]Clinical Medical Center Osijek, Division of Endocrinology, Department of Internal Medicine, Osijek, Croatia; [3]Josip Juraj Strossmayer University of Osijek, Faculty of Dental Medicine and Health, Osijek, Croatia; [4]Clinical Medical Center Osijek, Institute of Clinical Laboratory Diagnostics, Osijek, Croatia; [5]Clinical Medical Center Osijek, Division of Integrative Psychiatry, Department of Psychiatry, Osijek, Croatia

Introduction
Low concentrations of vitamin D are associated with decreased calcium absorption, negative calcium balance, and compensatory growth of parathyroid hormone, resulting in excessive bone resorption. The first step in preventing osteoporosis is to ensure a proper diet, especially calcium and vitamin D intake.
Aim of the study
The aim of this study was to determine the concentration of 25-hydroxyvitamin D3 (25-OH-D3) in Eastern Croatia in subjects aged 18 to 25 years at the end of winter and to examine whether there is a difference according to gender and compare the results with reference values.
Subjects and methods
The study was conducted on a sample of 59 subjects, with an average age of 23 years, of which 27 were men (45.8%) and 32 women (54.2%). Blood was drawn and centrifuged at 3.000 rpm for 10 minutes. After centrifugation, serum was collected, and the sample was analyzed by liquid chromatography combined with mass spectrometry (LC-MS/MS).
Results
The mean concentration of 25-OH-D3 was 16.36 ng/ml (SD 5.68; range 4.90 to 28.60). Men had a statistically significant higher concentration compared to women (18.96 vs. 14.16 ng/ml, p 0.01). The concentration was lower than the reference value (20 to 100 ng/ml). Only 28.8% of subjects (44.4% men and 15.6% women) had values greater than 20 ng/ml.
Conclusion
As many as 71.2% of young adults had vitamin D deficiency at the end of the winter period. Women had statistically significant lower concentrations. The observed deficit indicates the need to determine the optimal intake of 25-OH-D3 for the purpose of osteoporosis prevention. It is necessary to conduct research on a larger number of examinees over a longer period with monitoring of outcomes.

An audit of Multiple Endocrine Neoplasia type-1 (MEN-1) surveillance

Sing Yang Sim & Ma'en Al-Mrayat
University Hospital Southampton, Diabetes and endocrinology, Southampton, United Kingdom

Introduction
Multiple Endocrine Neoplasia type-1 (MEN-1) is an inherited autosomal dominant condition with a high degree of penetrance characterized by tumour occurrence in the form of pancreatic neuroendocrine (pNET), parathyroid and anterior pituitary gland tumours, among others. Treatment for MEN-1 associated endocrine tumour, particularly pancreatic, is more challenging than in those without MEN-1, given its multicentric nature and aggressive behaviour. Hence early detection through targeted surveillance is paramount.
Aim
The aim of the audit is to compare our surveillance of MEN-1 patients and benchmark against published guidelines.
Methods
We performed a search for patients with a diagnosis of MEN-1 using our hospital electronic records (notes, laboratory and radiology) and collected data retrospectively. We looked at the radiological and biochemical surveillance and their frequency.
Results
A record of 15 patients with a diagnosis of MEN-1 was found (males 4/15 (27%) and females 11/15 (73%). 13/15 (87%) had annual calcium profile and one at 3 years. For parathyroid hormone (PTH) 11/15(73%) had annual measurements, 3/15(20%) had 3 yearly profile. Screening frequency for fasting gut profile for 1 year, 2 years, 3 years were 9/15(60%), 2/15(13%) and 3/15(20%), pancreatic cross-sectional imaging were 7/15 (47%), 2/15 (13%) and 2/15(13%) respectively. The majority of patients had plasma prolactin and insulin-like growth factor 1 (IGF-1) checks annually 11/15 (73%) and 3/15 (20%) once every 3 years. For pituitary MRI surveillance: 10/15 (67%) were screened within the recommended 3–5 years timeline while 33% had longer interval between scans.
Conclusions
Overall our audit shows good compliance with existing MEN-1 guidelines, with our cohort of patients being regularly screened for the development of primary hyperparathyroidism, pNET and pituitary tumours. To improve this further our MEN-1 patients are now being reviewed in specialised clinics.

Attitudes of physicians towards the guideline-recommended LDL target levels in diabetic dyslipidemia

Naime Afşar Satiń & Dilek Gogas Yavuz[2]
[1]Marmara University Research And Education Hospital, Internal Medicine, İstanbul, Turkey; [2]Marmara University Research And Education Hospital, Endocrinology and Metabolism, İstanbul, Turkey

Aım
The aim of this study is to investigate the attitude of physicians, who are specialized in internal medicine, endocrinology, nurology and cardiology, on LDL target levels and antilipidemic treatments in Turkey.
Methods
This study outlines attitudes of physicians towards the guideline-recommended LDL target levels in diabetic dyslipidemia. An invitaiton to fill a questionnaire on demographic and profession characteristics as well as attitudes towards the guidelines. 564 physicians filled the questionairre.
Results
42.2% of the physicians participating in the survey are between the ages of 30–39 and 0.9% of them are over 70. 27.1% of them have been working as a physician for 5–10 years and 12.9% for 15–20 years. 55% of the physicians' profession are internal medicine, 27.1% endocrinology, 10.1% cardiology and 7.8% neurology. 95.2% of the physicians stated that they had been taking the guideline recommendations as reference and TEMD(Turkey Endocrinology and Metabolism Association) and ACC/AHA(American College of Cardiology/American Heart Association) guidelines were the most considered guidelines. While the majority agrees that LDL level is a risk factor for cardiovascular disease, 0.9% of the physicians are not sure and 0.7% of them disagree. 13% of the physicians disagree with the view of 'routine statin therapy should be initiated in high risk type 2 diabetic patients'. Although guidelines recommend keeping LDL below 55 mg/dl with high dose statin therapy in type 2 diabetic patients with cardiovascular disease, 8% of physicians do not agree with this recommendation. 30.2% of the physicians aim the LDL level < 55 mg/dl for the patients with type 2 diabetes accompanied by progressive atherosclerotic cardiovascular disease. 55.8% of those physicians are specialized in internal diseases. Only 9.3% of physicians aims LDL level < 55 mg/dl for the patients with type 2 diabetes accompanied by chronic renal failure. 40.3% of them are specialized in internal diseases. 28% of the physicians do not agree with the suggestion that statin therapy should continue for life.

Conclusions
Although physicians affirm that they follow the guidelines, LDL target level recommendations in current guidelines are not seem to be adopted. The guidelines recommend low LDL target levels, while physicians keep target levels higher.

Biological activity of thrombopoietin receptor agonists: development of *in vitro* functional and binding assays

Artem Dorotenko, Valeria Saparova, Alina Afanaseva, Igor Makarenko & Roman Drai
LLC 'Geropharm', Saint-Petersburg, Russian Federation

Introduction
Nowadays thrombopoietin receptor agonists (TPO-RAs) represent a promising approach for the patients with immune thrombocytopenia (ITP). Usage of two licensed TPO-RAs, romiplostim and eltrombopag, provide efficient support of ITP patients´ platelet count and, as a consequence, better control of disease. Both agents have an acceptable toxicity profile, but there are several another disadvantages in terms of usage of these drugs such as cost (especially for romiplostim), daily dosing (for eltrombopag) and specific adverse events. That´s why discovery of new TPO-Ras or development of similar products of existing TPO-Ras are emergent approaches to improve the life quality of ITP patients. The non-clinical development plan of both similar and new TPO-Ras should contain sensitive and specific *in vitro* pharmacology assays. Using two known TPO-Ras (recombinant human thrombopoietin (rhTPO) and romiplostim) in this study we have performed validation of the two *in vitro* assays to provide robust functional and binding data.
Methods
Romiplostim-TPO-R binding affinity was monitored with BLI technique using Octet RED96 instrument (ForteBio, Pall). In this study recombinant human thrombopoietin receptor with a C-terminal 6-His-tag (R&D Systems Inc.) was immobilized to anti-penta-HIS biosensors. Kinetic binding constants of romiplostim-TPO-R were determined through global fits using ForteBio Data Analysis. Association and dissociation rates were simultaneously fit to 1:1 ligand binding model to determine the affinity constant (KD) value. To evaluate functional effects of rhTPO murine 32D cell line expressed human TPO-R was developed. After transfection and during the development of stable and functional 32D-hTPO-R cell line clonal selection was performed. Presence of human TPO-R was determined using fluorescence-activated cell sorting analysis, Western blot analysis was used to evaluate TPO-R phosphorylation after rhTPO stimulation. Functional characterization of generated 32D-hTPO-R was performed in rhTPO-induced proliferation assay based on the CellTiter-Glo Luminescent Assay (Promega Corp.). EC50 values were analysed to measure functional proliferation response.
Results
In binding assay KD of romiplostim-TPO-R interaction was in 0.1228–0.134 nM range. In proliferation assay in 32D cells stable expressed functional human TPO-R for rhTPO EC50 was determined at 688 pg/ml. Both assays were validated in terms of main parameters such as linearity, specificity, precision. Acceptable degrees determined.
Conclusions
In this study our data demonstrated that binding and functional assays were well validated to receive robust data. Thus, *in vitro* pharmacology assays mentioned above can be used for the purpose of similar and new TPO-Ras drug development.

Parameters of successful telephone endocrinology consultation during covid-19 pandemic

Mitja Krajnc & Marija Kovše Krajnc
Maribor University Medical Centre, Department of Endocrinology and Diabetology, Maribor, Slovenia

Objective
The COVID-19 pandemic is an unseen international emergency causing major challenges in medical care delivery. Patients with some chronic endocrine disorders (obesity, type 2 diabetes, probably also hypertension, corticosteroid excess) have higher rates of acute COVID-19 complications and death. Due to the changes in outpatient management there is a clear danger of inadequate clinical support for endocrinology patients. The decision for face-to-face or remote consultation should be based on patient assessment. In our study, we aimed to identify parameters that define the success of a telephone endocrinology consultation.
Methods
By telephone, we performed a prospective study of 100 authors' consecutive patients of our institution's outpatient endocrinology clinic, scheduled for a regular visit. Thyroid and diabetic patients were not included. It was done during 2020 covid-19 pandemic from September to November. We defined a successful consultation as one leaving both a patient and a doctor with the overall feelings of success and satisfaction about its contents and way of interpersonal interaction (successful/unsuccessful). We collected data on patients' sex (M/F), age (20–40, 40–60, 60 + years), education (primary, secondary, higher), first or follow-up consultation, clinician's general assessment of the level of disease control (insufficient, sufficient), duration of consultation (less than 5, 5–15, more than 15 minutes). For statistical analysis, we performed chi-squared test based on the categories above using SPSS. Values of $P < 0.05$ were considered statistically significant.
Results
In 76% of our patients, a telephone consultation was considered successful. 56 females were included. 44 patients were older than 60, 48 were 40–60 years old. Sex, age, clinician's assessment of disease control and duration of consultation were not linked to the success of consultation ($P > 0.05$). Higher education and a previous face-to-face consultation were associated with success. 48 patients accomplished secondary and 22 higher education: χ^2 (2) 6.93, p 0.041. 31 patients had first and 69 follow-up consultation scheduled: χ^2 (1) 5.33, p 0.022.
Conclusion
In more than three quarters of our patients, a telephone consultation was assessed as successful by both a patient and a doctor during covid-19 pandemic. The success was associated with higher education level and previous face-to-face contact. Telephone consultations seem to be successful in most endocrinology patients while also being safe. In the future, the role of telephone consultations in outpatient setting should be better defined, especially in patients with higher risk of covid-19.

Role of estradiol and progesterone in fragmented sleep of castrated rats

Marisa Cabeza[1], Nayely Carrasco-Núñez[2] & Martha Romano[3]
[1]Universidad Autónoma Metropolitana Xochimilco Campus, Sistemas Biológicos, Ciudad de México, Mexico; [2]Universidad Autónoma Metropolitana Xochimilco Campus, Ciudad de México, Mexico; [3]Cinvestav, Fisiología, Ciudad de México, Mexico

Sleep is disturbed in both healthy and pathological aging, so it is essential to consider the role of ovarian hormones in both processes. Studies supporting the natural function of E2 (or elevated FSH) in fragmented sleep are inconsistent because when non-human animals have been used, they have mainly been male. Given this background, this study focused on determining the role of different estradiol and progesterone doses in the intermittent arousals of castrated rats maintained by two-month in controlled-conditions. These arousals were also determined in castrated rats without treatment and in sham-operated rats as experimental controls. The treatment scheme consisted of weekly increasing the dose of E2 and/or P4 to these females. The quality of sleep of the controls and the experimental evaluated by counting the animals' number of awakenings during the sleep cycle. This procedure was performed daily for five consecutive weeks, using video cameras. The results showed a significant difference between the number of awakenings of the ovariectomized rats and the sham-operated rats during the study weeks. The number of awakenings in the castrated rats treated with E2 and/or P4 gradually decreased as the hormonal doses were increased. In such a way, in the fifth week, the awakenings fell below those in sham-operated. E2 -treatment showed an effect from the first week with the first dose, and in the fifth week, it displayed a frankly anesthetic activity. Progesterone began to show activity on the third week, but it showed an anesthetic effect with the highest dose in the fifth week. However, both steroids combined showed significant activity, reducing the number of awakenings from the third week, without achieving the anesthetic effect seen with the steroids separately at the fifth week. These results suggested estrogens and progesterone-combination regulated the number of awakenings of the castrated rats since the third-week treatment. Plots of dose-response of these experiments indicated

that estradiol and progesterone effects were performing by different action mechanisms.

The (epi)genetic basis of gender incongruence

Rosa Fernandez[1], Sarah Collet[2], Karla Ramirez[1,3], Meltem Kiyar[2], Enrique Delgado-Zayas[1], Guy T'sjoen[2], Antonio Guillamon[4], Sven C Mueller[2] & Eduardo Pásaro[1]
[1]University of A Coruña, Center for Advanced Scientific Research (CICA), Department of Psychology, A Coruna, Spain; [2]Ghent University, Department of Endocrinology and Department of Experimental Clinical and Health Psychology, Ghent, Belgium; [3]Venezuelan Institute for Scientific Research (IVIC), Center for Biophysics and Biochemistry. Laboratory of Neurophysiology, Caracas, Bolivarian Republic of Venezuela; [4]UNED, Department of Psychobiology, Madrid, Spain.

In mammals, the gonads and the brain develop from bipotential organs that will differentiate into female or male organs, during a critical period of development. This process begins with the production of testosterone by the testes, which will be converted into estradiol in the brain, by the aromatase. While the end is defined by the moment when the inhibition of androgens (in males), or treatment with estrogens (in females), stops having an effect on brain dimorphism. But in humans, biological sex and brain sex are not always coincident. Thus, transgender females are born with male genitalia. Their sex is male, but their gender is female. In contrast, transgender males are born with female genitalia. Their sex is female but their gender is male. These people generally show gender incongruence (GI), due to the incongruence between sex and gender.
The origin of GI is complex, where neurological, hormonal and genetic factors play an important role. One of the current hypotheses suggests that GI could be related to a different sexual differentiation of the brain, not concordant with gender. But other processes are also involved. Thus epigenetics, specifically DNA methylation, can alter the chromatin structure, modifying the access of transcription factors to the promoter regions, modulating gene expression. Thus, 16 trans people were compared with 16 cis people, with the same geographic origin, ethnicity and sex. Methylation analysis was performed on blood, using the Infinium Human Methylation 850K BeadChip. The changes in methyloma were analyzed with the Partek Genomics Suite program. When we compared methylome of cis and trans populations with the same sex assigned at birth, we found significant differences in 71,515 CpGs that passed the criterion FDR p <0.05 (28.5% located in islands). When we compared cis men vs. trans women we found 20 CpG islands that passed both criteria (FDR p<0.05; fold change ≥ ± 2). The most significant CpGs were related to genes: *WDR45B*, *SLC6A20*, *NHLH1*, *UBALD1* and *PLEKHA5*. With respect to populations assigned female at birth, when we compared cis women vs. trans men, we found 4 CpGs that passed both criteria. The results of enrichment tests yielded significant over-representation for the categories of biological process, cellular component and molecular function ontologies: negative regulation of gene expression, positive regulation of catalytic activity, ribonucleotide binding, RNA binding, among others.

Growth hormone treatment in turner syndrome: How is the statural growth after one year?

Nada El Yamani, Wahiba Abdellaoui, Salma Ben Yakhlef, Rouf Siham & Latrach Hanane
Hospital Center, Oujda, Morocco

Introduction
Turner syndrome is a rare condition that affects only females. It results when one of the X chormoses is missing or partially missing. It can cause short height, ovarian failure, heart defects and other complications. It is an indication for growth hormone treatment. The aim of our study is to evaluate the statural growth over one year in turnerian patients treated with growth hormone.
Materials and methods
We conducted a retrospective study on 7 Turnerian patients admitted in the endocrinology department and treated with growth hormone. The results were collected and processed using the SPSS operating software V21.
Results
The prevalence of Turnerian patients treated with growth hormone was 36.8% of all Turnerian patients. The mean age of patients at diagnosis was 9.6 ± 4 years, and impuberism was noticed in all patients. At the beginning of growth hormon treatment, the mean height of the patients was 114.6 ± 9.8 cm, the mean standard deviation (SD) score for height was –2.8 SD ± 0.91 for the normal curve, and normal in the Turner curve. The median difference in bone age from chronological age was 33 months (from 12 months to 81 months). The mean dose of growth hormone at the initiation of treatment was 0.8 mg/day, giving an average of 0.04 mg/kg/day. After one year of treatment: The mean height was 120 ± 9 cm, the mean standard deviation score was –2.6 SD ± 1 in the normal curve, and normal in the Turner curve. The mean gain was 6 ± 2 cm, The median difference in bone age from chronological age was 8 months, (from 2 months to 48 months). IGF1 at one year of treatment was normal according to pubertal stage for all patients and no adverse effects of growth hormone treatment were detected during this period.
Discussion and conclusion
In our study, growth hormone treatment allowed an average statural gain of 6 cm over one year. Safety was assessed in all patients. Our results are in agreement with literature data regarding the interest of growth hormone treatment in Turner syndrome, allowing the optimization of the statural gain, especially when the treatment is started as early as possible.

The association of angiotensin converting enzyme inhibitors and receptor blockers with COVID-19 severity and mortality

Mitra Kazemijahromi[1], HamidReza Samimagham[2], Mohsen Arabi[2], Dariush Hooshyar[3] & mohammad sharifi[4]
[1]Department of Endocrinology, Hormozgan University of Medical Sciences, Bandar Abbas, Iran; [2]Departmant of Nephrology,Hormozgan University Of Medical SciencesmBandar Abbas,Iran; [3]Student Research Committee, Faculty of Medicine, Hormozgan University of Medical Sciences, Bandar Abbas, Iran; [4]Department of Family Medicine, Iran University of Medical Sciences,Tehran, Iran

Background
The available data on the effect of Angiotensin Converting Enzyme Inhibitors (ACEIs) and Angiotensin Receptor Blockers (ARBs) use on COVID-19 infection are both insufficient and controversial. The present study was conducted to investigate the effect of a history of ACEI/ARBs use on the severity and mortality of COVID-19 infection.
Methods
This study recruited 147 patients with confirmed COVID-19. The relationship between the severity of the disease was then assessed with a history of ACEIs/ARBs use, diabetes, ischemic heart disease, hypertension and Glomerular Filtration Rate (GFR). The effect of a history of ACEIs/ARBs use, GFR ≤ 60 (mL/min), a history of hypertension, a history of ischemic heart disease, diabetes, LDH ≥ 500 U/l, and lymphocyte count ≤ 1500 on COVID-19-related deaths was also assessed.
Results
The results showed a significant relationship between a history of ACEIs/ARBs use before infection and COVID-19 severity and mortality. The severity of the disease also had a significant relationship with a history of smoking, diabetes, hypertension, ischemic heart disease, and GFR. Moreover, the mortality rate had a significant relationship with GFR ≤ 60 (mL/min), diabetes, LDH ≥ 500 U/l, and lymphocyte count ≤ 1500.
Conclusion
The present study showed that a history of ACEIs/ARBs use before COVID-19 infection significantly increased severity and mortality of COVID-19 infection. This result can help modify health policies during the COVID-19 pandemic.

Acute pancreatitis in a covid-19 patient

Maria Zhao Montero Benítez, Cristina Contreras Pascual, Cristina Montalban Mendez, Antonio Moreno Tirado, Paloma González Lázaro, Florentino Del Val Zaballos, Julia Silva-Fernández, Amparo Lomas Meneses, Francisco Javier Gómez Alfonso & Inés Gómez García
Endocrinology Department. La Mancha Centro Hospital Centre, Spain

Acute pancreatitis (AP) is an inflammatory disorder of the pancreas, most commonly caused by gallstones and heavy alcohol consumption. The diagnosis is established with at least 2 of the following criteria: abdominal pain; increased serum lipase/amylase levels greater than 3 times the upper limit of normal value; or characteristic findings on contrast computed tomography (CT). Since the beginning of the severe acute respiratory syndrome coronavirus (SARS-CoV-2) pandemic, a few studies have reported a potential pancreatic injury related to SARS-CoV-2 infection. We are presenting a case of acute pancreatits in a pacient without any relevant risk factors other than a COVID-19 infection. A 74-year-old male with previous history of dyslipidemia and type 2 diabetes mellitus was hospitalized with general malaise, headache and nausea that had last for one week. Chest radiography showed bilateral beginning opacities, and results from testing of transcription polymerase chain reaction assay were positive for SARS-CoV-2. Severe pneumonia developed, with progressive dyspnea and hypoxic respiratory failure that required high-flow oxygen supplementation. We prescribed tocilizumab (anti-interleukin-6 receptor antibody) and corticoids, and so his oxygen requirements declined over the next several weeks, with gradual resolution of his pulmonary symptoms. On day 16, our patient reported diffuse abdominal pain without signs of peritoneal irritation. The blood test showed high levels of leukocytes (30.6×10^3 µl). The patient presents progressive worsening of abdominal pain with distension, so an abdominal CT is requested. The image showed acute pancreatitis with multiple associated necrohemorrhagic collections. Conservative medical treatment is decided, including bowel rest, intravenous fluids therapy, antibiotics and analgesia. After two days, the patient presented bilious vomiting and paralytic ileus, so he is treated with prokinetics, nasogastric tube, and rectal tube in turns. We also channeled drum for parenteral nutrition. The patient evolved favorably, being able to progress to enteral nutrition and later to oral nutrition, which he tolerated. Hydrolyzed supplements, phosphate and potassium are added. The patient was discharged and a follow-up CT scan was performed one month later, observing a decrease in collections. COVID-19 pathogenesis is thought to be mediated by angiotensin-converting enzyme-2 (ACE-2) receptor on the host cells, which are highly expressed in the pancreatic islets. Though the exact mechanism of AP by SARS-CoV-2 infection is unknown, the cytopathic effect or systemic inflammatory responses to the virus are thought to be responsible. Physicians should consider this possibility sooner or later in the course of COVID-19 illness.

DOI: 10.1530/endoabs.73.AEP454

AEP455

Profil of vitamin D in patients with idiopathic short stature: About 62 cases

Nada El Yamani, Wahiba Abdellaoui, Salma Ben Yakhlef, Rouf Siham & Latrach Hanane
Hospital Center, Oujda, Morocco

Introduction
Idiopathic short stature is a condition in which the height of the individual is more than 2 standard deviation below the corresponding mean height for a given age, sex and population, in whom no identifiable disorder is present. The aim of this study is to describe the vitamin D profile of patients followed up for idiopathic short stature in the endocrinology department of Mohamed VI University Hospital Center.
Materials and methods
We have collected 62 patients admitted in the Endocrinology Department of Mohammed VI University Hospital of Oujda, for the management of idiopathic short stature. The data were collected and processed using SPSS software V21.
Results
The average age of the patients was 11 ± 3 years, with a sex ratio M/F of 1.48. The mean height of our patients in admission was 128 ± 20 cm and the average weight was 26 ± 8 kg. The average standard deviation score was 2.7 ± 0.7 for height and 2.3 ± 0.9 for weight. The median difference in bone age from chronological age was 45 months (from 9 months to 144 months). The insulin growth factor 1 (IGF1) was low relative to pubertal stage in 12.9% of patients. Bone X-rays were performed in all patients and did not reveal any abnormalities. A propranolol-glucagon test was performed in 78.8% of patients and an insulin hypoglycemia test was performed in 16.1% of patients. No growth hormone deficiency was detected. The mean vitamin D value was 20 ± 8 ng/ml, in 62.9% of patients the vitamin D value was in the range 10–30 ng/ml, in 1.6% of patients it was less than 10 ng/ml, and in 9.7% it was greater than 30 ng/ml. The reminder of the phosphocalcic lobaratory test was normal in all patients.
Conclusion
The results of our study highlighted the value of vitamin D dosing in the context of idiopathic short stature, in order to detect any deficiency which may affect our children's growth.

DOI: 10.1530/endoabs.73.AEP455

AEP456

Carney complex – a rare cause of Cushing's syndrome

Joana Reis Guiomar[1], Carolina Moreno[1,2], Lúcia Fadiga[1], Diana Alexandra Festas Silva[1] & Isabel Paiva[1]
[1]Coimbra Hospital and University Center, EPE., Endocrinology, Diabetes and Metabolism Department, Coimbra, Portugal; [2]University of Coimbra, Faculty of Medicine, Coimbra

Introduction
The Carney Complex (CNC) is a rare, autosomal dominant, multiple endocrine neoplasia. It involves multiple endocrine glands, cardiac and skin myxomas, mammary fibroadenomas and mucocutaneous pigmentation. Cushing's syndrome, due to primary pigmented nodular adrenocortical disease (PPNAD), is described in 25% of the cases.
Case report
Woman, 21-year-old, was refered for secondary amenorrhea. Medical history significant for depressive syndrome and thrombophlebitis at 18-year-old. Medication: quetiapine 100 mg id. Family history: mother (52-year-old), DM type 2, hypertension and corticotropin-independent adrenal Cushing syndrome submitted to unilateral adrenalectomy, at 48 years old (histology: diffuse adrenal hyperplasia). Physical exam: BMI 18.7 kg/m^2, acne, facial erythrosis, hirsutism, purple striae, without mucocutaneous pigmentation. Biochemicaly: ACTH < 5 pg/ml (9–52), serum cortisol 14 µg/dl (5–25), urinary free cortisol (UFC): 345 µg/24 h (10–80) and serum cortisol after overnight dexamethasone suppression test 13.6 µg/dl. Adrenal glands on CT with normal morphology and contours. Genetic test positive for variant c.63C > Ap. (Tyr21 *) in heterozygosity in the PRKA1A gene. Diagnosis of Carney complex and Cushing's syndrome by PPNAD were made. Genetic testing of the mother identified the same mutation. No others manifestations associated with CNC were found. While waiting for bilateral adrenalectomy the patient started ketoconazole, 200 mg bid, with improvement of the signs and symptoms of hypercortisolism. On the last appointment the patient had no acne, her menstrual cycles were regular and she was feeling more energized. Biochemical: serum cortisol 9.3 µg/dl, UFC: 47 µg/24 h. Her mother's follow-up was started in our department.
Conclusion
CNC is rare multiple endocrine neoplasia with challenges in diagnosis. In the presence of Cushing's syndrome and PPNAD, CNC's diagnosis, although rare, should be considered, since bilateral adrenalectomy is essential for therapeutic success. Family screening, and management of other manifestations, are part of the follow-up and treatment of patients with Carney Complex.

Pituitary and Neuroendocrinology

AEP457

A rare case of pituitary apoplexy likely combined to hypophysitis in an old man with SARS-CoV-2 pneumoniae

Laura Gianotti[1], Giulia Racca[2], Nicoletta Fasano[3], Jacopo Giamello[4] & Gianpiero Martini[4]
[1]Azienda Ospedaliera S. Croce e Carle Cuneo, Division of Endocrinology, Diabetology & Metabolism, Cuneo, Italy; [2]Azienda Ospedaliera S. Croce e Carle Cuneo, Division of Internal Medicine, Cuneo, Italy; [3]Azienda Ospedaliera S. Croce e Carle Cuneo, Division of Neuroradiology, Cuneo, Italy; [4]Azienda Ospedaliera S. Croce e Carle Cuneo, Division of Emergency Medicine, Cuneo, Italy

Introduction
Neurological complications related to COVID-19 are described. The pituitary expresses ACE which is known as the entrance for Sarscov2 through binding to viral S-protein. Pituitary apoplexy (PA) is due to the sudden hemorrhagic infarction of pre-existing pituitary tumors or the gland itself and its symptoms and radiological findings can be similar to acute hypophysitis (AH) caused by viral infections.

Subjects and methods
We report a recent case of an 84-year-old caucasian male admitted to emergency department for sudden intense frontal headache for one day. The patient had been discharged three weeks earlier for SARS-CoV-2 pneumonia. He had type 2 diabetes mellitus and ischemic heart disease on acetylsalicylic acid therapy. At admission, an episode of atrial fibrillation occurred for which anticoagulation with enoxaparin was started.
Results
The nasopharyngeal swab for the SARS-CoV-2 virus RNA was positive, neutrophilic leukocytosis with marked increase of inflammation indexes were revealed, head CT scan showed a sellar mass in contact with the lower profile of the optic chiasm without sign of bleeding and chest CT showed bilateral sub-pleural densities with crazy-paving patterns compatible with late-stage SARS-CoV-2 pneumonia. Enoxaparin therapy was confirmed. The headache persisted with photophobia, nausea and vomiting. Later, third cranial nerve deficit with bilateral ptosis, ophthalmoplegia and anisocoria occurred followed by hypotension and confusion so that a cerebral magnetic resonance imaging (MRI) with contrast agent revealed the presence of necrotic-hemorrhagic regression in enlarged sellar tissue referable to PA in pituitary adenoma. Cortisol was < 5 mg/dl. Enoxaparin was interrupted and hydrocortisone was started followed by dexamethasone. Other anterior pituitary hormones were low and thyroxine was started. A second MRI was unchanged while a third MRI three weeks later showed change of pituitary lesion likely referable to combined AH. Accordingly, inflammation markers decreased after dexamethasone was started and the clinical conditions improved with partial recovery of ptosis and complete headache resolution.
Conclusions
PA as well as AH are very rare conditions. In this case a concomitant PA in an unknown macroadenoma and a likely AH have been found coexisting in a patient with SarsCov2 pneumoniae. We speculated on what connections between the two events might be present. Some triggering factors are recognized in PA, including anti-coagulation therapy as in our case. Moreover, SarsCov2 infection can induce reversible AH. Pituitary must be considered as a target organ in patients with Covid-19 for the rare though possible development of apoplexy or hypophysitis.

Pituitary apoplexy lead to disappearance of adenoma; two case reports

Imane Djerroumi, Aicha Boulgheraief, Yasmine Iraten, Dalila Foudil & Safia Mimouni
Pierre Et Marie Curie Center, Endocrinology and Métabolism, Algiers, Algeria

Introduction
Pituitary apoplexy is a rare endocrine and neurosurgical emergency. It corresponds to the occurrence of an hemorrhage or infarction in the pituitary gland, or most often within a pituitary adenoma. The usual presentation associates sudden headaches, visual disturbances, altered consciousness and endocrine disorders wich are dominated by corticotropic insufficiency. We present two cases of pituitary apoplexy, the first one complicating an underlying pituitary adenoma, the second one revealing the adenoma, where both cases have progressed well under conservative treatment, and the surprise is that in the two cases the adenoma has totally disappeared.
Case 1
70-year-old man has a nonfunctioning pituitary adenoma 25 mm, with Hypopituitarism, presented in emergency department with complaints of 1 day of fatigue, vomiting, fever 39.4°c, visual disturbances, and severe retroorbitar headache; BP was 200/70 mmhg; scored at 9 on the Glasgow scale; pituitary MRI done on D4 is compatible with apoplexy. the ophthalmological examination finds oculomotor paralysis, with reduced acuity, diplopia, ptosis in the right eye, without impairing the visual field. The evolution under conservative treatment was spectacular; marked by the recovery of consciousness after 24 h, ophthalmologic improvement from D7; total regression of the adenoma on MRI at 3 months; and even a restoration of the corticotropic function at least partial;an insulin hypoglycemia test could not be done due to age and unbalanced diabetes.
Case 2
33-year-old female, without a known pitutary lesion, presented to the emergency department in april 2019 with sudden onset of severe headache without other features. she had history of generalized weakness, cycle disorders for the last 2 years; headaches and infertility for the last year. Ophthalmic evaluation revealed bitemporal upper quadrantanopia, normal acuity and no papilledema. CT of head on day 3 and MR imaging on day 4 confirm the apoplexy of a pituitary adenoma. the hormonal exploration found an corticotropic insufficiency, with low prolactin, as well as central diabetes insipidus. The clinical outcome was favorable under conservative treatment; in MRI of control there is no adenoma.
Conclusion
The neurosurgical approach should be favored in the event of impaired consciousness or visual disturbances, worsening or not relying at corticosteroid therapy which must be started in all cases. The apoplexy can be a form of spontaneous healing of adenomas; although monitoring remains necessary.

Cushing's disease presenting as pituitary apoplexy: Challenges of diagnosis and treatment

Rasa Juskiene[1], Romena Laukienė[1] & Ieva Laukytė[2]
[1]Vilnius university hospital Santaros klinikos, Center of Endocrinology, Vilnius, Lithuania; [2]Faculty of Medicine of Vilnius University, Vilnius, Lithuania

Background
Pituitary apoplexy (PA) is a rare clinical syndrome, usually occurring in the pituitary adenoma due to a sudden bleeding and/or infarction. PA is usually seen in nonfunctional pituitary adenomas, but it can also be seen in ACTH secreting macroadenomas. The most common symptoms PA, which complicates 2 to 12% of pituitary adenomas, are severe and sudden headache, visual disturbances, or eye paralysis, and endocrinological abnormalities. PA is diagnosed by computed tomography or magnetic resonance imaging. Formerly considered as an urgent neurosurgical condition and treated only surgically, now PA is sometimes treated conservatively.
Clinical case
The 33-year-old woman was sent to the emergency department for persistent severe right-sided headache, nausea, vomiting, and impaired vision. Temporobasal subarachnoid hemorrhage on the right side, and aneurysm rupture was suspected on computed tomography (CT) of the brain. Patient was referred to ophthalmologist – right eye blindness and temporal hemianopsia in left eye were diagnosed. An additional MRI scan revealed a tumor in the sella turcica area. Patient was transferred to Vilnius University hospital Santaros Klinikos Center of Neurosurgery. Head CT angiography (CTA) was done to exclude intracranial vascular aneurysm. Subarachnoid hemorrhage, a large (24 × 15 × 26 mm) mass, significant pressure on the right segment of the right internal carotid artery (ACI) and dislocated optic chiasm were found. Blood samples showed increased ACTH, cortisol, and glucose levels (AKTH – 190 nmol/l, cortisol – 1068 nmol/l, glucose – 10 mmol/l), prolactin concentration was normal. During physical examination wide purple striae in the skin of the abdomen and arms, hirsutism, and cushingoid body appearance were noticed. The patient was never consulted by endocrinologist before. She underwent right pterional craniotomy and pituitary tumor removal. The final pathological diagnosis was necrosis and hemorrhage in the pituitary adenoma with probable ACTH expression and grain. Patient's right eye vision after surgery did not recover and she developed panhipopituitarism. A replacement treatment with glucocorticoids, levothyroxin and sex hormones were given.
Conclusion
The presented clinical case shows how unnoticed and undiagnosed Cushing's disease led to a pituitary adenoma apoplexy with various complications such as blindness in one eye and panhypopituitarism. Awareness of physicians of Cushing's disease symptoms could have allowed earlier diagnosis of the disease and avoided complications caused by apoplexy.

Pituitary tuberculosis: A clinical challenge

Hiba Allah Chatti[1], Ines Kammoun[1], Radhouane Gharbi[1], Arbaoui Ibrahim[1], Nagi Sonia[2], Hajer Kandara[1] & Manel Jemel[1]
[1]National Institute of Nutrition and Food Technology, Tunis, Tunisia, Endocrinology and Metabolic Diseases, Tunisia; [2]National Institute of Neurology, Tunisia, Radiology Department, Tunisia

Introduction
Cerebral tuberculomas are a rare form of tuberculosis due to the hematogenous spread of Mycobacterium Tuberculosis (MT). Pituitary localization is exceptionally uncommon with total reported cases in the literature fewer than a hundred. Symptoms and radiologic features are

nonspecific, leading sometimes to misdiagnosis. We report the rare case of a patient diagnosed with a primary pituitary stalk tuberculosis.
Observation
A 37-year-old woman was referred to our department for a suspected diabetes insipidus. A CREST syndrome treated by oral corticotherapy (10 mg of Prednisone) and benzodiazepin (120 mg of Diltiazem) marked her past medical history. She presented with a recent polyuria-polydipsia syndrome with about 10liters/day. No menstrual disorders were reported. Pituitary MRI showed a marked thickening of the pituitary stalk with nodular enhancement suggestive of granulomatosis. A water deprivation test confirmed the central diabetes insipidus with a rise in urine osmolarity after desmopressin administration and low arginine vasopressin (AVP) levels (< 0.5 pmol/l). The etiological diagnostic procedure begins with the search for possible other lesions suggestive of histiocytosis, sarcoidosis, tuberculosis or other etiologies elsewhere in the body that could be more easily biopsied, particularly because the biopsy of the stalk is difficult, harmful and often not contributive. We performed neck, thorax, abdomen, and pelvis CT scan, measurement of serum markers such as B2 microglobulin, angiotensin converting enzyme, anticytoplasmic antibodies and salivary gland biopsy. Tuberculin skin test (TST) showed a positive response with a skin reaction of 12 mm (> 10 mm). The pathological proof of the pituitary tuberculosis was thus obtained indirectly considering high tuberculosis endemicity in Tunisia, raw milk consumption and positive TST. Our patient was put on anti tuberculosis treatment and desmopressin substitution. Follow up MRI (3 months after tuberculosis medication stopped) showed complete resolution of the granuloma but with diabetes insipidus persistence.
Discussion and conclusion
Pituitary tuberculosis is an uncommon form of intra-cranial tuberculosis. Isolated pituitary tuberculosis in extremely rare and difficult to diagnose. The case we studied showed the difficulties encountered in the diagnosis of a thickened pituitary stalk.

A rare case of acromegaly developed in a patient with multicentric Castleman disease and complete disappearance of lymphadenopathies after treatment with Lanreotide Autogel

Hunkar Aggul[1], Ogun Bilen[1], Aysegul Isal Arslan[2] & Sayid Zuhur[1]
[1]Tekirdag Namik kemal University, Endocrinology and Metabolism, Turkey; [2]Tekirdag Namik kemal University, Pathology, Turkey

Introduction
Multicentric Castleman disease (MCD) is characterized by highly vascularized multiple lymph node enlargements throughout the body. MCD is generally treated with systemic cytotoxic chemotherapy, with its attendant risk for toxicity. Studies suggest the presence of growth hormone receptors (GHR) in lymphatic tissues of patients with Castleman disease. However, the effect of somatostatin analogs for the treatment of MCD is not reported so far. Herein we present a case of MCD who was diagnosed with acromegaly and treatment with long-acting somatostatin analog Lanreotide Autogel resulted in the complete disappearance of lymphadenopathies.
Case
A 32-year-old female patient with multiple abdominal lymphadenopathies underwent abdominal explorative laparotomy for a mass of 42 × 42 × 31 mm diameter in the right lower abdominal quadrant. Immunohistopathological analysis of paraffin-embedded tissue blocks was consistent with lymphatic tissue that was widely positive for Kappa and Lambda light chains, and also positive for IgG, IgM, CD-34, CD-138, and CD3/CD-5. CD-10 was positive in germinal centers. The result was consistent with MCD. Due to the presence of facial appearance, acral enlargement, and macroglossia, the patient was investigated for acromegaly. Insulin-like growth factor-1 (IGF-1) was 643 ng/ml (normal age and sex-matched values 71–234 ng/ml). Serum nadir growth hormone (GH) during a 75 gr oral glucose tolerance test (OGTT) was 13.8 ng/ml. A 16 × 15 mm macroadenoma was found on pituitary MRI. She had no clinical and laboratory results consistent with POEMS syndrome. The patient underwent transsphenoidal adenomectomy and the result of the immunohistopathological analysis was consistent with a GH secreting adenoma that was positive for GH and negative for prolactin. However, 3 months after surgery, treatment with a long-acting somatostatin analog Lanreotide Autogel was started once every 28 days, due to the high serum levels of IGF-1 and nadir GH on OGTT. Nevertheless, 6 months after remission of acromegaly assessed by the normalization of serum age and sex-matched IGF-1 and random GH levels, a contrast-enhanced abdominal CT demonstrated a complete disappearance of intra-abdominal lymphadenopathies.
Discussion
MCD has a less favorable outcome and is generally treated with systemic cytotoxic chemotherapy. However, recent studies suggested a high expression of the GHR in lymphatic cells of the patients with Castleman disease. Therefore, we believe that the complete disappearance of the lymphadenopathies in the index patient is probably due to the antiproliferative and apoptotic effects of somatostatin analogs. Further prospective studies are required to assess the effect of somatostatin analogs in patients with MCD.

Cardiac remodeling in patients with childhood-onset craniopharyngioma – Results of HIT-Endo and Kraniopharyngeom 2000/2007

Panjarat Sowithayasakul[1,2], Svenja Boekhoff[1], Leona Katharin Buschmann[1] & Hermann Müller[1]
[1]University Children's Hospital, Car von Ossietzky University Oldenburg, Department of Pediatrics and Pediatric Hematology/Oncology, Klinikum Oldenburg AöR, Oldenburg, Germany; [2]Srinakharinwirot University, Department of Pediatrics, Bangkok, Thailand

Hypothalamic obesity caused by childhood–onset craniopharyngioma results in long–term cardiovascular morbidity. Knowledge about clinical markers and risk factors for cardiovascular morbidity is scarce. A cross–sectional study on transthoracic echocardiographic parameters was performed to determine the associations with clinical and anthropometric parameters in 36 craniopharyngioma patients. BMI correlated with the thickness of interventricular septum in diastole (IVSd) ($r = 0.604$, $P < 0.001$) and left ventricular diastolic posterior wall in diastole (LVPWd) ($r = 0.460$, $P = 0.011$). In multivariate analyses on risk factors for cardiac remodeling, sex hormone replacement therapy, BMI and male gender were positively correlated with increased left ventricular internal diameter in diastole (LVIDd), R2 = 0.596, F = 10.323, $P < 0.001$. BMI and insulin resistance were selected as significant independent determinants of IVSd, produced R2 = 0.655, F = 29.441, $P < 0.001$. Due to wide range of disease duration, 17 pediatric and 19 adult patients were analyzed separately. In the adult subgroup (age at study ≥ 18 years), BMI correlated with IVSd ($r = 0.707$, $P = 0.003$), LVPWd ($r = 0.592$, $P = 0.020$) and LVIDd ($r = 0.571$, $P = 0.026$). In the pediatric subgroup (age at study < 18 years), no correlation between TTE parameters and BMI was observed. Only LVIDd correlated with disease duration ($r = 0.645$, $P < 0.001$). All cardiac functions were within the normal range, indicating no association with functional impairments.
Conclusions
Cardiac remodeling in patients with craniopharyngioma correlated with the degree of hypothalamic obesity, disease duration, sex hormone replacement therapy, male gender and insulin resistance. As echocardiography has limited sensitivity in patients with obesity, further research on more sensitive techniques for cardiac diagnostics in craniopharyngioma patients is warranted.

Epidemiology of acromegaly in south-eastern Norway

Camilla Maria Falch[1,2], Cristina Olarescu[1,2], Jens Bollerslev[1,2], Olaf M. Dekkers[3] & Ansgar Heck[1,2]
[1]Oslo University Hospital, Section of Specialized Endocrinology, Department of Endocrinology, Oslo, Norway; [2]University of Oslo, Faculty of Medicine, Oslo, Norway; [3]Leiden University Medical Center (LUMC), Clinical Epidemiology, Leiden, Netherlands

Objective
In order to improve therapeutic outcomes for patients with acromegaly, new treatment algorithms have been developed over the last decades. Valid epidemiological data of acromegaly in Norway is lacking. The overall aim of this study was to investigate incidence, prevalence and mortality of acromegaly in South-Eastern Norway, and to investigate effects of new treatment algorithms.
Design and method
Patients with acromegaly from South-Eastern Health region of Norway (56% of the total Norwegian population) diagnosed between 1999–2019 were included in a register-based cohort ($n = 262$). For every patient 100 age and sex matched controls from the general population were obtained

(n = 26200) and combined with individual data from the national cause of death registry. Mortality was assessed by Kaplan-Meier analysis, cox regression and hazard ratios (HRs).
Results
Mean age at diagnosis was 48.7 years (CI: 95%: 45.9–49.4) and did not differ between men and women (P = 0.811). The mean annual incidence rate was 4.7 (95% CI: 4.2–5.3) cases/10^6 persons and the point prevalence in 2019 was 83 cases/106. During the study period, 14 acromegaly cases died, five from cancer, three from cardiovascular disease and six from other causes. Overall mortality risk was elevated (HR: 2.79 (95% CI: 1.64–4.75). For patients diagnosed in period 1999–2005 and 2006–2012 the HR for mortality was 2.86 (95% CI: 1.35–6.05), and 2.96 (95% CI: 1.31–6.66). For the patients diagnosed in 2013–2019 this was 1.87 (95% CI: 0.26–13.50)). IGF-1 levels at diagnosis did not clearly influence mortality (HR: 0.59 (95% CI: 0.31–1.14)).
Conclusion
In South-Eastern Norway, the mortality in patients with acromegaly is elevated compared to the general population and comparable to results from other population-based studies in the Nordic countries and Europe.

The duration of postoperative steroid replacement therapy may not have a predictive role for recurrence risk of Cushing's disease

Gülnar Zeynalova[1], Feyza Yener Ozturk[2], Aslı Büyükkurt[1], Selvinaz Erol[2], Esra Cil sen[2], M.Masum Canat[2] & Yuksel Altuntas[2]
[1]University of Health Sciences Turkey, Faculty of Medicine, İstanbul Sisli Hamidiye Etfal Health Training and Research Hospital, Clinic of Internal Medicine, İstanbul, Turkey; [2]University of Health Sciences Turkey, Faculty of Medicine, İstanbul Sisli Hamidiye Etfal Health Training and Research Hospital, Clinic of Endocrinology and Metabolism, İstanbul, Turkey

Objective
In patients with Cushing's disease (CD), normal pituitary corticotrophs are suppressed by excessive and persistent cortisol secretion in responce to autonomous ACTH secretion by tumour. Therefore, patients exhibit signs and symptoms of ACTH deficiency shortly after resection of tumour and need steroid replacement therapy (SRT) until hypotalamo-pituitary-adrenal (HPA) axis recovery. We aimed to evaluate whether duration of SRT can serve as a predictive factor for disease recurrence in patients who underwent transsphenoidal surgery (TSS) and developed hypocortisolemia in early postoperative period.
Material-method
This retrospective study consists of thirty eight CD patients, aged 18–65 years who underwent TSS between 2003–2016 at University of Health Sciences Turkey, Faculty of Medicine, Istanbul Sisli Hamidiye Etfal Health Training and Research Hospital. Morning serum cortisol levels measured within first five postoperative days were < 5 μg/dl in 34 and < 10 μg/dl but with clinical features of adrenal failure in 4 patients. All patients were followed up with SRT and re-evaluated for HPA axis recovery every 3 months after withdrawal of SRT for at least 24 hours. HPA axis recovery was determined if morning serum cortisol was ≥ 18 μg/dl or if serum cortisol levels exceeded 18 μg/dl after ACTH stimulation. Patients with recovered HPA axis were assessed for disease recurrence in follow-up periodically. High 24 hour urinary free cortisol excretion, high midnight salivary cortisol and failure of cortisol suppression < 1.8 μg/dl after dexamethasone suppression tests were defined as markers for recurrence. Two groups according to disease status were designed as recurrence and remission groups and compared for early postoperative serum cortisol and duration of SRT.
Results
Remission and recurrence groups consisted 27 and 11 patients, respectively. The follow-up period was significantly high and age at presentation was significantly low in recurrence group. Duration of SRT didn't significantly differ between both groups.

Table 1. Data of patients in recurrence and remission groups. (P-value < 0.05 was determined as significant)

	RECURRENCE	REMISSION	P-value
	mean ± SD	mean ± SD	
Age at presentation (years)	38.5 ± 10.7	49 ± 12.3	0.026
POSTOPERATIVE			
Morning serum cortisol (μg/dl)	3 ± 2.1	3.1 ± 1.9	0.595
Follow-up duration (month)	76.4 ± 41.1	35.8 ± 24.5	0.001
SRT duration (month)	17.4 ± 19.9	12.6 ± 9.7	0.948

Conclusion
Although postoperative morning serum cortisol can be used for assessment of surgery success, how long the patient need SRT may not necessarily predict the recurrence risk. But if we lenghten the follow-up period in both groups, SRT may gain a significance in prediction of recurrence.

Hypothalamic-pituitary-adrenal axis activity in patients with primary polydipsia and healthy volunteers

Jill Kuehne[1,2], Clara Sailer[1,2], Ismael da Conceição[1,2], Julie Refardt[1,2], Mirjam Christ-Crain[1,2] & Bettina Winzeler[1,2]
[1]Universität Basel, Department of Clinical Research, Basel, Switzerland; [2]Universitätsspital, Endocrinology, Diabetology and Metabolism, Basel, Switzerland

Background
The pathophysiology of primary polydipsia, a disorder with increased fluid intake, is poorly understood. A dysregulation in the hypothalamic-pituitary-adrenal axis (HPA) is speculated and arises mainly from research in patients witch a schizophrenia spectrum disorder but data is contradictory. The aim of this study was to investigate markers of HPA axis activity in patients with primary polydipsia compared to healthy controls.
Methods
In this exploratory analysis data from 34 patients with primary polydipsia and 20 healthy volunteers of two different prospective studies with the same study design were combined. The main outcomes were differences in circadian rhythm of serum and salivary cortisol, 24-hour urinary free cortisol, and cortisol levels before and after ACTH stimulation between patients with primary polydipsia and healthy volunteers.
Results
34 patients with primary polydipsia (68% female) aged 29.5 years (IQR 26.0, 38.8) with a median body mass index (BMI) of 23.1 kg/m^2 (IQR 20.7, 25.5) were included in the analysis. Circadian rhythms of serum cortisol levels (P = 0.9), urinary free cortisol levels (P = 0.17), and serum cortisol upon ACTH stimulation (P = 0.77) were similar between patients with primary polydipsia and healthy volunteers. Circadian rhythms of salivary cortisol levels were significantly lower in patients with primary polydipsia as compared to healthy volunteers with an estimated difference of –3.7 nmol/l (95%-CI –5.5, –1.8 nmol/l, P = < 0.001).
Conclusion
Our results suggest no difference in HPA axis activity between patients with primary polydipsia and healthy volunteers. The observed difference in salivary cortisol levels may be linked to the increased amount of water consumed by patients with primary polydipsia rather than altered stress response. Our results improve the psychopathological understanding increased fluid intake.

Study of the brain system for motor control in prader willi syndrome

Laura Blanco[1], Laia Casamitjana[2], Jesús Pujol[1], Gerard Martínez-Vilavella[3], Joan Deus[4], Olga Giménez-Palop[2] & Assumpta Caixàs[2]
[1]MRI Research Unit, Department of Radiology, Hospital del Mar, Barcelona, Spain. Centro Investigación Biomédica en Red de Salud Mental, CIBERSAM G21, Barcelona, Spain; [2]Endocrinology and Nutrition Department, Hospital Universitari Parc Taulí, Sabadell, Spain. Medicine Department, Universitat Autònoma de Barcelona. Bellaterra, Spain. Institut d'Investigació i Innovació Parc Taulí (I3PT). Sabadell, Spain; [3]MRI Research Unit, Department of Radiology, Hospital del Mar, Barcelona, Spain; [4]Department of Clinical and Health Psychology, Autonomous University of Barcelona, Barcelona, Spain

Background
Prader Willi syndrome (PWS) is a genetic disorder with a broad clinical expression. Severe hypotonia with feeding difficulties during early infancy and delayed motor development are very characteristic. At older ages, common motor features in the PWS phenotype include decreased muscle strength, deficiencies in motor coordination and sequencing, gait disturbances and dyspraxic manifestations, with no clear pathophysiological mechanism yet identified. The motor symptoms in PWS may be, in part, the result of the same alteration(s) in the brain system involved in motor control.

Objective
We aimed to examine the brain's motor system in PWS using functional magnetic resonance imaging (fMRI) with motor activation paradigms.
Methods
Twenty-three adults with PWS (12 women, age mean ± SD, 30.6 ± 10.1 years) participated in the study. Twenty-three age- and sex-matched healthy participants served as a control group. fMRI testing involved the performance of three manual tasks of different motor complexity: (i) repetitive flexion-extension of one hand; (ii) bimanual anti-phase repetitive flexion-extension movements; and (iii) repetitive sequence of fingers-to-thumb opposition with the right hand. Behavioral measurements of overall motor function were also registered by evaluating hand grip strength using a Jamar dynamometer, functional mobility and risk for falls as assessed by the Timed Get Up and Go (tGUG) test, and a quantitative measure of balance using the Berg balance scale. Whole-brain activation maps were compared between groups and correlated with behavioral measurements.
Results
As expected, participants with PWS showed significantly lower scores than controls on all the behavioral measures of motor function. Performance of the motor tasks engaged cortical and subcortical neural elements typically involved in motor processing, including bilateral primary sensorimotor and premotor cortices, the supplementary motor area, the basal ganglia and the cerebellum. No significant between-group differences were found for the simplest task (repetitive flexion-extension of one hand). However, the more complex tasks (alternate flexion-extension of both hands and fingers-to-thumb opposition movements) evoked significantly decreased activation in patients with PWS in dorsal premotor cortices, the supplementary motor area, and the cerebellum. A significant negative correlation (i.e., poorer performance, lower brain activation) was found between scores in the tGUG test and brain activation during coordinate hand movements in bilateral sensorimotor cortices in the PWS group.
Comment
Our study provides novel insights into the neural substrates of motor control in PWS by demonstrating reduced motor cortical activation during motor coordination.

The GLP-1 receptor agonist dulaglutide reduces fluid intake in primary polydipsia: A randomised controlled trial

Bettina Winzeler[1], Clara Sailer[1], Coynel David[2], Davide Zanchi[3], Deborah Vogt[4], Sandrine Urwyler[5], Julie Refardt[5] & Christ-Crain Mirjam[5]
[1]University Hospital of Basel, Endocrinology, Basel, Switzerland; [2]Division of Cognitive Neuroscience, Department of Psychology, Switzerland; [3]Stanford University Graduate School of Business, United States; [4]Clinical Trial Unit, University of Basel and University Hospital Basel, Switzerland; [5]Department of Endocrinology, Diabetology and Metabolism, University Hospital Basel, Switzerland

Background
Primary polydipsia, characterized by excessive fluid intake, carries the risk of water intoxication and hyponatremia, but treatment options are scarce. Glucagon-like peptide-1 (GLP-1) reduces appetite and food intake. In experimental models, they also play a role in thirst and drinking behavior. The aim of this trial was to investigate whether GLP-1 receptor agonists reduce fluid intake in patients with primary polydipsia.
Methods
In this randomised, double-blind, placebo-controlled, 3-week crossover-trial, 34 patients with primary polydipsia received weekly dulaglutide (Trulicity) 1.5 mg and placebo (0.9% sodium chloride). During the last treatment week, patients attended an 8-hour evaluation visit with free water access. The primary endpoint was total fluid intake during the evaluation visits. The treatment effect was estimated using a linear mixed-effects model. In a subset of 15 patients and 15 matched controls, thirst perception and neuronal activity in response to beverage pictures were assessed by functional MRI.
Findings
Patients on dulaglutide reduced fluid intake by 490 ml [95%-CI –780, –199], $P = 0.002$, from 2950 ml [95% CI 2435, 3465] on placebo to 2460 ml [95% CI 1946, 2475] on dulaglutide (model estimates). This corresponds to a relative reduction of 17%. 24-hour urinary output was reduced by –943 ml [95%-CI –1473, –413], $P = 0.001$. Thirst perception in response to beverage pictures was higher in patients with primary polydipsia versus controls and lower on dulaglutide versus placebo, but functional activity was similar between groups and treatments.
Interpretation
GLP-1 receptor agonists reduce fluid intake and thirst perception in patients with primary polydipsia and could therefore be a novel treatment option for these patients.

The diagnostic and predictors of postoperative diabetes insipidus

Darya Mikhaylova, Larisa Dzeranova, Ekaterina Pigarova, Liudmila Rozhinskaya, Evgenia Marova, Andrey Grigoriev, Vilen Azizyan & Oksana Ivashenko
Endocrinology Research Centre, Neuroendocrinology, Moscow, Russian Federation

Objectives
To assess diagnostic and prognostic markers of permanent and transient postoperative diabetes insipidus.
Patients and methods
The study included 152 patients undergone endoscopic endonasal transsphenoidal surgery aged from 18 to 65 years with median 40 [31; 52] years. Seventy three patients had Cushing disease, 66 – acromegaly, 4 – prolactinoma, 9 – hormonally inactive adenoma, 1 – Nelson syndrome, 1 – TSH-oma. Patients were monitored for clinical presentation, fluid balance, serum electrolytes, plasma and urine osmolality, copeptin level.
Results
By the end of follow-up period, permanent DI (pDI) has developed in 15 patients (15.5%), transient (tDI) – in 34 (35.1%), 47 patients did not have any disturbances (48.5%, ND) and 1 patient (1%) had SIADH. The onset was seen on the 5th median day [1; 9.5] after surgery for the pDI and on the 1th median day [1; 4.5] for tDI; median for tDI's duration was 30 days [1.5; 195]. Thirst and dry mouth were significantly more frequent in patients with pDI and tDI in comparison with patients without disturbances (OR 61.9 (10.1; 382.2), OR 25.3 (5.3; 121.5), $P < 0.001$; OR 22.0 (4.6; 104.8), OR 30.7 (7.8; 121), $P < 0.001$), just like water intake and daily urine were increased ($P = 0.003$, ŕ=0.009 and $P = 0.002$, ŕ=0.007, respectively). When assessing the blood osmolality level, no significant differences were found, however, the blood sodium level was significantly higher in patients with tDI compared to patients without disorders (145_{pDI} [142; 148], 146_{tDI} [144; 150], 144_{ND} [141; 147] – $P = 0.008$). In patients with pDI and tDI the indices of urine osmolality (0.296 [0.163; 0.36]$_{pDI}$, 0.282 [0.163; 0.36]$_{tDI}$, 0.652 [0.465; 0.929]$_{ND}$) and urine specific gravity (1.002 [1.0; 1.01]$_{pDI}$, 1.003 [1.001; 1.008]$_{tDI}$, 1.01 [1.005; 1.02]$_{N}$D) were significantly lower compared to patients without disturbances ($P = 0.015$, $P = 0.001$; $P < 0.001$, respectively) and sodium urine indices were significantly higher (50 [28; 74]$_{pDI}$, 56 [33; 73]$_{tDI}$, 109 [72; 127]$_{ND}$ – $P = 0.005_{pDI\ vs\ ND}$, $P = 0.001_{tDI\ vs\ ND}$). When assessing the copeptin level, there were no significant differences between pre- and postoperative levels, but patients with a pDI had a sharp decrease in its level (median 10.1 [8.3;11] pmol/l before and 5.1 [4.9;6.2] after the intervention).
Conclusions
Clinical presentation, fluid balance, serum electrolytes, plasma and urine osmolality do not represent reliable diagnostic or prognostic markers of postoperative DI and its outcomes, but copeptin levels are a promising marker for further study.

The usage of aripiprazole as a single agent in the treatment of hyperprolactinemia associated with diogenes syndrome- a novel approach

Harleen Kaur Birgi[1], Waleed Fawzi[1] & Ashutosh Kapoor[2]
[1]East London NHS Foundation Trust, United Kingdom; [2]The Christie NHS Foundation Trust, United Kingdom

Introduction
Hyperprolactinemia is a condition in which a person has higher-than-normal levels of the hormone prolactin in the blood. It is a relatively common condition encountered in the world of endocrinology. It is often seen as a side-effect with usage of anti-psychotics. Treatment options when symptomatic usually constitute dopamine agonist therapy, the common agents being Cabergoline and Bromocriptine. The uniqueness of this case is attributed to the usage of low-dose Aripiprazole as a novel agent in the treatment of hyperprolactinemia associated with Diogenes syndrome (DS).

DS is a behavioural disorder, mostly seen in elderly population, characterized by self-neglect, domestic squalor, apathy, compulsive hoarding and lack of shame regarding one's living condition.
Case details
We report the case of a 77-year-old woman, not known to psychiatric services and on no anti-psychotic treatment, was subsequently diagnosed with Diogenes syndrome (DS). As part of workup prior to commencing antipsychotic therapy, she was found to have prolactin levels of 11146 (0–495 mU/l). Rest of her pituitary profile was unremarkable. She described none of the common features associated with hyperprolactinemia. Her clinical features of excessive hoarding, extreme self-neglect and lack of insight into her symptoms were consistent with DS. Brain imaging was done which revealed a Macroprolactinoma. Following this endocrinology opinion was sought and treatment with low dose Aripiprazole 10 milligrams as a single agent was started with the aim of improving her mental state in conjunction to her prolactin levels. Over the next 8 weeks, prolactin levels decreased to 476 accompanied by a steady improvement in her mental state.
Conclusion
We propose the utility of low dose Aripiprazole as a single agent for the treatment of hyperprolactinemia in comparison to conventional dopamine agonists or as adjunctive therapy in psychiatric settings. Aripiprazole exhibits partial agonistic activity on Dopamine (D2) receptors and serotonin receptors which renders it useful in the treatment of psychiatric disorders and improvement of hyperprolactinemia, accompanied by the advantage of having a low side effect profile. Literature review depicts limited evidence and reports of Aripiprazole being used as a single agent to treat hyperprolactinemia as opposed to significant number of studies where it has been used as adjunct therapy. Of note, frontal lobe dysfunction has been postulated to account for Diogenes syndrome, however on the other hand, the involvement of Pituitary lesions especially prolactinomas, has not been well documented.

Nonfunctioning pituitary adenomas: What can we do? What we did

Susana Mallea-Gil[1], Mariela Cuccia[2], Gloria Tubert[3], Sabrina Diez[4] & Carolina Ballarino[1]
[1]Hospital Militar Central, Endocrinology, Buenos Aires, Argentina; [2]Hospital J.A. Fernandez, Endocrinology, Buenos Aires, Argentina; [3]Hospital J.A. Fernandez, Buenos Aires, Argentina; [4]Hospital I. Pirovano, Endocrinology, Buenos Aires, Argentina

Nonfunctioning pituitary adenomas (NFAs) have no symptoms of hormonal overproduction and can be asymptomatic or have severe symptoms due to mass effects. The aim of our study was to assess clinical features and therapeutic outcomes in patients with clinically NFAs. We retrospectively collected data of 175 patients from 3 hospitals of Buenos Aires. Mean age: 51 years (r:13–90), 52% women, mean follow-up: 7.37 years. At diagnosis, clinical presentation was: visual field defects (VFD) 42%, headache 24%, incidentaloma 23%, hypopituitarism 8%; tumor size: macroadenomas 94% (17% giant adenomas). Surgery was performed in 132 patients (75%), transsphenoidal approach in 78%. The remaining patients were closely followed up. Radiotherapy was performed after surgery in 22%. Operated patients had larger tumors (31 ± 11 vs 18 ± 9 mm, $P < 0.000$), more VFD (80 vs 40%, $P < 0.000$) and hormonal deficiencies (70 vs 42%, p:0.002) compared with non-operated patients; no age differences between the groups. In operated patients, tumor type: gonadotroph 63%, null cell 26%, silent GH 3%, silent PRL 2%, plurihormonal 1% and silent ACTH 1%. Ki67 was available in 49%: < 3%: 77%, between 3–10%: 23%; positive P53 in 23%, positive cytokeratin in 85%. After surgery: 16% of patients presented empty sella, tumor size reduction was > 50% in 30%, the remaining had < 50% tumor reduction. VFD improved in 42%, no change in 49% and worsened in 9%. Hormonal axes improved in 12%, no change in 50%, added deficiencies: 37%. Of 132 operated patients, 86 underwent only 1 surgery, 46 had more surgeries. In non-operated patients tumor size was stable in 82.5%, reduced in 12.5% and increased in 5%; VFD had no changes in 92.5%, improved in 7.5%; hormonal deficiencies had no changes in 95%, improved in 5%. Comparing operated and non-operated patients, the first showed more improvement in VFD (47 vs 18%, P:0.03) and tumor size (80 vs 12.5%, $P < 0.000$). Operated patients, had significantly more hormonal deficiencies (40 vs 0%, P:0.001). No correlation was found between VFD and age or sex. Kaplan–Meier analysis showed no significant differences in progression between operated and non-operated patients.
Conclusions
In patients with NFAs, surgery was the first therapeutic option, radiotherapy was performed in only 22%. Operated patients presented improvement in VFD but added hormonal deficiencies. Close follow-up of non-operated patients was preferred in smaller tumors.

Association between fibroblast growth factor-21 and carotid intima media thickness in patients with acromegaly

Meliha Melin Uygur[1], Dilek Gogas Yavuz[2] & Dilek Yazici[3]
[1]Marmara University Pendik Training and Research Hospital, Internal Medicine, Division of Endocrinology and Metabolism, Istanbul, Turkey; [2]Marmara University Medical School, Internal medicine, Division of Endocrinology and Metabolism, Istanbul, Turkey; [3]Koç University Medical School, Internal Medicine, Division of Endocrinology and Metabolism, Istanbul, Turkey

İntroduction
The aim of this study was to evaluate the association between fibroblast growth factor-21 (FGF-21) levels and carotid intima media thickness (CIMT) in acromegalic patients in relation to the atherosclerotic complications.
Metarials and methods
The study goroup included 70 acromegalic patients. According to the disease activity, patients cathegorized inti 2 groups: controlled and active acromegaly. Seventy-two patients were recruited to the control group. FGF-21, GH, IGF-1, lipids, glucose, insuline levels were assesed. Patients with acromegaly and control subjects were evaluated for their body mass index (BMI) (weight/height squared). CIMT was measured with a B-mode ultrasound.
Results
Median FGF-21 levels were significantly higher in control group compared to acromegaly group (472.5 vs. 192.5 pg/ml, $P < 0.001$, respectively). Acromegalic patients had higher CIMT than controls (0.63 ± 0.15 mm, 0.44 ± 0.08 mm; $P < 0.001$). FGF-21 levels and CIMT were not significantly different between controlled and active acromegaly patients ($P = 0.34$; $P = 0.24$, respectively). Although, there was no correlation between FGF-21 levels and CIMT in acromegalic patients ($P = 0.44$); a positive correlation was found between High-density lipoprotein (HDL) cholesterol and FGF-21 level ($P = 0.02$). In multiple regresyon analysis, HDL-C was the only determinant of FGF-21 (β coefficient = 0.604, $P = 0.02$). Regarding CIMT in multiple regresion analysis, fasting plasma glucose (β coefficient=0.461, $P = 0.02$), LDL (low-density lipoprotein) cholesterol (β coefficient = –1.295, $P = 0.04$), and systolic blood pressure (β coefficient=0.511, $P = 0.04$) were the influencing factors.
Conclusion
Acromegaly is associated with increased mortality due to cardiovascular complications. Data on serum FGF-21 levels in acromegaly were limited and conflicted. We found lower FGF-21 levels in acromegaly group than controls, despite high CIMT in these group. There was no association between FGF-21 levels and CIMT. This result may be associated with the improving effects of growth hormone on liver fat where the main regulation of FGF-21 take place. We found that glucose intolerance, lipid dysregulation, and hypertension were the factors influencing CIMT in acromegaly.

Age and sex differences among patients with acromegaly

Anna Bogusławska[1], Aleksandra Gilis-Januszewska[1], Magdalena Godlewska[1], Andrzej Nowak[1], Jerzy Starzyk[2] & Alicja Hubalewska-Dydejczyk[1]
[1]Jagiellonian University Medical College, Department of Endocrinology, Kraków, Małopolskie, Poland; [2]Jagiellonian University Medical College, Chair of Paediatric, Department of Peadriatric and Adolescence Endocrinology, Kraków, Poland

Introduction
Acromegaly is a chronic, slowly progressing disease caused in most cases by growth hormone (GH)- producing pituitary neuroendocrine tumors (PitNETs). This rare disorder is associated with a spectrum of various clinical manifestations and treatment outcomes differ between patients. The aim of this study was to evaluate the impact of age at the onset of symptoms and sex on clinical features, comorbidities, biochemical status at the diagnosis, and the severity of disease.
Methods
This is a one-centre cohort study conducted in 2019 among consecutive adult patients with acromegaly and no family history of PitNETs. Baseline data regarding biochemical and radiological status were collected retrospectively, whereas information concerning diagnostic delay, age at the onset of symptoms, menarche, voice break were collected during a routine visit in the outpatient clinic. Statistical analysis was performed in two subgroups depending on sex and in three subgroups depending on age at the diagnosis.
Results
101 consecutive patients were interviewed in the outpatient clinic (60 women, 41 men) with mean age at the diagnosis 46 years (range 19–75). Male patients presented hypogonadism more frequently than female patients (54.1% vs 25.5%, $P < 0.05$) whereas the differences between sexes in the occurrence of hyperprolactinemia and macroadenomas were not statistically significant. The occurrence of hypogonadism positively correlated with tumour size and negatively correlated with remission of the disease after the first surgery. Baseline IGF-1 level above the upper limit of age-adjusted normal range level and ACTH level were higher in men than in women(529.1 ± 277.7 vs 399.8 ± 250.6 ng/ml and 53.9 ± 28 vs 38.3 ± 23 pg/ml, respectively). Both basal and nadir GH did not differ between sexes. Among younger patients (≤ 40 years) hyperprolactinemia, hypogonadism and macroadenomas were discovered more frequently at the time of diagnosis than in the middle-aged (41–59 years) and in the elderly (≥ 60 years) ($P < 0.05$). Contrarily, arterial hypertension, nodular goitre and diabetes mellitus or glucose intolerance were more common among elderly patients with acromegaly than in younger age groups ($P < 0.05$).
Conclusion
According to our results, the course of disease in acromegaly is influenced by patient's gender and age at the onset of symptoms. These differences should be considered when treating patients with acromegaly.

Panhypopituitarism without pituitary ischemia after hantavirus infection

Damla Tufekci[1], Yasemin Emur Gunay[1], Ahmet Suat Demir[1], Beyhan Guvercin[2], Muhammet Cuneyt Bilginer[1], Hulya Coskun[1], Irfan Nuhoglu[1], Ozge Ucuncu[1], Kubra Kaynar[2] & Mustafa Kocak[1]
[1]Karadeniz Technical University Faculty of Medicine, Department of Endocrinology and Metabolism, Trabzon, Turkey; [2]Karadeniz Technical University Faculty of Medicine, Department of Nephrology, Trabzon, Turkey

Introduction
Hantaviruses are a group of viruses causing hemorrhagic fever with renal failure syndrome (HFRS). HFRS is a disease characterized by bleeding, thrombocytopenia, increased vascular permeability, and acute renal failure. Hypopituitarism associated with HFRS often results from necrosis in the pituitary gland caused by ischemia or infarction. HFRS may be difficult to diagnose due to its unclear clinical features. In this report, we present a patient who developed panhypopituitarism with preserved pituitary function following HFRS.
Case presentation
A 43-year-old male patient presented to the emergency service due to the complaints of body pain, nausea, vomiting, diarrhea. On physical examination, the temperature was 38 °C and the diagnostics tests indicated kidney failure and thrombocytopenia (Table 1). The patient was diagnosed as having HFRS since the patient was positive for both hantavirus and Ig M/G and also had a suspicious history of contact with rodents. The patient was referred to our endocrinology clinic due to the development of hypotension, hypoglycemia and hyponatremia during medical treatment. The patient was also diagnosed with panhypopituitarism. The patient was initiated on methylprednisolone 3×20 mg therapy. After the completion of this therapy, levothyroxine 50 mg was added to the treatment and its dosage was gradually increased to 75 mg. Upon the improvement of clinical and laboratory findings, the steroid therapy was reduced and maintenance treatment was initiated with hydrocortisone 2×10 mg. Magnetic resonance imaging (MRI) revealed a normal pituitary gland in terms of both size and appearance. The patienet was initiated on intramuscular testosterone propionate (IM) 250 mg every 3 weeks due to the presence of hypogonadism.At a 6-month follow-up, pituitary MRI showed a normal pituitary gland in terms of size and appearance, and the patient is still being followed up in our endocrinology outpatient clinic due to panhypopituitarism.
Conclusion
Panhypopituitarism is an extremely rare complication that may arise following HFRS. Clinicians should keep this complication in mind even in patients with normal pituitary MRI findings and should promptly initiate replacement therapies to reduce morbidity and mortality.
Keywords: panhypopituitarism, hantavirus

Table 1. Laboratory findings

	Value	Reference range
GH (µg/l)	0.08	< 3
IGF-1 (mg/ml)	22	58–215
FSH (IU/l)	1.01	1.27–19.26

Pulmonary thromboembolism-caused acute severe euvolemic hyponatremia complicated by COVID-19 infection: A case report

Bojan Joksimovic[1], Milica Radovic[2], Bojan Mitrovic[3], Sasa Pancevacki[2], Vladimir Samardzic[1], Milena Lackovic[1], Milan Obradovic[4], Esma R. Isenovic[4], Zoran Gluvic[3], Sandra Pekic Djurdjevic[5] & Milan Petakov[5]

Introduction
Hyponatremia is frequently encountered in clinical practice. Euvolemic hyponatremia (Syndrome of Inadequate Antidiuresis, SIAD) represents diagnostic and management challenge regarding etiology unraveling, its gradual acute substitution, and later causal treatment.
Case report
A 68-year-old woman was admitted to the Emergency unit with acute psychosis. On examination, there were no focal neurological signs. On admission, she had severe euvolemic hyponatremia (repeated serum sodium level of 101 mmol/l), while other laboratory parameters were within normal range, except for mild normocytic anemia. Further investigations confirmed the diagnosis of segmental pulmonary thromboembolism as a possible cause of SIAD, after other causes were excluded (malignancy, drugs, CNS diseases…). Hyponatremia was corrected carefully with hypertonic saline infusion and fluid intake restriction. The patient recovered from psychosis immediately with a gradual increase in serum sodium levels and its normalization. She was treated with low molecular weight heparin followed by oral anticoagulant therapy. After three weeks of treatment, the patient's medical history was complicated by asymptomatic SARS CoV-2 infection, and the patient was transferred to a COVID treatment determined hospital. Even though she has belonged to the high-risk group regarding the clinical outcome of COVID-19, her chest X-ray was normal. During hospitalization, her sodium level remained in the reference range (138–142 mmol/l) on unrestricted fluid intake.

Conclusion
This case should alert a clinician regarding the possibility of reversible psychosis in a patient presenting with acute severe hyponatremia caused by pulmonary thromboembolism. Her condition was further complicated by a COVID-19 infection, from which she recovered with no additional complications. Even in the cases with life-threatening hyponatremia (101 mmol/l), complete recovery of patients could be obtained by simultaneous careful correction of hyponatremia and management of its possible cause.

Recovery of reproductive function under indomethacin treatment in a woman with langerhans cell histiocytosis: A case report

Tiziana Feola[1,2], Michelina Santopietro[3], Maura Arosio[4], Giovanna Palumbo[5], Fiorina Giona[5] & Marie-Lise Jaffrain-Rea[1,6]
[1]Neuromed IRCCS, Neuroendocrinology, Pozzilli, Italy; [2]Sapienza University, Department of Experimental Medicine, Rome, Italy; [3]AO San Camillo-Forlanini, Hematology and Haematopoietic Stem Cells Transplant Unit, Rome, Italy; [4]University of Milan, Endocrinology, Department of Clinical Sciences and Community Health, Milan, Italy; [5]Sapienza University, Hematology, Department of Translational and Precision Medicine, Rome, Italy; [6]University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, Coppito (AQ), Italy

Introduction
Langherans Cell Histiocytosis (LCH) is a rare disease due to a neoplastic proliferation of Langerhans-type cells. Hypothalamic-pituitary (HP) involvement may occur in 20–40% of the patients, presenting with diabetes insipidus (DI) and/or anterior pituitary dysfunction. Typically, such abnormalities are permanent and unresponsive to systemic treatment of LCH. We report the case of a young woman with pulmonary and HP localizations, and significant endocrinological improvement during indomethacin treatment leading to a spontaneous, premature multiple birth.
Case report
A 26-yr old female, smoker, was diagnosed with pulmonary LCH due to respiratory symptoms, that improved after stopping smoking. Six years later, she presented polyuria (up to 8000 cc/24 h), leading to the diagnosis of DI, due to LCH localization on the pituitary stalk. Desmopressin therapy was started, up to 180 mg/day. In the same year, she stopped estrogen-progestin contraception, with a 7-months secondary amenorrhea. Endocrine investigation revealed a normoprolactinemic hypogonadotrophic hypogonadism with GH deficiency and normal thyroid and adrenal functions. Stimulation with GnRH (100 mg) showed a mild and late response and she was put on hormone replacement therapy (HRT). A few months later, indomethacin was started (up to 50 mg three times a day) and the doses of desmopressin was progressively reduced to 60 mg/day. HRT was discontinued because the patient wanted to have a baby but amenorrhea recurred, despite a clear increase in estrogen secretion and basal and GnRH-induced gonadotropin secretion. Medically assisted procreation failed three times even though she progressively recovered irregular menses. One year after the last attempt, at the age of 38, she had a spontaneous pregnancy and delivered two healthy premature monozygotic twins (at 33 weeks). Indomethacin was withdrawn at the beginning of pregnancy. She breastfed for two months and resumed menstruation.
Discussion
Little is known about the recovery of pituitary function after systemic treatment of LCH, with only a few reports of spontaneous DI recovery and a single case of gonadotroph deficiency recovery 3 years after the last course of glucocorticoids. In our case the improvement of DI and recovery of reproductive function occurred during indomethacin treatment.
Conclusion
To the best of our knowledge this is the first report of significant endocrinological improvement occurring during indomethacin treatment, which has recently shown to be effective in bone localizations through the inhibition of prostaglandins production. This observation indicates that HP dysfunction may be reversible and supports further studies to evaluate the potential role of indomethacin in this localization.

Growth Hormone (GH) treatment in adults with Prader-Willi Syndrome (PWS) restores plasma kisspeptin to normal levels

Olga Giménez-Palop[1,2], Laia Casamitjana[1,2], Raquel Corripio[2,3], Rocío Pareja[1], Joan Carles Oliva[2], Néstor Albiñana[2], Neus Gómez Gerique[2], Mercedes Rigla[1] & Assumpta Caixàs[1,2]
[1]Corporació Sanitària Parc Taulí, Endocrinology Department, Sabadell, Spain; [2]Institut d'Investigació i Innovació Parc Taulí (I3PT); [3]Corporació Sanitària Parc Taulí, Pediatrics Department, Sabadell, Spain

Background
Central kisspeptin action is well known in reproductive regulation; however, its peripheral action is not well understood. Most studies reveal that kisspeptin signaling influences energy and metabolic status.
Objective
To compare serum kisspeptin levels 1) between adult patients with PWS, obese subjects matched for age, sex and BMI and healthy subjects; 2) in adult patients with PWS before and after treatment GH.
Methods
Twenty seven GH-deficient adult patients with PWS (15 women, 30 ± 9.4 years), 27 obese subjects and 22 healthy subjects were studied. We determined anthropometric, glucose homeostasis parameters, body composition by DEXA and serum kisspeptin levels in all subjects at baseline and after 12 m of GH treatment in the PWS group.
Results
At baseline, there were no differences in serum kisspeptin levels between groups, although healthy group showed the lowest levels (PWS: 141.7 ± 21.0 pg/ml; obese: 141.5 ± 31.7 pg/ml; healthy: 127.7 ± 27.8 pg/ml, $P = 0.136$). Kisspeptin levels correlated with body fat mass ($r = 0.373$, $P = 0.008$). In the PWS group, after one year of GH therapy, lean body mass increased in 2.1% ($P = 0.03$), total fat mass decreased in 1.6% ($P = 0.005$) and serum kisspeptin dropped significantly ($P = 0.027$) to levels similar to healthy subjects (129.6 ± 29.8 pg/ml, $P = 0.816$).
Conclusions
In GH-deficient adults with PWS, one year of GH therapy effectively improves body composition and restores serum kisspeptin to normal levels. Further studies are necessary to elucidate the physiological mechanism of the relationship between changes in kisspeptin and body composition.

Body composition and nuchal skinfold thickness in pediatric brain tumor patients

Junxiang Peng[1,2], Svenja Boekhoff[1], Maria Eveslage[3], Brigitte Bison[4], Panjarat Sowithayasakul[1,5] & Hermann Müller[1]
[1]University Children's Hospital, Car von Ossietzky University Oldenburg, Department of Pediatrics and Pediatric Hematology/Oncology, Klinikum Oldenburg AöR, Oldenburg, Germany; [2]Southern Medical University, Guangzhou, Department of Neurosurgery, Nanfang Hospital, China; [3]University Münster, Institute of Biostatistics and Clinical Research, Germany; [4]Augsburg Hospital, Department of Neuroradiology, Augsburg, Germany; [5]Srinakharinwirot University, Department of Pediatrics, Bangkok, Thailand

Background
Obesity, cardiovascular disease (CVD), and relapse/progression have impact on prognosis in pediatric brain tumor (BT) patients.
Methods
In a cross-sectional study, we analyzed nuchal skinfold thickness (NST) on MRI follow-up monitoring as a parameter for body composition (BC) and CVD in 177 BT patients (40 WHO grade 1–2 BT; 31 grade 3–4 BT; 106 craniopharyngioma (CP)), and 53 healthy controls (HC). Furthermore, BMI, waist-to-height ratio (WHtR), caliper-measured skinfold thickness (cSFT), and blood-pressure (BP) were analysed.
Results
CP patients showed higher BMI, WHtR, NST and cSFT when compared with BT and HC. WHO grade 1–2 BT patients were observed with higher BMI, waist circumference and triceps cSFT when compared to WHO grade 3–4 BT patients. NST correlated with BMI, WHtR, and cSFT. NST, BMI and WHtR had predictive value for CVD in terms of increased BP. In multivariate analysis, only BMI was selected for the final model resulting in an odds ratio of 1.25 (1.14–1.379). In CP patients with hypothalamic involvement/lesion or gross-total resection, rate and degree of obesity were increased.

Conclusions
NST could serve as a novel useful parameter for assessment of BC and CVD risk in BT patients.

Uncured acromegaly, the dark side of the moon: a cross- sectional study

Mariana Gomes Porras[1], Alexa Benítez Valderrama[1], Álvaro Zamarrón Pérez[2], Carlos Pérez López[2], Isabel Esteban Rodríguez[3], Rosa García Moreno[1], Beatriz Lecumberri Santamaría[1] & Cristina Álvarez Escolá[1]
[1]Hospital Universitario La Paz, Endocrinology and Nutrition, Madrid, Spain; [2]Hospital Universitario La Paz, Neurosurgery, Madrid, Spain; [3]Hospital Universitario La Paz, Pathological Anatomy, Madrid, Spain

Introduction
Although surgical treatment of acromegaly is the treatment of choice in most patients, a wide therapeutic arsenal is available. Medical treatment can be indicated as primary treatment, complementary and even as pre-operative treatment.
Objectives
To determine the prevalence of uncured acromegaly and the prevalence of controlled disease within this group. To clinically, biochemically and histologically characterize uncured acromegalics. To analyze the predictive factors for non-cure in acromegaly.
Material and methods
Retrospective study of adult patients with uncured acromegaly under follow-up in the Neuroendocrinology Unit of a tertiary hospital in Madrid during the period 2000–2020. Non-cure criteria were considered: elevated IGF-1 according to age and sex and random GH ≥ 1µg/l and/or post OGTT 75 gr ≥ 0.4 or ≥ 1µg/l, according to the analytical method used. Controlled disease criteria were considered: normal IGF-1 according to age and sex and random GH < 2.5µg/l. Continuous variables were expressed as mean and standard deviation and categorical variables as absolute values and percentages. Univariate and multivariate logistic regression models were analyzed to determine predictors of non-healing, significant $P < 0.05$.
Results
Of 97 adult patients with acromegaly, 52.7% ($n = 51$) did not meet cure criteria, of these, 46.5% ($n = 40$) after sphenoidal surgery. 56.9% were women, age 61 ± 18.7 years, BMI 28.4 ± 5 kg/m^2, IGF-1 956.2 ± 677.1µg/l and GH 30.0 ± 42.7µg/l. 75% presented pituitary macroadenoma, 82.1% with extrasellar extension. 50% were somatotropinomas and the rest secreted GH+PRL (35%), GH + PRL + TSH (10%) and PRL (5%). 84.6% and 41.7% had positivity for Ki67 (72.7% < 3% and 27.3% 3–10%) and p53, respectively. 94.1% ($n = 48$) received medical treatment, 20 patients in monotherapy (12 SSAs, 7 carbergoline and 1 pegvisomant) and 28 patients in combined therapy (12 SSAs + cabergoline, 6 SSAs + pegvisomant, 1 pegvisomant + cabergoline and 9 triple therapy). In total, 92% met criteria for controlled disease, 100% of those treated with SSA and pegvisomant in monotherapy and 85.7% with cabergoline in monotherapy (directly proportional to the dose), and 89.2% of those receiving combined therapy. 35.7% also received RT, with 93.3% controlling the disease. Predictive factors of non-cure after surgery were pituitary macroadenoma, initial GH and IGF-1 values and co-secretion of GH + PRL and GH + PRL + TSH.
Conclusions
The surgical remission rate exceeds 50%. Almost all patients who are not cured achieve control of the disease with pharmacological treatment. Medical treatment should be individualized according to the presence of pituitary macroadenoma, co-secreting hormone pituitary adenomas, initial levels of GH and IGF-1 and the clinical and hormonal evolution of the patient.

Background
Prolactinomas are the most frequent type of hormone-secreting pituitary adenomas. Prolactin(PRL)-receptor mediates intracellular signaling pathways that contribute to weight gain, dyslipidemia, impaired fasting glucose (IFG), type 2 diabetes mellitus (T2DM) and cardiovascular disease, parameters that improve along with PRL level control on dopamine agonist (DA) therapy.
Aim
To assess metabolic disturbances in prolactinomas at diagnosis and during follow-up.
Methods
Fifty-seven patients with prolactinomas (aged 50.2 ± 17.6 years, 37 M:20 W median PRL 838.45 mg/l) were retrospectively assessed for weight, lipids, fasting glycemia, blood pressure, cardiovascular events. Evaluation was made at baseline, at 6, 12 and 24 months after DA treatment (1–7 mg/week cabergoline/7.5–30 mg/day bromocriptine). Nadir PRL on therapy was 0.2 mg/l. Serum PRL was measured by chemiluminescence.
Results
At the time of diagnosis, 27.3% were overweight and 52.7% obese. Weight excess was significantly more prevalent in men (89.2%) vs. women (55), $P < 0.01$ and in macroprolactinoma (83.7%) vs. microprolactinoma (37.5%), $P < 0.01$. Nine subjects had central hypothyroidism, 46 central hypogonadism and 5 panhypopituitarism. Initial BMI (29.8 ± 5.4 kg/m^2) significantly decrease both at 6-months (29.1 ± 4.6 kg/m^2, $P = 0.04$) and 24-months (28.9 ± 5.6 kg/m^2, $P = 0.01$). Maximum decrease in BMI (0.7 kg/m^2) occurred at 6-months, despite the fact that only 63.2% had achieved disease control. At the time of diagnosis, 65.3% had dyslipidemia. Initial cholesterol level was 208.3 ± 40.7 mg/dl and significantly decreased both at 6-months (185.1 ± 39.6 mg/dl, $P < 0.01$) and 24-months (183.5 ± 44.04 mg/dl, $P < 0.01$). Significant decrease was also observed in LDL-cholesterol and triglyceride levels from 127.3 ± 38.9 mg/dl and 165.3 ± 135.3 mg/dl at baseline to 106.2 ± 28.8 mg/dl($P = 0.05$) and 133.1 ± 77.4 mg/dl($P = 0.01$) at 6-months and to 106.9 ± 31.4 mg/dl and 115.5 ± 72.8 mg/dl, respectively at 24-months ($P < 0.01$). HDL-cholesterol levels were similar at 6-months, but significantly lower at 24-months compared to baseline (42.3 ± 9.9 mg/dl vs. 49.1 ± 44 mg/dl, $P = 0.04$). Nine of 37 dyslipidemic patients (24.3%) received statin. Arterial hypertension (26.31%, $n = 15$) and chronic coronary syndrome (CCS) (10.5%, $n = 6$) prevalence was similar at the time of diagnosis and at 24-months: 29.8% ($n = 17$) patients with hypertension and 12.3% ($n = 7$) patients with CCS. At baseline, 21.8% ($n = 12$) had IFG and 5.3% ($n = 3$) DM. At 24-months evaluation, the prevalence of IFG and DM was 7.3% ($n = 4$) and 3.6% ($n = 2$), respectively.
Conclusion
Two years dopamine agonists treatment improved metabolic parameters in prolactinoma patients, with weight loss, decrease in total and LDL-cholesterol and triglycerides. Long term follow-up, larger studies are necessary to assess cardiovascular risk of patients with PRM, in order to stratify therapeutic intervention and to reduce associated mortality.

AEP480

What should be the optimal testosterone level to improve the symptoms of hypogonadism in male macroprolactinomas?

Ozge Telci Caklili[1], Ayşe Merve Çelik[1], Zulal Istemihan[2], Ozlem Soyluk Selcukbiricik[1] & Sema Yarman[1]
[1]Istanbul University, Faculty of Medicine, Endocrinology and Metabolism, Istanbul, Turkey; [2]Sincik County Hospital, Adiyaman, Turkey

Objectives
Male prolactinoma patients mostly have hypogonadotropic symptoms. While treatment with dopamine agonists (DAs; such as bromocriptine or cabergoline) leads to recovery of sexual glands, it can lead to impulsive control disorders as an undesirable side effect. The aim of this retrospective study is to determine the level of testosterone that eliminates symptoms, provides fertility and does not cause this undesirable side effect regardless of prolactin (PRL) level in macroprolactinomas with long-term follow-up.

Material and Methods
Twenty-seven male patients with macroprolactinoma followed in outpatient Pituitary Clinic were included to the study. There were 16 macro (≥ 1–2.8 cm), 7 large macro (≥ 2.9–3.9 cm) and 4 giant (≥ 4 cm) adenomas. From medical records PRL, LH, FSH, Testosterone (T) were evaluated and a timeline was created to analyze the progress regarding symptoms of hypogonadism and infertility. At each visit, their answers to hypogonadism symptoms and fertility questions were evaluated. PRL and T levels in the period when they were asymptomatic and fertile were recorded. Fertility-induced T levels were compared with age-matched thirty-three controls. Patients with children prior to admission were excluded from fertility statistical analysis.
Results
The mean age of patients was 38.8 ± 11.8 years, and 41.6 ± 10.2 years in the controls. The average delay in diagnosis was 4.3 years. Mean PRL, basal tumor diameter and shrinkage were 2846 ± 3415 ng/ml, 27.2 ± 10.2 mm and 63.4%, respectively. Basal T levels were 1.6 ± 1.0 ng/ml for patients and 4.4 ± 1.5 ng/ml for controls ($P < 0.001$). Mean T level in asymptomatic period was significantly lower than controls (3.2 ± 0.4 ng/ml vs. 4.4 ± 1.5 ng/ml, respectively, $P = 0.002$), and at this time mean PRL was slightly elevated than normal as 27.2 ng/ml. Mean maximum dose of bromocriptine and cabergoline were 11.1 ± 5.1 mg/daily and 1.7 ± 0.6 mg/weekly, respectively. The patients were followed up for an average of 8.3 ± 4.8 years. Fertility was achieved in 6 of the patients who desired fertility, and there was no difference between the T levels of these patients and the controls (3.7 ± 0.8 ng/ml vs. 4.4 ± 1.5 ng/ml, $P = 0.38$). When fertility was achieved mean PRL level was 26.9 ± 23 ng/ml. The highest T levels of the patients under therapy was not significantly different from controls (4.9 ± 1.6 ng/ml vs. 4.4 ± 1.5 ng/ml, respectively). Mean PRL level accompanying these T levels was 12.1 ± 15.2 ng/Ml.
Conclusion
The slightly elevated PRL should not be taken into account in these patients under treatment, when symptoms disappear, or fertility is restored. Therefore, patients should be carefully questioned in terms of their complaints at each visit and the dose of DA should not be increased unnecessarily to avoid possible adverse serious side effects.

AEP481

Pituitary function after transsphenoidal surgery including measurement of basal morning cortisol as predictor of adrenal insufficiency

Ida Staby[1], Jesper Krogh[1], Marianne Klose[1], Ulla Feldt-Rasmussen[1], Lars Poulsgaard[2], Jacob Bertram Springborg[2] & Mikkel Andreassen[1]
[1]Rigshospitalet, University of Copenhagen, Department of Endocrinology; [2]Rigshospitalet, University of Copenhagen, Department of Neurosurgery

Introduction
Patients with pituitary adenomas undergoing transsphenoidal surgery require pre- and post-surgery examination of pituitary hormones. There is currently no consensus on how to evaluate the adrenal axis post-surgery. The aims of this study were to investigate factors that may predict postoperative adrenal insufficiency (AI) and to investigate the overall effect of transsphenoidal surgery on the pituitary function.
Methods
One-hundred-and-forty-three consecutive patients who had undergone transsphenoidal surgery for pituitary adenomas were included. Data on tumour size, pituitary function pre-surgery, plasma basal cortisol measured within 48 hours post-surgery and pituitary function 6 months post-surgery were collected. Patients with AI prior to surgery, perioperative glucocorticoid treatment, Cushing's disease and no re-evaluation after 1 month were excluded ($n = 93$) in the basal cortisol analysis.
Results
Low plasma basal cortisol post-surgery, tumour size and previous pituitary surgery were predictors of AI (all $P < 0.05$). A basal cortisol cut-off concentration of 300 nmol/l predicted AI 6 months post-surgery with a sensitivity and negative predictive value of 100%, specificity of 81% and positive predictive value of 25%. New gonadal, thyroid and adrenal axis insufficiencies accounted for 2%, 10% and 10%, respectively. The corresponding recovery rates were 17%, 7% and 24%, respectively
Conclusion
Transsphenoidal surgery had an overall beneficial effect on pituitary endocrine function. Low basal plasma cortisol measured within 48 hours after surgery, tumour size and previous surgery were identified as risk factors for AI. We recommend measurement of basal cortisol post-surgery to secure glucocorticoids to patients at risk of AI and to avoid unnecessary glucocorticoid treatment.

Table 1. Association between basal cortisol and adrenal axis six months post-surgery

Basal cortisol level	Sufficient	Insufficient	Total	Cut-off limits	Specificity	Sensitivity	NPV	PPV
0–99 nmol/l	2	2	4	100 nmol/l	96%	67%	98%	50%
100–199 nmol/l	2	0	2	200 nmol/l	92%	67%	98%	33%
200–299 nmol/l	5	1	6	300 nmol/l	81%	100%	100%	25%
300–399 nmol/l	9	0	9	400 nmol/l	62%	100%	100%	14%
400–499 nmol/l	4	0	4	500 nmol/l	53%	100%	100%	12%
500–599 nmol/l	4	0	4	600 nmol/l	45%	100%	100%	10%
> = 600 nmol/l	21	0	21					
Total	47	3	50					

Grouping plasma basal cortisol levels according to sufficiency vs. insufficiency of the adrenal axis assessed by Synacthen-test six months post-surgery. PPV = Positive predictive value. NPV=Negative predictive value.

Factors that contribute to dopamine agonist resistance of prolactinomas

Maria Berdeli[1], Raluca Trifanescu[1,2], Andra Caragheorgheopol[3], Anda Dumitrașcu[3] & Catalina Poiana[1,2]
[1]'Carol Davila' University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania; [2]'C. I. Parhon' National Institute of Endocrinology, Pituitary and Neuroendocrine Tumors, Bucharest, Romania; [3]'C. I. Parhon' National Institute of Endocrinology, Bucharest, Romania

Introduction
Prolactinomas are the most common hormone-secreting pituitary tumours encountered in the clinic. They are usually treated with dopamine agonists (DA): bromocriptine (BRC) and cabergoline (CAB), which are highly effective in the majority of cases. DA resistance is the failure to achieve normal levels of prolactin and, or reduction of the adenoma with at least 50%.
Aim
to assess the prevalence of the known factors that contribute to DA resistance (male gender, younger age at diagnosis, large tumours, the invasiveness of the tumour) among patients that do not respond to medical treatment.
Materials and methods
222 patients with prolactinoma were retrospectively assessed for treatment responsiveness. Gender, age of the diagnosis, serum prolactin levels, the dimensions of the pituitary adenoma were compared in responsive and resistant patients. Prolactin was measured by chemiluminescence and tumour volume and extension by computed tomography scan or MRI.
Results
there were 188 patients responsive to DA therapy and 34 resistant ones. There is no significant gender differences between the 2 groups (M:F = 83:105 in responsive group vs. 16:18 in resistant group, n = ns, chi square test). Resistant patients tend to be younger (30.5 ± 12.5 years) than responsive ones (35.6 ± 13.6 years), P = ns. Serum median prolactin was similar in responsive patients (650 ng/ml) and in resistant ones (462 ng/ml). Median maximum diameter was also similar (2.1 cm vs.2.12 cm).
Conclusions
In our series, there were no significant differences regarding gender, age at diagnosis, initial prolactin levels or tumour volume between patients responsive or resistant to DA therapy. Attention should be payed to histological and genetic differences between these patients.

Electrolyte disturbances in hospitalized patients with COVID-19

Zaur Abilov, Anastasia Kononykhina, Daria Sardaeva, Nino Katamadze, Ekaterina Pigarova, Larisa Dzeranova, Evgenia Marova, Olga Yu. Rebrova, Galina Melnichenko & Natalia Mokrysheva
Endocrinology Research Centre, Moscow, Russian Federation

Introduction
SARS-CoV-2 has caused a global outbreak of coronavirus disease 2019 (COVID-19). It is known that this virus binds angiotensin-converting enzyme 2 (ACE2) of the renin-angiotensin system, which may exert substantial effects on sodium and potassium metabolism. Viral pneumonia and respiratory distress are well known etiologies for hyponatremia due to syndrome of inadequate secretion of antidiuretic hormone, and can worsen clinical course of the disease and outcomes.
Aim
To investigate the prevalence of electrolyte disturbances (hyponatremia, hypokalemia) in patients with COVID-19.
Materials and methods
We examined medical records of 153 patients, which were hospitalized for inpatient treatment of COVID-19 infection from May to June 2020. Study group included 75 men (49%) and 78 women (51%), median age 60 years [Q1 47; Q3 73], BMI 28.7 kg/m^2 [25.0; 32.9]. All patients were diagnosed with pneumonia due to SARS-CoV-2 with median percent of lung involvement 28.5% [15.3; 44.7]. Median SpO2 was 94% [92; 97], and median NEWS score was 3 [2; 6]. There were 10 lethal cases. 14 patients at admission received diuretic therapy.
Results
On admission, the median natremia was 137 mmol/l [135; 139], hyponatremia (Na < 135 mmol/l) was detected in 25% (95% CI 18–32%), profound hyponatremia (Na < 130 mmol/l) – in 4.6% (2–9%), hypernatremia (Na > 145 mmol/l) in 0.6% (0–4%) of patients. Median potassium levels were 3.8 mmol/l [3.5; 4.2], hypokalemia (K < 3.5 mmol/l) was detected in 17.6% (12–25%), hyperkalemia (K > 5.1 mmol/l) in 2.6% (1–7%) of patients. Diabetes mellitus (DM) was observed in 15% of patients and was associated with lower Na levels 135 mmol/l [132; 136] vs 137 mmol/l [135; 139] in patients without DM (P = 0.003, Mann-Whitney test), and not with K levels. Na and K levels at admission were not associated with diuretic use by patients.
Conclusions
Our data suggests that hospitalized patients with COVID-19 infection have the high prevalence of impairment of sodium and potassium homeostasis, up to 32% and 25% respectively.

Spontaneous remission of cushing's disease – a case report

Ana Maria Curt[1], Carmen Emanuela Georgescu[1], Adriana Bintintan[2] & Ioana Rada Popa Ilie[1]
[1]'Iuliu Hatieganu' University of Medicine and Pharmacy, Endocrinology, Cluj-Napoca, Romania; [2]County Emergency Hospital, Gastroenterology, Cluj-Napoca, Romania

Adrenocorticotropic hormone (ACTH) adenomas causing Cushing's disease (CD) have been recognized as an aggressive and invasive subtype of pituitary adenomas. Remission of CD without surgical or medical treatment is an extremely rare occurrence. Moreover, a clinically relevant peculiarity of these tumors, though rarely observed, is their ability to modify their clinical expression from a silent form to CD or vice versa, the latter even more unexpected. We describe the case of a 51-year-old woman referred to our clinic from the Gastroenterology Department in November 2018 with typical signs and symptoms of Cushing's syndrome. The laboratory tests supported an ACTH dependent Cushing's syndrome, with a high-normal ACTH and a high-dose dexamethasone suppression test with a more than 50% reduction of plasma cortisol, suggesting CD. Though initial, the brain MRI could not reveal a pituitary tumor, 10 months later a 6 mm pituitary microadenoma was described upon follow-up MRI. She was treated with metyrapone as part of the PROMPT study (a prospective multicenter, open-label, phase III/IV study). After a 12 weeks period of titration to achieve normal urine and serum cortisol levels, the patient entered the 6-month extension period during which she received 1500 mg of metyrapone daily, with significant clinical and biochemical (as defined by mean urine free cortisol (UFC) ≤ upper limit of normal) improvement. The treatment was stopped on 15 December 2019, according to study protocol and the patient was reevaluated 5 and, respectively, 6 months later. Surprisingly, she appeared much improved, though she did not receive any treatment to counteract hypercortisolism during this period. She had lost 18 kilograms and we could note the disappearance of cushingoid features as well as a remission of diabetes mellitus and arterial hypertension. These findings were further supported by the hormonal evaluation that excluded an active CD. Moreover, the pituitary-adrenal axis was normal (cortisol 8 a.m. = 6.9 μg/dl, ACTH = 29.3 pg/ml, 24-hour UFC = 152.3 μg/24 h), whereas the pituitary MRI revealed no pituitary mass as well as no signs of hemorrhage or infarction. There were no clinical and biochemical signs of recurrence 12 months later, in December 2020, either. This spontaneous remission from CD is puzzling and there seems to be no explanation for it. However, though regrowth of the pituitary adenoma and recurrence are even less encountered than spontaneous remission in CD, careful lifelong follow-up is mandatory in this patient.

Hypopituitarism in systemic diseases

Derbel Abir, Guermazi Mouna, Snoussi Mouna, Donia Chebbi, Dammak Chifa, Frikha Feten, Raida Ben Salah, Marzouk Sameh & Bahloul Zouhir Chu Hedi Chaker, Internal Medicine, Tunisia

Introduction
Hypopituitarism is a rare condition defined by loss of pituitary function due to involvement of hypothalamus and/or pituitary gland by infiltrative diseases mainly sarcoidosis and Langerhans cell histiocytosis (LCH). Central diabetes insipidus is the most frequent manifestation of LCH (10–50%) and rarely in neuro-sarcoidois. Herein, we describe 2cases of hypopituitarism due to neuro-sarcoidosis and LCH.
Case 1
A 38 year-old man was admitted in endocrinology department to be explored for central diabetes insipidus. MRI imaging showed multifocal osteolytic lesions in maxillary and mandibular bones, thick pituitary stem and disappearance of the T1 hyper signal from the post pituitary gland. The patient presented normal renal function, normal levels of ACTH and thyroid-stimulating-hormone as well as serum electrolytes (sodium: 137 mmol/l, potassium: 3.8 mmol/l; calcium: 8.8 mg/dl). Mandibular-bone-biopsy and histological findings confirmed the diagnosis of LCH with multi-system bone and post-pituitary involvement. The patient received corticosteroid in combination with vasopressin through the nasal route. He also underwent surgical resection of maxillary lesion and dental prosthesis. Evolution was marked by persistence of diabetes insipidus requiring continued substitution with vasopressin. 3 years later, he presented bilateral mixed hearing loss due to secondary chronic medial otitis and dyspnea. Thoracic CT showed diffuse micro-cystic lesions in the lung parenchyma. High doses of steroids, vinblastine and vasopressin were started. He was lost from sight for 4 years, he stopped treatment except vasopressin. He had persistent deafness. Biological assessment was normal. Radiological assessment showed the same pulmonary, mastoid and mandibular lesions observed 4 years ago. The patient was considered in remission.
Case 2
A 49 year-old women was presented in internal medicine department in 2006 with cutaneous lesions (erythematosis lesions/nodules) in the upper member and the trunk. She suffered from short breath and cough. CT scan showed bilateral hilar lymphnodes enlargement with interstitial lung lesions. Pulmonary function test revealed low static lung volumes with low DLCO. Skin and lymph nodes biopsies revealed granulomas without caseum necrosis. Hormonal evaluation demonstrated decreased thyroid-stimulating hormone secretion with decreased thyroid hormone. Pituitary magnetic resonance imaging revealed thickening of pituitary stalk. Treatment of central hypothyroidism by thyroid hormone replacement was administered. Corticosteroids at the doses of 0.5 mg/kg/day were prescribed for 4weeks followed by progressive tapering with total duration of 4 years.
Conclusion
Central diabetes insipidus canbe related to several etiologies. Rare causes must be kept in mind, especially infiltrative diseases such as sarcoidosis or histiocytosis. Systemic clinical presentation guides usually the diagnosis.

A successful surgical outcome in thyrotropin-secreting pituitary macrodenomas

Hessa Boharoon[1], Emma Hatfield[1], Gautam Das[2], Nigel Mendoza[3] & Karim Meeran[1]
[1]Imperial College Healthcare NHS, Endocrine, United Kingdom; [2]Saint Peter's Hospital, London, United Kingdom; [3]Imperial College Healthcare NHS, Neurosurgery, United Kingdom

Background
TSHomas are a rare cause of hyperthyroidism, and account for 0.5 to 3% of pituitary tumours. Incidence=0.15 per million per year. Prevalence=1 per million. Our limited experience of this condition can result in diagnostic and treatment challenges. Here we describe a case treated surgically lead to successful outcomes
Case
35 years old female referred to our service with secondary amenorrhea for the last two years. Amenorrhea Started after her delivery. She was on oral contraception pill before her pregnancy. She had associated increased tiredness, anxiety and palpitations. She has no medical or family history of endocrinopathy. Not on any regular medications. Clinically euthyroid. No eye disease or goitre, visual fields intact to confrontation. Initial bloods revealed high free T4 and T3 with inappropriate normal TSH level. Repeated bloods in different assay showed same results. Considered to be close to a state of syndrome of inappropriate secretion of thyroid-stimulating hormone. Accordingly investigations send looking for TSHoma Vs TSH resistance hormone. Sex hormone binding globulin, Alpha-glycoprotein subunits were both elevated suggestive of TSHoma. Thyroid releasing hormone test done showed flat response. Magnetic resonance imaging showed a macropituitary tumor.Started on larenotide however she could not tolerate it, surgery performed subsequently, histology confirm TSHoma. Few weeks later her thyroid function normalized and her symptoms improved including period become regular.
Conclusion
Surgery remains the first-choice treatment for TSHoma. If surgery is successful, recurrence is rare. Our case showed an excellent outcome in typical case of TSHoma, respond very well to the surgical intervention. Surgical option is the first line, however surgical failure can be seen in 40 percent of cases.

AEP487

Case report: Girl with short stature with no response to growth hormone treatment

Gheorghe Elena Teodora[1] & Albu Alice Ioana[1,2]
[1]Elias Hospital, Endocrinology and Diabetes Department, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Introduction
Growth hormone deficiency (GHD) is a rare disorder and severe forms of GHD may have a genetic basis. Familial isolated growth hormone deficiency (IGHD) is classified into 4 types, type IA being the most severe form. These patients present with severe growth failure with undetectable growth hormone (GH) concentrations and about 50% tend to develop antibodies on GH treatment.(1, 2, 3) The appearance of anti-GH antibodies may not be a regular finding even among members of the same family. There have been reported cases when these antibodies have disappeared after a few years. (4, 5).
Case report
We present the case of a young female patient who was referred for endocrinological evaluation for short stature at the age of 1 year. She came from a family with a very short mother (height of 145 cm) without an endocrinological evaluation and a sister treated with somatropinum for severe GHD for 9 years, with a good height response to treatment. The patient presented with severe short stature, height of 62 cm (–5.17 standard deviations, SD), with normal weight (body mass index (BMI) 16.64 kg/m^2). The paraclinical exam showed undetectable GH, low values of insulin growth factor 1 (IGF1), normal 25 hydroxyvitamin (25OHD), normal thyroid and adrenal function. Dynamic growth hormone evaluation showed unstimulated levels. Pituitary MRI (magnetic resonance imaging) showed adenohypophyseal hypoplasia. Based on the evaluation she was diagnosed with severe GHD and received treatment with somatropinum 0.23 microg/kg bw/day. At the six months reevaluation we found a height of 63.3 cm (–6.11 SD) and a BMI of 15.62 kg/m^2. The response to treatment was considered inadequate and an IGF1 generation test was performed without a significant increase of IGF1. The most probable explanation was the presence of GH antibodies, but the test was not available. She was followed for 1 year, but the height parameters were not improved (at the age of 2.5 years, height of 64.8 cm, -6.94 SD)
Conclusions
In patients with familial IGHD the response to somatropinum treatment could be affected by the appearance of anti-GH antibodies. Although these antibodies can disappear after few years, in cases with disabilitating short stature the lack of treatment can have a severe impact on the well being and the development of the patients. Although mecasermin might be an alternative in these cases, their approved indications can limit the access to treatment.

Pituitary surgery in northern ireland: A twenty year retrospective population based analysis

Paul Benjamin Loughrey[1,2], Stephanie Craig[1], Brian Herron[3], Stephen Cooke[4], Philip Weir[4], Debarata Bhattacharya[5], Erin Sturdy[5], Manuel Salto-Tellez[1,3], Eileen Parkes[6], Darragh McArt[1], Marta Korbonits[7], Steven Hunter[2] & Jacqueline James[1,3,8]8
[1]Queen's University Belfast, Patrick G Johnston Centre for Cancer Research, Belfast, United Kingdom; [2]Royal Victoria Hospital, Regional Centre for Endocrinology and Diabetes, Belfast, United Kingdom; [3]Royal Victoria Hospital, Department of Cellular Pathology, Belfast, United Kingdom; [4]Royal Victoria Hospital, Department of Neurosurgery, Belfast, United Kingdom; [5]Royal Victoria Hospital, Department of Neuroradiology, Belfast, United Kingdom; [6]University of Oxford, Department of Oncology, Oxford, United Kingdom; [7]Barts and the London School of Medicine and Dentistry, Queen Mary University of London, Centre for Endocrinology, William Harvey Research Institute, London, United Kingdom; [8]Queen's University Belfast, Northern Ireland Biobank, Belfast, United Kingdom

In Northern Ireland, the sole tertiary referral centre for pituitary disease which includes neurosurgery and endocrinology for ~1.9 million people, is based in the Royal Victoria Hospital, Belfast. A retrospective study has been commenced to examine clinical, biochemical, histopathological and radiological data for all patients operated on across an approximately 20 year period in Northern Ireland. Ethical approval was obtained from the Northern Ireland Biobank (study number NIB18–0282). We present preliminary clinical and histopathological data on this Northern Ireland pituitary surgery population cohort. To date, a total of 704 pituitary samples have been identified between 2000 to mid 2019, an average of 35.9 surgeries per year. During this time there were maximum two operating pituitary surgeons. There were 20 procedures for 17 paediatric patients, with the most common diagnosis being craniopharyngioma (n = 6). A total of 684 procedures for 633 adult patients were undertaken, of which 285 patients were female and 348 were male. Average age of the entire adult cohort at resection was 53.3 years (SD ± 15.1 years), with average resection age 50.6 years for female and 55.5 years for male. 591 surgeries were completed for pituitary neuroendocrine tumours (PitNETs) (86%), diagnosed on the basis of combined clinical, histopathological and radiological assessment. The majority of these procedures were undertaken for non-functioning PitNETs (n = 390, 66%). Other operated PitNET pathologies included acromegaly/gigantism (n = 112, 19%), Cushing's disease (n = 60, 10%), prolactinoma (n = 20, 3%) and thyrotropinoma (n = 7, 1%). Only two samples could not be completely characterized. There are seven patients known to have AIP mutations in this surgical cohort (1% of all patients). Other more frequent pathologies requiring surgical intervention or biopsy included craniopharyngioma (n = 27), Rathke's cleft cyst (n = 17) and hypophysitis (n = 7). Rare diagnoses included paraganglioma (n = 1), meningioma (n = 1) and Non-Hodgkin's B cell lymphoma (n = 1). There were two perioperative deaths (mortality rate 0.3%), both secondary to postoperative haemorrhage. In summary, from the beginning of the year 2000 to mid 2019 this Northern Ireland tertiary referral centre has averaged appoximately 36 adult pituitary procedures per year, the majority of which were undertaken for PitNETs (86%). Establishment of a pituitary database spanning nearly two decades will provide a valuable research resource suitable for integration with novel tissue based analysis and will assist in clinical service improvement to enhance our understanding of pituitary disease, particularly in Northern Ireland.

[2]Bakirkoy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Turkey, Department of Psychiatry, Istanbul, Turkey

Purpose
To assess the depression and anxiety and their relationship with disease activity in patients with Cushing's syndrome (CS) in the COVID-19 pandemic.
Material and methods
This is a cross-sectional study including 54 patients with CS (48 female/6 male). Beck Depression Inventory-II (BDI-II), State Trait Anxiety Inventory (STAI)-State, STAI-Trait were used to evaluate, scores and severity of depression, the current state of anxiety, and general anxiety, respectively. Patients with active CS (n = 10) were recorded as group 1, those who were still receiving glucocorticoid replacement therapy after surgery (n = 14) as group 2, and those in remission (n = 30) as group 3. The groups were compared in terms of parameters that could affect anxiety and depression scores. Correlation analyses were also performed.
Results
BDI-II scores were higher in group 1 than group 3 (P = 0.002), and STAI-State scores were higher in group 1 than group 2 (P = 0.03) while STAI-Trait scores and the other parameters were similar between the groups. Moderate and severe depression were detected in 60% of group 1, 25% in group 2, and 16% in group 3. High state anxiety was seen in 70% of patients in group 1, 50% in group 2, and 57% in group 3. There were positive correlations between BDI-II scores and disease activity (r = 0.438, P = 0.001), and STAI-State scores and disease activity (r = 0.297, P = 0.029).
Conclusion
Increased depression and state anxiety during the pandemic in patients with active CS suggested that psychiatric disorders may increase in those with a higher risk of severe COVID-19 disease.

Third month MRI predicts macroprolactinoma reduction after cabergoline therapy

Betina Biagetti[1], Silvana Sarria-Estrada[2], Karelis Ng-Won[2], Martinez-Saez Elena[2], Anna Casteras[2], Cordero-Asanza Esteban[2], Irene Hernández-Hernández[2], Efrain Cordero-Vazquez. [2], Rojano Alba[2] & Rafael Simo Canonge[2]
[1]Vall d'Hebron University Hospital, Endocrinology, Barcelona, Spain; [2]Hospital Universitari Vall d'Hebron, Barcelona, Spain

Background
Transsphenoidal surgery is in general the preferred first-line treatment for patients with macroadenomas except for prolactinomas, which is mainly indicated when the treatment with dopamine agonists (DA) fails. However, in those patients resistant to DA (i.e. volume reduction < 50% in the follow-up) this strategy delays the surgical procedure.
Objective
To identify predictors of DA resistance in order to select patients who may benefit from early surgery.
Methods
We retrospectively analysed a database of a tertiary reference centre searching for patients diagnosed of prolactinoma after 2010 (when medical records were computerized) and with active follow up in the last five years. The adenoma volume was analysed by MRI before 3 and 12 months of treatment. We used spearman rank to investigate if our main outcome: (volume reduction of ≥ 50% after 12 months of treatment with DA therapy), was influenced by several variables including age, gender, prolactin levels, DA doses and adenoma volume reduction at 3–4 month of treatment.Finally we tested by logistic regression which variables predict better the main outcome.
Results
A total of 185 prolactinomas where included: 124 (67.0 %) were microadenomas and 61 (33.0%) were macroadenomas. We excluded 28 patients with incomplete data or diagnosed before 2010 and 6 patients that underwent surgery in first line. Finally, 27 patients meet de inclusion criteria; mean age [44.4 years; CI 95%: (37.8–59.8)].), of whom 10 were women (37.0%) and 17 were men (63.0%). Mean follow up [67.5 months; CI 95%: (52.5.0–82.7)]. Ten (37.0%) patients (8 males: 80.0%) underwent surgery after more than one year of DA because a lack of tumour reduction. The volume reduction at the first MRI (3–4 months) was the unique valuable predictor: [OR: 1.16 (IC 95% 1.02–1.32)]. A cut off tumour volume reduction ≥ 35% by the first 3–4 months of DA therapy predicted subsequent volume reduction > 50% in the first year with an AUC 0.95 [CI: (0.76–0.99)].
Conclusion
The tumor shrinkage in the first 3–4 month after starting treatment with DA is the best predictor of future volume reduction resistance. These results could help in decision-making regarding the management of macroprolactinomas.

The role of cannulated prolactin test in females of reproductive age presenting with isolated mild persistent hyperprolactinaemia on random sampling

Hady Gad, Yaasir Mamoojee & Andy James
Royal Victoria Infirmary, Department of Endocrinology, Newcastle-upon-Tyne, United Kingdom

Introduction
Current guidelines recommend a single elevated prolactin measurement drawn without excessive venepuncture stress as sufficient for diagnosing hyperprolactinaemia. However, previous studies have demonstrated that the cannulated prolactin test is more reliable at eliminating stress-induced hyperprolactinaemia, thus avoiding unnecessary additional investigations. We routinely perform morning serial prolactin sampling immediately after brachial vein cannulation followed by repeat sampling at 30 and 60 minutes of rest, to rule out stress-induced hyperprolactinaemia.
Objectives
This retrospective study aimed at evaluating the incidence of stress-induced hyperprolactinaemia in females of reproductive age referred to our hospital with isolated mild hyperprolactinaemia on repeat random testing in the community. We investigated any correlation between presenting symptoms and diagnosis of true hyperprolactinaemia and the incidence of pituitary abnormality on MRI.
Methods
All adult female patients, aged between 18–53 years, undergoing cannulated prolactin testing at our Endocrine Unit between 2016 and 2020 were included. Exclusion criteria: presence of macroprolactinaemia, chronic kidney disease, genetic predisposition syndromes, previous diagnosis of pituitary tumours and those with abnormal thyroid biochemistry.
Results
55 patients were eligible, with an average age of 33 years. The mean level of referral prolactin was 979 mIU/l (min: 511, max: 3022, normal range < 496 mIU/l). 40% of patients presented with menstrual disturbances and 32% had galactorrhoea. 58% of patients had a normal prolactin level on cannulated testing, thus confirming stress-induced hyperprolactinaemia. Those with true hyperprolactinaemia were more likely to report galactorrhoea (48% vs. 21%, P < 0.05). 15/32 (47%) patients with stress-induced hyperprolactinaemia were asymptomatic (vs. 26%, P < 0.05). 52% of patients with true hyperprolactinaemia harboured an abnormality on pituitary MRI. Those with a lesion were younger (mean age 30 years vs. 40 years in those with normal MRI, P < 0.05). There was no statistically significant difference in baseline prolactin or symptomatology between the group with normal MRI finding and those with abnormal MRI. Notably 2/5 asymptomatic patients with true hyperprolactinaemia had a microadenoma evident of MRI.
Conclusion
The cannulated prolactin test reliably diagnosed stress-induced hyperprolactinaemia in our select cohort of female patients of reproductive age. Whilst asymptomatic patients are more likely to have stress-induced hyperprolactinaemia, 40% harbour a microprolactinoma if diagnosed with true hyperprolactinaemia on cannulated prolactin testing.

AEP492

GH and IGF-1 discrepancies in acromegaly patients after pituitary surgery – an observational single-center study

Agnieszka Tomasik, Maria Stelmachowska-Banaś & Wojciech Zgliczyński
Centre of Postgraduate Medical Education, Endocrinology Department, Warsaw, Poland

Introduction
Treatment of choice in acromegaly is transsphenoidal resection of GH-secreting pituitary adenoma. Its efficacy ranges from 28% to 83% depending on tumor size and location. Random GH < 1 μg/l or nadir GH in OGTT < 0.4 μg/l and normal IGF-1 are found to be the evidence of effective

surgery. However, some patients diagnosed with acromegaly remission after surgery present discordant GH and IGF-1 results.
Aim
Purpose of this study was to assess the frequency of discrepancy between GH and IGF-1 levels and identify parameters that might affect its occurrence.
Material and methods
Fourty seven patients (19 males, 40.4%) with acromegaly remission after pituitary surgery were included in the study. Random GH and IGF-1 measurements 3, 6, 12, 24 and more than 24 months after surgery were analyzed in terms of discrepancies. GH measurements in OGTT 3 months after surgery and later, if random GH > 1 μg/l, were performed. We defined discrepancy either as random GH > 1 μg/l or nadir GH > 0.4 μg/l in OGTT and normal IGF-1 or GH below levels listed before and elevated IGF-1. Clinical factors such as: sex, age, age at diagnosis, diagnosis delay, BMI, weight, tumour size, GH and IGF-1 at diagnosis and carbohydrate metabolism were analyzed in patients with and without GH and IGF-1 discrepancies. None of the patients required pharmacological treatment of acromegaly after surgery.
Results
The percentage of patients with GH and IGF-1 discrepancies was the smallest 3 months after surgery (42%), then increased 6 months after surgery (71%) and finally decreased over time (60% after 12 months, 55% after 24 months and 52% more than 24 months after surgery). The most frequent type of discrepancy was slightly elevated IGF-1 and random GH < 1 μg/l or nadir GH < 0.4 μg/l in OGTT (over 70% of patients with discordant GH and IGF-1 results within the first year after surgery). IGF-1 tended to decrease over time. Age, age at diagnosis, diagnosis delay, BMI, weight, tumor size, GH and IGF-1 at diagnosis were similar in patients with and without discrepancies ($P > 0.05$). A tendency to higher percentage of males in group with discrepancies was observed, 55% vs 30%, $P = 0.08$.
Conclusions
Discrepancy between GH and IGF-1 are common in patients with acromegaly remission after surgery affecting 42% to 71% of patients depending on time after surgery. Patients with GH and IGF-1 discrepancies should be observed, although the frequency of discrepancies decreases over time. Men may be more likely to present GH and IGF-1 discrepancies after effective adenomectomy.

Growth hormone treatment for adults with Prader-Willi syndrome: A meta-analysis

Anna Rosenberg[1], Caroline Passone[2,3], Karlijn Pellikaan[1], Durval Damiani[2], Aart Jan Van der Lely[1], Michel Polak[3], Wanderley Bernardo[4] & Laura De Graaff[1]
[1]Erasmus University Medical Center, Internal Medicine, Division of Endocrinology, Rotterdam, Netherlands; [2]Universidade de Sao Paulo, Pediatric Endocrinology Unit, Sao Paulo, Brazil; [3]Hôpital Universitaire Necker Enfants Malades, Université Paris Descartes, Pediatric Endocrinology, Gynecology and Diabetology, Centre de Référence des Pathologies Gynécologiques Rares et des Maladies Endocriniennes Rares de la Croissance et du Développement, Paris, France; [4]Universidade de Sao Paulo, Sao Paulo, Brazil

Background
Features of Prader-Willi syndrome (PWS) overlap with features of growth hormone (GH) deficiency, like small hands and feet, short stature, increased body fat and low muscle mass and strength. In children with PWS, GH treatment improves physical health, cognition and quality of life (QoL). GH treatment is standard of care in PWS children, but in adults this is not the case. A systematic review and meta-analysis was conducted to provide a concise overview of the current knowledge on GH treatment in adults with PWS.
Methods
The databases Medline, Embase and Cochrane Central Register of Controlled Trials were sought for studies on the efficacy or effectiveness of GH treatment for adults with PWS. Randomized controlled trials (RCTs) and non-randomized (un)controlled trials (NRCTs) that reported data for adults with PWS who received GH treatment for at least six months were selected. Data on body composition, body mass index (BMI), cardiovascular endpoints, bone, cognitive function, QoL and safety were extracted.
Results
Nine RCTs and 19 NRCTs were included. Body composition improved during GH treatment with an increase in mean (95% CI) lean body mass of 1.72 kg (0.33–3.10 kg) for 258 person-years of follow-up, and a reduction of mean (95% CI) fat mass of –1.94% (–3.30% to –0.57%) for 223 person-years of follow-up. BMI, low-density lipoprotein levels and bone mineral density did not change during GH treatment. GH treatment was safe for both GH naïve adults with PWS and for adults previously treated with GH.
Conclusion
GH treatment is safe and improves body composition in adults with PWS. As poor body composition plays a key role in the high cardiovascular morbidity of adults with PWS, these data suggest that GH treatment might reduce long-term cardiovascular complications in this vulnerable patient group.

Cabergoline treatment for non functioning pituitary macroadenomas

Dimitra Pappa, Pinelopi Thoda, Anastasia – Konstantina Sakali, Eleftheria Barmpa, Eleni Georgiou, Ioannis Gountios & Alexandra Bargiota
University Hospital of Larissa, Department of Endocrinology and Metabolic Diseases, Larissa, Greece

Introduction
Cabergoline seems to be a promising and effective medical treatment for the more agressive Non Functioning Pituitary Adenomas (NFPAs) by reducing or keeping tumor's size stable long-term. Here we present the experience of our center
Methods
We studied 7 patients with NFPAs attending our clinic the last 10 years (median period 42 months, range 12 to 114 months), in whom cabergoline was started due to threatening tumor rise approaching the optic chiasm. Five patients had prior pituitary surgery (transsphenoidal, and 2/5 an additional transcranial) for aggressive adenomas compressing the optic chiasm, histological and immunohistochemical findings negative for intact pituitary hormone expression and significant residual tumor or tumor regrowth post surgery. The other 2/7 had macroadenomas approaching the optic chiasm. We evaluated tumor's mass (cm), tumor's volume (cm^3), visual fields and pituitary function before and twenty-four months after the initiation of cabergoline. Tumor shrinkage > 25% from the baseline is considered significant, although even stabilization or reduction of the tumor at least 10% is consindered very important.
Results
Mean age of the patients was 67.29 ± 8.97 years old and mean cabergoline dose was 2.1 ± 0.95 mg/week. Mean tumor volume at baseline was 8.78 ± 6.73 cm^3 and on cabergoline 8.19 ± 6.50 cm^3 and 7.87 ± 6.56 cm^3 at six and twenty-four months respectively. 2/7 patients (28.57%) had no change on tumor volume during the study period. At six months in 2/7 (28.57%) a volume reduction less than 10% (4.76%, 3.57%) was observed and in 3/7 (42.85%) a reduction more than 10% (19.23%, 15.98%, 18.51%). After twenty-four months from baseline in 1/7 patient (14.28%) there was a volume reduction less than 10% (7.42%), in 3/7 (42.85%) a reduction more than 10% (15.98%, 15.58%, 23.55%) and in 1/7 patient (14.28%) a reduction more than 25% (61.69%). All patients had a remarkable improvement on visual fields defects. Hormonal hypersecression and side effects were not noted.
Conclusion
Our data indicate that cabergoline could be beneficial for aggressive NFPAs. However long-term trials with more participants are needed for more reliable and accurate conclusions.

Efficacy and safety of cyberknife stereotactic radiosurgery in acromegaly

Desiree Seguna[1], Scott A Akker[1], James Ahlquist[2], Aparna Pal[3], Antonia Brooke[4], Rachel Lewis[5], Nick Plowman[5], Jane Evanson[6] & William Martyn Drake[1]
[1]Saint Bartholomew's Hospital, Department of Endocrinology, London, United Kingdom; [2]Southend University Hospital NHS Foundation Trust, Department of Endocrinology, Southend-on-Sea, United Kingdom; [3]The Churchill Hospital, Department of Endocrinology, Oxford, United Kingdom; [4]Royal Devon & Exeter Hospital, Department of Endocrinology, Exeter, United Kingdom; [5]Saint Bartholomew's Hospital, Department of Oncology, London, United Kingdom; [6]Saint Bartholomew's Hospital, Department of Radiology, London, United Kingdom

Objective
Active acromegaly is associated with increased mortality. While surgery is the mainstay of treatment, it is not always curative. In selected cases, CyberKnife stereotactic radiosurgery (CK SRS) can be used as adjuvant treatment in patients with persistent disease.
Design
This is a retrospective review of the biochemical and imaging characteristics for patients with active acromegaly treated with CK SRS at St.Bartholomew's Hospital, between 2014–2019.
Methodology
Biochemical response was measured using serum IGF-1 levels, calculated as a percentage of the upper limit of normal (% ULN). Levels were recorded prior to treatment, at 6–12 months post-treatment and at the most recent follow-up visit. Anterior pituitary hormone deficits were assessed before and after treatment. Tumour size was followed up with MRI.
Results
A total of 10 patients (7 male, mean age 36 years [± 12.6, SD]) with active acromegaly were treated with CK SRS, delivered as a single session. Nine patients were treated following failure to attain biochemical remission with transsphenoidal surgery (TSS). One patient had primary CK SRS, having declined TSS. Two patients had previously received conventional fractionated external beam radiotherapy. The median maximal tumour diameter preceding therapy was 6 mm (IQR 5.2–10.5 mm). Cavernous sinus invasion was reported in 2 cases. The median radiation dose prescribed was 23 Gy (IQR 20–24 Gy). At the time of treatment, 4 patients were on dopamine agonist, 4 patients on somatostatin analogue and 2 patients were on pegvisomant. The mean follow-up period was 31.6 months (± 13.5 months, SD). The median IGF-1 % ULN was 146% pre-treatment (IQR 126.5–208.5), 109% at 6–12 months (IQR 76.5–131%) and 71% (IQR 59–91%) at last follow-up. By the last follow-up visit, 5 patients required additional treatment, 2 patients had no change in treatment, 2 patients underwent dose reduction and 1 patient was off medication. The mean radiological follow-up using MRI was 16.6 months (± 15.9 months, SD). No cases showed tumour enlargement. Before treatment, 6 patients had evidence of anterior pituitary hormone deficits. One patient with pre-existing hypogonadism developed secondary hypothyroidism post-treatment. Side-effects included headache (7 patients), blurred vision (1 patient), fatigue and nausea (1 patient). Two patients reported no side-effects. There were no new visual fields defects, cranial nerve palsies, cerebrovascular events or secondary tumours.
Conclusion
CK SRS appears safe and effective in selected patients with acromegaly, when there is failure to attain biochemical cure with surgery and in patients intolerant or resistant to medical treatment.

AEP496

Pituitary apoplexy: Clinical features, management and outcomes-a retrospective study

Izabella Czajka-Oraniec[1], Maria Stelmachowska-Banas[1], Arnika Szostek[2], Jakub Wydra[2] & Wojciech Zgliczynski[1]
[1]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland; [2]Bielanski Hospital, First Internal Ward, Warsaw, Poland

Introduction
Pituitary apoplexy (PA) is a rare medical emergency caused by acute haemorrhage and/or infarction within a pituitary or usually pituitary tumour. Typically, PA is characterised by severe headache, visual fields defects, decreased visual acuity, cranial nerve palsies and hypopituitarism. However, many patients present with mild or ambiguous signs and symptoms or even PA is an incidental radiological finding.
Aim
To evaluate clinical presentations, pituitary function and management of patients diagnosed with PA. Patients and methods: We conducted a retrospective analysis of medical records of patients diagnosed with PA between 2015 and 2020 at the Department of Endocrinology of the Bielanski Hospital. Diagnosis of PA was based on clinical presentation, hormonal and imaging results.
Results
Forty-three patients were identified, with women predominance (56% female), and mean age of patients 42 yrs. (SD 17.2, range 16–79). Precipitating factors such as pregnancy/labour, surgery, dopamine agonist treatment were identified in 44% of cases. Diagnosis of pituitary tumour was established prior to PA in 11 cases (26%), during PA in more than half of cases (53%), but in as many as 21% of patients, the tumours were discovered with a suggestion of past apoplexy. Majority of PA cases (81.4%) underwent conservative management (75% of symptomatic patients) and only 18.6% required surgical intervention (due to severe headache and visual defect). Most of the pituitary lesions (63%) were identified as non-functioning pituitary adenomas. The remaining tumours were: prolactinomas (16%), Rathke cleft cysts (12%), GH- secreting adenomas (5%). There were 2 cases of Sheehan's syndrome. Fifteen patients (35%) were asymptomatic but their imaging results strongly suggested PA. In symptomatic patients, the most common symptoms at presentation were headaches (79%), visual field defects (32%) and decreased visual acuity (50%). Other symptoms included: diplopia, isolated acute cranial nerve palsies, dizziness and impaired consciousness. The most common anterior pituitary dysfunction was gonadotroph deficiency (57%), followed by ACTH, TSH and GH deficiencies (in 46%, 46% and 36% respectively). Panhypopituitarism was present in 1 case (4%). Two patients had a second incident of PA apoplexy during follow up and 2 patients were diagnosed with encephalitis or meningitis simultaneously. Regrowth of pituitary tumour was observed in four patients (9.3%).
Conclusions
Although PA can be life-threatening and sometimes requires neurosurgery, most cases can be managed conservatively. We found less proportion of patients with anterior pituitary deficiency. The risk of tumour progression after PA makes long-term follow-up necessary.

Kallmann syndrome due to a mutation in ANOS1 gene and monoallelic mutation in GNRHR gene

Catarina Cidade-Rodrigues, Catarina Chaves, Mariana Martinho, Filipe Cunha & Margarida Almeida
Centro Hospitalar do Tâmega e Sousa, Guilhufe, Penafiel, Portugal

Introduction
Hypogonadotropic hypogonadism (HH) is a rare disease. When associated with anosmia/hyposmia, it is called Kallmann syndrome (KS). Several mutations in different genes have been implicated in its pathophysiology, the most frequent being ANOS1/KAL1, FGFR1 and GNRHR genes. This heterogenicity can be explained by the increasing detection of more than one pathogenic variant in the genes responsible for causing the disease (oligogenism). The prevalence of this phenomenon is estimated to be 2.5–11.3%. Therefore, the classical paradigm of monogenic transmission of the disease has been challenged over the past years.
Case report
Male patient, 32 years old, referred to our endocrinology clinic because of decreased libido and erectile dysfunction. He had been diagnosed with hypogonadism at the age of 13 due to pubertal delay and anosmia. No history of testicular or head trauma. He was temporarily supplemented with testosterone. Past medical history included diabetes *mellitus* type 2, obesity and gastroesophageal reflux disease. Family history: hypogonadism in his brother and maternal cousin. In the physical examination: weight 98 kg, height 172 cm, arm-span 170 cm and body mass index 33 kg/m^2. Testicular volume of 10 ml with no masses or lesions. He had normal secondary sexual characteristics and no gynecomastia nor synkinesis. Blood results: total testosterone 0.5 ng/ml, free testosterone 0.84 pg/ml, LH 0.2mU/ml, FSH 0.6mU/ml, prolactin 3.5 ng/ml, TSH 1.56 µUI/ml, IGF-1 79.2 ng/ml, 60-minute cortisol (tetracosactide stimulation test) 34.7 µg/dl, HbA1c 7.8% and C-peptide 5.24 ng/ml. Renal ultrasound showed no genitourinary abnormalities. Pituitary MRI evidenced a small-sized gland, no sellar/parasellar masses and absence of olfactory bulbs and tracts. Bone densitometry showed no signs of osteoporosis. Genetic next generation sequencing identified the variant (Arg457Ter) in ANOS1 gene in *hemizygosity* and the variant (Gin106Arg) in GNRHR gene in heterozygosity. He was diagnosed with KS due to the mutation of ANOS1 gene and was treated with testosterone, showing clinical and analytical improvement.
Discussion
This is the first case described of HH due to a hemizygotic mutation in ANOS1 gene and the additional presence of a mutation in GNRHR gene, which is usually associated with an autosomal recessive form of non-anosmic HH. It has been proposed that the presence of more than one heterozygous mutation of genes normally associated with an autosomal recessive disease can act synergically to the pathogeny. In this case, however, we cannot affirm that the GNRHR mutation contributed to the disease, since the ANOS1 mutation is usually sufficient to cause the disease in males.

The role of endoscopic ultrasonography for localization of sporadic and men-1 syndrome associated insulinomas: Case series

Ogun Bilen[1], Yuksel Altuntas[2], Hunkar Aggul[1] & Sayid Zuhur[1]
[1]Tekirdag Namik Kemal University, Endocrinology and Metabolism, Turkey; [2]Health Science University, Sisli Hamidiye Etfal Research Hospital, Endocrinology and Metabolism, Turkey

Introduction
The diagnosis of insulinomas is made biochemically. However, proper localization of insulinomas is essential before surgery. Non-invasive methods including magnetic resonance imaging (MRI), computed tomography, ultrasonography, glucagon-like peptide-1 receptor PET/CT, 68Ga-DOTATATE PET/CT, and invasive methods such as endoscopic ultrasonography (EUS) and selective arterial calcium stimulation test are used for preoperative localization. However, some of these methods are either expensive and may not be available in most centers, or highly invasive that requires particular expertise. Therefore, we aimed to evaluate the role of EUS in the localization of insulinomas.
Case series
This case series including 8 patients with biochemically proven insulinomas. The age, gender, MRI, EUS, and immunuhistopathological results of the patients are shown in Table-1. A mass on MRI was detected in only 2 of the 8 patients. However, EUS showed a mass in the pancreas of all patients. All patients underwent surgery according to the EUS results, and a diagnosis of insulinoma was made in all patients by immunohistopathological analysis. All patients achieved cure after surgery except a patient with MEN-1 disease who had multiple small insulinomas as well as a glucagonoma.
Discussion
More than 90% of insulinomas are benign, solitary, and < 2 cm. However, MEN-1 associated insulinomas may be multiple. The sensitivity of CT and MRI is between 33% -64% and 40% -90%. However, no mass could be found by CT or MRI in 25–30% of the patients. In our series, the mass could not be detected in 6 of the 8 patients by MRI while all of the insulinomas were localized by EUS. On the other hand, the sensitivity of EUS decreases in the presence of a large number of tumors and small tumors, as in cases with MEN-1 disease. Therefore, EUS should be performed in all cases suspected of sporadic insulinomas before any other invasive localization method, but in patients with MEN-1 disease, other invasive and non-invasive localization methods should be performed even in the presence of a tumor on EUS.

Patients	Gender/ Age	Presence of tumor on MRI (mm)	The tumor size on EUS (mm)	Histopathological results after surgery
1*	F/27	No	9	6 mm and 5 mm insulinomas and an 8 mm glucagonoma*
2	F/29	No	15	Insulinoma
3	F/33	No	15	Insulinoma
4	M/35	No	15	Insulinoma
5	F/44	No	14.5	Insulinoma
6	F/45	No	7	Insulinoma

Ectopic cushing's syndrome: Report of 5 cases from a tertiary care center

Eider Pascual-Corrales, Marta Marchan Pinedo, Maria Fernandez Argüeso, Manuel Luque-Ramírez & Marta Araujo Castro
Ramón y Cajal University Hospital, Endocrinology and Nutrition, Madrid, Spain

Introduction
Ectopic Cushing's syndrome (ECS) is a rare entity caused by ACTH secretion by a non-pituitary tumor. The management of these patients is challenging due to its low frequency and limited experienced. The objective of this study was to describe the patients with ECS treated in the Division of Endocrinology at the Ramón y Cajal University Hospital (Madrid, Spain) in the last six years.
Methods
Records of patients with ECS from 2016 to 2020 were retrospectively reviewed including clinical and biochemical data, imaging modalities to locate the non-pituitary source of ACTH production, management and follow up.
Results
The study group included 5 patients: two ECS secondary to bronchial carcinoid, one secondary to thymic carcinoma, one secondary to metastatic medullary thyroid carcinoma (MTC) and one occult ECS. Two were women and 4 men, median age of 44.6 (15.0–57.6) years at diagnosis. The specific clinical picture of Cushing syndrome developed in all patients with the exception of one patient with ECS due to bronchial carcinoid. Moreover, 2 patients presented hypertension, diabetes and obesity. Only the patient with ECS due to MTC had hypokalemia at diagnosis. The median urinary free cortisol and nocturnal salivary cortisol levels were 421.8 (30.6–47142) μg/24 h and 29.9 (3.4–2436) μg/dl, respectively, and the median plasma ACTH levels was 148.4 (46.1–929) pg/ml. The ectopic origin was confirmed by a combination of dynamic tests and imaging modalities. The tumor was identified in all patients except in one case, and 2 patients had metastatic dissemination. Primary treatment was surgery in 4 patients, one of them combined with chemotherapy and radiotherapy (thymic carcinoid), and medical treatment in 1 patient (occult ECS). Bilateral adrenalectomy was required in one patient. The medical treatments used to control hypercortisolism were ketoconazole in 3 patients and metopirone plus ketoconazole in one patient. After a mean follow-up of 67 months, 1 patient (MTC) died and 4 are still alive, 2 (bronchial carcinoid) cured and 2 (occult ECS and thymic carcinoid) with persistent/recurrent disease.
Conclusions
ECS is a rare disease caused by a wide spectrum of tumors with varied manifestations and associated increased morbidity and mortality. The most common tumor was bronchial carcinoid. Control of both tumor and hypercortisolism requires multiple treatment modalities, and surgery with removal of primary tumor was found to be the treatment of choice, if possible. Therefore, multidisciplinary management is recommended.

Cerebral infarction in childhood-onset craniopharyngioma patients – results of kraniopharyngeom 2007

Svenja Boekhoff[1], Brigitte Bison[2], Daniela Genzel[3], Maria Eveslage[4], Anna Otte[1], Carsten Friedrich[1], Jörg Flitsch[5] & Hermann Müller[1]
[1]University Children's Hospital, Car von Ossietzky University Oldenburg, Department of Pediatrics and Pediatric Hematology/Oncology, Klinikum Oldenburg AöR, Oldenburg, Germany; [2]Augsburg Hospital, Department of Neuroradiology, Augsburg, Germany; [3]University Hospital Würzburg, Department of Neuroradiology, Würzburg, Germany; [4]University Münster, Institute of Biostatistics and Clinical Research, Münster, Germany; [5]University Hospital UKE Hamburg-Eppendorf, Department of Neurosurgery, Hamburg, Germany

Background
Cerebral infarction (CI) is a known vascular complication following treatment of suprasellar tumors. Risk factors for CI, incidence rate, and long-term prognosis are unknown for patients with childhood-onset craniopharyngioma (CP).
Methods
MRI of 244 CP patients, recruited between 2007 and 2019 in KRANIOPHARYNGEOM 2007, were reviewed for CI. Risk factors for CI and outcome after CI were analyzed.
Results
Twenty-eight of 244 patients (11%) presented with CI based on reference assessment of MRI. One CI occurred before initial surgery and one case of CI after release of intracystic pressure by a cyst catheter. 26 of 28 CI were detected after surgical tumor resection at a median postoperative interval of one day (range: 0.5–53 days). Vascular lesions during surgical procedures were documented in 7 cases with CI. There was a trend ($P = 0.094$) towards higher initial presurgical tumor volume in CI patients compared with non-CI patients. No relevant differences with regard to surgical approaches

were found. In all 12 irradiated patients, CI occurred before irradiation. Multivariable analyses showed that hydrocephalus and gross-total resection at the time of primary diagnosis/surgery both were risk factors for CI. PFS was lower after CI (median survival=1.16 years) when compared with the subgroup of patients without CI (median survival > 5.62 years). After CI, quality of life (PEDQOL) and functional capacity (FMH) were impaired.
Conclusions
CI occurs in 11% of CP cases. Tumor size, degree of resection and increased intracranial pressure are risk factors, which should be considered in the planning of surgical procedures for prevention of CI.

Clinical features, diagnostic criteria and treatment outcomes in 40 patients with thyrotropin-secreting pituitary tumors

Diana Dimitrova, Elena Przhiyalkovskaya, Andrey Grigoriev, Vilen Azizyan, Anastasia Lapshina, Zhanna Belaya & Galina Melnichenko
Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Thyrotropin-secreting pituitary adenomas (TSH-omas) are rare. For this reason each case of TSH-secreting pituitary tumor can help expand extensive clinical experience in world practice.
Materials and methods
We included 40 patients with TSH secreting pituitary adenomas. Hormonal profile: TSH (0.25-3.5 mIU/L), FT4 (9-20 pmol/l) FT3 (2.5-5.5 pmol/l) were measured by Architect i2000SR (Abbott Laboratories, Abbott Park, Illinois, U.S.A). MRI was performed on GE Optima MR450w 1.5T.
Results
Forty patients with TSH-omas were under observation in our center from 2010 to 2020. The median age was 46 [32; 57] with a predominance of female (31 cases) over male (9 cases). Clinical manifestations included cardiac arrhythmias (80%); neurological changes (60%), impairment of bone metabolism (51.35%) hypopituitarism (10%) visual impairment (10%). At the beginning of the observation, 17 patients had increased TSH, FT3 and FT4 levels; in 10 patients FT3 and FT4 only; 5 patients had elevated TSH and either FT3 or FT4, and in 8 — an increase in one of the hormones. Mean value of TSH was 4.28 [2.4; 6.4] mIU/L, FT4 — 23.03 [20.03; 29.37] pmol/l, FT3 – 7.2 [5.9; 10.09] pmol/l. Sex steroid binding globulin, C-terminal telopeptide and osteocalcin were elevated in 62.86%, 62.07% % and 48.15% of cases, respectively. In 75% of cases short-term octreotide treatment led to thyroid hormone normalization. On MRI macroadenomas were registered in 72.5% cases. In 1 case there was no pituitary adenoma on MRI. In 20 patients, diagnosis was finally confirmed by immunohistochemical examination. In 13 patients, the diagnosis verification was based on remission after surgical or medical treatment. In the remaining 7 cases, the diagnosis was made on clinical and laboratory data. Remission was achieved in 33 patients: 25 (75.76%) after neurosurgery, 3 received treatment with somatostatin analogues and 5 required somatostatin analogues after neurosurgery; 2 out of 7 patients who did not achieve full remission were lost for observation.
Conclusion
At the time of diagnosis 72.5% of patients had macroadenomas and 80% had cardiac arrhythmias, suggesting a long duration of disease. However less than 50% of patients had all tests elevated emphasizing the necessity of multiple hormone testing and complex diagnostic evaluation.

AEP502

White blood cell count: A potential useful tool for suspected Cushing's syndrome

Ignacio Merlo, Miguel Paja, Adela Martinez, Andoni Monzon & Josune Rodriguez
Basurto University Hospital, Department of Endocrinology and Nutrition, Bilbao, Spain

Background
Suspicion of Cushing´s syndrome (CS) is usually suggested by non-specific clinical data. Chronic hypercortisolism associates changes in white blood cell count (WBC), essentially a higher count with relative lymphopenia. Our purpose is to investigate the prevalence of these findings among a local series of patients with Cushing's syndrome before and after the hypercortisolism revertion to assess the diagnostic value of these parameters in order to decide who must be evaluated for the disease.
Methods
Data from 34 patients, who underwent surgery for Cushing´s syndrome in our center from 2004 to 2020, were reviewed. The diagnosis of CS was made on the basis of standard clinic and analytical criteria. Urinary free cortisol (UFC), cortisol after 1 mg of dexamethasone (Nugent´s test), and morning cortisol concentrations were collected. WBC baseline parameters were gathered from the blood test preceding diagnosis and 1 month after surgery. We defined relative lymphopenia as <20.5% of WBC, and absolute lymphopenia as < 1300/µL, whereas relative neutrophilia encompassed neutrophils > 65% of WBC, and absolute neutrophilia > 5000/µL.
Results
26 out of the 34 patients were women, and mean age was 49.4 years (range 19-87). The mean baseline UFC levels was 494.8 ± 891.2 µg/24h, Nugent´s test was 24.6 ± 25.8 µg/dl and mean morning cortisol level was 27.2 ± 18.6 mcg/dl. 17 patients had CS due to adrenal causes, 13 were found a pituitary adenoma and 4 an ectopic ATCH production. 76% patients with CS had a relative lymphopenia (mean: 15%) and only 26.4% an absolute lymphopenia. In 82% and 91% patients we found a high absolute (mean: 7065 ± 4958/µl) and relative (mean: 73.8%) neutrophil count respectively. Only 2/34 patients did not have any WBC alterations. After treatment we found an improvement in all WBC lineages with only 11,7% of patients presenting relative lymphopenia (mean: 34%), 2,9% absolute lymphopenia (mean: 2927 ± 1720/µl), 44% absolute neutrophilia (mean: 5322 ± 6374 cel/µl), 11,7% relative neutrophilia (mean: 50%). Results also revealed a correlation between the WBC changes and the markers of CS severity, including UFC and morning serum cortisol.
Conclusions
WBC count may be a useful tool to suggest the evaluation for Cushing´s syndrome in patients with clinical unspecific symptoms like the association of diabetes and abdominal obesity. Specifically as a parameter with negative predictive value in the absence of any WBC alterations.

Screening of acromegalia among patients with endocrine and somatic pathology

Roman Nikolaiev, Oksana Khyzhnyak, Myroslava Mykytyuk, Iurii Karachentsev & Tatiana Gavrish
V. Danilevsky' Institute of Endocrine Pathology Problems, Clinical, Kharkiv, Ukraine

Introduction
The practice of screening for many chronic diseases, particularly endocrine pathology, is taking place all over the world. The relevance of screening increases significantly when we are talking about diseases with a torpid manifestation and absence of certain clinical symptoms in the debut. Such diseases include pathological conditions caused by pituitary hormone hypersecretion, in particular, acromegaly.
The aim
Of the study was to determine the informative value and specificity of the questions included in the acromegaly primary screening questionnaire on the basis of a comparative analysis.
Material and methods
A questionnaire for screening for acromegaly was developed, which in the final version included 11 questions representing the clinical and phenotypic signs of long-term hypersomatotropinemia. The evaluation was performed on a scale of points, with a maximum of 11 points. The survey was carried out in individuals from the 'risk group' who came to an outpatient visit to a general practitioner, therapist, cardiologist, endocrinologist for other reasons and in the presence of somatic and/or endocrine pathology (n=1660).
Statistical analysis
Variation statistics using the 'SPSS 19.0 statistical software' (IBM Corp., Armonk, NY, US).
Results
The maximum sum of points (11) in the questionnaire was found in 2 women in the older age group (over 65), which was 0.12% of the total number of respondents; 8 points in 4 women (0.24%); 7 points in 10 people (4 m/6 f) (0.61%); 6 points in 18 people (4 m/14 f) (1.10%); 5 points in 30 people (4 m/26 f) (1.84%). After in-depth clinical examination, 32 patients were examined to further verify the diagnosis. The examination revealed glucose intolerance in 9 patients (18.8%), diabetes mellitus type 2 in 5 patients (10.4%), hyperprolactinemia in 3 (6.3%) women aged 24 – 37 years, increased IGF-1 level in 2 patients (4.2%). Further examination revealed the

presence of pituitary microadenoma in 2 women with high level of blood prolactin. Two patients (1 m/1 f) aged 28 and 57 yrs old respectively with high IGF-1 levels were diagnosed 'acromegaly, tumor stage, active form'.
Conclusion
Screening in high-risk groups revealed hormonally active pituitary tumors (isolated prolactinoma (n = 2) and somatotropinoma (n = 2)) with a frequency of 0.15% per 1000. Such a rather high percentage of detected orphan pathology indicates the effectiveness of the proposed screening technique and the feasibility of its implementation in high-risk groups.
Keywords: acromegaly, primary screening.

Acromegaly: Knowing the enemy in order to win

Mariana Gomes Porras, Alexa Benítez Valderrama, Paola Parra Ramírez, Rosa García Moreno, Patricia Martin Rojas, Gumersindo Fernández Vázquez, Beatriz Lecumberri Santamaría & Cristina Álvarez Escolá
Hospital Universitario La Paz, Endocrinology and Nutrition, Madrid, Spain

Introduction
Acromegaly is an uncommon chronic disease with an insidious course. Due to the high morbimortality it causes, its early diagnosis and treatment are priority. The three therapeutic pillars are surgery, pharmacological treatment and radiotherapy, alone or in combination.
Objectives
To clinically, biochemically and histologically characterize patients with acromegaly under follow-up in a tertiary hospital in Madrid since 2000.
Methods
Retrospective study including 97 adult patients diagnosed with acromegaly under follow-up in the Neuroendocrinology Unit of the Hospital Universitario La Paz, Madrid, during the period 2000-2020. Data were obtained by review of medical records. Continuous variables were expressed as mean and standard deviation and categorical variables as absolute values and percentages.
Results
Of the 97 patients with acromegaly, 96.7% (n=94) had a pituitary origin and 3.3% (n=3) had an ectopic one (bronchial, pancreatic and adrenal, 33% in each case). Mutations in GNAS and MEN1 genes were found, 1% in each case. 55% were women, age 61.53±16.5years, BMI 28.67±4.2kg/m2, annular circumference 20.4±1.5cm, GH 21.2±36.5µg/L and IGF-1 754.7±544.8µg/L. Only 58.6% were diagnosed during the first 5 years of disease. 76.3% were diagnosed by clinical manifestations secondary to hormonal hypersecretion, 15.8% by compressive clinical manifestations and 7.9% incidentally. 57.6% had pituitary macroadenoma, 36.5% had microadenoma, 2.4% had empty sella turcica and 1.2% had normal pituitary. 66.7% of the adenomas were densely granular, 58% somatropinomas, and 34.5% and 88.9% were positive for p53 and Ki67, respectively. 5.7% had pre-surgery hormonal deficits (4 patients with secondary hypothyroidism and 3 hypogonadotropic hypogonadism) and 48.9% had post-surgery hormonal deficits (22 patients with secondary adrenal insufficiency, 19 hypogonadotropic hypogonadism, 16 secondary hypothyroidism, 8 transient diabetes insipidus, 3 permanent diabetes insipidus, 2 transient SIADH, 2 biphasic response, 1 adult GH deficiency). Transsphenoidal surgery was the first line of treatment in 88.7% (n=86) of patients, achieving a cure rate of 53.4% (n=46). 13.3% were surgically reintervened and 26.5% also received RT. Of the 51 patients not cured, 94.1% (n=48) received medical treatment, achieving disease control in 92% of cases. The main comorbidities were: dysglycosis (53.6%), nodular thyroid disease (57.7%), left ventricular hypertrophy (69%), arterial hypertension (39.4%), osteopenia (34%) and obstructive sleep apnea-hypopnea syndrome (25%).
Conclusions
Timely diagnosis of early stage acromegaly remains a challenge in routine clinical practice. The best biochemical marker is IGF-1. In the hands of expert neurosurgeons, the treatment of choice remains transsphenoidal surgery. It is essential to integral approach associated comorbidities.

Increased anxiety and perceived stress in active acromegaly during the COVID-19 pandemic

Seda Turgut[1], Hamide Piskinpasa[1], Didem Acarer[1], Ozlem Karaarslan[2], Evin Bozkur[1], Naim Pamuk[1], Ilkay Cakir[1], Meral Mert[1] & Sema Ciftci Dogansen[1]
[1]University of Health Science Bakirkoy Dr.Sadi Konuk Training and Research Hospital, Endocrinology and Metabolism, Istanbul, Turkey; [2]University of Health Science Bakirkoy Dr.Sadi Konuk Training and Research Hospital, Psychiatry, Istanbul, Turkey

Aim
To examine and compare the anxiety level and stress perception of acromegaly patients with controlled and active disease in the COVID-19 pandemic.
Material and Method
49 (23 females/26 males) patients admitted to the outpatient clinic during the first month after the pandemic period were recruited in this cross-sectional study. State-Trait Anxiety Inventory (S-Anxiety for state scale, T-Anxiety for trait scale) and Perceived Stress Scale-14 (PSS-14) were used to evaluate the event-related current state anxiety, the general tendency to anxiety, and perceived stressful situations. Patients were divided into two groups as active (n=14) and controlled (n=35) disease groups compared to parameters affecting psychiatric distress.
Results
The active acromegaly group had significantly higher scores on all of the S-Anxiety (p=0.011), T-Anxiety (p=0.002), and PSS-14 (p=0.007) scores after controlling for age, gender, BMI, education years, marital and occupation status, disease duration, and disease-specific medical treatment status covariates. S-Anxiety (p=0.021), T-Anxiety (p=0.004), and PSS-14 (p=0.009) scores were found significantly higher in single patients than in married ones.
Conclusion
This study showed significantly increased anxiety and perceived stress levels during the pandemic, especially in the active and single acromegaly patients. Psychiatric symptoms should be carefully evaluated in the follow-up of acromegaly patients. The necessary psychological support should be provided to patients by focusing on these symptoms to improve patient management, particularly in a health-related stressful situation as the COVID-19 pandemic.

The association of z-score with early postoperative remission and characteristics of bone mineral density in patients with cushing's disease: Single center study

emre gezer[1], Zeynep Canturk[1], Alev Selek[1], Berrin Cetinarslan[1], mehmet sözen[1], Özlem Elen[2], İhsan Anık[3] & Savaş Ceylan[3]
[1]Kocaeli University Faculty of Medicine, Endocrinology and Metabolism, Kocaeli, Turkey; [2]Kocaeli University Faculty of Medicine, Internal Medicine, Kocaeli, Turkey; [3]Kocaeli University Faculty of Medicine, Neurosurgery, Kocaeli, Turkey

Introduction
Various direct and indirect mechanisms by which glucocorticoid (GC) excess and elevated adrenocorticotropic hormone (ACTH) levels impairs bone metabolism have been described. In the literature, there are different factors described which affect the early outcome of pituitary surgery in patients with CD including preoperative ACTH levels and the clinical severity of the disease. Combining these data, we conducted a retrospective study to investigate the association of BMD Z-scores with early postoperative remission rate and clinical parameters of the patients with CD.
Method
Patients diagnosed with CD were retrospectively evaluated. After the exclusion of 230 patients, a final cohort of 87 CD patients were included. Early postoperative remission was defined as a morning cortisol concentration measured on the first day after surgery of less than 5 µg/dL. The diagnosis of BMD 'below the expected range for age' was defined as a Z-score ≤ -2.00 SD.
Results
No significant association was found between DXA results and early postoperative remission. There was also no significant difference in DXA results between eugonadal and menopausal groups. A significant negative correlation between preoperative morning cortisol level and BMD, T-score and Z-score of FT was shown, while there was a positive correlation between preoperative ACTH/Cortisol ratio and DXA results of L1-4 (Table 1).
Conclusions
To the best of our knowledge, this is the first study which investigates if the severity of bone loss is a predictive risk factor for the failure of transsphenoidal surgery for Cushing's disease and there was no statistically significant relationship between these two entities.

Treatment regimens affecting glucose metabolism and gastrointestinal hormones in acromegaly: A descriptive study

Nanna Jørgensen[1], Trine Erichsen[1], Marianne Klose[1], Morten Joergensen[2], Thomas Idorn[2], Bo Feldt-Rasmussen[2], Jens J. Holst[3] & Ulla Feldt-Rasmussen[1]
[1]Department of Endocrinology, Copenhagen University Hospital, Rigshospitalet, Denmark; [2]Department of Nephrology, Copenhagen University Hospital, Rigshospitalet, Denmark; [3]Department of Biomedical Sciences, and NNF Centre for Basic Metabolic Research Faculty of Health Science, Copenhagen University, Denmark

Context
Active acromegaly is associated with impaired glucose metabolism, which improves upon treatment. Treatment options include surgery, medical therapy with somatostatin analogues (SSA) and Pegvisomant (PEG) and in few cases irradiation.
Objective
To describe the differential effect of various treatment regimens on the secretion of glucose, insulin, glucagon, glucagon-like peptide-1 (GLP1), and glucose-dependent insulinotropic polypeptide (GIP) in patients with acromegaly.
Methods
Descriptive study of data from 23 surgically treated, non-diabetic patients with acromegaly and 12 healthy controls. Participants underwent an oral glucose tolerance test (OGTT) and subsequently isoglycaemic intravenous glucose infusion on a separate day, both with continuous measurement of the above-mentioned hormones. Analysis: Baseline hormone concentrations, time-to-peak and area under the curve (AUC) on the OGTT-day. Groups were compared using ANOVA.
Results
The patients treated with SSA (N=15) had impaired insulin, glucagon, GLP1 and GIP-response (AUC, P=0.007), and numerical impairment of all other hormone responses (AUC, P>0.05)(Table 1). Patients co-treated with pegvisomant (SSA+PEG, N=4) had a numerically increased secretion of insulin and glucagon compared to patients only treated with SSA (N=11) (insulin AUC mean (SEM), SSA+PEG 49 nmol/l*min (8.3) vs SSA%PEG 25 (3.4), P>0.05); glucagon AUC, SSA+PEG 823 pmol/l*min (194) vs SSA%PEG 332 (69), P>0.05). GIP secretion remained significantly impaired, whereas GLP1 secretion was numerically increased with PEG (SSA+PEG 3088 pmol/l*min (366) vs mono-SSA 2401 (239), P>0.05) (Table 1). Similarly, the incretin-effect was numerically increased in SSA+PEG compared to SSA%PEG. No difference was found between patients treated with/without radiotherapy nor substituted or not with hydrocortisone.
Conclusion
SSA impaired the insulin, glucagon and incretin hormones secretion. Co-treatment with Pegvisomant seemed to counteract the somatostatinergic inhibition of the glucagon secretion and improved the insulin response to OGTT. We speculate that Pegvisomant exerts its action via GH-receptors on pancreatic δ-cells.

TABLE 1. Hormonal response to OGTT in healthy controls and patients receiving SSA with/without additional Pegvisomant.

	Controls	SSA%PEG	SSA+PEG	P
N	6	11	4	-

Female central hypogonadism with or without organic pituitary lesions: diagnostic value of LH and FSH basal levels

Anna Loktionova & Irena Ilovayskaya
M.F. Vladimirsky Moscow Regional Research & Clinical Institute, Russia, Department of therapeutic Endocrinology, Moscow, Russian Federation

Central hypogonadism (CH) is a syndrome that can be revealed in women with hypoestrogenic amenorrhea due to the lack of normal response of gonadotropins to the hypoestrogenemia. CH can be caused by organic lesion of the hypothalamo-pituitary region or has idiopathic character – without any structural background. This syndrome is often called 'hypogonadotropic hypogonadism', but LH and FSH levels within 'normal' laboratory range does not exclude CH because insufficiency of impulse secretion can appear despite normal basal secretion.
Patients and methods
46 women with idiopathic CH (18-45 y.o., BMI 16-25 kg/m2), 25 women with CH due to the organic lesions (18-45 y.o., BMI 17-37 kg/m2), 68 healthy cycling women (control group, 19-45 y.o., BMI 17-31 kg/m2). Organic causes of CH were as follows: congenital empty sella turcica and pituitary hypoplasia; pituitary adenomas and craniopharyngiomas presently or earlier (treated by surgery). LH and FSH levels were measured in all participants by chemiluminescent immunoassay; in healthy women tests were performed in early follicular phase.
Results
According to Mann-Whitney test, LH and FSH levels were significantly lower in patients of both groups than in control group (p<0.0001 in all cases). Moreover, LH and FSH were significantly lower in group of organic lesions than in group of idiopathic CH (p=0.0017 for LH and p=0.0014 for FSH). ROC-analysis showed that LH<2.36 ME/l with sensitivity 82.61% and specificity 94.12% and FSH<5.075 ME/l with sensitivity 73.91% and specificity 80.88% pointed to central genesis of hypogonadism without organic lesions. Similar analysis was performed for patients with CH due to the organic lesions: LH<1.8 ME/l with sensitivity 96.0% and specificity 98.53% and FSH<3.145 ME/l with sensitivity 92.0% and specificity 95.59% speaks in favor of CH due to the pituitary organic lesion.
Conclusion
In female patients with hypoestrogenic amenorrhea LH<2.36 ME/l and FSH<5.075 ME/l are pointing to central genesis of hypogonadism with high sensitivity and specificity; LH<1.8 ME/l and FSH<3.145 ME/l in case of those female patients can point to organic cause of central hypogonadism, and thus can be considered as indication for pituitary region MRI if it was not performed earlier.

Self-administration of long-acting somatostatin analogues in NET patients forced by the COVID-19 pandemic – does it affect the clinical outcome?

Marta Opalinska[1], Anna Kurzyńska[1,2], Anna Sowa Staszczak[1,2], Joanna Paleń-Tytko[1], Helena Zwinczewska[1], Karolina Morawiec-Sławek[1,2] & Alicja Hubalewska-Dydejczyk[1,2]
[1]University Hospital, Department of Endocrinology, Kraków, Poland; [2]Jagiellonian University Medical College, Department of Endocrinology, Kraków, Poland

Background
Somatostatin analogues (SSA) (octreotide and lanreotide) are recommended as a first line treatment of locally advanced or metastatic well-differentiated neuroendocrine tumors (NETs) with a good expression of somatostatin receptor (SSTR). Both of them are usually used in injection repeated every 4 weeks.
The study objective
Was to compare the way of SSA administration (injection performed by professional medical staff before epidemic period and self-administration of the drug forced by the COVID-19 epidemic restrictions) to progression free survival (PFS) in patients with locally advanced or metastatic NETs.
Materials and methods
88 patients in 2019 and 96 patients in 2020 with locally advanced or metastatic well-differentiated NETs (G1 and G2) treated in the Clinical Department of Endocrinology in Krakow, Poland, were included to the study. All patients had a good expression of SSTR type 2 assessed in functional somatostatin receptor imaging and were treated for at least 3 months with a stable dose of lanreotide Autogel 120 mg or 30 mg of octreotide LAR every 4 weeks. Prior to change of way of drug administration at the beginning of the COVID-19 epidemic period all of them were trained in regards to drug self-injections by the professional NET nurses. A retrospective analysis was performed, based on the medical documentation. Time to progression (TTP) was defined as the time beginning from the use of the first SSA dose to the time of progression confirmed by radiological examinations: computed tomography (CT) or magnetic resonance imaging (MRI).
Results
The rate of NET progression in the study group in 2020 was higher than in 2019 28,1% vs 18,2% (27 vs 18 cases), p=0,079. The analyzed groups did not differentiate in regards to age, follow-up period, performance status and tumor burden (assessed as liver, lymph nodes and bone involvement). The mean TTP was in 2019 56.8 months (range: 8-144) and in 2020 56.0 months (range: 6-152). In 2019 no progressions were diagnosed in patients with G1 tumors, whereas in 2020 the progression was observed in 7 patients with G1. The greatest increase in the incidence of progression was seen among patients with small bowel NETs.
Conclusions
The way of long-acting SSA administration: injection done by professional medical staff vs self-injection of the drug may significantly affect the risk of NET progression. The unequivocal confirmation of such a relationship requires further observation.

Is this just vitiligo? Nelson is hiding

Maarten De Vis & Brigitte Velkeniers
UZ Brussel, Endocrinology, Jette, Belgium

A 64-year old man presented to our endocrinology clinic with progressive lumbar pain that had developed two months earlier. He had undergone bilateral adrenalectomy for Cushing disease and two years later transsphenoidal resection for Nelson tumor. On physical examination, the patient had remarkable hyperpigmentation due to ACTH hypersecretion periorbital, peri-auricular and in the lower-neck region. These findings were clearly evident in his case due to the extensive facial vitiligo. Findings on bone scintigraphy were suggestive for metastatic lesions and biopsy confirmed our suspicion of bone-invasive pituitary carcinoma. The patient was referred to the oncology department as a candidate for immunotherapy but opted for palliative care because of his weakened general condition. This case highlights the fact that hypercortisolism induces a state of immunosuppression. After remission of Cushing's syndrome, rebound immunity frequently results in overt autoimmune diseases. This immunological phenomenon has been described in both ACTH-dependent and -independent cases.

Microprolactinoma and pregnancy. A case report and review of literature

Marjeta Kermaj, Besa Hyka, Tea Shehu & Agron Ylli
UHC 'Mother Tereza', Endocrinology, Tirana, Albania

Introduction
Prolactinomas are the most common pituitary tumors and a common cause of infertility because of gonadal dysfunction, in young women. The treatment of choice is dopamine agonists, which can restore fertility and promote shrinking of the tumor in the majority of cases. Managing prolactinomas during pregnancy may be challenging. Treatment discontinuation is recommended once the pregnancy is confirmed in women with microprolactinoma. For microprolactinoma, the risk of symptomatic tumor enlargement during pregnancy is very low (<2%). Breast-feeding has no harmful effect on tumor growth. We present a case with microprolactinoma that had a good development of pregnancy and lactation period.
Case presentation
A 20-year-old female patient, was first diagnosed with left-sided, 8 mm cystic pituitary microprolactinoma 5 years ago. She began the treatment with Cabergoline 0.25 mg twice per week. Following a period of 3 years, she was periodically controlled with prolactin level and MRI. The adenoma size was constantly shrinking from 8 to 5 and then 2.6 mm. During this time, she was taking Cabergoline 0.25 mg twice per week. The last prolactin level was 1084,49 ng/mL (108,78 – 557,13) approximately twice normal level, Anti TPO 6,49 UI/mL (<34), TSH 3,11mUI/L. 5 days later, her pregnancy was confirmed, and Cabergoline was switched to bromocriptine 2.5 mg twice per day. She took the treatment for only one month and discontinued it because of arterial hypotension. The patient warned about the risk of tumor enlargement and alarming symptoms. She had clinical follow-up every 2-3 months. She didn`t complain of anything related to diseases' activity, and the pregnancy had no problem. She gave birth naturally at the right time a healthy boy. Her normal menstrual cycle begun 40 days postpartum. During the postpartum period and lactation, she did not take any medication, and prolactin levels were progressively decreasing from 61,5 to 49.6 and 30.04 ng/mL (6-29.9) during a time period of 11 months.
Conclusion:
Despite discontinuation of treatment once pregnancy has been confirmed, we didn`t notice any clinical progression of microprolactinoma during pregnancy, and no further examination was indicated. During the postpartum and lactation period, prolactin levels were progressively decreasing to normal, and no medication was needed.

When a common symptom leads to a rare diagnosis – prostate metastasis in the pituitary

Tarun Makker, Christo Albor, Hassan Ibrahim, Ayaz Hussain & Jawad Bashir
Basildon University Hospital, Basildon, United Kingdom

Common non-specific symptoms like fatigue can occasionally point towards a rare significant pathology. We report a similar case in which investigations for subtle symptoms revealed a serious unexpected diagnosis. A 76 year-old man presented to his GP for new onset mild fatigue. He had an underlying prostate cancer with no known metastases, treated only with hormonal therapy. This was under surveillance with urology team. GP sent off blood tests which showed a very low random serum cortisol (28nmol/L). Hence an urgent endocrine review and short Synacthen test (SST) was organised. SST showed secondary adrenal insufficiency. Baseline 9am ACTH = 41ng/L (>50ng/L) Baseline 9am cortisol = 116nmol/L (>420nmol/L) 60 min cortisol after Synacthen injection: 471nmol/L (>420nmol/L) The remaining pituitary hormonal profile showed secondary hypothyroidism (TSH=1.34mIU/L, T4=5.3mcg/dL) and raised prolactin (565 mcg/L). He was started on oral hydrocortisone after the above results whilst awaiting endocrine appointment. By the time patient attended the endocrine clinic in 3 weeks he was noted to be wearing a homemade eye patch over his left eye. On questioning he reported new diplopia and visual impairment for which he had consulted private optician who referred him to ophthalmologist. On examination there was with left oculomotor nerve palsy and bitemporal hemianopia. He was admitted in hospital from endocrine clinic and an urgent pituitary MRI was organised. This revealed a large sellar mass (1.8x2.2x3cm) with extension into the cavernous and sphenoid sinuses. These findings were consistent with a diagnosis of pituitary macroadenoma causing chiasm compression

and partial hypopituitarism. The final impression was non-functional pituitary macroadenoma causing compressive symptoms. He was urgently referred for trans-sphenoidal surgery. Trans-sphenoidal surgery proved to be complex leaving residual tumour and was complicated with post-operative diabetes insipidus with persistent visual impairment. Histology of pituitary tumour showed metastatic adenocarcinoma of prostatic origin. The patient later received radiotherapy. Unfortunately, surveillance imaging confirmed disease progression with enlargement of the remnant lesion and more extensive involvement of adjacent structures. Currently the patient is on palliative radiotherapy with full pituitary hormone replacement. Fatigue is a nonspecific common symptom. Low random cortisol is usually not expedited as an urgent test however in context of secondary hypothyroidism it should prompt urgent pituitary imaging especially in patients with history of prostate cancer. There have been only a handful of cases of prostate metastasis in the pituitary gland. This case reminds about rare metastatic presentations in pituitary gland.

Growth hormone deficiency in hypopituitary male patient with treated Cushing's disease

Sanja Borozan[1], Rada Sparavalo[2] & Sanja Vrbica[3]
[1]Clinical Centre of Montenegro, Department of Endocrinology, Podgorica, Montenegro; [2]General hospital Niksic, Department of Endocrinology, Podgorica, Montenegro; [3]General hospital Niksic, Department of Radiology, Podgorica, Montenegro

Impaired growth hormone (GH) secretion occurs in patients with Cushing's disease (CD) as a result of cortisol excess. After a surgical treatment, eventually accompanied with radiation therapy, recovery of GH secretion is seen in only variable proportion of patients. According to some studies, it is recommended to perform assessment of GH secretion one to two years after surgical cure of CD. We report a case of a 40-years-old male admitted to the hospital because of sudden loss of consciousness. At the age of 15 years, he was diagnosed with CD and underwent transsphenoidal surgery with the removal of an ACTH-secreting microadenoma. His height at that time was 148 cm, GH was low, with loss of pulsatility. One year postoperatively he received hydrocortison replacement and desmopressin. Three years after, a patient was reevaluated, value of GH was still below reference range, provocative testing using an insulin tolerance test (ITT) was not performed because of epilepsy. According to hormonal testing and petrosal sinus sampling, CD recurrence was diagnosed and radiotherapy successfully applied. After that, a patient has not been motivated for a regular follow-up for almost 20 years. On admission, his height was 165 cm, weight 68 kg (BMI 25 kg/m2), signs of hypogonadism were present. Hormonal examination showed TSH 4.83 mIU/l (0.4-4.0 mIU/l), fT4 4.2 pmol/l (10.3-23.1 pmol/l), GH 0.1 ng/ml (0.0-1.0 ng/ml), IGF-1 5 ng/ml (109-284 ng/ml), IGF BP3 0.7 ug/ml (3.4-6.7 ug/ml), FSH 1.8 mIU/ml (0.7-11.1 mIU/ml), LH 1.6 mIU/ml (0.7-11.1 mIU/ml), cortisol in daily profile 3…2…2 nmol/l. Pituitary magnetic resonance imaging demonstrated an empty sella. Bone mineral density assessed by DXA scan was normal. According to hormonal status, hydrocortisone and thyroxine replacement therapy was started. For the next 5 years, a patient was not followed again. In March 2019, he had an acute myocardial infarction and stent implantation; ejection fraction was preserved. Two months later, on reevaluation, IGF-1 was 29.0 ng/ml (53.3-215 ng/ml), IGF BP3 0.712 ug/ml (3.3-6.7 ug/ml) and GH replacement was finally initiated. During the next months dose adjustment was made (current GH 0.6 ng/ml, IGF-1 227 ng/ml, IGF BP3 4.44 ug/ml). As a result, quality of life and lipid profile are significantly improved (cholesterol 4.48 vs 5.05 mmol/l before treatment, LDL 2.05 vs 2.85 mmol/l, HDL 1.5 vs 1.35 mmol/l). In conclusion, because of multiple long-term benefits, assesment of GH status and GH replacement therapy should be considered in patients with CD in remission.

Control of acromegalo-gigantism with lanreotide: About a case

Samira Bichri, Nassim Essabah Haraj, Siham El Aziz & Asmaa Chadli
Department of Endocrinology and Metabolic Diseases University Hospital Center Ibn Rochd – Casablanca, Laboratory of Clinical Neurosciences and Mental Health Faculty of Medicine and Pharmacy – Hassan II University, Casablanca, Morocco

Introduction
Acromegalo-gigantism is a rare disease, occurring before the epiphyses weld, it causes a linear acceleration of growth in children and adolescents. Medical treatment with analogues of somatostatin (AS) well established can be used in cases where surgery is impossible or inadequate or in cases of surgical failure
Observation
This is a 14-year-old patient, followed for acromegalo-gigantism discovered at the age of 7. The patient has a height of 1.88 m (+3 SD), a Tanner stage G4P4 and features of acromegaly. The diagnosis was made in front of an IGF1 level at 791ng/mL (1.6 × normal) with pituitary MRI a pituitary macroadenoma of 16 × 11 × 11mm somatotropic on anathomopathologic pituitary examination with Ki-67 proliferation index < 1. The rest of the hypophysiogram was normal. The patient was operated on twice: in 2015 by the upper route and revision surgery by the transphenoidal route in 2017 associated with treatment with somatostatin analogues (octreotide 200 µg/day) were indicated for failure of the surgery. The course after surgery was marked by continued growth, an IGF1 level raised to 801 ng/mL (1, 6 × normal) and on pituitary MRI a residue of 11.7 × 7 mm. The patient is placed on lanreotide LP 120 mg/28 days with then reconciliation of the injections every 21 days.The course under treatment is marked by clinical improvement with slowing of the growth rate, normalization of the IGF1 level to 441ng/mL (115-489).
Discussion and Conclusion
Control of acromegaly with lanreotide is not always easysome are more sensitive than others, this is due to the involvement of specific genetic factors. The observation of our case highlights the difficulty of managing pituitary gigantism and the encouraging results of medical treatment with lanreotide.

Acromegaly revealed by pituitary apoplexy: A case report

Samira Bichri, Nassim Essabah Haraj, Siham El Aziz & Asmaa Chadli
Department of Endocrinology and Metabolic Diseases University Hospital Center Ibn Rochd – Casablanca, Laboratory of Clinical Neurosciences and Mental Health Faculty of Medicine and Pharmacy – Hassan II University, Casablanca, Morocco

Introduction
Apoplexy is a rare, serious and acute complication of pituitary adenomas, revealed by tumor syndrome, visual disturbances and hormonal deficits in 60% of cases. We report a case in which the diagnosis of acromegaly was revealed by pituitary apoplexy.
Observation
45-year-old patient. The examination found a tumor syndrome made up of headaches, reduced visual acuity and vomiting which had evolved for 10 days before admission. The clinical examination reveals a rapid deterioration of the general condition associated with a dysmorphic syndrome evoking acromegaly. The hormonal assessment showed a thyrotropic, corticotropic and hyper-prolactinemia deficit with a level of IGF-1 at 486.6ng/ml (88-140) or 3.47 times the normal and on MRI a sellar process. 32 × 23 × 30mm with hemorrhagic component. The patient underwent a large adenoma excision by the transphenoidal route with simple postoperative consequences. The hormone replacement therapy was: hydrocortisone parenterally and then orally with levothyrox.
Discussion and conclusion
The revelation of acromegaly by pituitary apoplexy is exceptional. Our observation has as a particularity a favorable and rapid evolution of the pituitary apoplexy complicated by anterior pituitary insufficiency after hormonal substitution and simple postoperative consequences.

Rare case of pituitary apoplexy after SARS-COV-2 infection

Elena Roxana Novac
Emergency hospital moinesti, Endocrinology, Moinesti, Romania

Pituitary apoplexy is a rare complication of a pituitary adenoma consisting in hemorrhage or infarctation usually in patients with preexisting comorbidities. SARS-COV-2 infection is a 'new' disease known to determine vascular impairment in some patients, although studies on this

particular issue are still rolling. We present the case of a 64 years old woman suffering from mild hypertension (well-controlled under sartans) who in may 2020 got the SARS-COV-2 infection and because of high fever (38,5 C) was hospitalized and placed on treatment with azitromicyne and antinflamatory treatment. 4 days later she develops severe headache with light visual impairment. The symptoms were considered to be in the context of the viral infection so no further investigation were made, but still the patient was placed on corticosteroids with good outcome. Three monts later she presents to our endocrinology department with severe asthenia, hypotension, generalized edema and constipation. She is immediately diagnosed with panhypopytuitarism and a pituitary IRM is being made which describes a pituitary adenoma with a hemorrhage zone of approximately 2 cm. Under treatment corticosteroids and thyroid hormones the evolution is good. The neurosurgical evaluation doesn't consider appropriate to undergo surgery at this time. 6 moths later the patient is in still in very good condition and the IRM reveals slight shrinkage of the tumor and some resorbtion of the hemorrhage area. The particularity of this case we consider to be the non-existence of comorbidities usually associated with pituitary apoplexy and also the late diagnosis of this life-threatening condition, mainly because of the low-experience with COVID manifestation and the general effect of the pandemic both on medical services and also on patients addressability during this period.

Septooptic dysplasia -a rare cause of congenital hypopituitarism

Valentina Soldat Stankovic[1,2], Snjezana Popovic Pejicic[1,2], Gabrijela Malesevic[1,2], Aleksandra Grbic[1,2] & Bojana Caric[1,2]
[1]University Clinical Centre of the Republic Srpska, internal medicine, Banja Luka, Bosnia and Herzegovina; [2]University of Banja Luka, Faculty of medicine, Banja Luka, Bosnia and Herzegovina

Septooptic dysplasia is a clinically heterogeneous disorder characterized by optic nerve hypoplasia, pituitary hormone abnormalities and midline brain defects.clinical diagnosis requires the presence of at least two of the features of the classical triad. Here is male presented on endocrinology consult for the first time at the age of thirthy five. On clinical examination height and weight were normal, face hypogonadal, sparced facial and body hair, testicle hypotrophy, normocytic anemia, reduced bone mineral density. Hormonal analyses showed complete deficiency in pituitary hormones. On MRI study there was corpus callosum agenesis and partial agenesis of the septum pellucidum, empty sella and hypoplastic hypothalamus. Ophtalmology evaluation revealed temporal paleness of optic discs and nonspecific peripheral visual field defects without significat visual impairment. Septooptic dysplasia is rare cause of congenital hypopituitarism. Most patient present with two out of three features, among which hypopitutarism with midline brain defects, presented here, is the rarest combination. Hypopituitarism varies from one to more hormone deficiencies, and during time additional hormone deficinecies may develop. Some patient, like the one presented here, has normal height despite growth hormone defiency, paradoxical growth without growth hormone, attributed to insulin and other growth stimulatory factors.

Spontaneous remission in Cushing's disease: A case report

Radvilė Dobrovolskytė, Birutė Žilaitienė, Robertas Knispelis & Renata Pauliukienė
Lithuanian University of Health Sciences, Department of Endocrinology, Kaunas, Lithuania

Spontaneous remission of Cushing disease might be a phase of cyclic disease, but could also be explained by an ACTH-microadenoma infarction or hemorrhage. True remission must be differentiated from cyclic Cushing's disease with prolonged follow up. 63-years-old female patient was referred to endocrinologist's and presented with uncontrolled hypertension, type 2 diabetes, central obesity, hirsutism, swelling of the face and legs and a 'buffalo hump'. After additional investigation elevated ACTH (24.1pmol/l (n1.63-14.15)), basal cortisol (1187nmol/l (n147-726)) and high 24-hours urinary free cortisol 2236.4nmol/l (n138-524) were determined. Cortisol was not suppressed after low-dose dexamethasone suppression test. Pituitary MRI revealed 0.5x0.2x0.3cm hypointense zone in posterior pituitary. Petrosal sinus sampling was planned, but the patient was admitted to the emergency department with panniculitis in her limbs. After chest and abdominal CT scan 3.1x2.4cm tumor in left ventricle and 0.6cm hypointense tumor in the liver was detected. Patient case was discussed at multidisciplinary team and it was concluded that at that moment biopsy benefit would not outweigh the risks. Patient was treated with iv a/b. When inflammation markers decreased petrosal sinus sampling was performed. It confirmed pituitary source of ACTH production and right side lateralization which coincided with MRI data. During two months period from the first suspicion of pituitary microadenoma till the petrosal sinus sampling was performed, clinical symptoms of Cushing syndrome significantly decreased as well as hormone levels: basal cortisol level 1187->403.16nmol/l, ACTH 24.1->7.1pmol/l. Diabetes control significantly improved as well. The situation was interpreted as spontaneous remission and it was decided to continue active observation of the patient. However, 10 months later worsening of patient's status was observed. Basal cortisol increased dramatically (1354nmol/l) as well as ACTH level (26.4pmol/l). Pituitary MRI was repeated: there was 0.5x0.2x0.6cm hypointense zone in posterior pituitary and transphenoidal pituitary adenoma surgery was performed. Histopathological analysis confirmed chromophobic pituitary adenoma. A few weeks after surgery increasing cortisol levels were observed, due to subtotal removal of pituitary adenoma (confirmed with MRI). For peristent hypercortisolism control, treatment with metyrapone was initiated. After 5 months of treatment metyrapone was halted due to development of adrenal insufficiency. The patient is normocortisolemic for 6 months already, despite of the remnants of pituitary adenoma on MRI and is only under the active follow up at the department. Spontaneous remission in Cushing's disease is a very rare situation. There is still lack of data on pathophysiology, management and follow up strategies for this condition.

Primary hypothyroidism associated with empty sella turcica and hypopituitarism

Chayma Besrour, Imen Rojbi, Youssef Lakhoua, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Hospital Charles Nicolle, Endocrinology-Diabetology, Tunis, Tunisia

Introduction
The empty sella syndrome is a rare disorder characterized by a flattened pituitary gland leaving place to the cerebrospinal fluid to fill in the sella turcica.The diagnosis is radiological and it is often discovered during pituitary disorders. Generally patients suffer from hypopituitarism, and primary hypothyroidism is found to be a rare association.
Observation
Herein the case of a young woman who consulted at the age of 33 year-old for recent onset of diabetes mellitus. The patient had an important retardation regarding the pondero-statural development (Weight: 18.5 Kg, Height: 102 cm) with impuberism (S0,P0 Tanner stage). The evaluation of the hypophyseal function showed firstly; a primary hypothyroidism (TSH >100 µU/mL, TPO antibodies negative) with a thyroid atrophia on the cervical ultrasound, secondly an hypogonadotropic hypogonadism (FSH 28.4 mUI/mL, LH 2.11 mUI/mL, Estradiol 13.4 pg/mL, Prolactin 125 mUI/L), thirdly a corticotropic deficiency confirmed by an insulin induced hypoglycemia test and a low level of ACTH (7.72ng/L), and lastly, a complete GH deficiency. In front of this hypopituitarism, an hypothalamic- hypohyseal MRI revealed an empty sella turcica with a normal pituitary stalk. The procedure to follow was to treat the patient with hormonal replacement therapy, and her state significantly improved with a gain of 11 cm in a period of five months (Height: 113 cm).
Conclusion:
This clinical presentation of the empty sella syndrome is atypical and only few similar cases were found in the literature.Hence the importance of diagnosing it, in order to improve the knowledge of this syndrome and its different aspects.

The paradox of growth hormone therapy during the covid-19 pandemics – high serum igf1 and poor growth

Mirela Iancu[1], Alice Albu1 & Dragos Albu[2]

[1]Spitalul Universitar de Urgenţă Elias, Endocrinology, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucureşti, Romania

Affecting multiple aspects of every-day living, Covid-19 could be a stress-promoting event, and short-stature patients could be an at-risk population. The scope of our study is to assess whether the on-going pandemic could affect children's response to growth hormone therapy. This was a retrospective study that evaluated children on growth hormone treatment who presented for clinical visits between September 2019 and January 2021 at the Pediatric Endocrinology Department of Elias University Clinical Hospital. Eighty patients were included, (48 boys/32 girls), with a mean age of 10.95±2.99 years. They received growth hormone treatment for a number of conditions, but the predominant indication was GH deficiency (63.7% of patients). The parameters assessed were height, standard deviation scores (SDS) for height, standard deviations for height gained before the pandemics, in the first 6 months of the pandemics and at 1 year interval and acquired centimeters at these intervals. The gains in SDS for height decreased over time from 0.20±0.19 before the pandemics to 0.15±0.21 at 6 months and to 0.12±0.24 at the last evaluation, but the statistical significance was not achieved (p=NS). Also, gains in centimeters decreased from 3.76±1.3 to 3.51±1.27 and 3.25±1.51 at 6 and 12 months, respectively, with a statistically significant difference between the first and the last evaluation (p=0.006). The dose of growth hormone treatment did not differ significantly between evaluations (p=NS). At the first evaluation, 10% of patients had a decrease in SDS for height. The proportion of patients with inadequate response to treatment increased significantly at 12 months (18.8%) in comparison with baseline (p=0.004) and six months evaluation (13.8%, p=0.009). We observed that over the course of the study, the mean SDS of IGF1 grew from 0.60 +/- 1.48 before the pandemics to 0.65 +/- 1.28 at the first evaluation, and 0.96 +/- 1.37 at the second evaluation with a statistically significant difference between the 6 month and one year evaluation (p=0.012). Our data suggest that the response to somatropinum treatment might be decreased during the Coronavirus pandemic, independently of treatment doses and other factors affecting IGF-1 level. Stress-induced activation of the adrenal axis may be responsible of the decrease in growth observed by mechanism of peripheral insensitivity to IGF-1.

Outcomes and complications of endoscopic pituitary surgery: A single-center study

Rocio Villar Taibo, Alicia Santamaría Nieto, Paula Andújar Plata, Antía Fernández Pombo, María Gemma Rodríguez Carnero & Ignacio Bernabeu Morón
University Clinical Hospital of Santiago de Compostela, Division of Endocrinology and Nutrition., Spain

Objectives
To present the results of our series of endoscopic surgery of PA, performed in a third level hospital by an experienced team.
Methods
Retrospective review of PA undergoing endoscopic surgery between 2011 – 2018 in our institution. Clinical variables and radiological characteristics and outcomes were collected at diagnosis, before surgery and for an average of 4.8 years of postoperative follow-up.
Results
121 patients with PA and endoscopic surgery were identified. Table 1 summarises baseline characteristics.

Table 1

Age at surgery (years)	57.8 ± 17
Sex (n male)	64 (52.9%)
Charlson Index score	2 (0-10)
Clinical presentation (at diagnosis)	
- Incidental	43 (35.5%)
- Hypopituitarism	65 (53.7%)
- Apoplexy	13 (10.7%)
- Compressive symptoms	51 (42.1%)
- Visual impairment	38 (31.4%)
Non-functioning adenoma	78 (35.5%)
Functioning adenoma	43 (64.5%)
- GH-secreting	26 (21.4%)
- ACTH-secreting	11 (9.0%)
- PRL-secreting	5 (4.1%)
- TSH-secreting	1 (0.8%)
Tumour characteristics	
- Tumour size	
- Macroadenoma	102 (84.3%)
- Maximum diameter (mm)	22.3 ± 11.0
- Extrasellar extension	92 (76.0%)
- Suprasellar	86 (71.1%)
- Sphenoidal	20 (16.5%)
- Cavernous sinus invasion	47 (38.8%)
- Knosp >3	28 (23.1%)

Data are n (%) values, mean ± SD or median (IQR).
Surgical evolution and post-surgical outcomes are shown in Table 2.

Table 2

Surgery indications	
- Functioning adenoma	41 (33.9%)
- Compressive symptoms	40 (33.1%)
- Large tumour size	30 (24.8%)
- Apoplexy	8 (6.3%)
- Resistance to medical treatment	2 (1.6%)
Complications:	
Intraoperative	4 (3.3%)
- CSF leak	1 (0.8%)
- Intracranial haemorrhage	2 (1.6%)
- Epistaxis	1 (0.8%)
Immediate postoperative (1st week	35 (28.9%)
after surgery)	13 (10.7%)
- DI	5 (4.1%)
- Infection	4 (2.8%)
- Epistaxis	3 (3.3%)
- CSF leak	10 (8.2%)
- Other	16 (13.2%)
Late postoperative	7 (5.7%)
- DI	2 (1.6%)
- Infection	1 (0.8%)
- CSF leak	6 (4.9%)
- Other	
Hospital stay (days)	7.3 ± 6.0
Postoperative status	
- Visual field improvement	25/38 (65,7%)
- Hormone excess normalization	22/43 (51,1%)
- Hypopituitarism	65 (53,7%)
- Macroscopic total resection	86 (71,1%)
- Absence of tumor rest (RM/TC)	82 (67,8%)
Final visit outcomes	
- Reintervention	19 (15.7%)
- Radiotherapy	14 (11.5%)
- Remission	76 (62.8%)
- Death	3 (2.5%)

Conclusion
Endoscopic pituitary surgery appears to be safe and effective when an experienced pituitary team is available.

Nonpituitary neoplastic mass lesions of the sellar region: Hematologic malignancies – A 16-year single-centre experience

Sandra Pekic Djurdjevic[1,2], Marko Stojanovic[1,2], Emilija Manojlovic Gacic[2,3], Darko Antic[2,4], Toplica Milojevic[5], Mihailo Milicevic[2,5], Mirjana Doknic[1,2], Dragana Miljic[1,2], Zvezdana Jemuovic[1], Marina Nikolic Djurovic[1,2], Danica Grujicic[2,5] & Milan Petakov[1,2]
[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, University Clinical Center, Department of Neuroendocrinology, Belgrade, Serbia; [2]Medical Faculty, University of Belgrade, Belgrade, Serbia; [3]Institute of Pathology, Belgrade, Serbia; [4]Clinic for Hematology, University Clinical Center, Belgrade, Serbia; [5]Clinic for Neurosurgery, University Clinical Center, Belgrade, Serbia

Introduction
Hematological neoplastic mass lesions of the sellar region are rare.
Aim of the study
To analyze a case series of patients with hematological malignancies affecting sellar region.
Patients and methods
A retrospective study of 1166 patients with sellar lesions diagnosed at Department of Neuroendocrinology over the 16-year period (2005-2020).The demographics, clinical presentation, laboratory features, radiological findings, histological diagnosis, course of treatment and outcomes are described.
Results
We identified five cases (0.4%) of sellar region lesions attributed to a hematological malignancy (all females, mean age 55.2±3.4years). The variety of hematological pathologies included: one patient with multiple myeloma (MM), one patient had acute myeloid leukemia (AML),while three other patients had lymphoma (intravascular large B cell lymphoma (IVL,n=1) or high-grade B cell non Hodgkin lymphoma (NHL,n=2/in one patient in leukemic phase). Three patients (except IVL and AML) presented with symptoms and signs suggestive for cavernous sinus infiltration (cranial nerve palsies and diplopia), one patient with NHL and large mass presented with visual field defects and one patient (AML) presented with diabetes insipidus (DI). Typically the duration of neurological and endocrine symptoms and signs was short. All patients were in poor general condition, with malaise, half of them with pronounced sweating and vomiting. All patients had elevated sedimentation rate and altered blood count (anemia, thrombocytopenia (n=4), thrombocytosis (n=1) and rapid progressive leukocytosis (n=1), while patients with lymphoma had elevated lactate dehydrogenase (LDH). On magnetic resonance, sellar mass was demonstrated in three patients while patient with IVL had empty sella. Patient with AML had loss of posterior lobe T1W hyperintensity. Two patients (IVL and NHL) presented with multiple anterior pituitary deficiencies and one patient (AML) had isolated DI. Hyperprolactinemia due to pituitary stalk compression occurred in 3 out of 5 patients (excluding IVL and AML). Two patients were operated by transsphenoidal approach (NHL and MM). All patients were treated with chemotherapy. Three patients had lethal outcome during treatment. Patient with IVL achieved long term remission with partial reversal of hypopituitarism. One patient with NHL is now treated with immunochemotherapy.
Conclusion
Suspicion of hematological malignancy in sellar region should be raised in patients with short duration of nonspecific symptoms, neurological signs (ophthalmoplegia), blood count alterations and LDH elevation, pituitary dysfunction and imaging features atypical for pituitary adenoma. Early diagnosis is crucial for timely initiation of hematological treatment aimed to induce disease remission and partial or full recovery of pituitary function.

Biliary ultrasound surveillance in patients with acromegaly treated with somatostatin receptor ligands: A large tertiary centre experience

Grigorios Panagiotou, Yaasir Mamoojee & Andy James
Royal Victoria Infirmary, Department of Endocrinology, Newcastle upon Tyne, United Kingdom

Background
Somatostatin receptor ligands (SRL) are commonly used in patients with acromegaly to control insulin growth factor 1 (IGF1) concentrations. Biliary sludge or gallstone formation are well-recognised biliary adverse events (BAE) from SRL therapy. Our current practice is to routinely monitor patients with acromegaly on SRL with ultrasound scanning (USS). Once BAE are detected, ursodeoxycholic acid (UDCA) therapy is initiated.
Objectives
This single centre retrospective study aimed to evaluate: 1) cholecystectomy rates in our cohort; 2) incidence of BAE and; 3) efficacy of UDCA therapy.
Methods
All patients with acromegaly treated with SRL at our centre were included. For those on pegvisomant therapy data were collected during previous SRL treatment only. Exclusion criteria were known cholelithiasis or cholecystectomy predating SRL therapy and absence of ultrasound surveillance. The following data were recorded: age at diagnosis, gender, baseline IGF1, baseline and follow-up USS findings, UDCA dose and duration of USS follow-up.
Results
Out of 57 eligible patients, 1 had pre-existing cholelithiasis, USS surveillance was absent in 6 patients and 9 individuals had only baseline USS data available. For the remaining 41 patients with complete dataset, mean age at diagnosis was 46 years, 60% were females and mean baseline IGF1 was 105 nmol/L. Median duration of follow up was 6 years (interquartile range 6). Cholecystectomy was performed in 4/56 patients (7.1%) for BAE; 3/4 required emergency admission for pancreatitis, cholecystitis and/or cholangitis. Moreover, 25/41 (61%) patients developed BAE (13 with gallstones and 12 with sludge) during follow-up. 22 patients were treated with UDCA with a median daily dose of 350mg (interquartile range 300-600mg). In 16/22 (73%) patients (7 with gallstone and 9 with sludge) a complete response was observed on follow-up USS.
Conclusion
BAE occured frequently in our cohort of patients with acromegaly on SRL. The use of UDCA therapy is highly efficacious at dissolving sludge and gallstones once detected on USS monitoring. Further studies are needed to establish whether low-dose UDCA prophylaxis may be useful to prevent BAE in patients on SRL therapy.

Effectiveness of bilataral inferior petrosal sinus sampling in diagnosis of ACTH dependent cushing syndrome

Selvinaz Erol[1], Feyza Yener Ozturk[1], esra cil sen[1], M.Masum Canat[1], Sezin Dogan Cakir[2], Emre Sedar Saygili[3], adnan batman[4], seda erem basmaz[5], duygu yildiz[1] & Yuksel Altuntas[1]
[1]University of Health Sciences, School of Medicine, Sisli Hamidiye Etfal Training and Research Hospital, Department of Endocrinology and Metabolism, istanbul, Turkey; [2]Adıyaman University Training and Research Hospital, Department of Endocrinology and Metabolism, adıyaman, Turkey; [3]Mehmet Akif Ersoy Canakkale State Hospital, Endocrinology Clinic, canakkale, Turkey; [4]Aksaray University Training and Research Hospital, Endocrinology Clinic, Aksaray, Turkey; [5]Karabük University Karabük Training and Research Hospital, Department of Endocrinology and Metabolism, Karabuk, Turkey

Purpose
We aimed to determine the effectiveness of bilateral inferior petrosal sinus sampling (IPSS) in the differential diagnosis of adrenocorticotropic hormone-dependent Cushing Syndrome (ACTH-dependent CS).
Method
51 patients diagnosed with ACTH-dependent CS between 2010-2019 in the Endocrinology Clinic in ıhı Hamidiye Etfal Health Training and Research Hospital were included in the study. The diagnosis of Cushing's Disease (CH) was made when the basal central/peripheral ACTH ratio was> 2 and/or the rate after CRH stimulation was> 3 in the IPSS procedure. With the inter-sinus ratio> 1.4, lateralization was determined. The diagnosis of CD was confirmed by immunohistochemical staining of pathology specimens. Sensitivity, specificity, positive and negative predictive values were calculated.
Results
In 51 patients with ACTH-dependent CS, IPSS was performed in 31 patients whose mass was not found on MRI or whose mass size was < 6 mm. One patients whose IPSS failed due to anatomical variation and 5 patients whose pathological confirmation could not be made were excluded. The data of 22 patients with pituitary cushing syndrome and 3 patients with ectopic CS (total 25 patients) were examined. In 2 0f 3 patients, ectopic CS was diagnosed primarily with the results of 8 mg dexamethasone suppression test, CRH stimulation test and sella MRI, and postoperative immunohistochemical staining was confirmed. While the sensitivity, specificity, positive and negative predictive values of IPSS in the differential diagnosis of pituitary and ectopic ACTH-dependent CS were 75%, 100%, 100%, 14,28% before CRH stimulation, they were 87.5%, 100%, 100%, and 25% after CRH stimulation, respectively. When the results were evaluated together before and after stimulation, these rates were found as 91,6%, 100%, 100%, and 33,3%, respectively. In 17 (77.27%) of 22 patients whose IPSS showed the pituitary, correct lateralization was confirmed by the operation.
Conclusion
IPSS is an effective test in the differential diagnosis of ACTH-dependent CS.Its sensitivity increases after CRH stimulation. However, while the efficacy of this procedure is high in the central/ectopic distinction, its capacity to lateralize the lesion is limited.

AEP525

Prognostic factors for remission in Cushing's disease after pituitary surgery 'bout 100 cases'

Samira Belkacem
Endocrinology, Pierre Marie Curie Center, of Medecine, Algiers, Algeria

Introduction
Cushing's disease described in 1973 by Harvey Cushing is the most frequent cause of endogenous hypercorticism in adults in 80-85% of cases of Cushing's syndromes, it is secondary to a pituitary microadenoma most often, its treatment is first-line neurosurgical.
Aim of the study
To evaluate the results of the short and medium term therapeutic management of Cushing's disease and to try to determine the predictive factors of remission.
Material and methods
Retrospective study: 85 patients recruited by CPMC. All of our patients underwent clinical, biological and morphological (CT and/or static MRI) pituitary and adrenal evaluation as well as petrous sinus catheterization (n = 9).
Surgical results
All our patients were operated on and 14% resumed Surgically; the transphenoidal route (TSP) has been the rule for all of our patients; the procedure performed is adenomectomy in 88% (selective 84% and enlarged 16%) and hemi-hypophysectomy in 12% of cases. 'The extirpated pituitary adenoma' is identified in 95% by histology. 8.33% of our patients underwent a positive immunohistochemical examination in all cases. Pituitary surgery in cushing's disease resulted in 69% remissions in microadenomas immediately after surgery. Reoperation may improve outcomes if initial surgery fails 8/12 (66%). However, the risk of long-term recurrence is high, 25% beyond 10 years.
Conclusion
Despite advances in diagnosis and treatment, CD is still difficult to treat. TSP surgery is the standard treatment. Our results are satisfactory: the experience of the neurosurgeon remains a fundamental asset. In the event of post-op recurrence, additional radiotherapy treatment is offered in combination with synthetic anti-cortisol drugs.

AEP526

Radiotherapy results non-functional pituitary adenomas about 50 cases

Samira Belkacem
Endocrinology, Pierre Marie Curie Center, of Medecine, Algiers, Algeria

Introduction
Non-functional pituitary adenomas (AHNF) are large tumors expressed primarily by neuro-ophthalmological signs in the foreground and pose a problem of therapeutic management and prognosis.
Materials and methods
We report a retrospective study of 50 files of 'non-functional' pituitary adenomas collected between 1993 – 2005 with the aim of evaluating the results of surgery and conventional pituitary radiotherapy with a minimum follow-up of 2 years for each patient. [Average follow-up: 60 months, range: 24-120 months].
Results
Our series was divided into 26 men and 24 women, the average age was 47 years with extremes of 17 to 80 years. The circumstances of discovery are the typical intracranial tumor syndrome in 26 cases (52%) and visual disturbances in 19 patients (38%). -On the neuroradiological level: it was an expansive pituitary macroadenoma in all cases (100%) and in 19% of cases of giant adenomas (≥ 4cm). - On the pituitary level: there was total or partial anterior pituitary insufficiency in 31 patients (62%) and diabetes insipidus in 3 cases (6%). - On the therapeutic level: 90% of our patients have been operated, including 20% resumed surgically; conventional radiotherapy (55 grays in 28 sessions) completed the surgery in 76% of cases.

Surgery			Surgery+ Radiotherapy	
Number	Progressive recovery (%)		Number	Progressive recovery (%)
n= 45	n= 23 (51%)		n =38	n=11(29%)
	remainder +	remainder		
	n=15	n= 8		

Conclusion
The so-called 'non-functional' pituitary adenomas are large pituitary tumors with significant locoregional and endocrine repercussions with a very mysterious physiopathological mechanism. They are now recognized with greater frequency thanks to advances in immunohistochemistry. The indication for surgical treatment is not the subject of any discussion. However, the therapeutic attitude in the event of postoperative tumor residue remains controversial. Recurrences can be observed very late and therefore justify very long-term monitoring.

Copeptin predicts clinical outcome in schizophrenia spectrum disorder

Clara Sailer[1,2], Jennifer Küster[3], Stefan Borgwardt[3] & Mirjam Christ-Crain[1,2]
[1]Universitätsspital Basel, Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]University of Basel, Department of Clinical Research, Basel, Switzerland; [3]Psychiatric University Hospital Basel, Basel, Switzerland

Background
Vasopressin, the main hormone regulating sodium-water balance, is involved in higher brain functions, e.g., cognition, emotion regulation and social functioning. In patients with an acute psychotic episode, increased vasopressin levels have been described and impaired higher brain functions are associated. Copeptin, the stable surrogate marker of vasopressin, has been shown to predict outcome in somatic diseases, i.e., stroke, myocardial infarction, and increases under psychological stress. In acute psychosis no reliable biomarker has proven to predict clinical outcome. The aim of this study was to investigate whether copeptin can be used as predictor of psychotic relapse in patients with an acute psychotic episode.
Methods
In this prospective, observational study we enrolled patients with an acute psychotic episode either within a schizophrenia spectrum disorder (SSD) or affective disorder. On hospital admission, baseline characteristics including current and prior medication, drug use and disease severity, i.e., Positive and Negative Syndrome Scale, Global Assessment of Functioning, Perceived Stress Scale, State-Trait Anxiety Inventory and Beck Depression Inventory, were assessed and fasting serum copeptin and cortisol were sampled. Psychotic relapse, defined as rehospitalization due to disease progression or reporting of psychotic relapse, was assessed one year after inclusion. The primary endpoint was copeptin at inclusion predicting time to psychotic relapse using Cox Proportional Hazard Model.
Results
We included 73 patients (74% male, mean [SD] age 35.3 [9.8] years) of whom 53 were diagnosed with SSD and 20 with affective disorder (n=17 bipolar, n=3 depression with psychotic symptoms). Serum copeptin predicted psychotic relapse with a hazard ratio (HR) of 1.1 (95%-CI 1.01-1.2, p=0.03) in patients with SSD, but not in affective disorder (HR 1.0, 95%-CI 0.8-1.1, p=0.6). Highest diagnostic accuracy for psychotic relapse was found at a copeptin cut-off of 7 pmol/l with a HR of 3.9 (95%-CI 1.3-11.8, p=0.01). Neither cortisol, prior or current antipsychotic medication, trigger of acute psychosis nor psychopathological ratings were significantly associated with psychotic relapse. Diagnosis of cannabis abuse was significantly associated with psychotic relapse in SDD (HR 3.3, 95%-CI 1.4, 8.0, p=0.008). Adjusting for cannabis abuse, copeptin remained significantly associated with psychotic relapse and identified patients with highest risk of psychotic relapse (p=0.015).
Discussion
Our study indicates that copeptin is a promising biomarker improving outcome prediction of psychotic relapse in patients with an acute psychotic episode within SDD. Our findings may be used to identify patients at risk of psychotic relapse and in need for a more intensive care.

Craniopharyngiomas presenting as incidentalomas – Results of KRANIOPHARYNGEOM 2007

Svenja Boekhoff[1], Brigitte Bison[2], Maria Eveslage[3], Panjarat Sowithayasakul[1,4] & Hermann Müller[1]
[1]University Children's Hospital, Car von Ossietzky University Oldenburg, Department of Pediatrics and Pediatric Hematology/Oncology, Klinikum Oldenburg AöR, Oldenburg, Germany; [2]Augsburg Hospital, Department of Neuroradiology, Augsburg, Germany; [3]University Münster, Institute of Biostatistics and Clinical Research, Muenster, Germany; [4]Srinakharinwirot University, Department of Pediatrics, Bangkok, Thailand

Purpose
Childhood-onset craniopharyngiomas (CP) are diagnosed due to clinical symptoms (symCP) or incidentally (incCP). We investigated clinical manifestations and outcome in incCPs and symCPs.
Methods
IncCP were discovered in 4 (3m/1f) and symCP in 214 (101m/113f) CP recruited 2007–2014 in KRANIOPHARYNGEOM 2007. Age, sex, height, body mass index (BMI), tumor volume, degree of resection, pre- and postsurgical hypothalamic involvement/lesions, pituitary function and outcome were compared between both subgroups.
Results
Reasons for imaging in incCP were cerebral palsy, head trauma, nasal obstruction, and tethered-cord syndrome, whereas headache (44%), visual impairment (25%), and growth retardation (17%) lead to imaging in symCP. Tumor volume at diagnosis was smaller in incCP (median 2.39 cm3; range: 0.14–4.10 cm3) when compared with symCP (15.86 cm3; 0.002–286.34 cm3). Age, gender, BMI, height, hydrocephalus, tumor location, and hypothalamic involvement at diagnosis of incCP were within the range of these parameters in symCP. Complete resections were achieved more frequently (3/4 patients) in incCP when compared with symCP (20%). Surgical hypothalamic lesions were distributed similar in incCP and symCP. Irradiation was performed only in symCP (33%). No noticeable differences were observed concerning survival rates, endocrine deficiencies, BMI, height, functional capacity and quality of life of the 4 incCP cases when compared with the symCP cohort.
Conclusions
IncCP are rare (1.8%) and characterized by lack of endocrine deficiencies, resulting in normal height and BMI, no hydrocephalus, and smaller tumor volume at diagnosis when compared with symCPs. Outcome of the observed incCP is similar with symCP.

Severe hyponatremia and syndrome of inappropriate antidiuretic hormone secretion (SIADH) as a primary presentation of neurosarcoidosis

Uzair Akbar Ali[1,2], Asad Amin[1] & Hafiz Irbaz Nazir[1]
[1]Saint Luke's General Hospital, Kilkenny, Ireland; [2]University Hospital Waterford, Waterford, Ireland

Introduction/Background
Sarcoidosis is a multi-system inflammatory disease of unknown etiology, characterized by abnormal collection of inflammatory cells termed as granulomas. This disease usually involves lungs, skin, or lymph nodes, but can less commonly affect the eyes, liver, heart and brain. Neurological involvement is rare and appears in 5-10% of the cases. Neurosarcoidosis most frequently affects the cranial nerves, the hypothalamus and the pituitary gland. Hyponatremia has been found in some patients with sarcoidosis and few case reports can be found in the literature. We hereby present the case of a 52 year-old gentleman who was diagnosed with SIADH secondary to neurosarcoidosis and presented with severe symptomatic hyponatremia.
Case report
A 52-year old gentleman presented with worsening confusion, lethargy and poor sleep. He had background history of seizures previously diagnosed as epilepsy and was on different anti-epileptic medications. There were no focal signs of neurological involvement other than intermittent confusion and difficulty in organizational skills. He was found to have severe hyponatremia with concomitant serum hypo-osmolality. Anti-epileptic medications were revised in the context of SIADH, but computed tomography (CT) of thorax, abdomen and pelvis revealed mediastinal and hilar lymphadenopathy with normal liver parenchyma. His serum angiotensin converting enzyme (ACE) levels were high, however; calcium levels were within normal range. He had mild hyperprolactinemia with slightly low thyroid stimulating hormone (TSH) and oestradiol levels. Magnetic resonance imaging (MRI) of his brain revealed features consistent with neurosarcoidosis and electroencephalogram (EEG) showed epileptiform activity likely secondary to the same disease. He underwent endobronchial ultrasound biopsy of the mediastinal lymph nodes that showed non-caseating granulomas thus confirming the diagnosis of sarcoidosis.
Treatment/Outcome
Patient was started on oral steroids, tab prednisolone 1 mg/kg body weight with fluid restriction. His sodium levels started improving with improvement in his clinical symptoms. He was advised follow-up in endocrinology and neurology clinics.
Conclusion
This case report highlights that SIADH presenting with severe hyponatremia can be an initial presentation of neurosarcoidosis. Sarcoidosis should be considered in the differential diagnoses of SIADH and hyponatremia.
Keywords: hyponatremia, granuloma, sarcoidosis, inflammation.

Case report of family form of multiple endocrine neoplasia syndrome type 1 with a non-classic course

Natalya Volkova, Yuliya Degtyareva, Ilya Davidenko, Irina Dzherieva, Lilia Ganenko, Alexander Zibarev, Yulya Sorokina & Igor Reshetnikov
Rostov State Medical University, Department of Internal Diseases #3, Rostov-on-Don, Russian Federation

Multiple endocrine neoplasia type 1 (MEN1) is a rare hereditary condition that most often manifests with primary hyperparathyroidism followed by other syndromes, but there are other variations in the clinical presentation, which can increase the risk of medical error and worsen prognosis. A 32-year-old woman presents with complaints of low glucose levels, hunger, weakness, sleep disturbances, which are stopped by taking sweets. At the age of 16, a pituitary macroadenoma, prolactinoma resistant to the treatment was diagnosed (4 years of treatment with bromocriptine, transnasal adenomectomy, followed by 10 mg per week cabergoline didn't achieve normoprolactinemia (prolactin increased to 18,000 mIU/ml). Normoprolactinemia was achieved after repeated surgery at the age of 30). At the age of 28, primary hyperparathyroidism was diagnosed. Ultrasound of the thyroid gland revealed multiple formations of the parathyroid glands. So, a clinical diagnosis of MEN1 was made. Total resection of 4 parathyroid glands was performed with autotransplantation of the least altered gland into the muscle of the left forearm. Postoperatively, hypocalcemia with severe convulsive syndrome occurred, which required intravenous calcium gluconate, after which it was transferred to calcium tablets and active metabolites of vitamin D. Genetic verification of MEN1 syndrome was carried out (R415X gene mutation). A year later, the patient's sister was diagnosed with hyperparathyroidism, genetic study revealed the same mutation. Subsequently, the formation of the adrenal glands (hormone-inactive) and the pancreas were detected. As part of this hospitalization, a fasting test was carried out (completed after 9 hours due to the development of hypoglycemic syndrome, at the end of the test C-peptide, insulin was within normal limits, proinsulin was significantly increased (29 mmol/L (0.7-4.3). According to the results of instrumental research methods, two formations were identified in the head and tail of the pancreas (0.8 and 2.5 cm). After selective blood sampling from the veins of the portal system, an organ-saving operation was performed. With further observation C-peptide, insulin, cortisol, parathyroid hormone remain within the normal range, but proinsulin remains elevated (up to 6-7.8 pmol/l). Given the presence of formations in both adrenal glands, in the head of the pancreas, it is not excluded that they acquire hormonal activity in the future, and therefore the patient will be screened. A detailed description of cases, especially with a non-classical course, can improve the preventive and therapeutic-diagnostic approach, which will have a beneficial effect on the quality of life and prognosis for such patients.

Transsphenoidal surgery in acromegaly: Experience in a tertiary hospital

Alexa Pamela Benítez Valderrama[1], Mariana Gomes Porras[1], Carlos Pérez López[2], Álvaro Zamarrón Pérez[2], Rosa María García Moreno[1], Beatriz Lecumberri[1], Marcelino Pérez Álvarez[2] & Cristina Álvarez Escolá[1]
[1]La Paz University Hospital, Endocrinology and Nutrition Department,

Madrid, Spain; [2]La Paz University Hospital, Neurosurgery Department, Madrid, Spain

Background
Acromegaly is an infrequent chronic multisystemic disease associated with a significant morbidity and mortality rate. The treatment of choice is transsphenoidal surgery (TSS) because of its low risk of mortality and few complications.
Aims
To determine the cure prevalence after TSS of growth hormone (GH) secreting pituitary adenomas. To analyze the predictive factors of non-remission after the surgery.
Materials and methods
Retrospective study of 97 patients with acromegaly diagnosis who underwent surgery (n=86) in La Paz University Hospital from 2000 to 2020. The surgery was carried by three neurosurgeons who meet the requirements of being experts in pituitary gland surgery. We performed a descriptive analysis of the patient`s baseline characteristics and surgery outcomes. A multivariate regression analysis was used to review the possible predictive factors of non-healing. Remission was defined if the age and sex-adjusted IGF-1 level were normal and either the basal GH was <1ng/ml or the nadir GH was <0.4ng/ml following oral glucose tolerance test and absence of tumor on MRI.
Results
Out of the total sample, 56.1% were female and 43.9% were male. Diagnostic suspicion was due to symptoms that were secondary to hormonal hypersecretion in 76.3%. GH-secreting pituitary adenoma was found in 94.1% (36.5% microadenomas and 57.6% macroadenomas) of the total patients. 70% of pituitary adenomas showed signs of extension (51% microadenomas and 65% macroadenomas). The surgical cure rate overall was 53.4% (76.9% microadenomas). Tumor remnants were found on MRI in 40% of the patients (23.07% microadenomas and 57.7% macroadenomas). Recurrence occurred in 2.7% of them. Surgical reintervention was performed in 13.3% and radiation therapy was required in 26.5%. Medical treatment was indicated in 94.1% of patients who were not cured and in 6.8% of patients with recurrence. Median GH levels after surgery were 1.6ng/dl (IQR 73.93ng/dl) and IGF-1 257ng/dl (IQR 1095 ng/dl). Multivariate analysis indicated that the non-healing post-surgical predictive factors were IGF-1 values above the upper limit of normal (x LSN) [OR: 9.95 (2.71-53.82)], GH x LSN [OR: 9.62 (3.04-41.65)], macroadenoma [OR: 21.57 (3.08-228.04)], GH + PRL cosecretion [OR 10.84 (1.68-103.4)] and GH + PRL + TSH [OR 33.86 (1.30-1390)].
Conclusions
1) TSS continues to be the first line treatment in acromegaly, although in large and/or invasive adenomas other therapies may be required. 2) Tumor size and initial GH and IGF-1 values are factors that most influence surgical outcomes. 3) TSS performed by an expert surgeon increased higher cure rates.

Gender differences in eating-related behaviour and traits of patients with craniopharyngioma

Sylvère Störmann[1], Josefine Roemmler-Zehrer[1], Veronika Geigenberger[1,2], Katharina Schilbach[1], Marcus Ising[3], Hildegard Pfister[3], Caroline Jung-Sievers[4], Günter Stalla[5] & Jochen Schopohl[1]
[1]Klinikum der Universität München, Medizinische Klinik und Poliklinik IV, München, Germany; [2]Helios Amper-Klinikum Dachau, Department of Neurology, Dachau, Germany; [3]Max Planck Institute of Psychiatry, München, Germany; [4]Klinikum der Universität München, Chair of Public Health and Health Services Research, Institute for Medical Information Processing, Biometry, and Epidemiology (IBE), München, Germany; [5]MEDICOVER München Neuroendokrinologie Prof. Stalla und Kollegen, München, Germany

Introduction
Craniopharyngiomas are rare and benign tumours of the suprasellar region along the craniopharyngeal duct. Their clinical manifestations result from tumour compression or therapy-induced damage of the surrounding tissue, namely visual impairment, pituitary deficiencies and increased intracranial pressure. Hypothalamic damage often leads to central obesity and fatigue. The impact of these changes on quality of life and body perception has been well described in the literature, but specific analyses of gender differences are scarce.
Methods
We assessed eating-related behaviour and traits in 26 patients with craniopharyngioma (15 female, 11 male) in a cross-sectional study using standardized questionnaires (Three-Factor-Eating-Questionnaire, TFEQ; Eating Disorder Examination Questionnaire, EDE-Q; Body Image Questionnaire FKB-20). We calculated group comparisons using the chi square test or Mann-Whitney U test with a significance threshold of 0.05.
Results
Female and male patients did not statistically differ in terms of age (mean 51.1 [range: 32-68] vs. 55.6 [26-77] years), BMI (32.1 [19.5-47.9] vs. 31.3 [23.9-41.0] kg/sqm), frequency of surgery or radiation, and pituitary deficiencies. Female patients had nominally, but not significantly higher insulin sensitivity as assessed by Matsuda ISI (f: 4.0 [0.9-17.3]; m: 2.4 [0.8-5.3]). Global score from EDE-Q was significantly higher in female patients (2.3 [0.8-3.7] vs. 0.9 [0.1-1.7]; p=0.002) as were the subscales eating concern (2.8 [0-5] vs. 0.9 [0-2]; p=0.001) and shape concern (3.2 [0.0-5.8] vs. 1.4 [0.0-2.9]; p=0.009). Women in our cohort also exhibited a significantly higher negative body assessment (AKB score in FKB-20; 32.2 [15-48] vs. 18.6 [11-28]; p=0.001) and significantly lower vital body dynamic (23.2 [15-35] vs. 31.2 [21-44]; p=0.007). Cognitive control of eating behaviour is increased in female patients (11.3 [4-20] vs. 7.1 [1-15]; p=0.042).
Conclusions
Female patients with craniopharyngioma exhibit a significantly impaired eating behaviour, body perception and cognitive concern with eating as compared to male patients. The reasons for these differences remain to be elucidated.

Improved response to somatostatin analogue (SSA) therapy in acromegaly following treatment pause

Roby Rajan[1], D Bhatt[1], S Philip[1], AJ Graveling[1], W Bashari[2], M Gurnell[2] & P Abraham[1]
[1]Aberdeen Royal Infirmary, Department of Endocrinology, Aberdeen, United Kingdom; [2]Welcome–MRC Institute of Metabolic Science,Cambridge Biomedical Campus, Cambridge Endocrine Molecular Imaging Group, Cambridge, United Kingdom

Background/methods
Patients with uncontrolled acromegaly or receiving high cost medical therapy despite initial treatment, usually transsphenoidal surgery (TSS), were considered for a ^{11}C-methionine PET-CT scan (11C-Met PET-CT). This imaging technique may identify a target for TSS or radiotherapy when MRI appearances are inconclusive[1]. In preparation, four patients on long-term SSA were taken off treatment 3 months prior to the scan. Due to issues with the cyclotron, 2 scans had to be deferred (increasing the duration of the treatment pause). We reintroduced SSA therapy in all 4 patients and noticed an improvement in biochemical response.
Results

Patient	1	2	3	4
Primary therapy	Medical	TSS	TSS	TSS
Treatment prior to 11C-Met PET-CT	Octreotide LAR 20 mg 6-weekly	Octreotide LAR 10mg 4-weekly	Lanreotide ATG 120 mg 4-weekly	Lanreotide ATG 120 mg 4-weekly
IGF1×ULN$^{\varphi}$ at diagnosis (year)	1.8 (1999)	6.1 (2011)	4.6 (2012)	2.1 (1994)
Duration of SSA treatment (years)	18	1	4	23

Duration of treatment pause (months)	8	6	4	8
IGF1×ULN$^{\varphi}$ prior to treatment restart	1.5	1.13	1.0	1.33
Duration of treatment post SSA restart (years)	3	2	3	3
Latest IGF1×ULN$^{\varphi}$	0.87	0.98	1.06*	0.8

11C-Met PET-CT outcome	Awaiting Surgery	Deferred	No surgical target	Deferred
Current treatment	Octreotide LAR 20 mg 6-weekly	Octreotide LAR 10 mg 6-weekly	Lanreotide ATG 120 mg 12 weekly*	Lanreotide ATG 120 mg 4-weekly

¥ Upper limit of normal; * Dose frequency increased from 12 weekly to 10 weekly (patient living abroad and had requested reduced dosing frequency)

Discussion

Tachyphylaxis is defined as a diminishing response to successive doses of a medication, rendering it less effective. SSA therapy is not anticipated to demonstrate tachyphylaxis in acromegaly[2], although there has been one report of partial tachyphylaxis[3]. Our four patients appear to have experienced a resensitisation to SSA therapy following a short treatment pause as evidenced by improved biochemical control; despite two of them having a reduced dosing frequency. The possibility of a treatment pause improving the sensitivity and biochemical control following reintroduction of SSA therapy has been reported in polycystic liver disease[4].

Does concomitant prolactin measurement increase the accuracy of inferior petrosal sinus sampling?

Tugce Apaydin[1], Mehmet Yasar[1], Feyyaz Baltacioglu[2], Goncagul Haklar[3] & Dilek Gogas Yavuz[1]

[1]Marmara University School of Medicine, Endocrinology and Metabolism, Istanbul, Turkey; [2]Marmara University School of Medicine, Department of Radiology, Istanbul, Turkey; [3]Marmara University School of Medicine, Department of Biochemistry, Istanbul, Turkey

Purpose

Inferior petrosal sinus sampling (IPSS) is the gold standard test for the differentiation of pituitary Cushing disease from the ectopic ACTH syndrome (EAS). The measurement of prolactin during IPSS can be helpful to improve the accuracy of the procedure. We aimed to evaluate the effect of measuring prolactin levels as a predictor for the accuracy of IPSS procedure and evaluate its' impact on the lateralization of adenoma.

Material and methods

In this retrospective cohort study, we reviewed 51 patients who had undergone IPSS for the investigation of ACTH-dependent hypercortisolism at Marmara University E&R Hospital between 2012 and 2019. Plasma ACTH (adrenocorticotropic hormone) and prolactin levels were measured both centrally and peripherally during IPSS procedure in all patients. The prolactin adjusted ACTH inferior petrosal sinus/peripheral (IPS/P) ratio was calculated to assess the accuracy of the sampling procedure.

Results

Forty-nine patients had proven CD, one was EAS. Forty-seven patients had above two ACTH IPS/P ratio at baseline, and all the proven CD patients' post-corticotropin releasing hormone (CRH) ACTH IPS/P ratio was above three. Prolactin IPS/ P ratio was above 1.8 in all patients. While prolactin adjusted ACTH IPS/P ratios were >1.3 in all patients with proven Cushing's disease, it was 0.7 in the patient with EAS. Both baseline ACTH and prolactin levels were positively correlated with post-CRH ACTH and prolactin levels (r:0.735, p<0.001; r:0.910, p<0.001, respectively). While post- CRH, ACTH levels were significantly increased from baseline to 3rd,5th,10th minutes in the P and IPS samples (p<0.001), prolactin levels were not showed a statistically significant increase after stimulation with CRH both in the P and IPS samples (p:0.116, p:0.712). Positive lateralization was observed in 55.1% of patients with ACTH gradient, but when prolactin adjusted ACTH IPS/IPS ratio used in addition to the ACTH gradient, the ratio was increased to 67.3%.

Conclusion

Prolactin IPS/P ratios are useful to define successful catheterization, and prolactin adjusted ACTH IPS/P ratio can be helpful to improve the accuracy of results during IPSS procedure.

The alpha-subunit of glucoprotein hormones and anatomopathological aspects of pituitary adenomas

Soumiya Berrabeh, Wahiba Abdellaoui, Imane Assarrar, Ouafae Elmehraoui, Siham Rouf & Hanane Latrech

Mohammed VI University Hospital, Department of Endocrinology-Diabetology-nutrition, Oujda, Morocco

Introduction

The pituitary glycoprotein hormones, luteinizing hormone (LH), follicule-stimulating hormone (FSH), thyroid-stimulating hormone (TSH) and human chorionic gonadotropin (hCG) are comprised of two separate noncovalently bound subunits:alpha and beta units. The alpha subunit is identical in all of the hormones,while the ńsubunit is unique for each hormone and confers the specific immunologic and functional activity.Hypersecretion of the glycoprotein alpha subunit has previously been reported in patients with pituitary,with or without concomitant hypersecretion of pituitary hormones. The objective of our work is to describe the variation of alpha subunits according to the anatomopathological aspects of patients with pituitary adenoma.

Material and methods

A retrospective study that focused on the cases of pituitary adenomas,collected at the Endocrinology-Diabetology and Nutrition Department of Mohammed VI University Hospital in Oujda, over a period of 6 years and a half.The data were collected from medical records and the analysis was done by SPSS version 21 software. Sub-unit rate was considered normal between 0.04 and 0.7mUI/ml.

Results

Thirty two percent out of 74 cases of patients with pituitary macro adenoma benefited from pre-operative measurement of alpha sub-units.A low level was found in 12.5% of the patients,whose anatomopathological type was respectively: one case of prolactinoma, one case of non-secreting pituitary adenoma and one patient with a multisecreting pituitary adenoma.Their average age was 31.6 years with a mean subunit rate of 0.03 Mui/ml. This rate was also elevated in 16.7% of cases,varying from 1.5 to more than 10times the normal range, in a patient with gonadotropic adenoma with concomitant elevation of serum FSH and LH gonadotrophins, in a case with non-functional adenoma, a patient with somatotropic adenoma and a patient with somatotropic adenoma. A normal rate was found in the majority of patients, i.e.70.8% of patients mostly women (53%of women) with a mean rate of 0.28mIUi/ml.These cases include:6 patients with prolactinoma, 5cases with non-functional adenoma, 3cases with corticotropic adenoma, 2cases with mixed adenoma secreting both prolactin, LH and GH and one case with somatotropic adenoma.

Conclusion

We conclude that a-subunit hypersecretion may be more common than previously recognized among patients with pituitary tumors. Its high rate may indicate the anatomopathological type of pituitary adenoma,but remains unspecific.The biological and clinical significance of a subunit cosecretion in patients with pituitary tumors is not known at this time.Whether such cosecretion is of importance in the pathogenesis of these tumors or whether it alters the clinical course or response to therapy deserves further study.

Pituitary apoplexy- a single-center, retrospective study of clinical outcomes

Sandra Ghenoiu[1], Diana Maria Gheorghe[2], Gheorghe Vasile Ciubotaru[3], Anda Dumitraşcu[1], Cristina Capatina[1,2] & Catalina Poiana[1,2]

[1]C.I. Parhon National Institute of Endocrinology, VI, Bucharest, Romania; [2]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania; [3]Emergency Clinical Hospital 'Dr. Bagdasar-Arseni', III, Bucharest, Romania

Introduction

Pituitary apoplexy is a rare entity characterized by abrupt hemorrhage and/or ischaemia of the constituents of sella turcica. It usually occurs in a previously unsuspected pituitary tumor. It may have an acute or subclinical presentation and it may represent a neuroendocrinological emergency.

Aim

This study aims to analyze predisposing or precipitating factors, clinical status, imaging and hormonal features, therapeutic management and its outcome for patients presenting with pituitary apoplexy.

Methods
We performed a retrospective analysis which included 36 patients diagnosed with pituitary apoplexy (we included both acute and subclinical presentations), evaluated during 2019 in Department of Pituitary and Neuroendocrine Pathology at the 'C.I. Parhon' The National Institute of Endocrinology Bucharest, Romania.
Results
36 patients with pituitary apoplexy were included (19 men, 17 women; mean-age at diagnosis 49.2 years, range 14-72 years). Half of the patients presented a classical pituitary apoplexy episode, whilst the other half had oligosymptomatic pituitary haemorrhage described on CT or MRI scan. Only 9 (25%) cases were previously known to have a pituitary adenoma (non-secreting adenoma in most cases). 8 patients (25%) presented at least one precipitating factor, hypertension being the most common. The top 3 symptoms of apoplexy in our patients are headache (44.4%), visual abnormalities (44.4%) and digestive manifestations (22.2%). 23 patients (63.8%) underwent neurosurgical intervention, 11 of them having typical clinical presentation. 75% of the patients had remnant intrasellar mass after the apoplectic event. At diagnosis, corticotropic deficiency was noted to be the most common deficit in patients with classical pituitary apoplexy (4/7 patients) while gonadotropic deficiency had the greatest prevalence in subclinical cases (6/ 9 patients). 25 patients (69.4%) remained with longterm hormone replacement therapy. Out of 16 cases with visual disturbances, 11 patients were operated and 5 managed conservatively. 9 of the operated patients and all cases with conservative treatment had improvement in vision. 4 cases (11%) developed postoperative diabetes insipidus.
Conclusions
Pituitary apoplexy should be managed with a multidisciplinary approach. Although there is an important visual recovery in these patients, the outcome of pituitary function is less favourable.

The perspective of patients with pituitary disease on work according to the expanded ICF model: A qualitative study

Merel Van der Meulen[1], Daniel J. Lobatto[2], Wouter R. van Furth[2], Sasja D. Huisman[1], Yvonne F. Heerkens[3], Thea P.M. Vliet Vlieland[4], Nienke R. Biermasz[1] & Cornelie D. Andela[1]
[1]Leiden University Medical Center, Medicine, division of Endocrinology, Leiden, Netherlands; [2]Leiden University Medical Center, Neurosurgery, Leiden, Netherlands; [3]HAN University of Applied Sciences, Research Group Occupation and Health, Nijmegen, Netherlands; [4]Leiden University Medical Center, Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands

Purpose
As the majority of patients with pituitary disease are of working age, their health situation may negatively impact their functioning at work. However, work participation can also be influenced by contextual (environmental and personal) factors. The aim of this qualitative study was to investigate the perspective of patients with pituitary disease on their functioning at work and on contextual factors contributing to work-related problems, using the expanded International Classification of Functioning, Disability and Health (ICF).
Methods
Semi-structured interviews, focusing on contextual factors influencing work ability and experience, were conducted with eight patients with different types of pituitary adenomas (Cushing's disease, prolactinoma, acromegaly, non-functioning adenoma). Following the steps of an experiential thematic analysis, forty categories were identified, which were organized into eleven themes according to the expanded ICF.
Results
Patients reported various problems in work-related activities (e.g., problems with reading and making more mistakes) and work participation (e.g., working fewer hours or losing their job). Influencing environmental factors included type of employment, perceived job security, financial security, relationships with colleagues/managers, collaboration with others, physical vs. mental work, managing position, flexibility at work, corporate culture, and physical work environment (work-related), and traveling distance to work, financial savings, and (non)professional support (other environmental factors). Influencing personal factors included professional ambition, sense of duty, motivation, job satisfaction, and feeling of fulfilment (work-related), and personality, acceptance, coping styles, and lifestyle (general personal factors).
Conclusion
The expanded ICF model used in this study can bridge the gap between the approach of occupational health professionals and healthcare professionals involved in care for people with a pituitary disease. Patients with pituitary disease report limitations in activities and restrictions in participation at work, which are influenced by several environmental and personal factors. Healthcare professionals and occupational health professionals should be aware of these influencing factors and should address those that are modifiable in order to provide holistic, multidisciplinary patient-centered care. This can improve patients' well-being and functioning at work with the ultimate goal to improve HRQoL.

Silent somatotroph giant pituitary adenoma with the first manifestation at the age of 15 with a 16-year follow up- case report

Magdalena Godlewska[1], Aleksandra Gilis-Januszewska[1], Anna Bogusławska[1], Elwira Przybylik-Mazurek[1], Grzegorz Zielinski[2], Alicja Hubalewska-Dydejczyk[1] & Beata Jurecka-Lubieniecka[3]
[1]Jagiellonian University Medical College, Department of Endocrinology, Kraków, Poland; [2]Military Institute of Medicine, Department of Neurosurgery, Warsaw, Poland; [3]Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice Branch, Department of Nuclear Medicine and Endocrine Oncology, Gliwice, Poland

Background
Silent somatotroph pituitary tumours are very rare, representing only 2-4% of all pituitary tumours in surgical series. Little is known about the course of the disease and efficacy of possible treatment modalities.
Presentation of the case
A male, born in 1990, was first admitted to the hospital at the age of 15, due to sudden ptosis of the right eye and headaches, present for 1 year before the diagnosis. Magnetic resonance imaging (MRI) of the head revealed a solid, homogeneous tumour in the Turkish saddle, 47x37x37 mm in diameter, described as slightly hyperintense in T2- images and FLAIR sequences, slightly hypointense in T1- images and homogeneously enhancing after contrast administration. The tumour expanded into the sphenoid sinuses, medial part of the left cavernous sinus and filled completely the right cavernous sinus, surrounding the whole circumference of the right internal carotid artery. It compressed the right temporal lobe, hypothalamus and the optic chiasm. The patient underwent a transsphenoidal partial resection of the pituitary tumour, with histopathological confirmation of pituitary neuroendocrine tumor (PitNET) with features of nuclear atypia. Immunohistochemistry was positive for growth hormone (GH), +/- for prolactin, negative for the remaining pituitary hormones, MIB1 10%. In electron microscope images, silent somatotroph, sparsely granulated PitNET was confirmed. Neither before surgery nor during 16-year observation did the patient present any clinical symptoms of acromegaly. Upon diagnosis, full endocrinological evaluation was not performed, however, Insulin-like Growth Factor-1 (IGF-1) concentrations were within the normal range, with elevated GH levels and no suppression in the oral glucose tolerance test. Medical treatment with long-acting somatostatin analogue was introduced. Since the surgery, the patient underwent both endocrinological and neurosurgical assessment regularly. Over time MRI images were stable: in the last MRI performed in 2019 a partially empty sella was described, with the invasion of right cavernous sinus by a 20x32x25 mm lesion surrounding the right internal carotid artery. Endocrinological follow-up revealed secondary hypothyroidism and proper function of the gonadal, adrenal and somatotroph axis, with normal concentrations of prolactin and no clinical nor biochemical symptoms of diabetes insipidus. No visual field deficits were discovered during ophthalmological examination.
Conclusion
Although antiproliferative effect of somatostatin analogues has been reported, very little data concerting silent somatotroph pituitary tumours and the treatment options is currently available. Further multicentre studies are needed to investigate the course of those very rare pituitary tumours and create the standards of treatment.

Assessing quality of life and cardio-vascular risk in patients with acromegaly: A single tertiary center case series

Alexandru Morea[1], Diana Lambrinoc[1], Ileana Nitu[2], Ionela Florina Baciu[1,3] & Catalina Poiana[1,3]

[1]Parhon Hospital Bucharest, Pituitary and neuroendocrine pathologies, Bucureńti, Romania; [2]Parhon Hospital Bucharest, Cardiology, Bucureńti, Romania; [3]Carol Davila University of Medicine and Pharmacy, Bucureńti, Romania

Background
Acromegaly is a rare disease, caused by an autonomous excessive secretion of growth hormone (GH). Apart from skeletal alterations, the GH excess leads to metabolic and visceral disease. Thus, one of the most frequent associated complications is the cardio-vascular one represented by hypertension, cardiomyopathy and ischemic heart disease. The presence of multiple complications in patients with acromegaly leads not only to increased morbidity and mortality but also decreased quality of life.
Methods
The study gathers 42 patients with acromegaly (16/26 m/f) divided into two subgroups on the basis of treatment (SA – somatostatin analogue as monotherapy/in dual therapy with dopamine agonist; PEG- GH receptor blocker- Pegvisomant- in monotherapy or dual therapy with SA). Assessment of the hormonal and metabolic status was performed in all subjects. Regarding cardio-vascular function, we calculated the SCORE risk using the European High Risk Chart and the Framingham Risk score for coronary heart disease, while also measuring several important parameters through 2D echocardiography. Quality of life was assessed using ACRO-QoL, a disease-specific questionnaire and SF-36, a generic questionnaire.
Results
There were no significant differences between the PEG and SA groups regarding total ACRO-QoL scores (76.64 ± 15.38 vs. 78.82 ± 17.65) and SF-36 (85.78 ± 37.43 vs. 87.89 ± 31.77). Instead we have found a significant lower personal relations score in the PEG group compared to SA (26.85 ± 6.024 vs. 27.96 ± 5.84, p=0.026). Concerning the cardio-vascular function, there was a significantly lower SCORE risk (1.72 vs. 1.91, p=0,034) and Framingham score (6.63 vs. 7.73, p=0,013) in the PEG group compared to the SA group and the PEG group had also lower blood pressures at the moment of examination using less antihypertensive drugs (1.75 ± 0.88 vs. 3 ± 1.14, p=0.038). Also, there were no significant differences regarding 2D echocardiography parameters in the two groups.
Conclusion
The results confirm that GH receptor blocker (Pegvisomant) has a better cardio-vascular outcome for the patients despite having similar quality of life scores compared to the SA group, the only difference being lower personal relations score assessed through ACRO-QoL questionnaire.

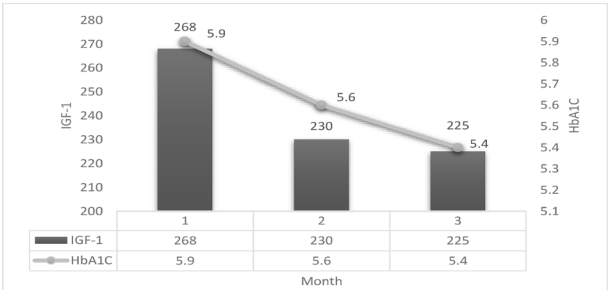
A micromegaly case: Difficult to determine whether a metabolic state or an acromegaly subset

Meliha Melin Uygur[1] & Dilek Gogas Yavuz[2]
[1]Marmara University Pendik Training and Research Hospital, Internal medicine, division of endocrinology and metabolism, istanbul, Turkey; [2]Marmara University medical school, Internal medicine, division of endocrinology and metabolism, istanbul, Turkey

Introduction:
Acromegaly is caused by excess levels of growth hormone (GH) and insulin-like growth factor 1 (IGF1), which usually result from a pituitary adenoma. At the presence of classical symptoms, the diagnosis is confirmed by increased serum IGF1 concentrations and high serum levels of GH that are not suppressed in an an oral glucose tolerance test (OGTT). A nadir GH cut-off of 0.4 µg/lwith ultrasensitive assays is considered as diagnostic. However, some patients with lower nadir GH despite elevated IGF-1 levels, also named as micromegalic, were reported.
Case
We present a case of 35 years-old woman, who got involved a clinical trial in outpatient clinic of Marmara University Medical School Endocrinology and Metabolism Deparment. An elevated IGF-1 level was detected by coincidence. The patient did not have acromegaly-related complaints. Her weight was 74 kg, height was 178 cm. Waist circumference was 92 cm. Her body mass index was 23.3 kg/m^2 and his waist to height ratio was 0.51 kg/cm. In biochemical evaluation, GH level was 3.36 µg/l, IGF-1 level was 268 (63.4-223) µg/l. After an oral glucose load, GH level supressed to 0.08 µg/l. During OGTT insulin levels were recorded as 10.65, 52.53, 31.41 mU/L; glucose levels were recorded 92, 95, 85 mg/dl at 0,60, 120 minutes; respectively. Hemoglobin A1c (HbA1c) level was 5.9%. The pituitary magnetic resonance imaging (MRI) showed a suspected 2 mm adenoma on the right side of the pitutary gland. According to the laboratory results regarding glucose intolerance, calori restriction and exercise were advised to the patient. IGF-1 and HbA1c levels decreased after life style intervention.



Conclusion
The pathologic mechanism of the discordance betwwen GH and IGF-1 in acromegaly is still unknown. Metabolic processes might be the underlying reason that was shown in a recent study which eucaloric very-low-carbohydrate ketogenic diet was useful in maintaining IGF-1 control. ń̀n our case, it is difficult to determine whether excess IGF-1 levels were a consequence of the glucose intolerance or GH-secreting pituitary adenoma.

Successful recovery after COVID-19 infection in a patient with diabetes insipidus and pituitary insufficiency due to a pituitary stalk tumor

Raluca Trifanescu[1,2], Sorina Schipor[3], Suzana Vladoiu[3] & Catalina Poiana[1,2]
[1]'Carol Davila' University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania; [2]'C. I. Parhon' National Institute of Endocrinology, Pituitary and Neuroendocrine Tumors, Bucharest, Romania; [3]'C. I. Parhon' National Institute of Endocrinology, Scientific research Lab, Bucharest, Romania

Background
Fluid balance in patients with diabetes insipidus and COVID-19 is very fragile. The prevalence of hyponatraemia in patients with pneumonia due to COVID-19 seems to be low, but in patients admitted to intensive care units (ICU) is high (up to 20.5%). In contrast, hypernatraemia may also develop in COVID-19 patients in ICU (up to 3.7% of cases), due to insensible water losses from pyrexia, increased respiration rate and use of diuretics. Both hypo and hypernatremia were associated with increased mortality and sepsis.
Case report
A 35 years old, non-smoker women with diabetes insipidus and pituitary insufficiency due to a pituitary stalk tumor (12/8/12 mm diameter) developed COVID-19 in august 2020. She also had obesity (BMI= 38.7 kg/m2), vitamin D insufficiency (25 OH vitamin D= 22.7 ng/mL) and dyslipidemia. Blood pressure, renal function were normal and she had no diabetes mellitus. Endocrine assessment 6 months prior to COVID-19 infection showed gonadotroph insufficiency (FSH=4.1 mUI/ml, LH=1.37 mUI/ml, estradiol<10 pg/ml), central hypothyroidism on levothyroxine treatment (TSH= 1.6 mUI/l, FT4= 9.2 pmol/l) and low normal basal 8 a.m. cortisol levels (4.77 µg/dl) with stimulation to low dose (1 µg, iv) short Synacthen test up to 19.6 µg/dl (ie 540 nmol/l) at 30 minutes and 16.2 µg/dl (ie 446.4 nmoll) at 60 minutes. 8 a.m. ACTH level was normal (16.4 pg/ml). Serum prolactin level was suppressed (0.4 ng/ml) on small dose dopamine agonist therapy (Cabergoline 0.5 mg/week). At COVID-19 diagnosis she was on Desmopressin 240 µg/day, Levothyroxine 50 µg/day, Cabergoline 0.5 mg/week, Cholecalciferol 500 IU/day and Rosuvastatin 5 mg/day. She presented a mild disease with fever, cough, but not pneumonia and did not required hospitalization'. Plasma sodium monitoring was not possible, but the patient did not experienced abnormal variations in fluid balance and body weight was stable. Due to suboptimal adrenal reserve, she was advised (by virtual counselling) taking oral glucocorticoids and to progressively decrease the dose after full recovery. She also received supportive treatment. She fully recovered and 2 months after infection she displayed normal serum natremia

(Na=145 mmol/l), high-normal serum osmolality, similar pituitary function and high titer of anti SARS Cov-2 IgG (95.1 IU/ml, normal range < 12 IU/ml).
Conclusion
Patient education, virtual patient counselling, careful monitoring of fluids intake and excretion, daily body weight monitoring and glucocorticoid dose adjustments are mandatory in patients with diabetes insipidus and pituitary insufficiency during Covid-19 infection.

Descriptive analysis of patients with Multiple Endocrine Neoplasia type 1. Experience at a tertiary hospital

Rosa María García Moreno, Mariana Gomes-Porras, Beatriz Lecumberri & Cristina Álvarez Escolá
La Paz University Hospital, Department of Endocrinology and Nutrition, Madrid, Spain

Background
Multiple Endocrine Neoplasia type 1 (MEN 1) is a genetic syndrome caused by inactivating mutations of the menin gene, which predisposes to the development of endocrine tumors. The causative mutations, clinical manifestations, and age of tumor development are highly variable. The objective of this study is to describe the characteristics of patients with MEN1 in our hospital.
Material and methods
We performed an observational, descriptive, unicentric study of patients diagnosed with MEN1 followed in the Department of Endocrinology of La Paz University Hospital in the last 10 years. Results of categorical variables were expressed in absolute or relative frequencies and those of continuous variables in mean and standard deviation.
Results
Eleven patients (7 women/4 men) with an average age of 39.4±16.0 years old were diagnosed with MEN1. Eight patients (72.7%) were the index case, and the other three were diagnosed during genetic screening. 63.6% of the patients had other affected relatives. Patients of the same family, who expressed the same mutation, differed in the clinical presentation. The most common manifestation was primary hyperparathyroidism (PH), which appeared in all the patients. The age at diagnosis of PH was 38.3±15.1 years and was the first manifestation in two patients. After surgery (subtotal parathyroidectomy or total parathyroidectomy with forearm auto-implantation), 63.6% of patients were cured, 18.2% developed transient hypoparathyroidism, and 27.3% permanent hypoparathyroidism. 81.8% of patients had pancreatic neuroendocrine tumors (pNET) (45.5% non-functioning pNET, 9.1% concomitant insulinoma and gastrinoma, 9.1% insulinoma, and 18.2% gastrinoma). Five patients had multifocal pNETs. pNETs were localized except for two patients, one patient with gastrinoma had lymph node metastases, and another with non-functioning pNET had liver and splenic metastases. The average age at diagnosis of pNET was 39.3±15.3 years, and it was the first manifestation in one patient. After surgery, 77.7% of patients with pNET developed insulin-dependent diabetes mellitus. 72.7% of patients had a pituitary adenoma (27.3% non-functioning adenoma, 36.4% prolactinoma, and 9.1% mixed prolactin-and-GH secreting adenoma). The average age at diagnosis of pituitary adenoma was 31.5±11.8, being the first clinical presentation in three patients. Other manifestations were an adrenal adenoma in three patients, lipomas in two patients, and thymoma in one patient.
Conclusions
It is a small but representative cohort of patients with MEN1. Our results are similar to those described in the literature. Thymoma is an atypical presentation rarely reported in MEN1 and was present in one patient of our cohort.

AEP543

Pituitary apoplexy secondary to anticoagulation for pulmonary thromboembolism

Inês Ferreira Barros, Rui Ramos, Rui Almeida & Olinda Marques
Hospital de Braga, Braga, Portugal

Introduction
Pituitary apoplexy (PA) consists of acute infarction/hemorrhage of the gland, involving mostly a previously unrecognized adenoma. One of its most documented precipitating factors is anticoagulation in the context of acute coronary syndrome treatment. To our knowledge only one report described a PA secondary to anticoagulation for pulmonary thromboembolism.
Case report
A 75-year-old men with known hypertension was hospitalized for bilateral pulmonary thromboembolism. At D2 of enoxaparin, complained of a sudden, strong, frontal headache. Pituitary-MRI confirmed a heterogeneous, T1-hyperintensive lesion of 28x22x26mm compatible with apoplexy. Analytical study showed hypogonadotrophic hypogonadism, high ACTH, hypercortisoluria, hypokalemia. The patient noticed tiredness, weight gain, and erectile dysfunction for 6 months, but there were no Cushing stigmata. It was decided a conservative management. At first month revaluation potassium and ACTH normalized. After three months pituitary imaging showed involution of the lesion and there were no other deficits. One year later developed hypercortisolism.
Conclusion
Considering the high prevalence of undiagnosed pituitary adenomas, physicians must be alert for risk factors for PA such as anticoagulation, used in multiple pathologies. Case reports in the context of pulmonary embolism are rare. Our case highlights the need to be aware of this emergent problem in order to prevent further complications.

30-year postoperative course of invasive prolactinoma in a male patient

Irina Vaychulis
South-Ural State Medical University, Internal Medicine Department, Chelyabinsk, Russian Federation

Most of prolactin secreting tumors excellently respond to low doses of dopamine agonists (DAs). However, management of giant, invasive prolactinomas, partially or completely resistant to DAs is a challenge. Male patient was referred to endocrinologist in 2008, at the age of 63 years, presented with headaches, pressure sensation behind the left eye, decreased vision and fatigue for the last 2 months. In 1986 (at the age of 40 years) blurred vision had appeared for the first time and pituitary macroadenoma (prolactinoma) with endo-supra-infra-laterocellar growth was revealed. Decreased libido had started earlier. In 1986 partial adenomectomy with subsequent gamma radiation therapy were performed. For 6 years after this treatment he received bromocriptine (BRC), L-thyroxine and testosterone with no signs of tumour remnant growth. In 1993 he had discontinued BRC, had no complaints and was lost to follow-up until 2008. At examination in 2008 gynoid type of obesity (BMI 39 kg/m2) and pronounced hyperprolactinemia with prolactin (PRL) level of 66928 mU/l (ULN 360) were revealed. Macroprolactinemia was excluded. Pituitary MRI showed adenoma 38ґ41ґ40mm with intrasellar and left paracellar growth, invasion to sphenoid sinus, infratemporal space and cavernous sinus, surrounding left carotid artery. Considering location and extension of pituitary mass repeat surgery was not recommended, and cabergoline (CAB) was started from 0,5 mg/week with stepwise dose increase. Under CAB treatment at increasing dose up to 3 mg/week PRL reduction from 66928 (ULN 360) to 1554 (ULN 407) mU/l was achieved by 2009. Pituitary MRI in 2010 showed a reduction of adenoma size to 29x27x25mm with signs of invasion. Unfortunately, further increase of CAB doses up to 5-7 mg/week along with correction of hypopituitarism was not effective. PRL level had increased up to 122000-172200 mU/l (ULN 407). Stereotactic radiation therapy in 2012, 2014 had also failed to stop further growth of macroadenoma (up to 86x43x55mm) with orbital invasion, compression of the left optic nerve and progressive visual deterioration. Patient had died in 2016. This case emphasizes the necessity of the permanent follow-up with continuous, usually lifelong administration of DAs in patients with macroprolactinomas after non-radical pituitary surgery. Initiation of CAB demonstrated dramatic (about 49 times) reduction of PRL level and positive MRI changes even in a patient with invasive giant prolactinoma. On condition of uninterrupted DAs treatment it would probably be possible to control hyperproplactinemia, improve patient's quality of life, to prevent further growth of residual tumour, development of CAB resistance and visual impairment.

Postoperative central diabetes insipidus after transsphenoidal adenomectomy in patients with Cushing's disease

Uliana Tsoy, Aizanat Bolatova, Vladislav Cherebillo & Elena Grineva
Almazov National Medical Research Center, Institute of Endocrinology, St-Petersburg, Russian Federation

Purpose
Postoperative central diabetes insipidus (PCDI) is one of the complications of transsfenoidal adenomectomy (TSA) in patients with Cushing's disease. Identification of predictors of PCDI development and clinical course could optimize the management of such patients.
Aim
To study the prevalence of PCDI in patients with Cushing's disease after transsphenoidal adenomectomy and to find the risk factors of its development.
Methods
Medical histories of 116 patients with Cushing's disease were retrospectively analyzed. All patients underwent TSA in Almazov Centre during the period from January 2016 to December 2018. 111 patients were operated on initially, and five were re-operated. Clinical, preoperative MRI images and histology data were studied.
Results
Among 116 patients PCDI developed in 25 (22%) cases (23 women (92%)). Eighteen patients (72%) had transient form of the disease, and seven (28%)-permanent. In two cases (8%) triphasic DI was confirmed. Adenoma size and localization did not differ in patients with and without PCDI. In 9 patients without PCDI and 8 patients with PCDI the presence of neurohypophysis tissue was confirmed by histological examination of the removed sample. Among 111 initially operated patients PCDI developed in 23 (20,7%), among five re-operated patients – in two (40%). Need for desmopressin therapy for 6 months or more indicated the permanent form of the disease. The average dose of desmopressin in patients with transient form of the disease was 120 mcg (min 30 mcg; max 240mcg). The average dose of desmopressin in patients with permanent PCDI was 210 mcg (min 60 mcg; max 360mcg).
Conclusion
The prevalence of central diabetes insipidus after TSA among patients with CD is high and amounts to 22%. In most cases the form of the disease is transient. Repeated surgery is the risk factor of PCDI development. The need for high doses of desmopressin increases the likelihood that diabetes insipidus will be permanent. The need for desmopressin therapy for 6 months or more indicates a permanent form of the disease.

A double-blind, randomized, placebo-controlled trial of SPI-62 safety and efficacy for the treatment of Cushing's syndrome

Maria Fleseriu[1], Irina Bancos[2] & David Katz[3]
[1]Oregon Health & Science University, United States; [2]Mayo Clinic, Unites States; [3]Sparrow Pharmaceuticals, United States

11ṕhydroxysteroid dehydrogenase type 1 (HSD-1) controls the intracellular cortisol pool that has access to cytosolic glucocorticoid and mineralocorticoid receptors. HSD-1 activity is elevated in patients with Cushing's syndrome (CS).1 Patients with CS and constitutionally low HSD-1 activity showed no hypercortisolism-related symptoms despite very high 24-hour urine free cortisol.2,3 A recent pilot trial of a HSD-1 inhibitor in patients with classical or mild CS showed positive trends on glycemic control and body habitus.4 SPI-62 is a potent, selective HSD-1 inhibitor. In four prior clinical trials once-daily SPI-62 dosing, without titration, was associated with few adverse events and substantially reduced intracellular cortisol.5-7 We have shown that in a double-blind, randomized, placebo-controlled, 6-week pilot trial in subjects with diabetes, SPI-62 was associated with clinically meaningful decreases on HbA1c, glucose, cholesterol, and triglycerides. Adult patients with ACTH-dependent CS will be randomized to receive SPI-62 followed by placebo, or placebo followed by SPI-62, in an upcoming international, multicenter clinical trial. Patients with urinary biomarker of HSD-1 activity (allotetrahydrocortisol + tetrahydrocortisol)/tetrahydrocortisone $\geq$ 1 will be eligible. Patients with recent radiation therapy or surgery, or planned surgery, for CS, and patients with pseudo-CS, cyclic CS, or exogenous CS will be excluded. Medical therapy for CS will be subject to washout before randomization, while medications intended to treat specific symptoms and comorbidities (except glucocorticoid or mineralocorticoid receptor antagonists) will be continued on stable regimens. Efficacy will be assessed based on glycemic control, body habitus, blood pressure, blood lipids, bone biomarkers, mood, cognition, and quality of life. Safety will be reported for all subjects who receive at least one dose of study drug and will include hypothalamic-pituitary-adrenal and hypothalamic-pituitary-gonadal axis monitoring. This will be the first randomized placebo-controlled trial of a HSD-1 inhibitor in the treatment of CS.

Long-term survival in a patient with corticotroph pituitary carcinoma and brain metastases

Izabella Czajka-Oraniec, Maria Stelmachowska-Banas, Arnika Szostek, Agnieszka Baranowska-Bik & Wojciech Zgliczynski
Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland

Background
Pituitary carcinoma (PC) is a very rare clinical entity, which is defined as a pituitary tumor that has metastasized to sites distant from the pituitary. It may present as hormone-secreting, invasive and recurrent macroadenoma causing a mass effect.
Case presentation
We present a 58-years old male patient with corticotroph pituitary carcinoma and brain metastases who underwent 9 neurosurgical interventions, radiotherapy and chemotherapy with temozolomide. In 1995 a non-functioning pituitary macroadenoma impinging the optic chiasm and causing visual filed defects was visualized on MRI. First debulking transcranial surgery was performed in 1995 and led to improvement in visual field but was complicated by anterior pituitary deficiency and diabetes insipidus. In 2006 a significant regrowth of a tumour was noted. The patient was again operated in 2006 and then due to aggressive tumor growth he required further debulking surgeries in 2007, 2008, 2009, 2010 and 2011. In 2012 ACTH-dependent Cushing syndrome was diagnosed and the patient was administered ketoconazole but long-term therapy was impossible because of the toxic liver injury. In 2013 stereotactic fractionated radiotherapy (5400 cGy/g) was applied and allowed for tumour size reduction and remission of hypercortisolemia. Despite clinical improvement, in 2014 routine pituitary MRI showed 3 brain metastases. Further imaging studies,i.e. 18-FDG PET/CT and somatostatin receptor scintigraphy were performed revealing increased radiotracer uptake only by a residual pituitary tumor mass. Transcranial biopsy from a lesion in the parietal lobe confirmed metastasis of corticotroph pituitary carcinoma. Pathology report from the next transcranial pituitary surgery in 2015 confirmed a highly proliferative Crooke cell corticotroph adenoma (ACTH (+) p53 >30%, Ki-67>5%, MGMT<5%). Subsequently, radiosurgery (gamma-knife) of 3 metastatic lesions was applied and temozolomide in a dose of 400mg/day for 5 days, 14 cycles in total, was initiated achieving stabilization of the disease. In 2017 MRI showed progression of the tumor requiring next transsphenoidal surgery and new brain metastases. Gamma-knife radiotherapy was performed again in 2019 to brain metastases and consecutive pituitary neurosurgery in 2020. Due to deteriorating symptoms of hypercortisolemia and positive response to short-acting pasireotide test, pasireotide LAR has been initiated in 2020.
Conclusions
The management of PC is challenging, requiring a multimodal approach using repeated neurosurgeries, radiotherapy and chemotherapy. Despite the usually described in the literature poor prognosis in PC, this multimodal management may lead to long-term survival, even 7 years as in presented case.

Clinical features and pituitary function in primary empty sella syndrome

Hadj Kacem Faten, Asma Zargni, Dhouha Ben Salah, Mohamed Abdellahi Mohamed Ahmed, Fatma Mnif, Nadia Charfi, Mouna Mnif, Nabila Rekik Majdoub, Mouna Elleuch & Abid Mohamed
Hedi Chaker Hospital, Departement of Endocrinology, Sfax, Tunisia

Introduction
Empty sella syndrome (ESS) is a rare condition in which the sella turcica is partially or completely filled with cerebrospinal fluid. ESS can be classified as primary or secondary, depending on the identification of underlying etiologies. Whether empty sella has any functional implications in causing pituitary hormonal disturbances needs to be understood. The aim of our study was to assess the incidence of pituitary hormonal disturbances in patients with ESS and to determine any association between empty sella and these hormonal abnormalities.
Methods
We report a retrospective study of 46 cases of ESS collected in the endocrinology department over the period from 1991 to 2020. The clinical and biochemical profile of ESS patients was analyzed.
Results
Our study included 46 cases with a male: female ratio of 1:3.5 suggesting female predominance. The mean age of our patients was 50.4 years (21-81 years). The frequency of primary ESS among ESS was 70% in our series. Headache was the most frequent reason for consultation, 66.67%. Obesity was noted in 20% and multiparity in 62%. On the endocrine examination, anterior pituitary insufficiency was found in 58% of cases and hyperprolactinemia in 14% of cases. Finally, 0.5% of our patients showed central diabetes insipidus. Hormone deficiency substitution was preconized. The evolution was marked by the persistence of signs of anterior pituitary insufficiency in 13% of cases and headaches with visual disorders in 48.2% of cases. The comparative study concluded that failure of lactation in the postpartum period was found to be significantly correlated with hormonal dysfunction (p=0.046). The presence of headache is significantly associated with the absence of hormonal impairment in patients with primary ESS (p= 0.01).
Discussion-conclusion
The primary empty sella syndrome is of increasing interest due to frequent radiological exploration of the sellar region using mainly MRI. It is important to consider this syndrome in front of an obese, multiparous woman with headaches, and to carry out an exhaustive hormonal and radiological exploration in order to detect hormonal deficiencies.

Primary lymphocytic hypophysitis diagnosed during pregnancy: Case report

Mouna Mezoued[1], habouchi amine[2] & Azzouz malha[3]
[1]Bologhine Hospital, Algeria; [1]Mustapha hospital, Radiology, Algeria;
[3]Bologhine Hospital, Endocrinology, Algeria

Primary lymphocytic hypophysitis is an autoimmune endocrinopathy affecting mainly women during pregnancy and psot-partum. We report the observation of a 28 year old patient, G5P2C2 with a progressive pregnancy at 32 SA, with a history of hypertension without any particular familial history. The patient had an ophthalmologic examination as part of the exploration of the repercussions of hypertension, which objectified an abnormal excavation of the left eye at the fundus examination supplemented by a visual field that found complete narrowing of the left eye and temporal hemianopsia of the right eye. A pituitary MRI without injection found an intra-selar mass with supra-selar extension evoking a pituitary adenoma. Clinical examination was without particularity, apart from headaches, On the hormonal level, a slight hyperprolactinemia of about 179 ng/ml was found. In this context, the diagnosis of pituitary disease is highly likely, and the patient was put on corticosteroid therapy at a dose of 3 bolus of 120 mg of methylprednisone with a relay of prednisone at a dose of 40 mg/day. After 3 days of CTC, the control visual field returned to normal, with a disappearance of a few drops of methylprednisone. Four months postpartum, magnetic resonance imaging showed complete resolution of the pituitary mass. In total: the diagnosis of Primary lymphocytic hypophysitis must be made in an evocative context such as pregnancy and postpartum, as early as possible, to avoid an unnecessary aggressive treatment and the evolution of the pathology with a risk of hormonal repercussions, essentially corticotropic.

Improvements in quality of life after treatment in three acromegalic patients

Plotuna Iulia-Ştefania, Mihaela Vlad & Melania Balas
University of Medicine and Pharmacy 'Victor Babeş', Timişoara, Romania, 2nd Departament of Internal Medicine, Discipline of Endocrinology, Romania

Acromegaly is a rare disease. In more than 99% of cases this is due to a benign pituitary growth-hormone secreting adenoma. This leads to changes in appearance, enlargement of the internal organs and, after a long period of time, to multiple comorbidities.
Objectives
To determine which factors might have contributed to the lower quality of life in three acromegalic patients.
Materials and methods
The patients completed a Romanian translation of Acromegaly Quality of Life Questionnaire (AcroQol) in two separate occasion, while they were re-evaluated in our clinic. All the other data were collected retrospectively, form their medical files. All three patients are female. Patient 1, aged 68 years old, was diagnosed and treated for a pituitary macroadenoma in 2013 by neurosurgery. Patient 2, aged 59 years old, was diagnosed in 2001 and was treated twice by neurosurgery (2003 and 2004) and in 2004 with Gamma Knife. Patient 3, aged 70 years old, was diagnosed with a mixt pituitary microadenoma, secreting GH and PRL, in 2001 and was treated with a dopamine agonist until 2013, when she underwent neurosurgery. All three patients are currently under treatment with a somatostatin analogue and have varying degrees of hypopituitarism for which they receive substitution therapy. Patient 2 and 3 have controlled disease and Patient 1 has partially controlled disease. Patient 1 and 3 are obese and have more than 3 comorbidities associated with acromegaly, including psychiatric disorders. AcroQoL is a disease-specific, self-administered questionnaire to asses quality of life in people diagnosed with acromegaly. It contains 22 items, divided into two scales, one evaluating physical and the other, psychological aspects (also divided in two sub-dimensions-physical appearance and personal relationships). The score varies between 0 (worst HRQol) and 100 (best HRQol).
Results and discussions
Patient 1 had a total score of 27.27 in 2017 and 48.86 in 2020. Patient 2 had a total score of 38.36 in 2017 and 56 in 2019. Patient 3 had a total score of 38.36 in 2017 and 45.45 in 2020. All three patients had the lowest score in the appearance sub-domain at the first presentation. Patient 1 had the lowest score in personal relationship sub-domain at the second re-evaluation. At the last evaluation Patient 3 had the lowest global score, while at the first presentation Patient 1 had the lowest score. In conclusions, for all these three patients the control of acromegaly improved quality of life.

MODY 3 and acromegaly: An improbable association treated with bromocriptine

Francisca Puga, Cláudia Amaral, Cláudia Freitas & Maria Helena Cardoso
Centro Hospitalar Universitário do Porto, Endocrinology, Portugal

Introduction
Maturity Onset Diabetes of the Young (MODY) is an autosomal dominant disease, diagnosed mainly in young individuals with a strong family history of diabetes, that results from mutations impairing pancreatic β cell function. The MODY 3 subtype, caused by a HNF1α mutation, with consequent deficit in insulin secretion, is the most frequent and responds more effectively to sulfonylureas, compared to metformin. Acromegaly is a rare condition characterized by hypersecretion of growth hormone, usually by a pituitary adenoma, that leads to multiple comorbidities, including insulin resistance. There is no association described in the literature between MODY 3 and acromegaly.
Case report
A 33-year-old man, with obesity, obstructive sleep apnea and colon polyposis, with family history of MODY 3, came to an endocrinology appointment after

being diagnosed with diabetes 3 years before. He was on insulin therapy since diagnosis, with negative pancreatic β cell immunity. At the first visit we noticed an acromegalic facies, a BMI of 31.8 kg/m^2, with a suggestive history of acromegaly for about 10 years. In this context, a pituitary study was requested that revealed hGH 5.04 ng/ml (N 0.06–5.00), IGF-1 773 ng/ml (N 71.2–234), ACTH 64.0 pg/ml (N 9–52), cortisol 14.2 µg/dl (N 6.2–19.4) and prolactin 404.0 ng/ml (N 4.04–15.2). At that time, he was on insulin glargine 10 units, gliclazide 60 mg/day and metformin 2000 mg/day, with a HbA1C of 7.4%. MRI revealed a pituitary macroadenoma with deviation of the pituitary stalk. Therefore, the diagnosis of acromegaly was assumed and the patient was started on bromocriptine 10 mg/day. Insulin was suspended and gliclazide increased to 90 mg/day. In the following months, he noticed a great improvement in glycemic control, leading to self-suspension of gliclazide. Six months after, metformin had been reduced to 1000 mg/day, with a HbA1c of 6.1% and a marked decrease in IGF-1 values (279 ng/ml), with normalization of prolactin levels. One year after diagnosis the patient is still kept on bromocriptine 10 mg/day and metformin 1000 mg/day, with HbA1c of 5.7%, and with a positive genetic study for MODY 3. Considering the favorable evolution, surgical treatment was postponed.

Conclusion

It is a rare case of association of MODY 3 and acromegaly. Bromocriptine therapy allowed a clear improvement of tumor secretion and glycemic control, highlighting the role of insulin resistance in the presented case.

AEP552

A complex case of refractory hypercalcaemia, end-stage diabetic nephropathy with pituitary mass and hypopituitarism– is there a unifying diagnosis?

David Fennell[1], John A Holland[2], Laura Corkery[2], Stephen Ludgate[1] & Siobhan McQuaid[1,3]

[1]The Mater Misericordiae University Hospital, Department of Diabetes and Endocrinology, Dublin, Ireland; [2]The Mater Misericordiae University Hospital, Department of Nephrology, Dublin, Ireland; [3]University College Dublin, School of Medicine, Dublin, Ireland

A 54-year-old female presented with one week of weakness, fatigue, headache, worsening constipation, and general malaise. Background history included long-standing type 1 diabetes (glutamic acid decarboxylase positive), on continuous subcutaneous insulin infusion, proliferative diabetic retinopathy, end-stage diabetic nephropathy on haemodialysis and subclinical hypothyroidism. Tertiary hyperparathyroidism was diagnosed (adjusted calcium 2.82 mmol/l, phosphate 1.42 mmol/l, parathyroid hormone 62.6 pmol/l (RR 1.6–6.9)). Calcium level had been controlled prior to admission on Cinacalcet 90 mg and alfacalcidol 0.5micrograms daily. The patient deteriorated, becoming progressively drowsy with frequent hypoglycaemia, despite insulin downtitration. Calcium levels further increased. Etelcalcetide, pamidronate and denosumab were all implemented as treatment. However, worsening hypercalcaemia (corrected Calcium 3.78 mmol/l, ionised calcium 1.91 mmol/l) warranted transfer to the Intensive Care Unit for continuous veno-venous haemodialysis. Computed tomography of brain, thorax, abdomen and pelvis identified no cause for hypercalcaemia. Following positive parathyroid imaging, a three-gland parathyroidectomy with implantation of the 4th gland was undertaken on day 34 of admission for refractory hypercalcaemia. Histology was consistent with parathyroid hyperplasia. Postoperatively, episodes of fluctuating cognition, ongoing headaches, nausea, hypotension, and hypoglycaemia prompted Magnetic Resonance Imaging (MRI) of the brain (Gadolinium contrast contraindicated due to end-stage kidney disease). This revealed an enlarged pituitary gland extending into the suprasellar space, with thickening of the pituitary stalk, new from MRI two years prior. Visual field testing did not reveal hemianopia. Hypopituitarism was subsequently diagnosed: cortisol 32 nmol/l, adrenocorticotropic hormone 17 ng/l, TSH 0.02 miu/l, free T4 10.7 pmol/l on L-thyroxine 50 micrograms, estradiol <92 pmol/l, follicle stimulating hormone 1.8 IU/l, luteinizing hormone <0.5 IU/l. Intravenous hydrocortisone resulted in symptom resolution within days. Positron emission tomography showed no abnormal tracer uptake in the pituitary gland or elsewhere. IgG4 level was normal at 0.344 g/l. Cerebrospinal fluid and serum angiotensin converting enzyme levels were raised at 3.6 U/l (0.5–2) and 79 U/l (8–65) respectively. Quantiferon study was indeterminate. Following multidisciplinary conference discussion, surgery was felt not to be indicated. Pituitary biopsy was not undertaken. MRI eight months later showed pituitary gland normalisation. Adrenal insufficiency (AI) remains. This case highlights the importance of maintaining a high index of suspicion for unusual diagnoses when met with puzzling clinical scenarios. While limited by lack of contrast-enhanced MRI and absence of tissue diagnosis, we believe that the pituitary mass, hypopituitarism and hypercalcaemia were related to the same disease process, likely a hypophysitis, given its resolution on follow-up imaging. AI symptoms are non-specific, and AI remains an important diagnostic consideration.

AEP553

A rare case of panhypopituitarism and diabetes insipidus secondary to sarcoidosis

Ciara Kilcoyne & Mensud Hatunic

The Mater Misericordiae University Hospital, Endocrinology Department, Dublin, Ireland

Introduction

Sarcoidosis is a multisystem disorder, characterised by the presence of non-caseating granulomas. 5–13% of cases involve the nervous system. Neurosarcoidosis carries a poor prognosis and can lead to an infiltrative process in the hypothalamo-hypophyseal region, resulting in panhypopituitarism and central diabetes insipidus (DI). These are rare but serious complications of neurosarcoidosis.

Case

A 26-year-old female with no past medical history was found unresponsive at home. While being transported to hospital in an ambulance she suffered a cardiac arrest. She was treated with two minutes of CPR and one shock for ventricular fibrillation. On arrival to the emergency department she was intubated, ventilated and admitted to ICU. Initial biochemical evaluation revealed deranged electrolytes: potassium 2.4 mmol/l, sodium 124 mmol/l and magnesium 0.68 mmol/l. ECG was abnormal with a prolonged QTc of 535ms. A collateral history revealed amenorrhoea, weight-loss and fatigue over the preceding 6 months. Pituitary hormonal evaluation prior to treatment was consistent with panhypopituitarism: thyroid-stimulating hormone: 0.29 miu/l, free-thyroxine: 9.8 pmol/l, ACTH: <2 n g/l, IGF1: 34 mg/l, oestrodiol: <92 pmol/l, FSH: <0.5 iu/l, with an inappropriately normal cortisol (331 nmol/l) for the concurrent illness. Following admission she developed polyuria of 10 litres/24-hours and repeat biochemistry testing revealed a fast rise in sodium to 141 mmol/l. DI was diagnosed based on evidence of significant polyuria, rapidly rising sodium and clinical improvement with a combination of frequent subcutaneous and oral desmopressin with IV hydrocortisone. Initial CT imaging revealed diffuse infiltrations in the liver and spleen. Liver biopsy confirmed non-necrotising granulomatous inflammation. Lumbar puncture showed elevated protein of 716 mg/dl. MRI-brain demonstrated thickening of the meninges, particularly enhancement of the pachymeninges around the skull base and pituitary infundibulum, in keeping with neurosarcoidosis. MRI-cardiac revealed increased intensity in the myocardium, consistent with sarcoidosis. CT-PET confirmed active sarcoidosis in the liver and spleen. Following a diagnosis of multisystem-sarcoidosis with panhypopituitarism and central-DI, treatment was initiated with intravenous corticosteroids, hormonal supplementation (desmopressin, levothyroxine) and immunosuppression (methotrexate, infliximab). An ICD was inserted for the prevention of sudden cardiac death. Over the following weeks she demonstrated a positive response to treatment with improved energy levels, normalization of electrolyte and hormone levels and resolution of polyuria.

Conclusion

Panhypopituitarism and central DI secondary to neurosarcoidosis is a rare clinical manifestation that should be considered in patients presenting with symptoms of neuroendocrine dysfunction. Immediate treatment with desmopressin, corticosteroids, thyroxine and immunosuppressants can prevent rapid decline and loss-of-life.

Assessment of a developmental neurotoxicity test using Ki-67 in ReNcell CX cells

Kang Min Kim, Seon Myeong Go, Sunhwa Jeong, Jimin Lee & Eui Bae Jeung

Chungbuk National University, Cheongju, Korea, Republic of South

Ki-67 can be solely detected within the cell nucleus, whereas in mitosis, most of the Ki-67 proteins are located on the chromosome surface. Ki-67 is present during all phases of the cell cycle (G1, S, G2, and M), but BrdU

is only present in the S phase. This study examined whether it is possible to establish a developmental neurotoxicity test in human neural progenitor cells using Ki-67 instead of BrdU (5-bromo-2'-deoxyuridine). In the present study, Ki-67-expressed ReNcell CX cells, a human neural progenitor cell line, were evaluated as a marker of proliferation in neurotoxicity, compared to propidium iodide (PI) and BrdU. ReNcell CX cells were treated with developmental neurotoxic chemicals (aphidicolin, hydroxyurea, cytosine arabinoside, 5-fluorouracil, and ochratoxin A) or non-neurotoxic chemicals (sodium gluconate, sodium bicarbonate, penicillin G, and saccharin). The PI-positive cell numbers were increased in neurotoxic chemicals (10^{-4} and 10^{-5} M), and non-neurotoxic chemicals (1 and 10^{-2} M) compared to the control, whereas the number of BrdU-positive cells decreased when exposed to the neurotoxic chemicals (10^{-4} and 10^{-6} M) and non-neurotoxic chemicals (1 and 10^{-2} M). Furthermore, the number of Ki-67-positive cells decreased when exposed to high doses of neurotoxic chemicals (10^{-4} and 10^{-6} M) compared to non-toxic chemicals (1 and 10^{-2} M). On the other hand, the number of Ki-67-positive cells decreased when exposed to non-neurotoxic chemicals at high doses (1 and 10^{-2} M). Furthermore, there was no difference in the results of BrdU and Ki-67, suggesting that Ki-67 could be used as a proliferation marker instead of BrdU in ReNcell CX cells

Keyword: Ki-67, ReNcell CX, PI, BrdU.

Abberant expression pattern of circadian clock genes in Type 1 gastric neuroendocrine neoplasms compared to ECL hyperplasia

Angeliki Karapanagioti[1,2], Kosmas Daskalakis[3], Narjes Nasiri-Ansari[2], Erasmia Vlachou[4], Georgios Kyriakopoulos[5], Evanthia Kassi[1,2], & Gregory Kaltsas[1]

[1]Medical School, National and Kapodistrian University of Athens, 1st Department of Propaupeudic Internal Medicine, Athens, Greece; [2]Medical School, National and Kapodistrian University of Athens, Department of Biological Chemistry, Athens, Greece; [3]Örebro University, Department of Surgery, Faculty of Medicine and Health, Sweden; [4]NIMITS Medical Institution Military Shareholder Fund, Department of Gastroenterology, Athina, Greece; [5]Evaggelismos, Department of Pathology, Athina, Greece

Purpose

There is a continuity of changes ranging from enterochromaffinlike (ECL) cell hyperplasia to type 1 gastric neuroendocrine neoplasms (GNEN1) with important clinical implications. Although the effect of the circadian clock system on tumorigenesis has been addressed, the role of the peripheral clock system in the transition from ECL-cell hyperplasia to GNEN1 remains to be explored.

Methods

Six patients diagnosed with GNEN1 and 10 patients with ECL-cell hyperplasia were included. Blood samples were collected at 0800 h, 1500 h and 2000 h for peripheral blood mononuclear cells (PBMCs) isolation. The mRNA expression of Clock-related genes (CLOCK, BMAL1, CRY-1, PER-2 ROR-α and REV-ERBbeta) were evaluated by real-time quantitative PCR from PBMCs.

Results

In patients with GNEN1, BMAL genes where lower expressed at night than early in the morning *(P* = 0.02), whereas patients with ECL-cell hyperplasia expressed lower transcript levels of PER2 and REV-ERB beta at these time points *(P* = 0.03, *P* = 0.05, respectively). In addition, patients with GNEN1 expressed lower transcript levels of CLOCK, PER2 and REV-ERB beta in the early evening than in the morning *(P* = 0.04; *P* = 0.03; *P* = 0.05, respectively). When comparing the two groups (GNEN1 vs ECL-cell hyperplasia) at the three different time points, we confirmed a marginal increase in CLOCK, PER2 and REV-ERB beta expression early in the morning *(P* = 0.06, 0.02 and 0.07, respectively); a marginal increase in REV-ERB beta expression in the early evening *(P* = 0.09) and a marginal increase in BMAL at night *(P* = 0.09) in patients with GNEN1.

Conclucions

Our findings point towards an uregulated expression of Clock-related genes in patients with GNEN1 as compared to EC-cellL hyperplasia, suggesting a possible involvement in GNEN1 tumorigenesis.

Value of cross- sectional area of the median nerve in acromegalic patients

Ivana Ságová[1], Dušan Pavai[1], Daniela Kantárová[2], Dana Holovárňová[3], Milan Dragula[2], Juraj Payer[4] & Peter Vaňuga[1]

[1]National institute of Endocrinology and Diabetology, ľubochňa, Slovakia, Department of endocrinology, ľubochňa, Slovakia; [2]Comenius University Jessenius Faculty of Medicine, 1st Department of Internal Medicine, University Hospital Martin, Martin, Slovakia, Martin, Slovakia; [3]Comenius University Faculty of Medicine, 1th Department of Internal Medicine, University Hospital Bratislava, Bratislava, Slovakia, Bratislava, Slovakia; [4]Comenius University Faculty of Medicine, 5th Department of Internal Medicine, University Hospital Bratislava, Bratislava, Slovakia, Bratislava, Slovakia;

Introduction

Median nerve neuropathy is commonly associated with acromegaly.

Objective

This study aims to investigate ultrasound examination of median nerve in acromegalic patients and assess the relationship with activity and duration of disease.

Patients and methods

We prospectively examined the cross sectional area (CSA) of median nerve with high-resolution ultrasound in 107 acromegalic patients (70 females and 37 males) and in 77 healthy controls (51 females and 26 males) matched for age, gender. The t-student tests and Pearson correlation were used for data analysis.

Results

The cross sectional area of median nerve was increased in acromegalic patients compared with controls (11.9 ± 0.5 mm^2 vs 7.8 ± 0.3 mm^2, $P < 0.001$). The average level of IGF-1 in acromegaly patients was ø 249,9ng/ml and for GH was ø 2,63 ng/ml. Positive correlation between was found the levels of IGF-1 and CSA in whole study group ($R = 0.400$, $P < 0.001$) and female population ($R = 0.466$, $P < 0.001$). In male population our results did not reach statistical significace ($P = 0.07$). Relationship between CSA and duration of acromegaly in both genders was not confirmed.

Conclusion

In our study we confirmed the enlargement of the median nerve in acromegaly patients. This enlargement is proportional to the degree of IGF-1 levels and is not dependent on the duration of the disease and age of patients.

Keywords: acromegaly, carpal tunnel syndrome, cross sectional area, median nerve.

Response to treatment with temozolomide in cases with invasive pituitary macroadenomas: A single-center experience

Ogun Bilen, Hunkar Aggul, Gulsah Elbuken & Sayid Zuhur

Tekirdag Namik Kemal University, Endocrinology and Metabolism, Turkey

Introductıon

Recent studies suggest temozolomide as an effective treatment modality in invasive pituitary adenomas that did not respond to conventional treatments. In this case series, we present three cases of invasive pituitary adenomas that did not respond to conventional medical treatments and radiotherapy and were subsequently treated with temozolomide.

Cases

The first patient had an invasive prolactinoma that did not respond to the maximum doses of cabergoline, the patient underwent trans-frontal surgery and conventional radiotherapy. On immunohistochemical staining, methylguanine DNA methyltransferase (MGMT) was negative. The treatment with temozolomide 150 mg/m^2 for five days every 28 days was started. Three and 20 months later, a significant decrease in prolactin level and a 50 and 95% decrease in tumor size were observed, respectively, and remained unchanged after five years of treatment. The second patient with acromegaly that could not be controlled by 2 transsphenoidal surgeries, conventional radiotherapy, and 40 mg octreotide LAR. Treatment with 150 mg/m^2 of temozolomide for five days every 28 days was started. However, despite a small decrease in serum IGF-1 and GH levels, a reduction in tumor size did not ensue. The third patient had a non-functioning pituitary adenoma and underwent 2 transsphenoidal and one transcranial surgery and subsequent gamma knife radiosurgery, she developed 3. and 6. cranial nerve palsies, so temozolomide treatment was started at a dose of 150 mg/m^2 for five days every 28 days. However, temozolomide treatment was

discontinued due to the absence of response after 3 months. Nevertheless, MGMT immunostaining was not performed in both cases.

Dıscussıon

Studies suggest temozolomide treatment as an effective treatment modality in invasive pituitary adenomas non-responsive to currently available conventional treatments. However, most of the information regarding the effect of temozolomide in invasive non-functional adenomas and GH secreting adenomas are sparse. Low tumoral expression of MGMT was suggested as a sign of favorable response to temozolomide. Although most GH-secreting adenomas are reported to express low levels of MGMT, our patients with acromegaly did not respond to temozolomide treatment. On the other hand, the patient with non-functioning pituitary adenoma did not respond to temozolomide as well. Therefore, temozolomide treatment may not be effective in cases with acromegaly and non-functioning invasive pituitary adenomas.

Patient	Age/ Gender	Diagnosis	Tumor size (mm)	Temozolomide treatment duration (months)	Response
1	38/M	prolaktinoma	58 × 47	18	complete
2	44/F	acromegaly	85 × 45	6	none
3	50/F	null-cell adenoma	50 × 28	3	none

Hypopituitarism secondary to a pituitary metastasis as a first manifestation of an invasive nasopharyngeal carcinoma

Hiba-Allah Chatti[1], Ibtissem Oueslati[1], Aymen Azaiez[2], Meriem Yazidi[1], Fatma Chaker[1], Gazi Besbes[2] & Melika Chihaoui[1]

[1]La Rabta hospital, university of Tunis El Manar, Faculty of medicine, Endocrinology, Tunis, Tunisia; [2]La Rabta hospital, university of Tunis El Manar, Faculty of medicine, Ear-Nose and Throa, Tunis, Tunisia

Introduction

Nasopharyngeal carcinoma is characterized by distinct geographical distribution and is particularly prevalent in East and Southeast Asia. Environmental factors, genetic structure, and Epstein Barr virus infection are involved in the etiology of the disease. While nasal and otological symptoms are the most common (80%), intracranial extension is prevalent among 8% of cases and pituitary localization is rarely described in the literature. We report the rare case of a patient in whom the diagnosis of nasopharyngeal carcinoma was mislead by its pituitary extension.

Observation

A 50-year-old woman was referred to our department for pituitary macroadenoma. Her past medical history was unremarkable. She presented with headache, visual disorders, weakness, nausea, vomiting, and increased episodes of hypoglycemia. No polyuria was reported. Pituitary MRI showed a large mass extending from the sella turcica to the sphenoid sinus, optic chiasm, and nasopharynx. The first diagnosis was an extending pituitary macroadenoma. On physical examination, she had a body weight of 51 kg, a body mass index of 21.7 kg/m^2, a blood pressure of 100/60 mmHg, a regular pulse of 80 beats/mn. Biological investigations revealed corticotrope deficiency, secondary hypothyroidism, hypogonadotropic hypogonadism, and hyperprolactinemia (31 ng/ml). The patient was put on hormone replacement therapy. After corticosteroid treatment initiation, a diabetes insipidus was revealed. The second MRI showed a nasopharynx infiltration. Endoscopic biopsy confirmed the diagnosis of undifferentiated nasopharyngeal carcinoma (NPC) with intracranial extension. The patient was referred to oncology department for chemo and radiotherapy.

Conclusion

Although pituitary metastasis is a rare condition, it should be a part of the differential diagnosis of pituitary macroadenoma with hypopituitarism. The management of this case necessitates a multidisciplinary approach.

A rare case of panhypopituitarism secondary to neurosarcoidosis initially treated as sepsis of unknown origin

Mehreen Anwar, Eman Abdulla & Vinod Joseph

Kings Mill Hospital , Diabetes and Endocrine , Nottinghamshire, United Kingdom

Sarcoidosis is a very rare inflammatory disease and UK prevalence was 8% between 2008 to 2012 of which only 15 % developed neurosarcoidosis. Our patient is a 83 year old gentleman who presented with symptoms of lethargy,low blood pressure and confusion over 2 weeks . He had multiple comorbidities including heart failure , chronic kidney disease ,permanent pacemaker , hypertension. His bloods showed normocytic anaemia and raised inflammatory markers , with eosinophilia and he was started on broad spectrum antibiotic but his condition continued to deteriorate . There was no evidence of infection. He had mild postural hypotension probably due to his comorbidities. His free thyroxine was low with inappropriately low normal TSH. He was commenced on thyroxine and his conscious levels dropped. Therefore cortisol level were checked, which were low therefore followed by full pituitary profile , and short synacthen test . Pituitary profile revealed low FSH , LH , IGF-1, testosterone in keeping with panhypopituitarism.Results of short synacthen test were inadequate suggesting a central cause. He also had CT scan of brain which was unremarkable. He later had CT pituitary as MRI was not compatible due to pacemaker but no significant abnormality was found . His autoimmune screen for vasculitis showed weakly positive p-ANCA. He was reviewed by neurology team and lumbar puncture was done which did not show any CNS infection but raised CSF-protein and CSF-ACE level . He also had high normal serum ACE level , raised calcium and peripheral eosinophilia . He was started on intravenous hydrocortisone 100 mg QDS and patient's conscious level and general condition improved remarkably. His hydrocortisone was changed to oral prednisolone 30 mg daily and confusion settled and mobility improved slowly over the next 2 weeks. The steroids were slowly weaned down to maintenance dose of 5 mg. The low dose levothyroxine was continued and he remains well on 5 mg prednisolone and 75 microgram of levothyroxine . Pan-hypopituitarism secondary to neurosarcoidosis is a rare manifestation and was considered in this patient but he was not suitable for tissue diagnosis due to comorbidities. We were unable to get MRI to see infiltration but clinical improvement with steroids and investigations-higher end of normal serum ACE levels ,raised CSF-ACE levels, eosinophilia and raised calcium are all in keeping with clinical diagnosis of neurosarcoidosis . Neurosarcoidosis can also present without pulmonary involvement and prompt diagnosis and treatment is life saving.

Treatment patterns, healthcare utilization and related costs of acromegaly in a real-world setting in finland

Ilona Iso-Mustajärvi[1], Anna Tuurinkoski[2], Juha Mehtälä[1], Tero Ylisaukko-oja[1], Merja Väkeväinen[2], Pia Jaatinen*[3],[4],[5], Camilla Schalin-Jantti*[6],[7]

[1]MedEngine Oy, Helsinki, Finland; [2]Pfizer Oy, Helsinki, Finland; [3]University of Tampere, Internal Medicine, Tampere, Finland; [4]Seinäjoki Central Hospital, Internal Medicine, Seinäjoki, Finland; [5]Tampere University Hospital, Internal Medicine, Tampere, Finland; [6]Helsinki University Hospital, Abdominal Center, Helsinki, Finland; [7]University of Helsinki, Endocrinology, Helsinki, Finland; & *These authors contributed equally to this work.

Introduction

Acromegaly is a chronic disease associated with multiple comorbidities and increased incidence of cancer and mortality. The diagnosis often takes several years after the onset of symptoms. The costs of acromegaly in Finland are not known. This study aimed to characterize the treatment patterns, healthcare resource utilization, and direct costs of acromegaly in Finland.

Methods

All adult (≥18 years of age) patients with first acromegaly (ICD-10: E22) diagnosis during 2010–2016 were identified from the electronic health records (EHR) of Helsinki and Tampere University Hospitals. The EHR data were complemented with data from the national Finnish patient registers. The study period was 2010–2019, which covered a two-year baseline period prior to, and a three-year follow-up period after the diagnosis of acromegaly.

Results

The cohort consisted of 63 newly diagnosed patients with acromegaly (37 male/26 female) with a mean age of 47.6 years. Altogether, 75% (30/40) of the patients with baseline information on tumor size, had a macroadenoma, and the median growth hormone (GH) and insulin-like growth factor-1 (IGF-1) values at diagnosis were 248% and 263% of the upper limit of normal (ULN), respectively. The most common comorbidities were hypertension (37%), sleep apnea (24%) and arthropathy (19%). The participants had on an average nine follow-up healthcare visits annually (range 1–21), approximately 2.8 months apart. Transsphenoidal surgery was the most common first-line treatment (75%). First-line pharmacotherapies were somatostatin analogues

(12% as monotherapy, 3% in combination with surgery), and dopamine agonists (7% as monotherapy, 2% with surgery). IGF-1, GH, and prolactin levels decreased gradually after the treatment initiation. Of the patients with a minimum 12 months of follow-up, 48% (24/50) reached a GH level <2,5 µg/l after 6 months of treatment initiation. The mean total annual cost was 10,500ń of which 69% (7,200ń) were related to healthcare resource utilization and 31% (3,300ń) to pharmacotherapy. The healthcare resource utilization cost was highest during the first year after the diagnosis (12,500ń), while annual pharmacotherapy costs increased gradually after the diagnosis.
Conclusions
The baseline patient demographics are in line with previous data from France and Sweden. In Finland, a vast majority of patients undergo surgery as first-line treatment. Approximately two-thirds of the total costs were related to healthcare resource utilization and one-third to pharmacotherapy.

AEP561

A growth retardation revealing a pituitary stalk interruption syndrome: A case report

Rihab Laamouri, Ghachem Aycha, Imen Rojbi, Chayma Besrour, Youssef Lakhoua, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Charles Nicole Hospital, Endocrinology Department, Tunisia

Introduction
Pituitary stalk interruption syndrome is an entity radiologically defined by the association of an absent or thin pituitary stalk, an ectopic posterior lobe and a hypoplasia or aplasia anterior lobe. It can manifest as a several of hormonal deficiencies. The circumstances of discovery are multiple. This case illustrates a pituitary stalk interruption syndrome revealed by a growth retardation.
Case presentation
An 11-year-old child consulted for a growth retardation. The diagnosis of complete growth hormone deficiency was retained. He was put on somatropin until the age of 18. The patient did not present a polyuria polydipsia syndrom. The examination found a height of 1 m 63 between –3 and –2 standard deviations, with a target height of 1 m 71. The external sexual organs were infantile masculine type, the penis was 6 cm, and testicles were lower size 2cm with a Tanner stage G1P2A1. His bone age was 13 years and 6 months with a chronological age of 19 years. Hormonal exploration showed a normal thyroid hormone assesment, intermediary cortisol level 240 mmol/l. He benefited from an insulin hypoglycemia test showing a cortisol peak at 394 nmol/l confirming corticosteroid insufficiency. Exploration of the gonadotropic axis showed low testosteronemia at 0.09 ng/ml (N: 0.5–5), normal FSH and LH levels at 2.32 and 0.72 miu/l respectively confirming a gonadotropic insufficiency. The patient was treated with hydrocortisone at a dose of 10 mg daily. Induction of puberty was initiated by testosterone enanthate at a dose of 62.5 mg in one monthly injection and then gradually increasing the dose to 250 mg per month. The evolution was marked by a clear improvement with a Tanner stage G2P3A3.
Conclusion
Pituitary stalk interruption syndrome is one of the etiologies of hypopituitarism. It is a congenital and progressive pathology. The earlier the diagnosis is made, the better the prognosis, especially in terms of growth, which has a significant psychological impact. Hence the importance of early diagnosis of this entity as well as regular monitoring of the pituitary gland assessment in order to treat any deficiency in time.

AEP562

Cognitive impairment, obesity, and hypopituitarism - several entities or one syndrome?

Juliana Marques-Sá & Maria Joana Santos
Hospital de Braga, Endocrinology Department, Braga, Portugal

Introduction
Prader-Willi syndrome (PWS) is a multisystemic genetic disorder caused by lack of expression of genes on the paternally inherited chromosome 15q11.2-q13 region. Despite PWS present manifestations from birth, affected individuals can remain undiagnosed until adulthood.
Clinical case
Woman, 40 years old, with cognitive impairment, referred to endocrinology due to morbid obesity (BMI 44.5 Kg/m^2). Despite being followed in a Nutrition consultation, she was unable to comply with the food plan, due to insatiable appetite and food voracity that was difficult to control. She had a previous diagnosis of hypothyroidism and was under levothyroxine (LT4) 100 µg id. She reported menarche after the age of 20 and oligomenorrhea. She also had occasional episodes of asthenia, lethargy, and hypothermia, with no defined etiology, especially when she had respiratory infections, in winter. A previous brain CT revealed an empty sella. On physical examination, she had short stature (1.51 m), characteristic facies (almond-shaped eyes, thin upper lip, lip inversion), small hands and centripetal obesity Analytically, she had TSH 1.24 (N 0.358–3.74) µUI/ml, free-T4 1.42 (N 0.76–1.46) ng/dl, under LT4, negative anti-TPO and anti-Tg antibodies, ACTH 23.0 pg/ml, morning cortisol 5.69 µg/dl, PRL 17.05 (N 2.8–26.0) ng/ml, IGF-1 52 (N 76–271) ng/ml), estradiol 215 pmol/l, LH 2.55 mUI/ml, FSH 3.02 mUI/ml and HbA1c 5.3%. Pituitary MRI showed a small pituitary gland. The diagnosis of hypopituitarism was established, and she started prednisolone 5 mg/day (in addition to LT4). After the introduction of the glucocorticoid, the patient did not have episodes of lethargy and hypothermia again and her general condition improved significantly. A genetic study was carried out by suspicion of PWS, which was confirmed. Along with a progressive weight gain, she developed type 2 Diabetes *mellitus*, being treated with Liraglutide 1.2 mg/day and metformin 850 mg BID, with good metabolic control.
Conclusion
SPW involves the hypothalamic-pituitary axis and is responsible for multiple endocrinopathies. The different syndrome components can appear progressively throughout life, delaying the diagnosis. In the presence of an obese patient, with food voracity since childhood and cognitive impairment, it is important to suspect of PWS and exclude the presence of hypopituitarism, to establish an appropriate therapeutic plan.

AEP563

Invasive Thyrotropin-secreting pituitary adenoma: A case report

Madhi Wiem, Manel Jemel, Wadiaa Said, Syrine Mereghni, Hiba Allah Chatti, Hajer Kandara & Ines Kammoun
National Institute of Nutrition, Endocrinology - Diabetology, Tunis, Tunisia

Introduction
Thyrotropin-secreting pituitary adenoma is a rare cause of hyperthyroidism which must be differentiated from other etiologies of inappropriate TSH secretion.
Observation:
We report the case of a 49 years old male patient with no particular pathological history, addressed for thyrotoxicosis (weight loss, irritability, thermophobia, dyspnea and palpitation) with no goiter or ophtalmopathy. Echocardiography showed dilated cardiomyopathy and pulmonary arterial hypertension. Hormonal testing revealed elevated TSH levels 27 and 69 mUI/l, associated with elevated FT4 level 29 pmol/l. Pituitary MRI showed intra and suprasellar expansive process, invading the base of the skull, measuring 46.7 × 67.9 × 50.5 mm with moderate hydrocephalus. Neurological examination revealed frontal syndrome and damage to the left nerve III. Exploration of the other pituitary axes concluded to central adrenal insufficiency and central hypogonadism with elevated GH levels; IGF1 and prolactin levels were not elevated. Surgical resection of adenoma was rejected by neurosurgeons due to its large size and operative risk. The evolution under hydrocortisone, treatment of heart failure including beta blocker, bromocriptin and somatostatin analogs was initially favorable with amelioration of hyperthyroidism symptoms and regression of behavioral disorder. However, control MRI revealed an increase in the volume of the adenoma 76 × 66 × 67 mm with significant loco regional invasion. Patient's evolution was marked by death secondary to cerebral herniation.
Conclusion
Invasive Thyrotropin-secreting pituitary adenomas are a therapeutic management problem. If pituitary surgery is contraindicated or declined, medical treatment reduces the symptoms of hyperthyroidism but tumor evolution is unpredictable.

Successful pregnancy in a female with a large prolactinoma after pituitary tumor apoplexy

Chtioui Sara, Asbar Hind, Rafi Sanaa, El Mghari Ghizlane & El Ansari Nawal
Mohammed VI University Hospital Center, Endocrinology, Diabetology and Metabolic Diseases Department , Marrakech, Morocco

Introduction
Pituitary apoplexy is a rare condition which may cause death of the patient in severe cases and many times leads to hypopituitarism. It results from haemorrhagic infarction of a pre-existing pituitary adenoma or within a physiologically enlarged gland .
Case report
Our patient is a 31-year-old female, with a history of macroprolactinoma for approximately 7 years . Who presented to our hospital with a history of severe headache, vomiting and visual disorders, she was pregnant in 24 weeks of amenorrhea. The magnetic resonance imaging (MRI) was compatible with apoplexy adenoma. The hormonal exploration finds a corticotropic and thyrotropic insufficiency and the prolactin level was 1048 ng/ml. After treatment with corticosteroid therapy, she underwent transsphenoidal excision of the pituitary adenoma .The condition of the patient improved within a few days. The patient had no further complaints during the pregnancy and at 38 weeks gestation delivered a healthy baby. And 3 months later, she became pregnant. An MRI without contrast was performed in 12 weeks of amenorrhea, which showed empty Sella syndrome. The decision was to discontinue cabergoline, and follow the patient regularly until delivery. A repeated MRI with contrast was performed after delivery which showed empty Sella syndrome.
Conclusion
This case shows an unusual course of a large prolactinoma following pituitary tumor apoplexy with resolution of the pituitary tumor. She had a successful pregnancy, and after delivery there was no regrowth of the pituitary adenoma.
Keywords : prolactinoma, apoplexy, pregnancy, empty sella syndrome.

AEP565

Recurrent hypoglycemia as an initial presentation of Isolated ACTH deficiency

Uzair Akbar Ali[1], Elsadig Abdelnour[2] & Praful Ghyar[1]
[1]University Hospital Waterford, Medicine, Waterford, Ireland; [2]University Hospital Waterford, Waterford, Ireland

Introduction:
Adrenocorticotropic hormone (ACTH) deficiency can occur either due to decreased or absent production of the hormone by the pituitary gland. A decline in the production of ACTH can result in adrenal insufficiency. The exact etiology of ACTH deficiency is unknown. A defect in the hypothalamus or pituitary gland may be the cause. This can also be congenital involving mutations of the TBX19 gene (also referred to as TPIT) on the long arm of chromosome one (1q23-q24) and the corticotropin releasing hormone (CRH) gene on the long arm of chromosome eight (8q13). The inheritance pattern is thought to be autosomal recessive.
Case report
The case report discusses the presentation of 66-year old lady with generalized weakness, blurred vision and diaphoresis. She presented twice to the emergency department with almost same symptoms or complaints. At first presentation, her hypoglycemic event was treated and considered as secondary to her poor oral intake. She was admitted on her second presentation and continued to have recurrent hypoglycemia during her hospital stay requiring emergency management. Her serum cortisol and ACTH levels were significantly low, but other pituitary hormone levels were within normal range. Short synacthen test showed adequate adrenal response, however; long synacthen test was inconclusive. Computed tomography (CT) of the adrenal glands was normal.
Treatment/Outcome
She recovered symptomatically with hormone replacement therapy with cortisol initially through intravenous route and later orally. She was advised follow-up with out-patient magnetic resonance imaging of pituitary gland and possible genetic testing.
Conclusion:
Isolated ACTH deficiency presents with general symptoms that sometimes delay the diagnosis or it is missed entirely. Early consideration of this entity is anticipated to facilitate making an early diagnosis.

Functioning gonadotroph adenoma accompanied by erythrocytosis in an elderly man

Elizaveta Mamedova[1], Svetlana Buryakina[2], Liliya Selivanova[3], Vilen Azizyan[4], Andrey Grigoriev[4] & Zhanna Belaya[1]
[1]Endocrinology Research Center, Neuroendocrinology and Bone Diseases, Moscow, Russian Federation; [2]Endocrinology Research Center, Radiology, Moscow, Russian Federation; [3]Endocrinology Research Center, Fundamental pathomorphology, Moscow, Russian Federation; [4]Endocrinology Research Center, Neurosurgery, Moscow, Russian Federation

Introduction
Clinically functioning gonadotroph adenomas (FGA) are rare, especially in men. We present a case of a LH/FSH-secreting functioning gonadotroph macroadenoma in an elderly patient, which manifested with visual impairment and was accompanied by secondary erythrocytosis.
Clinical case
A 62-y.o. male was admitted to our hospital with a 9-month history of visual impairment and a 5-year history of plethora of the face, neck and upper half of the trunk. Before admission, brain MRI was performed and revealed a pituitary macroadenoma. At admission, MRI confirmed a 40 × 41 × 33 mm pituitary macroadenoma with supra-infra-retro-para (D, S) extension (Knosp IV). Hormonal evaluation revealed secondary hypothyroidism (TSH 0.795 IU/l (0.25–3.5), fT4 6.95 pmol/l (9–19)), normal IGF-1 104.6 ng/ml (16–245) and late-night salivary cortisol 5.11 nmol/l (0.5–9.65). There were high FSH 22.5 IU/l (1.6–9.7) and high-normal LH 10.3 IU/l (2.5–11) and testosterone 28 nmol/l (11–28.2), which allowed us to suspect a FGA. Moreover, there were elevated hemoglobin 196 g/l (132–172), hematocrit 56.7% (40–51) and red-cell count 6.660.000 per mm^3 (4.300.000–5.800.000), which was consistent with secondary erythrocytosis due to testosterone excess. On ophthalmological examination bitemporal hemianopsia was found. The patient underwent transnasal transsphenoidal surgery. Before surgery, three procedures of blood exfusion were performed to minimize perioperative risks. Immediately after surgery, there was a rapid decline in FSH 4.19 IU/l, LH 0.513 IU/l and testosterone 0.62 nmol/l. However, secondary hypothyroidism persisted (TSH 0.088, fT4 5.78) and secondary adrenal insufficiency manifested (morning serum cortisol 175.6 nmol/l (171–536)), which required replacement with levothyroxine and hydrocortisone. Transient hyponatremia was also noted. The levels of hemoglobin (152 g/l), hematocrit (44.9%) and red-cell count (5.150.000 per mm^3) returned to normal. Immunohistochemical examination of the tumor showed positive FSH expression in 30% of cells and positive LH expression in 80% of cells. Ki-67 index was 3%.
Conclusion
This is a rare case of FGA with predominant LH expression leading to hyperandrogenism and secondary erythrocytosis in an elderly patient. As in the majority of the described cases this case manifested with visual impairment, though signs of erythrocytosis had manifested long before. Though drug-associated secondary erythrocytosis due to testosterone overdose is well studied, the possibility of endogenous testosterone overproduction in patients with erythrocytosis should also be considered.

AEP567

Lymphocytic auto immune hypophysitis : A case report

Rihab Laamouri, Imen Rojbi, Chayma Besrour, Elyes Kamoun, Youssef Lakhoua, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Charles Nicolle Hospital, Endocrinology Department , Tunisia

Introduction
Lymphocytic hypophysitis is an autoimmune inflammatory pathology of the pituitary gland responsible for partial or global hypopituitarism. In this context, we report a clinical case illustrating this entity.

Clinical case
A 31-year-old woman with a family history of hypothyroidism and a personal history of vitiligo was seen in the 8th month of pregnancy for headaches that have progressed rapidly in 4 weeks. She reported visual blurring, without asthenia nor polyuropolydipsic syndrome. Ophthalmologic examination showed normal fundus and bitemporal amputation of the visual field. The hormonal balance showed a thyrotropic insufficiency with a low TSH at 0.25 mui/l and a low ft4 at 10.2 pmol/l, an intact corticotropic axis, and normal baseline GH and IGF1 levels. The pituitary MRI showed symmetrical pituitary hypertrophy heterogeneous and hypersignal in T2 ponderation, and isosignal in T1, compressing the optic chiasma, the posterior pituitary lobe was in place with spontaneous hypersignal in T1 ponderation. Therapeutically, the patient received oral corticosteroid therapy at a dose of 0.5 mg/kg/day over a period of one month in the peri-partum followed by gradual decline over one month. The evolution was marked by the regression of the headaches. A cesarean delivery was decided because of the risk of intracranial hypertension. Pituitary imaging was practiced two months after childbirth, showing a marked decrease in pituitary volume at the expense of the suprasellar region with relief of compression on the optic chiasma. The patient underwent a hormonal reassessment thus eliminating iatrogenic corticotropic insufficiency after stopping corticosteroid therapy. She was treated with L-thyroxine replacement therapy in front of a deficient thyreotropic axis. Four months later the patient developed weight loss with orthostatic hypotension. Pituitary assessment showed corticotropic insufficiency and control imaging showed a decrease in pituitary size with an upper edge concave upwards. She was then put on hydrocortisone at a dose of 15 mg per day with a good clinical outcome.
Conclusion
Lymphocytic hypophysitis is a rare entity whose best known mechanism is an immune disorder. The presence of a history of autoimmune diseases, the female sex and the pregnant state are strongly suggestive of this etiology. The median and symmetrical nature of the pituitary hypertrophy on imaging is also ecovative of this diagnosis. This is an evolving pathology, so the deficit of the pituitary axes may appear later, hence the benefit of a regular clinical and biological monitoring of the pituitary axis.

Managing pituitary disease during COVID-19 pandemic: A case report

Roxana Dumitriu[1,2], Iulia Florentina Burcea[1,2], Roxana Dusceac[1,2], & Catalina Poiana[1,2]
[1]C. I. Parhon National Institute of Endocrinology, Department of Pituitary and Neuroendocrine Disorders, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Introduction
The COVID-19 pandemic has significantly affected health systems all over the world, putting on a hold medical care and delaying surgical interventions. Patients with pituitary tumors, especially those who associate hormonal hypersecretion or defficiency and mass effects represent a management challenge even in a non-pandemic time.
Case description
A 41 years old, non-smoker, overweight, male patient was admitted in our clinic for bitemporal hemianopsia, diplopia, diziness and erectile dysfunction, symptoms that had started six months prior. The patient did not associate other comorbidities. The magnetic resonance examination of the pituitary showed a large mass of 30.9/40.5/29.4 mm, with sellar and parasellar extension, invasion of the left cavernous sinus and compression the optic chiasm. Preoperatively, the hormonal profile revealed hypogonadotroph hypogonadism and no other hormonal deficiencies. We reccommended neurosurgical resection of the tumor, but during the hospitalization in our clinic he was diagnosed with SARS-CoV-2 infection which delayed the surgical intervention. The patient showed minimal COVID-19 symptoms, no lung damage and was referred to a COVID-19 support center, where he received symptomatic treatment and remained until the RT-PCR assay for SARS-CoV-2 was negative. Transsphenoidal surgery was performed, with favorable post-operative evolution and no complications. The histopathological exam established the diagnosis of pituitary non-functioning macroadenoma. Our patient underwent transsphenoidal intervention 9 days after he was discharged from de COVID-19 supportive center and was negative for SARS-CoV-2 (17 days after diagnosis). The post-operative pituitary MRI showed a tumor remnant of 19/33/25 mm. The hormonal evaluation showed persistence of gonadotroph pituitary insufficiency, with no other hormonal abmormalities and with visual field improvement. We started substitutive therapy with testosterone undecanoate, 1000 mg i.m. every 3 months, with good clinical response.
Conclusion
So far, there is no consensus on the management of the pituitary patients which associate COVID-19, only recommendations for several emergencies, including pituitary apoplexy and adrenal crisis. Endonasal pituitary surgery for SARS-CoV-2 positive patients is considered a high risk intervention and it must be postponed, except for major emergencies. The evolution of our patient was positive, without significant impact on disease progression of the delayed intervention.

Craniopharyngioma presenting with amenorrhea and a polyuric polydipsic syndrome

Chayma Besrour, Imen Rojbi, Elyes Kamoun, Rihab Laamouri, Youssef Lakhoua, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Hospital Charles Nicolle, Endocrinology-Diabetology, Tunis, Tunisia

Introduction
Craniopharyngioma is a rare type of benign brain neoplasm , arising from the pituitary stalk or gland and found most commonly in children . The clinical presentation is variable and may include endocrine or ophtalmogical disorders, intracranial hypertension syndrome and other neurological symptoms.
Observation
We report the case of a 16 year-old girl with a normal staturo-ponderal development and no medical history , who consulted for a nine months secondary amenorrhea associated to a polyuric polydipsic syndrome (volume of urines > 5L/day and urine density 1005), with no other symptoms . The biology showed an hypotonic urine and an hypogonadotropic hypogonadism ; low gonadotropin levels (FSH at 3.7 mU/ml , LH at 1.51 mU/ml) associated to oestradiol deficiency at 12.51 pg/ml . We completed the evaluation of the hypophyseal function and found a corticotropic and a thyrotropic insufficiency . In front of this hypopituitarism , a pituitary MRI was performed , revealing an heterogeneous tumor in the sella and supra sellar space , measuring 18 × 16 × 12 mm in diameter , with disappearance of the posterior pituitary signal .Taking in consideration the young age of the patient, the diagnosis of a pituitary macroadenoma is unlikely , and the cerebral CT-scan showed multiple calcifications in the periphery of the pituitary mass in favor of the diagnosis of craniopharyngioma . The clinical presentation of the tumor was in this case the association of secondary amenorrhea to a diabetes insipidus. The procedure to follow was to put the patient under hydrocortisone, levothyroxine and desmopressin treatement and preparing her for an endonasal transsphenoidal resection of the pituitary tumor .
Conclusion
Even though it is a benign tumor , craniopharyngioma is a serious pathology with severe repercussions if not early diagnosed and treated , and post surgical surveillance is a must, to detect any recurrence which is frequent .

Flow medicated dilation is associated with matrix metalloproteinase-2 in healthy postmenopausal women

Eleni Armeni[1], Georgios Georgiopoulos[2], Dimitrios Delialis[2], Areti Augoulea[1], Stavroula Paschou[1], Nikoletta Mili[1], Asimina Chondrou[1], Efthymios Kouerinis[1], Panagiota Chatzivasileiou[3], Georgios Kaparos[3], Makarios Eleftheriadis[1], Kimon Stamatelopoulos[2] & Irene Lambrinoudaki[1]
[1]Second Department of Obstetrics and Gynecology, Aretaieio Hospital, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece; [2]Vascular Laboratory, Department of Clinical Therapeutics, Alexandra Hospital, National and Kapodistrian University of Athens, Athens, Greece; [3]Hormonal and Biochemical Laboratory, Aretaieio Hospital, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece

Introduction
Menopausal transition has been associated with an increase in cardiovascular risk, which is possibly linked with the hormonal imbalance following ovarian senescence. Both insulin levels and circulating androgens (FAI) have been associated with endothelial dysfunction, through studies evaluating flow mediated dilation (FMD). We aimed to investigate whether the link between

these hormones and FMD might be explained by markers of oxidative stress, like metalloproteinases −2 and −9 or the heat shock protein 60 (HSP60).
Methods
This study included a total of 159 apparently healthy postmenopausal women, retrieved from a University Menopause Clinic. Exclusion criteria included intake of anti-hypertensive or dyslipidemic medications or menopause hormone therapy during the last 6 months, as well as previously diagnosed peripheral vascular disease or cardiovascular disease. We performed a fasting venous blood sample for biochemical, hormonal assessment and evaluation of markers of oxidative stress and the heat shock protein. Sonographical assessment took place immediately thereafter in one session, including brachial artery tonometry and assessment of flow mediated dilation (FMD).
Results
Correlation analysis showed that mean FMD values were associated with FAI (r = −0.238, P-value = 0.010) as well as with insulin levels (r = –0.196, p-value=0.032). There was a borderline correlation between MMP2 values and FMD (r = 0.159, P-value 0.061), while MMP2 values correlated with log-transformed HSP60 (r = −0.237, P-value=0.011). Multivariable analysis showed that FMD values were associated with FAI and MMP2 levels (Model R^2 14.2%, FAI b-coefficient = −0.354, P-value = 0.016; MMP2, b-coefficient = 0.286, P-value=0.029), but the effect of insulin was lost, in a model that also included age and menopausal age, SBP, body mass index. The results of the multivariable model remained significant after additional adjustment for log-transformed values of HSP60.
Conclusion
In this sample of postmenopausal women, values of FMD were independently associated with levels of free androgens and MMP2. The action of insulin on vascular endothelium seems to be mediated by MMP2. Further studies are needed to explore these findings.

Relationship between vitamin D and thyroid status in women of reproductive age with subclinical hypothyroidism and TPO-Ab +

Veronika Kulchinska
Ternopil State Medical University, Internal medicine №1, Ternopil, Ukraine

Background
Today thyroid diseases occupy the first place among all endocrine pathologies and remain one of the most difficult problems. The prevalence of subclinical hypothyroidism, according to various data, is 4–15%. The category of women of reproductive age deserves special attention, as thyroid dysfunction affects a woman's fertility and pregnancy. Vitamin D deficiency in the population remains a global problem. The purpose of the study is to determine the level of 25-hydroxy vitamin D3 [25 (OH) D3] in women with subclinical hypothyroidism and investigate the relationship between hypothyroidism and vitamin D deficiency.
Materials and methods
We examined 90 women with subclinical hypothyroidism, TPO-Ab + and 25 healthy women, the average age of women with subclinical hypothyroidism was 25.8 ± 1.6 years, of women in the control group was 24.4 ± 1.4 years. The levels of TSH, FT4, FT3, TPO-Ab and 25 (OH) D3 was determined. 25 (OH) D3 was measured by radioimmunoassay, the level of TSH, FT4, FT3 was measured by the immunochemical method.
Results
The level of 25 (OH) D3 was 18.24 ± 1.24 ng/ml (at a rate of 30–50 ng/ml) in women with subclinical hypothyroidism and 29.28 ± 1.02 ng/ml in women of the control group. In all women with subclinical hypothyroidism, vitamin D levels were defined as insufficient or deficient (vitamin D deficiency is detected at less than 20 ng/ml, vitamin D insufficiency is detected at 20–29.9 ng/ml), their TSH level was 5 , 7 ± 0.84, FT4- 14.6 ± 1.12, FT3–3.9 ± 0.82, TPO-Ab - 384 ± 2,46 (P <0.001). It was investigated that the level of 25 (OH) D3 was inversely correlated with TSH levels and TPO-Ab in women with subclinical hypothyroidism.
Conclusions
We investigated that low levels of 25 (OH) D3 were present in all women with subclinical hypothyroidism. An inverse correlation occurred between a decrease in the level of 25 (OH) D3 and an increase in the level of thyroid-stimulating hormone (r = –0.39, P <0.05), between a decrease in the level of 25 (OH) D3 and an increase in the level TPO-Ab (r = –0.37, P <0.05) In order to improve the compensation of hypothyroidism in women of reproductive age, it is recommended to add vitamin D supplements to the main treatment.

Relationship between KLK3 and the immune system of young women living in two areas with different environmental impact during a menstrual cycle. Preliminary data. (ECOFOODFERTILITY Project)

Mariacira Gentile[1], Giusy Esposito[1], Salvatore Raimondo[1], Tommaso Gentile[1], Felice Cuomo[1], Stefania De Filippo[1] & Luigi Montano[2]
[1]Laboratory Gentile s.a.s. - Gragnano NA- , Gentile Research Centre"- Gragnano NA- Italy, Seminology Unit, GRAGNANO, Italy; [2]Local Health Di Salerno, Andrology Unit and Service of Lifestyle Medicine in UroAndrology, Oliveto Citra, Italy

Introduction
Kallikreins are a subgroup of serine proteases which in women are produced by Skene's glands. It evaluated the variation of concentrations in KLK3 and immunoglobulins IgA, IgM, IgG and IgE in the menstrual cycle (follicular (FP), ovulatory (OP) and luteal (LF) in young women living in two areas with different environmental impact.
Materials and methods
82 women aged between 22 and 34, normo-menstruating, no smokers, no habitual drinkers, no professionally exposed, no intake of contraceptive pills for at least 2 years, living for at least 5 years in the selected areas, have been enrolled. 49 residing in high environmental impact area (group A) and 33 in low environmental impact area (group B).The technique used to measure in serum KLK3 is an ultra-sensitive enzyme immunoassay.
Results
88.3% of the group A shows a significant positive peak in the OP (P <0.0001: FP = 3.92 + 1.6, OP = 25.63 + 5.4 and LP = 5.1 + 2.1) and 94.3% of group B shows a significant negative peak in the OP (P <0.0001: FP = 4.43 + 2.1, OP = 1.42 +0.9 and LP = 8.95 + 2.9).It emerges: In group A, no relationship is examined. Group B;

- for IgA there is a significant negative peak in OP (P <0.005: FP = 332 + 31.7,
- OP = 320 + 38.3 and L P = 353 + 50.1).
- for IgM there is a significant positive peak in OP (P <0.001: FP = 171 + 8.9, FO = 180 + 12.1 and LP = 186 + 10.8).
- for IgG there is a not significant variation between the various phases (p = NS: FP = 1435 + 136.1 OP = 1435 + 240.5 and LP = 1438 + 176.4).
- for IgE there is a significant negative peak in OP (P <0.0001: FP = 25.86 + 3.9, OP = 21.45 + 4.5 and LP = 25.72 + 4.7). The group B shows variation in the concentrations of immunoglobulins which in the case of IgA and IgE is strictly correlated with the peaks concentrations of KLK3.

Conclusions
For group B, a correct immune regulatory function of KLK3 seems to be maintained given the correlation between KLK3 with IgA and IgE, while this does not happen for group A, where external environmental factors such as pollutants known to be present in the selected area could play an interference effect of molecular communication pathways.

Spontaneous thelarche and menarche in children with turner syndrome

Nadzeya Peskavaya[1], Anzhalika Solntsava[2] & Natallia Akulevich[1]
[1]Republican Center for Medical Rehabilitation and Balneotherapy, Minsk, Belarus; [2]Belarusian Research Center for Pediatric Oncology, Hematology and Immunology, Minsk, Belarus

Introduction
Turner syndrome (TS) is usually accompanied by hyperhonadotroic hypogonadism and primary amenorrhea due to gonadal disgenesis. One-third of girls with TS have spontaneous thelarhe (ST). Regular menstrual cycles occur in at most 6% of this patients.
Objectives
To analyze the characteristics of pubertal development in children with different karyotype variants of TS.
Methods
This is a retrospective study, analyzing clinical data from medical records of 135 patients with TS from 13 to 18 years, who were regularly followed-up in the Republican Center of Endocrinology (Minsk). Karyotype was identified in blood lymphocyte culture in all patients. Depending on the karyotype, 4 groups of patients were identified the first group with X-monosomy (n =72), the second group with mosaic variant 45,X/46,XX (45,X/47,XXX/46,XX; 45,X/47XXX) (n =18), the third group with isochromosome iXq (n =16) and the fourth group with other karyotypes (n =29). Retrospective

assessment of the age of thelarche and menarche was performed. The results were processed using SPSS.22.
Results
TS was diagnosed in patients with characteristic phenotypic signs according to the results of karyotyping at the age of 9.8 [3.8–12.8] years. A total of 17.8% (n = 24) of TS girls experienced ST. The average age of ST was 12.5 ± 1.61 years. Estrogen replacement was initiated in 78.5% (n = 106) of girls. Spontaneous pubertal development was more frequently observed in TS with mosaicism (50%) than in TS with X-monosomy (2.8%), isochromosome iXq (18.75%) and other karyotypes (34.5%) (χ^2 =29.4; P < 0.001). Spontaneous menarche was observed in 61.1% (n = 11) of TS girls over 15 years old with ST (9.1% of all patients). The average age of spontaneous menarche was 14 ± 0.97 years. 38.9% (n = 7) of TS girls with ST showed no progression of pubertal signs for 6 months and secondary amenorrhea, which required prescribing sex hormone replacement therapy. In patients with a mosaic variant of the karyotype 45,X/46,XX spontaneous completed pubertal was observed more frequently (50%, χ^2=28.8; P < 0.001). A regular menstrual cycle was also observed in a girl with a 45,X karyotype, suggesting the presence of mosaicism in the ovaries in monosomia X in peripheral blood leukocytes.
Conclusions
Our data showed much higher rates of ST and spontaneous menarche in girls with mosaic variant 45,X/46,XX (45,X/47,XXX/46,XX; 45,ŕ47ŕŕ) of TS compared to other karyotype variants. Karyotype should be taken into account when deciding on expected puberty and possibly reproductive potential.

Decline in AMH concentrations following radioactive iodine treatment in women with differentiated thyroid cancer: A systematic review and meta-analysis

Panagiotis Anagnostis[1], Panagiotia Florou[2], Julia Bosdou[1], Grigorios Grimbizis[3], Ioannis Iakovou[4], Efstratios Kolibianakis[2] & Dimitrios Goulis[1]
[1]Aristotle University of Thessaloniki, Unit of Reproductive Endocrinology, 1st Department of Obstetrics and Gynecology, Medical School, Thessaloniki, Greece; [2]Aristotle University of Thessaloniki, Unit of Human Reproduction 1st Department of Obstetrics and Gynecology, Medical School, Thessaloniki, Greece; [3]1st Department of Obstetrics and Gynecology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece; [4]Academic Department of Nuclear Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece

Purpose
Radioactive iodine (RAI) is frequently used as adjuvant therapy in patients with differentiated thyroid cancer (DTC). However, its effect on ovarian reserve has not been fully elucidated, with studies yielding inconsistent results. The aim of this study was to systematically review and meta-analyze the best available evidence regarding the effect of RAI on ovarian reserve in premenopausal women with DTC.
Methods
A comprehensive literature search was conducted in PubMed, Cochrane and Scopus, until December 6th, 2020. Data were expressed as weighted mean difference (WMD) with a 95% confidence interval (CI). The I^2 index was used to assess heterogeneity.
Results
Four prospective studies were included in the qualitative and quantitative analysis. Anti-Müllerian hormone (AMH) concentrations decreased at three (WMD –1.66 ng/ml, 95% CI –2.42 to –0.91, P < 0.0001; I^2 0%), six (WMD –1.58, 95% CI –2.63 to –0.52, P = 0.003; I^2 54.7%) and 12 months (WMD –1.62 ng/ml, 95% CI –2.02 to –1.22, P < 0.0001; I^2 15.5%) following a single RAI dose compared with baseline (three studies; n = 104). With respect to follicle-stimulating hormone (FSH) concentrations, no difference was observed at six (WMD +3.29 IU/l, 95% CI –1.12 to 7.70, P = 0.14; I^2 96.8%) and 12 months (WMD +0.13 IU/l, 95% CI –1.06 to 1.32, P = 0.83; I^2 55.2%) post-RAI compared with baseline (two studies; n = 83). No data were available for antral follicle count.
Conclusions
AMH concentrations decrease at three months and remain low at six and 12 months following RAI treatment in women with DTC. No difference in FSH concentrations post-RAI was observed.

AEP575

Erectile dysfunction as a marker of newly diagnosed endocrine and metabolic disorders

Rossella Mazzilli, Virginia Zamponi, Soraya Olana, lucilla bollanti, Nevena Mikovic, Angela Napoli, Francesco Conti, Giuseppe Pugliese & Antongiulio Faggiano
Endocrine-Metabolic Unit, Sant'Andrea University Hospital, "Sapienza" University of Rome, Italy

Aim
The aim of this study was to evaluate: a) the prevalence of a previously unknown endocrine / metabolic dysfunction, namely hypogonadism, thyroid dysfunction, hyperprolactinemia, and diabetes or prediabetes, in a population of patients affected by Erectile Dysfunction (ED); b) the differences in ED severity according to the presence/absence of specific endocrine / metabolic dysfunctions.
Material and Methods
A total of 1332 subjects, referred to the Andrology Unit (Sant'Andrea University Hospital of Rome) for a condition of ED, were studied. Exclusion criteria were: i) age <18 or >75 years; ii) already diagnosed of endocrine/metabolic disorders, as listed above. The study included: andrological clinical examinations and hormonal profile. The diagnosis of ED was made using the International Erectile Function Index-5 questionnaire (ED: total score ≤21). ED severity was considered according to presence/absence of spontaneous erections, maintenance/achievement deficiency.
Results
Overall, the mean ± SD age was 54.3±13.7 years. A rate of 88.3% of the patients had a stable relationship; 80.0% of the patients referred difficulty in the maintenance of the erection, while 19.9% in the achievement. The spontaneous erections were absent in 24.0% of patients, sporadic in 50.7% and present in the remaining 25.2%. In the 10.3% of the patients there was at least another one sexual or ejaculatory dysfunction (premature/delayed/retrograde ejaculation, anorgasmia, low sexual desire). A total of 19.4% of the patients were already in treatment for glycaemic disorders or endocrine dysfunctions. Among the remaining 1077 patients, the prevalence of subjects with unknown endocrine/metabolic disorders was 30%. Particularly, 190/1077 (17.6%) were diagnosed as affected by hypogonadism (total testosterone < 2.64 mg/dl) 56/1077 (5.2%) diabetes (DM; HbA1c: ≥ 6.5%) or prediabetes (HbA1c 6–6.5%), 40/1077 (3.7%) thyroid dysfunction (TSH<0.3 ulU/ml or TSH>10 ulU/ml), 37/1077 (3.4%) hyperprolactinemia (PRL >25 ng/ml). Among the subgroups, patients with hyperprolactinemia were younger compared to the total group (44.6±12.9 years; P < 0.05), and patients with new diagnosis of DM showed more severe form of ED compared to the total group (difficulty in the achievement of erection: 46/56 (82.2%, P < 0.05; absence of spontaneous erection 23/56 (41.1%), P < 0.05).
Conclusions
In this study, a new diagnosis of an endocrine and/or metabolic dysfunction was carried out in more than a quarter of cases. Since most endocrinologic causes of ED are treatable, every effort should be made to exclude potential hormonal aetiologies underlying ED at an early stage. Finally, ED should also be considered as an early marker of DM as well as endocrine dysfunctions.

A rare case of ovotesticular DSD by 46XX /46XY genetic chimerism

Cristina Ghervan[1], Eniko Varro-Bodoczi[1], Valentin Muntean[2], Liviu Ghervan[3] & Diana Miclea[4]
[1]UMF "Iuliu Hatieganu" Cluj-Napoca, Endocrinology, Cluj-Napoca, Romania; [2]UMF "Iuliu Hatieganu" Cluj-Napoca, Surgery 2, Cluj-Napoca, Romania; [3]UMF "Iuliu Hatieganu" Cluj-Napoca, Urology, Cluj-Napoca, Romania; [4]UMF "Iuliu Hatieganu" Cluj-Napoca, Genetics, Cluj-Napoca, Romania

Introduction
We present the very rare case of a patient with ovotesticular disturbance of sexual development (DSD) by 46 XX/46 XY genetic chimerism.
Case report
A 47-year-old patient with male appearance consulted for gynecomastia developed in the last 3 – 4 years. Clinical examination showed genital organs ambiguity with a small scrotum, no palpable testis, a clitoris instead of penis. Painful bilateral gynecomastia of 5–6 cm in diameter was present. From the patient's pathological antecedents we retain a surgical correction for hypospadias in 2001 and an inguinal hernia surgically cured in 2017. Hormonal dosages showed secretion of both *testosterone* (low level for male

values) and *estradiol* (elevated level for male values), a slight elevation of FSH and LH and normal Prolactin. No other hormonal disturbances were noted. An IRM investigation of the pelvis showed the presence of *an uterus* of 28/22 mm and *one ovary* of 20/28 mm, with follicular structure, the *absence of prostate and seminal vesicles*, in the right scrotum a small structure of 20/14 mm suggesting a testis, a small structure of 26/27mm suggesting a *clitoris*. All this features lead to the diagnosis of ovotesticular disturbance of sexual development, previously known as true hermaphroditism. The karyotype analysis showed the concomitant presence of 50% cells with 46XX karyotype and 50% cells with 46XY karyotype, indicating a genetic chimerism. The hormonal treatment consisted in Testosterone 23 mg/day in transdermal application and Raloxifen 60 mg/day for gynecomastia. The patient will be treated by removal of both uterus, ovary and testis followed by rseplacement therapy with testosterone, as the attributed and assumed sex is male.

Conclusion

Genetic chimerism is defined by *the simultaneous existence of two or more genetically distinct cell lines in a single individual*. 46XX/46XY is an example of tetragametic chimerism. It is a very rare condition resulting from several possible mechanisms, the most probable being the *intrauterine fusion of two different gametes*, one 46 XX and one 46 XY. leading to ovotesticular DSD.

A novel heterozygous mutation in CYP19A1 Gene c.456_462del p.(Ser153Profs*24) in a girl with aromatase deficiency

Isabel Inácio[1], Mafalda Simões[2], Vânia Leitão Martins[3], Fernanda Geraldes[2], Rita Cardoso[4], Joana Serra-Caetano[4], Isabel Dinis[4] & Alice Mirante[4]

[1]Endocrinology Department, Centro Hospitalar do Baixo Vouga, Aveiro, Portugal; [2]Gynecology Department, Maternidade Bissaya Barreto, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [3]Pediatric Department, Centro Hospitalar de Leiria, Leiria, Portugal; [4]Pediatric Endocrinology, Diabetes and Growth Department, Hospital Pediátrico de Coimbra, Coimbra, Portugal

Background

Aromatase deficiency is an extremely rare autosomal recessive condition due to mutations on *CYP19A1* gene. Despite the size and complexity of this gene, only about 40 cases with aromatase deficiency have been reported.

Case report

The patient was born at term from non-consanguineous parents. Maternal signs of virilization were verified during third trimester (deep voice, acne on arms and face enlargement). Ambiguous genitalia were recognized at birth. The patient was referred to the Pediatric Endocrinology Department (PED) and presented complete fusion of the labia majora, clitoromegaly, and a posterior urethra. Mother reported improvement in virilization signs few days after birth. Laboratory work-up at 2 days of life showed 17-hydroxy progesterone (17-OHP) of 18 (0.07–0.77) ng/ml, total testosterone (TT) of 0.7 (20–64) ng/dl, whereas ionogram, adrenocorticotropic hormone, dehydroepiandrosterone sulfate, aldosterone and renin were normal; at 15 days, 17OHP was 12.4 (0.13–10.6) ng/ml, TT <20.0 (20–64) ng/dl and androstenedione 2.8 (0.18–0.80) ng/ml. The karyotype was 46,XX and pelvic ultrasound revealed a normal uterus, vagina and bladder. At 11 months of age, she was submitted to vulvoplasty and the parents decided to suspend the follow-up at the PED. At 12 years and 4 months, she presented to the emergency department (ED) with severe pain in the left iliac fossa, absence of stool passage for 2 days and vomiting, presenting Tanner stage III pubic hair and Tanner stage I breasts. Laboratory findings showed 17-OHP 1.86 (0.11–0.98) ng/ml, TT 0.4 (0.07–0.28) ng/ml, LH 31 (0.02–4.7) mUI/ml, FSH 33 (1.0–10.8) mUI/ml and estradiol 16 (10–24) pg/ml. Pelvic MRI revealed a complex genital malformation, ovarian cystics and suspected hydrocolpos. Treatment with LHRH agonist was implemented. She underwent left oophorosalpingectomy and histology documented left anexal necrosis with multicystic left ovary torsion, without hydrocolpos, and treatment with LHRH agonist was suspended. At 13 years and 2 months, she was admitted to the ED with right ovary torsion and underwent urgent laparoscopic surgery. LHRH agonist was restarted. Genetic analysis of the patient revealed two probably pathogenic variants in heterozygote in the *CYP19A1* gene: a previously described mutation (c.1263+5G>A p.?) and a novel mutation [c.456_462del p.(Ser153Profs*24). Puberty was induced with transdermal estrogens.

Conclusion

We identified a novel mutation in the *CYP19A1* gene in a patient who presented with ambiguous genitalia and maternal virilization during pregnancy. Our case had large polycystic ovaries and two episodes of ovarian torsion. In addition, it shows the difficulties during the follow-up and the complexity of the disease. We speculate that these mutations can potentially result in partial aromatase activity with remaining estrogen biosynthesis.

Turner Syndrome–An unusual presentation of normal stature and incomplete puberty

Daniela Dias[1], FIlipa Serra[1], Carolina Neves[1], Leonor Real Mendes[2], Filomena Nogueira[3] & Inês Sapinho[1]

[1]Hospital CUF Descobertas, Endocrinology Department, Lisbon, Portugal; [2]Hospital CUF Infante Santo, Paediatrics Department, Lisbon, Portugal; [3]Hospital Lusíadas, Gynaecology Department, Portugal

Introduction

Turner syndrome(TS) is characterized by complete/partial monosomy or by a structural defect in one of X chromosomes. Despite clinical hallmarks of short stature(SS) and gonadal dysgenesis(GD), phenotype is variable and related to underlying chromosomal pattern. Loss of the distal segment of the short arm of x-chromosome(Xp-), including haploinsufficiency of short stature homeobox-containing (SHOX) gene, is thought to be the main factor for growth failure. Regarding GD, results from accelerated follicular atresia. Spontaneous puberty occurs in only 15–30%, but only half of those complete puberty with menarche. We report an uncommon presentation of a teenage TS female with normal stature, whose only apparent Turner feature was secondary amenorrhea(SA).

Case report

A 17-year-old girl was referred to our endocrine clinic for SA. Spontaneous menarche occurred at 13 years-old. Subsequent menstruation was regular during first 3 months, and became irregular, in the following 2.5 years. Thereafter, she became amenorrheic during 1.5 years. She was born at term, after an uneventful pregnancy. Her birth length and weight were 50.5 cm (0.48 SDS) and 3300 g (-0.2 SDS). She has mild intellectual disability. Height growth was on P50–75 until 12, with an increase to P90 since then. Her target height is 162.5 cm (-0.11 SDS). Physical examination, recorded 170 cm of height (1.09 SDS; P85), weighed 66 kg (SDS 0.95) and had low set ears. Her breast development and pubic hair were Tanner's stage III and IV, respectively. Endocrine evaluation revealed FSH levels of 106 UI/l and LH levels of 51.9 UI/l, and undetectable estradiol. The remaining pituitary hormones were within normal ranges, as haematological and biochemical tests. Anti-mullerian hormone was <0.01 µg/l. Pelvic ultrasound revealed an uterus of normal dimensions and ovaries were undetectable. Echocardiogram, audiogram and renal ultrasound were normal. Karyotype analysis showed a 46,X,psu idic(X)(q21.32) TS, representing partial monosomy of Xq and partial trisomy of Xp(long arm of x-chromosome). Low-dose oral contraceptive pill was initiated. Currently, at 20 years-old, she presents a complete pubertal development with a final height of 172 cm (1.34 SDS).

Conclusions

In this case, the SHOX gene overdose in Xp- may have mitigated the SS phenotype which is typical of TS. Additionally, TS karyotype may be a predictor of spontaneous puberty, being less frequent in the classic 45,X karyotype. TS should be considered in patients with SA despite no typical somatic stigmata. There is paucity of literature reporting TS with normal/tall height and spontaneous puberty.

Congenital GH deficiency in children: What are the differences between isolated and combined/total and partial somatotropic GH deficiency?

Dorra Dorraelguiche[1], Manel Jemel[2], Grassa Anis[1], Radhouane Gharbi[2], Hajer Kandara[2] & Ines Kammoun[2]

[1]National Institute of Nutrition and Food Technology, Department of Endocrinology, Tunis, Tunisia; [2]National Institute of Nutrition and Food Technology El Manar University, Department of Endocrinology, Tunis, Tunisia

Introduction
Growth hormone (GH) deficiency is a rare but not exceptional cause of statural delay in children. The results of GH stimulation tests and the exploration of other pituitary axes allow us to conclude on the nature of the deficiency: total or partial and its possible association with other pituitary deficits.
Methods
This is a retrospective descriptive study including 75 patients followed for congenital GH deficiency.
Results
The comparison of the demographic, auxological and biological characteristics between total and partial somatotropic deficits showed that the average age of discovery was 8.51 ± 4.21 years for the total deficit vs 9.62 ± 4.09 years for the partial deficit with no significant difference *(P* = 0.344). Male gender was predominant for both types of deficits (61% for total deficit vs 67% for partial deficit; *P* = 0.639). The initial SD height was –2.77 ± 1.5 SD for total deficit vs –2.19 ± 1.2 SD for partial deficit. BMI (SD) was 1.27 ± 0.5 for total deficit vs 1.75 ± 0.5 for partial deficit *(P* = 0.251). IGF1 (SD) was 3.36 ± 0.33 vs 2.81 ± 0.5 *(P* = 0.474). The hypothalamic-pituitary MRI was pathological for most patients with total somatotropic deficit (60%) and normal for most patients with partial deficit (67%) with a significant difference *(P* = 0.038). For the comparison between isolated and combined deficits, we found a significant difference only for IGF1(SD) (which was –3 ± 1.5 SD for isolated deficit and -3.44 ± 0.5 SD for combined deficit *(P* = 0.002).
Discussion and conclusion
The total deficit was mainly associated with pathological MRI in our series, which was consistent with the series in the literature. For the other series, patients with combined pituitary deficit compared to subjects with isolated deficit were significantly smaller in height, with a larger delta (target height-height) and lower weight.

Adverse effects of gender affirming hormonal therapy in transgender persons: assessing reports in the French pharmacovigilance database

Melissa Yelehe[1], Marc Klein[2], Pierre Gillet[1], Anais Maurier[3] & Eva Feigerlova[2,4]
[1]Centre Régional de Pharmacovigilance de Lorraine, Department of Clinical Pharmacology and Toxicology, Nancy, France; [2]University Hospital of Nancy, Department of Endocrinology,, Nancy, France; [3]Univesity of Tours, Centre de Pharmacovigilance, Tours, France; [4]INSERM UMR_S 1116 - DCAC , Medical Faculty, University of Lorraine

Background
Only limited data are available regarding adverse effects of gender affirming hormonal treatment (HT) mainly due to the lack of population-based studies with adequate controls, thus making spontaneous reporting systems a valuable tool to detect potential side reactions.
Objective
In this nationwide retrospective study, we aimed to analyse adverse drug reactions (ADRs) in relation to gender affirming HT reported in the French pharmacovigilance database by patients and by health care professionals and to categorize the type of ADRs.
Research design and methods
We requested for all the individual case safety reports related to gender affirming HT recorded in the French pharmacovigilance database (FPVD) before the 27th of May 2020. An endocrinologist and a pharmacologist reviewed all cases. We excluded cases that have already been published or for which gender affirming HT was not the suspected drug.
Results
A total of 38 reports of ADRs were identified. We excluded 5 cases where gender affirming HT was not the suspected drug and 5 cases that have already been published. Among the remaining cases, 6 concerned transgender men (age range 21–40 years) and 22 transgender women (age range 22–68 years). In transgender men all reported ADRs were cardiovascular events with pulmonary embolism in 50% of cases. Treatment with testosterone enanthate was involved in all subjects. Therapy was discontinued in 3 cases and total recovery was observed in 2 of them. In transgender women, antiandrogens, mainly cyproterone acetate (CPA), were involved in 68% of reported cases. Estrogens were implicated in 77% of cases, mostly in association with progestins or CPA. Cases of meningioma were the main ADRs observed, followed by cardiovascular ADRs such as ischaemic stroke or acute coronary syndrome. Two cases were related to self-induced drug intoxication. Gender affirming HT was completely discontinued in 14 transgender women and a total recovery was noted in 8 of them.
Conclusion
Our data show a previously unreported and non-negligible proportion of cases indicating cardiovascular ADRs in young transgender men treated with testosterone enanthate. In transgender women, meningioma was the most frequently reported ADRs followed by cardiovascular events. A continued vigilance and further research are necessary to identify risk factors that might lead to individualisation of treatment strategies. There is a necessity to increase the awareness and implement preventive and education measures.

Analysis of insulin like peptide 5 (INSL5) levels and their association between hormonal and metabolic parameters in polycystic ovary syndrome patients

Deniz Cengiz[1], Esra Nur Ademoglu Dilekci[2], Omur Albayrak[3] & Ozgur Mehmet Yis[4]
[1]University of Health Sciences Ataturk Chest Diseases and Thoracic Surgery Training and Research Hospital, Internal Medicine, Ankara, Turkey; [2]Bolu Abant Izzet Baysal University Training and Research Hospital, Endocrinology and Metabolic Diseases, Bolu, Turkey; [3]Bolu Izzet Baysal State Hospital, Gynecology and Obstetrics, Bolu, Turkey; [4]Bolu Abant Izzet Baysal University Training and Research Hospital, Biochemistry, Bolu, Turkey

Objectives
Polycystic ovary syndrome (PCOS) is the most common reproductive disorder that onsets peripubertally and increases morbidity by affecting quality of life. Insulin like peptide 5 (INSL5) is a relaxine/insulin family member gut-peptide hormone that is expressed by various tissues including the hypothalamus, pituitary and ovary. In the present study, we aimed to characterize serum INSL5 levels in PCOS women and determine association of circulating serum insulin like peptide 5 (INSL5) with serum AMH level, metabolic and hormonal parameters.
Materials and Methods
The present study included 45 women diagnosed with polycystic ovary syndrome between the ages of 18–35, who had not received medical treatment in the last six months, and 35 healthy women of the same age range as control group in Bolu Abant Izzet Baysal University School of Medicine, Department of Endocrinology and Metabolism. Anthropometric, hormonal, metabolic parameters and INSL-5 levels were determined in all patients. Pelvic ultrasonography was performed to examine ovarian size and follicle numbers.
Results
In the present study, INSL5 was 12.5 (3.8–59.5) ng/ml in the PCOS group and 15.5 (5.3–37.4) ng/ml in the control group. There was no statistically significant difference in terms of INSL5 between the groups *(P* = 0.103). INSL5 was negatively correlated with body mass index (BMI), free androgen index (FAI), insulin, HOMA-IR, triglyceride, total cholesterol, LDL, fat mass and positively correlated with sex hormone binding globulin (SHBG) in PCOS group. In multivariate linear regression analysis, FAI was significantly associated with serum INSL5 levels ($\beta = -1.1$, $P = 0.015$).
Conclusion
There was no statistically significant difference in INSL5 levels between PCOS patients and healthy subjects, suggesting that the peptide does not have a diagnostic value in PCOS. Negative correlation between INSL5 and FAI, insulin, HOMA-IR and atherogenic lipid profile supports the studies suggesting that this peptide might be related to glucose and lipid metabolism. In multivariate regression analysis, independent relationship of INSL5 with FAI indicates that further studies are required to evaluate the relationship between INSL5 and PCOS.
Key Words: PCOS, INSL5.

AEP582

Hyperandrogenism and portosystemic shunt - report of two cases

Inês Manique, Teresa Rego, Fernando Fonseca, Ana Agapito & José Silva-Nunes
Hospital Curry Cabral, Endocrinology, Diabetes and Metabolism, Lisbon, Portugal

Introduction
Severe hyperandrogenism is a warning sign in young women. Differential diagnosis includes neoplastic, non-neoplastic and iatrogenic causes. The association of hyperandrogenism and congenital or acquired portosystemic shunt (PSS) has been rarely described, with its pathophysiology being unclear.
Case 1
A 22 year-old woman with diagnosis of autoimmune hepatitis, portal hypertension and PSS since 15 years old, presented with a 4 years history of oligomenorrhea and hirsutism [Ferriman-Gallwey (FG) score 12]. Examination revealed BMI 30.7 Kg/m^2 and virilization signs. Total testosterone (TT) was 3.60 ng/ml (0.1–0.56) and androstenedione 12.4 ng/ml (0.5–4.7). 17OHP, S-DHEA and SHBG were normal. Serum glucose 83 mg/dl, insulin 20 uUI/ml (1.9–23), HOMA-IR 0.7. CT scan excluded adrenal lesions. Ultrasound showed "ovaries with 56 and 58 mm and multiple peripheral follicles". In view of the severe hyperandrogenism of probable ovarian etiology, catheterization of the ovarian veins was performed, excluding ovarian lateralization or central/peripheral gradient of androgen levels. The patient completed 17 months of goserrelin acetate with slight improvement in hyperandrogenism (TT 1.88 ng/ml, androstenedione 8.58 ng/ml). Due to poor therapeutic adherence and necessary contraception, an ethonogestrel implant was applied.
Case 2
A 18 year old woman, with portal hypertension due to portal vein agenesis diagnosed at 4 years old, presented with menstrual irregularities and hirsutism (FG score 10) since menarche at 14. She had a BMI 28.9 Kg/m^2 and no signs of virilization. TT was 2.12 ng/ml and androstenedione 5.27 ng/ml. 17OHP, S-DHEA and SHBG were normal. Serum glucose was 71 mg/dl and insulin 12.57 uUi/ml, HOMA-IR 2.2. On ultrasound, "right ovary (30.4 × 26.4 mm) with functional cyst and multifollicular left ovary (31.4 x16 mm)" stood out. Abdominal-pelvic MRI confirmed portal vein agenesis and excluded ovarian and adrenal lesions. In view of the mild clinical symptoms and the need for contraception, a levonorgestrel IUD was inserted.
Conclusion
PSS can cause hyperinsulinemia by direct passage of secreted insulin to the systemic circulation and consequent insulin resistance by downregulation mechanisms. This is a possible explanation for the hyperandrogenism associated with PSS, similarly to what happens in polycystic ovary syndrome. Decreased hepatic clearance of androgens, in particular testosterone, may be an additional factor. Treatment depends on age, degree of virilization and pregnancy goal which justified the different approach in these patients.

Low intelligent quotient (IQ) in patients with Klinefelter Syndrome are associated with impaired quality of life: A systematic review with meta-analysis

Brien Mehmet & Sofia Llahana
City, University of London, School of Health Sciences, London, United Kingdom

Objective
This was a systematic review with meta-analysis aiming to identify if patients with Klinefelter syndrome (KS) had a reduced full scale intelligent quotient (IQ) when compared to controls. Reduced IQ is shown to have a negative multifaceted effect on individuals' Quality of Life (QoL), having been shown as a *predictor of future success, increased criminal behaviour, post-traumatic stress disorder (PTSD), lower academic achievements and increased prosocial deficits*. Assessment of patients' IQ can support clinicians in delivering patient care intervention which can address individualised QoL deficits and patients' unmet needs. This is particularly relevant and crucial in achieving holistic nursing care to intervention.
Design
Meta-analysis was completed in Review manager 5.4, using continuous data and running an inverse variance random-effects model, using Std. mean difference for the effect measure, a forest plot was created. This analysed the results on full scale IQ from all studies that used both controls, KS participants and a validated measuring tool to record IQ. Seven studies in total were appropriate to be combined for meta-analysis. The seven studies included were extracted from the initial systematic review analysing factors that can influence QoL in patients with KS.
Data sources
Medline, Cochrane, Embase, Psychinfo, CINAHL, BASE and grey search from the reference lists of key publications.
Eligibility criteria
RCT's, Cohort studies, cross sectional studies and Epidemiology studies involving patients with KS and reporting on QoL parameters. Both adult and paediatric participants were included.
Results
The results from the meta-analysis suggest association with a lower full-scale IQ and a KS diagnosis. There is strong significant difference between patients with KS and Controls, significant P and Z values mean the probability of achieving the results by chance are lowered and the null hypothesis can be rejected. The statistical differences identified suggest a negative association between full scale IQ and KS when compared to controls, suggesting lower full-scale IQ can be associated with KS.
Conclusions
Significant Z & *P* values (Z=8.10, *P* <0.00001) indicate that men with KS have a significantly lower IQ than healthy controls which has a negative impact on patients' QoL. Currently there are no validated scales to measure QoL parameters, including IQ, for patients with KS. Future research is needed to develop a KS-specific scale for use in clinical practice to identify patients' deficits in QoL parameters and plan appropriate care management plans to improve patients' QoL.

Primary ovarian failure: descriptive study of 50 cases

Wajdi Safi[1], Mouna Elleuch[2], Dhouha BenSalah[1], Hamdi Frikha[1], Nadia Charfi[1], Nabila Rekik[1], Fatma Mnif[1], Mouna Mnif Feki[1], Faten Hadj Kacem[1], Mohamed Abid[1]
[1]Hedi Chaker hospital, Sfax; Tunisia, Sfax, Tunisia, Department of Endocrinology, Sfax, Tunisia

Introduction
Primary ovarian failure currently represents an increasingly frequent cause for consultation in endocrinology, from 4 to 18 % of the causes of primary amenorrhea and 10 to 28 % of the causes of secondary amenorrhea.
Objectives
In this context, we report a retrospective study of 50 patients followed between 2000 and 2020 for early menopause, in order to assess the etiologies and risk factors favouring this pathology as well as its subsequent impact.
Results
The average age of our patients was 31 years with extremes ranging from 10 years to 40 years. A family history of early menopause was noted in only 6% of women. The reason for consultation was secondary amenorrhea in 52% of cases followed by primary amenorrhea in 32%. In our study we found that the majority of women are nulliparous, in 68% of cases. The diagnosis was confirmed by an average FSH level of 87.25 mIU/l, LH at 28.45 mIU/l, the average E2 value was 2.4 pg/ml and the average prolactin value was 29.02ng/ml The study showed that the main aetiology was premature autoimmune ovarian failure in 58% of cases, a congenital cause in 24% of cases, and chemotherapy and radiotherapy are involved in 6% of cases. All the women in our survey presented complications following their menopause, of which 70% presented short-term complications, mainly sleep disorders, hot flashes and urinary genital disorders, 20% of the women presented metabolic complications at medium term and long term and 48% of women presented mainly cardiovascular complications.
Conclusion
Hormone replacement therapy is necessary to avoid the increased risk of all these complications, especially osteoporosis and cardiovascular complications. If you want to become pregnant, in vitro fertilization with oocyte donation is currently the most effective technique

Long-term psychosocial effects of gender affirming hormone therapy on transgender men

Emre Durcan[1], Basak Ecem Bircan[1], Selver Yaylamaz[1], Sabriye Sibel Taze[1], Hande Mefkure Ozkaya[1], Senol Turan[2] & Pinar Kadioglu[1]
[1]Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Department of Internal Medicine, Division of Endocrinology and Metabolism, Turkey; [2]Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Department of Psychiatry, Turkey

Background/Aims
Gender affirming hormone therapy (GAHT) has been reported to have positive psychosocial effects on transgender people. In present study, we aimed to investigate longitudinally the short-term and long-term impacts on social adaptation, body image, features of alexithymia and aggression changes in transgender men after GAHT administration.
Methods
The single center, longitudinally follow-up study included transgender men who had admitted to the Endocrinology and Metabolism outpatient clinic of Istanbul University-Cerrahpasa, Cerrahpasa Medical School. Thirty-nine transgender men were asked to complete the Social Adaptation Self-Evaluation Scale (SASS), the Toronto Alexithymia Scale (TAS-20), the Body Image Scale (BIS), and the Buss-Perry Aggression Questionnaire (BAQ) both before GAHT, and after 12 months of GAHT administration. GAHT involves the administration of intramuscular injections of either 250 mg of testosterone esters depot every 3 weeks, or 1000 mg of testosterone undecanoate every 12 weeks.
Results
In the first year of hormone therapy, there was no significant change in terms of social adaptation according to SASS (44.8 ± 6.4 vs 43.7 ± 6.3, P = 0.261). Although the body images scores of transgender men measured by BIS were in the borderline of statistical significance, they increased after GAHT compared to baseline (139 ± 27.9 vs 148.1 ± 26.5, P = 0.058). When transgender men were evaluated in terms of alexithymia, while it became more difficult for individuals to identifying feelings (P = 0.039) after GAHT, there is no difference emerged in terms of difficulty describing feelings (P = 0.797) and externally-oriented thinking (P = 0.522). On the other hand, there was no change in aggressive behavior after GAHT according to the BAQ total and subscales (physical aggression, verbal aggression, hostility and anger) (P > 0.05 for all).
Conclusions
Our findings indicate that GAHT causes transgender men to perceive their body images more positively, and has no effect on their social adaptation and aggressive behavior. On the other hand, GAHT may ended up with more alexithymic scores in transgender men population.
Keywords: social adaptation, body image, alexithymia, aggressive behaviors, gender affirming hormone therapy.

Changes in androgen profile in transgender women with or without gonadectomy

Sarah Collet[1], Justine Defreyne[2], Meltem Kiyar[1], Delphine De Meijer[1], Sarah Nobels[1], Martin den Heijer[3], & Guy T'Sjoen[2]
[1]Ghent University, Gent, Belgium; [2]Ghent University Hospital, Gent, Belgium; [3]Amsterdam UMC, locatie VUmc, Amsterdam, Netherlands

Objectives
The European Network for Investigation of Gender Incongruence (ENIGI) is a multicenter prospective cohort study. All participants receive a standardized gender affirming treatment (GAHT) protocol including regular follow-up. The current study compared changes in androgens upon starting GAHT and during follow-up in transgender women (TW) with or without gonadectomy by investigating serum total testosterone (TT), calculated free testosterone (cFT), DHEA, DHEAS, androstenedione and SHBG.
Methods
This research was part of the ENIGI study. Sex steroids were assessed at baseline and 12 and 24 months of follow-up using immuno-assay (SHBG, DHEAS) and LC-MS/MS (TT, DHEA, androstenedione). FT was calculated. GAHT was initiated at baseline: estrogens (oral or transdermal) and anti-androgens (cyproterone acetate 25–50 mg/day). After orchiectomy the anti-androgen therapy was stopped and the estrogens were continued unchanged. Data from 113 TW with ≥2 years of follow-up at Ghent, Belgium were analyzed prospectively. Subgroup analyses were performed in TW who underwent orchiectomy (group A, n = 59) vs TW who did not (group B, n = 54), at baseline, pre-operatively vs at month 12, and post-operatively vs at month 24.
Results
In group A, serum TT levels decreased from 572.69 ± 11.76 ng/dl to 18.71 ± 11.91 ng/dl (baseline vs pre-gonadectomy, P < 0.001) and cFT decreased from 11.34 ± 0.35 ng/dl to 0.26 ± 0.35 ng/dl (baseline vs pre-gonadectomy, P < 0.001). No further effect of gonadectomy on serum TT and cFT levels was assessed, although a trend towards decrease was observed. SHBG increased post-gonadectomy (P < 0.001). Androstenedione, DHEA, DHEAS decreased from baseline to pre-gonadectomy (P < 0,001), but remained stable afterwards. Similarly in group B, serum TT, cFT, androstenedione, DHEA and DHEAS decreased between baseline vs 12 months (P < 0.001), while SHBG increased (P < 0.001); all variables remained stable afterwards. Comparing groups after 24 months, no differences in serum TT levels were found. However, SHBG was higher in group A vs group B (73.2 ± 39.6 nmol/l vs 57.2 ± 37.2 nmol/l respectively, P = 0.004), whereas cFT (0,18 ± 0.12 ng/dl vs 0,26 ± 0.26 ng/dl, P = 0,016), androstenedione (71.0 ± 32.4 ng/dl vs 85.3 ± 37.2 ng/dl, P = 0.042) and DHEA (4.99 ± 3.61 µg/l vs 7.34 ± 4.62 µg/l, P = 0.002) were lower.
Conclusion
Serum TT and cFT levels remained unchanged post-orchiectomy compared to before, if low TT was confirmed when on GAHT (including anti-androgens) reflecting patient compliance. At 24 months, TW who underwent orchiectomy had lower cFT, androstenedione and DHEA and higher SHBG, compared to those with a continued stable dose of anti-androgens.

Endocrine features in Noonan syndrome

Inês Vieira[1], Margarida Bastos[1], Luísa Ruas[1], Dírcea Rodrigues[1,2], Leonor Gomes[1,2] & Isabel Paiva[1]
[1]Coimbra Hospital and University Center, Endocrinology, Portugal; [2]University of Coimbra, Faculty of Medicine, Portugal

Introduction
Noonan syndrome can result from different mutations, the most frequent being in PTPN11. The diagnosis is often made by the clinical picture of short stature, facial dysmorphisms and heart defects. From an endocrine point of view, growth retardation, hypogonadism and a higher frequency of thyroid autoimmunity are highlighted.
Objectives
To analyse endocrine features in patients with Noonan syndrome (SN).
Material and Methods
Review of the clinical files of patients with NS followed in an external endocrinology appointment since 1997.
Results
Data from 4 male patients with NS were analysed. D1: Clinical diagnosis in the 1st year of life and molecular confirmation at age 9 (PTPN11 mutation). Height-weight evolution below P5. Pubertal induction at age 14, with normal gonadal function after testosterone suspension. Currently 26 years old, 1.44m - below the target family height (TFH) of 1.69m - BMI 18.5 kg/m^2 and dyslipidaemia. D2: Early clinical diagnosis due to dysmorphisms and cardiac anomalies with posterior molecular confirmation (PTPN11 mutation). He presented normal growth rate, hypogonadism with puberty induced at 13 years and 5 months of age and subclinical hypothyroidism with negative autoimmunity. Currently the patient is 35 years old, has 1.74m (within the TFH - 1.75m), BMI 19.9 kg/m^2 and maintains testosterone therapy. D3: Clinical diagnosis in the postnatal period due to poor height-weight evolution and phenotype, molecular confirmation at age 14 (mutation in SOS1 - Noonan-Querubinism variant). Growth within P5, spontaneous puberty and no hypogonadism. Currently the patient is 23 years-old, 1.65m (TFH 1.79m), BMI 20.6 kg/m^2, without other endocrine anomalies. D4: Molecular diagnosis at age 14 (PTPN11 mutation). Growth curve at P25–50 and pubertal induction at age 16. Currently 22 years old, 1.73m (within the TFH - 1.70m), BMI of 20.0kg/m^2, maintains testosterone therapy. All the patients presented heart disease, bone malformations and delayed psycho-motor development. Ophthalmological and dental abnormalities were reported in 3 and haematological anomalies in 1 patient.
Conclusions
In this sample, the endocrine features were heterogeneous: 2 patients reached a stature below the TFH, 1 had short final stature; in all but one, there was a need for pubertal induction; 2 were diagnosed with hypogonadism. Follow-up in appointments allowed for growth monitoring, pubertal induction at the appropriate time, and continued testosterone therapy when indicated.

Establishment of an assay for the effects of neurodevelopmental toxicity using Sox1-GFP cells

Sunhwa Jeong, Seon Mi Park, Seon Myeong Go, Dinh Nam Tran, Jimin Lee & Eui-Bae Jeung

Laboratory of Veterinary Biochemistry and Molecular Biology, Veterinary Medical Center and College of Veterinary Medicine, Chungbuk National University, Veterinary Biochemistry and Molecular Biology, Cheongju, Korea, Republic of South

Developmental toxicity tests have been made by embryonic stem cell tests at the European Centre for the Validation of Alternative Methods or by embryonic body test in our laboratory. However, no neuronal-specific developmental toxicity test has been made yet. Therefore, this study was carried out using a 46C cell line, mouse embryonic stem cells with an endogenous Sox1-GFP reporter, to exploit the developmental neurotoxicity test. The expression of Sox1, a marker for neural progenitor, can be detected by green fluorescence and the fluorescence density is a critical factor to achieve neuronal differentiation. 46C cells were treated for 24 hours with 5-fluorouracil, hydroxyurea, chlorpyrifos, clioquinol, diazinon, nicotine and lead acetate as developmental neurotoxicants, or saccharin, sodium bicarbonate, sodium gluconate, and penicillin G as non-neurotoxicants. CCK-8 assays were performed to determine IC_{50} values after 48 hours of chemical treatment. The fluorescence intensity of GFP was measured after 4 days of treatment with cells using an automated digital microscope. Through CCK-8 assay, IC_{50} values of developmental neurotoxicant chemicals were obtained, whereas non-neurotoxicant chemicals showed low effects. In addition, the fluorescence intensity of GFP was not decreased with non-neurotoxicants. However, neurotoxicants decreased the fluorescence intensity of GFP at higher concentrations. This decrease of fluorescence intensity indicates that the neuronal differentiation of 46C cells is inhibited by the chemicals. Taken together, this study produced a model of the developmental neurotoxicity tests used embryonic stem cells that may use to evaluate the toxicity of new chemicals or new candidate drugs.

Growth retardation in hypothyroidism and growth hormone deficieny : A case report

Rihab Laamouri, Imen Rojbi, Chayma Besrour, Marwa Majdoub, Youssef Lakhoua, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Charles Nicolle Hospital, Endocrinology Department, Tunisia

Introduction
Growth retardation is a multifactorial process involving genetic, nutritional and hormonal factors. It has a significant psychological impact. The etiologies are multiple. This case illustrates a growth retardation related to more than one etiology.
Case presentation
A 22 year-old patient consulted in orthopedics for a right lameness. Diagnosis of primary hip osteochondritis had been suspected on standard X-ray and confirmed by magnetic resonnance imaging. He consulted in endocrinology for a small height relative to target height. Clinical examination showed a height at 1 m 56 (−3.3 standard deviations), a body mass index at 31.27 kg/m^2 and a Tanner stage G5P5A5. The bone age was less than chronological age with a difference of 6 years. Biology assessment showed a TSH at 100, low ft4 at 0.1 ng/ml, GH at 2.05 ng/ml and peak GH at 0.31 ng/ml (<5 ng/ml) in L-dopa test. The diagnosis of peripheral and complete growth hormone deficiency were confirmed. The rest of the pituitary assessment showed a cortisol at 358 nmol/l, hyperprolactinemia at 37 ng/ml secondary to hypothyroidism, testosteroemia at 7.95 nmol/l LH at 2.6 mUI/l concluding to a functional gonadotropic insufficiency related to hyperprolactinemia. The patient had a thyroid ultrasound showing a thyroiditis and an pituitary MRI showing a pituitary gland of normal size and morphology, a pituitary stalk and a posterior lobe in place with a normal signal. The patient has been treated with substitution by L thyroxin. He could not benefit from recombinant growth hormon since he had already a lean growth cartilage on the x-ray. The evolution was marked by the normalization of the thyroid serum level. He was referred to orthopedics for the management of his joint pathology.
Conclusion
Growth retardation is a frequent reason for consultation. Its psycological repercussions are significant. It may be secondary to one or more causes, especially when it is a severe delay. Hence the interest of looking for an associated growth hormone deficiency early to guarantee the child a gain in height via treatment with recombinant growth hormone.

Turner syndrome with isochromosome Xq (about two observations)

Fatima Zahra Outtaleb, Imelloul Nora & Dehbi Hind
Ibn Rochd University Hospital of Casablanca, Laboratory of Medical Genetics. Laboratory of Cellular and Molecular Pathology. Casablanca Faculty of Medicine and Pharmacy. Hassan II University, Casablanca, Morocco

Introduction
Turner syndrome is a chromosomal abnormality linked to the total or partial absence of the X chromosome. Its prevalence is 1/2500 female newborns. It constantly associates a stature delay and ovarian failure, with an increased risk of various malformations. The objectives of this study are to show the importance of the cytogenetic study in the management of patients with delayed height and / or primary amenorrhea, and to search for a possible correlation between cytogenetic abnormalities and the clinical expression of Turner syndrome.
Patients and methods
We report the medical observations of two patients followed at the medical genetics department of the Ibn Rochd University Hospital in Casablanca for Turner syndrome, with a mosaic karyotype, carrying a structural anomaly and a monosomy of the X chromosome.
Results and discussion
Stature delay and primary amenorrhea were the indications for the achievement of the constitutional karyotype. There are other circumstances in which Turner syndrome is discovered : prenatal on ultrasound signs, at birth in cases of lymphedema, or in adulthood in case of infertility. In addition to the delay in height, the clinical examination may find in 2/3 of cases a non-specific facial dysmorphia, as well as other associated anomalies, mainly coarctation of the aorta, which can be associated with arterial hypertension. or left heart failure in the perinatal period. The typical karyotype is characterized by a homogeneous X monosomy (45, X), but this cytogenetic type accounts for only 42 to 48% of the chromosomal abnormalities described in Turner syndrome. The homogeneous structural abnormalities of the X chromosome are found in 20 to 25% of cases, and the mosaic karyotype is responsible for 25% of cases, and it consists of a normal cell population and a cell population carrying a monosomy of the chromosome X. The originality of these two observations is that the cytogenetic study revealed a mosaic Turner syndrome, consisting of in the two reported cases of two abnormal cell populations, one carrying an anomaly in number and the another an anomaly in the structure of the X.
Keywords: Turner syndrome, mosaic, isochromosome, stature delay, primary amenorrhea.

Hypogonadotropic hypogonadism revealing a classic form of 21 hydroxylase deficiency in a 39 year old man

Ilboudo Alassane[1], Courtillot Carine[2], Sagnan Yempabou[3], Dubreuil Sophie[2] & Philippe Touraine[2]
[1]CHUSS , Médecine inrerne , Bobo-Dioulasso, Burkina Faso; [2]Hôpital Universitaire Pitié Salpêtrière-Charles Foix, Médecine de la reproduction IE3M, Paris, France; [3]CHUSS INSSA, Médecine Interne , Bobo-Dioulasso, Burkina Faso

Classical forms of 21 hydroxylase defisciency are generally observed during bith life and present as loss of salt or rapid puberty in young boy. We report a rare case of classical 21 hydroxylase defisciency presented as low gonadotrophines contrasted with normal level of testosterone. This was related to a 39 years old patient consulted for male infertility. Clinical exam was normal, including a normal level of blood tension. Liquid chromatography–tandem mass spectrometry revealed a high serum progesterone level, high 17-hydroxyprogesterone (17OHP) (262 ng/ml), and high levels of 17OHP metabolites, suggesting a classic form of 21OHD. Genetic exam has found heterozygoty with triple mutation of CYP21A2 gene including two forms of classical 21 hydroxylase defisciency. CT scann revealed a bilateral non nodular adrenal hyperplasia. Our case report illustrates the fact that a classic form of 21OHD can be diagnosed in late adulthood, manifested by hypogonadotropic hypogonadism and azoospermia , associated with elevated 17OHP.

Spuriously high testosterone concentrations testosterone gel users: A marker for detection

Sophie Schaper[1], Chantal Wiepjes[1], Martin den Heijer[1], Carolien Beukhof[1] & Annemieke C Heijboer[2]
[1]Amsterdam UMC, Vrije Universiteit Amsterdam, Department of Endocrinology and Center of Expertise on Gender Dysphoria, Amsterdam, Netherlands; [2]Amsterdam UMC, locatie AMC, Endocrine Laboratory, Department of Clinical Chemistry, Amsterdam, Netherlands

Context
Contamination of collected blood samples by application of testosterone gel near the venipuncture site can cause spuriously elevated serum testosterone concentrations. Often this will be detected only in case of extreme discrepancies between lab result and clinical effects. Because in vitro testosterone cannot be metabolized as the testosterone *in vivo* we hypothesized that measuring estradiol, as a metabolite of testosterone after aromatizing, could give a biochemical clue for contamination.
Objective
To assess the prevalence of high serum testosterone-to-estradiol ratio in users of testosterone gel compared to users of long-acting testosterone injections (testosterone undecanoate, TU).
Design and Methods
In this study of the retrospective Amsterdam Cohort of Gender Dysphoria (ACOG) study, 474 trans men with testosterone (in nmol/l) and estradiol (in pmol/l) concentrations measured at least one year after oophorectomy, were included between 2004 and 2018. The proportion of trans men with a testosterone-to-estradiol ratio above the 97.5% percentile of the median of the TU injection users was measured in both groups. Both testosterone and estradiol were measured by or recalculated to LC-MS/MS. Logistic regression was used for statistical analysis.
Results
168 trans men (42 ± 13 years) using testosterone gel and 306 trans men (35 ± 12 years) using TU injections were included. The groups had a similar average BMI of 26 kg/m^2. The mean testosterone-to-estradiol ratio of the TU injection users was 0.29 nmol/l per pmol/l, the limit of the 97th percentile was 0.59. Of the testosterone gel users, 8.3% (95% CI 4.6–13.6%) had a testosterone-to-estradiol ratio above 0.59, vs 2.7% (95% CI 0.6–7.6%) in the TU injection users. The odds ratio (OR) for this difference was 3.3 (95% CI 0.9–11.8). Using a cut-off point of 0.60 (99th percentile) we found 13 samples (7.7%, 95% CI 4.2–12.9%) with a higher testosterone-to-estradiol ratio in the testosterone gel group and one (0.9% 95% CI 0.0–4.9%) in the TU group (OR 9.3, 95% CI 1.2–72.2).
Conclusion
Trans men using testosterone gel sometimes show a considerably increased testosterone-to-estradiol ratio compared to those using TU injections, probably caused by contamination at the phlebotomy site. However, the prevalence of such a high ratio is still quite low. We conclude that the testosterone-to-estradiol ratio can be used in clinical practice as a biochemical clue for contamination. Further studies might reveal whether measurements of other testosterone metabolites might improve the detection of spurious elevations.

49, XXXXY syndrome associated with diabetes mellitus with insulin resistance, delayed neurocognitive behaviour, abnormal stature, and osseous deformity- a rare case

Kishore Behera[1], Ranjan Jena[2], Suprava Naik[2,3], Shree Mishra[2,4]
[1]All India Institute of Medical Sciences, Endocrinology, Bhubaneswar, India; [2]All India Institute of Medical Sciences, Neurosurgery, Bhubaneswar, India; [3]All India Institute of Medical Sciences, Radiodiagnosis, Bhubaneswar, India; [4]All India Institute of Medical Sciences, Psychiatry, Bhubaneswar, India

Back ground
49, XXXXY syndrome is a rare defect of sex chromosomes frequently considered as a variant of Klinefelter syndrome. It is often associated with more severe dysmorphic features, hypogonadism, mental retardation, musculoskeletal abnormality, and rarely with diabetes mellitus due to insulin resistance.
The goal: To describe clinical, biochemical, hormonal, radiological and developmental status of the patient with 49, XXXXY karyotype.
Report of the patient
22 years old male referred because of tall stature, sexual perversion with underdeveloped genitalia and poor scholastic performance. The patient was born by caesarean section, weight 2500 g, no history of hypoglycaemia or jaundice. He had delayed mile stone of development. He had normal height as per his fellow peer till the age of 15 yrs followed by rapid increase in height after that.
Physical examination
Revealed acanthosis nigricans with skin tag. Height 180 cm, Weight–80 Kg, BMI 24.7 height/m^2 with Arm Span of 183 cm, B/l, Testis of 2 ml size and Stretched Penile Length–6 cm, tanner stage 1, mid parental height - 164.75 cm, Upper Segment–80 cm, Lower Segment–100 cm with US: LS ratio 0.8. There was broad forehead and nasal bridge, hypertelorism, epicanthic folds, low set ears, pes cavus , deformity of left elbow joint , genu valgum ,clinodactyly, small 4th,5th toes.Psycho-cognitive development was retarded. Binet Kamat test of intelligence showed IQ of 45 (moderate mental retardation), behavioural problems with articulation difficulties. A chromosome study revealed the 49, XXXXY karyotype.
On radiographic examination
X-rays -hand and wrist- Delayed bone age with incomplete closure of growth plate. MRI of cranio-vertebral junction showed increased Atlanta-dental interval, suggestive of Atlanta-axial instability.
Biochemical tests
Metabolically, he had insulin Resistance, with fasting insulin 65.29 m U/l & FBS–112 mg/dl with HOMA-IR score of 18.1. His FBS 126 mg^5, PPBS 145 mg% with A1c 8.1%. Serum testosterone was 14.8ng/dl, LH 17.86 mIU/ml, FSH 19.79 indicating hypergonadotropic hypogonadism.
Medical advice
He was stared metformin 500 mg twice daily with life style modification in the form of diet and exercise. Testosterone injection 100 mg im was started. A clinical psychologist consultation was taken for behavioural therapy and parental counselling.
Conclusion
Patient with 49, XXXXY karyotype needs proper hormonal, psychiatric, appropriate skeletal, and cardiological evaluation. Early detection of deficit allows starting early intervention, parallel to behavioural and cognitive therapy, to support adequate management of this syndromic subject.

C173R and R273W mutations but not P108L in growth hormone secretagogue receptor 1a (GHSR1a) gene may cause short stature in Pakistani children

Nighat Kausar[1], Maleeha Akram[1], Gulbin Shahid[2], Afzaal Ahmed Naseem[1,3], Mazhar Qayyum[1], Fahim Tahir[4], Sarwat Jahan[5], Kiran Afshan[5] & Syed Shakeel Raza Rizvi[1]
[1]Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Department of Zoology/Biology, Rawalpindi, Pakistan; [2]Pakistan Institute of Medical Sciences (PIMS), Islamabad, The Children's Hospital, Islamabad, Pakistan; [3]University of Lahore, Islamabad Campus, Islamabad, Institute of Diet and Nutritional Sciences, Islamabad, Pakistan; [4]National Institute of Health, Islamabad, Reproductive Physiology, Public Health Laboratories Division, Islamabad, Pakistan; [5]Quaid-i-Azam University, Department of Animal Sciences, Islamabad, Pakistan

The combined physiological effects of somatotropic and gonadal axes have been demonstrated to cause acceleration in linear growth at puberty. In synergy, growth hormone (GH) and gonadal steroids (testosterone [T] and estradiol [E2]) stimulate longitudinal bone growth through direct stimulation of chondrocytes and osteoblasts. Amongst others, the secretion of GH is stimulated by ghrelin through its receptor called GH secretagogue receptor 1a (GHSR1a). Ghrelin is a peptide secreted by gastrointestinal mucosa of the digestive system. Ghrelin/GHSR1a system plays important roles in multiple physiological processes, especially in GH secretion and appetite regulation. The GHSR1a locus is one of the top sites suggested to contribute to the genetic variation of height. Therefore, the present study was designed to determine the association between GHSR1a variants and short stature in Pakistani population. Three SNPs, C173R, R273W and P108L in GHSR1a gene, were examined. Blood samples were obtained from 35 short stature patients (21 boys and 14 girls) exhibiting short stature and decreased appetite and 30 normal healthy controls. DNA was extracted, primers of exons of GHSR1a splice sites were designed and PCR-RFLP method was employed. The PCR product of GHSR1a digested by enzyme PstI for C173R mutation gave bands of two different genotypes, normal TT (381 and 155 bp) in 14 short stature boys and 7 short stature girls and heterozygous

TC (536, 381 and 155 bp) in 7 short stature boys and 7 short stature girls. All the controls gave normal TT genotype for C173R SNP. Furthermore, the PCR product of GHSR1a digested by enzyme PvuII for R273W mutation gave bands of two different genotypes, normal AA (144 and 32 bp) in 12 short stature boys and 9 short stature girls and heterozygous AT (176, 144 and 32 bp) in 9 short stature boys and 5 short stature girls. All the controls gave normal AA genotype for R273W SNP. On the other hand, the PCR product of GHSR1a digested by enzyme HeaIII for P108L mutation gave bands of CC (155 and 24 bp). The frequency of this genotype was 100% in controls and short stature children indicating absence of P108L mutation in both groups. In conclusion, C173R and R273W SNPs of GHSR1a gene might be associated with short stature in Pakistani population.

Long-term reproductive and behavioral effects of low dose bisphenol A introduction to rats during late gestation on F1 offspring

Oksana Faliush, Olga Sachynska, Anna Lymareva, & Alexander Reznikov
VP Komisarenko Institute of Endocrinology and Metabolism, National Academy of Medical Sciences of Ukraine, Dept. of Endocrinology of Reproduction and Adaptation, Kyiv, Ukraine

One of the most common environmental endocrine disruptor is bisphenol A (BPA), which mimics estrogen effects. Even at low expositional dose, BPA is capable of transferring across the human placenta in active unconjugated form. The purpose of this work was to investigate the long-term effects of low dose BPA introduction to rats during the critical period of sexual differentiation of the brain on the reproductive system and the behavior of F1 offspring. Wistar dams were exposed from 15 to 21 gestational day to BPA (by gavage, 25 μg/kg bw/day), or a reference estrogen (s/c, 10 μg estradiol diacetate (E2D)/kg bw/day), or were intact. The morphology of the reproductive organs and the male and female types sexual behavior were studied in adult offspring of both sexes. In males, BPA did not change the weight of testes, accessory sex glands, morphology of testicles and ventral prostate (VP), the number of sperm in the epididymis and the blood plasma levels of testosterone (T) and estradiol (E2) compared with intact males. However, almost complete inhibition of the copulatory components of male sexual behavior was observed. BPA-exposed males primed with E2 and progesterone showed pronounced lordosis behavior in the presence of a sexually active male. Prenatal E2D caused significant loss of the VP weight and degenerative changes in the epithelium of the VP. Males of the E2D group showed enhanced sexual motivation and copulatory behaviors on the background of significantly increased level of T. Besides, these males demonstrated active female and homosexual sexual behavior in the presence of sexually active male. None of the drugs affected the structure and duration of estrous cycle. The blood plasma E2 levels in the females of both groups were reduced. BPA caused degeneration of the follicular epithelium in part of the secondary and tertiary ovarian follicles with no changes in the number of follicles. Either prenatal BPA or E2D affected female type sexual behavior of female offspring. Female ♂ BPA and E2D groups exhibited male sexual behavior (5 from 5 and 4 from 5 animals respectively). We concluded that prenatal exposure to BPA at a dose below the currently acceptable human daily intake violates sexual differentiation of developing brain.

Novel Mutations in Human Luteinizing Hormone Beta Subunit Related to Polycystic Ovary Syndrome among Sudanese Women

Nidal Essa[1], Rashid Abdalla Rashid Abdalla[2] & Salaheldein Elzaki Salaheldein Elzaki[3]
[1]University of Medical Sciences and Technology, Clinical Chemistry , Khartoum, Sudan; [2]Alahfad University , Pharamacy, Sudan; [3]National Centre for Research, Department of Epidemiology, Sudan

Introduction
Polycystic ovary syndrome (PCOS) is a common disorder that is not fully understood. Multiple hormonal and metabolic factors impact on disease pathophysiology resulting in various phenotypic characteristics among the PCOS population. Luteinizing hormone beta subunit (LHβ) (protein ID P01229) is mapped on (chr19p13.3) and consists of three exons. It is specific beta (β) subunit giving to LH from the anterior pituitary its specific function. LH has a central role in stimulation ovarian steroidogenesis, in particular androgen production, and the promotion of ovulation.
Objectives
To determine the biochemical changes and the genetic mutations associated with PCOS among Sudanese families.
Methods
A prospective laboratory based cross-sectional study to examine genetic mutations in LHβ that associated with PCOS in families (cases; n= (35) families, (90) females and controls; *n* = (11) families, (30) females in Khartoum State, Sudan. Quantitative Enzyme Linked Immuno-Sorbent Assay (ELISA), enzymatic methods and polymerase chain reaction (PCR) used to analyze both the biochemical parameters and polymorphism detection followed by Sanger sequencing for genotyping in addition to bioinformatics software for protein structure and function.
Results
Investigation of the biochemical parameters of PCOS cases revealed significant increase with (*P*-value <0.001) in LH, testosterone, total cholesterol (mmol/l) and LDL (mmol/l) as compared to control. While fasting glucose (mmol/l), insulin (ng/dl); triglycerides (mmol/l) and HDL (mmol/l) were statistically significant (*P*-value <0.02); (*P*-value <0.012); (*P* < 0.001); (*P*-value < 0.03) respectively. There were no differences in FSH (ng/dl): (*P* = 0.984) and prolactin (ng/dl): (*P*-value = 0.068) when compared to control group. Sanger sequencing revealed five SNPs (rs5030775, A18T (AA); rs746167425, R22K (AA); rs1800447, W28R (CC); rs35270001, H30R (A/G); and rs34349826, I35T (CC)) located on (exon 2) of LHβ gene that were statistically correlated with serum LH, testosterone and insulin levels among PCOS families.
Conclusion
Based on these findings, it can be concluded that there is a genetic inheritance mode of PCOS within the Sudanese families, and a direct relationship between PCOS and infertility problems, dyslipidemia, and insulin resistance among PCOS population.

Keywords: PCOS, Luteinizing hormone, SNPs, infertility.

Triple-X syndrome as a cause of primary ovarian insufficiency

Catarina Cidade-Rodrigues, Catarina Chaves, Mariana Martinho, Filipe Cunha & Margarida Almeida
Centro Hospitalar do Tâmega e Sousa, Portugal

Introduction
Primary ovarian insufficiency (POI) occurs in 1% of women between puberty and 40 years old. Despite being idiopathic in 74–90% of the cases, there are other etiologies, such as genetic causes (in up to 16% of cases). Triple-X syndrome (TXS) is a common (estimated incidence of 1/1000 women) but frequently undiagnosed chromosomal abnormality. Most women are phenotypically normal, despite this fact, POI can still develop. We present a case of a woman with POI caused by a mosaicism 46XX/47XXX.
Case report
Female, 40 years old, with past medical history of idiopathic pulmonary thromboembolism, treated with apixaban. Gynecological history: 1G/1P, dystocic delivery, menarche at 11 years-old and menstrual cycles with duration of 28 days. Family history: maternal grandmother with early menopause and a paternal aunt with cognitive deficit. She presented with secondary amenorrhea, along with vasomotor symptoms, asthenia, insomnia, and headache. She had no history of previous menstrual irregularities, hirsutism, acne, alopecia, vaginal dryness, reduction of libido, visual impairment, or nipple secretion. In the physical examination, she had a body mass index of 31.6 kg/m^2, no signs of vitiligo, acanthosis nigricans, ecchymoses, moon face, buffalo hump, striae, or galactorrhoea. She also had no hypotonia, clinodactyly, scoliosis or known genitourinary anomalies. Her blood work showed: estradiol 172 pg/ml, FSH 47.9 mUI/ml, LH 53.7 mUI/ml, total testosterone 0.6 ng/ml, sDHEA 241 μg/dl, androstenedione 2.67 ng/ml, 17-OH-Progesterone 1.8 ng/ml, prolactin 12.0 ng/ml, free urinary cortisol 171.6 μg/day, TSH 2.05 μUI/ml and negative 21-hydroxylase antibodies. Bone densitometry had no evidence of osteoporosis. Karyotyping revealed a mosaicism 47, XXX[8]/46, XX[46]. She was diagnosed with POI secondary to TXS and was supplemented with calcium and vitamin D. She was not treated with oestrogen given the history of pulmonary thromboembolism, absence of osteoporosis and tolerance to the vasomotor symptoms.
Discussion
Although most POI cases are idiopathic, it is important to consider and investigate other etiologies, even in the absence of phenotypic traits.

This patient did not show any phenotypic trait suggesting chromosomal aneuploidies and the reason for this might be due to the fact that only some cells presented this abnormality. Nevertheless, women with 47, XXX karyotype can be phenotypically normal. To the best of our knowledge, these women are not at risk of having children who carry a chromosomal abnormality.

AEP598

Successful twin delivery in a patient with partial 46,XY gonadal dysgenesis

Kristina Semeniene[1], Ruta Navardauskaite[2] & Romualdas Tomas Preiksa[2]
[1]Lithuanian University of Health Sciences, Medical Academy, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Institute of Endocrinology, Lithuania

Introduction
Partial gonadal dysgenesis (PGD) is one of the rare 46,XY disorders of sex development (DSD), associated with variable degrees of impaired testicular development and function. Phenotypic appearance is related to the level of functional testicular hormones. Usually PGD is diagnosed in infancy because of significant genital anomaly at birth, however, spontaneous puberty is seen in up to 57% of all 46,XY PGD cases. Bilateral gonadectomy is performed in order to avoid malignancy and insufficient function of gonads, which leads to infertility. We are presenting a patient with diagnosed PGD in puberty and successful twin delivery after in vitro fertilization (IVF).
A case.
A 16-year-old female was referred to the pediatric endocrinologist due to primary amenorrhea. The patient's height was 180 cm (SDS: +2.12), weight 62 kg, BMI 19.1 kg/m^2 (SDS: –0.63), puberty development B_4P_4 Tanner stage. The ultrasound examination of minor pelvis revealed the uterus matched to a 12–13-year-old and ovaries of normal volume without follicles. The patient's FSH was 130 U/l, LH 35.6 U/l (NR 4.5–11 and 1.7–13.3 respectively), estradiol 72 pmol/l (NR 55–368), testosterone 2.1 nmol/l (NR 0.38–2.74) and prolactin 120 mU/l (NR 57–418). Human Chorionic Gonadotropin (*hCG*) stimulation test was negative. According to karyotype of peripheral lymphocytes, 46,XY DSD was diagnosed with suspected complete gonadal dysgenesis followed by laparoscopic bilateral gonadectomy. A histological analysis revealed Sertoli-like cells, a small amount of Leydig cells in the stroma with fine, round nuclei and eosinophilic cytoplasm, and no primary follicles were found. A diagnosis of PGD was confirmed. The hormone replacement therapy (HRT) was prescribed. At the age of 24 the patient underwent IVF using her cousin's donor oocytes and became pregnant with twins. The pregnancy was supported with exogenously administered hormones for the first trimester. The course of pregnancy was complicated: severe hypertension and pre-eclampsia developed (severe hypoalbuminemia with the need of albumin transfusions, pericardial effusion), one of the twins appeared in breech position. The fetuses underwent lung maturation with dexamethasone. During C-section at 29 gestational weeks, male twins weighing 1351 g and 1448 g and the APGAR score of 8 were delivered. The postnatal period was fluent.
Conclusion
The clinical case represents a rare, very phenotypically expressed and late diagnosed partial gonadal dysgenesis. As in most DSD cases, the patient's pregnancy after IVF was associated with complications, however, a successful delivery of twins was achieved.

Polycystic ovary syndrome, subclinical inflammation, DPP4 and the impact of a progestin test

Lisa Emmer[1], Susanne Weber[2], Olga Sydorivska[1], Peter Luppa[2] & Vanadin Seifert-Klauss[1]
[1]Technische Universität München, Fakultät für Medizin, Klinikum rechts der Isar , Klinik und Poliklinik für Frauenheilkunde , München, Germany; [2]Technische Universität München, Fakultät für Medizin, Klinikum rechts der Isar , Institut für Klinische Chemie und Pathobiochemie , München, Germany

Introduction
Women with PCOS frequently exhibit impaired insulin sensitivity. Low-grade chronic inflammation has been associated with insulin resistance and type 2 diabetes. DPP4, also known as CD26 (T-cell activation antigen CD26) is a prolin-specific serin-exopeptidase. With its binding partner ADA (Adenosine Deaminase complexing Protein) it cleaves numerous chemokines, mitogens, neuropeptides and peptide hormones and thereby influences metabolism, immune and endocrine system as well as cell adhesion and tumor growth. Previous publications found 6–7% higher activity of DPP4 in PCOS vs non-PCOS patients, and an influence of androgens on DPP4 transcription. Since progesterone is considered to possess anti-inflammatory effects, whereas estradiol promotes inflammation, we examined progestin effects on DPP4 and other markers of inflammation and insulin resistance.
Methods
315 patients with PCOS or ovulatory dysfunction with hyperandrogenemia in the gynecological endocrinology unit at the Technical University of Munich (TUM) were invited to participate in a prospective observational study on the effects of a standardised progestin test on hormone levels and markers associated with inflammation in serum. Women with menstrual cycle lengths ≥50 days, severe obesity (BMI >36 kg/m^2) and other endocrine or metabolic disorders were excluded from the study. Participants aged 18–45 years, without steroid treatment for at least 4 months prior to entry are monitored for five visits in three consecutive cycles. At baseline, medical history, waist-to-hip ratio, ovarian morphology and serum samples are taken in the early follicular phase of the cycle, before the participants take 10 mg dydrogesterone for 14 days (progestin test). Serum samples are drawn at four predefined time points (day 10–12 of the gestagen test, day 3–7 and 19–26 of the second cycle, day 3–7 of the third cycle). The analytes in the serum samples include CRP, progesterone, estradiol, LH, FSH, prolactin, testosterone, DHEAS and SHBG as well as proteins associated with hormones and inflammation, i.e., adropin, progesterone-induced blocking factor (PIBF) and dipeptidyl peptidase 4 (DPP4).
Results
Out of the 315 patients, only 60 met the criteria for entering the study. Early results show a significant PIBF increase with higher progesterone levels both with endogenous and exogenous progestin, while limited effects on adropin or DPP4 were found so far. DPP4 levels showed strong inter-individual variations, DPP4 concentrations and activity showed a linear correlation. 65% of the CRP values were lower than ≤ 0.1 mg/dl.
Discussion
We found no increase of DPP4 concentrations or activity attributable to progestins.

Assisted Reproductive Technology (ART) Success Rate Among Obese And Non-Obese Women, With Infertility Associated With Polycystic Ovary Syndrome (PCOS)

Carolina Chaves[1], José Luís Metello[2], Pedro Ferreira[2] & Isabel Simões Reis[2]
[1]Hospital Divino Espirito Santo, Division of Endocrinology and Nutrition, Ponta Delgada, Azores, Portugal; [2]Hospital Garcia de Orta, CIRMA (Center of Infertility and Assisted Reproductive Medicine), Almada, Portugal

Introduction
Previous studies in women with idiopathic infertility have shown that obesity does not independently contribute to the decrease in the success of assisted reproductive technology (ART) techniques. However, few studies evaluated the success rate of ART between obese and non-obese women in infertility associated with PCOS.
Objective
To compare the number of oocytes, mature oocytes, number of embryos and the rate of live births (LB), between obese and non-obese women with PCOS after an *In Vitro* Fertilization (IVF)/Intracytoplasmic Injection (ICSI) cycle.
Material and methodology
Retrospective study of all cycles of IVF/ICSI performed at our institution between 2012 and 2018. All women with PCOS-associated infertility were included. Only cycles with a live birth delivery after 24 weeks, or cycles with no surplus embryos left were considered. The participants were stratified by Body Mass Index (BMI) and the group of Obese/Overweight women (BMI ńł25 kg/m^2) was compared with the group with Normal/low Weight (BMI ń 24.9 kg/m^2).
Results
We analyzed 49 cycles. The median infertility duration was 48 months (min-max:10–144). Median age was 33 years (min-max: 21–39) and median BMI was 26.7 kg/m^2 (min-max:17–37). Median Anti-Mullerian Hormone (AMH) was 7.5 ng/ml (min-max: 2.2–18) and median antral follicle count was 30

(min-max: 4–50). In 47% (n = 23) of couples a LB was obtained. After stratification by weight, 61.2% of women were Obese/Overweight (n = 30) and 38.8% (n = 19) were Normal/low Weight. There were no differences between the two groups regarding median age (Obese/Overweight vs Normal/low Weight: 33.5 years, min-max: 21–39 vs 32, min-max: 26–39; P = 0.741), infertility duration (48 months, min-max: 24–144 vs 53, min-max: 10–120; P = 0.071, AMH (7.5, min-max: 2.9–18 vs 6.9, min-max: 2.2–15.7; P = 0.87), or antral follicle count 30, min-max: 13–50 vs 30, min-max: 4–50; P = 0.326). Regarding the results of ART techniques, Obese/Overweight women had a non-significantly higher percentage of newborns, compared to women with Normal/low Weight (50% vs 42%, P = 0.06). We also found no differences between the median number of oocyte (Obese/Overweight Vs Normal/low Weight: 15, min-max: 1–39 vs 13 min-max 1–48; P = 0.35), mature oocyte (12, min-max: 0–35 vs 11, min-max:1–45; P = 0.85) and obtained embryos (8, min-max: 0–24 vs 6, min-max:0–32; P = 0.62).

Conclusion

In PCOS, overweight/obesity does not seem to be a limiting factor of the success rate of ART. Other parameters are probably more important, such as age.

Hearing abnormalities in Turner patients

Nisrine Bouichrat[1], Messaoudi Najoua[1], Marouan Karrou[1], Ikram Mahroug[1], Siham Rouf[1] & Hanane Latrech[1]
[1]Mohamed VI University Hospital Center, Oujda, Department of Endocrinology-Diabetology and Nutrition, Oujda, Morocco

Introduction

Turner Syndrome is a relatively rare genetic disorder related to the total or partial absence of an X chromosome. Its clinical presentation is very heterogeneous. It can be associated with several organic abnormalities, including hearing disorders. The objective of our work is to study the prevalence of otologic abnormalities in our Turner patients.

Material and method

This is a retrospective descriptive study involving 17 patients followed for Turner syndrome in the Endocrinology-Diabetology and Nutrition Department of the Mohammed VI University Hospital Center of Oujda, Morocco. All patients were evaluated by otologic examination and audiometry.

Results

The mean age of diagnosis was 16.4 ± 12.4 years [3–41 years]. Thirty-five percent of patients were diagnosed in adulthood. The reason for consultation was dominated by short stature in 47% of cases. Twenty three percent of patients had recurring ear infections. One patient had an atelectasic otitis with a focal tympanosclerosis benefiting of a trans-tympanic ventilator. The examination found low ear implantation in 76.4% of the cases with detached ears in 29.4%. Conductive hearing loss was reported in 23.5% of cases, and mixed hearing loss in 11.7%. These otologic abnormalities were present in 55.5% of cases in patients with X monosomy, in 44.4% of cases in patients with mosaic of which 22.2% had an Xi isochromosome.

Discussion-conclusion

Otologic abnormalities are common in Turnerian patients, especially those with X monosomy. Sometimes patients may be clinically asymptomatic; therefore, screening at diagnosis and regular long term monitoring are recommended to detect middle ear disease and avoid its consequences.

Syndromic premature ovarian insufficiency: report of 2 cases with blepharophimosis-ptosis-epicanthus inversus syndrome type 1

Lilia Kraoua[1], Hana Fredj[1], Cyrine Adhoum[1], Ahlem Achour[1], Faouzi Maazoul[1], Mediha Trabelsi[1] & Ridha Mrad[1]
[1]Charles Nicolle Hospital, Department of Congenital and Hereditary Diseases, Tunis, Tunisia

Introduction

Premature ovarian insufficiency (POI) is defined by menstrual disturbance (oligomenorrhea or amenorrhea) before 40 years and confirmed by two FSH levels in the menopausal range, obtained at least a month apart. Some POI cases are syndromic such as Turner's syndrome or Blepharophimosis–Ptosis–Epicanthus inversus Syndrome type 1 (BPES). BPES type 1 (MIM: 110100) is a rare autosomal dominant syndrome caused by mutations in *FOXL2, a* gene involved in folliculogenesis.

Objective

Here we report two cases with confirmed BPES type 1 collected at the outpatient clinic of the genetic department at Charles Nicolle Hospital in Tunis.

Cases presentation

The patients were referred to genetic consultation for oligomenorrhea and facial dysmorphism. The first case was familial including two affected sisters aged 32 and 38. The second case, a 31 year-old woman, was sporadic. All patients had normal intelligence. Clinical examination of the three patients showed eye abnormalities with blepharophimosis, ptosis and epicanthus inversus, normal secondary sex characteristics, and normal growth. The hormonal tests showed high FSH levels. Their karyotypes were normal: 46, XX. Based on clinical findings, the diagnosis of BPES type 1 was strongly suspected. Direct sequencing of *FOXL2* gene showed the presence of a previously reported mutation NM_023067.3:c.655C>T; p. (Gln219*), confirming the diagnosis of BPES.

Conclusion

In case of POI, a careful clinical examination is recommended to look for syndromic causes such as BPES syndrome type1 easily recognizable on the ocular abnormalities, so that appropriate management and adequate genetic counseling could be done.

Swyer Syndrome, 46,XY complete gonadal dysgenesis in a patient with spontaneous menarche

Dana Larisa Geru[1], Alina Maria Dumitru[2], Georgiana Cristina Taujan[3] & Adina Simona Dragomir[1]
[1]C.I. Parhon National Institute of Endocrinology, Infertility and Gonadal Pathology, Bucharest, Romania; [2]C.I. Parhon National Institute of Endocrinology, Adrenal and Bone Metabolism, Bucharest, Romania; [3]Centre Hospitalier Universitaire Brugmann, Brussels, Belgium

46,XY complete gonadal dysgenesis, also known as Swyer Syndrome, is characterized by the presence of normal female external genitalia at birth, late puberty and primary amenorrhea. Spontaneous menses (due to hormone-secreting tumor) and breasts development occur in rare cases. With proper hormonal substitution, patients could carry pregnancies achieved through IVF with donor oocytes.

Case presentation

Female patient, aged 22, addresses endocrinology specialist for a routine examination. She mentions having first menses when she was 14, with spontaneous menses for the next 5 years followed by secondary amenorrhea, for which she started estroprogestative substitution after medical recommendation, resulting in regular menstrual cycles and normal breast development. She came to our clinic for amenorrhea after stopping the hormone substitution therapy. Clinical investigations contributed to the diagnosis of hypergonadotropic hypogonadism, with testosterone in normal range and low estradiol. A karyotype test was performed with the result of 46,XY genotype without structural or numerical abnormalities. FISH testing revealed the presence of SRY, DXZ1 and DYZ1, therefore, the patient was advised to seek further genetic analysis. MRI showed Mullerian structures, infantile uterus with Fallopian tubes but instead of gonads, fibrotic bands could be seen. Considering the risk of developing a gonadoblastoma or even a dysgerminoma in a patient with Disorders of Sexual Development, the patient was advised to present to the Surgical Department to undergo exploratory laparotomy and resection of dysgenetic gonads, followed by estroprogestative substitution. Histopathological examination and immunohistochemistry analysis revealed that one of the dysgenetic gonad was a dysgerminoma with Ki67 positive in 17% of tumor cells, and the other one was a testes having Wolffian and Mullerian structures with no tumor characteristics.

Hyperthyroidism on molar pregnancy about a case

Charlene Ludwine Bifoume Ndong[1], Farah Elgharroudi[1], Dandou Ange[2], Sana Rafi[1], Ghizlane El Mghari[1], Nawal El Ansari[1] & El Adib Ahmed Ghassane[2]
[1]CHU Mohammed VI, Marrakech, Maroc, Endocrinologie, Metabolic Diseases and Nutrition, Marrakech, Morocco; [2]CHU Mohammed VI, Marrakech, Maroc, Maternity Resuscitation, Marrakech, Morocco

Introduction
Hyperthyroidism during pregnancy can be caused by an hydatiform mole in its partial or total form. The biochemical particularities between hcg (human corionic gonadotropin) and Tsh (thyreo-stimulating hormone) in gestational trophoblastic disease can explain the thyrostimulating effect in it. We report a case of hyperthyroidism on molar pregnancy through an observation.
Observation
Patient of 27 years old, with a history of an intrauterine fetal death 5 years ago, admitted for incoercible vomiting on pregnancy estimated at 11 weeks with partial hydatiform mole. At the examination agitated patient without exophthalmia. She presented tachycardia at 118 beats per minute, fine tremor of the extremities, and no goiter. Laboratory results showed a stunt TSH at 0.01 mui/ml; T4l: 28.3 pmol/l, T3:7.9 pmol/l, HCG 540984 or +1.9 N. An obstetrical echography conclude on uterus increased in size, fetus in flattened death, placenta abnormally large with snowflake image reminiscent of a partial mole. Thyroid echography was normal. EKG: sinus tachycardia at 120 bpm. The rest of the balance sheet is without particularities, in particular the Ac anti RTS and TPO. The management consisted in the initiation of carbimazol 30 mg/day and propanolol 40 mg/d to obtain euthyroidism before uterine extraction. At day 4 we had improved symptoms and biological euthyroidism with T4L at 13 pmol/l after uterine evacuation.
Discussion
Clinical hyperthyroidism is a common complication of a hydatiform mole, in our case presented by incoercible vomiting and tachycardia. The structural homology between the TSH and HCG subunits and between their receptors gives HCG a thyroid-stimulating action. The presence of intrauterine fetal death could be attributed to the direct effects of thyroid hormones on the fetus. The treatment of hyperthyroidism induced by hydatiform mole is an uterine evacuation although in our case we first particularly used ATS and blockers.
Conclusion
The diagnosis of hyperthyroidism secondary to hydatiform mole is retained before a low or undetectable TSH, T4l elevated after eliminating transient hyperthyroidism from the large ratio to term, TRACK negativity and cervical ultrasound without hypervascularization. This is a resolutive table after uterine extraction.

Primary amenorrhea due to hypogonadotropic hypogonadism

Rada Sparavalo[1] & Sanja Borozan[2]
[1]General hospital Niksic, Department of Endocrinology, Niksic, Montenegro; [2]Clinical Centre of Montenegro, Department of Endocrinology, Podgorica, Montenegro

A diagnosis of primary amenorrhea (PA) is always a clinical challenge. By definition, PA is a failure to reach menarche by age 14 with the absence of secondary sexual characteristics or absence of menses by age 16 years regardless of the development of secondary sexual characteristics. It may result from a number of different conditions and requires comprehensive evaluation to identify a cause, along with a regular patient follow-up. The aim of this case report is to emphasize the significance of early diagnosis accompanied with timely treatment in patients with hypogonadotropic hypogonadism (HH). A 21-year-old female was referred to endocrinologist due to PA and possible uterine agenesis. She was born prematurely at 36 week and soon diagnosed with strabismus and congenital cataract. Previously, her mother had two miscarriages. At physical examination, her weight was 70 kg, height 167 cm (BMI 25.1 kg/m^2), hair growth reduced, breasts Tanner stage I, pubic hair Tanner stage II and high-arched palate was present. Basal hormonal evaluation revealed low estrogen (E2 126 pm/l), low levels of gonadotropins (LH 0.00 mIU/l, FSH 0.07 IU/l) and total testosteron of 1.76 nmol/l. Levels of IGF-1, IGF BP3, thyroid hormones, prolactin, basal cortisol and androstenedione were all in reference range. Glucose tolerance was not impaired. Magnetic resonance imaging (MRI) showed normal anatomy and appearance of hypothalamic-pituitary region. Pelvic MRI revealed a hypoplastic uterus with uncertain ovarian demarcation (right ovary 16×8 mm, properly located). LHRH and Pregnyl tests were performed and, according to all data, a diagnosis of HH was established. Additional analysis included cytogenetics: 46XX with pericentric inversion of chromosome 9 (inv[9][p11q13]). The patient also underwent psychological assessment. A treatment with estrogens was initiated, followed by combined, estrogen-progesterone replacement. As a result, patient is now with regular menstrual cycles and further development of secondary sexual characteristics. In conclusion, the precise and early diagnosis of HH along with appropriate replacement therapy can restore fertility in affected patients, preserve normal bone mineral density and prevent negative physical and psychological sequelae.

Translation of OAT syndrome infertility into normozoospermia after short duration testosteron therapy – case report

Dragan Tesic[1], Dragica Andric[2], Mirjana Tomic[3] & Pavle Pantelinac[1]
[1]Clinics of Internal Diseases, Clinic of Endocrinology, Diabetes and Metabolic Disorders, Novi Sad, Serbia; [2]Institut for Cardiovascular Diseases, Clinic of Cardiology, Sremska Kamenica, Serbia; [3]Clinics of Internal Diseases, Clinic of Hematology, Novi Sad, Serbia

Introduction
Infertility associated with hypergonadotropism is usually an unpromising condition related to acheiving fertilization. We describe the patient presented as oligoasthenoteratozoospermia (OAT syndrome), with laboratory primary hypergonadotropic hypogonadism but normal male fenotype, including typical male hair dustribution.
Case description
male, born 41 year ago, presented when he was 29 year old, as infertility with oligozoospespermia of sperm count of 0.2–0.4×0^6/semen volume, total motility of 14%, testosteron without Clomifen stimulation 9–11.5 nmol/l, FSH 11.8–18 mIU/ml, LH 6.8–9.1 mIU/ml, regularly on Profertil® therapy. When he was 35 year old he gave his consent for gonadotropin supression therapy with testosteron depo preparation od 125 mg im per 2 weeks. After 4 months od such a therapy his FSH was 2.1 and LH 0.1 mIU/ml, and as expected azoospermia. We discontinued testosteron therapy and after 1 year he came with FSH 11.4 mIU/ml, sperm count of 36.5×10^6/semen volume. After that time he has intermitently been on Clomifen and Profertil therapy, and sperm parameters more or less in normal ranges. His testosteron values has been in low values, when without Clomofen stimulation. In 2019 year for the first time we measured several times dihitrotestosteron levels which was always in normal ranges 454–785 ng/ml (referent 250–990) while testosteron was low 5.68–10.19 nmol/l.
Discussion
The aim of this case report is to emphasize the constelation of low testosteron levels and normal dihidrotestosteron in patient with normal male habitus but initialy with OAT syndroma. Although at the moment we have not been maesured precursors of testosteron and dihidrotestosteron we are in thinking about the so called ''backdoor'' pathway of androgen synthesis, until this time described only in animals and considered in human male development.

AEP607

Analysing by decade, testosterone undecanoat depot injectable does not increases prostate volume. Study during up to 13 years on hypogonadic patients. (January 2021)

Dan Peretianu[1], Matei Pisoschi[2], Mihaela Stanciu[3] & Bogdan Oprisan[4]
[1]Medical Center Povernei, Endocrinology, Bucharest, Romania; [2]CF2 Hospital, Urology, Bucharest, Romania; [3]Faculty of Medicine ''Victor Papilian'', Endocrinology, Sibiu, Romania; [4]Faculty of Medicine ''Gr. T. Popa'', Department of Byophysics and Physical Medicine, Iassi, Romania

Aim
Re-Analysing (starting 2007) the effect of injectable testosterone undecanoat depot (TUD) in hypogonadic patients.
Material-method
A. Patients: at onset 333 men with hypogonadism (median: 62 y).
B. Distribution: by decade (starting with 20y->90y); no = 6, 18, 35, 80, 104, 67, 21, 2.
C. TUD (Nebido^R-Bayer) 1000 mg injected one/3 months i.m.
D. Prostate volume (PV) by per-abdominal ultrasound: 3.5–5 MHz probe, elliptical/3D (cm^3).
E. Analysis in time: before testosterone (T0 = 333), after ½ month (T1 = 332), 3m (T2 = 273), 6m (T3 = 212), 1y (T4 = 175), 2y (T5 = 121), 3y (T6 = 84), 4y (T7 = 66), 5y (T8 = 59), 6y (T9 = 50), 7y (T10 = 43), 8y (T11 = 34), 9y (T12 = 26), 10 y (T13 = 19), 11y (T14 = 11), 12y (T15 = 5), 13y (T16 = 3).
F. Maximum increment percent from T0 noted Δ**M**%. Average increment percent noted Δ**A**%.
G. Statistical analysis: Student test.

Results
I. A. Mean prostatic volume before testosterone increased by decade (significance vs 20y): 13.17; 16.83 (0.24,NS); 22.25 (P = 0.016); 29.54 (P = 0.0003); 36.19 (P = 0.000004); 40.53 (P = 0.0000002); 44.67 (P = 0.000003); 33.75 (P = 0.001). **B.** All average prostatic volume post testosterone by decade and time were tabulated (see pdf).
II. Maximum increment post testosterone (Δ M %) per decade: 54.76; 44.44; 56.41; 68.92; 53.85; 68.18; 54.55; 29.00.
III. The moment of ΔM% – per decade: T10; T5; T8; T8; T3; T7; T5; T2.
IV. Average increment (ΔA%) per decade: +4.69; −12.02; −14.75; −1.48; −13.33; −45.29; +14.69; +14.63.
V. Considering all observations, TUD did not increase PV significantly. **A.** The average of increment (%) in all patients was negative: −6.61%. **B.** Per decade significance vs beginning TUD was P = : 0.34; 0.12; 0.67; 0.29; 0.77; 0.98; 0.28; 0.17.
VI. In many patients, especially from 30 to 79 years, TUD could decrease slightly prostatic volume.
Comments
After 3 month, many patients give up treatment. At 1 year, around half patients withdraw. However, comparing with 2019 (Lyon) data, patient number increased by 16.22%. 19 patients were operated before starting testosterone, 4 patients were operated during treatment. 5 patients received the diagnosis of prostatic cancer; to them, TUD was administrated when PSA < 1, usually after 3 years anticancer treatment. Surprisingly, 16 patients died after withdrawing TUD at 2–3 years.
Conclusions
Considering the risk for prostate (in elderly), testosterone undecanoat 1000 mg depot injectable is a safe treatment, even after 13 years of administration. Precautions should be accorded to men over 80 y old, after the 5th year of administration. Under strict control, TUD could be administrated also in prostatic cancer.

DOI: 10.1530/endoabs.73.AEP607

AEP608

After up to 13 years observation, testosterone undecanoat 1000 mg at 3 months did not increased Prostatic Specific Antigen level. Relation with prostatic volume (January 2021)

Matei Pisoschi[1], Mihaela Stanciu[2], Dan Peretianu[3] & Bogdan Oprisan[4]
[1]CF2 Hospital, Urology, Bucharest, Romania; [2]Faculty of Medicine "Victor Papilian", Endocrinology, Sibiu, Romania; [3]Medical Center Povernei, Endocrinology, Bucharest, Romania; [4]Iassi faculty of Medicine "Gr. T. Popa", Department of Byophysics and Physical Medicine, Iassy, Romania

Aim
We appreciate the effect of testosterone undecanoat 1000 mg intramuscular injection (Nebido®; Bayer) on both prostatic volume (see Peretianu, this congress) and PSA (this study) in hypogonadic patients after up to 13 years.
Material and method
A. PSA (ng/ml) was done in Bucharest accredited laboratories, appreciated at 1 year. **B.** Prostatic volume (PV): ultrasound, 3–5 MHz, per abdominal, in 3D (cm3).
C. Statistical analysis: Student test, simple correlation, multiple regression.
Results
A. Patients at onset: 309 men, age: 18–96 years, average: 61.02 years; median: 62.
B. Prostatic volume: average: 33.05 cm3.
C. Average PSA (no patients): before treatment = 1.52 (309); 1y = 1.66 (164); 2y = 1.48 (113); 3y = 1.47 (82); 4y = 1.67 (65); 5y = 1.58 (59); 6y = 1.71 (47); 7y = 1.68 (44); 8y = 1.58 (35); 9y = 1.76 (23), 10y = 1.75 (19), 11y = 2.06 (11), 12y = 0.77 (decreased)(5), 13y = 0.7 (decreased)(3).
D. Statistical difference of PSA averages from T0 to 11y: nonsignificant: P = between 0.29–0.87. T0 v 12y P = 0.04, T0 v 13y P = 0.002.
E. Correlation between age and PSA was significant at: T0: r = 0.33; 1y: r = 0.2 and 8y P = 0.05; and nonsignificant in rest. Significance is depending on group size.
F. Correlation between PSA and prostatic volume was significant, both before and after treatment at 1, 2, 3, 5, 6, 8, 9, 10 years (depending on group size, r = 0.13–0.54).
G. Multiple regression test between PSA before/after treatment, prostatic volume before/after treatment and the age. Statistical significance: P values < 0.01 for all years (except 6y-NS and 13 y-non 5 patients). P << 0.05: R^2 = 0.28–0.82, F = 6.67–12.48.
Conclusions
1. Testosterone undecanoat 1000 mg injectable i.m. at 3 months did not increased PSA level after up to 13 years administrations.
2. Based on multiple regression data, PV & PSA post testosterone does not depend on testosterone administration but on the age and the PV before treatment and depend on the initial PSA level, i.e. before testosterone administration.
Comments
Since PV and PSA level did not depend on testosterone administration, but on age we thing that: a. there could be a therapeutic window for testosterone, considered before 80 years old, b. the moment of testosterone administration should depend on testosterone decreased slope, c. therefore, testosteronemia should be performed every year from 20 years old.

Premature ovarian insufficiency associated with a small supernumerary marker chromosome 15: a case report

Sawsen Essayeh[1,1], Lilia Kraoua[2], Sabrina Ayari[1], Zouaoui Chadia[1], Ridha Mrad[2] & Haroun Ouertani[1]
[1]The Military Hospital of Tunis, Endocrinology-Nutrition, Tunis, Tunisia; [2]Charles Nicolle Hospital, Genetics, Tunis, Tunisia

Introduction
Premature ovarian insufficiency (POI) is characterized by the loss of ovarian activity before the age of 40. It is associated with hypoestrogenism, raised gonadotrophins and oligomenorrhea or amenorrhea. POI is a heterogeneous disease that can result from different etiologies, including genetic, autoimmune, and iatrogenic. Of the genetic causes, single-gene mutations and chromosomal imbalances involving X chromosome or autosomes have been associated with POI. Here, we report a case of a 36-year-old patient with POI associated with a small supernumerary marker chromosome 15 (sSMC(15)).
Case presentation
A 36-year-old woman with normal intellect and no particular past medical history, had menarche at age of 13 followed by regular menses. She had no pregnancies before and she presented a secondary amenorrhea evolving for 8 years. The physical examination was unremarkable especially she had normal height, normal secondary sex characteristics, and no dysmorphic features. Hormonal tests revealed normal FT4, TSH, prolactin, elevated FSH in the menopausal range (82.43 mUI/ml) and AMH was too low at 0.04 ng/ml (reference: 0.03–7.15). Therefore, the diagnosis of premature ovarian was made and the patient was treated with hormone replacement therapy. Pelvic ultrasound demonstrated a normally placed and normally developed uterus and the ovaries were small without follicles. Her karyotype showed in 86% of metaphases analyzed the presence of a small supernumerary marker chromosome. Fluorescence in situ hybridization (FISH) showed the sSMC to be originating from chromosome 15, dicentric and most likely containing only heterochromatic material [mos 47,XX,+mar[39]/46,XX[6]. ish idic(15)(q11)(D15Z4++,SNRPN-)]. Parental karyotypes were normal confirming the *de novo* occurrence of the sSMC.
Conclusion
Several studies reported an increased incidence of sSMC(15) in infertile males, whereas in females, relationship between SMCs and infertility is still debated. Further precise molecular studies on sSMC are needed in the future to characterize the implication of sSMC in POI.

Assessment of glycemic variability using the FreeStyle Libre flash monitoring system in pregnant women with gestational diabetes mellitus

Fatima Ushanova[1], Tatyana Demidova[1] & Mariyam Izmailova[1]
[1]Pirogov Russian National Research Medical University, Department of Endocrinology, Moscow, Russian Federation

Background and aim
Early control of gestational diabetes mellitus (GDM) can reduce the likelihood of adverse maternal and fetal outcomes. Glycemic variability (GV) is a more accurate parameter for assessing the risk of developing diabetic complications than traditional parameters of assessing compensation. In most cases, diet therapy is used to treat GDM, meanwhile the glycemia in pregnant women with GDM should correspond to the glucose level in healthy pregnant women. The aim of our work was to compare biweekly

glycemic profiles and glucose variability in healthy pregnant women and pregnant women with GDM on diet therapy using the FreeStyle Libre flash monitor system.
Materials and methods
Analysis of the glycemic profile of 40 pregnant women aged 25.47 ± 5.83 using the FreeStyle Libre continuous monitoring system. Pregnant women were divided into 2 groups: 20 healthy pregnant women and 20 pregnant women with GDM on diet therapy. Each group was evaluated for ambulatory glucose profile monitoring over a two week period using the FreeStyle Libre system.
Results
Age and HbA1c levels were comparable in both groups, but body mass index (BMI) before pregnancy was higher in the GDM group (P = 0.026). Women with GDM had higher blood glucose levels than healthy pregnant women, but within the target range. In patients with GDM, who were compensated for carbohydrate metabolism during diet therapy, there was a low variability of glycemia according to standard indices. There were significant differences in mean glycemia and J-index, which characterizes the maximum peak of glycemia (Table 1).

Measures of Glucose Variability	Patient group		n	P
	GDM	Healthy pregnant women		
SD, mmol\l	0.911	0.884	0–3.0	0.61
CONGA	3.980	3.875	3.6–5.5	0.27
LI	1.450	1.256	0–4.7	0.28
J-index	10.291	9.564	4.7–23.6	<0.05
HBGI	0.647	0.762	0–7.7	0.54
LBGI	4.728	5.665	0–4.6	0.16
MOOD	0.963	0.935	0–3.5	0.64
MAGE	2.31	2.263	0–2.8	0.72
ADDR	3.007	1.935	0–8.7	0.27
M-value	7.677	10.088		0.14
Mean glucose	3.6	3.1		<0.02

Findings
In order to obtain more detailed information about the glycemic profile, especially when it is difficult to assess the degree of compensation for GDM, modern devices for Flash glycemic monitoring can be of great value. Continuous monitoring allows a more thorough assessment of the effects of GDM therapy, at the same time, further researches are required to assess the significance of these data.

Vitamin D and sex hormones levels in men of different ages

Oksana Khyzhnyak[1], Vladimir Bondarenko[1], Yevheniia Sanina[1], Roman Nikolaiev[1] & Iurii Karachentsev[1]
[1]V. Danilevsky' Institute of Endocrine Pathology Problems, Clinical Endocrinology, Kharkiv, Ukraine

Introduction
Vitamin D (VitD) is thought to be essential for adequate testosterone (T) secretion in men. In the absence of D-hypovitaminosis, their blood T levels and T to estradiol (E2) ratio values are higher relative to those with VitD deficiency. The correlation between VitD levels and androgenization indices in men of different ages has not been practically studied.
The aim
To study blood levels of T and the androgen-estrogen balance depending on the blood concentration of VitD in young and middle-aged men.
Material and methods
47 men aged 23–59 years were examined: 1 group – young males (32.3 ± 1.1) yrs, n = 20; 2 group – middle age (53.0 ± 1.0) yrs without Diabetes Mellitus Type2 (DM2), n = 15; 3 group – middle age (54.0 ± 1.1) yrs with DM2, n = 12. In all three groups, the mean values of body mass index (BMI) did not differ from each other. Blood levels of total T, E2, and 25-OH VitD were determined in the patients by enzyme immunoassay. VitD insufficiency and deficiency were established according to the Endocrine Society Clinical Practice Guideline (2011). The studies were performed in the fall-winter period of 2020-2021.
Statistical analysis
SPSS 19.0 statistical software (IBM Corp., Armonk NY, US) Student's t-test, χ^2 method and Pearson correlation (r).
Results
The mean values of blood VitD levels in young men were significantly higher than those of middle-aged individuals (P<0.05). At the same time, they did not differ between the patients with and without DM2. In middle-aged patients of both groups, there was a significant decrease in the average values of blood T and T/E2 values relative to young men. At the same time, the frequency of androgen deficiency was significantly higher in group 2 (χ^2 = 4.49; P <0.05) and in DM2 patients (χ^2 = 5.75; P<0.05) compared to young men. However, the incidence of D-hypovitaminosis (blood VitD levels < 30.0 ng/ml), was not significantly different in middle-aged individuals than in men in group 1. Meanwhile, there was found a positive correlation between the blood VitD level and the index of the relative androgenization – T/E2 values, (r = 0.321; P<0.05) in the general group of examined patients.
Conclusion
Blood VitD content in middle-aged men, regardless of the presence or absence of DM2, is significantly lower in comparison with young men. A decrease in the blood levels of VitD can be a predictor of androgen–estrogen imbalance in men regardless of age.

Keywords
Vitamin D, sex hormones, androgen–estrogen balance.

Central hypothyroidism during pregnancy in a woman with Graves' disease

Tanguy Faustine[1], Safouane Hamdi[2], Chikh Karim[3], Glinoer Daniel[4] & Philippe Caron[1]
[1]CHU Larrey, Toulouse, Endocrinology, Toulouse, France; [2]CHU Purpan, Biology, Toulouse, France; [3]Centre Hospitalier Lyon, Biology, Lyon, France; [4]CH Saint Pierre, Endocrinology, Bruxelles, Belgium

Introduction
During pregnancy, women with Graves' disease are at risk of maternal and fetal hyperthyroidism caused by stimulating TSH receptor antibody. Here we report the unusual case of a woman with recurrent Graves' disease who developed central hypothyroidism transiently during pregnancy.
Case report and results
A 26-year-old woman was treated by antithyroid drug for a third episode of hyperthyroidism due to Graves' disease. At the beginning of her second pregnancy, cervical palpation showed a large vascular goiter. Thiamazole treatment was stopped in the first week of gestation. During the 3rd month, hormonal monitoring revealed central hypothyroidism: TSH = 1 mU/l (0.27–4.3), fT4 = 0.67 ng/dl (0.81–1.32), fT3 = 2.37 ng/l (2.47–4.1), in presence of anti-TSH receptor antibodies (3.5 UI/l) with stimulating activity (+ 285%) and elevated hCG levels (153 656 UI/l). During the second half of gestation, substitutive levothyroxine treatment restored an euthyroid state. Furthermore, anti-TSH receptor antibodies titers decreased progressively and were undetectable at the end of the second trimester. The woman gave birth to a healthy euthyroid baby girl (3.2 kg) without goiter. During the postpartum period, she breastfed normally. Her anterior pituitary function was investigated and shown to be normal: spontaneous menstrual periods, anterior pituitary hormones within normal range and normal pituitary IRM at 6-month *post-partum*. During *post-partum* follow-up, levothyroxine treatment was progressively decreased and the patient eventually developed 'classical' recurrence of Graves' disease with thyrotoxicosis 8 months after delivery.
Conclusion
We report the first case of transient central hypothyroidism during pregnancy in a woman with recurrent episodes of Graves' disease. Despite the presence of anti-TSH receptor antibodies with stimulating activity detectable during the first two trimesters of pregnancy, we suggest, as a unifying hypothesis to explain this highly unusual clinical and biological pattern, that this woman secreted a variant hCG molecule that binds both to the TSH receptor on follicular thyroid cells and on the folliculo-stellate cells of the anterior pituitary with inhibiting activity resulting in central hypothyroidism.

Bone metabolism in PCOS – influence of progestins

Olga Sydorivska[1], Susanne Weber[2], Lisa Emmer[1], Peter Luppa[2] & Vanadin Seifert-Klauss[1]
[1]Technische Universität München, Fakultät für Medizin, Klinikum rechts der Isar, Klinik und Poliklinik für Frauenheilkunde, München, Germany; [2]Technische Universität München, Fakultät für Medizin, Klinikum rechts der Isar, Institut für Klinische Chemie und Pathobiochemie, München, Germany

Introduction
The polycystic ovary syndrome (PCOS) affects about 6–10% of women of reproductive age and is associated with oligomenorrhoea and anovulation. Recently, a possible impairment of bone accrual in women with PCOS due to the chronic inflammation disposition has been postulated [Kalyan, 2017]. The lack of progesterone due to anovulation may also have effects on bone metabolism [Seifert-Klauss, 2015]. A progestin test is a classic tool for assessing oligo- and amenorrhoea. The presented observational study monitors the effects of the progestin test for oligomenorrhoea on bone metabolism markers, LH and other hormones as well as ovulation rates in the following cycle.
Methods
60 premenopausal women (18–45 years), all pre-diagnosed with PCOS, without steroid treatment for at least 4 months are monitored for five visits in three consecutive cycles. Women with menstrual cycle lengths of ≥50 days, severe obesity (BMI >36 kg/m^2) and other endocrine diseases or metabolic disorders are excluded from the study. At baseline, medical history, hip and waist circumference, ovarian morphology and serum samples are taken in the early follicular phase of the cycle, before the participants take 10 mg dydrogesterone for 14 days for their progestin test. Serum samples are drawn at four defined follow-up time points (day 10–12 of the gestagen test, day 3–7 and day 19–26 of the following cycle as well as day 3–7 of the third cycle). Analytes determined in serum samples include CRP, progesterone, estradiol, LH, FSH, prolactin, testosterone, DHEAS and SHBG as well as the bone metabolism markers procollagen type I N-terminal propeptide, bone-specific alkaline phosphatase, osteocalcin, C-terminal collagen type I telopeptide and tartrate-resistant acidic phosphatase 5b.
Results
12 participants of the targeted 60 PCO-patients have completed the study to date. Whereas progesterone levels at day 3–7 of all cycles were below 0.4 ng/ml, 75% of the participants exceeded progesterone levels of 2 ng/ml during the progestin test (average 6.2 ± 3.6 ng/ml) and 42% at day 19–26 of the following cycle without exogenous progestin (average 12.7 ± 7.0 ng/ml). The luteal phase was missed in 3 patients (27%), who showed significantly elevated LH levels on the scheduled day of visit 4 (cycle days 22, 26 and 31), most likely due to delayed ovulation in the cycle following the progestin test. Bone metabolism parameters will be presented.
Discussion
This study systematically characterizes changes in bone metabolism which may be attributable to inflammation, ovulation vs. anovulation and/or progestin deficiency.

Peculiarities of cytokin levels in women with infertility living in iodine deficiency regions of Bukovina

Halyna Koval[1], Nataliia Pashkovska[1], Nataliia Abramova[1], Ivan Pankiv[1], Antonina Piddubna[2], Yulia Marchuk[1] & Iryna Tsaryk[1]
[1]Bukovinian State Medical University, Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine; [2]Bukovinian State Medical University, Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine

Introduction
The problem of ecologically caused iodine deficiency is acute in many countries around the world, including Ukraine, where the endemic zone for the development of iodine deficiency is Northern Bukovina. The possible participation of iodine in the induction or manifestation of autoimmune processes in the thyroid gland and their role in reproduction is discussed. Iodine deficiency is significantly higher in infertile women than in women with normal fertility. In addition, immune mediators, in particular cytokines, have a clear relationship with iodine metabolism and thus are important regulators of fertility.
The aim of the study
To determine the features of the peripheral blood cytokine profile in women with infertility living in iodine-deficient regions of Bukovina.
Materials and methods
The analysis was conducted on the basis of detailed clinical, anamnestic and laboratory studies of 32 women who lived in iodine-deficient regions of Bukovina and who appealed to the clinic with complaints about infertility. The control group consisted of 30 women with infertility living in regions that are prosperous in iodine content. The comparison group consisted of 30 healthy women. Determination of cytokine levels (TNF-α, IL-2, INF-γ, IL-4, IL-6) in blood serum was performed by ELISA.
Results
In women of the study group compared with the control, the studied cytokines of Th1 (TNF-α, IL-2, INF-γ) there was a significant difference only for TNF-α – anincrease of 0.82 times (P <0.05), with insignificant changes in IL-2 and INF-γ levels. At the same time, there was a probable increase in the levels of both studied cytokines of the Th2 type: both IL-4 (0.98 times, P <0.05) and IL-6 (0.45 times, P < 0.05). It should be noted, that in the both studied and control groups compared to healthy women the levels of all studied cytokines had the same trend.
Conclusion
Thus, endemic iodine deficiency in infertile women aggravates the production of TNF-α, IL-4 and IL-6, which may indicate on the role of iodine deficiency in immune homeostasis and infertility, mainly by reason of impaired Th2 type immune response.
Key worlds
Cytokines, women with infertility, endemic iodine deficiency.

Y chromosome in Turner syndrome: preventive management Case report and review of the literature

Fatiha El Miski[1,2], Asmaa Hanafi[1,2], Houssine Boufettal[1,2], Sakher Mahdaoui[1,2] & Naima Samouh[1,2]
[1]Ibn Rochd University Hospital of Casablanca, Gynecology and Obstetrics Department, Casablanca, Morocco; [2]University Hassan II, Faculty of Medicine and Pharmacy, Casablanca, Morocco

Introduction
Turner syndrome (TS) is one of the most common types of aneuploidy; its etiology is associated with total or partial X-chromosome monosomy. In 5–12% of patients, mosaicism for a cell line with Y chromosome is identified. The presence of Y-chromosome increases the risk of gonadal tumors, especially gonadoblastoma and subsequent dysgerminoma. Here we report on the case of a girl with a rare 45X0/46XY mosaic TS exhibiting a primary amenorrhea and delayed puberty; she received preventive surgical treatment by resection of the ovarian strips under laparoscopy and hormonal supplementation.
Case report
The patient was diagnosed with TS at the age of 16 years, upon a diagnostic work-up for a primary amenorrhea, a delayed puberty and short stature without dysmorphic syndrome. Chromosome analysis revealed a mosaic karyotype (45X0/46XY). A physical examination revealed a Tanner stage I for breast and Tanner stage II for pubic hair development. Psychological evaluation showed normal global developmental with highschooler level, together with emotional and social maturity. Her bone age was 13 years. Pelvic magnetic resonance imaging and ultrasound demonstrated a small uterus with unseen ovaries. A laparoscopic exploration was performed which revealed a hypoplastic uterus with normal tubes with ovarian strips; preventive resection of the strips was performed with histology related to bilateral gonadal dysgenesis. In addition, a substitute hormonal treatment based on estrogen and progesterone was instituted to improve pubertal development.
Conclusion
Turner syndrome and Y chromosome material mosaicism is associated with an increased risk of gonadal tumors, prophylactic gonadectomy is recommended at the time of diagnosis.
Keywords
Turner syndrome, Y-chromosome, gonadoblastoma, preventive gonadectomy.

Phenotypic expression of a defects in androgen synthesis of action

Wajdi Safi[1], Bochra Ben Rhouma[2], Fatma Abdelhedi[2], Thouraya Kammoun[3], Neila Belghuith[2], Nabila Rekik[1], Hassen Kammoun[2], Mouna Mnif Feki[1] & Mohamed Abid[1]
[1]Faculty of Sciences of Sfax, Tunisia, Department of Endocrinology, Sfax, Tunisia; [2]Hedi Chaker Hospital, Sfax; Tunisia, Laboratory of Molecular and Functional Genetics, Sfax, Tunisia; [3]Hedi Chaker hospital, Sfax; Tunisia, Pediatric Department, Sfax, Tunisia

Sexual differentiation is a sequential process where several genes are involved, therefore a defect at any stage can lead to a divergence between genetic, gonadal and phenotypic sex. The objective of our work is to analyze the clinical and hormonal characteristics of 13 XY patients, explored between 1989 and 2007 and belonging to 10 different families. The average age of our patients was 18.9 years (2–33 years). The reason for consultation was sexual ambiguity in two cases, puberty delay in 5 cases, primary amenorrhea in 5 cases and inguinal hernia in the remaining case. Consanguinity was found in 50% of cases and the notion of similar cases in the family in 70% of cases. Insensitivity to androgens was suspected in 5 cases with elevated testosterone levels averaging 4 ng/ml (extreme 6–12 ng/ml) with a high LH level averaging 20 mIU/ml (extreme 32–63 mIU/ml). The molecular study confirmed the presence of a P752Z androgen receptor mutation (at exon 5 of the gene) in the 2 familial cases. A gonadotropin receptor abnormality was suspected in 5 cases with elevated LH levels on average at 15 mIU/ml (range 27–43 mIU/ml) and FSH levels at 11 mIU/ml (range 12–24 mIU/ml) contrasting with low testosterone level on average at 0.3 ng/ml (extreme 0.01–0.9 ng/ml) not stimulable by HCG. The absence of Leydig cells in the histological study of the testes confirmed the diagnosis in the 5 patients. The molecular study confirmed the presence of a Q525X missense mutation in the second extracellular loop of the LH receptor in 3 cases, among them two with familial incidence. The female phenotype in 46, XY DSD patients is a rare phenomenon of various etiolgies. Its management is a medical, social and psychological emergency and depends as much on the genetic anomaly and hormonal profile but also on the age of diagnosis, the sex of breeding and the psychological profile.

The prevalence of NAFLD in menopause: A systematic review

Anastasia Ntikoudi[1], Eugenia Vlachou[1], Eleni Evangelou[1], George Kanakis[2], Athanasios N. Tsartsalis[2], Violetta Vaitsi[3], John Komninos[2] & George Mastorakos[4]
[1]University of West Attica, Nursing, Athens, Greece; [2]Athens Naval & VA Hospital, Endocrinology, Athens, Greece; [3]Interbalkan Medical Center, Obstetrics-Gynecology, Thessaloniki, Greece; [4]Areteio Hospital, National and Kapodistrian University of Athens, Medical School, Athens, Greece

Introduction
The prevalence of Non-Alcoholic Fatty Liver Disease (NAFLD) varies according to age, gender and nationality. In the general population, the incidence is about 15–25%. Liver disease increases with age and its prevalence is higher in menopausal women suggesting that steroid sex hormone metabolism may play a role in the pathogenesis of NAFLD.
Aim
The purpose of this systematic review was to investigate the prevalence and association of NAFLD in menopause.
Method
An extensive literature search was conducted until January 2021 through electronic databases (PubMed, Scopus, Cinahl) with the Medical Subject Headings and entry terms of "menopause", "non-alcoholic fatty liver disease" and "prevalence". The search yielded 56 results, 5 of which fulfilled the inclusion requirements according to the PRISMA checklist.
Results
One Brazilian study investigated the prevalence and risk factors of NAFLD in 188 postmenopausal women. A higher prevalence of NAFLD was detected among postmenopausal women. The presence of metabolic syndrome, abdominal obesity, and insulin resistance appeared to be risk indicators for developing NAFLD. A Chinese study demonstrated that obese and postmenopausal women had a high prevalence of NAFLD with severe metabolic disorders. Similarly, a study of 197 premenopausal, postmenopausal women, and women with PCOS found that NAFLD had a higher prevalence among postmenopausal women and women with PCOS than in premenopausal ones. Another study that examined the relationship between menopause and the prevalence of NAFLD in 1.559 middle-aged women stated an increased prevalence of NAFLD in the late stages of menopause as well as in the postmenopausal stages, regardless of the potential confounders. A Korean study in 1793 postmenopausal women, evaluated the relationship between vascular motor symptoms and NAFLD in this population. Moderate to severe vascular motor symptoms were found to be significantly associated with a higher prevalence of NAFLD in otherwise healthy postmenopausal women.
Conclusion
In this systematic review, the prevalence of NAFLD in menopause was highlighted. However, these results were based upon data from a limited number of studies and it is unclear if this association is valid. Large randomized controlled trials and meta-analyses could provide more definitive evidence regarding the association of NAFLD and menopause. Due to the lack of an adequate number of studies and the heterogeneity of the study population, a meta-analysis was not possible to be performed at this time.

Effects of mitochondrial dynamics during myocardial differentiation in 3D model

Sunhwa Jeong[1], Minsu Lee[1], Seon Mi Park[1], Jimin Lee[1] & Eui-Bae Jeung[1]
[1]Laboratory of Veterinary Biochemistry and Molecular Biology, Veterinary Medical Center and College of Veterinary Medicine, Chungbuk National University, Veterinary Biochemistry and Molecular Biology, Cheongju, Republic of South Korea

Mitochondria, which are essential organelles for endocrine health, plays an important role in various physiological functions including hormonal biosynthesis, cell metabolism, proliferation and differentiation. Thus, mitochondrial toxicity can affect a variety of organs, such as liver, heart, muscle, kidney, and central nervous system. Mitochondrial toxicity is recognized as a contributor to drug-induced toxicity of various drugs such as hydroxytamoxifen, valproic acid, acetaminophen, doxorubicin, and amiodarone. Here we describe *in vitro* assay using 3D culture in embryonic body (EB) state and establish a novel model of idiosyncratic toxicity based on mitochondrial impairment. The EBs were cultured in 3D model, and exposed to chemicals for 4 days. This study aims to investigate mitochondrial dynamics during myocardial differentiation in mouse embryonic stem cells(mESCs). In the result, ID50 values under 10-3M each toxic chemical in EB state were obtained; the expression levels of mRNA associated mitochondrial complex were decreased in high concentration group. We also compared mitochondrial DNA copy numbers to examine the effect on the number of mitochondria in mESCs-derived cardiomyocytes. Taken together, the results suggest that mitochondrial toxicity of unknown chemicals can be estimated with our alternative *in vitro* assay.

Leydig cell tumor in childhood: a case report

Hadjer Bouguerra[1], Amina Khellaf[1], Amel Adimi[1] & Zakia Arbouche[1]
[1]Benimessous UH, Department of Endocrinology, Algeria

Background
In the pediatric population, the Leydig cell testicular tumor (TCL) is rare. It manifests communally in childhood with isosexual precocity gonadotropin-independent due to excess testosterone production.
Case report
We admitted a case of an 8.5 years old boy with the complaint of sexual precocity dating back to 4 years, which manifested by acne, hyper seborrhea, stature advance, penile enlargement, pubic hair development, and enlarged left testis. The testosterone level was 2.24 ng/ml. LH was 0.22 UI/l. Ultrasonography demonstrated a left testis increased in volume by presenting a well-limited central nodule of 20 mm, with scattered microcalcifications. An inguinal radical orchiectomy managed this mass. The pathological diagnosis was a benign Leydig cell tumor. Three months after surgery, the testosterone levels stayed high, facing an LH level of 3.26 UI/l.
Discussion and conclusion
The incidence of Leydig cell tumor is 1% of testicular neoplasms[1]. Its prognosis is not tumoral because they are benign in 90% of cases [2], but it has repercussions in terms of stature growth by accelerating the growth rate as they are associated with increased sex steroid production that caused the

LH-independent precocious puberty like in our case. Radical orchiectomy was performed. Post-orchiectomy surveillance showed pubertal levels of gonadotropins, which are thought to be likely triggered by hypothalamic–pituitary axis activation due to long-term sex steroid exposure. Further explorations are in progress.

Keywords
precocious puberty, Leydig cell tumor, stature advance.

Selected steroid hormones – their physiological effects and use in diagnostics and research

Michaela Duskova[1,2], Lucie Kolatorova[2], Markéta Šimková[1], Monika Šrámková[2], Maria Malíková[2], lenka Horackova[2], Jana Vítků[2] & Luboslav Starka[2]
[1]Institute of Endocrinology, Department of Steroids and Proteofactors, Praha, Czech Republic; [2]General University Hospital, Department of Medicine Strahov

The determination of steroid hormones and subsequent interpretation of results is accompanied by a range of difficulties. The amount of information that current technology can provide on the circulating concentrations of more than a hundred various steroid compounds can lead to problems with interpretation. The aim of this study is to help provide orientation in this maze of data on steroid hormones. First, we focus on specific aspects arising from the pre-analytical phase of steroid determination that need to be considered when planning sampling, whether for diagnostics or research. Then, we provide a brief summary of the characteristics and diagnostic relevance of several steroid hormones and/or their metabolites: (pregnenolone, 17ά-hydroxy-pregnenolone, dehydroepiandrosterone, hydroxyderivatives of dehydroepiandrosterone, androstenedione, testosterone, estrone, estradiol, estriol, cortisol, cortisone), which in our institute are determined with validated LC–MS/MS methods. For these steroids, we also provide newly calculated reference values in fertile women according to the phase of their menstrual cycle.

Experience of the transgender care unit

Paloma Moreno-Moreno[1], Ángel Rebollo-Román[1], Mª Rosa Alhambra Expósito[1] & María Ángeles Gálvez-Moreno[1]
[1]Hospital Universitary Reina Sofía, Endocrinology, Cordoba, Spain

Objective
Health care for transsexuals has changed in Andalucia since 2014. Our unit of attention to transsexual people began in 2015. The objective of this study is to analyze our experience.
Patients and methods
Retrospective study by reviewing the medical records of the transsexuals treated in our unit.
Results
145 transsexual people. Transsexual man to woman (TMW): 44.1%, Transsexual woman to man (TWM): 55.9%. 27.97 ± 8.14 years old. Start cross hormonal treatment 88.3%, 5 people have abandoned the treatment (4.8%): 1 planned pregnancy, 2 repentance, 2 another disease. Treatment complications have not been detected. Sex reassignment surgery: 41.5% (n = 54). TMW: 10 hysterectomy-oophorectomy and mastectomy, 16 hysterectomy-oophorectomy and mastectomy at same time (uncomplicated and preferred by people), 1 hysterectomy-oophorectomy, mastectomy and phalloplasty, 22 only mastectomy. TWM: 11 mammoplasty, 5 mammoplasty and feminizing genitoplasty. Private surgical intervention: 66.7%.
Conclusions
TWM is slightly more frequent in our series. Most people consult in the second decade of life, and most of them start cross hormonal treatment. Abandonment of cross hormonal treatment is uncommon. Treatment complications have not been detected. Only half of the people who start treatment have undergone sex reassignment surgery, half in the public health system. Hysterectomy-oophorectomy and mastectomy at same time has not more complications and it´s preferred by people.

Mayer-Rokitansky-Kuster-Hauser Syndrome type 2 – A case report

Teodora Dumitru[1], Miruna Anisia[1], Anca-Georgiana Tudorean-Olteanu[1], Cristina Preda[1,2], Letitia Leustean[1,2], Magdalena Starcea[2,3] & Maria Christina Ungureanu[1,2]
[1]“Sf. Spiridon” Emergency Clinical Hospital, Endocrinology, Iasi, Romania; [2]“Gr. T. Popa” University of Medicine and Pharmacy, Iasi, Romania; [3]“Sf Maria” Emergency Clinical Hospital for Children, Pediatric Nephrology, Iasi, Romania

Introduction
Mayer-Rokitansky-Küster-Hauser (MRKH) type 2 or MURCS (Müllerian duct aplasia, unilateral renal agenesis and cervicothoracic somite anomalies) syndrome is a congenital disease with an incidence of 1 in 4000–5000 female live births, with unknown etiology. Several chromosomal abnormalities were associated with the disease, with a normal 46XX karyotype and familial members to share the same associated anomalies as sporadic cases have been reported. Associated malformations include unilateral renal agenesis (23–28%) and one- or both kidney ectopia (17%) and the incidence of abnormally located ovary is significantly increased in patients with MRKH syndrome.
Case report
A 16-year-old girl presented for renal ectopia detected on a pelvic ultrasonography. We found out she was having primary amenorrhea, with normal breast and pubic pilosity development over the past three years (BVPV Tanner stage) and positive family history of renal and cardiac congenital anomalies. The abdomino-pelvic MRI described uterine and upper two-thirds vaginal agenesis, right kidney agenesis, ectopic left kidney, ovaries with abnormal morfology and topography, tubular aspect and situated high in the abdominal cavity. The karyotype was 46 XX and she had normal ovarian function. A diagnosis of Mayer-Rokitansky-Kuster-Hauser Syndrome type 2 was made.
Discussions
Here we describe a case of a young lady who presented with a renal anomaly that was diagnosed as a case of type 2 MRKH syndrome. The absence of obvious signs and symptoms and the normal development of secondary sexual traits and normal external genitalia causes the syndrome to be diagnosed most often in adolescence, with primary amenorrhea as the first symptom. Considering the renal, skeletal, hearing or cardiac congenital anomalies associated and the increased levels of psychological distress, the multidisciplinary approach of these patient is very important.

Perrault Syndrome, a case study

Bessaid Khadidja[1]
[1]El Djazair, El Djazair, Algeria

Introduction
Perrault syndrome is a rare recessive autosomal degenerative disease defined by the combination of ovarian dysgenesis 46XX with sensorineural deafness. Other manifestations can expand the clinical picture, particularly a cerebellar degeneration and/or peripheral neuronal sensitivo-motor.
Observation
We have reported a 14 years old patient case, from a 2nd degree consanguineous marriage with perceptive bilateral deafness history, who has consulted for impuberal primary amenorrhea, the clinical examination did not show a particular dysmorphic syndrome nor retardation, Limitation of the laterality of the gaze in abduction, hyper ligamentous laxity of the fingers. The biological exploration revealed a hyper gonadotropic hypogonadism as well as normal 46 XX karyotype, this eliminates Turner’s syndrome. The abdominal ultrasound showed ovarian atrophy with a prepubescent tubular uterus.

Discussion
The diagnosis of Perrault syndrome has been made in the presence of hyper gonadotropic hypogonadism, an ovarian imaging atrophy, a normal karyotype with bilateral congenital neurosensory deafness; however, the spectrum of the disease is wide, the neurological exploration must be systematic to the search for neuronal and/or cerebellar degeneration, for this reason, an EMG as well as a brain MRI are programmed for our patient. In the absence of gene therapy, hormone replacement therapy represents the only hope today, the patient has received oestrogen treatment then oestroprogestative with a good clinical evolution.

Systematic review and meta-analysis of the observational trials evaluating the functional impact of COVID-19 on sexual health

Deepak Jumani[1], Abhishek Jumani[2], Ghufran Lufti Ismaeel[3], Hemant Phatale[4] & Shashank Joshi[5]
[1]JJ Group of Govt Hospitals and Grant Medical College and My Best Doctor Clinic, Mumbai, India; [2]My Best Doctor Clinic, Mumbai, Mumbai, India; [3]University of Al-Ameed, Karbala, Iraq, Iraq; [4]Samrat Endocrine Institute, Aurangabad, India; [5]Lilavati Hospital, Mumbai, Mumbai, India

Background
Natural disasters resulting in psychosocial stress and endocrine imbalances are implicated for impacting sexual health. We postulate COVID-19 for its longer duration and global lockdown has implications on the sexual health
Methods
We analysed contemporary protocols of six ongoing trials through WHO International Clinical Trials Registry Platform and www.clinicaltrials.gov trials registry database. The latest evaluation was done on September 27, 2020 for trials registered from April to June 2020, evaluating the impact of COVID-19 on sexual health. Two researchers independently analysed the study designs.
Results
The trials evaluate female sexual behavior, marital and sexual health problems, sexual fantasies, postpartum sexual function, sexual function among healthcare workers, qualitative and quantitative aspects for fertility, urinary function, and STD. Six trials are cumulatively recruiting 868 participants; with two trials each in Turkey (n = 198) and Egypt (n = 520) and one each in Italy and France. Mean number of participants being enrolled is 145 (S.D. ± 130, maximum 400, minimum 50, range 350, 95% CI 8.4 to 281). Two trials enrol exclusively females (n = 198) and one trial only evaluates males (n = 50), with highest age 80 years and longest evaluation planned for one year. Interventions include questionnaire-based evaluation and diagnostic work-up. Established tools including IIEF-5, IPSS, SECRET questionnaire, Male Sexual Health Questionnaire (MSHQ), FSFI (Female Sexual Function Index), dyspareunia scale are utilised. SARS-CoV 2 RNA PCR evaluation in urine and semen and interleukin assessment in semen are being done
Conclusions
The utilisation of validated tools across varied spectrum of participants, for evaluation for impact of contagiousness of the virus to confinement due to lockdown is a collective strength of ongoing observational studies. Varied novel approaches are being explored to understand the implications of COVID-19 on sexual health and function.

Mycophenolate mofetil in sight threatening Graves' ophthalmopathy: a case report

Sawsen Essayeh[1], Sabrina Ayari[1], Chayma Hadj Sliman[1], Najla Bchir[1], Chedia Zouaoui[1] & Haroun Ouertani[1]
[1]The Military Hospital of Tunis, Endocrinology-Nutrition, Tunis, Tunisia

Introduction
Graves ophthalmopathy (GO) is an inflammatory autoimmune disorder of the orbit which is associated with autoimmune thyroid disease. The medical treatment of severe and sight threatening GO remains a challenge, it generally implies the use of glucocorticoids with others treatments. Mycophenolate mofetil (MMF) is a prodrug of mycophenolic acid that prevents T-cell and B-cell proliferation and the production of cytotoxic T-cells and antibodies. Furthermore, an antiproliferative effect on orbital target cells has also been considered. We report the case of a patient presenting with sight threatening GO treated with glucocorticoids and MMF.
Case presentation
A 44-year-old man with hypertension, presented since November 2019 Graves' disease diagnosed following the onset of bilateral proptosis. The evolution was marked by the worsening of his ophtalmopathy in July 2020. Emergency ophthalmological examination showed a visual acuity at 7/10 on the right eye and < 1/10 on the left eye, superficial punctate keratitis in both eyes, lazy photomotor reflex and slight papillary pallor in the nasal area of the left eye, limitation of the abduction and the presence of inflammatory signs in both eyes more accentuated on the left eye. Orbital MRI showed Graves' orbitopathy with bilateral exophthalmia grade III with greater compression of optic nerve on the left eye. The patient received methylprednisolone intravenously for three days (1 g/day) followed by oral corticosteroid therapy at a dose of 1 mg/Kg/day with improvement in inflammatory signs without improvement in visual acuity. The management was to combine mycophenolate mofetil at a dose of 1 g*3/day. The outcomes were favorable with resumption of vision on the left eye (8/10) and improvement of the visual acuity on the right eye (10/10) without serious adverse events.
Conclusion
The combination of MMF and glucocorticoids seem to be promising since it shows beneficial effect in sight threatening Graves' orbitopathy without major toxicities.

Inoperable papillary thyroid carcinoma with metastasis pulmonary: therapeutic alternative

Henricia Laurinda Pangui[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asmaa Chadli[1]
[1]Chu Ibn Rochd, Endocrinology, Casablanca, Morocco

Summary
Papillary thyroid carcinoma is rare in children and adolescents, most often discovered late by lung metastases. It is generally of good prognosis but can present cases difficult to operate requiring a targeted therapeutic approach. We report the case of a 15-year-old patient from a non-consanguineous marriage, with no history of irradiation, followed for Hashimoto's hypothyroidism since the age of 6 under Levothyrox 25 µg. Admitted for a multi-nodular goiter evolving for 3 years of progressive increase complicated 6 months before its admission by exertional dyspnea without signs of compression. On clinical examination we note a slight cyanosis of the lips, a polypnea at 30 cycles, an 80% SaO2, bilateral snoring rales, a firm grade 2 goiter, with 2 right and left nodules of 1.5 cm, not very mobile with lymphadenopathy left jugulo-carotid of 1 cm. A thyroglobulin at 4035 ng/dl. The cervical ultrasound describes a nodular goiter with endothoracic embedding, voluminous on the right of 32.5 mm, TIRADS 5. On the CT there is bilateral pulmonary carcinosis, a tracheal deviation to the right on the chest X-ray, on the RFE a tight restrictive syndrome with 39% FEV1. Fine needle aspiration concludes with papillary carcinoma. Faced with the risks associated with the surgery, the patient was put on Sorafenib 150 mg/m^2/day, i.e. 200 mg/day for 6 months with good tolerance and a respiratory improvement of 92% SaO2, thyroglobulin controlled at 500 ng/dl, stabilization of pulmonary metastases with reduction in the volume of the goiter. Surgery was performed, noting a fixed, adherent thyroid mass that could not be resected. Several biopsies were taken confirming the papillary carcinoma. In multidisciplinary discussion, the patient was put back on Sorafenib titrated at 400 mg not tolerated then put back at 200 mg/day, radiotherapy was started in addition to therapy. Sorafenib represents in our context a major asset in the management of inoperable papillary thyroid carcinoma.

Laser ablation versus radiofrequency ablation for benign non-functioning thyroid nodules: twelve-month results of a randomized, parallel-arm, open-label trial

Roberto Cesareo[1], Silvia Manfrini[2], Valerio Pasqualini[3], Cesare Ambrogi[3], Gianfranco Sanson[4], Andrea Gallo[5], Paolo Pozzilli[2], Claudio Pedone[6], Anna Crescenzi[7] & Andrea Palermo[2]
[1]"S. M. Goretti" Hospital, Latina, Italy, Unit of metabolic diseases; [2]Campus Bio-Medico University, Unit Of Endocrinology, Rome, Italy; [3]"S.

M. Goretti" Hospital, Latina, Italy, Department of Radiology; [4]University of Trieste, Clinical Department of Medical, Surgical and Health Sciences, Trieste, Italy; [5]Sapienza University of Rome, Italy, Department of Sense Organs; [6]Campus Bio-Medico University, Rome, Italy, Geriatric Unit, Rome, Italy; [7]Campus Bio-Medico university, Rome, Italy, Unit of Pathology, Rome, Italy

Background
Radiofrequency ablation (RFA) seems to achieve a significantly larger nodule volume reduction rate (VRR) than laser ablation (LA) in benign non-functioning thyroid nodules (BNTNs). We compared the efficacy and safety of both thermal ablation treatments at the 12-month follow-up in patients with solid or predominantly solid BNTN.
Methods
This 12-month, single-use, randomized open-label parallel trial compared the following primary endpoints between the RFA and LA groups 12 months post-treatment: (a) nodule volume reduction, expressed as a percentage of the nodule volume at baseline and (b) proportion of nodules with more than 50% reduction (technical success rate). We enrolled patients with a solitary BNTN or dominant nodule characterized by pressure symptoms/cosmetic problems or asymptomatic patients who experienced a volume increase of >20% within 1 year. This trial was registered with ClinicalTrials.gov (NCT02714946).
Results
Sixty patients were randomly assigned (1:1 ratio) to receive either RFA or LA, and 29 patients per group completed the study. Both groups had similar basal nodule volume, thyroid function, histology, and symptoms/cosmetic score, whereas a larger quantity of energy was delivered to patients who underwent RFA. At 12 months, the nodule volume reduction rate was 70.9 ± 16.9% and 60.0 ± 19.0% in the RFA and LA groups, respectively (P = 0.024). This effect was confirmed in the linear regression model that was adjusted for age, sex, and nodule baseline volume and proportion of cellular components (RFA treatment: β = 0.390; P = 0.009). No significant between-group difference was observed in the technical success rate at 12 months post-treatment (RFA: n = 26, 89.7%; LA: n = 22, 75.9%; P = 0.149). A statistically significant improvement was observed from the baseline to the 12-month follow-up for compression (RFA: 4.6 ± 2.6 and 1.3 ± 0.8, P<0.001 and LA: 4.6 ± 2.1 and 1.6 ± 0.8, respectively, P<0.001) and cosmetic (RFA: 3.4 ± 0.6 and 1.3 ± 0.5, P<0.001 and LA: 3.4 ± 0.5 and 1.4 ± 0.6, P<0.001) scores although the between-group differences were not significant.
Conclusion
RFA achieved a significantly larger nodule volume reduction at 12 months; however, the technical success rate was similar in the RFA and LA groups.

Graves' disease in patients with autoimmune polyendocrine syndrome type 3

Hadj Kacem Faten[1], Raida Ben Salah[2], Derbel Abir[2], Chouaib Sara[1], Bahloul Zouhir[2] & Abid Mohamed[1]
[1]CHU Hedi Chaker, Endocrinology Deparetement; [2]CHU Hedi Chaker, Internal Medicine

Introduction
Type 3 autoimmune polyendocrine syndrome (APS-3) is defined by the presence of an autoimmune thyroid disease and another autoimmune illness, excluding Addison's disease; this is a frequent combination. Graves' disease (GD) is an autoimmune disorder affecting approximately 0.5% of general population. It's occurrence in autoimmune polyendocrine syndrome (APS) is less common than Hashimoto thyroiditis. The aim of our study was to describe clinico-biological findings, therapeutic management and progess of GD in patients with APS type 3.
Methods
We analyzed clinical and biological findings of 10 patients with GD and APS. Data were gathered from files collected in internal medicine and/or endocrinology department from January 2000 to December 2017.
Results
Ten patients (21.7%) among 46 with APS had GD. GD was suspected face to clinical manifestations of hyperthyroidism in 8 cases and fortuitously in 2 cases. It was about 7 male and 3 female. The mean age of our population was at 31.5 years [14–50]. Among complaints, we found excessive sweating in 8 patients, weight loss with increase appetite in 6 cases, asthenia and tremor in 5 patients each. Diarrhea and nervousness were reported in 1 case each. Physical examination showed protruding eye ball in 6 patients, tachycardia in 5 cases and amyotrophy in 4 cases. Neck examination showed enlarged thyroid gland in all cases. Hyperthyroidism was complicated by cardiothyreosis, neuromuscular signs in 4 cases each and metabolic disorders in 6 cases. Thyroid function tests revealed a suppressed TSH level and elevated levels of serum T4 at 68.3 pmol/l [24.5–116]. Immunologic analysis found anti-TSH receptor antibodies in all cases, anti-thyroid-peroxidase antibodies in 8 cases and thyroglobulinin 3 cases. All patients presented mellitus Type 1 diabetes (DT1). DT1 was diagnosed after GD in 5 cases, before and at the same time of GD in 2 and 3 cases respectively. Anti GAD and anti IA2 antibodies were positive in 8 and 1 cases respectively. APS type 3 was retained in all cases. Treatment by anti thyroid drugs with beta-blokers was used in 9 cases. Radioactive Iodine Therapy (RAI) was performed in 7 cases. Surgical treatment by total thyroidectomy was indicated 1 case. Progress demonstrates remission in 8 cases with average follow-up of 90.5 months [25-156].
Conclusion
Patients with GD are at high risk to develop auto-immune disorders especially APS 3 type like our study. Screening of autoimmune diseases (DT1, Addison disease, celiac disease, pernicious anemia, connectivities…) in patients with GD should be done early and regularly in order to take appropriate action.

Long-term outcomes of radioiodine therapy in toxic solitary thyroid nodules

Francisca Puga[1], Maria Teresa Pereira[1], Cláudia Freitas[1] & Maria Helena Cardoso[1]
[1]Centro Hospitalar Universitário do Porto, Endocrinology, Portugal

Introduction
The toxic solitary thyroid nodule is a major cause of hyperthyroidism, especially in iodine-deprived regions. The most widely used therapy is iodine-131, which is effective in achieving normal thyroid function and reducing nodule dimensions, however, it may induce hypothyroidism. The aim of this study was to evaluate the outcomes of radioiodine therapy in patients with toxic solitary nodules and to determine predictive factors for the development of hypothyroidism.
Methods
A retrospective analysis of medical records of patients with toxic thyroid nodule submitted to radioiodine therapy between 2008 and 2018 in our center was conducted.
Results
During the study period, 100 patients received radioiodine therapy for toxic solitary nodule, with a minimum follow-up of one year (77% female, age at diagnosis 63±14 years). The most used doses were 20 mCi (61%) and 15 mCi (35%). The therapy was effective in reversing hyperthyroidism in 99% of patients. However, 56% developed hypothyroidism, 79% of them being diagnosed within 6 months after therapy. The evolution to hypothyroidism was greater in women and the hypothyroidism group were younger, had smaller nodule size and thyroid volume and higher doses of iodine per thyroid volume. Logistic regression confirmed female sex (OR 2.90, P = 0.034), nodule size [OR 0.95 (mm), P = 0.026], thyroid volume [OR 0.94 (ml), P = 0.013] and radioiodine dose per volume [OR 4.47 (mCi/ml), P = 0.039] as predictive factors for hypothyroidism. There were no differences regarding the previous TSH value, use of antithyroid drugs, total iodine dose or iodine dose per kilogram of weight. In ultrasound reevaluation, within four years after treatment, there was a significant absolute and relative nodule reduction of 10 mm (5–14) and 33% (24–49), respectively (P<0.001). Higher absolute and lower relative reductions were found in larger nodules (R = 0.26, P = 0.014 | R = –0.29, P = 0.006). There was an absolute and relative reduction in thyroid volume of 10 ml (6–17) and 53% (32–73) (P<0.001). The patients who developed hypothyroidism showed higher reductions in thyroid volume (72% vs 37%, P<0.001). There were no differences in nodule or thyroid volume reduction regarding sex, use of antithyroid drugs or total dose of radioiodine.
Conclusion
Radioiodine therapy is effective in the treatment of hyperthyroidism caused by toxic thyroid nodules, and induces significant reductions in nodule and thyroid dimensions. However, this treatment may induce hypothyroidism, found in more than half of the cases in the present study. Female sex, lower nodule size and thyroid volume and higher radioiodine dose per volume are predictive factors of its development.

Adverse childhood experiences and negative emotional responses : risk factors for thyroid autoimmune diseases?

Rosaria Ruggeri[1], Marco Liotta[2], Anna Ferraro[2], Salvatore Cannavò[3], Rosalba Larcan[2] & Francesca Cuzzocrea[4]
[1]Endocrin Unit, Clinical and Experimental Medicine, University of Messina, Messina, Italy; [2]Department of Clinical and Experimental Medicine, University of Messina; [3]Unit of Endocrinology, DETEV, Italy; [4]University of Catanzaro, Italy

Stressful condition and negative emotions can contribute to the overproduction of proinflammatory cytokines and promote immune dysregulation, which, in turn, increases the risk of various diseases, including autoimmune disorders. The present study was aimed at evaluating the relationship, if any, between psychological and individual characteristics (stress, coping and emotional intelligence) and thyroid autoimmunity.

Method

We enrolled 174 HT patients (gender: 157 female; 12 male; age: M = 47.01; s.d. = 13.36) and 133 euthyroid subjects (gender: 111 female, 21 male; aged M = 45.56; s.d. = 12.69) as controls. All subject had no personal and/or familial history of psychiatric disorders. All participants fell a set of psychological self-report questionnaires in order to measure psychological stress (MSP), coping strategy (Coping Inventory for Stressful Situations, CISS), trait emotional intelligence (TEIQue-SF) and Adverse Childhood Experiences (ACEs questioner).

Results

We found significant differences between patients and controls. MSP test showed greater levels of overall stress ($P = 0.001$) and stress subcategories, including psycho-physiologic sensations ($P = 0.000$), effort and confusion ($P = 0.02$), depressive anxiety ($P = 0.01$), pain and physical problems ($P = 0.000$), in HT patients than controls. Also, HT patients showed minor wellbeing ($P = 0.020$) and self-control ($P = 0.047$) compared to controls at TEIQue Test. Concerning coping strategies, HT patients seem to have more difficulties in adequately managing the emotional area ($P = .004$), which involves greater emotional responses, self-preoccupation, and a fantasizing tendency. Noteworthy, it emerged that HT patients have had a greater number of traumatic experiences in childhood ($P = 0.01$) than controls, with particular reference to physical abuse ($P = .001$), parental divorce ($P = 0.02$) and presence in the family of subjects suffering from mental illness ($P = 0.05$) or substance abuse ($P = 0.38$). The patha analysis on HT patients confirmed that the total stress is influenced by adverse childhood experiences ($\beta = .12$, $P = .04$) and by trait emotional intelligence ($\beta = -.16$, $P = 0.02$). It is conceivable that traumatic events occurring early in life might have had an influence on the subsequent development of autoimmune disease.

Conclusions

Our data suggest a correlation between psycho-social and immune factors. HT patients seem to have a very delicate psycho-affective equilibrium, difficulties in emotion regulation and impulse control, as well as in managing stress. Traumatic experiences in childhood and negative emotional responses may favor the subsequent development of autoimmunity, acting as an exogenous trigger in susceptible subjects. Autoimmunity, even in conditions of euthyroidism, can in turn negatively impact the psychological well-being of patients, who in fact appear less confident and optimistic.

AEP631

Features of Subacute Hhyroiditis in COVID 19

Ina Darashkevich[1], Tatjana V. Mokhort[2], Ivan Darashkevich[3] & Olga Martinkevich[4]
[1]Grodno State Medical University, Endocrinology, Grodno, Belarus; [2]Belarus State Medicul University, Endocrinology, Minsk, Belarus; [3]Grodno State Agrarian University, Administration, Grodno, Belarus; [4]Grodno University Clinic, Endocrinology, Belarus

The Sars-COV-2 virus is a recognized endocrine disruptor, which determines the possibility of endocrine dysfunctions associated with COVID 19. One of the endocrine diseases associated with COVID 19 is subacute thyroiditis (STh), which develops regardless of the severity of manifestations of the underlying disease. The aim of the study: to evaluate the clinical manifestations, therapy, and outcomes of STh in unvaccinated COVID 19 patients.

Materials and methods

The diagnosis of STh was established on the basis of generally accepted clinical criteria. As a result 26 patients from April to October 2020 were included in the study: group1 – with STh without COVID 19 in medical history ($n = 8$); group2 – COVID 19 convalescents who received glucocorticoids (GCs) in complex therapy (in the diagnosis of PT, the daily dose in terms of prednisone was 20 mg) ($n = 10$); group3 – COVID 19 convalescents who did not use GCs in COVID 19 therapy ($n = 8$). The levels of erythrocytes (Er), hemoglobin, leukocytes, lymphocytes, erythrocyte sedimentation rate, thyroid-stimulating hormone, free thyroxine, thyroid peroxidase antibodies, C-reactive protein (CRP) in the peripheral blood were determined; ultrasound examination of the thyroid gland, thyroscintigraphy with 99mTc-pertechnetate, with the calculation of the uptake index of the radiopharmaceutical were conducted as well.

Results

Comparison of indicators of the complete blood count revealed differences in the levels of Er, leukocytes, the proportion of lymphocytes, which were associated with the characteristics of treatment (use of GCs). The thyroid status at the time of STh establishment indicated a thyrotoxic phase, confirmed by thyroid status. For the treatment of STh in groups1, 3, a non-steroidal anti-inflammatory drug (NSAID) (nimesulide 200 mg/day) was prescribed. In 50% of patients in group1, 87.5% of patients in group3 required the addition of GCs using the average dose in terms of prednisolone (30 mg/day). Group2 required an increase in the GCc dose to 40 mg/day in terms of prednisone (NSAIDs were't). Beta-blockers were used to minimize hyperthyroidism's symptoms in individual doses. The duration of therapy up to resolution in group1 averaged 25 days, in group2 – 51 days, in group3 – 44 days and depended on the relief of symptoms, indicators of complete blood count, CRP. In 3 months hypothyroidism developed in 25% of patients from group1, in group2 – in 90% of the cases, in group3 – in 37.5% of the cases.

Conclusion

The results indicate a higher incidence of hypothyroidism after STh in COVID 19-patients to compare ordinary STh.

The use of Thyroid Uptake scan in non-malignant thyroid disease; a multicentre audit

Sardar Muhammad Shoaib Khan[2], Niels Larsen[2], Laura Mola Reyes[1], Riyad Sheikh[2] & Carlos Mauricio Hernandez Heredia[1]
[1]Hospital Central de la Defensa Gómez Ulla, Spain; [2]King's Mill Hospital Sherwood Forest Hospitals NHS Foundation Trust, Diabetes and Endocrinology, Sutton-in-Ashfield, United Kingdom

Thyroid uptake scan is a widely used thyroid investigation that provides valuable information regarding the structure and function of the gland and helps in differentiating some of the common thyroid pathologies. We present a multicentre audit of thyroid uptake scans done for non-malignant thyroid pathologies and try to analyse the usefulness of this investigation in different situations.

Methods

This audit includes thyroid uptake scans from two centres (King's Mill Hospital Sherwood Hospitals NHS Foundation Trust Nottinghamshire UK and Hospital Central de la Defensa Gómez Ulla Madrid Spain) done over two years (2018 and 2019). Medical and electronic records were examined to get the data on presenting thyroid functions, TSH receptor antibodies (TrAB), clinical neck examination, thyroid uptake scan results, final diagnosis and management.

Results

A total of 117 cases were analysed; 27 from UK and 90 from Spain. 113 of these patients were hyperthyroid. 26 patients had positive TrAB (TrABs not available in 7). Clinical examination data was available for 98 patients; 27 normal, 38 diffuse goitre, 21 single nodule, 12 multiple nodules. Final diagnosis was Graves' disease in 27, thyroiditis in 11, toxic multinodular goitre in 30, toxic nodule in 19 and 10 patients had other diagnoses. 20 patients were found to have non nodular hyperthyroidism with negative TrABs. We also performed subgroup analyses to see whether thyroid uptake scans significantly altered diagnosis or management. Unsurprisingly, there was no significant benefit from the thyroid uptake scan in those with hypothyroidism (4) or secondary hyperthyroidism (2). In those with TrAB positive hyperthyroidism (Fig 1) and a non-nodular thyroid examination, thyroid uptake scan did not add any significant information to aid in diagnosis or management; merely confirming the diagnosis of Graves' disease in all patients.

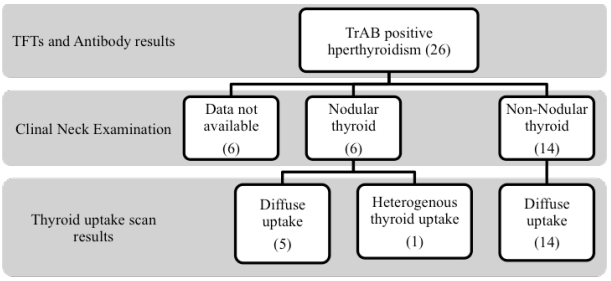

Fig 1: Sub group analysis of TrAB positive hyperthyroidism.

In those with TrAB negative hyperthyroidism (fig 2), thyroid uptake scan significantly altered the pre scan probable diagnosis but whether it changed the eventual management in all of these patients is not entirely clear.

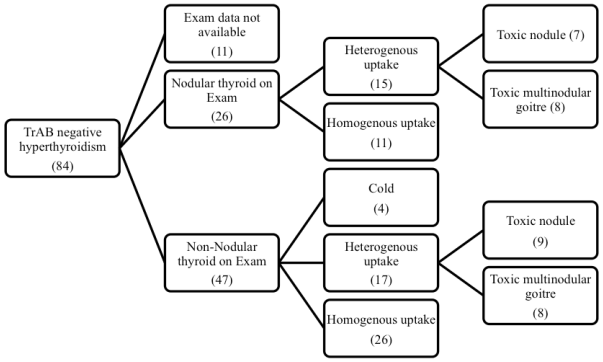

Fig 2: Sub group analysis of TrAB negative hyperthyroidism.

Conclusion

Our results show that thyroid uptake scan can be useful in patients with TrAB negative hyperthyroidism and TrAB positive hyperthyroidism with a nodular thyroid on examination. Amiodarone induced thyrotoxicosis is also an accepted indication of thyroid uptake scan. Clinicians should evaluate each case on an individual basis to see if uptake scan will significantly alter the diagnosis or management before requesting.

Efficacy of transcutaneous laryngeal ultrasonography (TLUS) in the diagnosis of vocal cord function in an endocrine surgery referral center.

Chiara Offi[1], Giovanni Antonelli[1], Umberto Brancaccio[1], Edoardo D'Ambrosio[1], Maria Grazia Esposito[1], Claudia Misso[1], Roberto Maria Romano[2] & Stefano Spiezia[1]

[1]Local Health Authority Naples 1 Center, Italy, Department of Endocrine Surgery, Napoli, Italy; [2]University of Campania "Luigi Vanvitelli", Napoli, Italy

Introduction

Thyroid diseases affect a large population worldwide and total thyroidectomy (TT) is the most common curative treatment [1]. Recurrent laryngeal nerve (RLN) lesions are the most dangerous complication [1]. The intraoperative neuromonitoring (NIM) is a useful tool in reducing the incidence of nerve injury, but a preoperative examinations of vocal cords function through flexible fiberoptic laryngoscopy (FFL) is recommended [1]. FFL is uncomfortable and expensive evaluation, so transcutaneous laryngeal ultrasonography (TLUS) has been proposed as alternative indirect examination of vocal cords function [2].

Materials and methods

We conducted a retro prospective on 100 consecutive patients with benign and malignant thyroid disease underwent to TT and preoperative and postoperative evaluation with FFL and TLUS. All TLUS was performed by one experienced investigator.

Results

Demographic data and results are showed in Tables 1 and 2, respectively.

Table 1. Patients' demographic and clinical information

	Population
Mean age ± s.d.	50.63 ± 12.15
Gender, %	
Male	24 (24%)
Female	76 (76%)
Diagnosis, %	
Benign	68%
Malignant	4%
Indeterminate cytology	28%
Preoperative FFL, %	
Normal	100%
Vocal Impairment	0%
Preoperative TLUS, %	
Normal	100%
Vocal cord impairment	0%
Correct correlation with FFL	100%
Incorrect correlation with FFL	0%
Normal visualization	91%
Lateral visualization	9%
Postoperative FFL, %	
Normal	80%
Unilateral vocal cord hypomobility	12%
Unilateral vocal cord paralysis	8%
Postoperative TLUS, %	
Normal	80%
Unilateral vocal cord hypomobility	8%
Unilateral vocal cord paralysis	8%
Normal visualization	98%
Lateral visualization	2%
Correct correlation with FFL	98%
Incorrect correlation with FFL	2%
Postoperative diagnosis, %	
Benign	76%
Malignant	24%

Table 2. Statistical data (PPV+, predictive positive value; PNV, predictive negative value).

	CI of 95%
Sensitivity	0.833 (0.743–0.898)
Specificity	1.000 (0.954–1.000)
Prevalence	0.120 (0.066–0.204)
PPV+	1.000 (0.954–1.000)
PNV–	0.978 (0.919–0.996)

Discussion

In the literature, there are discordant data that give a sensitivity greater than 90% and others a 33%, while the specificity is always greater than 90% [1,2]. Our study showed a sensitivity of 83.3%, a specificity of 100%, PPV+ of 100% and a PNV– of 96.7%. TLUS is safe in recognizing healthy patients but has some limitations in recognizing patients with chordal hypomobility, particularly in male patients with prominent and/or calcific thyroid cartilage.

Evaluation of fetuin-A levels in patients with autoimmune thyroiditis

Berta Eszter[1,2], Sándor Halmi[1], Inez Mercédesz Lengyel[1], Mónika Katkó[1], Mariann Harangi[3], Endre V Nagy[1], György Paragh[3] & Miklós Bodor[1,2]

[1]Faculty of Medicine, University of Debrecen, Department of Endocrinology, Debrecen, Hungary; [2]Faculty of Pharmacy, University of Debrecen, Department of Clinical Pharmacology, Debrecen, Hungary; [3]Faculty of Medicine, University of Debrecen, Department of Metabolism, Debrecen, Hungary

Background
Hypothyroidism due to autoimmune thyroiditis (AITD) leads to atherogenic lipid profile and therefore might increase the cardiovascular risk of patients. Fetuin-A is a hepatokine with a role in the regulation of mineralization, metabolism and the cardiovascular system. Fetuin-A levels are known increased in obesity-linked diseases. To date, the role of fetuin-A in autoimmune thyroiditis has not been thoroughly investigated.
Subjects and methods
In our study we investigated the association between thyroid hormone levels, thyroid antibodies, the components of lipid metabolism, anthropometrical parameters and fetuin-A. We enrolled eighty-six patients (7 men, 79 women, mean age 43 ± 13 years, median BMI 25.3 (23.4–30.5) kg/m^2) from the outpatient clinic of Endocrine Department of University of Debrecen, Faculty of Medicine. All patients had autoimmune thyroiditis with various thyroid hormone status from hypo- to hyperthyroidism. Serum fetuin-A concentrations were determined with enzyme-linked immunosorbent assay (ELISA). Thyroid hormone levels, anti-thyroperoxidase (aTPO) concentration and lipid parameters were measured by routine laboratory methods.
Results
Median serum fetuin-A level was 929.7 (822.0 – 1038.3) mg/l, LDL-C was 3.2 (2.6–3.8) mmol/l, HDL-C was 1.5 (1.3–1.8), triglyceride was 0.84 (0.49–1.45) mmol/l, while mean total cholesterol level was 5.3 ± 1.1 mmol/l. Mean fT3 and fT4 were 4.67 ± 0.67 and 17.8 ± 3.6 pmol/l, respectively. Significant positive correlation was found between fT3 and fetuin-A levels (r = 0.273, P = 0.013). There was a significant negative correlation between age (r = −0.406; P<0.001), daily levothyroxine dose/body weight (r_s = −0.370, P = 0.001), total cholesterol (r = −0.287, P<0.01), ApoB100 (r = −0.300, P<0.01) and fT3. However, we could not find correlation between fetuin-A and aTPO levels. Among patients receiving levothyroxine substitution, a correlation between CRP and fT3 was present (r = −0.251, P = 0.047).
Conclusions
The significant correlation between fetuin-A and fT3 levels might indicate a regulatory effect of T3 on metabolism. However, further clinical investigations are needed to clarify this relationship.

Long term outcomes of Graves' Orbitopathy treatment; a clinic's experience

Dimitra Pappa[1], Pinelopi Thoda[1], Anastasia – Konstantina Sakali[1], Eleftheria Barmpa[1], Eleni Georgiou[1], Ioannis Gountios[1] & Alexandra Bargiota[1]
[1]University Hospital of Larissa, Department of Endocrinology and Metabolic Diseases, Larissa, Greece

Introduction
In this study we present data on the long-term outcomes of treatment of patients with moderate and severe GO.
Methods
98 patients with GO attending our clinic for the last 13 years and received treatment for moderate to severe GO were evaluated for their long-term response to treatment. Initial decision for treatment was based on activity and severity of the disease, assessed by CAS-score and NOSPECS respectively and the presence of ocular muscle edema (OME) at the MRI–STIR imaging. Patients with moderate to severe disease received iv corticosteroids according to the EUGOGO protocol (totally 4.5 g methylprednisolone for 12 weeks), and those with persisting disease continued with per os prednisolone (30 mg daily, tapered over 3 months). Response to treatment was evaluated based on changes of both CAS-score and OME at the MRI–STIR. Thyroid and liver function, and smoking status were also assessed.
Results
The patients' mean age was 52.08 ± 13.11 years. 30/98 patients (30.61%) had mild GO (mean CAS-score 2.58 ± 0.47, no or mild OME at the MRI-STIR) and received no treatment. 68/98 patients (69.38%) had moderate to severe GO (mean CAS-score 4.13 ± 1.26, intense OME at the MRI–STIR) and received iv treatment. 20/68 patients (29.41%) had a significant improvement (mean CAS-score 3.04 ± 0.07, mild to moderate disease, and no or mild OME at the MRI–STIR) and received no further treatment. The rest 48/68 patients (70.58%), due to persisting disease (mean CAS-score 3.30 ± 1.21, and intense OME at the MRI–STIR), continued with the per os protocol and were improved at the end of treatment (mean CAS-score 2.27 ± 1.14, no or mild OME at the MRI–STIR). Only 3/68 patients (4.41%) who received iv corticosteroids developed mild transaminasemia. All patients were euthyroid at the initiation of treatment and 6/68 continued smoking. Recurrence observed in 11/68 patients (16.17%) who had prior treatment, with mean CAS-score 3.64 ± 1.28 and intense OME at the MRI–STIR, at a mean 21.5 ± 32.3 months (range 1–108 months). They received additional iv treatment (1.5 g methylprednisolone for 6 weeks) and all improved significantly (mean CAS-score 2.97 ± 0.95, no or mild OME at the MRI–STIR).
Conclusion
Treatment with iv corticosteroids followed by oral corticosteroids in those with persistent disease based on CAS and MRI–STR findings is effective for patients with moderate to severe GO, minimizing the recurrence rate and has no serious side effects. MRI–STIR imaging of the ocular muscle is a useful tool for treatment initiation and evaluation of response.

Comparison of metabolic parameters between women with autoimmune thyroiditis on levothyroxine replacement therapy and euthyroid healthy women

Antoaneta Argatska[1] & Boyan Nonchev[1]
[1]Medical University of Plovdiv, Department of Endocrinology, Plovdiv, Bulgaria

Introduction
The association between thyroid function within the normal range and body weight and related metabolic parameters has been the subject of numerous studies with inconsistent results not only in euthyroid healthy population but also in treated patients with autoimmune hypothyroidism.
Objective
To compare body mass index (BMI), blood glucose and serum lipids between women with autoimmune thyroiditis on levothyroxine replacement therapy and euthyroid healthy women.
Patients and methods
127 women with autoimmune thyroiditis receiving levothyroxine therapy (42.6 ± 1.9, 20–64 years) and 361 age-matched healthy women (40.6 ± 0.6, 19–65 years) were included in this retrospective study. All women were euthyroid with TSH and FT4 levels within reference range. TSH and FT4 levels were measured using ECLIA, fasting blood glucose, total cholesterol, HDL, triglycerides were measured and LDL was calculated using Friedewald's formula. Women in the study did not have any significant comorbidities, diabetes mellitus, did not take metformin, lipid-lowering or estrogen-containing medications.
Results
Women on levothyroxine had higher levels of TSH (2.38 ± 0.09 vs 1.98 ± 0.05 mIU/l, P<0.01) and FT4 (11.50 ± 0.12 vs 10.89 ± 0.07 pmol/l, P<0.01) compared to healthy women. No significant differences between treated hypothyroid and healthy women were found in terms of BMI (26.7 ± 0.5 vs 27.3 ± 0.3 kg/m^2, P = 0.30), blood glucose (5.12 ± 0.05 vs 5.20 ± 0.03 mmol/l, P = 0.162), total cholesterol (5.21 ± 0.09 vs 5.27 ± 0.06 mmol/l, P = 0.638), HDL (1.43 ± 0.03 vs 1.43 ± 0.02 mmol/l, P = 0.483), LDL (3.27 ± 0.07 vs 3.32 ± 0.05 mmol/l, P = 0.681) and triglycerides (1.13 ± 0.06 vs 1.14 ± 0.03 mmol/l, P = 0.956) after adjustment for TSH and FT4. In women on levothyroxine TSH had positive correlation with HDL and FT4 was negatively associated with total cholesterol and LDL after adjustment for age and BMI. In healthy women TSH had positive association with total cholesterol and LDL and FT4 showed negative correlation with total cholesterol, HDL and triglycerides.
Conclusion
Women with autoimmune thyroiditis receiving levothyroxine have similar BMI, blood glucose and lipids compared with healthy euthyroid women provided that TSH is within reference range. Since there is no relationship between TSH and metabolic risk characteristics in euthyroid women on levothyroxine replacement therapy there would be no benefit in adjusting levothyroxine dose to achieve low-normal TSH.

Persistently elevated procalcitonin levels in Covid-19 pneumoniae leading to medullary thyroid cancer diagnosis

Laura Gianotti[1], Salvatore D'Agnano[2], Francesco Tassone[1], Giorgio Pettiti[3], Giuseppe Lauria[4], Valerio Del Bono[5] & Giorgio Borretta[1]

[1]Azienda Ospedaliera S. Croce e Carle Cuneo, Division of Endocrinology, Diabetology & Metabolism, Cuneo, Italy; [2]Azienda Ospedaliera S. Croce e Carle Cuneo, Division of Internal Medicine, Cuneo, Italy; [3]Azienda Ospedaliera S. Croce e Carle Cuneo, Division of Rheumatology, Cuneo, Italy; [4]Azienda Ospedaliera S. Croce e Carle Cuneo, Division of Emergency Medicine, Cuneo, Italy; [5]Azienda Ospedaliera S. Croce e Carle Cuneo, Division of Infectious Diseases, Cuneo, Italy

Objective
We report a case of acute respiratory syndrome coronavirus 2 (SARSCoV2) pneumonia in which persistently high procalcitonin (PCT) allowed the diagnosis of sporadic medullary thyroid cancer (MTC).
Methods
We describe the history of 43-year-old male with bilateral Sars-Cov-2 pneumoniae, in whom persistent increased PCT despite reduction of C reactive protein lead to investigate other causes of high PCT. Serum calcitonin (CTN) was measured and a painless, right latero-cervical swelling as well as thyroid nodules were found.
Results
Serum PCT and CTN were 94 ng/ml and over 2000 pg/ml, respectively. A thyroid ultrasound and cytological examination by fine needle aspiration confirmed the diagnosis of MTC. The patient underwent total thyroidectomy with bilateral cervical lymph nodes dissection. Histological analysis confirmed MTC of right thyroid lobe and metastasis at lymph nodes of the central right midneck area.
Conclusions
Although CTN represents the gold standard biochemical parameter for the diagnosis and follow-up of MTC, it can be affected by physiologic and pathologic conditions. PCT has recently been regarded as potential marker of MTC achieving high sensitivity and specificity. In the present case, high levels of PCT in the absence of signs of bacterial infection, allowed to diagnose MCT. Hence, in the absence of any other sign of infection, a complete clinical assessment, including neck palpation, calcitonin measurement and thyroid ultrasound should be performed in the presence of persistent elevated PCT. PCT could be a new diagnostic tool or a supplementary biomarker in the management of MTC.

Graves' disease presenting with hypercalcaemia, thymic hyperplasia and lymphadenopathy

Mehreen Anwar[1], Muhammad Athar Iqbal Khan[1], Sardar Muhammad Shoaib Khan[1], Yamin thant[1], Steve G. Jones[2] & Devaka Fernando[1]
[1]Kings Mill Hospital, Diabetes and Endocrinology, Nottinghamshire, United Kingdom; [2]Kings Mill Hospital, Consultant Haematologist, Nottinghamshire, United Kingdom

We would like to report an interesting case of Graves' disease which presented with thymic hyperplasia, bilateral generalised lymphadenopathy and hypercalcaemia, along with other typical manifestations of hyperthyroidism. A 53 year old lady was admitted following an opioid overdose as she was suffering from depression after a recent slipped disc injury which had resulted in poor mobility. She suffered an out of hospital respiratory arrest, underwent cardiopulmonary resuscitation including treatment with nalaxone and was subsequently admitted. History revealed weight loss, anxiety, sweating and palpitations and she was noted to be in atrial fibrillation. She was found to have hyperthyroidism with TSH <0.01 mU/l (normal range 0.3–4.2 mU/l) and FT4 of 39 pmol/l (normal range 12–22 pmol/l) with positive TSH receptor antibodies. Bloods also showed mild hypercalcaemia with adjusted calcium of 2.72 mmol/l (normal range 2.20–2.60 mmol/l) and supressed PTH of 4 ng/l (normal range 16–65 ng/l) with normal vitamin D. CT thorax, abdomen and pelvis done to rule out malignancy showed generalised small volume lymphadenopathy in the neck, mediastinum and left axilla, nodules in the lung fissures bilaterally and some anterior mediastinal soft tissue. Myeloma screen and tumour markers were negative. She was started on carbimazole and anticoagulation with rivaroxaban and was referred to the Lung and Lymphoma MDTs for imaging review. The MDT discussions suggested a diagnosis of thymic hyperplasia, hypercalcaemia and lymphadenopathy secondary to thyrotoxicosis and did not recommend a biopsy. She responded well to antithyroid drug treatment with resolution of thyrotoxicosis and hypercalcaemia and an interval CT scan at three months showed complete resolution of the thymic hyperplasia and lymphadenopathy. Her symptoms of anxiety have also improved. Thymic hyperplasia is a known but rare manifestation of Graves' disease which is thought to be caused by the action of TSH receptor antibodies on thyrotropin receptors in the thymus. Similarly, hypercalcaemia has also been reported in severe untreated Graves' disease. This is thought to be an affect of thyroid hormones causing increased bone resorption. Generalised lymphadenopathy is also described with Grave's disease. Hypercalcaemia, generalised lymphadenopathy and a neck mass on a background of weight loss would otherwise suggest a malignancy, such as lymphoma, but all of these are known features of severe untreated Graves' disease. This complex case demonstrates the importance of a multidisciplinary approach to ensure that the patient is not subjected to unnecessary invasive investigations and is managed optimally.

Importance of lymph extranodal extension to therapy outcomes in patients with thyroid follicular epithelial cell-derived carcinoma evaluated at one year

Fernando Hernández Olmeda[1], Patricia Espinosa De Los Monteros[1], Xavier Pérez Candel[1], Celia Lopez Nevado[1], Raquel Pallarés[1], Inés Jiménez[1] & Maria Cristina Familiar Casado[1]
[1]Hospital Clínico San Carlos, Endocrinology and Nutrition, Madrid, Spain

Introduction
The number of lymph node metastasis (NM) and the existence of extranodal extensión (ExEx) are not included among prognosis variables used in the most common staging systems for differentiated thyroid cancer as AJCC and ATA risk systems.
Objective
In patients with NM at diagnosis, to analyze the association between the number of NM and the presence of ExEx with response to therapy.
Patients and methods
Patients were included if they had undergone surgery at our center between december 2011 and january 2018 with a definitive diagnosis of thyroid follicular epitelial cell-derived carcinoma (TC) with NM and had had at least one follow-up after 12 months except for those died from TC. At one year, patients were classified in two groups according to the response to therapy: the group of Adequate Responders (AR) if they matched the definition of Excellent or Indeterminate Response and the group of Incomplete Responders (IR) in case of Biochemical or Estructural Incomplete Response based on the definitions endorsed by ATA. The variables evaluated at diagnosis for their potential relation to IR included: number of NM, ExEc and traditional factors as sex, age, presence of cancer (incidental or clinical), tumour size, unfavorable histology, distant metastasis (DM), multifocality, macro and microscopic extrathyroidal extension and incomplete surgical resection.
Results
103 patients (men: 26.2%) were included (median age of 49 ± 15.8 years) with a median of 3 (p25-p75: 2-6.25) resected MN. ExEx was demonstrated in 26.7 % of cases. Presence of Clinical cancer, incomplete resection, distant metastasis and macro and microscopic EE were found in 62.4%, 16.1%, 4.9%, 7.8 and 38.8% respectively. At one year, 19.6% of patients were classified into the IR group. Severals factors were clearly associated with IR: median tumoral size, presence of ExEx (18.8% in AR versus 62.5% in IR, $P< 0.05$) and DM (1.2% in AR versus 15% in IR, $P<0.05$). Multivariate analysis showed ExEx as an independent factor for IR (OR 5.6, IC 95% [1.2–26.3]). Specific mortality (3 cases) was associated with age (8.1 % versus 0 % in patients younger or older than 55 years of age respectively, $P < 0.05$) and unfavorable histology.
Conclusion
In CT patients with NM, the inclusion of ExEx to the variables frequently known at diagnosis could improve the prognosis value on mortality and recurrence of traditional AJCC and ATA risk systems.

Efficacy of multidisciplinary approach in thyroid nodules: analysis of factors used for predicting malignancy

Savas Volkan Kisioglu[1,2], Huseyin Atacan[3], Emel Cakir[4], Sukru Oguz[5], Serdar Karakullukcu[6] & Halil Onder Ersoz[2]
[1]Health Sciences University Kanuni Training and Research Hospital, Department of Endocrinology, Turkey; [2]Karadeniz Technical University, Department of Endocrinology, Turkey; [3]Karadeniz Technical University, Internal Medicine, Turkey; [4]Karadeniz Technical University, Department of Pathology, Turkey; [5]Karadeniz Technical University, Department of Radiology, Turkey; [6]Bayburt Community Health Center, Community Health Center, Turkey

Background
To date, numerous molecular tests have been developed for preoperative evaluation of thyroid nodules. Nevertheless, these tests cannot be administered in many centers due to their imprecise diagnoses and high costs. The present study aimed to investigate the effect of making surgical decisions in a council through a multidisciplinary approach after clinical, ultrasonographic, and pathological evaluation of nodules on the accuracy of the decisions.
Materials and methods
The retrospective study included patients with thyroid nodules who underwent preoperative ultrasonography (USG) followed by FNAB, which was confirmed by postoperative pathological examinations between January 2017 and January 2019. Relationship between USG features of nodules and malignancy was analyzed. A comparison was performed between patients that were referred for surgery through the multidisciplinary versus non-multidisciplinary approach.
Results
A total of 255 nodules in 211 patients were evaluated in the study. The prevalence of malignancy was 100% in nodules with hypoechogenicity + microcalcification + margin irregularity (P<0.001). The likelihood of malignancy was significantly higher in dual combinations of these three adverse conditions (P<0.001 for all) (Table 1). Margin irregularity was found to be the most predictive model for malignancy (CI: 1.9–13.8, OR: 5.249, P<0.001). The multidisciplinary approach was superior to the non-multidisciplinary approach in the detection of malignancy (P = 0.008)(Table 2).
Conclusion
Margin irregularity had the highest predictive value for the detection of malignancy. Employing the multidisciplinary approach in preoperative evaluation of thyroid nodules can be highly effective in detecting malignancy and preventing unnecessary surgery.

Table 1. Multivariate Logistic Regression Analysis for Independent Factors for Predicting Thyroid Malignancy

Us Features	Beta Coefficient	Odds Ratio	95% Confidence Interval	*P* Value
Hypoechogenicity	1.336 ± 0.329	3.804	1.996, 7.250	<0.001

Percutaneous laser ablation of metastatic lymph nodes, role of minimally invasive thyroid treatment in center of reference of endocrine surgery.

Chiara Offi[1], Umberto Brancaccio[1], Giovanni Antonelli[1], Edoardo D'Ambrosio[1], Maria Grazia Esposito[1], Claudia Misso[1] & Stefano Spiezia[1]
[1]Local Health Authority Naples 1 Center, Italy, Department of Endocrine Surgery, Italy

Background
The incidence of papillary thyroid cancers is increase in last decades due to easier ultrasound diagnosis. The papillary thyroid cancers metastasize via lymphatics to the lymph nodes of the central and later cervical neck compartment. According to 2015 ATA guidelines, the recurrence rate is less 1–2% [2]. The treatment of choice in lymph node recurrences is surgery, but it is burdened by a higher rate of complications (25% of recurrent laryngeal nerve palsy) [2]. Therefore, laser ablation of recurrent lymph nodes has been recognized as an alternative treatment with minimal invasiveness, low complication rate and curative effect [3].
Cases presentation
We report 6 cases of patients undergoing total thyroidectomy for papillary thyroid cancer diagnosed with fine needle aspiration cytology (FNAC) positive for malignant cells. All patients underwent metabolic radiotherapy, as indicated in the ATA guidelines, and experienced a lymph node recurrence 12–18 months after therapy. The diagnosis of relapse was made with ultrasound suspicion, FNAC with dosage of Thyroglobulin in the eluate. Three patients had a recurrence in the IV compartment, one in Vb compartment and two patients had a recurrence in the III compartment. The patients were treated with ModìLite™ laser ablative session using a multisource laser system (EchoLaser, Elesta SpA, Calenzano, Italy) with 1064 nm wavelength. The laser energy per each patient was delivered by a single 300 µm flat tip fiber introduced in target tissue through 21G Introduce needle. Hydrodissection of the lesion with 9% saline was performed in all patients. The energy delivered was 1560.28 ± 3213.84 Joule (Power, 3W). No major or minor complications were reported. At one-month follow-up, a volumetric reduction of the lesion of 39.67 ± 3.07% was reported. At 3 months of 48.83 ± 2.63% and at 6 months of 58.67 ± 3.07%. At 6 months, a fine needle aspiration was performed, negative for malignant cells and with a negative dosage of Thyroglobulin in the eluate.
Conclusion
Our experience has shown that laser ablation is an effective alternative to surgical treatment.

Estimating risk of recurrence of differentiated thyroid cancer patients: a real-world multicenter validation of the american thyroid association initial risk stratification and dynamic re-assessment after 5 years of follow-up.

Gianluca Cera[1], Giorgio Grani[1], Efisio Puxeddu[1], Emanuela Arvat[1], Alfredo Pontecorvi[1], Celestino Pio Lombardi[1], Massimo Torlontano[1], Maria Chiara Zatelli[1], Alessandro Antonelli[1], Giovanni Tallini[1], MARIA GRAZIA CASTAGNA[1], Laura Fugazzola[1], Sebastiano Filetti[1] & Cosimo Durante[1]
[1]On behalf of Italian Thyroid Cancer Observatory, Italy

Background
Most Differentiated Thyroid Cancer (DTC) cases typically show indolent biological behavior and a low mortality rate. Various prognostic systems are used to assess disease recurrence risk, to tailor treatment and follow-up strategies. The initial Risk Stratification System (RSS) and dynamic Response to Therapy Re-stratification (RTR) system, recommended by the 2015 American Thyroid Association (ATA) Guidelines, are the most employed. Still, they have been validated only in retrospective cohorts of single tertiary referral centers. This study aimed to verify their real-world ability to predict disease recurrence five years after initial treatment and to clarify the specific weight of the dynamic RTR system compared to the initial RSS.
Methods
A prospective and multicentric cohort of DTC patients collected by the Italian Thyroid Cancer Observatory was analyzed. The inclusion criteria were: (i) histological diagnosis of DTC: (ii) complete information on initial treatment and 1- and 5-year follow-up visits. Patients were grouped by the RSS and RTR criteria. The correlation between risk group and structural evidence of disease was evaluated by univariate and multivariate logistic regression. The predictive performances of the two systems were also compared.
Results
Seven hundred eighty patients from 24 centers were included. The risk of recurrent disease, based on the RSS, was classified as low in 450 (57.7%), intermediate in 278 (35.6%), and high in 52 (6.7%) patients. One-year response to treatment was excellent in 576 (81.2%), indeterminate in 98

(13.8%), biochemical incomplete in 12 (1.7%) and structural incomplete in 23 (3.2%) patients. At the 5-year follow-up visit, structural evidence of disease was observed in 25 patients (3.2%): 1.1% of low, 4.7% of intermediate and 13.5% of high-risk patients; 0.3% of patients with 1-year excellent response, 6.1% with an indeterminate response, 8.3% with a biochemical incomplete response and 56.5% with a structural incomplete response (χ^2 test, *P*-value <0.0001). Multivariate logistical models showed statistically significant predictive performance for both RSS (intermediate risk: OR 4.37; 95% CI 1.54–12.38; high risk: OR 13.84; 95% CI 4.22–45.41) and RTR (1-year indeterminate response: OR 18.72; 95% CI 3.72–94.14; biochemical incomplete response: OR 26.09; 95% CI 2.20–309.54). Moreover, the dynamic stratification showed better predictive power, especially when combined with the initial risk.

Conclusions

Both ATA initial risk estimation and dynamic risk re-stratification systems effectively predict DTC recurrence, in a real-world, heterogeneous, and multicenter cohort. The dynamic stratification showed better predictive power, and it is even better when the two systems are combined.

Assessment of hearing impairment in adult patients with euthyroid Hashimoto's thyroiditis

Ömercan Topaloğlu[1] & Bayram Şahin[2]
[1]Kocaeli Derince Training and Research Hospital, Endocrinology, Derince/Kocaeli, Turkey; [2]Kocaeli Derince Training and Research Hospital, Otorhinolaryngology, Derince/Kocaeli, Turkey

Introduction

Hearing loss may be associated with autoimmune diseases, but it was less studied in Hashimoto's thyroiditis (HT). We aimed to evaluate hearing impairment by audiometric assessments in adults with euthyroid HT.

Materials and Methods

Adult patients with euthyroid HT (normal thyroid functions, positive AntiTPO/AntiTg and sonographic findings) were compared with controls. We excluded pregnant or older patients (>50-year-old), those with history of otological/audiological disease or surgery, otitis media, acoustic trauma, chronic illnesses, use of alcohol, cigarette, medications, rheumatoid factor, antinuclear, antimitochondrial, antiparietal, antineutrophil cytoplasmic, anti-smooth muscle, or antigliadin antibodies, abnormal biochemical or otological findings. Tympanometry which indicated tympanic peak pressure (TPP, daPa), acoustic reflex testing (ART), pure tone average (PTA), and transient evoked otoacoustic emission (TEOAE) were performed. We grouped the participants according to ART (positive/negative), TEOAE (normal/undetected), PTA (≤20/>20 dB).

Results

Air conduction thresholds on right ear at 500, 4000, 6000, 8000 Hz, PTA average, and left ear at 250, 4000, 6000, 8000 Hz were higher in euthyroid HT ($n = 36$) than in controls ($n = 40$) ($P<0.05$). We found less negative TPP and a higher ratio of negative ART in euthyroid HT ($P<0.05$). Euthyroid HT predicted undetected TEOAE and increased hearing threshold on right ear at 500 and 8000 Hz ($P<0.001$). TEOAE detected hearing impairment at a higher rate. AntiTPO level was positively correlated with TPP and air conduction thresholds except right ear at 8000 Hz.

Conclusions

Hearing may be impaired in euthyroid HT. We recommend close monitoring of hearing functions in these patients. TEOAE more specifically indicates hearing impairment.

Table 1. Logistic regression analysis showing the association between categorical parameters and HT.

Assessment of clinical burden and practice patterns in patients with chronic hypoparathyroidism in the united states (us): a claims data analysis using diagnosis-based criteria

Dolly Sharma[1], Kathleen L Deering[1], Soraya Allas[2], Michael D. Culler[3], Patrick Loustau[3], Blandine Weiss[3], Deborah Michelle Mitchell[4], Danette Astolfi[5] & Michael Mannstadt[4]
[1]EPI-Q Inc, Oak Brooks, IL, United States; [2]Amolyt Pharma, Ecully, France; [3]Amolyt Pharma, Cambridge, MA, United States; [4]Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, United States; [5]Hypoparathyroid Association, Wescosville, PA, United States

Objectives

There is a paucity of real-world studies analyzing comorbidities, lab testing and treatment patterns of patients with chronic hypoparathyroidism (cHP). This study describes a large cohort of cHP patients identified using a diagnosis-based approach from a US claims database.

Methods

This retrospective study was conducted using a large (130 million individuals) claims database (HealthVerity Closed Payer Claim Medical and Pharmacy databases: Private Source 20) from Oct 2014 to Dec 2019. Patients were eligible if they had ≥2 diagnosis claims of HP that were 6–15 months apart, a prescription claim for either active vitamin D, calcium, PTH or thyroid replacement therapy between the first HP claim and within 30 days of the second HP claim, and were continuously enrolled for one year before the index date (the date of the first of two qualifying HP diagnosis claims) and ≥16 months after. Patients were followed up to two years after the index date. Demographics, comorbidities, lab testing and treatment patterns were analyzed.

Results

Out of 43 640 patients with a diagnosis claim for HP, 4118 met the eligibility criteria. In this cohort, the mean age was 56.5 years ± 18.6 (S.D.), and 76.4% were females, similar to data from other large cohort studies. The most common comorbidities during the 1-year follow-up were hypertension (56.0%), hypocalcemia (38.7%), cancer (30.5%, of which 24% were thyroid cancers), diabetes (29.4%), chronic pulmonary disease (24.1%), cardiac arrhythmias (17.4%), CKD stage 3–5 (17.0%), osteoporosis (9.6%) and neuropsychiatric disorders, including depressive disorders (22.0%), anxiety (21.6%), and sleep-wake disorders (18.4%). During the 1-year follow up, commonly ordered lab tests included serum calcium (89.9%), eGFR/creatinine (85.7%), 25-hydroxy vitamin D (61.1%), and intact PTH (43.9%). Serum phosphorous (36.3%), serum magnesium (35.4%) and 24 h-urine calcium (10.5%) were evaluated much less frequently. In addition, BMD was measured in 10.9% patients. During the same follow-up period, 67.1% of patients had a prescription claim for thyroid replacement therapy, 60.5% for calcitriol, 15.7% for ergocalciferol, and 3.4 % for PTH.

Conclusion

This study highlights the high comorbidity burden in cHP patients which is aligned with the observed monitoring patterns. Kidney health appears to be a key concern in this population, and may be an important consideration in therapeutic intervention. The comorbidities and practice patterns observed are consistent with the results found using a surgery-based approach to identify cHP patients within the same claims database. Future analyses will include the economic burden of cHP.

Phenotypical changes of thyroid disease in a patient with Turner Syndrome

Imen Halloul, Asma Ben Abdelkerim, Wafa Ben Othman, Ghada Saad, Maha Kacem, Amel Maaroufi, Molka Chaieb, Yosra Hasni & Koussay Ach
Farhat Hached University Hospital, Department of Endocrinology and Diabetes, Sousse, Tunisia

Introduction
Turner syndrome (TS) is among the most common chromosomal abnormalities in females, resulting from structural or numeric abnormalities in the X chromosome. Autoimmune disorders, especially thyroid diseases have a high prevalence among these patients. Usually Hashimoto's thyroiditis (HT) is the most frequent one, whilst the association between this syndrome and Graves' disease (GD) has been less often reported. Here we report a case of patient with TS who has developed both autoimmune thyroid diseases over the course of her follow-up.
Case report
A 16-year-old female patient was referred to our endocrinology department for symptoms of hyperthyroidism. The patient was diagnosed with TS at the age of 9 when she had consulted for short stature. The diagnosis was confirmed with a karyotype showing a deletion in the short arm of the X chromosome: 46, X del(p12). Shortly after, she developed hypothyroidism and was put under levothyroxine. The patient has a family history of hyperthyroidism in her mother and her uncle. The antithyroid peroxidase (anti-TPO) and anti-thyroglobulin (anti-TG) antibodies were negative at the time. At the age of 15, the patient started showing signs of hyperthyroidism such as weight loss, exophthalmia and tachycardia, with a thyroid stimulating hormone (TSH) level at 0.010 mUI/l (0.51 – 4.94 mUI/l). The immunological tests were positive this time with an anti-TPO level at 1300 UI/ml (<60 UI/ml), an anti-TG level at 354.9 UI/ml (<100 UI/ml) and a TSH receptor antibody level at 33 UI/l (<2 UI/l). A neck ultra-sound was performed and showed a hyper vascular goiter. All these exams confirmed the GD in our patient. A treatment with benzyl thiouracil was started for almost a year and the patient thyroid function became normal. At her last consultation, she presented signs of hypothyroidism even after stopping benzyl thiouracil for more than a month and the TSH level was high >100 mUI/l. Therefore, the patient was put again under levothyroxine to eventually achieve normal thyroid function.
Conclusion
Autoimmune thyroid diseases may begin in early childhood in patient with TS, and its prevalence increases with age. HT and GD are caused by two distinct paradigms. Nevertheless, it has been sporadically reported that GD and HT may follow one another in the same individuals, due to a sequential phenotypic conversion from HT to GD, or vice versa. In fact, patients with TS and associated HT were found to be at higher risk of progressing toward GD than the general population.

Hypothyroidism causing acute kidney injury (AKI)

Marjan Gohar[1], Yagoub Abdelgader[2] & Vikram Aarella[2]
[1]Nottingham City Hospital, United Kingdom; [2]Pilgrim Hospital, United Kingdom

AKI is a potentially a life threatening condition and it is extremely crucial to investigate the root cause it order to manage the patient appropriately.
Case report
A 30 years old female presented with complaints of generalized muscle weakness, lethargy and mood changes. She was found to have raised creatinine with significant drop in her GFR to 41. Rest of her electrolytes and full blood count were within normal range. She was commenced on Intravenous fluids with strict input/output monitoring. No obvious trigger for her decline in renal function could be found. In order to find the cause for renal deterioration and in view of her clinical presentation, thyroid function tests and creatinine Kinase was done subsequently. Her blood tests revealed TSH >100 mU/l with T4 <1.0 pmol/l. Creatnine Kinase was minimally raised around 322 u/l. Provisional impression of hypothyroidism induced myopathy and AKI was made. She was treated with levothyroxine 100 µg. Her Thyroid peroxidase AB -TPO (303 IU/ml) was positive. Rest of the renal investigations were normal. Renal team were in agreement of concluding that acute kidney injury was perhaps due to severe undiagnosed Autoimmune hypothyroidism. Following adequate rehydration and after commencing thyroxine, she improved significantly both clinically and biochemically. Her creatinine gradually decreased over time with reciprocal improvement in her GFR.
Discussion
Hypothyroidism causing acute kidney injury is a very rare presentation. The exact mechanism for kidney failure still remains unknown. It has been postulated that absence of thyroid hormone alters mitochondrial oxidation and reduces glycogenolysis resulting in muscular atrophy leading to decreased number of fast-twitching (Type 2 fibers) Subsequently, increased deposition of glycosaminoglycan and hypertrophy of slow muscle fiber occurs causing myopathy and increased fatigue. It has also been proposed that T4 deficiency alters muscle permeability resulting in release of muscle enzymes, known as creatnine kinase. Its accumulation, known as rhabomyolysis is a well-known attribute of AKI. Some studies have shown effect of Thyroid hormone on renal perfusion (Renal plasma flow) which can subsequently alter GFR and affect kidney function. It is also noteworthy that majority of the rare cases reported demonstrates rhabdomyolysis as major cause of AKI in Hypothyroidism. However, in our case, patient had minimally raised levels of CK and was found to be in AKI. This is the first case to be reported that doesn't meet the criteria for rhabomyolysis in presence of AKI.

Graves' disease; relapse or fake news with Biotin

Rahul Sakarwadia[1], Hassan Ibrahim[1], Ayaz Hussain[1], Christo Albor[1], Solat Hasnain[1] & Jawad Bashir[1]
[1]Basildon University Hospital, Basildon, United Kingdom

A 41 year old lady presented to emergency department with tremors and palpitations. Her examination and routine bloods were normal but ECG showed sinus tachycardia (heart rate = 141 bpm). She was treated with propranolol and discharged. She was readmitted in emergency department with ongoing palpitations, lethargy and tremors. On examination, she had a diffuse goitre but no signs of Graves' eye disease. The blood tests showed overt thyrotoxicosis (TSH<0.01 mU/l, FT4 = 49.1 pmol/l, FT3 = 27.7 pmol/l) with positive anti TSH receptor antibodies (Anti-TRAb levels = 11.3 IU/l) and a thyroid ultrasound revealed a diffusely enlarged goitre. She was started on treatment for Graves' disease with carbimazole 15 mg BD along with propranolol. She was on 8 weekly endocrine follow up to monitor thyroid function tests (TFT). Within 4 months, her weight increased from 86.5 kg to 93.5 kg. She had the anticipated mild iatrogenic subclinical hypothyroidism (TSH = 7.35 mU/l, FT4 = 5.8 pmol/l, FT3 = 5 pmol/l). The dose of carbimazole was reduced to 5 mg once daily. Six months later, there was mild relapse of Graves' disease (TSH<0.01 mU/l, T4 = 24.2 pmol/l, T3 = 9.2 pmol/l). Carbimazole was increased from 5 mg to 20 mg again. Her thyrotoxicosis went into remission (TSH = 1.56 mU/l, T4 = 9.9 pmol/l) 11 months after initial diagnosis, but the anti-TRAb was still positive (3.7 IU/l). Carbimazole was continued at 5 mg. Her TFTs started to show an unusual pattern of remission with normal TSH but raised FT4 and FT3 whilst being on carbimazole 5 mg.

- TSH = 2.05 mU/l, T4 = 19.1 pmol/l and T3 = 8.1 pmol/l
- TSH = 1.08 mU/l, T4 = 26.9 pmol/l and T3 = 14 pmol/l

This was discussed with the biochemist as it wasn't the common pattern of early relapse with fully suppressed TSH(<0.01 mU/l). Hence it was thought to be an interference with biotin. On direct enquiry, the patient confirmed taking a variety of over the counter supplements containing biotin to help improve her hair and nail growth. This correlated well with the timing of unusual pattern of TFT. The carbimazole was stopped and her TFT on repeat check were completely normalised. Graves' disease has a relapsing remitting course. It is not unusual to make frequent changes of carbimazole dosages based on TFT results every 6–8 weeks. The usual duration of treatment of Graves' disease is 12–18 months to achieve remission and normalization of Anti-TRAb. Biotin has been reported to interfere with thyroid hormone assays and also give falsely elevated anti-TRAb levels. This can lead to inadvertent use of carbimazole in a patient with Graves' disease in remission. This case highlights the importance of identifying use of supplements like biotin which can interfere with TFT results.

Case report : A rare case of leucinosis decompensated by hyperthyroidism

Fetta Yaker[1], Busiau Pauline[1], Herrou Anne-Flore[1], Abouleka yawa[1], Gippa Sandrine[1], Dao Myriam[2], Evrard Diane[3], Roussel Ronan[1] & Potier Louis[1]
[1]Bichat Hospital, Department of Diabetology Endocrinology and Nutrition, Paris, France; [2]Necker Hospital, Nephrology department, Paris, France; [3]Bichat Hospital, Otorinolaryngology Department, Paris, France

Leucinosis also called Maple syrup urine disease (MSUD) is a rare inherited disorder of branched-chain amino acid metabolism classically characterized by poor feeding, lethargy, vomiting and a maple syrup odor in urine with an evolution to encephalopathy and central respiratory failure if untreated. When diagnosed at birth, treatment is based on nutrition therapy aiming at rapidly reducing of toxic metabolites through dietary restriction, shifting towards and preventing or minimizing endogenous protein catabolism. Any state of catabolism can cause leucinosis' decompensation: intercurrent infectious disease, fever, anorexia, vomiting, surgery, excess protein instake. We report a case of MSUD decompensated by hyperthyroidism with complex management. A 20 years old woman had a family history of leucinosis and a diagnosis of MSUD at birth. At 13, an hyperthyroidism caused by Graves' disease was diagnosed. She was treated by carbimazole for 7 years with relapses when decreasing treatment. Between September and October 2020, she experienced 3 successive hospitalizations for middle to major leucinosis decompensations due to thyrotoxicosis occurring despite an increase to maximal doses of carbimazole and use of ursodeoxycholic acid. Therapeutical options were limited by formal contraindication to use corticoid, poor experience with radioactive iodine therapy and difficulties to organize surgery with strict metabolic conditions. However, after a multidisciplinary discussion, surgery was chosen as a radical treatment due to the major risk of new decompensation. Leucinosis is a very rare disease and its association to hyperthyroidism was never reported before.

Hyperthyroidism and exophthalmos in a patient with Erdheim–Chester disease

Kamila Mitka, Grzegorz Sokołowski, Dorota Pach & Alicja Hubalewska - Dydejczyk
Jagiellonian University Medical College, Department of Endocrinology, Kraków, Poland

We present extremely rare case of a female patient with the coincidence of hyperthyroidism, exophthalmos and Erdheim–Chester disease (a rare form of non-Langerhans cell histiocytosis, positive BRAF mutation). The patient was hospitalized due to exacerbations of the primary disease and symptoms of thyroid dysfunction. For about two months, the patient has reported increased feeling of heat, sweating, palpitations, weight loss of about 10 kg for 3 months, significant intensification of exophthalmos, pain in the eyeballs, lacrimation, feeling of sand under the eyelids. In addition, the patient has been taking amiodarone for 1.5 years (due to ventricular arrhythmias). The medical history also revealed central diabetes insipidus, progressive retroperitoneal and peraortic fibrosis involving the adrenal glands, aorta, inferior vena cava, spreading into the mediastinum, condition after insertion of JJ catheters into both ureters due to stagnation in the calicapelic system, multiple osteosclerotic changes. During the diagnostics and treatment, it was found that the exacerbation of eye symptoms (bilateral exophthalmos) was caused by the masses of fibrous tissue formed in the course of the underlying disease – the patient was referred to orbits decompression. During the observation, due to the diagnosed hyperthyroidism, the patient was qualified to radical treatment with radioiodine – it was obtained euthyreosis with substitution treatment with l-thyroxine. This case illustrates the importance of careful attention of diagnostics, treatment and monitoring even despite the most typical course of hyperthyroidism – and if necessary to accelerate and extend the treatment with additional tests.

Myxedema coma in a COVID-19 patient

Catarina Cidade-Rodrigues, Marta Dalila Martins, Verónica Cardoso, Rita Linhas, Filipa Viveiros, Rogério Ruas, Rita Ferraz & Filipe Cunha
Centro Hospitalar do Tâmega e Sousa, Portugal

Introduction
Myxedema coma is a rare condition with an estimated incidence of 0.22 per million per year in the western world and a mortality rate around 30–50%. It can occur as the result of severe longstanding hypothyroidism or be precipitated by an acute event, such as infection. We present a rare case of myxedema coma in an elderly woman with SARS-CoV-2 infection.
Case report
An 82-year-old woman, with no previous history of hypothyroidism, presented with signs of breathing difficulty for the past 2 days associated with progressive lethargy and constipation. She had history of arterial hypertension, dyslipidaemia, and chronic kidney disease (KDIGO 4 stage). She had a uterine neoplasm discovered in contrasted CT scan but refused to undergo further studying. Her chronic medication included simvastatin, clopidogrel, furosemide, irbesartan and hydrochlorothiazide. In the physical examination, she was pale and dehydrated. Glasgow coma scale (GCS): 9 points. Blood pressure was 84/56 mmHg, heart rate of 60 bpm, temperature 36.2ºC and peripheral oxygen saturation of 94% at room air. Cardiopulmonary auscultation was normal. Her abdomen was diffusely tender to palpation and she had no peripheral oedema. Her initial blood work showed anaemia (10.3 g/dl), hyponatremia (126 mmol/l), hyperkalemia (5.7 mmol/l) and acute kidney injury (creatinine 1.67 mg/dl and urea 113 mg/dl). SARS-CoV-2 PCR testing was positive. Chest roentgenogram demonstrated signs of bilateral pneumonia. Head CT showed no recent vascular events. She was admitted and started fluid resuscitation with 0.9% saline. On the second day of hospitalization, she became unresponsive (GCS: 3 points) and presented oxygen desaturation, needing supplemental oxygen therapy with FiO2 80%. She was hypotensive (90/56 mmHg), bradycardic (45 bpm), and hypothermic (32.4ºC). She showed signs of inadequate perfusion of extremities, with barely palpable peripheral pulses. Her blood work evidenced pancytopenia, elevated transaminases, hyponatremia (132 mmol/l), hyperkalemia (5.3 mmol/l), PCR 24.5 mg/dl, procalcitonin 0.22 ng/ml, free T4 <0.25 ng/ml and TSH 52.67 µU/ml. She was diagnosed with myxedema coma triggered by SARS-CoV2 infection and treated with 200 mg hydrocortisone and 200 µg L-thyroxine intravenously. Despite these measures, she showed no signs of response and died within a few hours.
Discussion
Myxedema coma diagnosis requires a high level of clinical suspicion. This is the second described case of myxedema coma in a COVID-19 patient. In this patient, factors favouring this diagnosis were the coma status, hypoventilation, hypotension, bradycardia, hyponatremia and hypothermia. The SARS-CoV2 infection, a virus with known neurological tropism, might have impaired the ventilatory response even more.

Evolution of SARS-CoV-2 related atypical thyroiditis

Ilaria Muller[1,2], Tiziana Re[3], Matteo Varallo[4], Anita Daturi[4], Daniele Cannavaro[4], Benedetta Nadiani[4], Davide Dazzi[5], Virgilio Longari[6], Marco Cuzzocrea[6], Andrea Gori[7,8], Giovanna Mantovani[1,2], Maura Arosio[1,2] & Mario Salvi[2]
[1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology, Milan, Italy; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Medicine – Acute Medical Unit, Milan, Italy; [4]University of Milan, Milan, Italy; [5]Casa di cura Val Parma SRL, Langhirano (PR), Italy; [6]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Nuclear Medicine, Milan, Italy; [7]University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy; [8]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Infectious Diseases, Milan, Italy

Background
We provided the first description of thyrotoxicosis due to atypical thyroiditis in patients hospitalised for severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) pandemic disease (Covid-19), not associated with neck pain, more common in men, correlated with disease severity and coexisting with non-thyroidal illness syndrome. Classic viral subacute thyroiditis is often followed by permanent thyroid dysfunction and autoimmunity, thus we have started a longitudinal thyroid study, also including patients newly infected with SARS-CoV-2.
Methods
Baseline (at hospital admittance) and longitudinal (quarterly) study of patients hospitalised for moderate-to-severe Covid-19 disease, without known history of thyroid disorders, assessing serum thyroid function and autoantibodies, inflammatory markers and thyroid ultrasound scan (US).

Patients showing US focal hypoechoic areas suggestive for thyroiditis also underwent subsequent thyroid ^{99m}Tc or I^{123} uptake scan.
Results
To date 185 Covid-19 patients have been studied, of whom 53 (29%) already evaluated at follow-up. At baseline, 44/185 (24%) had low serum TSH concentrations and 23/185 (12%) thyrotoxicosis (low TSH and/or high free-thyroxine). TSH positively correlated with lymphocyte count (0.38, P<0.001) but not with C-reactive-protein (−0.12, P = 0.09) and interleukin-6 (0.01, P = 0.936). Thyroid US performed during hospitalisation showed one or more focal hypoechoic areas suggestive for thyroiditis in 8/20 (40%) patients. At 3 months of follow-up the serum median (IQR) TSH concentrations were increased in all patients (n = 53) compared with baseline: 1.6 (1.0–2.2) mIU/l versus 0.9 (0.5–1.8) mIU/l, respectively (P<0.001). Serum free-thyroxine, free-triiodothyronine and inflammatory markers also normalised compared with baseline. Seven patients (13%) had positive anti-thyroglobulin (TgAb) and/or anti-thyroid-peroxidase (TPOAb) autoantibodies and were excluded from the thyroid imaging study. Thyroid US showed focal hypoechoic areas of thyroiditis in 14/46 (30%) patients; thyroid ^{99m}Tc/I^{123} scintigraphy resulted normal in 3/12 (25%), focally reduced in 8/12 (67%) and diffusely reduced in 1/12 (8%). The prevalence of thyroid focal hypoechoic areas at US was 53% and 27% in patients with low or normal TSH at baseline, respectively (P = 0.05). At 6 months of follow-up the thyroid function remained normal, no patients developed TgAb/TPOAb and the thyroid US and ^{99m}Tc/I^{123} scintigraphy studies are ongoing.
Conclusions
Thyroid dysfunction during moderate-to-severe Covid-19 disease is mild and transient, however atypical areas of focal thyroiditis at US persisted at 3 months in about one third of patients and long-term consequences are still unknown. The association of low serum TSH concentrations with both lymphocytopenia and focal areas of thyroiditis at US supports the hypothesis of thyroid gland involvement in SARS-CoV-2 infection.

Pre-operative vitamin D deficiency is a risk factor for post-thyroidectomy hypoparathyroidism: a systematic review and meta-analysis of observational studies

Konstantina Vaitsi[1,2], Panagiotis Anagnostis[1,2], Stavroula Veneti[3], Theodosios S. Papavramidis[4] & Dimitrios Goulis[1]
[1]Unit of Reproductive Endocrinology, 1st Department of Obstetrics and Gynecology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece, Greece; [2]Department of Endocrinology, Police Medical Center of Thessaloniki, Thessaloniki, Greece, Greece; [3]1st Propedeutic Department of Internal Medicine, Medical School, Aristotle University of Thessaloniki, AHEPA Hospital, Thessaloniki, Greece; [4]1st Propedeutic Department of Surgery, AHEPA University Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece

Context
Whether pre-operative vitamin D deficiency (VDD) contributes to post-operative hypoparathyroidism (hypoPT) risk is unknown.
Objective
To meta-analyze the best available evidence regarding the association between pre-operative vitamin D status and hypoPT risk.
Data Sources
A comprehensive literature search was conducted in PubMed, CENTRAL and Scopus databases, up to October 31, 2020.
Study Selection
Patients undergoing thyroidectomy with pre-operative vitamin D status and post-operative hypoPT data.
Data Extraction
Two researchers independently extracted data from eligible studies.
Data synthesis
Data were expressed as risk ratio (RR) with 95% confidence interval (CI). The I^2 index was employed for heterogeneity.
Results
Thirty-nine studies were included in the quantitative analysis (61 915 cases with transient and 5712 with permanent hypoPT). Patients with VDD demonstrated a higher risk for transient hypoPT compared with those with pre-operative vitamin D sufficiency (RR 1.92, 95% CI 1.50–2.45, I^2 85%). These results remained significant for patients with pre-operative 25(OH) D concentrations ≤20 ng/ml (mild VDD; RR 1.46, 95% CI 1.10–1.94, I^2 88%) and ≤10 ng/ml (severe VDD; RR 1.98, 95% CI 1.42–2.76, I^2 85%). The risk of permanent hypoPT was increased only in cases with severe VDD (RR 2.45, 95% CI 1.30–4.63, I^2 45%). No difference was evident in subgroup analysis according to study design or quality.
Conclusions
Patients with pre-operative VDD are at increased risk of transient hypoPT following thyroidectomy. The risk for permanent hypoPT is increased only for those with severe VDD.

AEP653

Metabolic effects of levothyroxine as a part of multicomponent therapy in patients with a combination of arterial hypertension, type 2 diabetes mellitus and subclinical hypothyroidism

Vira Zlatkina, Valeriya Nemtzova & Iryna Ilchenko
Kharkiv National Medical University, Clinical Pharmacology and Internal Medicine, Kharkiv, Ukraine

Objective
To establish the association of the dynamic changes in carbohydrate, lipid metabolism parameters and blood pressure (BP) profile in patients with combined course of arterial hypertension (AH), type 2 diabetes mellitus (DM) and subclinical hypothyroidism (SH) and to determine the efficacy of the applied scheme. We examined 106 patients – 45 women and 61 men aged 45–55 years with AH stage II grade 2 and type 2 DM which were divided on SH presence into two groups: gr.1 – with SH which additionaly to the main antihypertensive scheme received levothyroxine (n = 47) and without SH (n = 59) – gr.2. Levothyroxine was administered in an individually selected dosage by titration in accordance with the obtained laboratory parameters.
Methods
BP profile, HOMA-insulin resistance (IR), glycated hemoglobin (HbA1c), lipid metabolism parameters (LDL-C, HDL, TG), thyroid-stimulating hormone (TSH) levels.
Results
Analysis of patients monitored during the year with multimorbid pathology – gr. 2 showed more expressed disorders of carbohydrate metabolism – fasting glucose, HbA1c, compared with similar indicators in gr.1, which demonstrates more significant metabolic changes, and subjectively indicates an increase in cardiovascular risk. Patients of gr. 2 are characterized by more pronounced manifestations of dyslipoproteinemia in the form of increased LDL-C (P<0.05) and hypertriglyceridemia and lower levels of HDL. In the dynamics of combined antihypertensive treatment in patients from gr. 1 and gr. 2, a sufficient antihypertensive effect was found, which was to achieve the target BP levels of 76.43 % and 69.27 % of those surveyed, respectively. Significant differences after 12 months of therapy were reached by the value of systolic BP in all examined groups (P<0.05). Diastolic BP was significantly reduced in all groups compared to the initial values (P <0.05). Administration of levothyroxine led to a significant reduction in proatherogenic lipids, in group 2, where LDL-C from (3.6 ± 0.33) mmol/l to (2.5 ± 0.27) mmol/l, P <0.05, and TG from (3.3 ± 0.44) mmol/l to (1.85 ± 0.31) mmol/l, P <0.05, whereas SH promotes the development and progression of atherosclerosis despite hypolipidemic therapy.
Conclusions
Additional administration of levothyroxine to the standard combined scheme in patients with AH, type 2 DM and SH improve lipid, carbohydrate metabolism and hemodynamics in the form of a significant reduction in dyslipidemia, normalization of fasting glucose levels and HbA1c which definitely reduces the risk of cardiovascular events in this category of patients.

Autoimmune polyendocrine syndrome in patients with thyroid autoimmunity

Hadj Kacem Faten[1], Derbel Abir[2], Chouaib Sara[1], Abid Mohamed[1], Raida Ben Salah[2] & Bahloul Zouhir[2]
[1]Chu Hedi Chaker, Endocrinology, Sfax, Tunisia; [2]Chu Hedi Chaker, Internal Medicine, Sfax, Tunisia

Introduction
Autoimmune Polyendocrine Syndrome (APS) is defined by the presence of 2 or more autoimmune induced endocrine failures in a single patient. There are 4 types of APS: type1 including chronic muco-cutaneous candidiasis,

hypoparathyroidism, Addison disease (AD) and ectodermal dystrophy, APS type 2 and 3 containing autoimmune thyroide disease (AITD), type1 diabetes (DT1) with (type2) or without adrenal failure (type3) and type 4 not falling into the above categories. The aim of our study was to precise the prevalence of APS in a group of patients with AITD and their clinical and serological evaluation.
Methods
Retrospective study including 46 patients suffering from APS among 113 with AITD was performed in internal medicine and/or endocrinology department hospital from January 2000 to December 2017.
Results
46 patients (40%) with AITD had APS. 60% of population was female (sex-ratio = 1.87). The mean age was 34.13 years [14–65 years]. We noticed history of thyroid disease in 26% of cases and family auto-immune disorder in 8.6%. In our study, we identified 7 cases of APS type2 and 39 cases of APS type3. AITD was type Grave's disease in 10 cases, Hashimoto thyroiditis at hypothyroidism stage in 23 cases, hyperthyroidism stage in 6 cases and euthyroidism in 7 cases. On clinical presentation, APS manifests itself as one of the major autoimmune diseases: adrenal failure and/or DT1 and/or hypo/ hyperyroidism in all cases. Diabetes preceded APS in 50% of cases. Minor autoimmune disorder type Vitiligo was diagnosed preceding the development of APS in 2 cases and concomitantly in 1 case. Thyroid gland was enlarged in 67% of cases. Serum analysis showed diabetes in 56.5%, hypothyroidism in 50%, hyperthyroidism in 35%, euthyroidism in 15% and adrenal insufficiency in 15.2% of patients. Immunologic investigations showed Thyroid peroxidase autoantibodies in 91%, thyroglobilin-autoantibodies in 43%, Glutamic-Acid-Decarboxylase autoantibodies in 67%, TSH-receptor autoantibodies in 21.7%, adrenal autoantibodies in 16.2%, antinuclear antibodies in 6.5%, antigliadin antibodies in 4.3%, anti-ovarian, antiparietal-cell and anti-transglutaminases auto antibodies in 2.1% respectively. Multiple autoimmune syndrome (type3) was retained in 6 patients (13%). Extra endocrine auto-immune disorders founded were: vitiligo (3 cases), lupus, celiac disease and pernicious anemia (1 case each).
Conclusion
Prognosis of APS depends on individual glandular failures. Considering the high incidence of APS in patient with family and/or personal autoimmune history, regular screening in specialized centers must be performed. In our series containing 46 cases of AITD with APS, type3 was more observed (84.8%) unlike other studies in which APS type2 was more prevalent.

Vitamin D deficiency is associated with increased thyroid autoimmunity in Georgian adults

Meri Davitadze[1], Eka Melson[2,3], Ann Kobaidze[4,5], Nino Tedoradze[4,6], Emma Ooi[7] & Punith Kempegowda[3,8]
[1]Georgian-American Family Medicine Clinic "Medical House", Tbilisi, Georgia; [2]Ninewells Hospital, United Kingdom; [3]Institute of Metabolism and Systems Research, University of Birmingham, United Kingdom; [4]V. Iverieli Endocrinology, Metabology, Dietology Center "ENMEDIC", Georgia; [5]National Screening Center, Georgia; [6]Zhordania Clinic, Georgia; [7]RCSI & UCD Malaysia Campus, Malaysia; [8]Queen Elizabeth Hospital Birmingham, Department of Endocrinology, United Kingdom

Introduction
Recently, apart from its main physiologic role, the active form of vitamin D has also been recognised to have anti-inflammatory and immune-modulating properties. Accumulating evidence suggests that Vitamin D deficiency is associated with increased prevalence of various autoimmune diseases, and in particular, with autoimmune thyroid disease. Despite contradicting evidence, the balance is tipping towards inverse correlation between vitamin D deficiency and autoimmune thyroid diseases. To the best of our knowledge, this association has not been studied before in South Caucasia, a large geographical area spanning across four countries, including Georgia. Therefore, this study aimed to investigate whether vitamin D deficiency was associated with increased prevalence of autoimmune thyroiditis among Georgian adults.
Methods
Study population consisted of patients aged >18 years with measurements of both serum vitamin D (25OHD) and thyroid peroxidase antibody (TPOAb) levels in two medical centres in Georgia from July 2016 to August 2020. The participants were divided into cases (vitamin D deficient) and controls (vitamin D sufficient/insufficient). 25OHD and TPOAb baseline levels were compared using Kruskal–Wallis rank-sum test. The strength of association was quantified by odds ratio. The strength and direction of association between vitamin D and TPOAb were measured with Spearman's rank-order correlation. Statistical significance was accepted at 95% confidence interval (P<0.05).
Results
170 patients had measurements of both 25OHD and TPOAb, and were included in the analysis, with a mean age of 43.9 ± 15.49 years (male to female ratio of 1:4.28). 59.4% (n = 101/170) had vitamin D deficiency and 53.5% had positive TPOAb (n = 91/170). In the case group, 60.4% (n = 61/101) had positive TPOAb, compared to 43.5% (n = 30/69) in controls. TPOAb baseline levels were higher in cases (mean: 191.0, S.D.: 53.9), compared to the controls (mean: 102.7, S.D.: 155.4) (P = 0.0328). TPOAb was significantly higher in the case group (P = 0.0439) with an odds ratio of 2.0 (OR>1, 95% CI: 1.1–3.7, P = 0.0308). When adjusted for age, gender, and BMI, a percentage change of 14.8% was observed, increasing the odds ratio to 2.3 (OR>1, 95% CI: 1.2–4.5, P = 0.0169). A significant inverse correlation was observed between vitamin D and TPOAb levels (rho = –0.16, P = 0.0367).
Conclusion
Our findings suggest a significant and inverse correlation between vitamin D deficiency and thyroid autoimmunity among Georgian adults. Further prospective studies are warranted to ascertain a causal relationship between vitamin D deficiency and autoimmune thyroiditis in our population.

Features of large intestinal microbiota of patients with diffuse toxic goiter

Antonina Piddubna, Nataliia Pashkovska, Nataliia Abramova, Ivan Pankiv, Galina Koval, Yulia Marchuk & Iryna Tsaryk
[1]BSMU, Chernivtsi, Ukraine

It is well known that the range of disorders of various organs and systems in thyroid dysfunction is diverse, due to the scale of the impact of thyroid hormones on the body. One of the most characteristic clinical manifestations of thyrotoxicosis is changes in the gastrointestinal tract in the form of dysbiosis. Some studies have found inconsistencies in the association of these filotypes with the presence of thyrotoxicosis. In addition, there is no data in the literature on the change in the content of the main filotypes of the intestinal microbiota depending on the state of compensation of thyrotoxicosis.
The purpose of the work was to study the species composition and population level of microflora of the intestinal cavity in patients with diffuse toxic goiter, as well as to study the content of the main filotypes of intestinal microbiota in these patients.
Material and methods
We examined 40 patients with accidents (15 men and 25 women) aged 30 to 73 years (mean age 47.8 + 8.9 years) in the stage of compensation and decompensation of the disease and 51 almost healthy donor who formed the control group. The first group (20 patients) consisted of patients in a state of compensation, the second group (20 patients) – in a state of decompensation of the disease.
Results and discussion
Analysis of changes in the species composition and population level of the microflora of intestinal cavity made it possible to establish that in all examined patients with accidents revealed intestinal dysbiosis. Grade IV dysbiosis was found in 27.5% patients, grade III dysbiosis in 22.5% patients, grade II dysbiosis in 18 patients 45% and grade I dysbiosis in 5% patients. Imbalance developed due to elimination and deficiency of autochthonous anaerobic and aerobic obligatory bacteria (*Bifidobacteria, Lactobacteria and Enterococci*), contamination of the large intestine with hemolytic *Escherichia*, opportunistic pathogenic enterobacteria, life expectancy and increase in staphylococci and yeast-like fungi of the *Candida* type.
Conclusion
Thus, the content of Firmicutes in patients with accidents was significantly higher, and the content of Bacteroidetes – significantly lower than in healthy individuals (P<0.05). Analyzing the content of the main microbial filotypes depending on the state of accident compensation, it was found that in patients in state of compensation and decompensation of accident the content of Firmicutes was significantly higher (P<0.05) and the content of Bacteroides – significantly lower in patients in the state of compensation and healthy individuals (P<0.05).

AEP657

A case of Grave's disease following SARS-Cov 2 infection

Ines Bayar, Soumaya Tahri, Ekram Hajji, Bilel Ben Amor, Hanene Sayadi, Héla Marmouch & Inès Khochteli
University Hospital of Monastir, Endocrinology and Internal Medicine, Monastir, Tunisia

Introduction
Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is a novel coronavirus that caused a global pandemic in 2020. The virus has infected more than 100 million people worldwide and the pandemic is still spreading. It can affect practically all organs. Data on the impact of SARSCoV-2 on the thyroid gland are very scarce. Two patients with Graves' disease (GD) and COVID-19 have been recently published(1). We present a case GD occurring after SARS-CoV-2 infection.
Methods
We describe the clinical findings, thyroid function tests, and neck ultrasound of a patient presenting with thyrotoxicosis signs.
Results
A 38-year-old, Tunisian female, having a medical history of autoimmune diseases, had been hospitalized on september, 2020, at COVID-19 department (a naso-pharyngeal swab test for SARS-CoV-2 was positive, and chest high resolution computed tomography without iodinated contrast agents) showed bilateral ground glass areas typical of SARS-CoV-2-related interstitial pneumonia. Due to persisting asthenia and onset of tremor and palpitations, thyroid function was assessed on November, 2020, showing suppressed serum TSH (<0.01 mU/ml) with increased serum-free thyroxine (FT4 31.6 pmol/l). Physical examination revealed a non-tender goiter. TSH receptor antibodies were positive (14.1 IU/l). Therapy with corticosteroid and propranolol was started with improvement of symptoms and thyroid function. Anti-thyroid drugs were not started because the patient has leukopenia contraindicating this treatment. Clinical presentation and positive TSH receptor antibodies are compatible with a diagnosis of GD (autoimmune hyperthyroidism). Our cases of hyperthyroidism were diagnosed 2 months after the clinical onset of COVID-19.
Conclusion
In conclusion, we report a case of Graves' disease after COVID-19, with no previous known thyroid disease. Of course, with Graves' disease being the most frequent cause of hyperthyroidism, especially in middle-aged women, the association might be casual. However, the increasing number of publications on autoimmune diseases related to COVID-19 suggests that SARS-CoV-2 could act as a trigger of latent or new-onset autoimmunity. Physicians working in COVID-19 departments should be aware of possible connections between SARSCoV-2 and thyroid dysfunction, both subacute thyroiditis and Graves' disease, which should be investigated by future prospective studies.

Neurogenesis pathway-focused gene expression analysis in patients with primary hypothyroidism and autoimmune thyroiditis

Iryna Kamyshna[1] & Aleksander Kamyshnyi[2]
[1]I. Horbachevsky Ternopil National Medical University, Department of Medical Rehabilitation, Ternopil, Ukraine; [2]I. Horbachevsky Ternopil National Medical University, Department of Microbiology, Virology, and Immunology, Ternopil, Ukraine

Abstract
Important regulators of metabolism are thyroid hormones. They play an important role in the development and maturation of the central nervous symptom and their failure in the prenatal period leads to irreversible brain damage, however, their effect on the brain of an adult has not been fully studied. On the other hand, Hashimoto encephalopathy is associated with autoimmune thyroiditis. With the discovery of neurogenesis in the adult brain many recent studies have been focused on understanding the basic mechanisms controlling this process. Many neurogenesis regulatory genes not only transcribed but also translated into blood cells. The focus of our study was to analyze the transcriptional activity of neurogenesis regulatory genes in peripheral blood cells in patients with thyroid pathology.
Methods
We used the pathway-specific PCR array (Neurotrophins and Receptors RT^2 Profiler PCR Array, QIAGEN, Germany) to identify and validate neurogenesis regulatory gene expression in patients with thyroid pathology and control group.
Results
The results showed that GDNF, GFRA3, NGFR, NRG1, NTF3, NTRK1, NTRK2 significantly decreased their expression in patients with autoimmune thyroiditis with rising serum autoantibodies. The patients with primary hypothyroidism as a result of autoimmune thyroiditis and postoperative hypothyroidism had significantly lower expression of BDNF, CBLN1, FGF2, NGFR, NRG1, NTF3. The mRNA level of CNTFR, MEF2C was markedly decreased in the group of patients with postoperative hypothyroidism. ARTN, CNTF, PSPN, TFG, MT3, NELL1 did not change their expression in all groups of patients.
Conclusion
The finding indicates that a decrease of thyroid hormones and a high level of autoantibodies such as anti-thyroglobulin antibody and anti-thyroid peroxidase antibody influence the expression mRNA neurogenesis-regulated genes in patients with thyroid pathology.

Outcome of Long Term Antithyroid Therapy in Patients with Graves' Hyperthyroidism

Grigoiu Simona Andreea[1,2], Maria Lavinia Popa[1], Emma Margarit[1], Ionela Baciu[1,2], Dan Alexandru Niculescu[1,2], Cristina Capatina[1,2], Raluca Trifanescu[1,2], Serban Radian[1,2], Nicoleta Baculescu[1,2] & Catalina Poiana[1,2]
[1]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania; [2]C I Parhon National Institute of Endocrinology, Pituitary and neuroendocrine diseases, Bucharest, Romania

Graves' disease is an autoimmune thyroid disease which, untreated, carries a significant morbidity risk. Treatment options for Graves's disease have changed over the decades.
Aims
To evaluate the outcome and risk factors for relapses of patients with Graves's disease treated with antithyroid drugs for at least 2 years.
Methods
A retrospective, analytic study on 360 consecutive patients admitted between Jan 2011–Oct 2019 and evaluated at diagnosis, after restoring of euthyroidism and at final visit. Clinical evaluation, thyroid function tests, TRAb (TSH receptor antibodies), goiter volume were obtained.
Results
There were 296F/64M, age at diagnosis: 44.5 ± 13.78 [13–81 years], freeT4 = 41.8 ± 22.68 pmol/l (N = 12–22), 226(62.8%) with ophtalmopathy, 34 (9.4%) with atrial fibrillation, 41 (11.4%) with heart failure. After diagnosis, all received methimazol, 28.15 ± 20. 52 mg/day. Normal free T4 was obtained after 9.37 ± 16.2 months and normal TSH after 12.97 ± 17.8 months. Patients were treated by thyroid surgery (109 pts, after 51 ± 46 months), radioiodine therapy (58 pts, after 58 ± 52 months), radioiodine and surgery (n = 9 pts) and 193 pts received longterm thionamides (55.64 ± 38.5 months). 6/193 patients only medically treated were cured at final visit. 228/360 patients had relapses. Risk factors for relapses were: young age (P = 0.002) and heart failure at diagnosis (P = 0.004). Serum levels of TRAb >10 ng/ml predicted active disease at final evaluation (Sn = 61.3%, Sp = 51%, P = 0.03).
Conclusions
Patients with Graves's disease have longer duration of antithyroid treatment before ablation, with frequent relapses. Young patients with severe disease at diagnosis (TRAb >10 ng/ml, heart failure) should receive thyroid ablation, because only 5% medically treated became cured.

Factors affecting development of hypothyroidism at patients with subacute thyroiditis

İnan Anaforoglu[1] & Murat Topbaş[2]
[1]Maslak Acıbadem Hospital, Endocrinology and Metabolism, İstanbul, Turkey; [2]Karadeniz Technical University, Public Health, Trabzon, Turkey

Introduction
The aim of the present study was to determine the possible factors contributing to the development of hypothyrodisim in patients who had a subacute thyroiditis (SAT) attack.
Methods
Medical records of patients who were diagnosed with SAT between September 2014 and January 2020 were analyzed retrospectively in one center in Trabzon city of Turkey. The medical records of the patients were searched with ICD-10 code E06.1. There were 283 patients recorded with ICD-10 code E06.1; 119 of them had appropriate records and enough data to be involved into the study. Patients known to have previous thyroid disease were excluded. Patients who were followed at least 6 months after SAT attack cured were included. The demographic data of the patients; laboratory results including erythrocyte sedimentation rate (ESR), C reactive protein (CRP), thyroid stimulating hormone (TSH), triiyodotronine (T3), thyroxine (T4), anti-thyroid antibodies; the character and spread of neck pain; ultrasonography (USG) findings; the medications; the need to steroid therapy and the duration of steroid therapy; presence of hypothyroidism; occurrence and frequency of recurrences were recorded. The relationship between these parameters and development of permanent hypothyroidism were searched.
Results
The mean age of the patients was 42.3 ± 10.9 (24–78 year). The frequency of SAT was higher among women than men (93 women vs 26 men; 78.2% vs 21.8%, respectively). SAT was more frequent during spring and summer, but there were no statistical differences in means of the months or the seasons (P= 0.329, 0.534, respectively). Eighty-eight (69.7%) of the patients described a viral/flu-like disease before neck pain started. Almost half of the patients (n = 68, 57.1%) had gone to a different specialty other than endocrinology; 55 (46.2%) to otorhinolaryngology, 10 (8.4%) to internal medicine, 2 (0.02%) to emergency clinic and 1 (0.01%) to infectious disease until taking a SAT diagnosis. Thirty-four (28.6%) of the patients had been prescribed antibiotics for misdiagnosis of an upper tract infection. There were 10 patients (8.4%) who developed hypothyroidism after SAT attack. Mean steroid using time was longer at patients with hypothyroidism (17.7/16.4 vs. 8.9/5.9 weeks; P = 0.021). Hypothyroidism was more frequent among patients who did not have thyrotoxicosis during SAT attack; p= 0.004 and who had recurrent SAT attacks p= 0.035.
Conclusions
Patients who need steroid for a longer period, who have recurrent SAT attacks and who did not have thyrotoxicosis during SAT attacks should be closely monitored in means of developing hypothyroidism.

Iodine excretion in schoolchildren of Vilnius

Lina Zabuliene[1,2], Marius Miglinas[3], Ernesta Macioniene[3], Valdas Banys[3], Nomeda Bratcikoviene[4], Ausra Linkeviciute[3], Dovile Petronyte[3], Mykolas Urbonas[4] & Algirdas Utkus[4]
[1]Faculty of Medicine, Vilnius University, Institute of Clinical Medicine, Vilnius, Lithuania; [2]Centro Out-Patient Clinic, Vilnius, Lithuania; [3]Vilnius University Hospital "Santaros klinikos", Vilnius, Lithuania; [4]Faculty of Medicine, Vilnius University, Vilnius, Lithuania

Iodine deficiency is the main cause of preventable mental retardation in children. Urinary iodine excretion is a marker of recent iodine intake and is used to monitor the iodine status of population. Iodine excretion in Lithuanian schoolchildren was previously investigated in 2001. The main objective of this study was to evaluate iodine excretion in children, ages 6–12, living in Vilnius, Lithuania.
Methods
Urine samples were collected from June 2019 to January 2021 at 3 outpatient clinics during "NATRIJOD" – a national program conducted to evaluate sodium and iodine status in Lithuania. Parents signed informed consent forms. Questionnaires about the child's gender, age, height, dietary habits, use of medications and dietary supplements were collected. Urinary iodine was measured spectrophotometrically by a method based on the Sandell–Kolthoff reaction. The method was approved by the Ensuring the Quality of Urine Iodine Procedures quality assurance program. Urinary creatinine was measured enzymatically by Architect (Abbott, USA) analyser. Urinary iodine concentration (UIC, µg/l) was measured in spot urine samples and estimated 24hour urinary iodine excretion (UIE, µg/day) was calculated dividing UIC by creatinine and multiplying by expected 24h creatinine excretion referenced from values of German children with the respective gender and height.
Results
Data of 117 subjects were analysed. Median UIC was 214.68 µg/l and median UIE was 128.92 µg/day. 69.2% of children had UIE within the recommended range. 30.8% of participants had iodine deficiency (UIE <100 µg/day) with a higher rate among girls (40.7%) compared to boys (22.2%) (P = 0.030). 37.8% of 6–7 year-olds, 33.3% of 8–9 year-olds and 22.7% of 10–12 year-olds had iodine deficiency. Median UIE in 6–7 year-olds and in 8–9 year-olds was lower compared to children aged 10–12 (respectively 121.54 µg/day vs 173.15 µg/day, P = 0.049 and 124.23 µg/day vs 173.15 µg/day, P = 0.008). Iodine deficiency rate in children with no diet restrictions was lower than in those who had diet restrictions (25.8% vs 55.0%, P = 0.010). UIE in children who mainly ate home-cooked food was higher compared to those who ate at school or processed food from stores (137.61 vs 99.71 µg/day, P = 0.011).
Conclusion
Compared with the data from 2001 the iodine intake of schoolchildren has increased. However, a considerable portion of children remain at risk of iodine deficiency. Continued monitoring of iodine intake using 24-h urine samples is needed to ensure that the actual iodine intake of schoolchildren is sufficient.

An audit of thyroidectomy in Graves' Disease, in a large UK tertiary centre

Larissa Jones, Shaila Khan, Neil Tolley, Fausto Palazzo, Jeremy Cox, Rochan Agha-Jaffar & Stephen Robinson
St Mary's Hospital, United Kingdom

Background
Thyrotoxicosis with Graves' Disease is treated with thionamide, radio-iodine treatment and thyroidectomy. Surgery is an important choice, especially when Graves' Disease is complicated by thyroid orbitopathy. Pre- and post-operative protocols for thyroidectomy are imperative.
Aims
1) To assess pre-operative preparation of patients, with potassium iodide, vitamin D, beta blockade, and the pre-operative thyroid function.
2) To assess the post-operative monitoring and complications.
Method
The patient cohort came from a large UK tertiary centre from 2014-19. Every thyroidectomy is recorded in the BAETS database which facilitated ascertainment of subjects. The anonymised data were analysed to calculate percentages for each parameter within the aims of the audit.
Results
Ninety-two patients were included in the cohort, aged 19–74 years. It was found that 85% of patients were euthyroid pre-operatively, with 2% hyperthyroid pre-operatively and 13% hypothyroid. 48% received pre-operative vitamin D; 49% received pre-operative potassium iodide; and 53% were on a beta-blocker or alternative. Post-operative calcium checks took place the same and following days, performed in 99% and 100% respectively. Post-operative parathyroid checks took place the same and following days, performed in 97% and 98% respectively. Post-operative hypocalcaemia occurred in 26% but was temporary in 92%. Vocal cord palsy was reported in 11%, but in all cases was a temporary neuropraxia. The rate recorded in the BAETS 2017 national database is 7.8% for temporary vocal cord palsy, although the database notes that this is likely an underestimation due to lack of post-operative laryngoscopies (1). The national rate for persistent vocal cord palsy, over 6 months, is 1.2% for total thyroidectomy (1).
Discussion
The results show low complication rates in this cohort, with the majority of complications being temporary. Post-operative investigation for calcium and parathyroid hormone was achieved in almost all cases. Pre-operative optimisation with vitamin D, potassium iodide and beta blockers was not always achieved in more urgent cases. A proforma is presented, to ensure not only that pre-operative optimisation occurs, but that it is also clearly documented for each patient. This audit would suggest that if done by experienced surgeons, surgical management of Graves' Disease confers low complication rates and can be an effective option in the management of Graves' Disease.

AEP663

Thyroid-receptor antibodies, immunoglubulin E and antinuclear antibodies in patients with Graves' disease and their association with Graves' orbitopathy and smoking habits

Mariya Stoynova, Alexander Shinkov, Georgi Kirilov & Roussanka Kovatcheva
Medical University of Sofia, Endocrinology, Sofia, Bulgaria

Introduction
Thyrotropin-receptor antibodies (TRAb) play a key role in the pathogenesis of Graves' disease (GD) and Graves' orbitopathy (GO) and are important for the diagnosis of both diseases. Elevated levels of immunoglobulin E (IgE) and antinuclear antibodies (ANA) were also found in GD patients. Smoking is a risk factor for GD and GO development and GO progression. We aimed to assess the associations between TRAb, IgE and ANA, and the presence and severity of GO and smoking in GD patients.
Material and methods
A total of 103 GD patients (mean age 51.2, 84 females) were divided into three subgroups: moderate-to-severe GO (n = 36), mild GO (n = 32) and "only GD" subgroup (n = 35). Forty healthy controls (HC) (mean age 51.2, 36 females) were also included. TRAb were measured in all GD subgroups by a thyrotropin-binding inhibitory immunoglobulin (TBII) assay. TBII<2 IU/ml were considered negative. All subjects were tested for IgE- and ANA-positivity and were categorized as smokers (current and ex-smokers) and non-smokers according to their smoking habits.
Results
The GD group had significantly higher number of smokers (P<0.01), higher IgE-positivity rate (P = 0.04) and a similar percentage of ANA-positivity compared to HC. The moderate-to-severe GO subgroup had significantly higher TBII (P<0.01) and significantly lower TBII-negativity rate (P<0.01) compared to the other two subgroups. The percentage of positive IgE did not differ significantly between GD subgroups, but the moderate-to-severe GO subgroup was the only subgroup, whose IgE-positivity rate was significantly higher than HC (P = 0.01). The moderate-to-severe GO subgroup also had the highest ANA-positivity rate amongst the three subgroups (P = 0.02). Mild GO and "only GD" patients did not differ significantly in terms of TBII level, TBII-negativity rate, IgE and ANA. Both GO subgroups had significantly higher smoking rate than the "only" GD subgroup (P = 0.01). There was a positive correlation between smoking and TBII (ρ = 0.245, P = 0.02) and between smoking and IgE (ρ = 0.23, P = 0.03).
Conclusions
GD patients exhibit different immunological patterns depending on the presence and severity of GO. Smoking might affect the clinical and immunological manifestations of GD, but is not the only factor involved.

How Does Age Influence Disease Outcome in High Risk Papillary and Follicular Thyroid Cancer Patients?

Evert Van Velsen[1], Robin Peeters[1], Merel Stegenga[1], Folkert van Kemenade[2], Tessa van Ginhoven[3], Frederik Verburg[4] & W. Edward Visser[1]
[1]Erasmus Medical Center, Academic Center for Thyroid Diseases, Department of Internal Medicine, Netherlands; [2]Erasmus Medical Center, Academic Center for Thyroid Diseases, Department of Pathology, Netherlands; [3]Erasmus Medical Center, Academic Center for Thyroid Diseases, Department of Surgery, Netherlands; [4]Erasmus Medical Center, Academic Center for Thyroid Diseases, Department of Radiology and Nuclear Medicine, Netherlands

Background
The 2015 American Thyroid Association (ATA) Risk Stratification System for differentiated thyroid cancer (DTC) is designed to predict response to therapy and recurring disease. Although age is not incorporated as a risk factor, recent research suggests that the addition of age can improve this system. However, these studies comprised low number of patients with ATA High Risk, low numbers of patients with follicular thyroid cancer (FTC), and did not distinguish between papillary thyroid cancer (PTC) and FTC. The aim of our study was therefore to investigate the influence of age on disease outcome in ATA High Risk patients with a focus on differences between patients with PTC and FTC.
Methods
We retrospectively studied adult patients with DTC who were diagnosed and/or treated at a Dutch university hospital between January 2002 and December 2015. All patients fulfilled the 2015 ATA High Risk criteria. Logistic regression and Cox proportional hazards models were used to estimate the effects of age and several age cutoffs (per five years increment between 20 and 80 years) on four disease outcomes: (i) response to therapy, (ii) developing no evidence of disease, (iii) recurrence, and (iv) disease specific survival (DSS).
Results
We included 236 patients with High Risk DTC (32% FTC) with a mean age of 56 years and a median follow-up of 6 years. During follow-up, 14% of the 79 patients that achieved excellent response developed a recurrence. For both PTC and FTC, age had a significant influence on having an excellent response after initial therapy, developing NED, recurrence, and DSS. For FTC, an age cutoff of either 65 years or 70 years seemed to be statically optimal for the different disease outcomes, while this was either 50 years or 60 years for PTC.
Conclusion
In a population of patients with High Risk DTC, age has a significant inverse influence on disease outcomes. Slightly different optimal age cutoffs were identified for the different outcomes, and these cutoffs differed between PTC and FTC. Therefore, age should be considered to be included as a risk factor in the ATA Risk Stratification System, and when doing this, PTC and FTC should be treated as separate entities.

Could ultrasound characteristics guide us on the presence of malignancy in thyroid nodules with Bethesda III cytology?

Suset Dueñas Disotuar, Ana R. Romero LLuch & Elena Navarro
Hospital Universitario Virgen del Rocío: Centro de Diagnóstico y Tratamiento, Endocrinology, Sevilla, Spain

Background
Thyroid nodules with indeterminate cytology represent a therapeutic challenge. The probability of malignancy had been established between 5 and 15%, but it varies among the published data. Nowadays we have molecular tests to help in therapeutic decisions, but they are not available at all centers leaving uncertainty regarding appropriate management.
Objectives
– To know the percentage of malignancy in thyroid nodules with Bethesda III (AUS/FLUS) cytology in our center.
– To establish whether there is an association between the ultrasound characteristics of the B. III nodules and malignancy.
Materials and methods
WECe selected Bethesda III nodules from 1034 FNAs performed in our center between May 2012 – October 2016. Age, sex, ultrasound suspicious characteristics (central vascularization, microcalcifications, taller than wide shape, irregular margins and hypoechogenicity), TIRADS score and definitive histology were registered. The association between malignancy and the cited variables was analyzed.
Results
6.96% (102/1034) of cytologies were B.III. 46.2% (47) of these nodules B.III had surgery, while 20.5% (21) are waiting for surgery and 33% (34) are in clinical ultrasound follow-up. *Results in operated patients (n = 47):* 76.6% were women; Age 54 [10–75] years. 48.9% (23) had 1 single B.III cytology and in the remaining 51.1% (24) the FNA was repeated (5 B.III, 7 unsatisfactory, 6 benign, 3 suspicious of malignancy and 3 Follicular neoplasm). 42.6% (20) of the B.IIIs nodules operated were thyroid carcinomas: 75% (15) papillary carcinoma, 5% (1) Hurthle cell carcinoma, 10% (2) minimally invasive follicular carcinoma, 5% (1) medullary carcinoma and 5% (1) were anaplastic carcinoma. Within TIRADS 2 nodules, the percentage of malignancy detected was 0%, while in TIRADS 4a was 28.6% and it rises to 75% in TIRADS ≥4b (P = 0.008). The only ultrasound characteristic that was associated with malignancy by itself was irregular margins (P = 0.039). The risk of malignancy increased with the addition of suspicious ultrasound characteristics, without detecting statistical differences here (P = 0.09): 3 or more = 72.7% malignancy; 2 = 50%; 1 = 27.8%; 0 = 0%.
Conclusions
The percentage of malignancy in B.III nodules in our center in these preliminary results is between 34-46.2%. Both the TIRADS and the addition of suspicious ultrasound characteristics correlate well with the presence of malignancy and constitute a helpful tool when considering whether surgery or clinical follow-up is the best option (high percentage of malignancy when there are 2 or more ultrasound data of suspicion or score ≥4b on the TIRADS scale).

Increased gene expression of TIMP1 and CHI3L1 in fine-needle aspiration biopsy washouts from papillary thyroid cancer

Inna Dimitrova[1], Alexander Shinkov[1], Rumyana Dodova[2], Radina Ivanova[1], Radka Kaneva[2] & Roussanka Kovatcheva[1]
[1]Medical University of Sofia, Department of Endocrinology, Sofia, Bulgaria; [2]Medical University of Sofia, Molecular Medicine Center, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria

Aim
To assess the relative expression of tissue inhibitor of metalloproteinase-1 gene (TIMP1) and chitinase-3-like protein 1 gene (CHI3L1) in fine-needle aspiration biopsy (FNAB) washouts and the serum levels of their protein products (TIMP-1 and chitinase-3-like protein 1 also known as YKL-40) in patients with histologically confirmed papillary thyroid cancer (PTC) and with benign nodules. Further, we evaluated the correlation between the gene expression and the circulating protein product.
Materials and methods
Eighty subjects (72 females, 8 males, mean age of 40.6 ± 11.3 years) were recruited from the routine patient flow referred for FNAB of thyroid nodules in one tertiary center. Forty patients with cytology Bethesda V and VI were operated and PTC was confirmed. The other 40 patients were with benign cytology (Bethesda II) and were considered a benign group. TIMP-1 and YKL-40 serum levels were measured in all subjects. The gene expression of TIMP1 and CHI3L1 was assessed in cytological specimens from 20 patients with PTC and 20 benign cases using quantitative real-time PCR.
Results
The PTC group was sex-matched with the benign group and the male-to-female ratio was 1:9. There was no significant difference between the mean age in the study groups (P = 0.922). The relative expression of TIMP1 and CHI3L1, assessed in FNAB washouts, was significantly higher in the PTC group than in the benign nodule group (P <0.001 for TIMP1; P = 0.018 for CHI3L1). The serum level of TIMP-1 was significantly higher in the PTC group compared to the benign group (82.0 ng/ml; 48.2–133.6 ng/ml *vs.* 91.8 ng/ml; 38.1–164.5, P = 0.036). We did not find significant difference in YKL-40 levels between the two study groups (71.4 ng/ml; 42.0–206.4 ng/ml in the benign group *vs.* 71.0 ng/ml; 20.4–229.2 ng/ml in the PTC group, P = 0.447). There was no correlation between TIMP1 and CHI3L1 expression and the serum levels of their protein products TIMP-1 and YKL-40 (P = 0.089, P = 0.517, respectively). TIMP1 relative expression showed better diagnostic value compared to CHI3L1 gene (P = 0.037) and to serum TIMP-1 (P = 0.004).
Conclusions
The increased expression of TIMP1 and CHI3L1 implies a possible role of these genes in the PTC carcinogenesis. Their identification in FNAB washouts could be used as additional diagnostic marker.

Molecular landscape of the multiple endocrine neoplasia type 2 syndrome in the Belarusian population

Yuliya Dydyshka[1], Alla Shepelkevich[1], Tatsiana Chakhovich[2], Alina Shloma[2], Sergey Smirnov[2], Kseniya Ruksha[2], Alena Subach[2], Anna Portyanko[2], Victor Kondratovich[3], Tatiana Leonova[3] & Alexandra Sosedkova[3]
[1]Belarusian State Medical University, Department of Endocrinology, Belarus; [2]N.N. Alexandrov National Cancer Centre of Belarus, National Molecular Genetics Centre of Cancer Research, Belarus; [3]Public Health Institution Minsk City Clinical Oncologic Dispensary, Belarus

Background
The multiple endocrine neoplasia syndrome type 2 (MEN-2) is characterized by medullary thyroid cancer (MTC) as a permanent feature; the combination with pheochromocytoma and parathyroidism is referred as MEN-2a syndrome. The reason for hereditary forms of MTC is mutations in the proto-oncogene RET (RE-arranged during Transfection).
The aim of the study was to establish the molecular determinants frequency of MEN-2 syndrome in patients with MTC in the Republic of Belarus.
Materials and methods
The study included 194 patients with MTC diagnosis. The selection was made according to the Cancer Register of the Republic of Belarus and the medical documentation of the Republican Center for Thyroid Tumors. Testing of 5, 8, 10, 11, 13–16 exons of the RET gene was performed by the method of molecular sequencing according to Sanger on the ABI 3500 genetic analyzer.
Results
From 1987 to 2017 years 26930 new cases of thyroid cancer were detected (4899 men and 22 031 women), the share of MTC was 2.2% (591 people). Genetically determined MTC with various clinical manifestations (MEN-2A, MEN-2B, familial MTC) was detected in 18.6% of cases (36/194). Pathogenic mutations were detected in exons 11, 13, and 10 of the RET gene (78%). Analysis of the gene disorders spectrum showed predominance in codon 634 of exon 11 of the gene (C634R\F\W\Y), which is associated with the development of familial MTC or MEN-2A syndrome. Rarer alterations are presented by polymorphisms Y791F, C620GW, L790F, S649L, V804M/L, S904F, R912P, M918T. The pathogenic variants L790F and C611Y were compiled for one case. Pathogenic variants in 634 codons were detected in 27.8% of cases (n = 10). The penetrance of pheochromocytoma was 50.0% (n = 5), the average age was 31.9 years. Among patients with mutations in other codons of the RET proto-oncogene, pheochromocytoma was found in one case (2.7%) in a patient with variant M918T. The penetrance of pheochromocytoma in patients with this pathogenic variant (n = 2) was 50.0%. A genotype–phenotype correlation was found between the presence of pheochromocytoma and mutations in exon 11 of the RET proto-oncogene (P = 0.009).
Conclusions
High frequency of occurrence of hereditary forms of MTC was found in the Republic of Belarus, similar to the spectrum of mutations in the RET proto-oncogene described in the literature, and the presence of a genotype-phenotype correlation in identifying various variants of gene alterations. The presented data are intermediate and will be clarified in the course of further implementation of research work.

AEP668

Characteristics of medullary thyroid cancer in the Republic of Belarus and prognosis factors

Victor Kondratovich[1], Tatiana Leonova[1], Alla Shepelkevich[2], Yuliya Dydyshka[2], Alexandra Sosedkova[1], Tatsiana Chakhovich[3], Alina Shloma[3], Sergey Smirnov[3], Kseniya Ruksha[3], Alena Subach[3] & Anna Portyanko[3]
[1]Public Health Institution Minsk City Clinical Oncologic Dispensary, Belarus; [2]Belarusian State Medical University, Department of Endocrinology, Belarus; [3]N.N. Alexandrov National Cancer Centre of Belarus, National Molecular Genetics Centre of Cancer Research, Belarus

Background
Medullary thyroid cancer (MTC) is a calcitonin-producing C-cell tumor and accounts about 5% in the structure of thyroid malignancies. There are sporadic and hereditary variant of MTC, which is a mandatory component of endocrine neoplasia syndrome type 2. The aim of the study was to determine the relationship between the aggressiveness of the clinical course of MTC and demographic characteristics.
Materials and methods
The study is carried out of the state program "Oncological Diseases" on the assignment "To develop and implement effective technologies for the diagnostic detection and monitoring of patients with multiple endocrine neoplasia type 2a syndrome." Patient inclusion criteria for the study: morphologically verified diagnosis of MTC, written informed patient's consent, ability to follow instructions throughout the study.
Results
The data obtained from the Belarusian cancer-register during 1987–2017 years. The research included the information about 591 patients with MTC. The MTC incidence index in the Republic of Belarus is constant, makes 0.2 per 100 thousand population. The number of MTC cases increased by 3.6 times, annually increased from 5 to 30 cases. It is explained by the improvement of diagnostics' quality and the of average population's life expectancy. The increase of MTC incidence was observed after the age of 40 with subsequent increase by the age of 60. MTC was more often observed among women (71.1%), than among men (28.9%). The essential difference in incidence among city residents and villagers wasn't revealed in the last decade. It confirms equal opportunities of diagnostics for the both of groups. The distribution of patients by region over the past 10 years has been uniform. There were 45.2 % patients with metastatic form of disease in this research, 44.8 % of them with neck lymph node metastases and 5 % had distant metastases. More common tumors were more often diagnosed in male. As a result of univariate analysis, prognostic factors influencing specific survival were revealed: male sex (P<0.05), extrathyroid tumor

growth (P<0.001), the presence of metastases in regional lymph nodes (P<0.05) and distant metastases (P< 0.001).
Conclusions
The incidence rate of MTC in the Republic of Belarus has increased more than 6 times over the past 30 years (0.03 and 0.2 per 100 000 population). Male sex, extrathyroid tumor growth, the presence of metastases in regional lymph nodes, distant metastases are prognostically unfavorable factors for the specific survival of patients with MTC.

Clinical and laboratory features of patients with medullary thyroid cancer in the Republic of Belarus

Alla Shepelkevich[1], Victor Kondratovich[2], Tatiana Leonova[2], Yuliya Dydyshka[1], Alexandra Sosedkova[2], Tatsiana Chakhovich[3], Alina Shloma[3], Sergey Smirnov[3], Kseniya Ruksha[3], Alena Subach[3] & Anna Portyanko[3]
[1]Belarusian State Medical University, Department of Endocrinology, Belarus; [2]Public Health Institution Minsk City Clinical Oncologic Dispensary, Belarus; [3]N.N. Alexandrov National Cancer Centre of Belarus, National Molecular Genetics Centre of Cancer Research, Belarus

Background
The management of patients with medullary thyroid cancer (MTC) has an important endocrinological aspect, because MTC can be a manifestation of multiple endocrine neoplasia syndrome (MEN), a genetically determined pathology with an autosomal dominant inheritance. MEN-2 syndrome is characterized by of MTC as a permanent feature, the combination with pheochromocytoma and/or adenoma of the parathyroid glands. The aim of the study was to determine the clinical and laboratory characteristics of patients with medullary thyroid cancer in order to form a database of patients with MEN2A.
Materials and methods
The research is carried out of the state program "To develop and implement effective technologies for the diagnostic detection and observation of patients with MEN2A." According to the Belarusian Cancer Register in 1987–2017 years 26930 new cases of thyroid cancer were identified (4899 men and 22 031 women), the share of MTC was 2.2% (591 people). Examination of 79 patients with MTC was carried out. Patients collected and recorded in the form of primary reporting data of anamnesis and general clinical examination.
Results
In 16.5% (13 patients) hyperplasia of regional lymph nodes was detected, a puncture biopsy was performed, and in 5.0% (4 patients) a relapse of the disease was revealed. No data were found for parathyroid hyperplasia. 91.1% (72 patients) underwent ultrasound of internal organs, revealed minor abnormalities. Computed tomography of the chest and internal organs was performed in 39.2% (31 patients). Data for tumor pathology and progression of the disease have not been established, but in 7.6% (6 patients) adrenal formations were revealed, which requires further examination. The TSH level was normal in 46.0% (36 patients). 8.9% (7 patients) simultaneously had two histotypes of cancer: medullary and papillary, so they had to receive a suppressive dose of levothyroxine. TSH was suppressed in 43.0% (34 patients), hypothyroidism was noted in 2.5% (2 patients). 55.7% (44 patients) take calcium and vitamin D supplements. Differences in the content of serum calcium in patients depending on the intake of calcium and vitamin D were not established (2.31 ± 0.04 vs 2.31 ± .03; P>0.05). Transient postoperative and manifest hypoparathyroidism was found in 19.0% (15 patients). In 7.6% (6 patients) calcium levels do not reach the lower limit of normal, which is associated with a lack of adherence to treatment.
Conclusions
Patients with MTC require a multidisciplinary laboratory and instrumental examination due to the possible combined pathology, which, in turn, determines the subsequent therapeutic and surgical treatment of patients.

Primitive thyroid Lymphoma: about two cases

Hajar Khouchaf, Nassim Essabah Haraj, Siham El Aziz & Asmaa Chadli
HUC Ibn Rochd, Department of Endocrinology and Metabolic Diseases, Casablanca, Morocco

Introduction
Primary thyroid lymphomas (LTP) are a rare entity, characterized by their histological and clinical heterogeneity. They represent 5% of thyroid tumors and 2% of extra-ganglionic lymphomas. We report two observations of LTP by specifying the epidemiological, diagnostic and therapeutic features.
Observations
Observation 1
70-year-old patient, followed in internal medicine for Sd sec, having undergone a total thyroidectomy in 2004 with diffuse large B-cell anapathic malignant lymphoma (LMNH) on LMNH of MALT associated with a lymphocytic thyroiditis. The patient benefited from 4 chemotherapy sessions (CHOP), with Levothyrox 100 µg/day put on. Complete remission was obtained with a normal cervical ultrasound.
Observation 2
68-year-old patient with no particular history, in particular no thyreopathy, thyroidectomized in 2016 with a histological appearance compatible with a Hodgkin's lymphoma scleronodular form, the immunohistochemical study showed an intense and diffuse positivity of tumor cells to antibodies anti-CD15 and anti-CD30, the patient received 6 courses of chemotherapy (ABVD protocol) and radiotherapy on the tumor bed, the patient currently on Levothyrox 100 µg/day with clinical and radiological monitoring.
Conclusion
Despite its rarity and unusual location, lymphoma of the thyroid gland must be known and taken into account in the differential diagnosis of thyroid tumors. Early diagnosis and management allow favorable treatment results to be obtained.

Case report of multifocal papillary thyroid cancer in thyroglossal duct cyst.

Mohammad Bilal Jajah[1] & Eidhah Aljoied[2]
[1]West Suffolk NHS Foundation Trust, Diabetes and Endocrinology, Bury St Edmunds, United Kingdom; [2]Alhada Armed Forces Hospital, Taif, Saudi Arabia

Papillary thyroid carcinoma is one of the important but rare differential diagnosis of midline neck masses in adults. Other causes include thyroglossal duct cyst (TGDC) which is the commonest, ectopic thyroid gland, lymph node enlargement, and dermoid cyst. We report a rare case of unusual presentation of papillary thyroid cancer in a TGDC.
Case report
A 40-years-old female patient presented with a midline mass in the upper part of the neck. It was neither associated with pain nor dysphagia, or dysphonia. The mass was hard, mobile, non-tender, measuring 1×2 cm. Thyroid function tests were normal. On bedside neck ultrasound, the mass was hypoechoic, heterogenous, hypovascular, measuring 0.7×1.2 cm with irregular margins and multiple microcalcifications. there were two small hypoechoic hypovascular nodules in the right thyroid lobe measuring 0.7×0.6 cm and 0.5×0.5 cm respectively. There was no significant cervical lymphadenopathy. Ultrasound guided FNA from the midline mass and from the thyroid nodules were both positive for papillary thyroid carcinoma (PTC). Thyroglobulin determination in the needle washout from the midline mass was significantly high. Patient underwent total thyroidectomy and level VI lymph node dissection in addition to surgical removal of the TGDC using Sistrunk's procedure. Histopathological assessment confirmed the diagnosis of PTC in the right lobe of the thyroid and in the thyroglossal duct cyst. Five lymph nodes out of eight were PTC metastasis. The diagnosis of a multi-focal PTC in the thyroid gland (2 foci) with extrathyroidal extension to the TGDC and central lymph nodes was made. Following surgery, therapeutic strategy was completed with radioactive I^{131} ablation and suppressive levothyroxine therapy. Radioactive iodine total body scans have revealed no remnant thyroid tissue. Thyroglobulin levels were undetectable 12 months after follow-up.
Discussion
The development of carcinoma in TGDC is very rare but well recognized. It is diagnosed in approximately 0.7% to 1% of thyroglossal duct remnants. Clinical examination of TGDC almost always fails evaluate for potential of malignancy within the cyst. TGDC carcinoma should be suspected if neck U/S revealed any suspicious sonographic features and US-guided-FNA should be done as the next diagnostic approach. In our case, we have decided to complete by a radioactive iodine therapy because of the disease multifocality. In the absence of clear guidance and recommendations, the

management of TGDC carcinoma depends on the clinical situation and the team experience.

AEP672

Side-effects of calcitonin stimulation tests with calcium gluconate

Mara Baetu[1], Cristina Olariu[1], Ileana Nitu[2], Gabriel Moldoveanu[3], Cristina Corneci[3] & Corin Badiu[2]
[1]National Institute of Endocrinology, Thyroid related disorders, Bucharest, Romania; [2]National Institute of Endocrinology, Cardiology, Bucharest, Romania; [3]National Institute of Endocrinology, Intensive care unit, Bucharest, Romania

Introduction
Over time, different substances and protocols have been used and tested for stimulating calcitonin (CT). Some of them proved to be useful in diagnosing medullary thyroid carcinoma (MTC). However, these are associated with side-effects, with various duration, intensity and severity.
Objective
To report the side-effects observed during CT stimulation test with calcium (Ca) gluconate.
Materials and methods
A dose of 25 mg/kgBW (kilograms per body weight) of Ca gluconate was administered in 3–5 min (adjusted to the patient's ideal weight) after informed consent, with a total of 191 explorations: 124 in women (median age = 47 ± 13.3 years, range: 21–78) and 67 in men (median age = 54 ± 13.8 years, range: 22–79). We further classified the side-effects by severity after Food and Drug Administration (FDA) 21 312.32 Code of Federal Regulations in: Adverse event (AE), Life-threatening adverse event (LTAE) and Serious adverse event (SAE).
Results
21 types of side-effects were recorded, the most frequent being warmth in 175 tests (91.62%), altered taste in 37 tests (19.37%) and bradycardia in 11 tests (5.75%). No gender significant difference was noted regarding the occurrence of side-effects in general, but men were more predisposed to experience cardio-vascular side-effects than women: bradycardia/tachycardia, hypotension/hypertension, angina, atrial/ventricular extrasystoles, asystole, $P<0.02$. Cardio-vascular side-effects were not correlated with values of basal CT (normal/increased) or with peak-values of stimulated CT. Regarding FDA classification of severity, amongst 191 tests: no side-effects were noted in 9 (4.71%), AE in 160 (83.76%), SAE in 22 (11.51%) and LTAE was noted only in 1 test (0.52%). There was no link between patients' age, sex, weight or body-mass-index and severity.
Conclusion
Ca stimulation test is safe, with few mild side-effects. A specific protocol and cautions should be applied to minimize the possibility of a serious cardiac event, the most important being continuous cardiac monitoring during and after the test.

AEP673

Graves' disease with spontaneous resolution following ocrelizumab in primary progressive multiple sclerosis

Diana Borges Duarte[1], Ana Martins da Silva[2], Cláudia Freitas[1] & Maria Helena Cardoso[1]
[1]Centro Hospitalar e Universitário do Porto - Hospital de Santo António, Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]Centro Hospitalar e Universitário do Porto - Hospital de Santo António, Department of Neurology, Porto, Portugal

Introduction
Immune reconstitution therapies (IRT), which include antibody-based cell-depleting therapies targeting CD52+ (alemtuzumab) or CD20+ (rituximab, ocrelizumab) leukocytes, are approved for the treatment of multiple sclerosis. Thyroid autoimmunity is a common adverse effect of alemtuzumab treatment, Graves' disease being the most prevalent manifestation. To date, thyroid autoimmunity events have not been reported with CD20 targeting monoclonal antibodies.
Case report
Fifty-nine-year-old woman with primary progressive multiple sclerosis, non-smoker, with no prior personal history of thyroid disease or autoimmunity (confirmed before the IRT initiation). She was started on ocrelizumab in July 2018; 6 months later, immediately prior to her second ocrelizumab administration, her thyroid function tests revealed an overt hyperthyroidism with strong positivity for TRAb, TPOAb and TgAb; she had no signs of ophthalmopathy. Due to the temporal association of Grave's disease (GD) diagnosis with ocrelizumab infusion, absence of symptoms and our experience with alemtuzumab-induced GD, with a frequently unpredictable course and occasional rapid evolution to hypothyroidism, we decided for an active surveillance strategy and antithyroid drugs were not started. On the following 6 months, she underwent spontaneous resolution of hyperthyroidism with TRAb negativity and a mild and transitory period of subclinical hypothyroidism, while she continued the biannually ocrelizumab administration schedule. To present date, she has maintained close clinical and biochemical surveillance with normal TSH, fT4 and fT3 levels and undetectable TRAb.
Discussion
To our knowledge, this is the first case of GD reported after ocrelizumab administration. The timing of diagnosis, onset and course of the reported case is similar to alemtuzumab-induced GD, usually interpreted as an "immune reconstitution syndrome"; however ocrelizumab cell count depletion is inferior in severity, cell population affected and duration of depletion. An older CD20-targeting therapy, rituximab, has been proposed for treatment of Graves ophthalmopathy; however, although it depletes B-cells it does not reduce TRAb levels making unlikely a sporadic GD ethology, incidentally detected and treated by anti-CD20- targeting therapy. This case highlights the importance of pre-screening and follow-up with thyroid function tests in patients treated with ocrelizumab. As a novel therapeutic antibody, further investigation is required to unravel underneath causes of thyroid autoimmunity with ocrelizumab.

AEP674

A case of thyrotoxic periodic paralysis induced by super-stimulation of na–k–atpase in a competitive bodybuilder with thyrotoxicosis factitia.

Clare Bonnar, John Brazil & Francis Finucane
Centre for Diabetes, Endocrinology & Metabolism, HRB Clinical Research Facility, Galway University Hospital, Galway, Ireland

Thyrotoxic periodic paralysis (TPP) is a rare endocrine emergency where early diagnosis of both hypokalaemia and thyrotoxicosis are vital to allow prompt treatment to prevent life-threatening complications and prevent recurrences. We present the first reported case of TPP in which four known stimulants of Na–K–ATPase acted simultaneously to produce profound hypokalaemia. A 32 year-old competitive body-builder took thyroxine supplements & a long-acting β2 agonist, Clenbuterol and followed a strict diet, in preparation for a body-building competition. Following this, he went on an extreme food-binge lasting several hours. Several hours later, he developed bilateral lower limb weakness, which progressed over the next 15 hours. He attended the emergency department 24 hours after the onset of symptoms, with severe bilateral, symmetrical weakness of the lower limbs. He had no family history of thyroid disease or intermittent paralysis. Hypokalaemia of 2.3 mmol/l was found, dropping to 1.9 mmol/l in the presence of primary respiratory alkalosis (pH-7.44, pCO2-5.2). ECG showed features of hypokalaemia, including prolonged QT/QTc-intervals of 520 msec/640 msec, respectively. Hyperinsulinaemia was confirmed (276 pmol/l), with blood glucose of 7.4 mmol/l. TSH was suppressed (<0.02 mIU/l) indicating biochemical thyrotoxicosis, with normal free-T4 (12 pmol/l) and slightly reduced total-T3 (1.02 nmol/l). FSH & LH were both suppressed (<0.5 IU/l), total testosterone was normal (23.7 nmol/l) but oestradiol was elevated (224 pmol/l. Urine was screened using ultra-performance-liquid-chromatography, mass-spectrometry (UPLC-TOF-MS) for over 1300 drugs and metabolites & was positive for Clenbuterol & the anabolic steroids Trenbolone and Oxandrolone. From simultaneous samples we were thus able to document that hyperthyroidism, hyperinsulinaemia, β-agonist activity and alkalosis were all acting in concert in this patient, to stimulate Na–K–ATPase and cause significant hypokalaemia and profound muscle weakness. All four elements were entirely self-induced. Serum potassium normalised within 12-hours with parenteral potassium and fluid replacement, with return of full muscle power and normalisation of the ECG. The patient discontinued his thyroxine supplements and at outpatient review 1 month later, his thyroid-function tests were normal. This case outlines the vital necessity of checking thyroid-function tests & doing full medicines reconciliation in any patient presenting with hypokalemia and muscle weakness. It also highlights the possibility that competitive bodybuilders

may constitute a unique 'at-risk' group for TPP by virtue of the supplements they take, which often include thyroxine and β-agonists.

DOI: 10.1530/endoabs.73.AEP674

Multiple endocrine neoplasia type 2a (men 2a) case with bilateral medullary thyroid carcinoma and papillary thyroid carcinoma presentation

Ahmet Suat Demir, Damla Tufekci, Yasemin Emur Gunay, Hulya Coskun, Ozge Ucuncu, Muhammet Cuneyt Bilginer, Irfan Nuhoglu & Mustafa Kocak
Karadeniz Technical University Faculty of Medicine, Department of Endocrinology and Metabolism, Trabzon, Turkey

Introduction
MEN 2A is an autosomal dominant disease,a familial syndrome with a mutation at RET proto-oncogene. %25 of medullary thyroid carcinoma (MTC) is a part of MEN 2A. Herein, we presented a patient with MEN 2A who was found to be heterozygos for RET mutation cause of the association of MTC and papillary thyroid carcinoma (PTC) is very rare.
Case
63 year old patient was admitted to the endocrinology clinic after total thyroidectomy as the thyroid tissue contains both MTC and PTC focuses in each thyroid lobe. As there was family history of MEN syndrome, the patient was evaluated for MEN syndrome. Abdominal MRI revealed a mass in the left adrenal, 28×23 mm in size, showing heterogeneous signal loss in the external phase sequence,and heterogeneously enhanced pheochromocytoma in the arterial phase. The dopamin level in the 24 hour urine collection measured at two different occasions were 442.91 and 536.98 µg/day (65–400) respectively. The level of calcium,phosphorus and parathyroid hormone (PTH) were normal. On postop neck USG, an appearance compatible with residual throid tissue with dimensions of 22×15 mm in the localization of the left throid gland was detected. Calcitonin level was 33.6 pg/ml (<8.4). Thyroglobulin level was <0.1 mcg/l (1.15–50.03), anti-thyroglobulin level was < 0.9 IU/ml (0–4). One alelle (heterozygous) had c.23706>T(*P*.L790F) due to RET mutation. With these results,the patient was evaluated as MEN 2A. Left adrenalectomy and reoperation of residual thyroid tissue were recommended. Patient wanted to go another center for surgery.
Conclusion
The other components of MEN 2A should be investigated for all patients diagnosed with MTC. Family screening, serum calcitonin level, neck USG, existence of RET mutation and biochemical panel for pheochromocytoma should be investigated. Coexistence of MTC and PTC is very rare. There is no sufficient data to prove this association. However, it is assumed that the RET proto-oncogene would lead to the thyroid kinase activation.

Introduction
The coexistence of pulmonary adenocarcinoma and papillary carcinoma of the thyroid is a rare event. The relationship between these two cancers is still unclear; Far from being a coincidence, it's most often attributed to a genetic mutation (of which that of BRAF's the most common). The management must focus on the most aggressive carcinoma. In this case, it's pulmonary adenocarcinoma since the latter carcinoma is known for its indolent evolution and a better prognosis than the first.
Observation
A 45-year-old patient, with a family history of malignant thyroid neoplasia, underwent total thyroidectomy with central and lateral lymph node dissection for a thyroid nodule initially classified as Tirads 5. The histopathological examination was in favor of invasive papillary carcinoma of 3 cm, with the presence of vascular embolism, classified pt3bN1Mx. Radioiodine ablation therapy was performed. The postoperative evaluation objectives a dry cough that has been around for more than 3 months with a deterioration of the general condition; a chest X-ray supplemented by a CT scan revealed a pulmonary masse of 7 cm localized at the left lower lobe, scintigraphy was performed, and showed an absence of uptake by the pulmonary tumor. An echoguided biopsy of the mass showed pulmonary adenocarcinoma. Faced with the coexistence of these 2 primary tumors, we suspected a BRAF mutation that we confirmed its presence by the genetic study, and we completed the screening of other possible cancers. the CA 19 9 returned x5 the normal limit, the somatic examination found a naveus of 3 cm without malignancy signs. Our patient underwent a left lobectomy.
Discussion
BRAF represents one of the most frequently mutated protein kinase genes in human tumors. BRAF mutation can be observed in melanoma, papillary thyroid carcinoma, colorectal carcinoma, leukemia… In these cancers, various genetic aberrations of the BRAF proto-oncogene, such as different point mutations and chromosomal arrangements, have been reported. The most common mutation is BRAF V600E which can be detected by DNA sequencing and immunohistochemistry on fixed formalin, paraffin-embedded tumor tissue.
Conclusion
BRAF is one of the most frequently mutated protein kinases in cancer. Data to date support a role for BRAF as a driver of mutation that influences phenotype in different ways and indicates that it's an important therapeutic target for patients with cancer.

Importance in monitoring and treatment of thyroid cancer with new third-generation thyroglobulin assays

Aurora Lopez-Martos, Miguel-Angel Ruiz-Gines, Elena De-Rafael-Gonzalez, Patricia Fuentes-Bullejos, Fernando Sanchez-Escribano-Del-Palacio, Elena Valera-Nuñez, Maria-Carmen Lorenzo-Lozano & Mercedes Agudo-Macazaga
Virgen de la Salud University Hospital, Laboratory Medicine, Toledo, Spain

Introduction
Up by 30% of patients have recurrence in the first years after treatment of differentiated thyroid cancer (DTC) so it is necessary to have highly sensitive assays that allow adequate long-term follow-up. Nowadays, the measurement of serum thyroglobulin (Tg) is used as a tumor marker to monitoring DTC and must be determined along with levels of antithyroglobulin antibodies, since they can interfere in Tg immunoassays. Therefore, it is recommended to determine both using the same method and equipment.
Objective
The aim of this study was to evaluate the interchangeability between the Tg-ultrasensitive results using two types of immunoassays.
Materials and methods
Parallel determination of serum Tg concentration in 80 samples of patients with thyroid pathology, using the analyzers Modular E-170® (electrochemiluminescence; Roche-Diagnostics) and Architect i4000SR® (chemiluminescent-microparticle-CMIA; Abbott-Diagnostics). The statistical analysis has been developed with the Method-Validator software (v1.19), following the recommendations of the Spanish Society of Laboratory Medicine (SEQCML) for comparison of measurement procedures, performing the analysis of the agreement by Bland-Altman plot and regression by the methods of Deming and Passing-Bablok.
Results

Pearson's correlation coefficient (r): 0.999			
Method agreement analysis			
Bland-Altman	Confidence Interval (CI) 95%	–0.288 a 0.508	
	Dm	0.11	
Regression Analysis		CI 95%	Mean
Deming	Slope	0.976 a 1.02	0.998
	Ordinate	–0.092 a 0.355	0.131
Passing-Bablok	Slope	1.057 a 1.15	1.109
	Ordinate	0.00 a 0.01	0.007

Conclusions
By the data obtained, both methods would be interchangeable according to Bland–Altman analysis (the value 0 is included within CI) and Deming's method (value 0 for the ordinate at the origin and the value 1 for the slope are within their respective CI). As well as the regression analysis can be performed ($r \geq 0.975$). However, Passing-Bablok method indicated the presence of a systematic proportional difference since the value 1 is not within the CI for the slope, although it is very close. This type of error could be due to the fact that both assays have different methodology in their immunoassays and could be associated with the presence of different interferences described in the literature (Streptavidin/Biotin technology), thus the patients should always be tested with the same highly sensitive assay. It would be necessary to increase the number of samples in order to cover the dynamic range of both techniques. Although this minimal difference has no clinical relevance, it is a priority to guarantee highly accurate results at the detection limit, in order to detect tumor recurrence and/or persistence early.

COVID-19: a new trigger of subacute thyroiditis in pregnant women?

Iryna Kostitska[1,1], Iryna Basyuga[1], Antonina Piddubna[2], Olga Zhurakivska[1] & Viktor Zhurakivskiy[1]
[1]Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine; [2]Bukovinian State Medical University, Chernivtsi, Ukraine

Introduction
Recently, there has been an increasing number of reports about subacute thyroiditis (SAT) developing after COVID-19. SAT and transient gestational thyrotoxicosis constitute the majority of emerging thyrotoxicosis during pregnancy.
Case report
A 27-year-old, 34-week pregnant women complained of pain in a very small area on the anterior side of her neck and fatigue. Thyroid function tests performed four months ago were found to be in the normal range. A nasopharyngeal swab test for SARS-CoV-2 was negative but both IgM and IgG against SARS-CoV-2 were positive. On physical examination of the patient, there was no symptoms other than pain in the neck, and bilateral thyroid gland was large with tenderness. Thyroid function was assessed, showing suppressed TSH (0.1 mIU/ml, normal range 0.27–4.2), normal free thyroxine (fT4 – 1.6 ng/dl, normal range 0.93–1.7), and elevated free triiodothyronine (fT3 – 4.96 pg/ml, normal range 2.0–4.4), anti-thyroid peroxidase (anti-TPO) were negative (12.24 IU/ml, normal range <34.0), thyroid receptor antibody (TRAb) and thyroglobulin antibodies (anti-TG) were also positive (TRAb –5.78 IU/ml, normal range <1.75, anti-TG – 200 IU/ml, normal range < 138). C-reactive protein (CRP) were increased (10.49 mg/l, normal range <10.0), and D-dimer were normal (310 ngFEO/ml, normal range < 800.0). In the blood sample were increased white blood cells (WBC) – $9.8 * 10^9$ (normal range 4.0–9.0), red blood cells (RBC)- $4.95 * 10^{12}$ (normal range 3.7–4.7), erythrocyte sedimentation rate (ESR)- 46 mm/h (normal range <20.0). In the thyroid gland ultrasound both lobes were large and parenchymal blood flow was not increased. There was a distinct view of SAT. Paracetamol (daily dose – 1500 mg) was started because of the thyroid's pain. The subject's pain was significantly decreased 5 days later. Clinical and laboratory findings in pregnant woman was compatible with SAT. During 2 weeks pain and tenderness in the thyroid lodge was completely relieved. After repeated laboratory tests were normal levels and patient didn't experience any problem during pregnancy and when she was 38 weeks pregnant delivered a healthy girl who weighs 3560 g.
Conclusion
This case report demonstrates a new trigger of subacute thyroiditis in pregnant women due to COVID-19. When determining the differential diagnosis of gestational thyrotoxicosis, subacute thyroiditis should also be considered and detailed history and physical examination of the thyroid gland should not be neglected during pregnancy.

Subacute thyroiditis cases increasing in pandemic: 2 cases of covid-19 associated subacute thyroiditis

Derya Sema Yaman Kalender, Guzide Gonca Oruk & Dilek Karakus
Katip Çelebi University Hospital, Department of Endocrinology and Metabolism, Izmir, Turkey

Objective
Subacute thyroiditis (SAT) was first described by Fritz De Quervain in 1904 and is generally a self-limiting disease causing pain, fever and temporary hyperthyroidism. It generally develops as a result of postviral inflammatory response following viral upper respiratory tract infections, and it has increased since the covid-19 pandemic in March 2020. We aim to present 2 SAT cases associated with COVID-19.
Case Summary
We present 2 SAT patients associated with COVID-19 who are health workers.
Case-1
A 54-years old female patient was admitted to hospital with sore throat and fever in July 2020. Laboratory values were TSH:0.08 uIU/ml (low), freeT4:1.21 ng/dl (in normal range), freeT3:3.4 pg/ml (in normal range) and erythrocyte sedimentation rate (ESR):41 mm/h, c-reactive protein (CRP):5.76 mg/l.
Case-2
A 52-years old female patient was admitted to hospital with sore throat, fever and fatigue in August 2020. She was euthyroid but ESR:85 mm/h and CRP:74.81 mg/l. For both cases, there is no history of trauma, contrast agent exposure and infection in another part of the body. They did not have any comorbidities. Thyroid autoantibody levels were negative and ESR and CRP levels were very high. Ultrasonographic evaluation revealed decreased echogenicity and focal thyroiditis, no nodule was detected. Both of the patients stated that they had a mild upper respiratory tract infection a few months ago but didn't have a PCR test because they didn't have severe symptoms but laboratory values measured for COVID-19 antibodies were very high. Both of them didn't benefit from the nonsteroid antiinflammatory drugs, but improved with methylprednisolon. After 8 weeks, patients recovered without any symptom.
Conclusions
The COVID-19 pandemic was declared by the WHO in March 2020, thus healthcare professionals focused on COVID-19 patients who presents with respiratory symptoms, but over time, the multisystem effects began to be noticed. As clinicians, it was noticed that the number of patients with SAT increased during the pandemic period. Just few studies and case reports are known. In some patients genetic disposition such as HLA-B35 is recorded. Severe SAT can be observed even after asymptomatic COVID-19 disease as in our cases. Although these sypmtoms can be confused with COVID-19, it should be kept in mind that they may be associated with postcovid SAT.
Key Words
Subacute thyroiditis, COVID-19, Viral infection

Benign and malignant thyroid pathology in Albanians living in the Genoa district, Italy: a comparison with data from the Tirana district, Albania

Marsida Teliti[1], Ilir Akshija[2], Migena Osmani[3], DIego Ferone[3] & Massimo Giusti[3]
[1]IRCCS AOU San Martino, Endocrine Unit, Genova, Italy; [2]Mother Teresa Hospital, Statistics Department, Tiranë, Albania; [3]University of Genoa, Department of Internal Medicine, Genova, Italy

Background
In Liguria, a region of north-western Italy, the Albanian population is currently estimated to be around 20 000, constituting 15% of foreign citizens living in this area; approximately 50% of these Albanians reside in the Genoa district.
Methods
We retrospectively reviewed the medical records of all the outpatients of the Endocrine Unit of San Martino Polyclinic Hospital from 2002 to 2019. Data on subjects born in Albania and now living in the Genoa district were extracted and compared with that reported in a database registered in the same period in the district of Tirana, Albania. The International Classification of Diseases – 9th revision – Clinical Modification (ICDM-9) was used for diagnosis classification. The management of differentiated thyroid cancer (DTC) was also evaluated. The 8th edition of the AJCC was used for DTC staging.
Results
We identified 48 Albanian patients affected by benign thyroid pathology. Our data were compared with those recorded in 2915 people living in the Tirana district. Similar F/M ratios were found in both districts (Genoa: 5:1 and Tirana: 4:1). Excluding cases of congenital hypothyroidism, the median age at the time of first examination was the same (41 years). No statistically

significant differences in the incidence of simple and unspecified goitre, thyrotoxicosis with or without goitre, or other thyroid disorders were found between the Genoa and Tirana districts. Non-toxic nodular goitres were less frequently diagnosed in Genoa (29%) than in Tirana (64%, $P<0.0001$), while acquired hypothyroidism and thyroiditis were more often recorded in Genoa (29% and 19%, respectively) than in Tirana (3%, $P<0.0001$; 4% $P = 0.0003$). From 2002 to 2019, 401 DTC patients were followed up at our centre; 8% were not Italian and 19% of non-Italians were Albanian ($n = 6$; stage 1–2). The median age of the Albanians on diagnosis (59 years) was similar to that of the Italians (53 years). Structural disease was observed in 2 Albanian DTC patients, in whom initial surgery had been performed in Tirana and further treatments were needed in Italy. The rate of loss to follow-up was similar in Albanian subjects (19%) and in other patients (10%) of the DTC cohort. At present, all DTC Albanians in the Genoa district are alive.

Conclusion

A difference in nutritional iodine load and in facilities for laboratory evaluations could explain the significant differences observed in some ICDM-9 between Albanians living in Genoa and those living in Tirana. The diagnosis and surgical treatment of thyroid malignancy probably needs to be improved in Albania.

Thyroid function in adults with Prader-Willi syndrome.

Karlijn Pellikaan[1], Fleur Snijders[1], Anna Rosenberg[1], Sjoerd van den Berg[1,2], Aart Jan Van der Lely[1] & Laura De Graaff[1,3,4]

[1]Erasmus University Medical Centre, Internal Medicine, Division of Endocrinology, Rotterdam, Netherlands; [2]Erasmus University Medical Centre, Clinical Chemistry, Rotterdam, Netherlands; [3]Erasmus University Medical Centre, Academic Center for Growth Disorders, Rotterdam, Netherlands; [4]Dutch Center of Reference for Prader-Willi Syndrome

Introduction

Prader-Willi syndrome (PWS) is a complex genetic syndrome in which hypothalamic dysfunction leads to hyperphagia and pituitary hormone deficiencies (PHD), among others. The majority of patients have intellectual disability (ID) and use of psychotropic drugs is frequent. Due to hypotonia and the low muscle mass associated with the syndrome, adults with PWS have a low basal metabolic rate (BMR). Combined with hyperphagia, this results in high risk of obesity. Therefore, exercise is extremely important. However, PHD like hypothyroidism can cause fatigue and exercise intolerance. If left untreated, hypothyroidism can lead to a further decrease in BMR, an increase in Body Mass Index (BMI) and increased cardiovascular risk. As mortality in PWS is high (3% yearly) and often related to cardiovascular problems and obesity, it is important to optimize thyroid function and other factors affecting BMR.

Objectives

To investigate the prevalence of hypothyroidism in adults with PWS and to provide practical screening recommendations.

Methods

In 122 adults with PWS (median age 29 y [IQR 21–39], median BMI 29 kg/m^2 [IQR 26–36]), we measured TSH, free T4 and T3 and searched the medical history for use of medication and any pre-existing diagnosis of hypothyroidism. Moreover, we performed an extensive literature search and summarized the current literature on hypothyroidism, T3 and T4 levels in adults with PWS.

Results

Hypothyroidism was present in 17% and more prevalent in females (23%) than in males (10%), even though this difference was not statistically significant ($P = 0.06$). Although within the reference range, serum T3 levels (reference range: 1.3–2.3 nmol/l) were relatively high compared to free T4 levels (reference range: 13.5–24.3 pmol/l). T3 levels were significantly lower in patients that used psychotropic medication ($n = 45$) than in patients that did not (median 1.7 [IQR 1.5–2.0] vs 2.1 [IQR 1.7–2.3], $P = 0.013$).

Conclusion

We found a prevalence of hypothyroidism of 17% in PWS-adults (compared to 3% in the non-PWS population). Levels of the active thyroid hormone T3 were significantly lower in patients using psychotropic medication. Based on our findings, we recommend 1) yearly screening of thyroid hormone levels in adults with PWS to avoid negative effects of untreated hypothyroidism on BMR, BMI and cardiovascular risk and 2) extra monitoring of the active thyroid hormone T3 in patients using psychotropic drugs.

AEP682

Relationship between vitamin D status and metabolic parameters in premenopausal women with autoimmune hypothyroidism

Oksana Chukur

Ternopil National Medical University, Internal Medicine №1, Ternopil, Ukraine

Background

Vitamin D deficiency is a global health problem. Nowadays is intensively studied the influence of vitamin D on the course of autoimmune diseases of the thyroid gland.

Objective

To study the relationship between vitamin D status and metabolic parameters in premenopausal women with autoimmune hypothyroidism.

Methods

146 premenopausal women with autoimmune hypothyroidism were examined. The mean age of patients was 46.8 ± 0.73 years. All women underwent anthropometric, general clinical, biochemical examinations, including determination of lipid and hydrocarbon metabolism, assessment of the functional state of the thyroid gland: TSH level, free thyroxine (FT4), free triiodothyronine (FT3), thyroid antibodies (TPOAb, TGAb). The collected data were statisstically analyzed using the Statistica 12 ($p<0.05$).

Results

The average level of TSH was 4.40 ± 0.21 uIU/ml; fT3 –1.97 ± 0.09 pmol/l; fT4 – 12.96 ± 0.37 pmol/l; TPOAb –112.87 ± 5.61 IU/ml; TGAb –152.25 ± 5.04 IU/ml, $p<0.05$. The mean level of 25 (OH) D in women with hypothyroidism was 16.42 ± 0.57 ng/ml, which corresponds to vitamin D deficiency (<20 ng/ml). Vitamin D deficiency was found in 78.8%, insufficiency in 17.1% of premenopausal women with hypothyroidism. There was a significantly strong ($P<0.05$) negative correlation between 25 (OH) D and TPOAb ($r = –0.77$), TSH ($r = –0.72$), TGAb ($r = –0.33$). Positive correlations of medium strength were found between 25 (OH) D and the level of fT3 ($r = 0.46$) and fT4 ($r = 0.44$), $P<0.05$. The body mass index averaged 29.4 ± 0.29 kg/m^2. The mean level of glucose 5.49 ± 0.06 mmol/l, basal insulin level 28.63 ± 0.88 mIU/l, HOMA-IR 3.31 ± 0.08 ($p<0.01$). Hypercholesterolemia averaged 6.1 ± 0.12 mmol/l, cholesterol LDL 3.72 ± 0.07 mmol/l, cholesterol HDL 1.37 ± 0.02 mmol/l, TG 3.73 ± 0.09 mmol/l, atherogenic coefficient (AC) >3 was observed in 64%, $P<0.01$. Analysis of the relationships of metabolic parameters showed a significantly strong ($P<0.05$) negative correlation between 25 (OH) D with BMI ($r = –0.74$), AC ($r = –0.65$), the level of cholesterol HDL ($r = -0.72$), cholesterol LDL ($r = –0.58$), TG ($r = –0.46$), HOMA resistance index ($r = –0.57$).

Conclusion

Low vitamin D status is significantly associated with autoimmune thyroid dysfunction and determines the degree of metabolic disorders and cardiovascular risk in premenopausal women with autoimmune hypothyroidism.

Prevalence of thyroid dysfunction in untreated chronic hepatitis C

Lyudmyla Mazur[1]

[1]Ternopil National Medical University, Ternopil, Ukraine

In Ukraine, in 2017, an estimated 53000 people were living with chronic hepatitis C virus (HCV) infection, and its prevalence rate was 123.7 patients per 100000 citizens. Symptoms of at least one extra hepatic manifestations appear in more than 50% of HCV-positive patients, and thyroid abnormalities are rather common. The purpose of the study was to determine the prevalence of thyroid function tests and anti-thyroid autoantibodies abnormalities in the untreated patients with chronic HCV infection. This retrospective study included 58 HCV (RNA+) patients, 18 males (31.0%) and 40 females (69.0%), and 23 apparently healthy controls. The mean age of patients was 40.4 ± 5.9 years. Routine clinical assessment and tests, and thyroid gland sonography were performed at the baseline. Thyroid function tests, including serum thyroid-stimulating hormone (TSH), free thyroxine (FT4), free

triiodothyronine (FT3), and antibodies to thyroid peroxidase (TPO) were performed by an ultrasensitive immune chemiluminescent noncompetitive assay. Ultrasound thyroid abnormalities included heterogenous parenchyma in 14 (24.1%) and grade 1 goiter in 16 (27.6%) cases. TPO were three times higher in HCV patients, 26.06 ± 1.23 IU/ml as compared to 8.69 ± 0.87 IU/ml in control. The mean TSH levels were significantly higher in HCV patients versus control, 3.78 ± 0.41 uIU/ml and 2.08 ± 0.54 uIU/ml respectively. FT4 and FT3 levels were not changed significantly. Mean FT4 concentration in HCV patients versus control was 1.18 ± 0.05 and 1.25 ± 0.08 ng/dl, and mean FT3 level – 4.95 ± 0.51 and 5.28 ± 0.47 pmol/l respectively. Increasing of TPO levels over upper normal limit was found in 15 (25.9%) cases, 11 (27.5%) females and 4 (22.2%) males. In 5 (12.5%) females observed clinically significant TSH rising. In 4 (10.0%) of them increased TSH was accompanied by high TPO and specific ultrasound abnormalities, thus autoimmune thyroiditis with hypothyroidism was diagnosed. In 1(2.5%) female patient subclinical hypothyroidism was diagnosed due to isolated TSH increasing in the subclinical range of hypothyroidism, and absence of clinical signs. Therefore, increasing of TPO levels was detected in more than 25%, and hypothyroidism was diagnosed in 12.5% untreated patients with HCV infection; HCV-associated thyroid dysfunction was specific for females.

AEP685

Iodized salt is sufficient to obtain an adequate nutritional status of iodine in pregnant woman

Silvia González Martínez[1], Ana Isabel Escudero Gomis[2], Elias Delgado[2] & Edelmiro Luis Menendez Torre[2]
[1]Hospital Vital Álvarez Buylla, Santullano, Spain; [2]Hospital Universitario Central de Asturias, Oviedo, Spain

Introduction
Iodine is an essential micronutrient used by the thyroid gland to produce thyroid hormones. Iodine deficiency during pregnancy is related to impaired neurocognitive development of fetus and neonate. The WHO recommends iodization of salt as main measure to prevent iodine deficiency disorders. In pregnant population other international organizations recommend the use of iodine supplements to guarantee adequate nutritional status of iodine (median urinary iodine concentration [UIC] ≥ 150 µg/l). The objectives of the study are to know nutritional status of iodine in our pregnant women and its relationship with iodine intake.
Materials and methods
Descriptive and analytical observational study carried out in 2017 in 318 women in the first trimester of pregnancy at Hospital Universitario Central de Asturias, Spain. Pregnant women with diagnosis of thyroid disease before pregnancy or multiple gestations were excluded. Information on dietary habits was collected by midwives in the primary care centers. The questionnarie contained items related to consumption of iodized salt, dairy products and iodine supplements. UIC was determinated in a first morning urine sample. The statistical analysis was performed using the R program (R Development Core Team), version 3.6.0, applying the Chi-square and Student's T statistical tests.
Results
Mean age of pregnant women was 34.10 ± 5.45 years, with a mean gestation age of 7.19 ± 2 weeks.
Results of the iodine intake questionnaire were as follows
– Consumption of iodized salt: 51.10%
– Consumption of dairy products (≥ 2 servings day): 48.9%
– Use of iodine supplement: 87.08%
Median UIC (Q1–Q3) was 171.5 µg/l (116–265 µg/l). 60.4% of pregnant women had ioduria greater ≥150 µg/l.

	UIC ≥150 µg/l	UIC < 150 µg/l	*P*	Median UIC (Q1–Q3) µg/l	*P*
Iodized salt					
No	55 (48.7%)	58 (51.33%)	0.001	147 (102–206)	0.016
Yes	97 (69.3%)	43 (30.7%)		191.5 (131.5–285)	
Dairy products					
<2 servings/day	78 (56.1%)	61 (43.9%)	0.269	168 (96–258)	0.48
≥ 2 servings/day	84 (62.7%)	50 (37.3%)		172 (122.25–255.75)	
Iodine supplement					
No	21 (53.9%)	18 (46.1%)	0.455	158.5 (113–199.5)	0.027
Yes	157 (60.1%)	104 (39.9%)		172.5 (116–285.75)	

Conclusions
Our pregnant population presents an adequate nutritional status of iodine. In our sample, the intake of iodized salt was sufficient to obtain an adequate UIC, being the main measure to achieve it. The use of iodine supplements increases UIC but has no protective effect against UIC <150 µg/l. We agree with the WHO recommendation on the use of iodized salt in pregnant women.

Comparison of body composition and insulin sensitivity changes in patients with Graves disease after radioiodine or antithyroid drugs treatment

Ewa Szczepańska[1], Piotr Glinicki[1], Wojciech Zgliczyński[1], Helena Jastrzębska[1], Jadwiga Słowińska-Srzednicka[1], Renata Kapuścińska[1], Stefan Zgliczyński[1] & Małgorzata Gietka-Czernel[1]
[1]Medical Centre of Postgraduate Education, Endocrinology Department, Warsaw, Poland

Thyroid hormones (TH) are key regulators of basal metabolic rate and body weight. They increase resting energy expenditure by increased synthesis of uncoupling protein-1 (UCP-1) in brown adipocytes which stimulates energy dissipation as a heat. TH also increase appetite by central adrenergic stimulation. Body weight change is a key symptom of thyroid dysfunction especially the weight gain observed in patients treated for hyperthyroidism
AIM: To compare the influence of different methods of Graves disease treatment on body composition and insulin sensitivity.
Methods
Pairwise comparison of 50 patients with Graves disease treated with radioiodine or antithyroid drugs (ATDs) in hyperthyroid state and three months after euthyroidism was established. Body composition changes were determined with dual energy X-ray absorptiometry (DXA). Glucose and insulin serum concentration were measured and QUICKI index calculated. Body composition analysis was performed separately in women ($n = 43$) and men ($n = 7$).
Results
Independently of treatment method there was significant increase in body fat (BF) and lean tissue mass (LTM), with BF rise dominating in men whereas LTM increase being more pronounced in women. BF increased by 2.43 (0.58;3.0) kg in women and 4.18 (0.25; 8.09) kg in men, whereas LTM increased by 3.84 (1.75 ; 4.35) kg in women and 0.77 (0.2–6.10) kg in men. There was no difference in BF, trunk body fat, legs body fat and LTM in women treated with radioiodine ($n = 33$) as compared to ATDs treated women ($n = 10$) (2.57 vs 1.3 kg, $P = 0.711$; 1.37 vs 0.88 kg, $P = 0.702$; 0.68 vs 0.72 kg, $P = 0.596$; 3.68 kg vs 2.13 kg, $P = 0.910$ respectively) and in a small sample of men ($n = 7$). In radioiodine treated group insulin sensitivity improvement was observed. There was decrease in serum insulin and glucose levels {7.40 (5.28; 9.55) vs 5.05 (3.70; 6.4) uIU\ml, $P = 0.018$; 95.18 (91.77; 101.32) vs 92.06 (87.89; 96.47) mg%/ $P = 0.023$ respectively} and increase in QUICKI index (0.36 ± 0.04 vs 0.38 ± 0.04 ; $P = 0.014$). Insulin decrease was greater in radioiodine treated as compared to ATDs treated patients {−2.35 (−3.85; 0.35) vs 0.12 (−1.89; 2.14) uIU\ml, $P = 0.056$} however glucose, QUICKI and HOMA didn't differ significantly between groups.
Conclusions
There was no difference in BF and LTM changes between radioiodine and ATDs treated patients. In women body weight increase was predominately caused by LTM rise. Despite of body weight gain there was improvement of insulin sensitivity after radioiodine treatment.

AEP687

Interconnection between obesity, thyroid function, insulin resistance, and cardiovascular risk factors in patients with subclinical hypothyroidism

Yuliia Yevstratieva
I.Ya.Gorbachevsky Ternopil National Medical University, Ternopil, Khmelnitsky, Ukraine

Background and aim
The epidemic of overweight and obesity presents a major challenge to chronic disease prevention and health across the life course around the world. The putative relationships between thyroid hormones, body weight, and adipose

tissue homeostasis have been the focus of several studies in recent years, but the causal relationships between these parameters have not been well established. Aim of the study: to investigate the relationship between serum *thyroid stimulating hormone* (TSH), insulin resistance (IR), and cardiovascular risk factors in a sample of obese persons with subclinical hypothyroidism.
Materials and methods
A retrospective, longitudinal analysis of 145 obese persons was performed. The TSH and free thyroxine (fT_4) levels, anthropometric measurements, and laboratory test results were analyzed. Euthyroid patients were also divided into two groups according to TSH levels. There has been some discussion about lowering the upper value of TSH to 2.5 µIU/ml. This discussion is based in some data that indicated that patients with TSH $\geq$ 2.5 may have different profiles than those with TSH < 2.5 µIU/ml
Results
35 individuals presented with TSH levels above the normal level (subclinical hypothyroidism). Their waist circumference (WC) was significantly higher than those of euthyroid individuals. Serum TSH was positively correlated with the homeostasis model assessment of insulin resistance (HOMA-IR) index, triglycerides (TG) and high-density lipoprotein cholesterol (HDL-C). Using TSH and BMI as independent variables, TSH levels were shown to be independently related to HOMA-IR (P = 0.002) and triglycerides (P = 0.006). Among euthyroid subjects, individuals with TSH values <2.5 mIU/ml exhibited statistically significant decreases in waist-to-hip ratio, HDL-C levels, and HOMA-IR scores and a tendency toward lower WC values.
Conclusion
Subclinical hypothyroidism in overweight and obese persons appears to be associated with excess weight, especially visceral weight. In the present sample of obese persons, TSH levels appear to be associated with insulin resistance.
Keywords
subclinical hypothyroidism, obesity, cardiovascular risk factors.

Acoustic radiation force impulse elastography findings of achilles tendon in patients with hypothyroidism

Hale Turnaoğlu[1], Feride Pınar Altay[2], Feride Kural Rahatlı[1], Yusuf Bozkus[2], Ozlem Iyidir[2] & Kemal Murat Haberal[1]
[1]Başkent University Ankara Hospital, Radiology, Turkey; [2]Başkent University Ankara Hospital, Endocrinology and Metabolism, Turkey

Introduction
There are very limited number of clinical studies and data on the effect of thyroid dysfunction in hypothyroidism on connective tissue. Tendinitis can be the first complaint in hypothyroidism and symptomatic relief can be provided with the appropriate treatment of primary thyroid deficiency. There are studies, showed softening in Achilles tendon with age, in patients with intermittent claudication, diabetes patients, and chronic kidney failure patients. To our knowledge, there are no studies in the literature on ARFI elastography findings of the Achilles tendon in hypothyroidism patients. The aim of our study was to investigate the effect of thyroid dysfunction on tendons and the contribution of Acoustic Radiation Force Impulse (ARFI) elastography to the diagnosis of tendinopathy.
Methods
Eighty Achilles tendons of 40 patients under levothyroxine treatment, who had previously known hypothyroidism but high serum TSH levels, and 80 Achilles tendons of 40 healthy individuals were evaluated with ARFI (Virtual Touch Quantification®). 19 of 40 of the patients with hypotiroidism' Achilles tendons were re-evaluated after thyroid stimulating hormone levels reached to normal limits following the adjustments in thyroid hormone replacement therapy. The middle portion of the each Achilles tendon was chosen for the examination. Every examination consisted of three to five independent measurements (shear wave velocity – meters per second). The mean shear wave velocity value was calculated for each tendon, and used for statistical analysis.
Results
The stiffness values of both left and right Achilles tendons, represented as shear wave velocity, were similar in patients with hypothyroidism and control group (Right achilles 5.07 ± 1.14 vs 5.36 ± 1.11, P = 0.245; left achilles 5.09 ± 1.16 vs 5.21 ± 1.11; P = 0.662). There was no significant difference between the Achilles tendon shear wave velocity measurements of 19 of 40 hypothyroidism patients who were re-evaluated after the adjustments in thyroid hormone replacement therapy (right achilles 5.14 ± 1.45 vs 4.7 ± 1.37, P = 0.269; left achilles 5.34 ± 1.36 vs 4.7 ± 1.17, P = 0.097)
Conclusions
The lack of significant difference in Achilles tendon stiffness between non-naive hypothyroid patients and the control group may be explained as a positive clinical effect of thyroid hormone replacement therapy. This study is important in terms of being a pilot study on a subject that can be considered new for the literature. Further prospective studies with larger sample size, which also include naive hypothyroidism patients, are needed to identify the causal relationship between the sonoeleastographic changes in Achilles tendon and hypothyroidism.

The SARS-CoV-2 infection and thyroid disorders: review on the literature

Anna Dabrowska[1,2] & Jaroslaw Dudka[1]
[1]Medical University of Lublin, Department of Toxicology, Lublin, Poland; [2]Endocrinology Outpatient Clinic, Lublin, Poland

Introduction
Coronavirus disease (COVID-19) caused by SARS-CoV-2 infection, resulted in serious respiratory and other systemic complications, has spread worldwide since December 2019. In patients with the infection, many organ systems can be involved with potentially fatal results due to robust and disorganized systematic immune activation.
The state of the art
Since the outbreak of the SARS-CoV-2 pandemic, many reports of autoimmune diseases related to COVID-19, have been revealed. Regarding thyroid disease, the occurrence of Graves' disease, Hashimoto's and postpartum thyroiditis after the viral infection, has been reported. SARS-CoV-2 could act as a trigger of latent or new-onset autoimmunity. Moreover, the molecular mimicry of the viral and thyroid epitope relating to the presentation on HLA molecule, might be a possible mechanism for post-COVID-19 subacute thyroiditis. It has been indicated that antibodies against SARS-CoV-2 spike protein strongly react with thyroid peroxidase and may play also a role in initiating the autoimmune responses. Induction of inappropriate apoptotic reactions seems to be other common features of the virus-induced disease processes. What is more, it has been proven that thyroid gland shows higher expression of the angiotensin-converting enzyme 2 (ACE 2) cell receptors (the main receptors for SARS-CoV-2 acting) compared with the lungs. Thus, the direct cell damage in the thyroid gland may occur and the possibility of thyroiditis may arise. However, during the SARS-CoV 2002 outbreak, the absence of SARS-CoV per se in the damaged thyrocytes in autopsy patients' material, was strongly indicative of exaggerated innate and adaptive immune responses to COVID-19 (cytokine storm), as a main mechanism leading to damage of tissues and destructive thyroiditis. On the other hand, thyroid hormone abnormalities seem to be associated with an enhanced risk of severe SARS-CoV-2 infection. Thyroid hormones are important in the regulation of innate immune response so their excess or deficiency may lead to its dysregulation. What is more, increased levels of proinflammatory cytokines such as TNF-ńand IL-6, were observed in patients with thyroid diseases as well as in ones with severe COVID-19. Moreover, some patients with subacute thyroiditis use corticosteroids – the drugs which have been proven to be associated with higher mortality in COVID-19 patients.
Conclusions
SARS-CoV-2 infection may be associated with the development of thyroid diseases. The several mechanisms have been proposed of thyroid organ damage from the immune overreaction to direct cellular destruction with apoptosis. The presence of thyroid dysfunction may lead to deterioration of the course of COVID-19.

LOW calcium level and thyroid diseases

Rajmonda Tare[1]
Spitali Xhafer Kongoli, Endocrinology, Elbasan, Albania

Background
The thyroid gland helps regulate the calcium levels in the body. It produces the hormone calcitonin that works by decreasing the available amount calcium in the bloodstream. When the thyroid gland is disrupted, calcium

concentrations in the body can be affected as well. It is important that those with thyroid disorders be treated to prevent the effects of hipocalcemia.
Aim
The objective of this study were the measure the serum calcium level in patients with thyroid diseases.
Material and methods
The study includes 110 persons who came to our outpatient service for thyroid diseases from September 2020 to December 2020. Among them 85.4% were female and 14.6% were male. Was measured total calcium level, TSH, freeT4, freeT3, and ultrasound thyroid, total bilirubin, ALT, AST, total protein. The level of calcium was measured with the photometer method. Normal range of calcium 8.5-10.5 mg/dl.
Results
According to thyroid function in 62.7% were determined euthyroid goiter (TSH 1.77 mIU/l), in 12% hyperthyroidism (TSH 0.1 mIU/l), in 9% Hashimoto's thyroiditis (TSH 10 mIU/l and high levels of antithyroid antibodies) and 16.3% normale people. Low calcium levels were found in 12 patient with euthyroid goiter, the average value of calcium was **7.9 + 0.35** s.d.,(min = 7.1 mg/dl,max = 8.4 mg/dl), in 6 patient whith hyperthyroidism, the average value was **8.1 + 0.33** s.d.,(min = 7.4 mg/dl,max = 8.4 mg/dl), in 4 normale people, the average value was **8.22 + 0.14** s.d.,(min = 8.0 mg/dl,max = 8.4 mg/dl),in 1 patient with Hashimito's thyroiditis. The average level of calcium it was not comparable between the groups. Lower calcium levels than the norm was more in individuals with euthyroid goiter than in hyperthyroidism, and normale people. There were no significant differences in blood total bilirubin, ALT,AST and total protein.
Conclusion
There was low calcium levels in patient with thyroid diseases when compared to normale people. The number of people with low calcium level was twice high in euthyroid goiter compared to hyperthyroidism, three times higher compared to normale people.
Keywords
Total calcium level, euthyroid goiter, hyperthyroidism, Hashimoto's thyroiditis.

Hypocalcemia post total thyroidectomy : incidence and management
Meherzi Abir, Amany Mallat, Takwa Belaid, Kermani Wassim, Mouna Bellakhdhar & Abdelkefi Mohamed
ENT Department Farhat Hached Hospital Sousse, Sousse, Tunisia

Goals
The most common complication of thyroidectomy is hypocalcaemia. The aim of this work is to determine the epidemiological, ethiopathogenic and therapeutic characteristics of hypocalcemia after total thyroidectomy.
Material and methods
This is a retrospective study of 27 cases of patients operated on for a total thyroidectomy complicated by hypocalcemia, over a period of 9 years (2009–2017) collected by ENT Farhat Hached Sousse.
Results
27 of 320 patients operated on for total thyroidectomy presented with postoperative hypocalcaemia (8%). The average age was 40.5 years [17–78 years], with a clear predominance of women (92.6%). Systematic preoperative serum calcium was correct in all cases. Calcium assay was systematic on D3 postoperatively. Hypocalcaemia was asymptomatic in 48% of cases. The clinical manifestations were observed on D1 postoperative in 3 patients and on D2 postoperatively in 11 patients. Paresthesia of the extremities was the most common symptom (85.7%). Muscle cramps were observed in 2 patients. No patient presented with a heart rhythm disturbance or an attack of tetany. The mean serum calcium was 1.67 mmol/l [1.4–1.9 mmol/l]. A parenteral, intravenous correction was necessary in 18 patients. Oral relay in combination with Vit D was initiated in all patients. The mean duration of treatment was 3.7 months [1–9 months]. The course was marked by regression of symptoms and biological correction in all cases.
Conclusion
Hypocalcaemia is a frequent complication of total thyroidectomy, which can be feared by its cardiac and respiratory complications that can be life-threatening, hence the importance of detecting it by systematic dosing after surgery. Understanding of ethiopathogenic mechanisms is necessary for correct management.

Amiodarone-induced thyrotoxicosis in children: a clinical case
Tatiana Ivannikova, Alexey Kalinin, Natalia Strebkova, Maria Kareva & Olga Bezlepkina
Endocrinology Research Center, Moscow, Russian Federation

Introduction
Amiodarone is a drug commonly used for the treatment of refractory atrial or ventricular arrhythmias. In 20% of patients, amiodarone may cause subclinical or clinically overt hypothyroidism or hyperthyroidism. The high iodine exposure caused by amiodarone treatment interferes with thyroid autoregulation. Two underlying mechanisms are considered to be involved in the pathogenesis of amiodarone-induced thyrotoxicosis (AIT). AIT1 is more common in patients with underlying Graves' disease or nodular goiter and results in excessive synthesis of thyroid hormones due to the high iodine intake by amiodarone. In AIT2, a destruction of thyroid follicles due to amiodarone toxicity (subacute and destructive thyroiditis) is observed leading to uncontrolled thyroid hormone release. Also mixed forms are described. We present the patient with amiodarone-induced thyrotoxicosis developed in two years after amiodarone therapy initiation.
Case description
We examined 15-year-old girl whose arrhythmia in the form of a ventricular extrasystole was first diagnosed at the age of 10 (2015) during a preventive examination. A cardioverter-defibrillator was implanted in 2018 and Amiodarone therapy was initiated. Her current Amiodarone dose is 500 mg per day. She regularly underwent examinations and only the thyroid volume increase was noted by ultrasound while hormonal examination always showed euthyroidism. In December 2020 (2.5 years after initiation of amiodarone therapy) patient began to complain of increased heart rate. Hormonal analysis identified a decrease in thyroid-stimulating hormone level (0.0001 uIU/ml; N: 0.35–5.5 uIU/ml) and a pronounced increase in free-thyroxine (fT4) (52.11 pmol/l; N: 11.5–22.7 pmol/l) and free-triiodothyronine (fT3) (7.35 pmol/l; N: 3.5–6.5 pmol/l) levels. Therapy with Prednisolone was initiated at a starting dose of 30 mg per day. Two weeks after the start of therapy, it was possible to achieve the decreasing of fT4 (18.49 pmol/l; N: 10.1–17.9 pmol/l) and fT3 levels (3.5 pmol/l; N: 2.8–6.3 pmol/l). Also, according to the results of ultrasound of the thyroid gland, a decrease in the volume to 14.2 ml was noted (from 21 ml initially). The girl was consulted by cardiologists, the cancellation of therapy was started. We continue to monitor her condition.
Conclusion
Amiodarone-induced thyroid dysfunction is usually atypical; therefore, monitoring of thyroid status before, during, and after Amiodarone treatment is demanded. AIT could significantly deteriorate the clinical status of children with complex cardiac diseases. Early and proper diagnose of AIT allows the introduction of immediate and appropriate treatment considering the cardiac condition of the young patient.

The value of serum thyroglobuline alteration after ultrasonography-guided fine-needle biopsy of suspicous cervical lymph nodes in the diagnosis of metastasis in patients with differentiated thyroid cancer
Fatma Dilek Dellal[1], Cevdet Aydin[2], Abbas Ali Tam[2], Sevgul Faki[1], Afra Alkan[3], Şefika Burçak Polat[2], Ahmet Dirikoc[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara City Hospital, Endocrinology and Metabolism, Turkey; [2]Ankara Yildirim Beyazit University, Faculty of Medicine, Endocrinology and Metabolism, Turkey; [3]Ankara Yildirim Beyazit University, Faculty of Medicine, Biostatistics, Turkey

Aim
It is known that serum thyroglobulin (TG) can increase after fine-needle biopsy of thyroid nodules. We aimed to determine whether TG is increased after ultrasonography guided fine needle capillary biopsy (FNC) of suspicious cervical LNs in thyroidectomized patients and investigate the possible association between change in TG and cytology results.
Material and methods
Data of 188 patients who underwent FNC of suspicious cervical LNs were retrospectively evaluated. Demographical features, radioactive iodine (RAI) treatment status, thyroid-stimulating hormone (TSH), TG, anti-TG antibody and ultrasonography features of LNs were noted. TG levels before FNC ($TG_{b\text{-}FNC}$), after FNC ($TG_{a\text{-}FNC}$), $TG_{a\text{-}FNC}/TG_{b\text{-}FNC}$ ratio and the number of patients with increased TG were determined. Patients were grouped as

benign, nondiagnostic, suspicious for malignancy and malignant according to the cytological results.
Results
The age, gender, clinical diagnosis, history of RAI treatment and TSH levels were similar in different cytological groups. $TG_{a\text{-}FNC}$, $TG_{b\text{-}FNC}/TG_{a\text{-}FNC}$, and rate of patients with increased TG were significantly higher in malignant cytology group than other groups (P<0.001)(Table). The optimal cut-off level of TG increase that was predictive for malignancy was 7.6% with a sensitivity of 73.7% and specificity of 85.2%. TG increase was not associated with age, sex, TSH level, antiTG positivity and US features of LNs while signficantly lower in patients who received RAI treatment. Among 31 patients with positive anti-TG, $TG_{b\text{-}FNC}/TG_{a\text{-}FNC}$, and rate of patients with increased TG were higher in malignant compared to benign and nondiagnostic cytology groups.
Conclusions
Serum TG increment and rate of patients with increased TG after FNC of suspicious cervical LNs were higher in patients with malignant cytology than with all other cytology results both in all study group and in sub-group of anti-TG positive patients. Increase in TG after FNC might be an additional tool for determining LN metastasis.

Table. Demographical, clinical and ultrasonography features and thyroglobulin levels in patients with respect to the cytological results of lymph nodes

Characteristics	Benign (n = 124, 66.0%)	Malignant (n = 19, 10.1%)	Nondiagnostic (n = 38, 20.2%)	Suspicious for malignancy (n = 7, 3.7%)	P-value
$TG_{a\text{-}FNC}$ (mcg/l)	0.076 (0.012–0.471)[1]	1.283 (0.207–7.931)[1,2]	0.224 (0.036–1.385)[2]	0.161 (0.026–0.998)	<0.001
$TG_{b\text{-}FNC}$ (mcg/l)	0.072 (0.014–0.382)[1]	2.313 (0.437–12.247)[1,2,3]	0.196 (0.037–1.037)[2]	0.071 (0.013–0.375)[3]	<0.001
$TG_{b\text{-}FNC}/TG_{a\text{-}FNC}$	1.000 (1.000–1.000)[1]	1.408 (1.068–1.839)[1,2,3]	1.000 (0.824–1.000)[2]	0.821 (0.531–1.000)[3]	<0.001
Increased TG	18 (14.5)[1]	14 (73.7)[1,2,3]	7 (18.4)[2]	0 (0.0)[3]	<0.001

Quantitative and categorical variables are summarized by median (IQR: 25th–75th percentiles) and frequency (%), respectively.
[1,2,3]The same numbers indicates that the corresponding groups are significantly different from each other.

Predictive factors of thyroid differentiated cancers

Mohamed Masmoudi, Thabet Wadii[1], Rihab Guizani[1], Mehdi Hasnaoui[1] & Mighri Khalifa[1]
Tahar Sfar Hospital Mahdia, ENT Department, Mahdia, Tunisia

Introduction
Thyroid nodules are common. They are mostly benign nodules. Thyroid cancer is rare: 1 % of all cancer sites. Thyroid differentiated cancers are the most common histologic types. There are several factors that can predict the malignancy in patients with thyroid nodule. The purpose of this study is to identify the predictive factors of thyroid differentiated cancers.
Material and methods
This retrospective study included 333 patients who underwent surgical treatment for thyroid nodule(s), from 2010 to 2020 at our institution. The diagnosis of thyroid cancer was determined according to the histological results. We chose $P < 0.05$ for statistical significance.
Results
The study included 294 women and 39 men. The mean age was 44 years [10 years – 92 years]. Histologic exam revealed a thyroid cancer in 43 cases (13 %) and a benign nodule in 290 cases (87 %). Histologic types of thyroid cancer were: papillary thyroid carcinoma in 37 cases (83 %) and vesicular thyroid carcinoma in 6 cases (14 %).Predictive factors of thyroid differentiated cancers were: male sex ($P = 0.04$), unique nodule ($P = 0.01$), the presence of lymph node ($P = 0.017$), size > 4 cm ($P < 0.001$), solid nodule (ultrasound) ($P < 0.001$), hypoechoic nodule ($P = 0.004$), central ($P < 0.001$) and mixed ($P = 0.006$) vascularization and the presence of microcalcifications ($P < 0.001$).
Conclusion
Many epidemiological, clinical and ultrasonographic factors of thyroid differentiated cancers, have been reported in the literature. Knowing these factors allows for an adequate selection of patients needing fine needle aspiration and surgery.

Systemic erdheim-chester disease associated with braf-positive papillary thyroid carcinoma

Iuliana Ilie[1], Jean Francois Emile[2], Natalie Chereau[3], Julien Haroche[3], Camille Buffet[3], Gabrielle Deniziaut[3], Teodor Constantin[4], Bogdan Bercu[5], Luciana Oprea[6], Andreea Banica[6] & Madalina Musat[6]
[1]Gral Medical Clinic, Endocrinology, Bucharest, Romania; [2]Hôpital Ambroise Pare, Paris, France; [3]University Hospitals Pitié Salpêtrière – Charles Foix, Paris, France; [4]Gral Medical Clinic, Oncology, Bucharest, Romania; [5]Dr. Carol Davila Central Military Emergency University Hospital, Bucharest, Romania; [6]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

Erdheim-Chester disease (ECD) is a rare histiocytic neoplasm with distinctive clinical and immunophenotypic features, involving somatic mutations of *BRAF* and activation of *MAPK* pathway. Other *BRAF* mutated neoplasms such as papillary thyroid carcinoma (PTC), may also occur synchronous with EDC. There are several reports in the literature of concurrent Langerhans Cell Histiocytosis (LCH) and PTC which suggests that the association is not random, however ECD with systemic involvement and PTC has only been reported in one case only. We report a second case of EDC and concurrent PCT in a 30 years old young man, who first presented in our service with two years history of bilateral exophthalmos and progressive asthenia. Thyroid function was normal, excluding Graves disease. He had no polyuria and no other signs of hypopituitarism. The MRI of the orbit showed bilateral retroorbital pseudonodular masses of 3 cm. PET-CT scan was performed to reveal additional retroperitoneal pararenal masses with partial ureteral obstruction, bilateral and symmetric osteosclerosis of the meta – and diaphysis of femur and humerus, cardiac involvement with pericardial effusion and a right thyroid nodule with high metabolic activity. Bone scintigraphy unveiled typical lesions for ECD. Left retroorbital biopsy was performed and histiocytes with frothy cytoplasm were observed. Genetic and IHC testing of retroorbital tissue revealed BRAF V600E mutation. IHC of the histiocytes was positive for CD163 and for Phospho-ERK. EDC with central nervous system, bone, retroperitoneum and cardiac involvement was diagnosed and treatment with BRAF inhibitor vemurafenib was commenced, with rapid improvement of both exophthalmos and retroperitoneal masses at 3 and 6 months of treatment. FNAB for the thyroid nodule was performed that was suspicious of malignancy and followed by total thyroidectomy. Pathology report revealed a right papillary thyroid carcinoma T2N1b, with the presence of high cell component expressing BRAF V600E mutation. Radioiodine therapy was also performed and patient is currently under surveillance with levothyroxine substitution. This case outlines the systemic involvement of EDC and its association with *BRAF*-positive PTC with a view of considering an EDC diagnosis workup in a non-LCH histiocytic lesion with A BRAF(V600E) mutation.

Multiple etiology pericardial effusion in a young woman

Iulia Alexandra Pirga[1] & Marius Lucian Popescu[2]
[1]Filantropia Hospital, Endocrinology, Craiova, Romania; [2]Emergency County Hospital, Cardiology, Craiova, Romania

Context
Severe hypothyroidism and Systemic Lupus Erythematosus can both be causes for the development of pericarditis with concomitant pericardial effusion.
Case illustration
We report the case of a 23 year-old woman admitted in the ER for progressive dyspnoea, increasing fatigue and peripheral edema, associated with hepatosplenomegaly and polyadenopathy. Transthoracic echocardiogram confirmed severe pericardial effusion and an urgent pericardiocentesis and left evacuatory toracocentesis were performed. Pericardial fluid analysis was negative for any malignancy and infection. The patient was referred to an Endocrinology Unit, where she was diagnosed with primary autoimmune myxoedema (TSH = 56 UI/ml N:0.5–4.5; FT4 = < 5.15 pmol/l N:9–19; thyroperoxidase antibody titre = 949.87 mUI/ml N:0–35) and started on oral thyroxine replacement of 75 mg/day, following by a gradual improvement with this treatment. However, two weeks later, she was readmitted to the hospital where the recurrence of pericardial effusion was confirmed. New investigations showed an active systemic lupus erythematosus serology: low complement levels with C3 61 mg/dl (normal range 90–180 mg/dl) and C4 3.43 mg/dl (normal range 10–40 mg/dl), positive anti-nucleosome

antibodies,raised C reactive protein (CRP) 5.9 mg/l (normal range 0–5 mg/l, elevated erythrocyte sedimentation rate (ESR) of 62 mm/h (normal range – 2–12 mm/h. The patient was started on methylprednisolone pulse therapy, then prednisone at 1 mg/kg/day and hydroxychloroquine 200 mg/day for active lupus, with favorable evolution.
Discussion
Autoimmune thyroid diseases can be frequently be associated with SLE. In this case, there is the possibility that both conditions might contributed to the development of pericardial effusion.
DOI: 10.1530/endoabs.73.AEP696

AEP697

Pembrolizumab as definitive treatment for persistence of Graves's disease: a case report
Alexandr Tsiberkin[1] & Olga Kravchuk[2]
[1]Almazov National Medical Research Centre, Institute of Endocrinology, Saint Petersburg, Russian Federation; [2]Private Practice, Saint Petersburg, Russian Federation

Background
The usage of Immune checkpoint inhibitors such as pembrolizumab grows over time due to their positive effect on survival and quality of life in patients with advanced cancer. The frequency of immune-related adverse events (IRAEs) associated with this drugs grows over time accordingly. Several endocrine-IRAEs of pembrolizumab are described in the literature and the thyroid disfunction is the most common.
Case description
A 55 year old man was referred to endocrinologist due to progressive fatique, memory troubles and 15 kg weight gain over past 3 months. His past medical history included a persistence of Graves disease for last 5 years after course of antithyroid drug treatment. Patient refused to undergo surgery or radioiodine treatment, so low dose methimazole was continued. One year ago patient was coincidentally found to have an advanced lung cancer: T4N3M1c, stage IVb. At the time of diagnosis patient was euthyroid on 5 mg of methimazole: TSH, free T4 and free T3 levels were 2.9 mIU/l, 12.8 (9.0–19.1) pmol/l and 5.6 (2.6–5.7) pmol/l respectively. The patient was given pembrolizumab (200 mg every 3 weeks) and was referred to endocrinologist with upper mention complaints when he had just received 11th cycle of pembrolizumab treatment. Thyroid function tests done after referral showed a TSH level of 112 mIU/l, free T4 level of 5.15 (9.0–19.1) pmol/l and free T3 level of 1.64 (2.6–5.7) pmol/l. The methimazole was stopped and replacement therapy with levothyroxine started. Six weeks later the patient reported a significant improvement in well-being. Three months later TSH level was 2.1 and fT4 level was 14.4 (9.0–19.1) pmol/l and current dose of 100 µg levothyroxine was continued.
Conclusion
Pembrolizumab treatment is associated with wide range of thyroid dysfunction which can shift from one form to another. This can misguide diagnosis and treatment process unless there is a high index of suspicion.

Central hypothyroidism under Bexarotene: a significant side effect.
Farah El Hadadi[1], Zineb Mhamdi[2], Laila Benzekri[1] & Karima Senouci[1]
[1]Department of Dermatology, Mohammed V University in Rabat, Ibn Sina University Hospital, Morocco; [2]Department of endocrinology, Mohammed V University in Rabat, Ibn Sina University Hospital, Morocco

Introduction
Retinoids are a class of molecules, structurally related to Vitamin A, used in various disorders of keratinization (acne, psoriasis, ichthyosis, etc.). these molecules bind two families of Retinoid Nuclear Receptors (RNR): the RA receptors (RAR), which natural ligand is retinoic acid, and the Retinoid X Receptors (RXR), which natural ligand is 9-*cis*-retinoic acid. Among synthetic retinoids, isotretinoin, acitretin, tazarotene and adapalene are ligands of the RAR, bexarotene is the first 3rd generation retinoid (ligand of the RXR), known for the treatment of cutaneous T cell lymphomas. It is the only medication that cause central hypothyroidism in 30% of patients.
Case report
A 61-year-old man, with a history of mycosis fungoides cutaneous T-cell lymphoma (T2 N1 M0) treated with different chemotherapy drugs (methotrexate, puvatherapy, INF alpha, Gemcitabine) without any improvement. Due to the several treatments failures, the Bexarotene 75 mg was introduced: 4 capsules per day the first month associated with fenofibrate 200 mg per day after a pre-therapeutic thyroid assessment: TSH = 0.981 u/ml, T3 = 3.28 pg/ml, T4 = 0.98 ng/dl, with a normal level of HDL, LDL, and TG.1 month later the dose of bexarotene was increased to 6 capsules per day. 25 days later we noticed an elevation of lipid parameters with a disruption of the thyroid function HDL = 0.20 g/l, LDL = 1.71 g/l, TG = 1.69 g/l, cholesterol = 2.25 g/l, T3 = 1.79 pg/ml, T4 = 0.70 ng/dl, TSH = 0.023 iu /ml), we decided to stop bexarotene, introduce L-thyroxine 50 µg for 4 days and increase the doses up to 75 µg for 4 days. After one week, the thyroid function was normal.
Discussion
Bexarotene is a 3rd generation synthetic selective retinoid X receptor (RXRc) agonist. Once activated, these receptors regulate cell differentiation and proliferation. Central hypothyroidism and elevated blood lipid levels are the main side effects. The exploration of the pituitary axis by MRI and hormonal assay confirms the integrity of the anterior pituitary gland, concluding in a specific impairment of the Thyrotropic axis by Bexarotene (only thyrotropic cells of the antehypohysis express RXRc). This hypothyroidism is a transient and reversible condition when the treatment is stopped or when L-thyroxine is added. Euthyroidism is usually achieved with an average dose of L thyroxine 1.6 µg/kg/day.
Conclusion
Retinoid-induced central hypothyroidism is a condition that should be known by endocrinologists and dermatologists. Monitoring the thyroid function is essential in patients with substituted central hypothyroidism in order to adjust the dosage of L-thyroxine, once a week the first month, then monthly.

Pembrolizumab induced Thyrotoxicosis in patient with bladder cancer
Francesca Heard[1], Yagoub Abdelgader[2] & Vikram G. Aarella[2]
[1]Nottingham City Hospital, United Kingdom; [2]Pilgrim Hospital, United Kingdom

Background
Pembolizumab is a highly specific, monoclonal antibody directed against the programmed cell death receptor, PD-1 and its ligand PD-L1. It is licenced as an immunotherapy for use in locally advanced or metastatic urothelial cell carcinoma, amongst other malignancies. Whilst rare, endocrinopathies, including thyroid dysfunction, are recognised side effects of immunotherapy such as Pembroluzimab. However, hyperthyroidism is much less common than hypothyroidism. When hyperthyroidism is present, it usually precedes a hypothyroid phase, which was not evident in this case.
Case Presentation
A 68-year old female who had recently received her first cycle of Pembrolizumab for locally advanced transitional cell carcinoma of the bladder presented with diarrhoea, vomiting and weight loss. The patient was clinically hyperthyroid, with tachycardia and goitre present. This was confirmed biochemically with a laboratory thyroid panel: Thyroid Stimulating Hormone (TSH) was 0.04 mU/l (reference range 0.27–4.5 mU/l), free T4 35.3 pmol/l (reference range 11–23 pmol/l) and free T3 6.42 mol/l (reference range 3.1–6.8 pmol/l). Thyroid ultrasound revealed benign nodules within both right and left lobes. The patient's diarrhoea progressed to grade 3 and was managed with steroids. Radiologically there was no evidence of colitis. A euthyroid state was achieved with carbimazole. She made a full recovery and was able to continue with the second cycle of Pembrolizumab as planned.
Conclusion
This case demonstrates an unusual presentation of immunotherapy related thyrotoxicosis in a patient on Pembrolizumab, requiring anti-thyroid therapy. It is important for physicians to be aware of immunotherapy-related endocrinopathies as they can present similarly to other oncological emergencies – in this patient, sepsis or colitis were also suspected. European Society of Medical Oncology (ESMO) recommends regular monitoring of thyroid function tests during immunotherapy. Steroids can be used to relieve symptoms.

Factitious thyrotoxicosis, a diagnostic challenge

José Abuín Fernández[1], Viyey Kishore Doulatram Gamgaram[1], Araceli Pineda Cantero[2], Ignacio Ruíz García[1] & Gabriel Olveira Fuster[1]
[1]Hospital Regional Universitario de Málaga, Endocrinología y Nutrición; [2]Hospital Regional Universitario de Málaga, Medicina Interna, Spain

Introduction
The term factitious thyrotoxicosis is defined as an excess of thyroid hormone in the body caused by the ingestion of exogenous thyroid hormone. It can be intentional, usually in patients with psychiatric disorders, or accidentally. Another possible cause is the inappropriate use of thyroid hormone for the treatment of obesity, depression or infertility.
Case report
We present the case of a 32-year-old woman, with gestational hypothyroidism during her second pregnancy on treatment with Levothyroxine 50 µg and withdrawal of the treatment. She came to the clinic 2 years later, referring tachycardia, loss of 30 kg in the last 3 months, no fever or compressive symptoms. In laboratory tests she presented TSH 0.01 µIU/ml, FT4 57.67 pmol/l, T3L 14.1 pmol/l. Treatment with antithyroid drugs (Carbimazol 5 mg, 5 tablets a day) was started and a thyroid scintigraphy was requested. At the review appointment these were the blood test results: TSH <0.01 µIU/ml, FT4 97.39 pmol/l, FT3 18.1 pmol/l, TPO antibodies (TPOAb) 525.1 IU/ml, TSH receptor antibodies (TRAb) <0.8 IU/l. Thyroid scintigraphy showed absence of uptake. Due to the absence of improvement and the clinical repercussion of the patient, she was admitted to hospital for study and treatment. During admission, the patient remained in sinus rhythm with a heart rate between 60 and 100 bpm. Laboratory tests showed Thyroglobulin 1.68 ng/ml, Thyroglobulin antibodies (TgAb) <20 IU/ml. Whole body scintigraphy showed absence of thyroid uptake (ruling out struma ovarii), thyroid ultrasound with normal glandular size with heterogeneous echogenicity and no nodules. Serial analyzes were performed throughout one morning showing significant fluctuations in FT4 levels: 57.67 pmol/l – 76.98 pmol/l – 79.39 pmol/l – 80.55 pmol/l. The main suspicion was factitious thyrotoxicosis due to the coexistence of a high concentration of FT4 without thyroglobulin increase and the absence of uptake on scintigraphy. The patient did not admit the surreptitious taking of Levothyroxine and requested voluntary discharge. At discharge she was indicated treatment with cholestyramine and she was referred to a Mental Health consultation. The patient has not returned to our consultations.
Conclusion
In order to diagnose factitious thyrotoxicosis, a differential diagnosis must be made between several diseases that present with low iodine uptake on scintigraphy, such as subacute thyroiditis, iodine-induced hyperthyroidism, struma ovarii, and differentiated thyroid cancer metastases.

Grave's disease in a patient with thyroid hemiagenesis

Eleanor Jane Pang[1], Aminath Aifa Aboobakuru1, Sardar Muhammad Shoaib Khan1 & Niels Larsen[2]
[1]King's Mill Hospital Sherwood Forest Hospitals NHS Foundation Trust, United Kingdom; [2]Royal Derby Hospital, University Hospitals of Derby and Burton

Introduction
We present the case of a 50-year-old lady who was referred to the endocrine clinic with a clinical and biochemical picture suggestive of severe thyrotoxicosis. CT scan of thorax, abdomen and pelvis (CT TAP) was performed to rule out malignancy, which showed left lobe agenesis.
Case
50-year-old lady presented to the GP with hyperhidrosis and unintentional weight loss. She also reported symptoms of lethargy, increased bowel frequency, tinnitus, periorbital oedema, cold insensitivity, oligomenorrhoea, palpitations, essential tremor and irritability. She had a background of asthma and depression with a maternal history of hypothyroidism. Initial TFTs showed severe thyrotoxicosis which was sustained when repeated 6 weeks later in the endocrine clinic. Thyroid peroxidase antibodies and TSH receptor antibodies were positive which confirmed the diagnosis of Grave's disease. CT TAP was arranged through primary care to rule out malignancy and incidentally showed a missing left lobe of the thyroid but intact isthmus and right lobe. There was no previous history of thyroidectomy so a diagnosis of thyroid hemiagenesis (THA) was made. The patient was treated with carbimazole with a good response and this is being titrated based on her 6 weekly TFTs.
Discussion
THA is a rare, congenital developmental disorder of the thyroid gland, characterised by the absence of one thyroid lobe. The exact aetiology is unknown but there are several theories based on embryological descent and lobulation, development of blood vessels, and genetic factors. The majority of cases have an absent left lobe. Absence of one lobe of the thyroid usually has no clinical significance and patients are usually biochemically euthyroid and asymptomatic. However, reports have shown that patients with THA are more likely to develop thyroid disorders with hyperthyroidism being the most common clinical presentation. Patients with THA are generally asymptomatic and diagnosis is often incidentally made on routine clinical examinations or imaging modalities. There is also a 7:1 female to male ratio of THA which indicates a possible gender association. Our case is a typical presentation of THA as we had a female patient with a missing left lobe with features of thyrotoxicosis. The aim of treatment in THA is to correct any thyroid hormone imbalance; medically or surgically, manage symptoms and prevent recurrence.

Management of Graves's disease during pregnancy in Covid-19 pandemic conditions - case presentation

Mervat Hassan, Ioana Golu & Mihaela Vlad
"Victor Babeş " University of Medicine and Pharmacy, Discipline of Endocrinology, Timisoara, Romania

Introduction
The global pandemic caused by the SarsCov2 virus has brought great challenges to the medical system, the management of some cases, especially for those belonging to risk categories, such as pregnant women, being often difficult in this context. Telemedicine has been used frequently during this period, facilitating reducing patient's risk for exposure to COVID-19, providing continuous support, and coordinating the necessary services to prevent acute care necessity, or in our case mother/child short-term/long-term complications.
Objective
Presenting the management during the pandemic, of a case with Graves' disease in pregnancy, using telemedicine.
Case-presentation
A 27-year-old female patient, known with Graves' disease, previously treated with Methimazole (MMI), discontinued on her own decision, addresses to our clinic on 31.03.2020, following an obstetrical consultation (on 26.03.2020) which confirmed that she was 7 weeks pregnant. The hospital to which our clinic belongs, treats patients with Covid19, so we preferred to avoid the patient's exposure, thus management was assessed through telemedicine. We recommended her to perform thyroid functional and immunological tests (FT4, FT3, TRAb) complete blood count and liver function tests, the results confirming Graves' hyperthyroidism. Antithyroid drugs (ATD) therapy was restarted (Propylthiouracil 50 mg, 3 × 1/day), subsequently periodically monitoring the biological parameters, as well as clinical parameters, weight as well as blood pressure and heart rate. She did not require ß-blockers therapy. Entering the second trimester, PTU was replaced with MMI, starting with a dose of 7.5 mg/day, followed by dose adjustment as the pregnancy progressed.
Results:
It was possible to obtain a favorable evolution of the thyroid functional parameters and the decrease of the necessary ATD dose to a minimum required level. Pregnancy ended successfully. At 39 weeks of gestation, she gave birth, by caesarean section, to a healthy female newborn, weighing 3290 grams, Apgar score 9; with favourable postpartum evolution for both mother and newborn. The newborn was screened for thyroid dysfunction after birth and both, functional and immunological thyroid tests, were normal. The patient continued postpartum, after breastfeeding, with MMI therapy 2.5 mg daily, thyroid functional parameters being within normal range.
Conclusions
The SarsCov2 pandemic imposed the consultation and management of several patients by using telemedicine, to avoid the risk of viral exposure. Once established the diagnosis, the adjustment of ATD for Graves' disease during pregnancy was possible using telemedicine. In this case we succeed to manage it even during these difficult conditions, with favorable results so far, both for mother and child.

Collision tumor of the thyroid: follicular thyroid carcinoma plus metastatic renal cell carcinoma

Cristina Elías Ortega[1], Inmaculada Venegas Nebreda[1], Maria Teresa Aramburu Calafell[1], Nerea Egaña Zunzunegui[1], Ismene Bilbao Garay[1], Cristina Garcia Delgado[1], Pablo Aguirre Echevarria[2], Jorge Rojo Alvaro[1], Alfredo Yoldi Arrieta[1] & Miguel Maria Goena Iglesias[1]
[1]Paseo Doctor Begiristain, Endocrinology, San Sebastián, Spain; [2]Paseo Doctor Begiristain, Pathology, San Sebastián, Spain

Introduction
The term collision tumor refers to the coexistence of two histologically distinct malignant neoplasms. The two malignancies can originate from the same organ or occur as metastases from other regions. This type of tumors involving the thyroid gland are especially rare. Reported cases are usually involving papillary thyroid carcinomas in coexistence with other types of tumors like medullary carcinoma, follicular carcinoma or metastasic disease. Metastasic disease to the thyroid is uncommon but can develop after long-disease free intervals. Among the carcinomas metastasizing to the thyroid, renal cell carcinoma is one of the most frequent.
Case report
A 68-year-old man was referred to endocrinology due to a hyper metabolic focus in the upper pole of the thyroid lobe (Suv 3.7). He has a history of 6,5 cm clear cell renal carcinoma with sarcomatous pattern. Right laparoscopic radical nephrectomy was performed six years ago. On physical examination, a soft multinodular goiter was palpable at the expense of the right thyroid lobe, and nodules were not delimited. The thyroid profile was in the normal range. A thyroid ultrasonography showed a 14 mm hypoechoic nodular image in the right thyroid lobe, not well defined, without increased vascularity. In addition a solid, hypoechoic nodule with irregular borders and an anteroposterior diameter of 11 mm was observed in the left thyroid lobe. USG-guided fine needle aspiration of the right thyroid lobe nodule was requested, which corresponded to the uptake observed on PET-CT. A pathology compatible with Bethesda II was obtained. Follow-up was carried out with laboratory tests and ultrasonography. In the control thyroid ultrasonography, a suspicious nodule with a greater craniocaudal diameter than anteroposterior and central and peripheral vascularization of 11 × 11 × 9 mm was observed in the upper pole of the right thyroid lobe. USG-guided fine needle aspiration was performed on said nodule, which was compatible with Bethesda III. Therefore, a total thyroidectomy was performed. Histologically, the thyroidectomy specimen revealed a 1.2 × 0.9 × 0.5 cm follicular thyroid carcinoma in the left thyroid lobe, as well as metastasis due to clear cell renal carcinoma in the right thyroid lobe.
Conclusion
This case report emphasizes that for any patient with a known history of malignant carcinoma, metastatic disease should be considered if new suspicious thyroid nodules appear. The role of pathological anatomy is important in the identification of collision tumors.

Anxiety is more common than depression in indian subjects with recently diagnosed mild subclinical hypothyroidism

Vipan Talwa & Gourav Talwar
Golden Hospital, Endocrinology, Jalandhar, India

Background
With the availability of sensitive and accurate TSH assays, the entity of Mild Subclinical hypothyroidism (SCH) is being diagnosed more frequently in clinical practice. A variety of neuropsychiatric and cognitive complications have been noted in hypothyroid patients but there is a dearth of literature on the psychopathology associated with mild SCH.
Objective-
This study was undertaken to determine the prevalence of depression, anxiety in Indian subjects with recently diagnosed mild SCH.
Methods
Participants were 112 subjects recently diagnosed with mild SCH and a similar number of age matched euthyroid controls. Mild SCH was defined as serum TSH level more than 4.0 mIU/l but less than 10 mIU/l with normal FT3 and FT4. All participants underwent clinical and anthropometric evaluation along with relevant investigations. The patients were administered the Hamilton Rating Scale for Depression (HAM-D) and Hamilton Rating Scale (HAM-A) for Anxiety. The data was analysed statistically using SPSS software.
Results
Females constituted 65% of the sample. The mean age of patient group was 47.4 ± 8.9 years and BMI 26.7± 5.6 kg/m^2 which were comparable to controls. Mean TSH value was 7.1 ± 2.7 mIU/l in patients and 2.4 ± 1.3 mIU/l in controls (*P*–0.001). Among all the participants, based on HAM-D, some degree of depression was present in 17.8% of patients (males- 15.6% and females- 19.2%) and 8.9% of controls (*P*–0.03), whereas based on HAM-A, some degree of anxiety was present in 43.7% of patients (males-35.6% and females-49.7%) and 11.6% of controls (*P*–0.012). Prevalence of anxiety or depression was not affected by age, BMI and TPO antibody level.
Discussion-
Mild SCH is a unique entity often considered separate from hypothyroidism and higher degrees of SCH in respect to clinical implications and treatment criteria. In this study we found anxiety and depression to be more prevalent in subjects with mild SCH compared to the euthyroid subjects. Among the subjects with mild SCH, anxiety was more common than depression (*P*–0.001). These findings suggest that the cognitive aspects in mild SCH subjects are different from the patients with frank hypothyroidism and higher degree of SCH, who are reported to be having higher prevalence of depression along with a spectrum of other emotional and cognitive problems. Mood changes especially anxiety in mild SCH may have an important impact on the patient's quality of life. Further studies in larger populations are needed to validate these findings.

Graves' disease and isolated langerhans cell histiocytosis, a rare case presentation

Yusuf Emre Uzun[1], Ersan Eroglu[2], Omur Kayikci[3], Ilker Ersozlu[4] & Esra Suheda Hatipoglu[5]
[1]Memorial Bahçelievler Hastanesi, Internal Medicine, Istanbul, Turkey; [2]Memorial Bahçelievler Hastanesi, general surgery, Turkey; [3]Memorial Bahçelievler Hastanesi, hematology, Turkey; [4]American Hospital, pathology, Turkey; [5]Başakşehir Çam ve Sakura Şehir Hastanesi, endocrinology and metabolism, Turkey

Introduction
Langerhans cell histiocytosis (LCH) is a rare monoclonal disease characterized by abnormal proliferation and accumulation of bone marrow-derived Langerhans cells in various tissues. Heterogeneous collections of Langerhans cells with neutrophils, lymphocytes, eosinophils, histiocytes and Birbeck granules are observed in biopsy materials. Endocrinologic features of LCH are usually due to posterior pituitary involvement. Thyroid infiltration is rare and LCH confined only to thyroid gland is even a rarer condition. Here in we present a care with isolated thyroid LCH presenting with Graves' disease. (GD)
Case Presentation
A 41-year-old, 21 weeks pregnant, patient was referred to the endocrinology clinic because of hyperthyroidism. She had been followed up with the diagnosis of GD for 3 years and received methimazole treatment. With pregnancy her treatment was switched to PTU in the first trimestr Her test results were as follows TRAb 2.55 (<1.75 U/l), TSH 0.017 (0.27–4.20 mIU/l); FT3: 5.23 (2–4.4 pg/ml); FT4: 1.96 (0.93–1.70 ng/dl). Ultrasound showed diffused hypoechogenicity and enlargement in both sides of thyroid. A 12×11 mm hypoechoic nodule on the right and a 11*7.6 mm hypoechoic nodule on the left were detected. Upon completion of her pregnancy total thyroidectomy was performed due to on going GD. Pathologic examination revealed langerhans cell histiocytes which were positive for Langerin, S-100, CD1a in immunohistochemical staining. There was concomitant diffuse hyperplasia of the thyroid gland. With all these result was consisted with LCH and GD of the thyroid gland. Bone marrow aspiration biopsy, contrasted cranial MRI and PET-CT ruled out multisystemic involvement of LCH. After thyroidectomy she is followed with LT4 treatment. No additional systemic treatment was required due to local involvement of LCH. Her medical condition is stable under thyroid hormone replacement therapy.
Discussion
Thyroid involvement of LCH is a rare condition and of those with thyroid involvement only 1.5% present with subclinical hyperthyroidism.(1). Number of cases with LCH related with GD has been rarely reported in literature. Here in we report a case with isolated thyroid LCH who first presented with GD. We speculate that immunologic changes due to LCH may trigger autoimmunity which subsequently may cause GD.

Awareness of EUGOGO guidelines and attitudes regarding smoking in Graves' orbithopathy in Croatia

Maja Baretić[1;2], Jelena Juri Mandić[2;3], Sanja Kusačić Kuna[2;4], Lara Gudelj[2], Marija Radić[2], & Mirna Zlatar[5]
[1]University Hospital Centre Zagreb, Department of Endocrinology and Diabetes, Zagreb, Croatia; [2]School of Medicine, University of Zagreb; [3]University Hospital Centre Zagreb, Department of Ophthalmology, Zagreb, Croatia; [4]University Hospital Centre Zagreb, Department of Nuclear Medicine and Radiation Protection, Zagreb, Croatia; [5]General Hospital Virovitica, Department of Ophthalmology, Virovitica, Croatia

Background
In 2008 EUGOGO (European group on Graves' orbitopathy) published consensus statement on the management of Graves' orbitopathy (GO) that was widespread ever since. Having in mind unknown general perception and practical usage of the statement amongst Croatian clinicians, we conducted a survey evaluating the awareness and practical usage of the EUGOGO guidelines among physicians treating Graves' disease in daily practice. Also, the idea was to explore their attitude towards importance of smoking as a risk factor for GO.
Participants and methods
An internet based, anonymous online survey was conducted among 40 ophthalmologist, 36 endocrinologists and 24 nuclear medicine specialists, members of Croatian national societies. Median age of participants was 51.15 yrs., 68% were females. From 100 participants 46% worked at Clinical Hospitals, 28% at County Hospitals and 27% at Outpatient Clinics. Two questions we concentrated on were: "Do you use EUGOGO guidelines in daily practice for diagnosis and treatment of GO?" and "Do you know which factors according to EUGOGO guidelines are associated with progression and outcome of the treatment in GO?"
Results
Results of the survey showed that 26% of the participants are not using EUGOGO guidelines; 22.5% of all ophthalmologist (9 of 40 participants), 27.8% of all endocrinologists (10 of 36 participants) and 29.2% nuclear medicine specialists (7 of 24 participants). Even 30% of all participants did not recognize smoking as risk factors determining the outcome of the disease; 37.5% of all ophthalmologist (15 of 40 participants), 16.7% of all endocrinologists (6 of 36 participants) and 37.5% nuclear medicine specialists (9 of 24 participants).
conclusion
EUGOGO guidelines were made with the aim to provide proper diagnosis and treatment for patients with GO; a third of Croatian clinicians involved in treatment of the disease still do not use it. Similar percentage of them were not aware of the clear causal association between smoking and development of GO. There is unambiguous recommendation in the EUGOGO statement for the physicians to urge all patients with Graves' disease, irrespective of the presence or absence of the GO, to refrain from smoking. Following the guidelines represents best clinical practice for the physicians treating GO. Smoking, the strongest risk factor of the progression of the GO, is easy to modify.

Genetic investigation of thyroid dyshormonogenesis in a Tunisian consanguineous family

Wajdi Safi[1], Faten Hadj Kacem[1], Hana Charfi[1], Mouna Mnif Feki[1], Mohamed Abid[1] & Noura Bougacha-Elleuch[2]
[1]Hedi Chaker Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Faculty of Sciences of Sfax, TUNISIA, Laboratory of Molecular and Functional Genetics, Sfax, Tunisia

We aimed to identify causal mutation(s) in 2 patients (P1 and P2) with thyroid dyshormonogenesis (TD) from a consanguineous Tunisian family. Patient P1 developed TD at age 10; while P2 developed it at a late age (30 years) with no goiter. Scintigraphy showed homogeneous uptake of ^{131}I in P1 patient. Genetic analysis was performed using candidate gene approach. Thus, sequencing of the 17 exons of the *TPO* gene revealed only presence of rs4927611 polymorphism (Ala257Ser) at the homozygous state in P1 and P2. Structural modeling of the rs4927611 polymorphism showed that it is rather lying in the entrance of the active site of TPO enzyme. The presence of a hydrophilic residue (Ser) instead of a hydrophobic one (Ala) might influence the substrate selection. Segregation analysis of this polymorphism showed that it was also present in unaffected family members, excluding involvement of *TPO* gene in TD in this family. In a second step, and in order to target responsible gene, we have performed perchlorate test in patient P1. The test result ruled out any form of defect in iodine organization, and rather suggested a possible defect in iodine transport. We then moved to sequencing of coding region (15exons) and the 5ŕand 3ŕUTR of *NIS* gene. No causal mutation was reported in P1 patient. However, we have identified rs7250061 polymorphism (c.699–75C> T) in intron 5 (MAF = the frequency of the minor allele T = 0.1113). ESEfinder program showed that this substitution creates a new splicing enhancer sequence "CAGAAGT" which is recognized by the splicing factor SRSF1 / SRSF1 (IgM-BRCA1) with a score of 3.46589 and 2.87763 respectively therefore significantly higher than the threshold values of 1.956 and 1.867 respectively. MFOLD program showed that the c.699–75C> T substitution has no marked effect on the RNA structure, excluding thus NIS gene in this family.
Search for causing TD gene will be performed using exhaustive approach (genome scan, exome analysis...) since informativeness of the studied family. Such gene identification may help to develop a genetic screening protocol for congenital hypothyroidism in Tunisia.

Surgical treatment of Graves' disease in children and adolescents

Mohamed Masmoudi, Regaig Marwa, Thabet Wadii, Mehdi Hasnaoui & Mighri Khalifa
Tahar Sfar Hospital Mahdia, ENT Department, Mahdia, Tunisia

Introduction
Graves' disease is the most common cause of hyperthyroidism in children and adolescents. Treatment strategy includes antithyroid drugs, radioactive iodine and thyroidectomy. The optimal treatment of Graves´ disease is still controversial. Our aim is to describe the surgical treatment of Graves's disease in children and adolescents.
Material and methods
We report the clinical, therapeutic aspects and long-term results of 9 patients (< = 18 years old) operated for Graves' disease, from 2000 to 2016.
Results
We identified 9 patients with mean age at diagnosis of 15.8 years [9 years – 18 years]. Our study included 3 boys and 6 girls. One patient had coeliac disease. Indications for surgery were: failed medical therapy after 2 years of treatment (5 cases) and presence of a compressive goiter (4 cases). Total thyroidectomy was performed in all cases. The postoperative course was complicated by transient hypocalcemia in one case. After an average follow-up of 5 years, all patients had control of the disease manifestations with biological euthyroidism.
Conclusion
Total thyroidectomy for Graves' disease offers rapid and durable control of hyperthyroidism. Surgery seems to be the appropriate treatment for children and adolescents.

Antithyroid drugs as treatment of neutropenia in hyperthyroidism

Sawsen Essayeh[1], Manel Jemel[2], Hiba Chatti[1], Wiem Madhi[1], Radhouane Gharbi[2], Hajer Kandara[2] & Ines Kammoun[2]
[1]National Institute of Nutrition and Food Technology, Department of Endocrinology, Tunis, Tunisia; [2]National Institute of Nutrition and Food Technology El Manar University, Department of Endocrinology, Tunis, Tunisia

Introduction
Hematological abnormalities are frequently observed in hyperthyroidism and are part of complex, multifactorial pathogenetic mechanisms that are still poorly understood, which can affect the three hematopoietic lineages in isolation or in combination. For the endocrinologist, they raise the issue of the risk of their aggravation under the hamatotoxic effect of antithyroid drugs (ATDs).
Case presentation
A 28-year-old man, with no particular past medical history, presented palpitations with irritability and weight loss. Hormonal tests revealed hyperthyroidism: free thyroxine (FT4) =38 pmol/l (reference: 8.6–25

pmol/l) and thyroid stimulating-hormone (TSH) < 0.005 μUI/ml (reference: 0.4–4 μUI/ml). The physical examination didn't find a goiter or eye signs. TSH receptor autoantibodies were positive at 12,6 UI/l (reference: <1 UI/l). Therefore, the diagnosis of Graves 'disease was made. The complete blood count (CBC) showed a neutropenia with polynuclear neutrophils (PNN) = 800/mm^3 controlled at 850/mm^3. After obtaining the consent of the patient, a treatment with ATDs was started and the CBC after five days of treatment showed PNN at 1080/mm^3 and 1200/mm^3 after 12 days. The ATDs were maintained and the PNN were 2300/mm^3 after euthyroidism.

Conclusion

The threshold of neutropenia contraindicating the prescription of ATDs could well be lowered with vigilance and warning of the patient. Some authors speak of the physiological phenomenon of margination of white blood cells falsely underestimating the count of the lineage, a situation worsened by hyperthyroidism but bot contraindicating the introduction of ATD.

Thyroglobulin and thyroglobulin antibody measurements in the follow-up of differentiated thyroid cancer: practical implications for laboratories illustrated by means of a new highly sensitive thyroglobulin assay

Lise Schoonen[1], Marjolein Neele[1], Hans van Toor[2], Caroline van Kinschot[3,4], Charlotte van Noord[3], Edward Visser[4], Sjoerd van den Berg[2] & Snježana Kos[1]

[1]Maasstad Hospital, Department of Clinical Chemistry, Rotterdam, Netherlands; [2]Erasmus Medical Center, Department of Clinical Chemistry, Rotterdam, Netherlands; [3]Maasstad Hospital, Department of Internal Medicine, Rotterdam, Netherlands; [4]Erasmus Medical Center, Department of Internal Medicine, Academic Center for Thyroid Diseases, Rotterdam, Netherlands

Introduction

Measurements of thyroglobulin (Tg) and Tg antibodies play a crucial role in the follow-up of treated differentiated thyroid cancer (DTC) patients, for instance to determine the response to therapy and the use of additional investigations and therapies. The aim of this study was to explore, from a laboratory perspective, the practical implications of the substantial clinical role of these measurements being imposed by national and international guidelines.[1–3]

Methods

The newly released DiaSorin LIAISON Tg II assay and the corresponding Tg antibody assay, as well as the established BRAHMS Kryptor hTg and anti-Tgn assays, BRAHMS DYNOtest Tg-pluS IRMA assay, Roche Cobas Elecsys Tg II and anti-Tg assays and Phadia EliA anti-Tg assay, were evaluated and compared in the light of the recommended cut-off values indicated in the relevant guidelines. Additionally, storage stability of the markers was evaluated using different assays, as this is an underexposed aspect in the evaluation of Tg and Tg antibody assays that may have a significant impact on both the daily clinical use of the assays and the use of the assays in clinical studies.

Results

The Tg assays showed a maximum difference of a factor two. Between the different types of Tg antibody assays, a bad correlation was generally observed. In almost all method comparisons, disconcordant results were found looking at the appropriate cut-off values. Additionally, unique data was obtained regarding the storage stability of Tg and Tg antibodies using the assays described in this study.

Conclusion

Tg and Tg antibody assay differences could potentially have a significant clinical impact on the follow-up of DTC patients. Both clinicians and laboratory professionals should be aware of this and should use these measurements accordingly. This study is an example of how unavoidable, inherent assay differences of endocrinological markers complicate use of fixed cut-offs in the guidelines.

Follicular epithelial dysplasia of the thyroid gland on the background of Hashimoto Thyroiditis

Tamuna Gvianishvili & Liana Gogiashvili

Ivane Javakhishvili Tbilisi State University, Alexandre Natishvili Institute of Morphology, Clinical and Experimental Pathology, Tbilisi, Georgia

Morphologically, the follicular cells of the thyroid gland on the background of chronic lymphocytic (Hashimoto) thyroiditis may exhibit atypical changes in the nucleus, expansion of the nucleus, crowding, irregularities of nuclear membranes, intranuclear grooves and purification of chromatin. Also be observed proliferative foci of thyroid follicular cells with follicular epithelial dysplasia (FED) were as presumed premalignant conditions in chronic lymphocytic thyroiditis. These foci with Hashimoto Thyroiditis (HT), which differ from the surrounding parenchyma, are less than 0.1 cm in size, do not have invasive growth, the structure of the papillary thyroid gland or intranuclear pseudo inclusions were considered as presumed premalignant conditions in chronic lymphocytic thyroiditis. Also, FED foci exhibit an immunohistochemical (IHC) profile similar to papillary thyroid carcinoma (PTC). Observation was carried out on operative materials. A total 59 cases (37 patients with HT and 22 patients with PTC in HT background). Paraffin embeded and Hematoxylin and Eosin stained samples were used for histopathological examination. IHC staining was performed on Formalin-fixed paraffin embedded tissue sections with antibodies against the following markers: 1. Thyroid transcription factor 1 (TTF1); 2. CD56; 3. p63. As control - histochemical panel: 1. CK19, 2. Cyclin-D1, 3. Galectin-3. With the results obtained, the main histopathological discovery in HT was the atrophy of the thyroid parenchyma, accompanied by lymphoid infiltration, lymphoid follicular hyperplasia, the formation of a secondary germinal center and an abundance of macrophages and plasma cells. Foci of thyroid follicular cells with atypical nuclear features (dysplastic foci) were also seen. In cases of HT without associated PTC, immunoreactivity from moderate to severe p63 was found throughout the thyroid parenchyma, including thyroid follicles, as well as squamoid regions, which is consistent with solid nest cells. In our study, Similar pattern of CD56 and p63 immunoreactivities was observed in foci of PTC arising in the background of HT - strong diffuse staining of Galectin-3 (40%), Cyclin-D1 (70%). Particularly noteworthy is the negative response to CD56 immunostaining in the HT regions of the dysplastic epithelium (FED): Thyroid nuclei showed atypical signs, but versus lymphocytic thyroiditis (40%), they did not have a set of PTC nuclear markers (26%). We can conclude, that the panel of these immunomarkers can potentially be used as a diagnostic tool to differentiate these two forms of thyroiditis, as well as to predict the risk of developing PTC, especially during preoperative evaluation in small diagnostic tissue samples.

Covid 19 associated with diabetes mellitus tip 2 and hyperthyroidism in one doctor patient

Anila Rrupulli[1] & Viktoria Xega[2]

[1]Elbasan, hospital, Elbasan, Albania; [2]The Research Institute of McGill University Health Centre, Montréal, Canada

SARS-CoV2 can induce multiple immunological and endocrinological changes. Diabetes and thyroid disorders tend to coexist in patients. Both conditions involve a dysfunction of the endocrine system. Thyroid disorders can have a major impact on glucose control. On one hand, thyroid hormones contribute to the regulation of carbohydrate metabolism and pancreatic function, and on the other hand, diabetes affects thyroid function tests to variable extents. SARS-CoV-2 uses ACE2 receptor combined with the TMPRSS2 as the key molecular complex to infect the host cells. Interestingly, ACE2 and TMPRSS2 expression levels are high in the thyroid gland and more than in the lungs. Physiological concentrations T4 and T3 stimulate the production and release of cytokines, which are also components of "cytokine storm" potentially characterizing systemic viral infections. COVID-19 might also predispose infected individuals to hyperglycemia. In November 2020, a 55 years old chirurg doctor presented the symptoms headache and tachycardia, dyspena, polyuria and polydisia,temperature of 39.0.He had 3 days with this symptoms.Before, he has no history of diabetis mellitus tip 2 or hyperthyrosis. The initial ECG showed a sinus tachycardia with a frequency of up to 120 beats per minute. Laboratory results revealed elevated thyroid hormone levels fT3 6.9 pg/ml; [2.0–4.4]; fT4 26 pg/ml; [9–17) as well as a supressed TSH (0.01 μU/ml; [0.27–4.20]). As thyroid autoantibodies (antithyroid peroxidase (TPO) antibody, anti-thyroglobulin (Tg) antibody and thyroid-stimulating

hormone receptor (TSHR) antibody) were negative and thyroid ultrasound was normal. Glycemia 400 mg/dl.HbA1C 5.0%,PCR 10,eritrosedimention rate 30,lymphopenia 1.06G/l.Ct scan of chest pozitiv for COVID 19.The patients was treated with anticovid treatment,no oxygen therapy, amaryl 2 mg 1 tb in the morning and vitagliptin 50 mg 1 tb in dark,unimazol 5 mg 2 tb in morning 2 tb in the dark.After 5 days we had a good improvement of glycemia,tachycardia and dyspnea.The patient was clinically better.After 1 month the patients was stabilized of Covid 19 and had good profile of glycemic control but he had supressed TSH 0.07.The antidiabetic oral and antithyroidien therapy is continued.We assume SARS-CoV-2 infection can induce a destruction of thyroid issue. All patients with COVID-19 should be monitored regarding endocrinological changes, especially diabetes, but also TSH, fT3, fT4 should be assessed. Hyperthyroidism may mimic clinical features of COVID-19 like fever, tachycardia, and diarrhoea. Thyroid dysfunction may be due to coincident primary thyroid disease, but also viral affection of the thyroid should be taken into account.

A male patient with subacute thyroiditis after COVID-19 infection

Carolina Chaves[1], Carolina Vidal[2] & João Anselmo[1]
[1]Hospital Divino Espirito Santo, Division of Endocrinology and Nutrition, Ponta Delgada, Azores, Portugal; [2]Hospital Divino Espirito Santo, Division of Palliative Care, Ponta Delgada, Azores, Portugal

Introduction
Subacute thyroiditis is a rare cause of thyrotoxicosis arising in the context or following viral infections. This disorder is more frequent in women than in men (male/female ratio of 1:4). In addition to respiratory symptoms, the SARS-CoV-2 infection (COVID-19) has been associated with extrapulmonary manifestations. Herein we report a male patient with hyperthyroid symptoms starting four-week after a positive test for COVID-19.
Case presentation
We present the clinical case of a 63-years-old caucasian man, with a past medical history of obesity, hypertension, and a recent COVID19 infection. He started complaining of neck discomfort together with anorexia, fatigue, palpitations and, heat intolerance, four weeks after a positive RT-PCR nasopharyngeal swab for SARS-CoV-2. He remained asymptomatic the 2 weeks after the positive test and was discharged from the COVID19 surveillance program. When first seen by one of us, he was anxious, tachycardic (108 beats/min), presenting a fine tremor of both hands and a discrete bilateral eyelid retraction. He had lost 8 Kg during the previous two weeks. His thyroid was slightly tender. The patient denied a past medical history of thyroid disorders. Blood tests revealed a high C-Reactive Protein (CRP) 5.65 mg/dl (<0.5); TSH 0.007 mIU/l (0.7–4.20); FT4 2.81 ng/dl (0.70–1.48); FT3 7.41 pg/ml (1.58–3.91); TPO ab 137.7UI/ml (0–60); Thyroglobulin of 127 ng/ml (<10). TRAB <1.10. Hemoglobin was 11.2 g/dl and white blood cells count of $10.2x10^6$ (59.4% neutrophils). Serum titers of IgG anti SARS-CoV-2 was 100.0 U/ml (<12) and IgM 2.74 U/ml (<1.1). Thyroid ultrasounds showed a heterogeneous gland of normal size with areas of low echogenicity and decreased tissue vascularity in Color Doppler evaluation. He was started on prednisone 40 mg/day PO. One week later blood test revealed FT4 2.03 ng/dl; FT3 3.95 pg/ml and TSH 0.01. Prednisone was reduced to 20 mg/day. One more week and CRP was 0.750, TSH 0.01 mIU/l with normal FT4 and FT3. Prednisone was taper. Two weeks later, he reported complete resolution of the symptoms. At this time, blood tests showed an increase in TSH indicating a clear biphasic evolution of thyroid function.
Conclusion
Subacute thyroiditis can be triggered by the new coronavirus (SARS-CoV-2) in a similar way to other viral infections. Therefore, clinicians must be aware of the possibility of thyroid dysfunction after COVID-19 infection. Early recognition and timely steroid treatment may successfully improve the outcome of the disorder, preventing permanent hypothyroidism.

Thyroid disease in insulin- treated type 2 diabetes mellitus

Rahma Khalaf, Zohra Hadj Ali, Yosra Htira & Faika Ben Mami
National Institute of Nutrition, c, Tunis, Tunisia

Background and aim
Abundant evidence suggests an association between thyroid disease and type 2 diabetes mellitus (T2DM). To determine the interaction between these co-existing pathologies, we analyzed insulin-treated type 2 diabetes patients with diagnosed thyroid disease.
Patients and methods
This retrospective study was performed in 54 type 2 diabetes patients who had been admitted for insulin-treatment and diagnosed thyroid disease. Patients were divided into two groups: Group 1(G1) thyroid disease diagnosed after diabetes onset and group 2 (G2) thyroid disease diagnosed prior to diabetes onset.
Results
Among the 54 patients studied, 75.92% of participants were females and 25.92% had family history of thyroid disease. Sub-clinical hypothyroidism constituted 44.44% of the thyroid dysfunction in the T2DM patients, clinical hypothyroidism was 25.94% and hyperthyroidism was 29.62%. Thyroid disease was predominantly diagnosed after diabetes onset (G1: n = 42, 77.77%): Hypothyroidism was predominantly diagnosed after T2DM onset while hyperthyroidism was predominantly diagnosed prior to diabetes onset. BMI and HbA1c did not statistically differ among the two groups (30.47 kg/m^2 vs 29.22 kg/m^2, 11.21% vs 11.16% respectively). G2 patients were older at diabetes onset (53.33 years vs 44.21 years, $P = 0.01$) and were younger at thyroid disease onset than G1 patients (48.91 years vs 52 years, $P = 0.38$). Patients with type 2 diabetes and prior appearance of thyroid disease(G2) required insulin therapy significantly earlier with median insulin-free period of 4 years compared to patients who had thyroid dysfunction after diabetes onset(G1) with median insulin-free period of 8.07 years, P =0.01 Group 1 patients (thyroid after diabetes) developed thyroid disease on average only after the initiation of insulin treatment. However, a clear negative correlation was observed between age at diabetes onset and insulin-free period ($r = -0.3$, $P = 0.05$). The older the patient the sooner insulin treatment was started.
Conclusion
Patients with thyroid disease prior to T2DM required significantly earlier insulin therapy compared to patients without thyroid diseases at the time of diabetes onset. Further studies are needed to elucidate mechanisms of interaction of thyroid disease in type 2 diabetes patients.

Voluminous primary mediastinal multinodular goiter as a rare cause of hyperthyroidism.

Asma Kardi[1], Ibtissem Oueslati[1], Fatma Chaker[1], Nadia Znaidi[2], Mohamed Sadok Boudaya[3], Meriem Yazidi[1] & Melika Chihaoui[1]
[1]La Rabta Hospital, University of Tunis El Manar, Faculty of medicine, Endocrinology, Tunis, Tunisia; [2]Charles Nicolle Hospital, University of Tunis El Manar, Faculty of Medicine, Pathology, Tunis, Tunisia; [3]Charles Nicolle Hospital, University of Tunis El Manar, Faculty of medicine, Surgery, Tunis, Tunisia

Introduction
Primary mediastinal goiter is an extremely uncommon entity. The majority of primary mediastinal goiters were reported as incidental findings on chest imaging of asymptomatic patients. Symptoms related to compression of adjacent structures and hyperthyroidism were rarely described. Herein we report a case of subclinical hyperthyroidism secondary to a primary mediastinal goiter.
Observation
A 50 year-old woman was referred to our department for hyperthyroidism. She presented with palpitations and hand tremors for 4 months. No history of dysphagia, dyspnea or hoarseness was reported. Physical examination found homogeneous thyroid gland and no superior vena cava syndrome. Thyroid function tests revealed subclinical hyperthyroidism. Thyroid peroxydase antibodies and thyrotropin receptor antibodies were negative. Thyroid ultrasound showed a normal-sized thyroid gland with a 7.5 mm nodule classified TIRADS II and a voluminous anterior mediastinal mass of 75 mm, hyperechoic, heterogeneous and containing multiple calcifications. Cervico-thoracic CT scan revealed a 120 × 70 × 128 mm anterior mediastinal mass independent from the thyroid gland, containing multiple calcifications, with a large tight contact with the aortic arch, the supra aortic trunks and the superior vena cava. A complete resection of the mediastinal tumor was performed through a total median sternotomy. There were no vascular or tissular connections between the mass and the thyroid gland. The feeding artery was dependent on intrathoracic vessels. The histopathological findings revealed a multinodular colloid hyperplasia with no signs of malignancy. The postoperative outcome was marked by a spontaneous euthyroidism.

Conclusion
Our case highlights necessity to keep in mind that ectopic mediastinal goiter, although uncommon, can induce hyperthyroidism. The final diagnosis of primary mediastinal goiter is made by histopathological examination.

Pattern of autoimmune thyroid disease among patients with goitre at a tertiary hospital, lagos nigeria

Funmilayo Diyaolu
Lagos University Teaching Hospital, Medicine, Lagos, Nigeria

Introduction
Thyroid disorders are second largest endocrine condition seen in clinics. The most common manifestation of thyroid dysfunction is the appearance of goitre. The elimination of iodine deficiency as a cause of goitres decades ago has demanded a closer look into autoimmune aetiology of thyroid disease in our population. The characteristic features of these autoimmune goitres: Graves' Disease (GD) were also explored in this study. The finding of a higher than reported prevalence of Marine Lenhart syndrome in this study raises the concern for possible induction of autonomous nodules in the presence of iodine sufficiency.
Methods
One hundred and thirty-four participants with goitres were recruited for the study. Seventy-seven of these participants with goitre had features of toxic goitre confirmed with low TSH and elevated free Thyroxine and Triiodothyronine had Thyrotropin Receptor Antibody (TRAb) assayed to determine autoimmune hyperthyroidism. Thyroid ultrasonography was carried out on all participants.
Results
The TRAb is a confirmatory test for Graves' disease, of the 77 with clinical, radiological and /or biochemical diagnosis of Toxic goitre tested, 60 were positive with a Prevalence rate of 77.9%, of which males were 20 and females 40. The prevalence of autoimmune thyroid disease among the general population using Anti-Thyroid Peroxidase was 38.7% while among those with goitre; 53.7%. Out of 77 with toxic goitres tested, 72 had positive Anti-TPO with a prevalence of thyroid autoimmunity at 93.5%. 18 males and 54 females. Both Antibodies were positive in 48 of the 77 tested giving a prevalence of 62.3%. Among those with toxic goitre tested using TRAb, 7.6% had other clinical diagnosis other than GD as clinical /provisional diagnosis. Fifty percent of the subjects with clinically indeterminate diagnosis between Toxic Multinodular Goitre (TMG) and GD had positive TRAb result while 66.7% of those who had clinical and radiological diagnosis of TMG had positive TRAb. There is an increased prevalence of Marine Lenhart Syndrome in this study of 10% compared to previous reports of 0.8–4.1 percent
Conclusion
Diagnosis of GD (Autoimmune Hyperthyroidism) is most certain with TRAb. The use of clinical features alone is prone to misdiagnosis while isolated use of Anti-TPO for diagnosis of GD could lead to inappropriate diagnosis. The high prevalence of TRAb-positive nodular goitres raises the concern of possible association between autoimmune thyroid disease and possible iodine sufficiency in which autonomous thyroid nodules are spontaneously developed.

Thyroid carcinoma in cowden syndrome

Khelil Nour El Houda & Meghelli Sidi Mohammed
Abou Bekr Belkaid University, Department of Medicine, Tlemcen, Algeria

Cowden's syndrome (CS), also called multiple hamartoma syndrome is an orphan pathology which associates pathognomonic cutaneous-mucosal manifestations with multiple and disseminated hamartomas (skin, mucous membranes, gastrointestinal tract, thyroid, breasts and genitourinary system) and an increased risk of the development of certain malignant tumors, in particular breast, thyroid and endometrial tumors, which are very serious.

Observation
Case 1
A 41-year-old woman followed from a young age in dermatology for skin lesions associated with macrocephaly. She also has a history of multinodular goiter operated on 4 times, the micro-invasive follicular carcinoma is diagnosed, it was extended to the 3rd and 4th tracheal rings and cervical lymph node. The treatment is completed by two iratherapy (cumulative activity: 448 mCi). The diagnosis of Cowden syndrome is confirmed and other explorations are made, they have resulted in the discovery of 3 gastric polyps of 6 to 8 mm, multiple colonic polyps of 10 mm, and more recently, left breast cancer currently undergoing chemotherapy.
Case 2
A 20-year-old women with a history of a 20 mm granulosis tumor of the right ovary, operated on at the age of 14. A left nodular goiter is discovered accidentally, a thyroidectomy is performed and the diagnosis of trabeculo-follicular carcinoma is made. The treatment is completed by iratherapy (105 mCi). During follow-up, a bilateral breast biopsy is performed. The histological study confirms benign adenofibroma. The association of ovarian tumor, thyroid carcinoma, adenofibromas of the breasts with skin lesions such as papillomatous papules of the nose, of the neck, of the gums and nasal mucosa suggests the diagnosis of Cowden syndrome. The digestive tract could not be explored because the patient's refusal, the ultrasounds made during the follow-up did not find any lesion of the urinary or the genital system.
Discussion
CS is a tumor predisposition syndrome related to a mutation in the tumor suppressor gene PTEN located on the long arm of chromosome 10 (10q 22–23) whose loss of function leads to activation of the PI3K/Akt/ pathway. mTOR involved in cell growth, migration and proliferation. The hamartomatous lesions characteristic of CS concern organs from 3 embryological outlines: ectoderm, mesoderm and endoderm, its diagnosis is purely clinical based on the association of major and minor criteria established by the international Cowden consortium. a rare but potentially serious pathology due to the frequency and aggressiveness of the malignant neoplastic lesions characterizing it, requiring multidisciplinary management is close monitoring.

Primary diffuse B-cell thyroid lymphoma: A case report

Marwa Majdoub, Imen Rojbi, Meriem Adel, Chayma Besrour, Lakhoua Youssef, Nadia Mchirgui, Ibtissem Ben Nacef & Khiari Karima
Charles Nicolle Hospital, Tunis, Tunisia

Introduction
Primary thyroid lymphoma (PTL) is a rare affection that represents only 1% to 5% of thyroid malignancies and 1% to 2% of extranodal lymphomas. It involves by definition only the thyroid gland and adjacent neck lymph nodes, at diagnosis.
Case presentation:
A 65-year-old woman with a controlled Hashimoto's thyroiditis presented with a 12-month history of painless neck swelling, recently increasing in size and occasionally causing hoarseness. Physical examination showed a large no tender nodular goiter, anterior cervical adenopathies and a positive Pemberton's sign. Cervical ultrasound revealed a 6 cm left thyroid nodule EU-TIRADS 5. Fine needle aspiration was suggestive of a high-grade lymphoma. Thyroid and cervical lymph node biopsies later confirmed the diagnosis of diffuse large B-cell lymphoma (DLBCL). On immunohistochemical staining, the tumor cells were positive for CD20, CD10, Bc16 and Ki67 (70%). No other dissemination was found on the thoracic-Abdominal-Pelvic scan nor the bone marrow biopsy. So the lymphoma was classified IIE on the Ann Arbor classification. The chemotherapy was delayed for 2 months because of the patient's Covid-19 infection, she then was started on an 8-cycle chemotherapy regimen including cyclophosphamide, adriamycin, vincristine and prednisone in association with rituximab. Adjuvant radiotherapy is scheduled.
Discussion and conclusions
Similarly to our case report, PTL is usually observed in middle to older aged females, but it commonly has a faster progression. DLBCLs account for 50 to 80% while mucosa-associated lymphoid tissue lymphoma, presents 20–30% of all PTLs. Autoimmune chronic lymphocytic thyroiditis is a well-established risk factor with an 80-fold risk compared to individuals without Hashimoto's thyroiditis, which suggests a pathogenesis related to chronic inflammatory stimulation. Our Patient has a low intermediate International Prognostic Index (IPI). Prognostic factors include age, Size of the tumor, stage of the disease, the presence of symptoms due to B-cells, levels of

LDH. The conventional chemotherapeutic regimen for PTL includes cyclophosphamide, doxorubicin, vincristine, and prednisone. Rituximab, a monoclonal antibody anti-CD20, represented an advance in the treatment of DLBCL. Currently, most authors support combined chemo-radiation therapy since it ensures a better outcome for five-year overall survival.

AEP719

Medullary thyroid carcinoma development five years after thyroidectomy for benign non-toxic goiter

Boyan Nonchev[1], Antoaneta Argatska[1], Rosen Dimov[2,3] & Veselin Chonov[4]
[1]Medical University of Plovdiv, Department of Endocrinology, Plovdiv, Bulgaria; [2]Medical University of Plovdiv, Department of Special Surgery, Plovdiv, Bulgaria; [3]Medical Simulation Training Center at Research Institute of Medical University of Plovdiv, Plovdiv, Bulgaria; [4]Medical University of Plovdiv, Department of General and Clinical Pathology, Plovdiv, Bulgaria

Total thyroidectomy is the preferred surgical procedure in patients with high-grade multinodular goiter. The necessity for long-term neck ultrasound (US) surveillance after thyroidectomy for benign diseases remains unclear as the risk of recurrence is very low. However, in a minority of patients a thyroid neoplasm could arise from very small thyroid remnants. We report a case of a 65-year-old female who underwent thyroidectomy for nontoxic multinodular goiter in 2013. Histological examination was consistent with benign nodular hyperplasia. Levothyroxine replacement therapy was started thereafter but regular US examination was not performed. Five years later the patient presented with newly developed persistent dysphonia and was diagnosed with vocal cord paralysis. The subsequent US neck imaging found a big hypoechoic nodule in the left thyroid bed with irregular shape, blurred margins infiltrating the trachea (EU-TIRADS 5). Lymph nodes with metastatic US features were detected in the left lateral compartment (level IV). Serum calcitonin was significantly elevated. Fine needle aspiration biopsy revealed cytological evidence of malignancy and the extremely elevated calcitonin in the cervical lymph nodes washout confirmed metastases from medullary thyroid cancer. The patient was referred to surgery but due to the local invasion complete tumor resection was not possible. Following surgery targeted therapy with tyrosine kinase inhibitors was initiated to prevent further disease progression. The clinical case suggests that aggressive thyroid malignancy can develop from microscopic tissue remnants several years after thyroidectomy. Ultrasound examination is a valuable tool in the long-term follow-up after thyroidectomy even for benign disorders.

Post covid-19 myxedema a case report

Islam Naser, Manal Abushady, Yara Eid, Salah El Halawany, Mina Nesim, Marina Amir, Mona Eldepp, Amany Talaat, Diana Girgis, Riham Mahmoud & Mena Adel
Ain-Shams University Hospitals, Internal Medicine Department-Endocrinology and Metabolism Unit, Cairo, Egypt

A 65 year old female presented to ER with progressive massive lower limb oedema and dyspnea on mild exertion of insidious onset. The patient started to complain of progressive lower limb oedema shortly after her discharge from Hospital ICU in June 2020 where she was being treated for severe COVID-19. She presented then with acute kidney injury, generalized oedema and was diagnosed with COVID-19 based on clinical, laboratory criteria, PCR, and CT findings. She is a known patient with type 2 diabetes and hypertension since 20 years on premixed insulin, she was diagnosed with heart failure since 3 years for which she was receiving diuretics and she had a past history of recurrent cellulitis since 10 years. Family history was negative for thyroid illness. Following her post Covid-19 discharge she started to suffer of progressive lower limb oedema that was assumed to be exacerbation of her cardiac condition and consequently the diuretics therapy was titrated up to 500 mg Lasix daily, followed by metozolone 10 mg and spironolactone 100 mg twice with no response. Lower limb oedema extended to thighs, incapacitating the patient ability to move, skin started to be dry, scaly with oozing blisters. On examination she was obese BMI = 35 kg /m^2, orthopneic, her neck showed congested pulsating neck veins and no goiter, her Left UL and both lower limbs exhibited lymphoedema, her chest revealed moderate pleural effusion. Her laboratory profile showed renal impairment creatinine= 1.8 mg/dl on admission, normocytic normochromic anemia Hb=9 gm/dl,hypoalbuminemia = 3 gm/dl and hyperuricemia = 15 mg /dl.She underwent pleural tap that revealed exudative pleural effusion. Screening for thyroid functions showed a TSH of 33.5 mIU/l. Patient was instituted on escalating dose of levothyroxine starting with 25 mgm/dl followed by 50 mgm/dl and by the end of 10 days marked decrease of pleural effusion was noted and improvement of kidney functions creatinine = 1.3 mg/dl. To our knowledge this is the second case reporting myxedema complicating COVD-19 that hypothesized invasion of thyroid tissue via surface expressed ACE2 receptors.[1]

Conclusion

COVID-19 had a short and long term extrapulmonary effects. Thyroid state should not be overlooked in the assessment of post and long COVID states.

A novel DUOXA2 mutation in russian family with thyroid dysgenesis

Ekaterina Shreder, Tatiana Vadina & Olga Bezlepkina
Endocrinology Research Center, Moskva, Russian Federation

Background

DUOXA2 mutations in patients with congenital hypothyroidism (CH) was first described in 2008 as rare cause of CH. mRNA of *DUOXA2* is expressed predominantly in thyroid and less in salivary glands. Human *DUOXA2* gene is located on 15q21.1 and inherited in an autosomal recessive pattern. In most cases *DUOXA2* gene mutations were described in patients with thyroid dishormonogenesis. Last investigations conferred *DUOXA2* susceptibility to thyroid dysgenesis (TD).

Methods

Twenty one genes related to CH (AITD3, DUOX2, DUOXA2, DUOX1, FOXE1, FOXE2, GLIS3, GLIS4, GNAS, IYD, NKX2–1, NKX2–5, PAX8, SECISBP2, SLC16A2, SLC26A4, SLC5A5, THRA, THRB, TPO, AITD4) were sequenced and screened for variations by next-generation sequencing (NGS) in this family.

Case report

1 patient: adult 24 yrs. female with congenital hypothyroidism caused by thyroid dysgenesis. Neonatal TSH was 173.7 mU/l, serum TSH – 301.1 mU/l. She was followed in endocrine research center from infancy. Ultrasound imagines did not reveal thyroid tissue, thyroglobulin was low (less 0.1 ng/ml). She gave birth to a baby at 24. The pregnancy proceeded normally and the delivery was without complications. 2 patient (proband): daughter of patient 1, five weeks aged, with no signs of hypothyroidism in neonatal period. Neonatal screening conducted on the third day of life. TSH was slightly increased to 9.5 mU/l and 22 mU/l on 3d and 14th day, respectively. Before onset of therapy, serum TSH was increased to 78 mU/l and fT4 decreased to 7.5 pmol/l, serum thyroglobulin level was high as 125 ng/ml (reference range 0–50). Ultrasound imaging did not show thyroid gland in typical position of the neck, during following investigation thyroid tissue was found near the hyoid bone. Heterozygous novel variant mutation c.552A > G:p.L184L in *DUOXA2* (NM 207581.4) was detected in mother and proband with thyroid dysgenesis.

Conclusions

We report a novel heterozygous *DUOXA2* mutation in the family with thyroid dysgenesis (mother and daughter). Homozygous *DUOXA2* mutations described in patients with thyroid dyshormonogenesis. However last investigations revealed heterozygous mutations in *DUOXA2* gene in TD patients. The significance of our heterozygous mutation remains unknown and require further researching.

[1]Bogomolets National Medical University, Anesthesiology and Intensive Care, Kyiv, Ukraine; [2]Ukrainian Scientific and Practical Center of Endocrine Surgery, Transplantation of Endocrine Organs and Tissues of Public of the Ministry of Health of Ukraine, Anesthesiology and Intensive Care, Kyiv, Ukraine; [3]Alexander Clinical Hospital, Kyiv, Ukraine

Objectives.
A prospective study to analyze anesthetic risks and anesthesia particularities in thyrotoxicosis syndrome (TTS) patients who were undergone thyroidectomy.
Materials.
It was analyzed 880 operated the TTS patients. Surgical interventions were performed under general anesthesia with mechanical ventilation by using the inhalation anesthesia (IA) with sevoflurane in 698 (79.3%) patients, by the total intravenous anesthesia (TIVA) with propofol in 182 (20.7%) cases. We assessed the physical status on the American Association of Anaesthesiologists (ASA) classification, the frequency of concomitant pathology, the anesthesia particularities of the according to anesthesiologist's recording reports.
Results
Among TTS patients, the 596 (68%) patients had diffuse toxic goiter (DTG), 208 (23%) patients had a multinodular goiter (MNG) with TTS, the rest of patient were with toxic adenoma - 44 (5%), 24 (3%) patients were with relapse of previously operated DTG or MNG. In 8 (1%) cases there was a combined pathology - papillary cancer in the background of MNG with TTS. The average age had a significant difference ($p < 0.01$) by Wilcoxon test between the groups DTG and MNG and was 42.1 ± 1.6 and 52.8 ± 1.7 years, respectively. According to ASA only 210 patients (23.9%) had - ASA I. 76.1% out of 880 TTS patients had ASA II–IV class. 21.1% of patients were at high risk ASA III and IV. It was analyzed that the anesthesiologists performed systemic haemodynamic and cardiac rhythm correction by administering antihypertensive, antiarrhythmic, sympathomimetic drugs in 404 (45.9%) cases, of which 320 (45.8%) – IA with sevoflurane, 84 (46.2%) – with TIVA with propofol ($P = 0.551$, no statistically significant difference). Bradycardia appeared in 9.5% and 2.2% of cases of IA and TIVA respectively ($P < 0.05$). Perioperative hypertension, which required medication, arose in 26.1% of cases and 25.3% with IA and TIVA respectively ($P > 0.05$). The most commonly observed concomitant diseases in patients with DTG were dismetabolic cardiomyopathy – 55.0%, and the patients with MNG with thyrotoxicosis had arterial – 64.3%. No fatal case was observed.
Conclusions
TTS impairs the ASA physical status. There was 76.1% of patients with thyrotoxicosis, who had one or more concomitant pathologies - ASA II-IV class. 21.1% of the patients had ASA III and IV. Abnormal anesthesia were noted in 404 (45.9%) cases, that means than the personified approach to the choice of type of anesthesia is needed.

Thyroid morphologic characteristics assessment in a cohort of patients with different glucose tolerance status

Irene Gagliardi[1], Elisa Dinatolo[1], Paola Franceschetti[2], Alessandro Mella[2], Sabrina Lupo[2] & Maria Chiara Zatelli[1,2]
[1]University of Ferrara, Section of Endocrinology and Internal Medicine, Dept of Medical Sciences, Italy; [2]University Hospital of Ferrara, Unit of Endocrinology and Metabolic Diseases, Dept of Oncology and Specialty Medicine, Italy

Background
Thyroid diseases and diabetes are the two most common endocrinopathies. A relationship between these two conditions is suggested by many studies, as diabetic population seems to present increased thyroid impairment. However, clinical data are still very sparse.
Aim
To evaluate thyroid morphologic characteristics among patients with different glucose tolerance status.
Material and methods
This retrospective study was conducted on 227 patients who underwent both an oral glucose tolerance test (OGTT) and an thyroid ultrasound (US) exam at our center. The following data were collected: thyroid US characteristics, thyroid nodules cytology, glucose tolerance defined as normal (N), impaired (I) and type 2 diabetes (D). HOMA index was also calculated.
Results
The cohort included 44 males and 183 females. After OGTT, 58%, 34% and 7% of patients were identified as (N), (I) and (D), respectively. (D) were significantly older (67.4 ± 6.8 yr) as compared to (I) (56.9 ± 13.5 yr) and (N) (52.3 ± 16.5 yr), without differences concerning thyroid function and gender distribution. (D) presented higher mean thyroid volume than others, but this difference did not reach statistical significance. Thyroid volume was significantly higher in euthyroid patients as compared to hypothyroid patients on L-thyroxine replacement therapy. Mean insulin peak levels after glucose load was consistently higher in (D). The incremental area under the curve (AUCins) increased from (N) to (I) to (D). Simple linear regression did not show any correlation between thyroid volume and insulin level nor HOMA index. Thyroid nodules were diagnosed in 68% of (N), 64% of (I) and 82% of (N). Thyroid nodules presented US characteristics suspicious for malignancy in (D) more often than other groups. 174 out of 203 nodules underwent to cytology investigation. Benign cytology was prevalent in all three groups.
Conclusion
Our data suggest a correlation between impaired glucose tolerance and increased thyroid volume, in agreement with literature evidence. More prospective studies with larger samples are needed in order to confirm this association. Finally, impaired glucose tolerance was not found to be predictive of malignancy at US and cytology.

Post-operative resistant hypothyroidism of Graves' disease patient resistant to anti-thyroid treatment

Yasemin Emur Gunay, Damla Tufekci, Ahmet Suat Demır, Muhammet Cuneyt Bilginer, Hulya Coskun, Irfan Nuhoglu, Ozge Ucuncu & Mustafa Kocak
Karadeniz Technical University Faculty of Medicine, Department of Endocrinology and Metabolism, Trabzon, Turkey

Introduction
Graves' Disease resistance to anti-thyroid treatment and poor treatment compliance with levothyroxine treatment (pseudomalabsorption) are not common conditions. We presented this case because of the inability to provide euthyroidism with anti-thyroid treatment before the surgery and with levothyroxine after the surgery in the same patient.
Case Report
A 24-year-old female patient was admitted with complaints of hair loss, tremors in the hands, weight loss, and palpitations. Methimazole was initiated in the patient, whose biochemical results (Table 1) supported Graves' disease as a result of ultrasonography and scintigraphy. In the patient whose hyperthyroidism did not improve despite high dose methimazole (80 mg/day) treatment, lithium 600 mg, Lugol 3 × 5 drops, methylprednisolone 40 mg, and plasmapheresis were administered to the patient, and underwent total thyroidectomy. After the surgery, levothyroxine replacement was started for the patient as 1.8 mg (microgram)/kg/day. Upon the arrival of fT4 (free T4) < 0.15 ng/dl and TSH (thyroid-stimulating hormone) > 47.900 mIU/l at the control admission, the patient was hospitalized. She was taking medication regularly and there was no history of drug use that could affect levothyroxine absorption. The Celiac antibodies (Anti-gliadin Ig A, Anti-endomysium Ig A, Anti-transglutaminase Ig A) and helicobacter pylori test (pathological diagnosis), which were done for malabsorption, were negative. Despite the LT4 (levothyroxine) replacement treatment under observation, she had no increase in sT4 levels, and a challenge test with supervised intake of 1,000 µg of levothyroxine was performed. Based on the 2–3 times increase in sT4 levels and decrease of approximately 40% in TSH levels, the patient was diagnosed with pseudomalabsorption. The patient was discharged with a daily dose of 2.2 mg/kg/day levothyroxine. The laboratory results of the patient after the discharge are given in the table (Table 1). The patient is followed by us.

Table 1. Biochemical results

	Before surgery	Hospitalization	2nd Week after discharge	Referance range
TSH	<0.005	>47.900	0.21	0.270–4.2 mIU/l
sT3	15.68	1.55	4.51	2–4.4 ng/l
sT4	6.9	<0.15	1.83	0.93–1.7 ng/dl
Anti-thyroid peroxidaz	397			0–9 IU/ml
Anti-thyroglobulin	10.2			0–4 IU/ml
TSH reseptor antibody	5.4			<1 U/l

Conclusion
Drug compliance, malabsorption, and the presence of antibodies against drugs and intrathyroidal drug concentration measurements are recommended in patients resistant to anti-thyroid treatment. In case of failure to provide euthyroidism despite high-dose hypothyroidism treatment, malabsorption syndromes must be eliminated, and the patient must be evaluated for pseudomalabsorption. In these patients it is recommended that higher doses be given than normally needed.

Vitamin D deficiency and Hashimoto's thyroiditis

Sergio Roman Gimeno[1], Rosana Urdaniz Borque[1], Elena Pérez Galende[1], Borja Sanz Martín[1] & Jose Jorge Ortez Toro[2]
[1]Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain; [2]Hospital Reina Sofía, Tudela, Spain

Introduction
The main role of vitamin D is regulating bone metabolism, but over the past years, the importance of vitamin D in non-skeletal actions has been studied. Vitamin D deficiency is very common in our environment. This deficit has been associated with higher risk of many chronic diseases, such as osteoporosis, hypertension, diabetes and even obesity. Recent evidence has demonstrated an association between low vitamin D status and autoimmune thyroid diseases such as Hashimoto's thyroiditis. Moreover, vitamin D plays a significant role in modulation of the immune system, enhancing the innate immune response while exerting an inhibitory action on the adaptive immune system.
Objectives
To evaluate whether there is a higher prevalence of vitamin D deficiency among patients with Hashimoto's hypothyroidism and whether it is correlated with laboratory parameters such as TSH, free T4 or the levels of anti-peroxidase (TPO) and anti-thyroglobulin antibodies.
Methods
The medical history and laboratory tests of 200 patients with autoimmune hypothyroidism treated in our hospital (Hospital Clínico Lozano Blesa, in Zaragoza; Spain) were collected for this study. Vitamin D levels under 30 ng/ml were considered to be vitamin D deficiency. Student's T test was used for statistical analysis.
Results
Vitamin D deficiency was frequent among hypothyroid patients (42.6%). In addition, higher mean values of anti-tiroglobulin antibodies have been obtained in patients with low vitamin D (235.14 IU/ml versus 102.32 IU/ml, $P = 0.011$), as well as higher mean values of TSH (20.45 mU/l vs 8.45 mU/l $P = 0.028$). There were no differences between the FT4 values or anti-TPO antibodies of both groups.
Discussion and conclusion
A high prevalence of vitamin D deficiency was found among patients with Hashimoto's thyroiditis. Moreover, those with higher TSH and/or higher anti-thyroglobulin antibody levels had lower vitamin D levels. Various studies have recognized the pleiotropic roles of vitamin D, which have suggested a beneficial role of this vitamin in the management of thyroid disease. However, only an ambiguous causal relationship has been reported to date, so the potential of vitamin D as a treatment in thyroid diseases remains debated. Long-term, randomized controlled trials are required to determine whether patients with low vitamin D levels are at increased risk of developing autoimmune thyroiditis, and to provide insight into the efficacy of vitamin D as a therapeutic agent for this disease.

Proposal of a predictive scoring system for the accurate diagnosis of Hashimoto's thyroiditis

Ramakanth Bhargav Panchangam[1], Sabaretnam Mayilvaganan[2], Ramesh Bangariahgari[3], Rajesh Bangaraiahgari[4], Rafi Md[3] & Rajkiran Reddy Banala[5]
[1]Endocare Hospital, Endocrine and Metabolic Surgery, Vijayawada, India; [2], Endocrine and Metabolic Surgery, Vijayawada, India; [3]Surabhi Medical College, Biochemistry, Vijayawada, India; [4]Surabhi Medical College, Anatomy, Vijayawada, India; [5]Sunrise Hospitals, Genetics, Vijayawada, India

Background
The protean and non-specific nature of diagnostic criteria of Hashimoto's thyroiditis leads either to overdiagnosis or underdiagnosis. The aim of this study is to propose a comprehensive diagnostic scoring system based on objective clinic-investigative criteria.
Methods
A case-control study of patients who underwent surgical thyroidectomy, were compared a with a set of clinical, biochemical, pathological parameters in patients with Hashimoto's thyroiditis ($n = 75$) and controls ($n = 75$), in order to design a comprehensive multi-parametric scoring system. We analysed twelve criteria - Age, Sex, goiter grade, associated pathology, duration of disease, euthyroid/ hypothyroid status; family history, presence of auto-immune features, anti-thyroid peroxidase titer, anti thyroglobulin antibody titer, thyroid cytopathological diagnosis of HT, extent of thyroidectomy. All these features were analysed and scored in comparision with histopathology as gold standard. A different validation cohort of 56 patients were reviewed and classified according to the score. Linear correlation and descriptive statistics were performed with SPSS 20.0 version.
Results
The study parameters were dichotomized in to major criteria (euthyroid/ hypothyroid status; family history, presence of auto-immune features, anti-thyroid peroxidase titer, anti thyroglobulin antibody titer, thyroid cytopathological diagnosis of HT) and minor (Age, Sex, goiter grade, associated pathology, duration of disease, extent of thyroidectomy) criteria. Diagnostic accuracy of various combinations of major criteria was – with 6 = 100%; 5 = 100%; 4 = 100%; 3 = 100%, 95%, 85%; 2 = 90%; 1 = 82%. Finally, score of atleast ≥ 3/6 major criteria, with mandatory elevated anti Tg and anti TPO Ab titer was diagnostic of HT. This diagnostic accuracy was statistically significant compared to controls.
Conclusions
This multi-parametric scoring system appears to be a comprehensive, accurate and simplistic in the diagnosis of Hashimoto's thyroiditis and resultant optimal management.
Keywords: Hashimoto's thyroiditis; goiter; histopathology; thyroidectomy; thyroglobulin.

The impact of treatment adherence on the control of the thyroid function in Hashimoto's thyroiditis patients

Chayma Besrour, Meriem Yazidi, Ibtissem Oueslati, Nadia Khessairi, Wafa Grira, Fatma Chaker & Melika Chihaoui
University of Tunis el Manar, Faculty of Medecine of Tunis, La Rabta Hospital, Endocrinology, Tunis, Tunisia

Hashimoto's thyroiditis (HT) is a chronic disease that needs a daily substitution by thyroid hormones. The purpose of this study was to assess the level of therapeutic adherence to the hormonal treatment in HT patients and its impact on the thyroid function control.
Methods
It is a cross sectional study including 43 patients treated for hypothyroid Hashimoto's thyroiditis by levothyroxine (LT4). The patient adherence to treatment was evaluated by using the Girerd questionnaire in its Tunisian version. The level of adherence was considered good if the score was equal to 0, medium if it was equal to 1 or 2, and poor if it was equal to 3 or more.
Results
The mean age of the study population was 50.0 ± 12.9 years (41 women and two men). The mean duration of the disease was 7.9 ± 6.3 years. The TSH level was above the therapeutic target in 19% of the patients. The adherence was good in 9% of the patients, medium in 44% of the patients and poor

in 47% of the patients. A TSH level higher than the therapeutic target was found in 0% of subjects with a good therapeutic adherence level, 21% of subjects with a medium therapeutic adherence level and 20% of subjects with a poor therapeutic adherence level ($P = 0.6$).
Conclusion
Poor adherence to hormonal treatment is frequent in HT patients. However, its impact on the control of the thyroid function is uncertain. This, may be explained by the extended half-life of the levothyroxine which is between 6 and 7 days, allowing occasional forgetfulness.

A case of Graves' disease (GD) associated with HIV disease and late immune reconstitution inflammatory syndrome (IRIS) following initiation of antiretroviral therapy (ART)

Stephen Ludgate[1], Stephen P Connolly[2], David Fennell[1] & Siobhan McQuaid[1;3]
[1]Mater Misericordiae University Hospital, Department of Diabetes and Endocrinology, Dublin, Ireland; [2]Mater Misericordiae University Hospital, Department of Infectious Diseases, Dublin, Ireland; [3]University College Dublin, Dublin, Ireland

GD following ART occurs rarely, in 3% of HIV-infected women[1]. It is suggested that CD4 cells increase in a biphasic pattern following ART initiation, with the expansion of naïve CD4 cells following months after the initial redistribution of memory CD4 cells from lymphoid tissue[2]. A 40-year-old Brazilian lady was diagnosed with HIV in late 2016 following admission with cryptococcal meningitis and salmonellosis, requiring treatment with anti-fungal agents and high dose steroids. Initial CD4 count was 17 cells/μl (540–1660), CD4% 4% (32–60) and HIV viral load was 1804502 copies/ml. Primary adrenal insufficiency was confirmed and treated following presentation with persistent hypotension and fatigue (peak Cortisol post Synacthen of 407 nmol/l, ACTH 111 ng/l (7–63), adrenal and TPO antibodies negative, CT adrenal showed no infiltrative process). ART (emtricitabine/tenofovir, alafenadmide and darunavir/ritonavir) was deferred until five weeks post admission. She developed fevers, vomiting and headaches five days after the initiation of ART, which was attributed to IRIS. 19 months post original diagnosis, she presented with cervical lymphadenopathy (CD4 count 585 cells/μl, undetectable HIV viral load). Following extensive work up, including biopsy, a late IRIS to cryptococcus was diagnosed. High dose steroids resulted in complete resolution of lymphadenopathy. 45 months after ART initiation, she developed symptomatic Graves' hyperthyroidism with weight loss, tremor and hair thinning. Free T4 (FT4) was 28.9 pmol/l (9–20), thyroid stimulating hormone (TSH) <0.01 mIU/l (0.35–4.94) and TSH receptor antibody 3.7 IU/l (< 1.8)). Prior TFTs and thyroid imaging were normal. Family history was negative for thyroid and autoimmune disease. FT4 reduced to 12 pmol/l on carbimazole 10 mg daily. The onset of GD post ART in this case is outside of the reported 12–36 months heretofore documented[2]. We cannot be definitive if the GD was of new onset independent of HIV status or if it occurred as part of an IRIS. However, the diagnosis of documented late IRIS to cryptococcus may suggest that the GD is a consequence of ART immune reconstitution. This case highlights the importance of remaining vigilant for potential endocrine effects that can occur during clinical follow-up in patients following ART initiation.

A case report of ectopic thyroid gland with Hashimoto's thyroiditis

Mohammad Bilal Jajah[1] & Maryam Alharthi[2]
[1]West Suffolk NHS Foundation Trust, Bury St Edmunds, United Kingdom; [2]Alhada Armed Forces Hospital, Family Medicine, Taif, Saudi Arabia

Introduction
Ectopic thyroid gland (ETG) is a rare developmental disorder, and when occurs in the midline of the neck, it mimics the clinical presentation of thyroglossal duct cyst (TGDC). inadvertent surgical removal of ETG simulating TGDC has been reported in the literature in spite of the modern diagnostic methods for this pathology.[1,2]. We report a case of a 27-year-old female with Hashimoto's thyroiditis of ectopic thyroid in whom a preliminary clinical diagnosis of thyroglossal duct cyst was made clinically and planned for surgery.
Case Report
A 27-year-old female was referred to for evaluation of an anterior upper neck mass that had been present since the age of 6 years without significant change in size. There was no complaint of pain, dyspnea, dysphagia, or voice change and no history of radiation exposure or familial thyroid disease. Patient was evaluated earlier and provisionally diagnosed to have thyroglossal duct cyst and planned for surgery. Preoperative investigation revealed hypothyroidism, so she was referred to our department for the management of hypothyroidism prior to excision. Physical examination showed a palpable rounded smooth mass (3 × 3 cm in size) of rubber-like consistency, that moved upwards on swallowing. It was non-tender, mobile, not attached to overlying skin and skin over the mass was normal. Serologic testing revealed normal FT4 and FT3 of 4.81 pmoL/l, and elevated TSH level of 9.56 mIU/l. Thyroid peroxidase antibodies was strongly positive of 1299 IU/ml. Ultrasonography of the neck revealed a solid soft-tissue mass with diffuse heterogeneous echotexture corresponding to the palpable lesion. The thyroid gland was not visualized in the normal thyroid position. A 99mTc Pertechnetate SPECT/CT Scan showed a single focus of radiotracer uptake anteriorly n the submental region at the site of the palpable mass (Fig 2). There was no evidence of other functioning thyroid tissue in the lower neck region or in other ectopic position. The diagnosis of midline neck ectopic thyroid with subclinical hypothyroidism and Hashimoto's thyroiditis was made. Replacement with L-thyroxine 50 mcg/day was started and no surgery was performed. On follow-up, patient is doing well, her TSH was 4.3 miU/ml with slight reduction in the size of the ectopic thyroid.

Intravenous thyroxine administration in hospitalized patients, a common but unreported practice: A single institution recent experience

Karen Tordjman, Nancy Bishouty & Yona Greenman
Tel Aviv Sourasky Medical Center, Institute of Endocrinology, Metabolism and Hypertension, Tel Aviv, Israel

Background
Intravenous levothyroxine (IVT4) is FDA-approved for the treatment of myxedema coma (ME). We noticed that at our hospital, IVT4 is administered more frequently than expected.
Aim of study
To assess the extent of IVT4 administration, the indications for such a treatment, and its outcome at a tertiary facility.
Methods
A retrospective study of IVT4 administered to adult inpatients at Tel Aviv-Sourasky Medical Center between 01/2017 and 07/2020. Patients' charts were searched for relevant clinical and laboratory data.
Results
107 patients (62 W/45 M), age 62.5±17.3 y (range 20–97) received IV T4, in the course of 113 hospitalizations. 94 subjects had primary hypothyroidism (PH), 10 had central hypothyroidism, while 3 subjects had no documented evidence of hypothyroidism. ME was likely *in only 4 cases* (3.5%). The leading stated indication for IVT4 was profound hypothyroidism in 57 instances (50.4%), jeopardized enteral route in 11 (9.7%), while no obvious indication was found in 39 cases (34.5%). In subjects with PH, median serum TSH prior to treatment was 36.4 mIU/l (IQR 8–42), while free T4 was 0.4 ng/dl (IRQ 0.22–0.61, normal 0.8–1.7). In subjects with no ME, altered consciousness was present in 19%, bradycardia in 6.3% and 4.5% were hypothermic. The median initial dose of IV-T4 was 150 mg (range 20−500). Repeated administrations ranged from 1 to 29 times, with a median cumulative dose of 250 mg (IQR 150−400, range 20−3300). We could not identify adverse events directly attributable to IV-T4. Of the 113 admissions, 61 ended in patient's recovery and discharge (54%), 22 (19.5%) in transfer to a rehab or nursing facility, while there were 30 cases of death (26.5%). Only one of the 4 patients with presumed ME died. In a logistic regression model, that also included age, gender, and ICU admission, the only variable that significantly predicted death was a need for artificial ventilation (OR:27.8, CI 3.5−189). In contrast, free T4, TSH, hospitalization

length, altered consciousness, and other potential variables, were excluded from the equation.
Conclusions
IVT4 administration is a common practice at our hospital. In a small minority of cases (13.2%), it is given for approved clinical conditions, while in all the others it appears to be unjustified. Reports on this practice are all but absent from the literature. Studies from other institutions are needed to determine its global extent, safety, and efficacy. Until it is proven safe and cost-effective, greater caution should be exercised before allowing it.

Hypothyroidism in the elderly: clinical and therapeutic aspects

Hadj Kacem Faten, AbdelMouhaymen Missaoui, Cherifa Fourati, Hana Charfi, Dhoha Ben Salah, Fatma Mnif, Nadia Charfi, Mouna Mnif, Nabila Mejdoub, Mouna Elleuch & Abid Mohamed
Hedi Chaker University Hospital, Endocrinology Departement, Sfax, Tunisia

Introduction
Hypothyroidism (HT) is widespread in all age groups particularly within the increasing elderly population while its diagnosis is challenging owing to extremely varied and atypical symptoms. The objective of this study is to outline the clinical and biochemical features of HT and determine its main etiologies in a geriatric population.
Methods
We reviewed the medical charts of 53 patients aged 65 years and over, who had been diagnosed with HT and hospitalized between 2009 and 2019 at the endocrinology department of Hedi Chaker university hospital, Sfax, Tunisia.
Results
The mean age of our sample was 72.7±5.5 years with a female predominance (sex ratio=1.94). A medical history of ischemic cardiopathy or arrhythmia was found in 18.86%. HT was diagnosed based on the worsening of some "usual" aging-related symptoms such as asthenia (81%), cognitive and psychomotor limitations (77%), constipation (50%), dry skin (47%), hearing loss (19%), and myalgia (17%). A goiter was encountered in 23%. Complicated forms seem to be more frequent in seniors than in younger patients for insistence: myxomatous coma (1.88%), pericarditis (7.55%), and hypothyroid myopathy (5.66%). At diagnosis, the mean TSH and T4 levels were 68.13±55.24 mUI/l and 6.11±1.2 pmol/l, respectively. Subclinical hypothyroidism (SCH) was detected in 9.43% with a mean TSH level of 6.9 mUI/l. Lipid metabolism was troubled in 39.62% of cases with a mean total-cholesterol and triglycerides levels of 5.06±1.49 and 1.83±1.24 mmol/l, respectively. Rhabdomyolysis and hyperuricemia were observed consecutively in 23% and 13% with mean uric acid and Creatine phosphokinase levels of 1060±112.1 UI/l and 326.4±95 µmol/l, successively. Anemia was underlined in 60% and the normocytic form in 43% with a mean hemoglobin rate of 10.75±2 g/dl. Leading etiologies of HT were: autoimmune thyroiditis (81%), amiodarone use (9%), total thyroidectomy (6%), and radioactive iodine therapy (2%). Considering the severity of HT, a hormone replacement therapy (HRT) by stepwise approach was adopted by increasing the dosage by 12.5 µg every three days reaching a mean thyroxine dose of 109.57 µg/day. The evolution was favorable in all patients excepting one senior who developed atrial fibrillation during HRT. We opted for HRT in patients having SCH associated with goiter and/or positive thyroid autoantibodies.
Conclusion
Hypothyroidism should be screened for in the elderly in front of cognitive and functional changes even those usually attributable to aging. HRT must be conducted gradually and carefully considering the frailty and cardiovascular comorbidities to target an age-appropriate TSH range (age/10 mUI/l).

Pulmonary embolism and pulmonary arterial hypertension: Atypical complication of hyperthyroidism

Hajar Khouchaf, Nassim Essabah Haraj, Siham El Aziz & Asmaa Chadli
HUC Ibn Rochd, Department of Endocrinology and Metabolic Diseases, Casablanca, Morocco

Introduction
Basedow disease is the most common etiology of hyperthyroidism; the cardiac manifestations seen in hyperthyroidism often affect people over 60 years of age, manifested mainly by sinus tachycardia, atrial rhythm disturbances or increased cardiac output. Pulmonary arterial hypertension and pulmonary embolism are atypical manifestations.
Observation
39-year-old patient, followed for basedow disease for 14 years on carbimazole 20 mg/day, Basedowian orbitopathy for 2 years having received corticosteroid boluses. Clinically, the patient presented with bilateral exophthalmos, sinus tachycardia, tremors, and pretibial myxedema. Palpation found a homogeneous goiter. TSH was collapsed with T4L at 0.7 µg/ml and positive TSH receptor antibodies 40 IU/l. During hospitalization, the patient developed dyspnea. The cardiac ultrasound revealed significant pulmonary hypertension at 73 mmHg, and increased cardiac output. A pulmonary CT angiogram revealed a bilateral basal sub-segmental pulmonary embolism with the presence of a submerging thyroid goiter. The patient was put on LMWH curative dose with good clinical outcome. The dose of carbimazole was reduced to 10 mg/day.
Conclusion
Basedow disease, a potentially serious endocrinopathy, leads to a prothrombotic and hypofibrinolytic state. This observation underlines the importance of determining the place of this risk factor within the various risk factors of thrombotic disease already known and the need to put in place preventive strategies for thrombosis.

Background and aims
In the Republic of Belarus treatment of hypothyroidism in the adult population is regulated by the order of the Ministry of Health dated 2013. Levothyroxine is available in tablet form (dosage in increments of 25 µg). Liothyronine are not registered in the Republic of Belarus, but patients can purchase them on their own abroad. Thus, the aim was to study of possible endocrinologists' preferences of choosing the levothyroxine formulation.
Materials and methods
From 01.10.2020 to 26.12.2020 there was survey using THESIS questionnaire: Treatment of Hypothyroidism in Europe by Specialists: International Survey (Russian version). 210 members of Belarusian Public Medical Association 'Endocrinology and Metabolism' received the mailing with questionnaire in Word and Excel formats, agreed to participate and filled out the questionnaire. Taking into account the duration of medical practice for more than 5 years, the experience of working with patients with hypothyroidism and the mandatory specialization as an endocrinologist, 146 doctors were included in the study.
Results
132 (90.4) women and 14 (9.6%) men responded. LT4 as the first choice of the hypothyroidism therapy indicated 99.3% (145) respondents, and 0.7% (1) LT4 and LT3 combination. there was Clinical experience in prescribing LT3 was identified in 3.4% (5 persons), desiccated thyroid – 0.7% (1 person), LT4 and LT3 combination – 6.2% (9 persons). The LT4 and LT3 combined may be used in following cases: for a short period, in patients recovering from protracted hypothyroidism – 41.8% (61 responses), in patients with normal serum TSH and hypothyroidism symptoms – 10.3% (15 responses), in hypothyroid patients with normal serum TSH and unexplained weight gain – 1.4% (2 responses); never be used – 46.5% (68 responses). General clinical experience shows next form of LT4 is better absorbed: tablets 64.4%

(94 responses), soft-gel capsules 4.1% (6 responses), liquid solution 4.1% (6 responses), no major changes with different formulations 27.4% (40 responses). Choice of levothyroxine formulation in patient who self-reports intolerance to various foods raising: tablets – 55.5% (81 responses), soft-gel capsules – 14.4% (21 responses), liquid solution – 14.4% (21 responses), no major changes –21.2% (31 responses). Choice of levothyroxine formulation for patient who has unexplained poor biochemical control of hypothyroidism: – tablets 78.8% (115 responses), soft-gel capsules –7.5% (11 responses), liquid solution 4.8% (7 responses), no major changes 17.1% (25 responses).

Conclusions

Based on general clinical experience, it is possible to use combination therapy with the introduction of both LT4 and LT3. The preference for alternative forms varies with clinical situations.

Fazzi Hospital, Division of Endocrinology, Lecce, Italy; [9]Regina Apostolorum Hospital, Department of Endocrinology and Metabolism, Albano, Rome, Italy; [10]Royal Victoria Infirmary, Department of Endocrinology, Newcastle upon Tyne, United Kingdom

Background and aims

It has been reported that some patients with hypothyroidism treated with levothyroxine continue to experience persistent symptoms despite normal serum TSH. Thus, the aim was to study of causes of hypothyroidism symptoms in euthyroid patients.

Materials and methods

From 01.10.2020 to 26.12.2020 there was survey using THESIS questionnaire: Treatment of Hypothyroidism in Europe by Specialists: International Survey (Russian version). 210 members of Belarusian Public Medical Association 'Endocrinology and Metabolism' received the mailing with questionnaire and agreed to participate. 146 endocrinologists with the medical practice for more than 5 years, the hypothyroidism working experience were included in the study.

Results

Persistent hypothyroidism symptoms despite normal serum TSH and levothyroxine treatment has been reported by 88.4% (129 persons) respondents. 52.1% (76 persons) respondents notice the symptoms in less than 5% of patients, and 32.9% (48 respondents) in 6–10% patients. Possible clinical conditions for thyroid hormone treatment in euthyroid subjects were admitted: unexplained fatigue – 7.5% (11 responses), obesity resistant to life-style interventions – 7.5% (11 responses), as a complementary treatment in severe hypercholesterolemia – 8.2% (12 responses), depression resistant to anti-depressant medications – 8.2% (12 responses), female infertility with high level of thyroid antibodies – 34.2% (50 responses), simple goiter growing over time – 24.7% (36 responses), treatment is never indicated for euthyroid patients – 57.5% (84 responses). Doctors who did not prescribe levothyroxine for normal TSH were comparable in gender (8 (5.5%) men vs 76 (52.0%) women, χ^2= 0.00001, p=0.975), age (under 40 years 23.3% (34) vs over 40 years 34.3% (50), χ^2= 0.046, P = 0.829) and medical experience (< 10 years in medical practice – 16.4% (24) vs > 10 years – 41.1% (60), χ^2= 1.090, p=0.296). Using score range of likely causes from 1 (most likely) to 8 (least likely) explanations for persistent symptoms in patients with normal TSH were identified: psychosocial factors – 2 (1–4) score, comorbidities 2 (1–4) score, chronic fatigue syndrome – 2 (1–4) score, the burden of chronic disease– 2 (1–4) score. The least likely explanations were inability of levothyroxine to restore normal physiology – 8 (7–8) score and the burden of having to take medication – 8 (6–8) score. As neutral factors were assessed patient unrealistic expectations (4 (2–6) score) and presence of underlying inflammation due to autoimmunity (6 (4–8) score).

Conclusions

Despite the appointment of levothyroxine, symptoms of hypothyroidism in such patients are noted by 88.4% of endocrinologists, that is probably due to psychosocial factors, comorbidities, chronic fatigue syndrome and the burden of chronic disease.

Block-replace therapy in the management of Graves' disease

Ana-Maria Stancu, Monica Gheorghiu, Mariana Purice, Daniela Alexandrescu & Corin Badiu

National Institute of Endocrinology, Thyroid Related Disorders, Bucuresti, Romania

Introduction

Anti-thyroid drugs (ATDs) are the first line treatment in Europe for hyperthyroidism due to Graves' disease (GD). Adding levothyroxine to ATDs, so called block and replace therapy (BRT) is still controversial.

Aim

To follow up the outcomes after treating patients with Graves' disease in a block and replace regimen.

Patients & methods

A prospective study which enrolled 33 patients with Graves's disease, from 1st January 2020 until 28th January 2021. Inclusion criteria were: age > 18 years, new diagnosis of hyperthyroidism due to GD, patients with GD following block and replace therapy. Exclusion criteria were: age<18 years, pregnancy, GD treated with radiotherapy or surgical. Recorded data at diagnosis and each visit in the hospital were regarding to thyroid function tests (TSH (N:0.5–4.5 mUI/l), fT4 (N:9–19 pmol/l), T3 (N:80–200 ng/ml)) and specific thyroid antibodies (TRAb (N:<1.75 IU/l)), thyroid ultrasonography, level of 25OH-vitamin D. Data were recorded in Microsoft Excel and analyzed in Minitab v19.

Results

28 women, aged 44.32±12.54 years and 5 men, aged 54.6±18.6 years were included. New diagnosis of GD was made for 16 women and 4 men, the rest of them were already in a BRT. The group was characterized by insufficient levels of vitamin D (mean: 20.35±9.19 ng/ml, range 7.1–35 ng/ml). At diagnosis: TSH=0.0076 ±0.0107 mUI/l; TRAb=16.2±11.8 UI/l. BRT had a mean dose of 18±17.85 mg per day of Methymazole and 38.24±23.58 mg/day of Levothyroxine. From diagnosis to first visit in a BRT, fT4 decreases from a mean of 38.6±23.2 pmol/l to 14.59±8.31 pmol/l (P < 0.05), but it was in normal range. During BRT, TRAb titer decreased from 11±13.3 UI/l at first visit to 8.6±13.3 UI/l at the second visit in the Institute. One patient had adverse reaction to Methymazole so she was switch to Propylthyouracil. The volume of thyroid gland measured by ultrasound was 25.35±13.03 cm^3. Twelve patients associated Graves' ophthalmopathy, but only two of them needed steroids.

Limitations

Small number of patients, limited time for observation, heterogeneous group (patients newly diagnosed with GD, patients in BRT for more than 6 months).

Conclusion

BRT can maintain normal levels of TSH and fT4 and can decrease TRAb levels using combined Methymazole and Levothyroxine.

Nutritional status of iodine in the basque country

Alicia Martín Nieto[1,2], Isabel Benito Castaño[1], Ines Urrutia Etxeberria[1,3,4,5], Mercedes Espada Saenz-Torre[6], Eunate Arana Arri[1], Juan Del Olmo Sedano[2], Anibal Aguayo Calcena[1,2], Josep Oriol Casanovas Marsal[1], Sonia Gaztambide Saenz[1,2,3,4,5,7] & Luis Castaño Gonzalez[1,2,3,4,5,7]

[1]Biocruces Bizkaia Health Research Institute, Bizkaia, Spain; [2]Hospital Cruces, Bizkaia, Spain; [3]CIBERDEM; [4]CIBERER; [5]EndoERN; [6]Normative Laboratory of Public Health of the Basque Government, Spain; [7]UPV/EHU

Background

Iodine is an essential nutrient necessary for the synthesis of thyroid hormones. Humans need a daily intake of 90–250 μg per day. The WHO criteria on the adequate iodine intake in the general population is: median iodine 100–199 μg/l, levels <100 μg/l in <50% of the population; <50 μg/l in <20% of the population and iodized salt consumption in >90% of households.

Objectives
The aim of this study was to establish the nutritional status of iodine in the adult population of the Basque Country, measured by the excretion of iodine in the urine.
Methods
Randomly selected participants from the study of the incidence of diabetes in the adult population (18–90 years old) in the Basque Country (2017–2018) were invited to take part in this observational study. Of the 847 selected participants, 409 provided a urine sample for the study. Ioduria was determined by chromatography. Clinical, sociodemographic and laboratory data were obtained, including thyroid hormones. All participants completed a lifestyle and eating habits survey.
Results
The mean age was 58 years old and 57.5% of the participants were women (235/409). The mean ioduria was 159 μg/l (SD 106) and the median 133 μg/l (P25-P75: 90–204 μg/l). Based on the WHO criteria, 40% of the population had an adequate iodine intake, 32% a deficit of iodine and 28% excessive levels. There were no significant differences in ioduria regardinggender, age or geographic location. Only 41% of the study population confirmed they take iodized salt.
Conclusion
According to our study, the population of the Basque Country has an adequate intake of iodine; however, the intake of iodized salt is well below the 90% recommended by the WHO. We therefore believe that public health campaigns are necessary to promote the consumption of iodized salt in our population, as well as periodic evaluations of the nutritional status of iodine.

Thyrotoxic crisis induced by amiodarone therapy

Marianna Bystrianska[1] & Adrian Bystriansky[2]
[1]University Hospital Banska Bystrica, Department of Internal Medicine, Banska Bystrica, Slovakia; [2]The Central Slovak Institute for Cardiovascular Diseases Banska Bystrica, Department of Arythmology, Banska Bystrica, Slovakia

Background
Thyrotoxic crisis (TxC) is a medical emergency status needed rapid diagnostic a urgent treatment, presented by failure or multiorgan dysfunction. Amiodarone induced thyrotoxicosis (AIT) is one of the severe complications caused by amiodarone therapy.
Aim
Analysis of patients suffered from thyrotoxic crisis induced by Amiodarone therapy, with focus on clinical picture, laboratory findings and therapeutic options.
Methods and results
A total of 35 consecutive patients with AIT during the period 2005–2019 were included. We performed retrospective analysis of 4 consecutive patients with thyrotoxic crisis, who were hospitalized on department of Internal Medicine University Hospital Banska Bystrica. All of patients were men (mean age 55 ± 4.7 years), All of analysed patients (n = 4) have been treated for arterial hypertension, 25% (n = 1) ischaemic heart disease, 50% (n = 2) suffered from heart failure and 50% (n = 2) had implantable cardioverter defibrillator. Indication for Amiodarone therapy was atrial fibrillation (n = 2) and ventricular tachyarrhythmias (n = 2). The average time of use of amiodarone until development TxC was 937 ± 241 days, median 883 days. Mean TSH in the time of diagnosis was 0.007 ± 0.06 mIU/l and mean free T4 was 55.0 ± 16.1 pmol/l (median 59 pmol/l). Mean volume of thyroid gland was 22.21 ml. Three pacients have been diagnosed as mixed type AIT, and the one of threm as AIT type 2. All of patients (n = 4) have been treated with antithyroid drugs and corticosteroids at the maximum recommended doses. 75% (n = 3) underwent urgent thyroidectomy and one was threated conservatively. The thyroid papillary microadenocarcinoma was histologically confirmed in 1 of observed patients. When comparing the two cohorts with and withoud TxC, we found that patients with TxC are 8 years younger, have higher fT4, larger volume of thyroid. The dose and duration of Amiodarone use did not differ in both groups.
Conclusion
Thyrotoxic crisis induced by Amiodarone is an endocrine emergency which is charecterized by multiple organ failure due to sever thyrotoxicosis. Risk factors of thyrotoxic crisis development in patient with AIT are: younger age, higher fT4, larger volume of thyroid, atrial fibrillation and heart failure.

Hyperparathyroidie primary & pregnancy : A case report

Merrouche Amina[1] & Azzoug Said[2]
[1]Mohamed Lamine Dabaghine Hospital, Department of Endocrinology and Metabolic Diseases EPH, Algiers, Algeria; [2]Mustapha Bacha Hospital, Department of Endocrinology and Metabolic Diseases CHU, Algiers, Algeria

Introduction
Parathyroid diseases are infrequent during pregnancy, but produce significant perinatal morbidity and maternal mortality if not diagnosed and properly managed. Primary hyperparathyroidism (PHP) is a rare disease in women of childbearing age. The incidence of the disease is unknown, but it is certainly rare, and most of the reported cases have been simple supplemented by a review of the literature.
Case presentation
We report the case of a 34 year old woman, G4P0 (03 caesarean section), pregnant at 19 weeks of amenorrhea, presents to the consultation for asthenia and a polyuro-polydipsic syndrome accompanied by muscle weakness. Biological data show hypercalcemia at 112 mg/l (81–104), hypophosphoremia at 22 mg/l (25–48), PTH 163 pg/ml (15–65) compared to a normal vitamin D with hypercalciuria at 922 mg/kg/24 h (100–300). Cervical ultrasound reveals a homogeneous highly hypoenogenic left lobar formation of irregular contours measuring 10.2 × 9.7 × 12.5 mm consistent with a parathyroid adenoma, with thyroid gland and left parathyroid lodge without abnormality. These data are therefore in favour of primary hyperparathyroidism on parathyroid adenoma. Abdomino-pelvic ultrasound: no visible lithiase, unpasceded excretory cavities. The patient benefits at 20 weeks of amenorrhea from the surgical exenosia of the left parathyroid adenoma under complicated local anesthesia of a left recurrent paralysis, anatomopathological analysis in favor of a parathyroid adenoma. Calcemia normalizes rapidly after surgery, and the patient gives birth without complication at 39 weeks of amenorrhea.
Discussion
The prevalence of primary hyperparathyroidism during pregnancy is unknown. Etiology is in 85% of reported cases, a unique parathyroid adenoma. Diagnosis is difficult due to physiological changes in pregnancy that can mask the clinical and biological symptoms of hypercalcemia (digestive disorders, hemodlution, hypoememia). Surgical exeresis is usually proposed in the second trimester of pregnancy when calcemia is greater than 2.75 mmol/l despite medical treatment, and represents an acceptable therapeutic solution as evidenced by favourable clinical-biological evolution of the mother and fetus without major complications due to surgery.
Conclusion
Primary hyperparathyroidism during pregnancy is rare, but needs to be researched in the face of a clinical presentation associated with hypercalcemia, in order to rapidly establish appropriate treatment, and reduce the risk of maternal and fetal complications

Thyroid cancer detection in routine clinical setting-pilot study

Tereza Grimmichova[1;2], Petra Pačesová[1], Martin Hill[1], Eliska Vaclavikova[1], Barbora Pekova[1], Jitka Moravcova[1], Jana Vrbikova[1], Zdenek Novak[1] & Vlasta Sykorova[1]
[1]Institute of Endocrinology, Prague 1, Czech Republic; [2]University Hospital Kralovske Vinohrady and Third Faculty of Medicine, Charles University, Department of Medicine, Prague 10, Czech Republic

Background
Most thyroid nodules are benign, but therefore it is crucial to correctly stratify the malignancy risk of nodules to avoid unnecessary invasive procedures and/or surgery, but and still identify aggressive tumors. The aim of our study was to address the potential for improvement of malignancy detection in routine clinical setting using clinical examination, risk stratification of thyroid nodules on ultrasound using the American College of Radiology Thyroid Imaging Reporting and Database System (ACR TI-RADS) and fine-needle aspiration cytology (FNAC) concurrently with molecular diagnostics.
Methods
A prospective study in 105 patients was performed. DNA from FNA samples was used for next generation sequencing to identify mutations in genes: BRAF, HRAS, KRAS, NRAS and TERT. RNA was used for Real Time

PCR to detect RET/PTC1, RET/PTC3 and ETV6/NTR3 rearrangements. All specimens were histologically confirmed. Multivariate regression (a method of orthogonal projections to latent structure, OPLS) was used for data evaluation.
Results
FNA samples were cytologically evaluated as Bethesda II (n = 16; 15.2%), III (n = 23; 21.9%), IV (n = 18; 17.1%), V (n = 24; 22.9%) and VI (n = 24; 22.9%). Histologically, 48 findings were malignant (45.7%); especially papillary thyroid carcinoma (93.8%); 54 were benign and 4 were borderline tumors (MB). Total detection rate of mutations was 4/54 in benign tissues, 41/48 in malignant and 1/4 in MB. Total detection rate of mutations was 4/16 in Bethesda II; 6/23 III; 3/18 IV; 14/24 V and 20/24 VI. The strongest relevant positive predictors for malignancy were the presence of genetic mutation (t-statistic = 14.10; $P < 0.01$), FNAC (10.39; $P < 0.01$), ACR TI-RADS (4.02; $P < 0.01$), positivity of anti-thyroglobulin antibodies (4.09; $P < 0.01$), TSH (3.6; $P < 0.01$), presence of neck resistance (2.86; $P < 0.05$) and lymphadenopathy (2.33; $P < 0.05$). In common, FNAC, ACR TI-RADS and genetic testing reached sensitivity 86.3% (95% CI 74.3–93.2), specificity 88.9% (95% CI 77.8–94.8) and diagnostic odds ratio 50.3 (15.7–161.2).
Conclusion
FNA molecular testing has seemed to have substantial potential for thyroid malignancy detection. Clinical examination, FNAC and risk stratification of thyroid nodules on ultrasound have been other relevant factors. However, a broader spectrum of molecular markers must be involved to make correct diagnosis in all patients in a routine clinical setting.

Medullar thyroid carcinoma in a patient with Hashimoto's thyroiditis – A case report

Marjeta Kermaj, Adela Haxhiraj, Violeta Hoxha, Klodiana Poshi, Dorina Ylli, Edlira Elezi, Thanas Fureraj & Agron Ylli
UHC "Mother Tereza", Endocrinology, Tirana, Albania

Introduction
Hashimoto's thyroiditis (HT) has been linked to papillary carcinoma of the thyroid, Hurthle cell cancer or even lymphoma. In contrast, there are only a few reports of co-existence of HT with medullary thyroid carcinoma. The link between them is unknown. An overall prevalence of medullary carcinoma of only 0.35% has been reported in HT patients. This prevalence is higher in female rather than male. We present the case of a female patient treated for Hashimoto's Disease that was diagnosed with medullary thyroid carcinoma during her routine medical appointment with the endocrinologist.
Case description
The patient, female of 45 years first came with headache, hair loss and extreme fatigue. She was diagnosed previously with chronic thyroiditis and was under treatment with Levothyroxine. Her physical examination did not reveal anything in particular. Her blood tests were as followed: CEA 126 ng/ml (<6.3), Calcitonin > 2000 pg/ml (<10), TG 64, TSH 14.58 (0.3–4.5), fT4 14.04 (9–20), TPO antibody 874.6 (0–30) and TG antibody 2229 (<115). Other laboratory tests were within normal range. Neck ultrasound revealed: the thyroid gland had heterogeneous hypoechoic structure, aspect HT. In the right lobe, it was evident a nodule, isoechoic, taller than wide, with dimensions 2.44 × 2.16 × 1.9 cm, with diffuse micro calcifications inside. Schinti scan with TC99 revealed a cold nodule in the right thyroid lobe. Patient's past medical history: was unremarkable, without neck irradiation. Family history: without thyroid diseases. The patient underwent total thyroidectomy and lymph nodes dissection. Histopathological examination of total thyroidectomy specimen revealed Hashimoto's thyroiditis along with medullary thyroid carcinoma, oncocytic variant inside the nodule. She was discharged from the hospital under thyroid hormone replacement treatment. A month after surgery, Calcitonin and CEA levels dropped sharply. Their measurements were repeated after 3, 6, 9, 12 months and resulted normal. The patient continues to be under endocrinologist's follow up, euthyroid and cancer-free.
Conclusion
The prevalence of the co-existence of Hashimoto's thyroiditis and medullary thyroid carcinoma is low and rarely described. It is important to know this, in order to be diagnosed and treated in time.

Cardiovascular outcome in thyroid cancer patients with thyroidectomy: a systematic review and meta-analysis

Eunkyung Lee[1], Hwa Young Ahn[2], Eu Jeong Ku[3], Won Sang Yoo[4], Kee-Hyun Nam[5], Young Jun Chai[6] & Yuh-Seog Jung[1]
[1]National Cancer Center, Goyang-si, Korea, Republic of South; [2]Chung ang University Hospital, Korea, Republic of South; [3]Chungbuk National University, Cheongju, Korea, Republic of South; [4]Dankook University Hospital, Cheonan, Korea, Republic of South; [5]Yonsei University Medical School, Korea, Republic of South; [6]Boramae Hospital, Korea, Republic of South

Thyroid dysfunction is associated with increased risk of cardiovascular disease (CVD) in general population, but it remains controversial whether the treatment of differentiated thyroid cancer (DTC) including thyroidectomy and thyroid stimulating hormone suppression add any risk of CVD compared to general population. We performed a systematic review of observational studies reporting associations between DTC and CVD in MEDLINE, EMBASE, Web of Science and other source (PROSPERO: CRD42020223057). We excluded studies with CVD evaluated as a comorbidity prior to thyroid cancer diagnosis or those with active surveillance without thyroidectomy. Risk of bias was assessed by ROBANS version 2.0. Risk estimates were pooled using random-effects and fixed-effects models when ≥ 3 studies reported data for each outcome. Eighteen studies were included. Compared to general population, DTC was associated with higher risks of atrial fibrillation (pooled risk ratio (RR) 1.55 [95% confidential interval (CI) 1.41–1.71]), coronary artery disease (RR 1.09 [1.01–1.17]), and cerebrovascular accident (RR 1.14 [1.09–1.20]), but not heart failure (RR 0.96 [0.78–1.18]) nor all-cause mortality (RR 1.31 [0.81–2.11]). To elucidate the direct effect of treated DTC on cardiovascular disturbance, clinical, echocardiographic, and hemodynamic parameters were also analyzed. DTC was associated with the higher heart rate (standardized mean difference [SMD], 0.34; 95% CI, 0.15–0.56; P = 0.002) and left ventricular mass index (SMD, 0.66; 95% CI, 0.43–0.90; $P < 0.00001$) and lower E/A ratio (SMD, −0.42; 95% CI, −0.79–0.05; P = 0.03), but not with ejection fraction nor blood pressure. In conclusion, results suggested possible association between DTC and the higher risk of CVD and atrial fibrillation as well as increased heart rate and left ventricular mass. A large prospective study with long term follow-up is required to confirm the association of two disease entities.

AEP742

Anomalous uptake of 131-iodine in an endometriosis cyst

Ana Rita Elvas, Bernardo Marques, Joana Couto, Raquel G. Martins, Jacinta Santos, Teresa Martins, Sofia Oliveira & Fernando Rodrigues
Portuguese Institute of Oncology of Coimbra FG, EPE, Endocrinology Department, Portugal

Introduction
Radioiodine whole-body scintigraphy plays an important role in the follow-up of patients with differentiated thyroid carcinoma (DTC), as it is highly accurate in detecting thyroid residues and recurrent disease. Unusual 131-iodine uptake outside the thyroid bed and areas of physiological uptake is strongly suggestive of distant metastasis. However, uncommon uptake may occur and lead to diagnostic errors.
Case report
A 45-year-old woman with a history of DTC underwent total thyroidectomy and dissection of the involved lateral neck compartment in 2005. The anatomopathological examination revealed papillary thyroid right lobe carcinoma with 25 mm - pT1b N1a Mx (8th Edition AJCC TNM Staging). She received two 131-iodine treatments in 2005 and 2006. The second post treatment whole-body scan showed a focal uptake in the left pelvic cavity. A CT scan and transvaginal ultrasound were performed, that showed a 5.6 cm cystic lesion in the left ovary. She underwent total hysterectomy and bilateral adnexectomy in 2007. The histological examination revealed an endometriosis cyst. A radioiodine whole-body scan was performed a year later and there were no areas of abnormal uptake. The patient is being kept under surveillance with no evidence of recurrent disease.
Discussion
We present a case of unusual 131-iodine uptake in the pelvic region, originated by an endometriosis cyst in the left ovary. This entity is a rare cause of incidental uptake of iodine-131, whose mechanism is not yet

completely understood. Anomalous uptake in the pelvic region requires a gynaecological evaluation and complementary tests.

DOI: 10.1530/endoabs.73.AEP742

Is there a role of measuring preoperative serum thyroglobulin?

Ana Rita Elvas, Bernardo Marques, Joana Couto, Raquel G. Martins, Jacinta Santos, Teresa Martins & Fernando Rodrigues
Portuguese Institute of Oncology of Coimbra FG, EPE, Endocrinology Department

Introduction
The measurement of serum thyroglobulin (Tg), a glycoprotein produced exclusively by follicular thyroid cells, is an important tumour marker used in the follow-up of patients with differentiated thyroid carcinoma (DTC) and residual or recurrent disease. However, its role as a screening tool before thyroid surgery is not yet defined, as benign conditions can result in its increase.
Objective
The aim of this study was to retrospectively assess whether there is a relationship between high preoperative serum Tg levels and thyroid carcinoma patients undergoing thyroid surgery.
Material and methods
Retrospective review of the medical records of patients who underwent thyroid surgery in our Institution for nodular goitre, whose serum Tg levels were assessed preoperatively.
Results and conclusions
Thirty-three patients (22 female/11 male) were identified, with a mean age of 51.7 ± 15 years. Twenty-seven (81.8%) underwent total thyroidectomy and six (18.2%), lobectomy alone. High levels of serum Tg were identified in 23 patients: 13 patients (56.5%) among 23 with malignant histopathological features and in 10 patients (43.5%) among 13 with benign histology (P = 0.143). Among four patients with higher Tg levels (Tg > 1000 ng/ml), only one had a malignant histology. Preoperative elevated levels of serum Tg showed a 56.5% sensitivity, 15.4% specificity, a positive predictive value of 54.2% and a negative predictive value of 16.7% in detecting DTC. In conclusion, there was no statistically significant association between preoperative serum Tg levels and the diagnosis of thyroid carcinoma. These results confirm the current recommendations in the management of patients with nodular thyroid disease.

Coexistence of primary hypothyroidism and hypopituitarism due to pituitary adenoma – pitfalls during levothyroxine supplementation

Aleksandra Młodoćeniec[1], Renata Orłowska-Florek[1,2] & Agnieszka Gala-Bladzinska[1,2]
[1]St. Queen Jadwiga Clinical District Hospital No.2 Rzeszów, Department of Internal Medicine, Nephrology and Endocrinology, Rzeszow, Poland; [2]Medical College of Rzeszów University, Rzeszów, Poland

95% of all cases of overt hypothyroidism are primary. It is defined as low levels of blood thyroid hormone due to disorder of the thyroid gland causing decreased synthesis and secretion of thyroid hormones. Levothyroxine is recommended as the preparation of choice for the treatment of this disease. The therapy should eliminate the symptoms of hypothyreosis, lead to the normalization of thyroid axis hormones and the avoidance of iatrogenic thyrotoxicosis. Serum TSH is the parameter recommended to monitoring the treatment. The target serum TSH depends on patient age and underlying comorbidities.[1,2]. Sometimes, such monitoring may be insufficient. We report the coexistence of primary hypothyroidism and pituitary insufficiency due to pituitary adenoma.
Case report
The patient underwent total thyroidectomy due to giant goiter (histopathological examination excluded neoplasm of thyroid gland) in 2008 year. Postoperative hypothyroidism was treated successfully. The TSH level was stable within limits (1–3 uIU/ml) on levothyroxine dose 150 and 125 μg alternately. In 2018, the TSH level was decreased (TSH <0.05 uIU/ml).The patient was asymptomatic. His weight was unchanged. There were no new medications, supplements or mistakes in levothyroxine treatment. The dose of the drug was reduced to 125 mg. The control results reveled the level of TSH,ft3 and ft4 below the normal range. The patient was admitted to the hospital. The diagnostic test revealed low levels of cortisol, ft4, ft3, testosterone,LH,GH. An MRI scan showed a 34x39x39 mm pituitary adenoma. Unfortunately, ischemic stroke complicated hospitalization, so surgery was delayed. In 2019, the patient underwent transsphenoidal tumor resection. Hydrocortisone and levothyroxine 150 μg were used as replacement therapy. Ft4 levels normalised, TSH level was 0.3 uIU/ml and ft3 remained low due to NTIS.
Conclusions
We should measure ft3 and ft4 during the monitoring of primary hypothyroidism treatment, especially when TSH level declines. TSH levels lowering during the monitoring of primary hypothyroidism treatment may be the marker of concomitant hypopituitarism.

Secondary intrathyroid localization of bronchial micro- papillary carcinoma

Mohamed Masmoudi[1], Mehdi Hasnaoui[1], Rihab Lahmar[2], Rihab Guizani[1] & Mighri Khalifa[1]
[1]Tahar Sfar Hospital Mahdia, ENT Department, Mahdia, Tunisia; [2]Tahar Sfar Hospital Mahdia, Mahdia, Tunisia

Objective
To highlight the diagnostic difficulties that a pathologist may encounter in identifying intra-thyroid metastasis when the primary cancer is not known.
Case report
A 73-year-old woman with no specific pathological history, admitted for the management of a right mean spinal swelling that had appeared two months earlier and is gradually increasing in size. The evolution was marked by the association of dyspnea and discomfort to swallowing but without signs of thyroid dysfunction. On physical examination, the thyroid lodge was free. No neck nodes are palpable. Ultrasonography of the neck showed multiple jugular-carotid and sub-digastric right glands and thyroid nodule isthmic 8 mm. A lymph node biopsy concluded to a lymph node metastasis of partly papillary carcinoma compatible with thyroid origin. The Patient had a total thyroidectomy with a bilateral recurring and straight functional neck dissection with simple operating suites. The anatomopathological examination with immunohistochemistry concluded to a thyroid metastasis of a pulmonary-induced micropapillary carcinoma. Thoracic CT showed multiple parenchymal nodules and two focal areas of right basal pulmonary parenchymal condensation.A bronchial endoscopy with biopsy showed bronchial adenocarcinoma in its micropapillary variant. The patient received 3 chemotherapy cures based on cysplatyl and Vepeside with good evolution.
Conclusion
The frequency of intrathyroidal metastases are probably underestimated. The examination of the thyroid and a fine needle aspiration cytology at the slightest doubt represents a logical course of action. Thyroidectomy, when possible, improves patient survival. The prognosis depends on the primary lesion and the uni- or multi-visceral character of the metastasis.

Case report: Inaugural diabetic ketosis revealing hyperthyroidism

Sanaa Bammou, Chtioui Sara, Rafi Sana, El Mghari Ghizlane & El Ansari Nawal
Mohamed VI University Hospital Center, Department of Endocrinology, Diabetology, Metabolic Diseases Nutrition, Marrakech, Morocco

Introduction
Secondary diabetes mellitus is seen in 10 to 70% of cases depending on the endocrinopathy involved; it can be indicative of the disease and often associated with other metabolic disorders. We report the case of a patient with inaugural diabetic ketosis revealing hyperthyroidism.

Case report
It's a 42-year-old patient with a history of gestational diabetes not followed 5 years ago, with diabetic inheritance in the brother and sister profile T2DM. Accepted for inaugural ketosis. On examination: the symptoms go back to 4 months with the onset of polyuropolydipsic syndrome with 3 nocturnal awakenings associated with urination burns and vaginal pruritus. The clinical examination revealed a goiter at the expense of the right lobe. The patient was in ketosis with normal renal and hepatic function, the infective workup is negative and the thyroid workup demonstrated hyperthyroidism with TSH at 0.01 mIU/l, T4 at 19.8 pmol/l and T3 at 7 pmol/l. Cervical ultrasound showed multiple nodules in the goiter classified as EU-TIRADS 4.3 and 2. Management of diabetes consisted of correcting ketosis and putting on premix insulin. As well as a treatment of the etiology, synthetic antithyroid drugs dose of 20 mg/day. A fine needle aspiration of the nodules is planned.
Conclusion
Diabetes mellitus secondary to endocrinopathy is not that rare. The physiopathological mechanisms are diverse. In the presence of clinical manifestations giving rise to strong suspicion of an underlying endocrinopathy, the latter should be actively sought so as not to intensify the antidiabetic treatment without treating the primary disease.

Agranulocytosis due to antithyroid drugs : A case report

Chayma Besrour, Imen Rojbi, Elyes Kamoun, Youssef Lakhoua, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Hospital Charles Nicolle, Endocrinology-Diabetology, Tunis, Tunisia

Introduction
Hyperthyroidism is a very common disease due to an overactive thyroid gland. Antithyroid drugs (ATD) represent the first line treatement. Their side effects can be severe and even potentially fatal. Among them, agranulocytosis, defined as an absolute neutrophils count less than 500/µl is the most feared one.
Observation
We report the case of 57 year-old woman with no medical history, recently diagnosed with hyperthyroidism due to Grave's disease (Anti R-TSH antibodies 19.2 UI/l). She was put under thiamazol and beta-blockers treatement. One month later, she consulted for fever (40°C), a poor state of health, labial herpes, buccal aphthous and a sore throat. The blood count revealed a leucopenia at 1660 /µl, an agranulocytosis at 0/µl and an anemia at 8.4 g/dl. The CRP level was high at 77 mg/dl. Four blood cultures were performed with a normal result, and the cytobacteriological examination of the urine as well as the chest x-ray and the abdominopelvic ultrasound did not show any abnormalities. The bone marrow biopsy concluded to a toxic agranulocytosis due to the antithyroid treatement. The thiamazol was immediately interrupted and the patient received antibiotherapy and granulocyte colony-stimulating factor (G-CSF). After 10 days of treatement, the blood count improved significantly with a white blood cell level at 13290/µl and a polynuclear neutrophils level at 10170/µl. Thus, all antithyroid drugs are contraindicated in this case and the patient benefited from a radioactive iodine therapy and she is currently with hypothyroidism.
Conclusion
Even though agranulocytosis is a rare complication that occurs in around 0.2–0.5% of patients under ATD, it can be life threatening. There for blood count surveillance before and after the initiation of the ATD is the key to an early diagnosis and an effective treatement.

Paraneoplastic hyperthyroidism in hCG-secreting metastatic testicular cancer

Bohdan Patera, Gaia Fazzino, Nicola Lanzo, Silvia Lepanto, Daniela Gallo, Adriana Lai, Eliana Piantanida & Maria Laura Tanda
Insubria University - Ospedale di Circolo e Fondazione Macchi - ASST Sette Laghi, Department of Medicine and Surgery, Endocrine Unit, Varese, Italy

Introduction
We report a case of severe thyrotoxicosis due to a metastatic testicular tumor secreting human chorionic gonadotropin (hCG), known to have a TSH-mimicking effect due to alpha-subunits' structural similarity.
Case report
In November 2020 a 38-year-old man was referred to our Department for thyrotoxicosis of unknown etiology. He had no family history of thyroid disease and his medical history had been unremarkable until August 2020, with normal thyroid function. He denied alcohol or substance abuse, was a nonsmoker and was taking no medication. One month before, a lumbosacral MRI performed because of recurrent back pain incidentally discovered multiple lesions in the aortocaval region. A CT scan showed fourty-seven bilateral solid lung lesions and extensive retroperitoneal and iliac chain lymphadenopathy. Tumor markers panel showed 180-fold increase of alpha 1-fetoprotein levels and a subsequent testicular US revealed multiple nodules with calcifications in the left testis. Pulmonary and pelvic lesions biopsies and left orchifunicolectomy were performed, with histological diagnosis of metastatic nonseminomatous germ-cell tumor (AJCC stage IIIC; 75% Embryonal carcinoma, 15% Teratoma, 10% Yolk sac carcinoma, <1% Choriocarcinoma). Clinical examination revealed tachycardia (HR 104 bpm), but no neck pain or ocular signs. The patient complained of agitation and weight loss. Laboratory tests showed suppressed TSH levels, a marked rise in free-thyroxine (FT4 36.1 pg/ml, normal range 9.3–17) and free-triiodothyronine (FT3 10.9 pg/ml, range 2–4.4) levels, with no serological evidence of thyroid autoimmunity (AbTg, AbTPO, TRAb); dramatically increased hCG levels (745.506 mU/ml, range 0–2) were detected. Thyroid US revealed normal volume, homogeneous isoechogenic echotexture (vascular pattern not available), without solid nodules. A diagnosis *per exclusionem* of HCG-induced hyperthyroidism was established and treatment with Methimazole 20 mg/day and Propranolol 40 mg/day was initiated. One week later, FT4 levels improved (FT4 26 pg/ml) and FT3 levels normalized (FT3 3.33 pg/ml). Concurrently, chemotherapy with cisplatin, etoposide and bleomycin (PEB) was started, then shifted to cisplatin, etoposide and ifosfamide (VIP) because of respiratory failure. After a sharp rise (>1.000.000 mU/ml), HCG levels progressively decreased to almost physiological levels and the thyroid function normalized as well; Methimazole treatment was tapered to 5 mg/day.
Conclusions
HCG overproduction by germ cell tumor represents a rare cause to consider in differential diagnosis of hyperthyroidism; the presence of misdiagnosed paraneoplastic thyrotoxicosis could negatively impact on clinical and pharmacological management and on patient's QoL.

Warthin-like variant of papillary thyroid carcinoma

Nádia Mourinho Bala[1], Nuno Raposo[1], José Maria Aragüés[1], Sílvia Guerra[1], Delfina Brito[2] & Cristina Valadas[1]
[1]Hospital Beatriz Ângelo, Endocrinology, Portugal; [2]Hospital Beatriz Ângelo, Pathology, Portugal

Introduction
A rarely reported histologic subtype of the papillary thyroid cancer is the Warthin-like variant (WLPTC). This carcinoma resembles the *Warthin tumour* of the *salivary gland* by virtue of a papillary pattern of *eosinophilic* tumour cells associated with a rich lymphoplasmacytic infiltrate in the cores of the papillae. Due to the its rarity, the pathological characteristics and clinical behavior of WLPTC are not well documented.
Case report
We report a case of a 51 year old female patient, with no relevant personal history and no familial history of thyroid disease. Due to the presence of palpable thyroid nodules the patient underwent a thyroid ultrasound scan. The exam documented the presence of an heterogeneous thyroid, hypoechogenic in nature, with multiple millimetric hypoechogenic nodules, favoring the diagnosis of thyroiditis. Of particular interest a 28 mm hypoechogenic solid nodule was identified on the left thyroid lobe, and two strongly hypoechogenic nodules on the right thyroid gland (13 mm and 15 mm), surrounded by multiple punctiform hyperechogenic foci. The fine-needle aspiration cytology of the largest right lobe nodule was compatible with papillary carcinoma while the left lobe largest nodule was benign. Thyroid function exams were normal and anti-thyroid antibodies were positives. The patient underwent complete thyroidectomy. The histology revealed the diagnosis of WLPTC, two foci on the right lobe, 25 mm and 5 mm in size, with no angioinvasion nor extrathyroidal extension, associated to Hashimoto thyroiditis, with large lymphoid follicles and normofollicular nodular hyperplasia. After a follow-up of six months, there is no evidence of disease.

Discussion
The Warthin-like variant of *papillary carcinoma thyroid* is a rare and relatively unknown variant of papillary thyroid carcinoma. This variant is frequently associated with *Hashimoto's thyroiditis* and it is classically diagnosed in females over the age of 50 years. The prognosis is expected to be similar to that of classic papillary thyroid carcinoma.

Increasing levothyroxine requirements in a patient with previously stable hypothyroidism

Maria Batool[1], Sinead Cadogen[2], Tommy Kyaw Tun[2], Seamus Sreenan[2], Mark Denton[3] & John Mcdermott[2]
[1]Connolly Hospital Blanchardstown, Endocrinology, Dublin, Ireland; [2]Connolly Hospital Blanchardstown, Dublin, Ireland; [3]Beaumont Hospital, Dublin, Ireland

A 44 year old woman presented with leg swelling. Past history included hypothyroidism and ulcerative colitis treated with eltroxin (100 mg/day) and azathioprine (100 mg/day) respectively. Clinical examination revealed pitting oedema to knees and a 'puffy face'. Free T4 was 5.8 pmol/l (12–22 pmol/l), TSH 84.61 mU/l (0.27–4.20), serum albumin 24 g/l (40–49 g/l). She reported good compliance with L-thyroxine and no recent gastrointestinal symptoms. L-thyroxine dose was increased to 150 μg daily. Further investigations revealed 4+ proteinuria on urine dipstick with normal creatinine. 24 hr urine collection showed 12 g proteinuria. Renal biopsy was performed. Light microscopy was normal but electron microscopy showed diffuse podocyte effacement. A diagnosis of minimal change disease likely secondary to NSAID exposure was made. She was commenced on prednisolone 60 mg/day, with remission of her nephrotic syndrome. Her thyroid function normalized and she reverted to 100 mg of eltroxin daily. Our patient presented with gross hypothyroidism and oedema which could have been mistaken for myxoedema. Her hypothyroidism had previously been stable on replacement, however, and she was compliant with her medication. Nephrotic syndrome results in urinary loss of free and protein-bound thyroid hormones and can result in increased thyroxine requirements[1]. When evaluating patients with increasing thyroxine requirements, nephrotic-range proteinuria should be considered in addition to causes such as poor compliance with treatment or malabsorption of thyroxine.

Topiramate Induced Hyperthyroidism –? New emerging evidence.

Mohammad Farhan Malik, Maha Khalid, Jesse Kumar, Siva Sivappriyan & Samantha Anandappa
Maidstone and Tunbridge Wells Hospital, Maidstone, United Kingdom

Case Presentation
A 25-year-old lady presented with symptomatic hyperthyroidism. She had a 4–6-week history of unexplained weight loss, pain in her neck and difficulty swallowing. Bloods confirmed mild hyperthyroidism with TSH 0.19 mU/l (reference range 0.27–4.2) with free T4 24.4 pmol/l (reference range 12.0–22.0), and she was commenced on carbimazole. There was no evidence of inflammation with CRP < 1 mg/l. Her mother had a thyroidectomy for thyroid cancer. Ultrasound of the thyroid showed multiple nodules with U2 features with no evidence of thyroiditis. She had positive TPO antibodies 415 IU/ml (reference range 0–5.5). Carbimazole was rapidly tapered to the lowest dose, and thyroid function stabilised. She has been under the sleep disorder clinic for severe sleepwalking and sleep-related eating disorder (SRED), which was treated with Topiramate with modest effect. Topiramate was considered a possible cause of thyroiditis, on a background of elevated TPO antibodies, and this medication was therefore discontinued.
Discussion
Topiramate was initially approved in 1995 in the UK as adjunctive treatment of partial-onset seizures. It blocks voltage-dependent sodium and calcium channels, inhibits the excitatory glutamate pathway while enhancing the inhibitory effect of GABA and inhibits carbonic anhydrase activity. In an open-label retrospective trial, Topiramate was found to be highly effective in reducing nocturnal eating in patients with chronic SRED. There have been no peer-reviewed studies of Topiramate induced hyperthyroidism; however, there are a few cases reports in the literature with no exact mechanism postulated. It is unclear whether Topiramate interacts with the immune system as postulated in non-thyroidal side effects. In our case, as the thyroid peroxidase antibodies were elevated this may have contributed to the possible effect of Topiramate on thyroid function.
Learning Points
Drug-related hyperthyroidism and thyroiditis need to be considered in biochemical thyrotoxicosis. Thorough drug history and clinical evaluation with correlating biochemistry are vital; however, there is often no definitive cause. In addition to the previous case reports of thyroid derangement observed with Topiramate, we also wanted to highlight our patient's possible link. Further research is required into the exact mechanisms however thyroid autoimmunity may be an indicator of individuals who require thyroid function monitoring during treatment with Topiramate.

Characteristics of differentiated metastatic thyroid cancers: experience at the endocrinology service of chu ibn rochd of casablanca, morocco

Kenza Sekkat, Nassim Essabah Haraj, Siham El Aziz & Asmaa Chadli
Department of Endocrinology, Diabetology and Metabolic Diseases Ibn Rochd University Hospital, Casablanca, Morocco

Introduction
Differentiated thyroid cancers DTC are metastatic in 10% of cases. The most frequent sites are the lungs, the bones, the brain and the liver. The presence of a metastasis reduces the life expectancy of patients by 60%. The objective of this work is to describe the characteristics of metastatic DTC in our service.
Methodology
Descriptive retrospective study of 740 patient files monitored at the endocrinology department of the CHU IBN ROCHD for DTC from January 1986 to April 2019. All cases of DTC with regional or distant metastases were included. The variables studied: age, histological variant, capsular intrusion, TNM stage and multifocality. Statistical analysis performed by IBM SPSS Statistics 25 software.
Results
75 patients had presented regional or distant metastases, a prevalence of 9.7%. The mean age at diagnosis was 46.4 years ± 14.2 years. The sex ratio M/F: 0.1. All patients had undergone a total thyroidectomy, 49% of them with lymph node dissection. 78% of patients underwent ira therapy with an average delay of 19 months after surgery. Metastasis were revealed in 14 cases. 56 patients had lymph node metastasis, 17 patients had bone metastasis and 13 patients had lung metastasis. The most frequent histological types were classical papillary carcinoma (53%), papillary carcinoma with vesicular differentiation (24%), followed by vesicular carcinoma (11%). Regarding the histological characteristics, capsular effraction was found in 34% of cases, vascular emboli in 16% and multifocality in 23% of cases. Analysis of the variables studied showed that patients aged over 55 had more vascular emboli with no statistically significant difference $P = 0.06$, capsular effraction was statistically more common in women $P = 0.02$. The presence of bone metastases was statistically correlated with the presence of vascular emboli $P = 0.006$.
Conclusion
The regional or long-term recurrence rate of differentiated thyroid cancers in our series is relatively similar to that found in the literature

AEP753

Predictive factors of central lymph node involvement in differentiated thyroid cancers

Mohamed Masmoudi, Mehdi Hasnaoui, Thabet Wadii, Ben Njima Marwa, Zitouni Chaima & Mighri Khalifa
Tahar Sfar Hospital Mahdia, ENT Department, Mahdia, Tunisia

Introduction
Papillary and follicular thyroid carcinomas are the most common forms of endocrine carcinomas. Lymph node involvement seems to be a low risk factor for death, but it increases the risk for loco-regional recurrences and distant metastasis. Lymph node involvement is more seen in case of papillary thyroid carcinoma, less reported in vesicular carcinoma. The aim of this work is to determine the clinicopathologic predictive factors of central lymph node involvement.
Material and methods
A retrospective study of 75 patients treated for a differentiated thyroid cancer, between 2000 and 2016.
Results
Our population consisted of 75 patients (66 women and 9 men). The mean age was 44 years [15 years - 78 years]. The mean consultation delay was 19 months. Histologic types were: papillary thyroid carcinoma (92%) and vesicular thyroid carcinoma (8%). Total thyroidectomy was performed in 74 cases, associated with a central lymph node dissection in 69 cases: unilateral in 23% of cases and bilateral in 77% of cases. Lateral lymph node dissection was performed in 25 cases: unilateral in 16% of cases and bilateral in 84% of cases. Multifocal involvement was noted in 31% of cases. Extrathyroidal extension was detected in 19% of cases. We noted a lymph node involvement in 50.6% of patients: central in all cases and lateral in 16 cases. After statistical analysis, 2 factors were identified as predictive of central lymph node involvement: multifocality ($P = 0.000$) and extrathyroidal extension ($P = 0.023$). Sex, age, histological type, tumour size and presence of vascular emboli were not correlated with central node involvement. Involvement of the central area was not significantly predictive of the involvement of the lateral area ($P = 0.105$).
Conclusion
Prophylactic central neck dissection in differentiated thyroid cancer is controversial and should only be performed selectively in high-risk patients. Our study, as well as other studies, clearly shows the possibility to estimate pre and intraoperatively, the risk of lymph node involvement in differentiated thyroid carcinomas and thus avoid unnecessary prophylactic central lymph node removal with all its morbidity.

Follicular thyroid carcinoma with lymphatic and macroscopic vascular extension

Dardouri Teheni[1], Nouira Manel[1], Chouchane Lobna[2], Boudrigua Hajer[1], Ezzine Abir[1], Charfi Hela[1], Sfar Raja[1], Ben Fredj Maha[1], Abdelkefi Mohamed[2] & Chatti Kaouthar[1]
[1]Hospital University Sahloul, Nuclear Medecine, Sousse, Tunisia; [2]Hospital University Farhat Hached, ENT department, Sousse, Tunisia

Introduction and aims
Macroscopic angioinvasion associated to lymph node metastasis from follicular thyroid carcinoma (FTC) is scarce and leads usually to a poor outcome.
Subjects and methods
We report a case of FTC with extensive vascular invasion into the right jugular vein and numerous lymph nodes. We reviewed clinical records of our patient and analysed clinical outcomes and thyroglobulin rate as well as imaging findings after radio-iodine therapy.
Results
Our patient was 60 years old female, who underwent total thyroidectomy. Histopathology exam revealed a FTC infiltrating the thyroid parenchyma and the thyroid capsule minimally with no search for malignant thyroid nodules which are supposed to be exceptional in this pattern. The patient was referred for RAI therapy. The initial post therapeutic whole body scan showed cervical uptake with high thyroglobulin levels (500 ng/ml). The second iodine scan revealed a left thoracic uptake corresponding to a costal metastasis, with persistent cervical uptake and elevated thyroglobulin. A hard dyspnea with facial and neck edema have marked the evolution of the disease, requiring a curative subcutaneous treatment with heparin and morphological exams. Cervical Tomography (CT) scan revealed a neoplasic thrombus infiltrating intraluminally the right jugular vein and numerous metastatic lymph nodes confirmed by magnetic resonance imaging (MRI). Highly challenging cooperative operation for thrombus and lymph nodes ablation has been practiced to avoid worsening clinical symptoms and mortality. Histological examination has confirmed the metastatic origin of the lesions.
Conclusion
Lymph node metastasis occur in less than 10% of patients with FTC but do not impact disease specific mortality.Vascular malignant infiltration from FTC is more frequent, and may uncommonly turn to potential life threatening clinical entity like for our patient. It requires specific management strategies with anticoagulation regimens and mostly targets the prevention of thrombus expansion as well as embolic phenomena. When feasible, thrombectomy should be seen as the best surgical procedure when an intraluminal extension of the disease is evident.

AEP755

Is there a link between the levels of vitamin D and differentiated thyroid cancer risk in multinodular goiter patients?

Alina Tudorache[1], Alice Albu[1,2] & Tatiana Scarabnii[1]
[1]Elias Emergency University Hospital, Endocrinology, Bucureńi, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucureşti, Romania

Introduction
Both vitamin D insufficiency and multinodular goiter (MNG) are widespread throughout the world, with Romanian population being no exception. However, at this point in time there is insufficient data whether there is a connection between the two or is it just a coincidence. The aim of this study is to evaluate whether there is a relationship between serum level of 25-hydroxyvitamin D (25OHD) and the risk of differentiated thyroid cancer (DTC) in patients with multinodular goiter.
Materials and methods
we performed a retrospective study which included 129 patients evaluated for euthyroid nodular goiter in a tertiary Endocrinology Department. Patients ages ranged between 18-79 years, with exclusion criteria as follows: hypo/hypercalcemia, associated endocrinopathies (excepting: diabetes, obesity, primary osteoporosis, hyperparathyroidism due to vitamin D deficiency, adrenal incidentalomas, non-functioning pituitary adenomas without pituitary disfunction), active cancer, drugs (glucocorticoids, vitamin D supplements). Laboratory evaluations included a CBC, ESR, biochemistry, TSH, fT4, 25OHD levels and a FNA, if indicated. We investigated the differences between replete and non-replete vitamin D groups, Bethesda risk groups, and correlations using SPSS 26.0.
Results
Out of the 129 patients with euthyroid MNG, 95 (73.6%) had their vitamin D levels tested with a median value of 22.30 (13.19) ng/ml. Seventy five% of the patients presented vitamin D insufficiency (10–30 ng/ml), whereas 6.25% of patients had vitamin D deficiency (<10 ng/dl). Chi-square tests showed no differences regarding the Bethesda risk among the groups defined as vitamin D replete (>30 ng/ml) ($n = 18$) and non-replete ($n = 78$) ($P = 0.445$). Patients were divided in two groups: group 1 ($n = 111$) with Bethesda I-III, including those without a FNA indication, and group 2 ($n = 18$) with Bethesda classification ranging from IV to VI. Patients in group 2 were younger (p 0.043) and had a higher TSH level (p 0.028) than patients in group 1. The two groups were similar in terms of serum level of 25OHD (p 0.445). TSH levels correlate with a Bethesda risk above IV in MNG patients in Kendall's tau correlation (p 0.028).
Conclusions
our study did not find a relationship between serum level of 25OHD and an increased risk for DTC evaluated by Bethesda classification system. Higher TSH levels were associated with a higher risk for DTC. We recommend further research to this matter.

Papillary thyroid cancer presenting with splenic infarction

Miguel Saraiva[1], Magda Garça[2], Ana Rita Costa[3], Guiomar Pinheiro[3], Ana Rita Cruz[3], Sofia Ribeiro[3], Cláudia Freitas[1] & André Carvalho[1]
[1]Porto, Endocrinology, Diabetes and Metabolism, Universidade do Porto, Portugal; [2]Hospital de Santo Espírito da Ilha Terceira, Portugal; [3]Porto, Internal Medicine, Porto, Portugal

Introduction
The close relationship between cancer and thrombotic phenomena has been widely recognized and paraneoplastic organ infarctions may occur. Reports of papillary thyroid cancer associated to paraneoplastic phenomena are particularly scarce.
Case report
A 39-year-old man with no prior relevant medical history was evaluated for acute onset of fever, malaise and mild pain referred to his left hypochondrium.

He had no clinical suspicion of infection or alterations on the complete blood count, but had an elevation of serum C-reactive protein (75.4 mg/l). His abdominal ultrasound was suggestive of splenic infarction. Despite reporting no history of intravenous drug use nor having any other obvious entrance point, the main initial diagnostic suspicion was infective endocarditis. Blood culture sets were sterile. Transthoracic echocardiogram and transesophageal echocardiogram were both negative for infective endocarditis. The patient underwent a further pro-thrombotic study which also revealed no abnormal results. Thoraco-abdominopelvic CT scan confirmed the splenic infarction with no other abnormal findings except for a contrast-enhanced nodular lesion on the right lobe of the thyroid gland. Ultrasound thyroid evaluation revealed an EU-TIRADS category 5 thyroid nodule measuring 19 × 21 × 28 mm. Fine needle aspiration cytology revealed a Bethesda category VI pattern. His thyroid function tests and calcitonin levels were within normal range. A total thyroidectomy was performed and confirmed the presence of a classical variant of papillary carcinoma. Lymph node metastasis in the central compartment were documented (T2N1Mx). The patient then underwent radioiodine ablation with 100 mCi. At last follow-up evaluation (about 6 months after radioiodine ablation) he met criteria for an *indeterminate* biochemical response (thyroglobulin 0.7 ng/ml).

Discussion

Splenic infarctions with no obvious cause are frequently attributed to endocarditis but a paraneoplastic etiology must always be discarted. In our case, a papillary thyroid carcinoma with nodal metastasis was found and assumed to be linked to this rare paraneoplastic feature. To our knowledge, this case represents the first report of organ infarction associated with a differentiated thyroid cancer. When evaluating patients with thrombotic events with no other recognizable cause, our case reinforces the need for searching occult tumors that should include the thyroid gland.

Fetal and neonatal thyrotoxicosis after 12 years from thyroid surgical ablation for Graves disease

Roxana Bohaltea[1], Alina Sucaliuc[2], Elena Szini[1], Corina Grigoriu[1] & Corin Badiu[2]

[1]"Carol Davila" University of Medicine and Pharmacy, Obstetrics, Bucharest, Romania; [2]National Institute of Endocrinology, Thyroid related disorders, Bucuresti, Romania

Clinical fetal thyrotoxicosis is a rare disease occurring in 1-5% of pregnancies with Graves disease. Although transplacental passage of maternal TSH receptor stimulating autoantibodies (TRab) to the fetus does occur early in gestation, the fetal concentration is low until the end of second trimester, but reaches maternal levels in the last period of pregnancy. The mortality of fetal thyrotoxicosis is 12–20% mainly due to heart failure. We present a case of fetal and neonatal thyrotoxicosis with favorable development and evolution in a 37-year-old woman, known with Graves disease with ophthalmopathy and thyroidectomy performed 12 years ago, with hypothyroidism and post-surgical hypoparathyroidism, in substitution treatment, which has in history a complicated pregnancy with fetal anasarca, premature birth and neonatal death. Pregnancy begins with euthyroid status and persistently increased TRAb (40 IU/l), whose value reaches 101 IU/l at 20 weeks gestational age, decreases rapidly within 1 month to 7.5 IU/l at the same time with the installation of fetal tachycardia in the absence of any other signs of fetal thyrotoxicosis, rapidly remitted under methymazole 20 mg/day. The patient gives birth by cesarean section at 37 weeks gestational age to a live, male fetus, 2530 g with mild congenital hyperthyroidism (fT4 = 3.46 ng/dl. fT3 = 7 pg/ml), TRAb titer 18.6 UI/l, which gradually disappears under methymazole (0.5 to 2 mg/kg body weight/day) and propranolol within 8 weeks postpartum. In conclusion, monitoring for signs of fetal thyrotoxicosis by periodically assessing fetal growth, heart rate, and constant monitoring of maternal anti-TSH antibody titer to detect massive decline through massive transplacental passage may successfully guide the progression of pregnancy associated with Graves disease.

AEP758

Prevalence of autoimmune thyroid diseases in patients with prolactinomas and non-functioning pituitary adenomas

Aytan Hajizada[1] & Gonca Oruk[2]

[1]İzmir Katip Celebi University, Ataturk Education and Research Hospital, Division of İnternal Medicine, Turkey; [2]İzmir Katip Celebi University, Ataturk Education and Research Hospital, Endocrinology Clinic, Turkey

Aim

Prolactinoma, which is the most important cause of hyperprolactinemia, is an adenoma that originates from lactotropic cells of the pituitary and causes excessive prolactin release. Besides various physiological effects, the immunoregulatory effect of prolactin and its role in the development of autoimmune diseases are well known. The thyroid gland is one of the organs most frequently affected by autoimmunity. However, in our country, there are few studies examining the relationship between autoimmune thyroid disease (AITD) and prolactinoma. With this study, we aimed to investigate the prevalence of AITD in patients diagnosed with prolactinoma and non-functional pituitary adenoma and to determine the necessity of investigating prolactinoma patients in terms of AITD after diagnosis.

Material and methods

A total of 231 patients were included in the study. 93 patients (66 women/27 men) were included in the prolactinoma group, 68 patients (47 women/21 men) in the NFPA group, and 70 patients (45 women/25 men) in the control group. Pituitary size in patients with prolactinoma and NFPA, serum prolactin level in patients with prolactinoma, thyroid function tests, thyroid autoantibody (anti-Tg and / or anti-TPO, TRAB), thyroid US findings, thyroid fine needle aspiration biopsy and thyroidectomy results of all patients were recorded.

Results

AITD was found in 38.7% (n: 36) of patients in the prolactinoma group, 27.9% (n: 19) of patients in the NFPA group, 37.1% (n: 26) of patients in the control group, and total it was detected in 35% (n: 81) of the patients. There was no significant difference between the groups in terms of the presence of AITD (p: 0.334). Autoantibody positivity and AITD were more common in individuals with microadenomas in the prolactinoma group (p: 0.039, p: 0.019, respectively).

Conclusion

Although there was no statistically significant difference in the prevalence of AITD between the groups, the frequency of AITD in the prolactinoma group was higher than the frequency of AITD reported in previous studies. Another result was that AITD was detected more in patients with microadenoma in patients with prolactinoma than in patients with NFHA. For this reason, it would be beneficial to investigate all newly diagnosed prolactinoma patients in terms of AITD in case of clinical necessity.

Keywords: prolactinoma, hyperprolactinemia, non-functioning pituitary adenoma, autoimmune thyroid disease, hashimoto.

The fluctuation the oxygen delivery during thyroidectomy in the thyrotoxicosis syndrome patients

Sergii Dubrov[1], Gennadii Suslov[1], Sergii Tarasenko[1], Vladyslav Maznichenko[1], Volodymyr Palamarchuk[2] & Volodymyr Voitenko[2]

[1]Bogomolets National Medical University, anesthesiology and intensive care, Kyiv, Ukraine; [2]Ukrainian Scientific and Practical Center of Endocrine Surgery, Transplantation of Endocrine Organs and Tissues of Public of the Ministry of Health of Ukraine, endocrine surgery, Kyiv, Ukraine

Objectives

Impact of inhalation anaesthesia (IA) during thyroidectomy in the thyrotoxicosis syndrome (TTS) patients on the fluctuation the oxygen delivery (DO2).

Materials

90 TTS patients undergoing thyroidectomy. Depending on the type of anaesthesia, patients were divided into the «balanced analgesia-sevoflurane» group (BA-S) – 44 patients (where bilateral superficial cervical plexus blockade (BSCPB) was added to IA and was used IA in minimal flow scheme with FGF = 400 ml/min) and «control-sevoflurane» group(C-S) – 46 patients (monoanaetsthesia with FGF = 1000 ml/min). The anaesthetic depth control was performed by monitoring the bispectral index. The perioperative period was divided into the following stages: Stage 1 – primary examination by the anaesthesiologist; Stage 2 – the patient arrived at the operating room and connected to the monitoring; Stage 3 – immediately after anaesthesia induction and trachea intubation; Stage 4 – surgery start; Stage 5 – thyroid removal; Stage 6 – after wound suturing (end of surgery); Stage 7 – 24 hours after surgery. At all stages were assessed the hemodynamic parameters with measuring cardiac output (CO) by the estimated continuous cardiac output (esCCO) monitoring and oxygen delivery (DO2).

Results

The results indicate that IA with sevoflurane has an effect on hemodynamic parameters. The highest depression of DO2 has been noted at the stage 3 – after the IA induction and its initiation. Decreasing DO2 values was noted in

both groups vs initial stages nr.1-2 (see Table.). It was found that in the next stages 4–6, the highest DO2 values were significantly noted in BA-S vs C-S, where use less aggressive scheme of IA due to better nociceptive control with BSCPB. The use of FGF = 2000 ml/min for IA induction and 400 ml/min for basic IA in BA-S reduces DO2 to a lesser extent compared to FGF = 4000 ml/min and 1000 ml/min in C-S respectively.

Table. Oxygen delivery (ml/min × m^2) in groups (M ± m)

Groups	BA-S	C-S
Stage 1	544.4 ± 12.2	542.3 ± 17.1
Stage 2	545.9 ± 11.8	546.3 ± 14.1
Stage 3	498.7 ± 13.1	478.1 ± 14.2
Stage 4	505.8 ± 12.0	483.8 ± 11.1
Stage 5	521.5 ± 10.5	513.7 ± 10.4
Stage 6	498.9 ± 10.7	481.2 ± 10.0
Stage 7	495.6 ± 13.9	480.2 ± 9.9

Conclusions.
The study highlights the negative impact of both scheme general IA with sevoflurane on oxygen delivery in TTS patients, however use BSCPB affords reduced negative impact on oxygen delivery due to less doses IA.

Graves' Disease after COVID-19

Antonio Moreno Tirado, Paloma González Lázaro, Cristina Contreras Pascual, Cristina Montalban Mendez, Maria Zhao Montero Benítez & Florentino Del Val Zaballos
La Mancha Emergency Hospital Center, Endocrinology, Alcázar de San Juan, Spain

Introduction
Graves' Disease is an autoimmune syndrome that include hyperthyroidism, goiter, thyroid eye disease, and occasionally, a dermopathy called pretibial or localized myxedema. As each autoinmune ailment to develop in sufferers with genetic susceptibility after a certain environmental exposure (infection, stress…). COVID-19 can cause both pulmonary and systemic inflammation, potentially determining multi-organ dysfunction. Since the outbreak of the SARS-CoV-2 pandemic, there have been many reviews of autoimmune illnesses brought about with the aid or associated with COVID-19. Our objective is to report a case of Graves' Disease ocurring after recuperation from moderate coronavirus disease 2019 (COVID-19).
Case report
We describe a case of autoinmune hyperthyroidism (Graves' Disease) ocurring after SARS-CoV 2 infection. A 24-yeas-old woman was admitted to hospital emergency department on October 29, 2020 reporting fever, myalgia, cough and general malaise for three days. Naso-pharyngeal swab test for SARS-CoV-2 was positive and chest X-ray turned into normal. She did not require hospitalisation and was discharged symptomatically. A week later she returned to the emergency room beacause of a sense of dizziness, tremor and palpitations. The EKG confirmed sinus rhythm at one hundred thiry beats per minute without others alterations. Thyroid function was assessed, showing suppressed serum TSH with increased free thyroxine. Also this analysis showed IgM and IgG against SARS-CoV-2 were positive. The female pronounced having lost 3-5 kgs in the last month, sweating and distant tremor. No goiter was found and she referred no cervical pain. She denied Family history of thyroid diseases. We requested thyroid antibodies and treatment with a combination of methimazole and beta blocker was started on Nov 13th, 2020. The patient started follow-up. On Dec 15th, 2020 and refered clinical improvement. The laboratory testing results included suppressed TSH, normal free T4 and free triiodothyronine, TSH receptor antibodies were positive. Clinical presentation, ultrasound and positive TSH receptor antibodies are well matched with a diagnosis of Graves' disease.
Conclusions
We file the development of Graves' Disease in a patient 1 week after the medical onset of SARS-CoV-2 infection. Previous chencking out of thyroid function was normal, and she had no medical signs or symptoms of hyperthyroidism previous to her contamination with COVID-19. Whether COVID-19 contributes to the development of Graves' Disease, or the occurrence is coincidental, calls for definitive studies. This presentation may also align with the idea of a viral link in the development of autoimmune thyroid disease in people with genetic predisposition.

Management and outcome of Graves orbitopathy

Hiba-Allah Chatti, Ibtissem Oueslati, Rihab Laamouri, Meriem Yazidi, Fatma Chaker & Melika Chihaoui
La Rabta Hospital, University of Tunis El Manar, Faculty of Medicine, Endocrinology, Tunis, Tunisia

Introduction
Graves orbitopathy is the main extra thyroidal manifestation of Graves' disease, though severe forms are rare (< 5%). Management of Graves orbitopathy is often suboptimal, largely because available treatments do not target pathogenic mechanisms of the disease. The aim of our study was to evaluate different treatment modalities and assess their impact on the outcome of Graves orbitopathy.
Patients and methods
We conducted a retrospective study including 50 patients with Graves orbitopathy. Clinical and therapeutic data were collected.
Results
Participants had a mean age of 41.1 ± 16.6 years and a sex-ratio (M/F) of 0.38. Eighteen patients were smokers. Proptosis was bilateral in 96% of cases and asymmetric in 57%. Referring to EUGOGO criteria, 32 patients had a mild form, 15 patients did not receive any treatment and 17 had local topical eye care. The outcome was marked by stabilization in 20 patients, remission in 2 patients and regression of manifestations in 7 patients. Thirteen patients had a moderate to severe form and were put on oral glucocorticoids (Prednisone 0.5−1 mg/kg/d) in 5 cases and on intravenous glucocorticoids (Methylprednisolone 1 g/d for 3 consecutive days) followed by oral glucocorticoids in 8 cases. The outcome in this group was marked by worsening in one case. Five patients had a very severe orbitopathy and were treated with intravenous glucocorticoids (Methylprednisolone 1 g/d for 3 consecutive days followed by 500 mg repeated every week for 6 weeks). Two of them got their ocular manifestations regressed and two patients got their orbitopathy stabilized. Absence of response was noticed in one case.
Conclusion
Our study illustrated the difficulty of management of Graves orbitopathy which remains a therapeutic challenge and dilemma. Novel pharmacological treatments are on the horizon and might target pathogenetic mechanisms of the disease better than glucocorticoids.

clinical aspects of cardiothyreosis in adult population of southern tunisia

Sawssan Ben Teber, Mouna Elleuch, Hadj Kacem Faten, Dhoha Ben Salah, Nadia Charfi, Nabila Mejdoub, Mouna Mnif, Fatma Mnif & Mohamed Abid
University Hospital Hedi Chaker, Endocrinology, Sfax, Tunisia

Introduction
Cardiothyreosis is the most dreadful complication of hyperthyroidism. In Tunisia, cardiothyreosis has rarely been analyzed. The aim of our study was to describe the clinical aspects of this disease in an adult population of southern Tunisia.
Methods
Retrospective study (January 1999 to December 2018) including all cases of hyperthyroidism with cardiothyreosis followed in our department.
Results
100 cases of cardiothyreosis were collected with a prevalence of 16, 3%. Mean age was 49, 3 ± 13 years and sex ratio was 0, 75. The most common causes of hyperthyroidism were Grave's disease (61%), Hashimoto thyroiditis (21%) and toxic multi-nodular goiter (11%). The delay of cardiothyreosis appearance was 18, 94 months and cardiothyreosis was inaugural in 54%. The most common symptoms of hyperthyroidism were weight loss (91%) and flushing (86%). The mean concentration of TSH and free T4 (FT4) were 0,042 µUI/ml and 59, 6 pmol/l, respectively. Subclinical hyperthyroidism was found in 11% of patients. Hypocholesterolemia (85%) and hepatic cholestasis (80%) were the most frequent biological abnormalities. Echocardiographic findings showed low left ventricular

ejection fraction in 44,6%, pulmonary hypertension in 43% and right ventricular dilatation in 33.8% patients. Atrial fibrillation (AF) and cardiac heart failure (CHF) were the most noted manifestations of cardiothyreosis (75% and 56% patients, respectively). 37% of patients had concomitant AF and CHF. Those patients were significantly younger, have more anemia, hepatic cholestasis and pulmonary hypertension ($P > 0.05$).
Conclusion
The prevalence of cardiothyreosis is relatively frequent in our country. Cardiac complications are dominated by atrial fibrillation and CHF. Cardiothyreosis may occur in young patients and during subclinical hyperthyroidism.

Immune-related adverse effects as predictors of the response to ANTI-PD-1 immunotherapy: a clinical and diagnostic challenge

Maria-Piedad Picazo-Perea[1], Miguel-Angel Ruiz-Gines[1], Julia Sastre[2] & David Melguizo-Melguizo[1]
[1]Virgen de la Salud University Hospital, Laboratory Medicine, Toledo, Spain; [2]Virgen de la Salud University Hospital, Endocrinology, Toledo, Spain

Introduction
Current rise in use of monoclonal antibodies to Immune Check Point inhibitors (ICPIs) has led to the appearance of a great variety of immune-related adverse effects (irAEs), mainly affecting gastrointestinal tract, skin, liver and endocrinological system. With a variable prevalence (4–21%), thyroid dysfunction (TD) is the most common immune-mediated endocrinopathy. However, in the literature, it occurs in different patterns and levels of severity and its etiology is still unknown. Nivolumab is a monoclonal antibody, ICPI, indicated in advanced melanoma which acts by binding to the PD-1 receptor (programmed cell death protein 1), enhancing the immune response against tumor cells. We report a case of Nivolumab-induced thyroiditis in a woman with non-mutated BRAF cutaneous melanoma.
Case
An 82-year-old woman with non-mutated BRAF cutaneous melanoma (T3N0M1c) begins treatment with Nivolumab. The patient has no history of thyroid disease. After first cycle of Nivolumab, it is observed: TSH 0.008 uU/ml (0.50–4.00), FT4 1.80 ng/dl (0.80–2.00) and FT3 2.290 pg/ml (1.70–4.00). In following cycles, laboratory analysis revealed hypothyroidism: TSH 62.229 uU/ml, FT4 <0.400 ng/dl and FT3 <1.070 pg/ml. Due to sudden elevation of thyrotropin, antithyroid antibodies are requested: anti-peroxidase IgG (TPO) 27.56 IU/ml (0.00–5.61) and anti-thyroglobulin IgG (ATG) 518.59 IU/ml (0.00-4.11). At this time, replacement therapy with levothyroxine 50 micrograms is prescribed. Hypothyroidism continues in next cycle (TSH 66.638 uU/ml) and it is decided to increase the dose of Levothyroxine to 175 micrograms. Subsequently, TSH decreases to 3.143 uU/ml and the patient is currently continuing her anticancer treatment (Nivolumab) and thyroid replacement, remaining euthyroid.
Conclusion
Thyroiditis induced by amiodarone, lithium or interferon-alpha are well known. However, ICPI immune-mediated thyroiditis constitute a pathology whose characteristics, patterns and prevalence have yet to be determined. We present a case of thyroiditis with a sudden suppression of TSH, prior to its extraordinary elevation, which later normalizes with administration of levothyroxine, which reflects the importance of early diagnosis to avoid suspending antitumor treatment. Thyroid function monitoring is crucial to allow optimization of causal treatment since it may be necessary to modify anti-PD-1 dose or proceed to withdrawal in severe thyroid disfunction. Recent studies associate ICPI immune-mediated thyroiditis and increase of antithyroid antibodies with an improved overall survival and progression-free survival. So, in the future these irAEs could be considered a new prognostic marker in cancer patients with Anti-PD-1 immunotherapy and should be diagnosed correctly.

Amiodarone-induced hyperthyroidism

Mouna Elleuch, Hamdi Frikha, Dhoha Ben Salah, Salah Ameni, Nadia Charfi, Fatma Mnif, Nabila Rekik Majdoub, Mouna Mnif, Hadj Kacem Faten & Abid Mohamed
Hedi Chaker Hospital, Department of Endocrinology, Sfax, Tunisia

Background
Amiodarone is a widely-used anti arrhythmic medication. Amiodarone-induced hyperthyroidism (AIH) develops in 3% of amiodarone-treated patients. AIH is classified as type 1 or type 2. Type1 AIH occurs in patients with underlying thyroid condition while Type2 AIH is a result of amiodarone causing a subacute thyroiditis. Appropriate therapy for amiodarone-induced hyperthyroidism requires a careful diagnosis that may be difficult to achieve.
Aim
The aim of this study is to describe epidemiological, clinical and biological features of AIH, study the followed therapeutic strategies and report their clinical and biological outcomes.
Methods
We retrospectively analyzed the data of Tunisian patients affected with AIH from 1996 to 2020.
Findings
We reported data of 15 patients affected with AIH (5 men, 10 women), aged 54 years old on average, all from the Tunisian south. Type1 AIH was reported in 10 patients and type2 AIH in 5 patients, none of them was known to have a prior thyroid condition. Amiodarone was prescribed to treat atrial fibrillation in all patients with a dose of 200 mg daily, 5 days per week. Average symptoms onset term was 5.4 months for type1 AIH (0–24) and 16 months for type2 AIH (2-30). All patients exhibited clinical signs related to thyrotoxicosis. Most common symptoms were tremor, nervousness, palpitation, and sweating. No sign has shown to be statistically related to a AIH subtype except for exophthalmia which was seen only in patients with type1 AIH. Goiter was identified in all patients with type1 AIH but only in 2 patients with type2 AIH. Biologically, all patients had high FT4 and low TSH serum level except for one who had high TSH and FT4 serum level. Only 3 patients, all from type 1 AIH group, had serum antithyroid auto-antibodies. Scintigraphic imaging showed mild iodine fixation in type1 AIH group and absence of iodine fixation in type2 AIH group. While all patients were ordered to interrupt Amiodarone protocols, different antithyroid treatments were used for type1 AIH patients, 50% of them evolved to hypothyroidism. Patients with type2 AIH were followed up until euthyroidism was obtained (8 months on average).
Conclusion
Amiodarone-induced hyperthyroidism is a major adverse effect of Amiodarone. Careful history, physical examination, immunological tests and thyroid imaging are key to distinguish between AIH subtypes which is an important step for determining further management. Finally, we argue for the assessment of thyroid function before and while using Amiodarone.

Graves' disease and myasthenia gravis: About a rare association

Hind Asbar, Maryame Benlafqih, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
Mohammed VI University Hospital of Marrakesh, Department of Endocrinology, Diabetes, Metabolic Diseases and Nutrition, Mohammed VI University Hospital, Marrakesh, Marrakesh, Morocco

Introduction
Graves' disease is found in 5% of patients with myasthenia gravis. It's a described but rare association that addresses pathophysiological, diagnostic and management challenges. We report a case of Graves' disease revealed by an orbitopathy in a patient with coexisting mysthania gravis.
Case report
A 40-year-old woman with established myasthenia gravis presented to the emergency room with upper eye lid ptosis and bilateral eye protrusion for 3 months. It was associated with a two-week history of palpitations, tremors, irritability and moderate weight loss. Thyroid function was assessed, showing suppressed TSH (0.01 µUI/ml), elevated free thyroxine (46 pmol/l) and positive autoantibody tests. Ultrasound found an enlarged hypervascular thyroid gland. The diagnosis of graves' ophtalmopathy with coexistent myasthenia gravis was retained. Treatment initially consisted of antithyroid drug by carbimazol before performing a thyroidectomy.
Discussion
The association between Graves' disease and myasthenia gravis has been described for decades, but the exact mechanism for such coexistence is not clearly understood. It seems, however, that autoimmunity and genetic factors play a role in this association. The symptoms of the two conditions may overlap. Graves' ophthalmopathy shares with myasthenia gravis the presence of extraocular muscle damage but is differentiated by the presence of a red, inflammatory eye and exophthalmos. Treatment of the two conditions can be challenging, as the treatment of an entity can worsen

the other. Propanol is contraindicated in this case and radical treatment of hyperthyroidism is recommended.
Conclusion
The association between Graves' disease and myasthenia gravis has been recognized. The distinction between the two autoimmune diseases can be difficult as symptoms may overlap. This association should be known by physicians as it implies diagnostic and therapeutic measures.

Thyroidian abscess (about an observation)

Ghammmam Monia, lobna chouchane, Mouna Bellakhdhar, Bel Hadj Miled Heyfa, Kermani Wassim & Abdelkefi Mohamed
Farhat Hached Hospital, ENT, Sousse, Tunisia

Aims
Studying the clinical presentation, paraclinical explorations, and therapeutic modalities of thyroid abscess.
Materials and methods
We report the observation of a diabetic patient with multiple thyroidian abscesses, hospitalized in the ENT department.
Observation
The patient is 55 years old, diabetic, treated one month before admission for urinary tract infection. She came to us for increasing lower anterior cervical enlargement rapidly evolving volume in a febrile environment. On examination: Swelling of 3cm of large firm axis, mobile at swallowing, softening with Inflammatory signs looked on. The rest of the exam was without peculiarities. Biology: biological inflammatory syndrome (leukocytosis at 12100, accelerated VS and CRP high) blood glucose 10 mmol/l, hyperthyroidism with TSH at 0.11 µUI/l and T4 at 30 pg/ml. Cervical ultrasound: thyroid gland of altered appearance heterogeneous site of multiple formations cystic hypoechogenic. Cervical CT: multiple well-defined hypodense lesions with peripheral elevation after injection. The puncture brought back frank pus with bacteriological examination: a Klebsiella pneumoniae. Before the history of urinary tract infection, an ECBU was practiced, it allowed to isolate after culture the same germ. The patient was given antibiotic therapy adapted to the isolated germ. Evolution: collection at the end of 5 days which had needed its flattening under general anesthesia. The suites were simple.
Conclusion
Thyroid abscesses are a rare pathological entity. This may be suppurated thyroiditis complicated by an abscess, a thyroid abscess developed in contact with a contiguous infectious home, or from a secondary location to a remote infectious home. The diagnosis of thyroid abscesses is often delayed given the polymorphism of clinical pictures. The most commonly encountered germs are streptococcus and staphylococcus. Treatment is based on intravenous antibiotic therapy adapted to the antibiogram associated with a surgical procedure.

Thyrotoxicosis and its association with sarcopenia

Gergana Marinova[1] & Mira Siderova[1,2]
[1]Medical University "Prof. P. Stoyanov", Varna, Department of Endocrinology and Metabolic Diseases, Varna, Bulgaria; [2]University Hospital "St. Marina", Clinic of Endocrinology and Metabolic Diseases, Varna, Bulgaria

The aim of this study was to assess the physical well-being among women with thyrotoxicosis. It was important to investigate the relationship between thyrotoxicosis and muscle quantity and quality as being components of sarcopenia.
Methods
36 women over 40 years of age with thyrotoxicosis took part in this cross-sectional study. After excluding factors affecting physical performance and body composition 13 women remained (mean age 64 ± 9.38 years). Anthropometric parameters were measured. Grip strength was used to assess muscle strength. As recommended by The European Working Group on Sarcopenia in Older People 2 (EWGSOP2), appendicular skeletal muscle mass (ASM), adjusted for body size (ASM/height^2) was used to asses muscle quantity. Physical performance was measured by gait speed test. We divided women in two groups: group A- patients with newly diagnosed thyrotoxicosis prior to treatment and group B- patients who had already started treatment. Group A consisted of 46.2% of the participants (6 women) and group B- 53.8% (7 women).
Results
We found no association between thyroid hormone levels and grip strength, gait speed or ASM/height^2. Only the anti-thyroid peroxidase antibodies (TPO-Ab) correlated negatively with borderline significance with gait speed (r –0.546; p 0.054). A statistical significant positive correlation was established also between TPO-Ab and ASM/height^2 (r 0,697; p 0.008). Although insignificant, a tendency for decreasing values of muscle strength and mass in group A compared to group B was observed. Probable sarcopenia is identified by low muscle strength and while it didn't reach the cut-off point for sarcopenia, it was lower in group A (23.5 ± 10.291 kg). It tended to increase and reached normal levels in group B (31.86 ±10.107 kg). The same tendency was observed for muscle mass and gait speed - they were lower in group A and increased in group B. Only 2 of the patients in group A had grip strength less than 16 kg, and there was 1 patient with borderline value (19 kg). All the three of them were diagnosed with severe sarcopenia by additional documentation of low muscle quantity and low physical performance. Thus the frequency of sarcopenia was 50% in newly diagnosed patients with thyrotoxicosis. None of the women in group B met the criteria for sarcopenia.
Conclusions
Despite the small number of women in this study, we can conclude that untreated thyrotoxicosis is a risk factor for decreased muscle strength, muscle quantity and physical performance and thus could cause secondary sarcopenia.

Is it necessary to perform a thyroid evaluation on patients who will undergo parathyroidectomy for primary hyperparathyroidism?

Andrea Cruz[1], Rocío Revuelta[1], Ana castro[1], Almudena Vicente[1], Enrique Castro[1], Julia Sastre[1], Manuela Mollejo[2] & Miguel Carrasco[1]
[1]Complejo Hospitalario de Toledo, Endocrinology and Nutrition, Spain; [2]Complejo Hospitalario de Toledo, Pathology, Spain

Introduction
The association of autoimmune, nodular or neoplastic thyroid disease and primary hyperparathyroidism (PHPT) has been reported in 17 to 84% of cases. In the surgical treatment of PHPT, simultaneous thyroidectomy may be necessary to optimize surgical access and / or when there is abnormal thyroid pathology. On the other hand, an incomplete diagnosis in the previous study of PHPT increases the risk of not removing clinically significant thyroid lesions.
Objective
To analyze the prevalence of thyroid disease (TD) associated with PHPT in patients undergoing parathyroidectomy, as well as the frequency with which simultaneous thyroidectomy had to be performed.
Methods
The medical records of 156 patients diagnosed with PHPT and operated on in our Hospital between 2005 and 2017 were retrospectively reviewed. The statistical analysis was performed with the SPSS V21 program.
Results
The mean age was 56.4 years (± 12.7), with 80.3% being women. The prevalence of TD was 52.6% (n = 82), being significantly more frequent in women (89% vs 11%; P <0.01). Thyroid nodular disease (TND) was diagnosed in 36.5% (n = 57) (34% multinodular goitre and 2.5% single nodule). Autoimmune thyroid disease (ATD) in 23.6% (n = 37) and papillary thyroid cancer (PTC) in 3.2% (n = 5). Fifty-two patients (33.3%) underwent simultaneous total or partial thyroidectomy, of which 75% (n = 39) had TND. PTC was incidentally diagnosed in one patient. TND was diagnosed preoperatively by radiological imaging techniques in 92.3% (35 by ultrasound and 1 by CT scan).
Conclusions
1. In our series of PHPT patients undergoing surgery, TD was associated in more than half of the cases. 2. Simultaneous thyroidectomy was required in 33.3% of all parathyroidectomies performed, with only 1 case of malignant lesion detected incidentally. 3. These findings highlight the need for a pre-surgical diagnosis of TD in patients with PHPT who are going to be operated on.

Fluctuations of thyroid autoimmunity pattern in a female patient with excessively elevated TRAb titers- a case report

Dimitrios Askitis[1] & Athanasios Zissimopoulos[2]
[1]Private Practice for Endocrinology, Alexandroupolis, Greece; [2]University Department of Nuclear Medicine, University Hospital of Alexandroupolis, Alexandroupolis, Greece

Introduction
Thyroid autoimmunity comprises a dynamic entity and may manifest with different forms over the course of time at the same patient, thus causing fluctuations in thyroid functionality. Hereby, we present the case of a patient treated for hypothyroidism of autoimmune etiology, who developed hyperthyroidism accompanied by an excess of thyrotropin receptor autoantibodies (TRAb) and was followed by multiple swings in the thyroid state over an 1.5-year period of time.
Case report
A 36-year old smoking female patient receiving supplementation therapy with levothyroxine 88 μg in terms of chronic hypothyroidism presented for endocrinological evaluation due to newly detected symptomatic hyperthyroidism. She reported no signs/symptoms of orbitopathy. The neck ultrasound revealed a pattern typical of autoimmune thyroiditis with diffuse heteroechogenicity and inhomogeneity accompanied by elevated blood flow; the adjunctive laboratory evaluation showed an excess of thyroid autoantibodies and TRAb-titers of 23 IU/l (reference range <2). As a diagnosis of thyrotoxicosis due to Graves' disease seemed to be confirmed, levothyroxine was paused and the patient was started on methimazole 15 mg daily but developed in 6 weeks overt hypothyroidism. Due to the rapid manifestation of iatrogenic hypothyroidism a switch of diagnosis to a possible rare variant of late-onset hashitoxicosis with elevated thyrotropin-receptor blocking autoantibodies was presumed. The thyrostatic therapy was paused and the patient became euthyroid in one month. The euthyroid state persisted over the next 5 months, but a relapse of subclinical hyperthyroidism with partially suppressed TSH and a new onset of hyperthyroid symptoms were manifested and a low dose of methimazole (2.5 mg daily) was prescribed. Euthyroidism was restored in one month and mild subclinical hypothyroidism developed 2 months later. A cessation of methimazole led to moderate subclinical hyperthyroidism relapse without thyroid specific symptoms. The patient underwent thyroid scintigraphy, which showed a pattern typical of Graves' disease. As euthyroidism was automatically restored after scintigraphy performance the patient remained without thyroid specific medication and is actually clinically and biochemically euthyroid.
Conclusion
Thyroid dysfunction due to autoimmunity has a potential of multiple swings and manifestations, possibly due to the switch of relative activity of thyroid related autoantibodies, thus causing unexpected fluctuations from hypo- to hyperthyroidism and vice versa. Although these swings do not represent the typical pattern of autoimmune thyroid disorders they should always be taken into account as they may trigger rapid changes in the thyrometabolic state and influence the path to diagnosis confirmation and subsequent choice of medical treatment.

Thyroid pathologies in acromegaly

Ajili Rihab, Hasni Yosra, Ben Abdelkarim Asma, Saad Ghada, Kacem Maha, Maaroufi Amal, Chaieb Molka & Ach Koussay
Farhat Hached Sousse, Endocrinology, Tunisia

Introduction
Acromegaly is a rare disease, but serious in its complications. It is a multisystemic pathology also affecting the thyroid. The aim of our work is to study thyroid involvement in acromegaly.
Patients and methods
This is a retrospective study of acromegalic patients, in the endocrinology department of Sousse over a period of 20 years.
Result
These are 40 acromegaly patients, with a sex ratio (M/F) of 0.74. The mean age was 38.9 years [13–77]. The mean IGF1 level was 937 ng/ml [367–1700]. Anterior pituitary insufficiency was present in 32.5% of cases and thyrotropic insufficiency in 17.5% of cases. Thyroid ultrasound was performed in 20 patients. It was normal in 12 patients (60%). A multi-nodular goiter was found in a quarter of the cases and it was indicative of the disease in one case. Nodules on a normal-sized thyroid were found in 20% of cases. Fine needle aspiration was performed in two patients, showing a benign appearance. A thyroid scintigraphy done in three patients showed one cold and two hot nodules. There was no correlation between the level of IGF1 and the onset of goiter.
Discussion and conclusion
It is well established that acromegaly can affect pituitary function, including the thyrotropic axis. On the other hand, it is associated with an increased prevalence of goiter, as thyroid follicular cells express IGF-I receptors. Studies suggest a positive relationship between thyroid volume and elevated serum IGF-I levels. Hence the interest of a systematic exploration of the thyroid to the discovery of acromegaly and during the follow-up.

AEP771

A case of Grave' s disease complicated with thyrotoxic hepatic failure and thyrotoxic period paralysis.

wiem saafi[1], Asma Ben Abdelkarim[1], Bouthaina Ben Abdallah[1], Ghada Saad[1], Aya hammami[2], wafa ben ameur[2], Amel Maaroufi[1], Maha Kacem[1], Molka Chaeib[1], Hanen Jaziri[2], Yosra Hasni[1] & Koussay Ach[1]
[1]Farhat Hached University Hospital, Endocrinolgy, Sousse, Tunisia; [2]Sahloul University Hospital, Gastroenterology, Sousse, Tunisia

Introduction
Grave's disease is an autoimmune thyroid disorder. It is the most frequent cause of hyperthyroidism with variable manifestations. When not recognized in time and not adequately treated, Graves' disease poses serious risks and can have severe complications.
Observation
A 63-year-old female was admitted to the endocrinology department for severe thyrotoxicosis. She was diagnosed in 2011 with Grave's disease medically treated using Benzylthioluracil. She has been in remission since 2015. She had a SARS-CoV-2 infection three months ago. Two months before her admission, the patient presented vomiting and diarrhea with a weight loss and jaundice. The physical examination revealed no signs of thyroid eye disease and no goiter with a regular pulse rate of 120 beats and a normal blood pressure. The patient had no hepatomegaly. she was alert and oriented with 1/5 strength in the lower extremities with no sensory deficits. Laboratory investigations confirmed the diagnosis of hyperthyroidism showing high serum free T4 (7.7 ng/dl) and low serum thyroid-stimulating hormone (TSH <0.001 IU/l). Sodium 140 mmol/l , potassium 2.4 mmol/l. Hepatic function tests revealed cytolysis cholestasis and hepatic failure: total bilirubin 519 μmol/l, direct bilirubin 300 μmol/l, alkaline phosphatase 84 U/l, gamma-glutamyl transferase 22U/l, aspartate aminotransferase 249 U/l, and alanine aminotransferase 174 U/l; prothrombin time 40% a normal factor V level. Viral serologies and investigations for other autoimmune disease and hepatic disease antinuclear antibodies, anti-smooth muscle antibodies, anti-liver kidney microsomal antibodies and anti-mitochondrial antibodies were negative and abdominal imaging did not show hepatic lesions. The diagnosis of thyrotoxic hepatitis associated with a thyrotoxic periodic paralysis was retained. The patient was treated with corticosteroids and a high dose of Benzylthioluracil, and a potassium correction. Ten days after treatment initiation, the thyroid function was normal with regression of cytolysis and cholestasis. The patient regained normal strength, and she received radioiodine therapy.
Discussion
In this case, we report two different complications of Grave's disease. Liver injury caused by thyrotoxicosis is relatively common and can be conveniently divided into hepatitis or cholestatic types. It represents a real problem since it can limit the use of antithyroid drugs and prolong the state of hyperthyroidism, exposing the patient to more severe complications. As for thyrotoxic period paralysis, it is a severe and rare complication of hyperthyroidism. When not recognized, it can lead to respiratory failure and possibly death.

Hyperthyroidism diagnosed in a patient hospitalized for COVID-19 hypoxaemic pneumonia : Diagnostic and therapeutic challenges

Najoua Lassoued[1], Rebai Senda[1], Ajili Rihab[1], Chelli Jihen[2], Zantour Baha[1] & Sfar Mohamed Habib[1]
[1]Taher Sfar University Hospital, Endocrinology Department, Mahdia, Tunisia; [2]Taher Sfar University Hospital, Department of Infectious Diseases, Mahdia, Tunisia

Introduction
Patients who are critically ill can have alterations of thyroid function tests, known as non-thyroidal illness syndrome (NTIS). Moroever thyrotoxicosis can result from SARS-CoV-2 directly infecting the thyroid gland, as described in other viral infections. We report a case of hyperthyroidism diagnosed in a patient hospitalized for COVID-19 severe hypoxemic pneumonia.
Observation
A 78-year-old patient admitted to the COVID Unit for pneumonia related to COVID-19. On clinical examination, there was no sign of hyperthyroidism or pain on palpation of the thyroid. In biology, the TSH level was at 0.07 mU/l and the FT4 level was at 16.1 pmol/l (NR: 6–14). There were no arrhythmias on the electrocardiogram. The diagnosis of subacute thyroiditis related to COVID-19 was made and the patient was put on a low dose of methimazole.
Discussion
The most likely diagnosis was subacute thyroiditis related to COVID-19. The subacute thyroiditis is characterized by self-limiting thyrotoxicosis of variable duration, lasting a period of weeks or months, followed by hypothyroidism with final restoration of euthyroidism. However, the likelihood of pre-existing hyperthyroidism discovered incidentally is not ruled out in this case. There may be a direct effect of SARS-CoV-2 on thyroid function, potentially leading to exacerbation of preexisting autoimmune thyroid disease. The immunological investigation was postponed in our patient. A thyroid ultrasound and a thyroid scintigraphy would be scheduled after improvement of his condition. FT4 was not as high as the level of suppression of TSH, which can be explained by the coexistence of a NTIS. The decision to prescribe antithyroid drug was based on the age of the patient and the stage of hyperthyroidism. The stage II of hyperthyroidism (TSH < 0.1 mU/l) in patients older than 65 years should be treated according to the 2015 ATA Guidelines. Arrhythmias are not uncommon in COVID-19 patients related to COVID-19 myocarditis. This risk of arrhythmias may be increased by hyperthyroidism, another argument to prescribe antithyroid drug in this case.
Conclusion
This case presented both diagnostic and therapeutic challenges. The most likely diagnosis is subacute thyroiditis secondary to COVID-19. Despite the fact that hyperthyroidism is believed to be transient in this case, antithyroid drug were prescribed for several reasons.

AEP773

The lower information...the greater risk of malignancy. A retrospective study of 50 patients underwent thyroid surgery

Iciar Martín Timón, Beatriz Ugalde Abiega, Inmaculada Moreno-Ruiz, Juan Jose Marin-Peñalver, Olalla Meizoso-Pita, Isabel Huguet & Cristina Sevillano-Collantes
Hospital Universitario Infanta Leonor, Endocrinology, Madrid, Spain

Objective
The aim of the study was to evaluate the overall malignancy rate on final histopathology in nodules with Bethesda III or IV surgically excised and review the ultrasound and cytological features given
Material and methods
Is a retrospective analysis of patients referred to our outpatient clinical of endocrinology after thyroid surgery with a previous thyroid nodule FNA cytology in Bethesda III or IV category. We also reviewed the information given in the ultrasound (echogenicity, margins, presence and type of calcifications, shape if taller than wide, vascularity and the presence or absence of any suspicious cervical lymph nodes in the central or lateral compartments) and cytopathology (architectural and/or nuclear atypia) reports
Results
Of the 50 patients: 72% underwent a total thyroidectomy and 28% hemithyroidectomy. In Bethesda III nodules 77.41% total vs 22.58% hemithyroidectomy and in Bethesda IV nodules 63.15% total vs 36.48%. The overall malignancy rate was 42%; in Bethesda III 35.48% and in Bethesda IV 47.36%. Papillary thyroid cancer represents 10%, follicular thyroid cancer 8%, incidentally thyroid microcarcinoma (<5 mm) 16% and NIFTP 6%. The US report inform about echogenicity and cervical lymph nodes in 62%, size in three diameters in 50%, vascularity in 36%, calcifications in 24%, margins in 22% and no one taller than wide. Only 20% of cytopathology reports information about cytologic or architectural atypia. In those with cytologic atypia the malignancy rate was 50%. Only in 16% the FNA was repited. The medium nodule size was 2.84 cm
Conclusions
Our malignancy rate (42%) was higher than estimated risk of malignancy predicted by Bethesda system. However more than a half correspond with incidentally thyroid carcinomas <5mm and NIFTP. The high rate of thyroidectomies is possibly related to the limited information obtained in the reports. Both of them are remarkable

Variables related to Response to Therapy in 340 patients with thyroid follicular epithelial cell-derived carcinoma

Patricia Espinosa De Los Monteros, Fernando Hernández Olmeda, Celia Lopez Nevado, Xavier Pérez Candel, Mario Pazos, Clara Marcuello Foncillas & Maria Cristina Familiar Casado
Hospital Clínico San Carlos, Endocrinology and Nutrition, Madrid, Spain

Introduction
Response to Therapy, according to ATA's dynamic classification, provides a description of the clinical situation in patients with thyroid cancer (TC) a year or more after treatment. It gives us more accurate information than the obtained at diagnosis by static staging systems as AJCC and ATA risk system.
Objetives
To analyse the association between some factors collected at diagnosis and the type of Response to Therapy in TC patients.
Patients and methods
Subjects included in the study underwent TC surgery in our hospital between January 2011 and December 2018 with a minimum follow-up of 18 months, except those who died from CT. Response to Therapy was evaluated a year after diagnosis and at the last visit. Two types of Response to Therapy were defined based on dynamic risk stratification: Adequate Response (AR) and Incomplete Response (IR). AR included both Excellent Response and Indeterminate Response, while IR included Biochemical and Structural Incomplete Responses. The variables evaluated at diagnosis for their potential association with IR were demographic variables, cancer presentation (clinical or incidental), maximum tumour size, and the presence or absence of: nodal and distant metastases, macro and microscopic extrathyroidal extension (EE), multifocality and incomplete resection.
Results
We describe 340 patients (5.6% men) with an average age of 54 ±15 years. A year after diagnosis, 91.2% of subjects were in the AR group, rising to 94.4% at the last visit. 12 months later, IR was significantly associated with clinical presentation of cancer, tumour size, presence of nodal and distant metastasis, presence of macro and microscopic EE and incomplete surgical resection. At the last visit, except for microscopic EE, same variables were found associated with IR in addition to male gender. Multivariate analysis showed that nodal metastasis represented independent risk factors for IR at both one year (OR: 3.2, CI 95% [1.1–9.6] and the last visit (OR: 5.3, CI 95% [1.4–20.3]. Other independent risk factors found were macroscopic EE at one year (OR : 7.6, CI 95% [1.1-51.4] and incomplete resection at the last visit (OR: 5.9, IC 95% [1.3–26.9]
Conclusions
Evidence of nodal metastases, macroscopic EE and incomplete resection are independent factors and lead to a worse Response to Therapy in patients with TC. Based on these findings, a more aggressive therapy during the initial stage should be considered**.**

Behind seeming sepsis. An outstanding clinical debut of medullary thyroid carcinoma

Andoni Monzón Mendiolea, Miguel Paja Fano, Aitzol Lizarraga Zufiaurre, Amelia Oleaga Alday, Adela Leyre Martínez Martínez, Ignacio Merlo Pascual, Miren Josune Rodríguez Soto & Jon Izquierdo Coca
Basurto University Hospital, Endocrinology, Bilbao, Spain

Procalcitonin (PCT) is a sepsis diagnostic marker and mortality predictor, although its elevation can be related to other diseases such as medullary thyroid carcinoma (MTC). A 72-year-old woman was transferred to the intensive care unit of our institution from another center. One week before, she had been admitted with a clinical picture of progressive malaise, fever, and dyspnea. Weeks before her admission, she had consulted for dyspnea, anorexia, asthenia, and weight loss. Initial studies revealed bilateral lung infiltrates with leukocytosis and high C-protein reactive (CPR), starting

antibiotics after discarding SARS-COV-2 infection. Despite active treatment and support, the clinical condition worsened, with renal and respiratory failure, needing orotracheal intubation. A computerized tomography scan (CT) showed persistent lung infiltrates and a 14 mm nodule in the right lung's lower lobe. After transferring to our center, she showed leukocytosis, high CPR, and remarkably high PCT (4560 ng/ml). She was treated with meropenem, trimethoprim-sulfamethoxazole, levofloxacin, vancomycin, and caspofungin. CPR levels and leukocytosis improved, but PCT levels did not. Another CT showed persistent lung infiltrates and two nodules in the left thyroid lobe. We determined calcitonin (11.072 pg/ml) and carcinoembryonic antigen (CEA) levels (521.4 ng/ml) and performed a core needle biopsy (CNB) of the thyroid nodules, revealing an MTC. There was no ultrasonographic evidence of cervical nodal disease. The patient's clinical condition worsened, with no evidence of any infectious foci and sustained PCT levels. A whole-body magnetic resonance imaging (MRI) seven days after admission showed multiple hepatic, osseous, and cerebral metastatic foci. The patient died three days later. The present case reflects an outstanding clinical debut of a metastatic MTC. The first signs of the disease were disproportionately high levels of PCT, mimicking a septic shock. The usual presentation of MTC is the detection of a cervical mass. It can also be detected in family studies after discovering a germinal RET mutation, and exceptionally by clinical symptoms, derived from hormonal hyperproduction, either diarrhea or flush secondary to calcitonin or paraneoplastic (Cushing's syndrome secondary to ACTH production). In this case, PCT levels were exceptionally high despite intensive sepsis treatment and other sepsis markers improvement. The thyroid nodule evaluation and calcitonin and CEA evaluation reassured the MTC suspicion, confirmed by CNB. Calcitonin levels suggested metastatic spread, not confirmed by CT but established by MRI.

Epidemiological, clinic-pathological, evolutionary profile of papillary thyroid microcarcinomas

Hajar Khouchaf, Nassim Essabah Haraj, Siham El aziz, Asmaa Chadli
HUC Ibn Rochd, Department of Endocrinology and Metabolic Diseases, Casablanca, Morocco

Introduction
Papillary carcinoma is the most frequent histological form of malignant thyroid tumors, increasingly diagnosed at the microcarcinoma stage. Papillary microcarcinomas, often localized, are classified as very low risk.
Objective of the study
To describe the epidemiological and clinical characteristics, the evolutionary profile as well as to determine the predictive factors of recurrence of papillary microcarcinomas.
Methods
Retrospective study including 232 patients followed for papillary thyroid microcarcinomas collected at the Endocrinology and Diabetology department of Ibn Rochd Casablanca University Hospital, spread from 1986 to December 2019. The analysis was carried out by SPSS version 25 software.
Results
The mean age of our patients was 44.31 years, with a clear predominance of women (93.1% of cases). The most frequent symptomatology was cervical swelling in 88.36%, the discovery was fortuitous in 11.63%. In our series 71% patients had multinodular goiter, 1.7% followed for dysthyroidism, 26.7% had no personal history and 1 patient (0.6%) followed for Basedow's disease. All patients had clinical and biological euthyroidism except 4 patients who had hyperthyroidism. All patients underwent total thyroidectomy with pathologic papillary thyroid microcarcinoma, the most frequent histological variant is the classic papillary with an average size of 4.5 mm. Multifocality was objectified in 70 patients. Lymph node dissection was performed in only 11 patients. Iratherapy was performed in 88 patients. The remission rate was objectified in 94%. The predictive factors of recurrence were multifocal character ($P = 0.004$), size > 5 mm ($P = 0.002$), and unencapsulated character ($P = 0.001$).
Conclusion
Papillary thyroid microcarcinomas have an excellent prognosis. However, certain predictive factors of aggressive evolution justify a surgical and isotopic maximalist attitude. The limitation of this study was the lack of the genetic study.

DOI: 10.1530/endoabs.73.AEP776

AEP777

Prognostic factors and therapeutic strategy for patients with bone metastases from differentiated thyroid carcinoma

Wiem Gherissi, Fatma Hamza, Hana Charfi, Issam Jardak, Mohamed Maaloul, Faouzi Kallel, Wissam Amouri, Salma Charfeddine, Khalil Chtourou, Fadhel Guermazi
Hbib Bourguiba Hospital, nuclear medecine, Sfax, Tunisia

Thyroid differentiated carcinomas are of good prognosis except in case of metastatic dissemination. These distant metastasis, especially the bone one, are a major cause of altered quality of life and death. This study concerns a cohort of 21 patients treated from 1995 to 2011.The aim of our work is to study the characteristics of patients who had *bone metastases* in association with *thyroid cancer* to determine their prognostic factors. 18 of our patients were over 45 years of age with a majority of vesicular carcinoma (81%). Distribution of patients according to the anatomopathological characteristics of the tumor were: multifocality 28.6%, thyroid capsule invasion 52.2%, complete lymph node chain resection 66.7%. Bone metastases are often multiple. They are located in order of decreasing frequency: limbs 76%, spine 46%, skull 38%, pelvis 33.3% and sternum 28.5%. They have been associated with other types of metastasis, especially pulmonary metastases (13 patients) and brain (2 patients). The mean stimulated thyroglobulin (sTg) level before radioactive iodine therapy was 762.95 ± 484.64 ng/ml with extremes from 3 to 2000 ng/ml. The average number of radioactive iodine therapy (RIT) cures received by patients was 9 ± 8.25. Consequently, bone metastases fixing iodine was noticed for 20 patients. (RIT) had as a result the disappearance of bone uptake in 1 case, reduction in 2, and stabilization in 9. More intensive uptake was noted in 7 cases. Thus, the (sTg) level was declining for 4 patients, stable for 5 and rising for 12 patients. In addition, radiotherapy of bone metastatic sites was performed for 10 patients and Only 4 patients (19%) had metastases removal surgery. The 5-year survival was 74% for patients who have had radiotherapy. After an average delay of 6.4 years from time carcinoma firstly diagnosed and 3.4 years its bone metastases: a partial remission was notable for only 1 patient, a stationary state was observed for 9 patients and clinical aggravation was observed for 11 patients. Overall survival was 65% at 5 years and 49% at 10 years. With a multidisciplinary treatment adapted to each case, it was possible to obtain long survival in 10% of cases.
Conclusion
The treatment of *bone metastasis* in association with *thyroid cancer* represents a difficult challenge requiring, as a result, more extensive treatment.

Thyroid nodule classified as Bethesda III: Our clinical experience and management strategy

Borja Sanz Martín[1], Sergio Roman Gimeno[1], Elena Pérez Galende[1], Patricia Sota Ochoa[2], Carlos Miguel Peteiro Miranda[3], Jose Jorge Ortez Toro[4] & Rosana Urdaniz Borque[1]
[1]Lozano Blesa Clinical Hospital of Zaragoza (Zaragoza), Department of Endocrinology, Spain; [2]Lozano Blesa Clinical Hospital (Zaragoza), Department of Anatomic Pathology and Histology, Spain; [3]Hospital of Viladecans, Department of Endocrinology, Spain; [4]Reina Sofía Hospital of Tudela (Tudela), Department of Endocrinology, Spain

Background
The prevalence of malignancy among Bethesda category III (atypia of undetermined significance) cytologies is variable in different studies.
Objective
The aim of this paper is to evaluate the risk of malignancy of thyroid nodules classified as Bethesda III in our hospital.
Methods
We have reviewed the medical records of 146 patients who underwent FNA with Bethesda III results between January 2017 and June 2020 in our hospital. From those, 26 patients were excluded because they didn't have enough follow -up information ($n = 120$). We analyzed the result of the second FNA (in those patients in which it was performed), then, the histological result from surgery and the echographic characteristics of each nodule.
Results
The mean age of the patients at the time the FNA was performed was 57,16±11,7 years. 71,67% of them were women. A second FNA was performed in 65.83% of the patients (79/120) resulting in Bethesda 1 (non-diagnostic) 29.11% of them, 2 (benign) in 40.51%, 3 (undetermined) in 24.05%, 4 (suspicious for follicular neoplasm) in 1.27% and 5 (suspicious

for malignancy) in 5.06% of them. 33.33% of all the patients suffered from hypothyroidism (40% of them had a benign nodule and 17.5% had a malign one). In 61 patients surgery was indicated: 57.38% had a hemithyroidectomy and 42.62% had a total thyroidectomy. Postsurgical complications occurred in 14.76% of the patients (6.56% suffered from dysphonia, 6.56% partial recurrent laryngeal nerve paralysis and 1.64% hypoparathyroidism). These complications appeared in 19.23% from total thyroidectomized patients, against 11.42% of hemithyroidectomized ones. From the 61 patients undergoing surgery, the histology was benign in 62.29% of the cases and malignant in 36.07% (26.6% were papillary thyroid cancer, 3.27% follicular thyroid cancer, 3.27% NIFTP and 3.27% Hürthle cell carcinoma). In addition, the ultrasound characteristics of benign and malignant nodules were compared. From those with malignant histology, 13.63% showed microcalcifications (compared to 7.89% of benigns); 31.81% had irregular margins (compared to 7.89% of benigns); 54.54% had hypoechoic consistency (vs 36.84% in benigns) and 36,36% showed absent of hypoechoic halo (vs 47.36% of benigns) 52.63% of benign nodules occurred in the context of multinodular goiter (compared to 31.81% of malignant nodules).
Conclusion
More than one third of the Bethesda III patients who underwent thyroidectomy had thyroid cancer.

Management of papillary thyroid carcinoma in children

Mohamed Masmoudi, Rihab Guizani, Rihab Lahmar, Lazid Sara, Mehdi Hasnaoui, Mighri Khalifa
Tahar Sfar Hospital Mahdia, ENT Department, Mahdia, Tunisia

Objective
Thyroid cancer is a rare disease in children and adolescents; it accounts for only 1.4% of all pediatric malignancies. Papillary carcinoma is the most common histological type. Furthermore, its treatment remains controversial. The aim of our work is to illustrate the clinical, histological and therapeutic features of pediatric papillary thyroid carcinoma.
Materials and methods
This is a retrospective study of 5 cases of papillary thyroid carcinoma, for which the upper age limit at the time of diagnosis was set at 15 years. This study was carried out over a period of 10 years from 2007 to 2017.
Results
The average age of our patients was 14 years, with a sex ratio of 1.5. No personal history of cervical irradiation or thyroid pathology was found. All of patients consulted for a thyroid nodule, associated with cervical lymphadenopathy in two case. A total thyroidectomy with central compartment lymph node dissection is performed in all cases. Only two patients had a lateral lymph node dissection. The diagnosis of papillary carcinoma was confirmed on the histopathological examination of the surgical specimen. The tumor was multifocal in all cases with capsular invasion and Lymph node metastases. After surgery, I-131 therapy was carried out in all patients. The evolution was favorable in all cases. No case of recurrence was noted with a mean follow-up of 4 years.
Conclusion
Compared with adults, papillary thyroid cancer in children display a greater frequency of lymph node metastases and distant metastases at the time of diagnosis and higher rates of recurrence after treatment. For this reason it should be treated differently with a long-term follow-up. The treatment is based on total thyroidectomy with lymph node dissection followed by I-131 therapy, usually giving a good prognosis.

Parathyroidian cysts: About an observation

Ghammmam Monia[1], Lobna Chouchane[1], Mouna Bellakhdhar[2], Dardouri Teheni[3], Kermani Wassim[1] & Abdelkefi Mohamed[1]
[1]Hospital University Farhat Hached, ENT department, Sousse, Tunisia; [2]University of medecine of sousse, ENT department, Sousse, Tunisia; [3]Hospital University Sahloul, nuclear medecine, Sousse, Tunisia

Introduction
The parathyroid cyst is a benign lesion that develops at the expense of the gland parathyroid. It is rarely revealed by palpable cervical swelling and is often a surgical discovery. The purpose of our work is to report an observation of parathyroid cyst, and specify the methods of pre-operative diagnosis and the different therapeutic possibilities.
Materials and methods
We report an observation of a 65-year-old patient with no pathological history individuals who presented for bone pain with functional impotence of the lower limbs.
Results
The cervical examination noted a right lower paramedian cervical swelling of 4 cm large axis, firm, mobile to swallowing. Biological assessment objectivated hypercalcemia with hyperparathyroidism (PTH: 2406 pg/ml). Cervical CT showed a cystic lesion at the lower part of the right thyroid lobe and another heterogeneous on the side left. A resection of the lower right parathyroid gland, which had a wide cystic component, was performed as well as resection of the left parathyroid. The anatomopathological examination concluded in a lower right parathyroid cyst with parathyroid parenchyma hyperplasia of both parathyroid glands. Surgical suites were simple with normalization of calcemia and parathormone levels.
Conclusion
Parathyroid cysts account for 3.2% of parathyroid diseases. They affect preferably women whose age varies between 40 and 50 years. They mainly cause differential diagnosis with isolated thyroid nodules. The treatment is often surgical

Neuroendocrine carcinoma of the thyroid: About of a case

Monia Ghammem[1], lobna chouchane[1], Mouna Bellakhdher[1], Heyfa BelHadj Miled[1], Tahani Dardouri[2], Wassim Kermani[1] & Mohamed Abdelkefi[1]
[1]ENT and Neck Surgery Department Farhat Hached Hospital, Susa, Tunisia; [2]Nuclear Medicine Departement Sahloul Hospital, Susa, Tunisia

Goals
The purpose of this work is to study histological, clinical, and therapeutic features neuroendocrine carcinomas of the thyroid.
Materials and methods
We report a case of neuroendocrine carcinoma of the thyroid colliged in ENT department of sousse.
Observation
The case involved an 83-year-old woman with a history of family dysthyroidism who had significant cervical swelling, rapidly increasing in size over the past month, and associated signs of compression (inspiratory dyspnea, dysphagia, and dysphonia). The clinical examination showed an anterolateral cervical swelling, poorly limited, fixed in relation to both planes, more marked on the right side with altered laryngeal mobility. The chest CT scan revealed a latero-cervical 9 cm mass, extended to the anterior mediastinum, pushing back the esophagus and the trachea, and compressing the carotid artery, left subclavian and right internal jugular which is thrombosed, cervical lymphadenopathy: right spinal (20mm) and right upper clavicular (17 mm). There weren't lung parenchyma abnormalities. A biopsy showed a neuroendocrine carcinoma little differentiated expressing chromogranin. The abdominal ultrasound did not object to remote metastasis. The multidisciplinary staff opted for external radiotherapy. The evolution was marked by the rapid increase of the size of the tumor with a significant alteration of the general state. A tracheotomy was performed in emergency before the aggravation of dyspnea. The patient died before she could begin radiotherapy.
Conclusion
Clinical presentation of neuroendocrine carcinomas is aggressive and rapidly progressive with an often invasive tumor and extensive necrosis sites. The immunohistochemical study confirms the diagnosis by showing an expression of neuroendocrine markers. The lymph nodes are almost constant. Given the rarity of this histological type, the treatment remains poorly defined. However, radiation therapy is still more appropriate than surgery. The prognosis is often bad with a high mortality rate.

Heterozygous 461A> T (p.Asp154Val) Mutation in POR gene in a male case

Müge Keskin[1], Konul Ahmadova[1], Nurcan İnce[1], Narin Nasiroglu İmga[1], Ahmet Cevdet Ceylan[2], Cevdet Aydin[3], Oya Topaloglu[3], Reyhan Ersoy[3] & Bekir Cakir[3]

[1]Ankara City Hospital, Endocrinology and Metabolism, Turkey; [2]Yildirim Beyazit University Faculty of Medicine, Genetics, Turkey; [3]Yildirim Beyazit University Faculty of Medicine, Endocrinology and Metabolism, Turkey

Background
Cytochrome P450 oxidoreductase (POR) deficiency is an autosomal recessive steroidogenesis disorder similar to combined deficiencies of 17ήhydroxylase, 17,20-lyase, 21-hydroxylase. POR deficiency (PORD) is a very rare type of congenital adrenal hyperplasia(CAH) characterized by sexual development disorders and skeletal anomalies. We present a case that was evaluated with a prediagnosis of nonclassical CAH and was found to have a heterozygous mutation in the POR gene.
Case report
A 23 years old male patient applied to our clinic with complaint of excessive hair. These symptom had started on her arms and legs at 6 years old, appeared on her back at 8 years old, then spread to all over the body. He has reached his final adult height at about 15 years old. He had no history of chronic illness, his 47 years old mother and 56 years old father were consanguineous. On physical examination, his blood pressure was 120/80mm/hg, height was 161cm, the length of the penis was 9.5cm and testicular volume was 20 ml. Laboratory tests were as follows; glucose 89 mg/dl (70–99), sodium 138 mEq/l (132–146), potassium 4.7 mEq/l (3.5–5.5), cortisol 20.3 µg/dl (5.2–22.4), ACTH 37.8 pg/ml (<46), TSH 1.6 mU/l (0.55–4.78), sex hormone binding globulin 7 nmol/l (10–57), FSH 3.2U/l (1.4–18.1), LH 6.9U/l (1.5-9.3), progesterone 1.26 µg/l (0.28–1.22), total testosterone 383 ng/dl (164–753), dehydroepiandrosteronesulfate 698.72 µg/dl (34.5–568.9), 17-alpha-hydroxyprogesterone (17-OHP) 1.22 ug/l, free testosterone 26.6 pg/ml (15–50), androstenedione 13.5 nmol/l (2.1–10.8). Maximum 17-OHP was 3.36 mg/l after ACTH-stimulation. Abdominal magnetic resonance imaging showed normal adrenal glands. Scrotal ultrasonography was normal. Bone age was 18 years. Genetic testing revealed that the patient was heterozygote for c.461A > T(p.Asp154Val) mutation in exon 5 of POR gene while CYP21A2, CYP17A1, CYP11B1, HSD3B2, STAR genes were normal. Subsequent genetic testing of parents showed that his mother also had POR(NM_000941.3):c.461A > T(exon5) heterozygote mutation, while there was no mutation in his father.
Conclusion
A great number of POR variants affecting more than 130 amino acids in the POR protein have been reported. There is clinical heterogeneity in patients with POR gene mutations, making the diagnosis difficult. Considering that the POR gene mutation shows ethnic differences, we think that the determination of variant cases in our society will clarify its importance in this case in the future.
Keywords: cytochrome P450 oxidoreductase, POR heterozygote mutation.

Cortisol measurement post steroids (Dexamethasone) treatment for COVID-19

Randa Eltayeb[1], Oliver Marwood[2], Shaun Kellam[3] & Helen Simpson[1]
[1]London, Department of Endocrine and Diabetes, London, United Kingdom; [2]UCL Medical School, London, United Kingdom; [3]London, Department of Critical Care, London, United Kingdom

Introduction
We are currently mid Covid-19 pandemic. In the last year there have been 116,135,492 confirmed Covid-19 cases worldwide, with an estimated 2,581,976 deaths.
The RECOVERY trial reported for patients hospitalized with Covid-19, the use of dexamethasone (6 mg for 10 days) resulted in lower 28-day mortality among those who were receiving either invasive mechanical ventilation or oxygen alone at randomisation. Adrenal insufficiency (AI) is a serious, potentially life-threatening side effect of glucocorticoids which cause suppression of the hypothalamic-pituitary-adrenal (HPA) axis.
Objective
We aimed to investigate the effects of Covid dexamethasone protocols on adrenal function.
Methodology
We collected data from patients admitted with a diagnosis of Covid-19 by searching electronic patient records from November 2020 to March 2021 at our institution. We included patients with a diagnosis of COVID-19 treated with Dexamethasone, Hydrocortisone, or prednisolone for 7 days or more. We also recorded factors that may also affect adrenal function including.
• Patients on long term corticosteroids (i.e inhaled, topical, injectable, and oral)
• Patients on CYP3A4 enzyme inhibitors
• Patients on opioids
Adrenal function was screened by 0900 h cortisol, at least 24 hours off of steroids. Cortisol levels >300 nmol/l excluded adrenal insufficiency. levels between 100-300 nmol/l underwent further assessment. Concentration <100 nmol started on hydrocortisones replacement and further surveillance.
Results
77 patients were alive at the time of data collection, data being available for 53. 42/53 patients had 7–10 days 6 mg dexamethasone whilst 9/53 had additional ARDS regimen of dexamethasone (reducing dose over 12 days starting at 33 mg/day). To date 13/50 had suboptimal cortisol level, 5 had cortisol <100 nmol 24–48 hours post stopping Dexamethasone, 4 of these having had ARDS regimen of prolonged dexamethasone. These have been started on hydrocortisone and further testing planned when on lower doses of hydrocortisone. 8 had cortisol 100-300 nmol/l, confirmatory testing is awaited. Data is therefore awaited for 27 patients along with the SST results.
Summary
Whilst this is a small data series it highlights the risk of adrenal insufficiency after treating with dexamethasone, with almost 50% of patients on ARDS regimen on ICU having adrenal insufficiency. It is important to be aware and screen for AI as these patients will be at risk of adrenal crisis if left undiagnosed. These data also suggest that Covid-19 itself does not cause adrenal insufficiency. Larger numbers are needed to confirm these data.

New biomarkers to predict cardiovasculer risk in patients with adrenal incidentaloma; irisin and nesfatin-1

Mustafa Can[1], Muhammet Kocabas[1], Mellia Karakose[1], Yakup Alsancak[2], Fatma Hümeyra Yerlikaya Aydemir[3], Hatice Çalıkkan Burgucu[1], Ilker Cordan[4], Cengiz Kadıyoran[5], Mustafa Kulaksizoglu[1], & Feridun Karakurt[1]
[1]Meram Tıp Fakültesi Hastanesi, Department of Endocrinology and Metabolism, Turkey; [2]Meram Tıp Fakültesi Hastanesi, Department of Cardiology, Turkey; [3]Selçuk Üniversitesi Tıp Fakültesi Mediko Sosyal, Department of Biochemistry, Turkey; [4]Edirne Sultan Murat 1. State Hospital, Department of Endocrinology and Metabolism, Turkey; [5]Meram Tıp Fakültesi Hastanesi, Department of Radiology, Turkey

Objectives
Evidence from recent studies suggests that patients with adrenal incidentaloma have increased cardiovascular risk. In our study, we aimed to investigate the levels of irisin, nesfatin-1 and the relationship between levels of these relatively new molecules with cardiometabolic risk markers; carotid intima-media thickness (CIMT), epicardial adipose tissue (EAT) thickness and abdominal subcutaneous adipose tissue (SCAT) thickness in patients with nonfunctional adrenal incidentaloma (NFAI).
Methods
Patients with NFAI (n = 59) and age-, sex- and body mass index-matched healthy control subjects (n = 59) were enrolled in this study. Serum glucose, insulin, C-reactive protein (CRP), lipid, irisin and nesfatin-1 levels were measured in patients and controls. In addition, echocardiographic CIMT and EAT thickness measurements of patients and controls were made.
Results
The irisin level was 17.58 ± 4.38 pg/ml in the NFAI group and 14.03 ± 4.03 pg/ml in the control group, and it was significantly higher in the NFAI group ($p < 0.001$). Nesfatin-1 level was 194.98 ± 119.15 pg/ml in the NFAI group and 303.48 ± 200.78 pg/ml in the control group, and it was significantly lower in the NFAI group ($P < 0.001$). There were no difference between two group in terms of CIMT and EAT thickness ($P > 0.05$) Positive correlations were found between irisin level and CIMT (r: 0.384, p: 0.003) and EAT thickness (r: 0.333, p: 0.010) in the NFAI group. In addition, positive correlations were also found between nesfatin-1 level and CIMT (r: 0.323, p: 0.013) and EAT thickness (r: 0.292, p: 0.025) in the NFAI group.
Conclusions
In our study, we found that irisin level was higher and nesfatin-1 level was lower in patients with NFAI, and both irisin and nesfatin-1 levels were associated with CIMT and EAT thickness in NFAI patients. Irisin and nesfatin-1 can be used as markers to predict the cardiovasculer risk in patients with NFAI.
Keywords: nonfunctional adrenal incidentaloma, irisin, nesfatin-1, carotid intima-media thickness.

The role of radiological assessment with CT in the characterisation of adrenal nodules: use of size, pre-contrast attenuation and washout studies

Amy Younger[1], Wael Elsaify[2], Mohamed Shawgi[2], Sara Alfifi[1], Jeremie Nsengimana[1] & Mavin Macauley[2]
[1]Newcastle University, Newcastle upon Tyne, United Kingdom; [2]South Tees Hospitals NHS Foundation Trust, Middlesbrough, United Kingdom

Background
Advances in imaging techniques combined with the increase in the number of patients undergoing radiological investigations have contributed to the increased detection of adrenal nodules. Prior to the publication of the European Society of Endocrinology (ESE) guidelines on the management of adrenal incidentalomas in 2016, there was marked variability in the management of adrenal nodules. The objective of this study is to validate the diagnostic performance of the radiological thresholds (size of nodule, pre-contrast attenuation and washout studies), as per the ESE guidelines 2016.
Methods
The histological diagnosis (gold standard) for 68 patients who had adrenolectomy between January 2011 – February 2020 was obtained from hospital records. CT reports of these patients were reviewed to collate data on size (n = 68), pre-contrast attenuation (n = 47) and absolute washout (AW) (n = 31) and relative washout (RW) (n = 31). Univariate models were used to analyse the diagnostic accuracy of these radiological thresholds. ROC analyses were conducted and standard thresholds were used to derive sensitivity, specificity, negative predictive value (NPV) and positive predictive value (PPV). We propose new thresholds providing better estimation of these parameters.
Results
The malignancy prevalence in the dataset was 10.4%. Univariate analysis using the chi-squared test, demonstrated that size ($P < 0.0001$) and pre-contrast attenuation ($P = 0.01$) were significant predictors of benign histopathology. Receiver operating characteristic (ROC) area under the curve (AUC) was 0.89 ($P = 0.005$) for size and 0.88 for pre-contrast attenuation ($P = 0.03$). The AUC for RW ($P = 0.08$) and AW ($P = 0.24$) were not significant.
With the size cut off ≥4 cm (current standard) for diagnosing a malignant lesion, the NPV and PPV values were 0.96 and 0.17 respectively (sensitivity 0.80, specifity 0.53). A new threshold of ≥8cm for diagnosing a malignant lesion gave a NPV 0.98 and PPV 0.67 (sensitivity 0.80, specifity 0.95). Similarly, a pre-contrast cut off of >10HU (current standard) for a malignant lesion diagnosis had NPV 1.00 and PPV 0.18 (sensitivity 1.0, specifity 0.59). A new cut off 29.5HU had NPV 0.97 and PPV 0.40 (sensitivity 0.67, specifity 0.91).
Conclusions
These data show that size and pre-contrast attenuation are good predictors of benign histopathology. The low number of patients with cancer in the cohort has an impact on any test sensitivity, but these early data show that different thresholds might be required than currently in use. Larger cohort studies are required to investigate this further and to understand the role of washout studies in determining adrenal histopathology.

Prevalence of primary aldosteronism in patients with acute stroke: A prospective study

Van Nguyen[1], Tian Ming Tu[2], Marlie Jane[3], Jovan Lai[4], Meifen Zhang[3] & Hai Kiat Puar[3]
[1]Duke-NUS Medical School, Singapore, Singapore; [2]National Neuroscience Institute, Singapore, Singapore; [3]Changi General Hospital, Singapore, Singapore; [4]National University of Singapore, Singapore, Singapore

Background
Primary aldosteronism (PA) affects 5-20% of all patients with hypertension, and is likely the most common treatable cause of hypertension. Patients with PA have higher risk of cardiovascular disease, atrial fibrillation and stroke. We aimed to estimate the prevalence of PA in patients with recent stroke.
Methods
We prospectively recruited 300 patients who were admitted to the acute stroke unit of a single tertiary centre with the diagnosis of cerebrovascular accident (both ischemic and haemorrhagic) or transient ischemic attack. At 2-4 months post-stroke, all patients had screening blood tests for serum aldosterone (ng/dl) and plasma renin activity (ng/ml/hr) Patients with aldosterone-renin-ratio (ARR) >10 underwent confirmatory seated salt loading test (SLT). This study was registered with Clinicaltrials.gov (NCT03789357).
Results
300 patients were recruited, of which 192 underwent ARR screening. Mean age of the 192 patients was 56.7 ± 10.6 years, 55 (28.6%) were females, and 130 (67.7%) had hypertension. 156 (81.3%) had ischemic stroke, 20 (10.4%) had haemorrhagic stroke and 16 (8.3%) had transient ischemic attack. 26 of 192 (13.5%) patients had positive ARR. Patients with positive ARR were more likely to have AF, 4 of 26 (15.4%), compared to those with negative ARR, 5 of 166 (3.0%), P =0.021, and they also had higher baseline diastolic blood pressure. 4 of 12 (25%) patients who underwent confirmatory SLT had post-saline aldosterone >5ng/dl. One patient had baseline aldosterone >20 ng/dl with suppressed renin and spontaneous hypokalaemia, which was consistent with diagnosis of PA. In total, 5 patients were diagnosed with PA, giving a prevalence of 2.6% in all stroke patients, and 3.9% amongst those with hypertension. Prevalence rates were higher in certain subgroups of patients: 16.7% (2 of 12) in those with hypertension and hypokalemia, 22.2% (2 of 9) in hypertension and AF, and 6.1% (3 of 49) in young stroke patients aged ≤50 years. If screening for PA was only done in patients with hypokalemia or age ≤50 years, half of the cases would have been missed.
Conclusion
In addition to current guideline recommendations to screen for PA in certain subgroups of hypertensive patients, e.g. resistant hypertension, hypertension with hypokalemia, it will be worthwhile to screen hypertensive patients with previous stroke, who are at high risk of cardiovascular events. In post-stroke patients who have good functional recovery, accurate diagnosis and treatment of PA can improve and potentially cure hypertension, and prevent a subsequent stroke which could be catastrophic.

Prospective clinical trial comparing 11c-metomidate pet-ct and adrenal vein sampling in identifying unilateral surgically-curable primary aldosteronism

Hai Kiat Puar[1], Colin Tan[2], Aaron Tong[3], Chin Meng Khoo[4], Alvin Tan[5], Lih Ming Loh[3], Peng Chin Kek[3], Szemen Yee[6], Daphne Lee[7], Matthew Chuah[8], Anthonin Reilhac[9], Edward Robins[9] & Roger Foo[4]
[1]Changi General Hospital, Singapore, Singapore; [2]Mount Elizabeth Novena Hospital, Singapore, Singapore; [3]Singapore General Hospital, Singapore, Singapore; [4]National University Hospital, Singapore, Singapore; [5]Tan Tock Seng Hospital, Singapore, Singapore; [6]Ng Teng Fong General Hospital, Singapore, Singapore; [7]Khoo Teck Puat Hospital, Singapore, Singapore; [8]Sengkang General Hospital, Singapore, Singapore; [9]National University of Singapore, Singapore, Singapore

Introduction
Unilateral PA can be cured with unilateral adrenalectomy. Adrenal vein sampling (AVS) is the current reference test to identify unilateral PA, but it is invasive and technically-difficult. 11C-metomidate PET-CT offers a non-invasive alternative to AVS. We compared the accuracy of AVS and PET-CT in identifying patients with unilateral surgically-curable PA.
Methods
In this prospective multi-centre clinical trial, patients with confirmed PA underwent both AVS and 11C-metomidate PET-CT. All results were reviewed at a multi-disciplinary meeting to decide on the final diagnosis and treatment. Primary outcome was the accuracy of each diagnostic test compared to biochemical cure of PA post-surgery as defined by Primary Aldosteronism Surgery Outcomes (PASO) criteria. Secondary outcome was the accuracy of each diagnostic test compared to the final diagnosis (ClinicalTrials.gov: NCT03990701).
Results
25 patients were recruited, and all patients had a successful AVS procedure, and 11C-metomidate PET-CT. Final diagnosis was unilateral in 22 patients, bilateral in two patients, and indeterminate in one patient due to discordant lateralization on AVS and PET-CT. 20 of 22 patients with unilateral PA underwent surgery, and all were biochemically cured six months post-surgery. For the primary outcome, sensitivity of AVS was 15/20 (75%), and PET-CT was 16/20 (80%). For the secondary outcome, the sensitivity and specificity of AVS was 15/22 (68.2%) and 2/2 (100%), and PET-CT was 18/22 (81.9%) and 2/2 (100%), respectively. Six patients had PET lateralization without AVS lateralization, of which four patients had AVS lateralization ratios between 2.8–3.5, while two had bilateral low aldosterone levels on AVS. Three patients had AVS lateralization without PET lateralization. There were no differences in clinical outcomes (blood pressure) using PASO criteria between patients identified on PET-CT and

those with AVS. Patients with higher PET lateralization ratios also had higher AVS lateralization ratios, and higher peripheral aldosterone levels during AVS, but similar aldosterone and cortisol levels during PET-CT, compared to those with lower PET lateralization ratios.
Conclusion
11C-metomidate PET-CT performs comparably with AVS in identifying unilateral PA and can also identify patients not currently detected with AVS. Being non-invasive and non-operator dependent, it may allow identification of more patients with unilateral surgically-curable PA.

Significant regression of primary adrenal lymphoma after acute steroid replacement therapy: a case with an insufficient initial biopsy

Burcak Helvaci[1], Bugra Durmus[1], Ozgur Ozcelik[1], Narin Nasiroglu Ünmga[1], Mehmet Ali Sendur[2], Oya Topaloglu[3], Reyhan Ersoy[3] & Bekir Cakir[3]
[1]Ankara City Hospital, Endocrine and Metabolism, Ankara, Turkey; [2]Yildirim Beyazit University Faculty of Medicine, Ankara City Hospital, Medical Oncology, Ankara, Turkey; [3]Yildirim Beyazit University Faculty of Medicine, Ankara City Hospital, Endocrine and Metabolism, Ankara, Turkey

Objective
There is limited clinical data available on bilateral adrenal masses (BAM). Here we present a case with BAC and adrenal insufficiency. The patient's lesions disappeared after steroids, re-grew in the follow-up, allowing a biopsy.
Case
A 60-year-old male patient presented with abdominal pain, nausea, and weakness to another hospital. Hyponatremia and hyperkalemia accompanied by hypotension were detected. Abdominal tomography revealed, "irregularly demarcated hyperdense mass lesions, 60 × 44 mm in the right and 75 × 26 mm in the left adrenal." Upon referral to our hospital, we employed PET-CT, which demonstrated "mass lesions of 49 × 52 × 71 mm in the right and 56 × 57 × 75 mm in the left adrenal as well as pathological hypermetabolism in multiple foci in the skeletal system." After diagnosing adrenal insufficiency, we initially gave the patients intravenous hydrocortisone, followed by oral maintenance. There were no pathological findings in tuberculosis tests, viral and autoimmune panel, and malignancy screening. Urine and plasma catecholamine and 17-hydroxy progesterone levels were normal. CT-guided biopsy of the adrenal mass revealed fat necrosis. After 45 days, we attempted a repeat biopsy without success due to almost wholly regressed adrenal masses. Also, bone lesions could not be visualized. Adrenal MRI showed "14 mm lesion on the right and, only diffuse thickening on the left adrenal." A control PET-CT was obtained. "Evident decrease in the size of the adrenal lesions, in addition to the fairly reduced metabolic activity of adrenal masses and bone lesions." We performed a biopsy from the most active bony lesion; however, it was inadequate. Two months after the initial presentation, he was admitted with abdominal pain. His lesions had progressed. In CT he had, 70 × 41 mm right adrenal mass invading liver and IVC, 56 × 38 mm left adrenal mass, and numerous metastasis in his liver and lungs. Adrenal biopsy, this instance was compatible with "CD20 + B cell lymphoma infiltration." Patient died of cerebrovascular incident, whilst awaiting biopsy results.
Conclusion
Primary adrenal lymphoma is a rare etiological cause of BAM with only a handful of reported cases. Adrenal lesions vanishing after steroids should raise the suspicion of adrenal lymphoma. The shrinkage of tumors may lead to diagnostic difficulties such as our patient.

Admission of patients with chest pain and/or breathlessness from the emergency department in relation to risk stratification and Copeptin; a prospective observational study

Lee Ti Davidson[1,2], Emilia Gauffin[3,4], Preben Henanger[3,4], Maciej Wajda[1,2], Daniel Wilhelms[1,5,6], Bertil Ekman[3,4], Hans Arnqvist[3,4], Martin Schilling[1,2,7], Simona Ioana Chisalita[3,4]
[1]Linköping University, Department of Emergency Medicine, Linköping, Sweden; [2]Linköping University, Department of Clinical and Experimental Medicine, Linköping, Sweden; [3]Linköping University, Department of Medical and Health Sciences, Linköping, Sweden; [4]Linköping University, Department of Endocrinology, Linköping, Sweden; [5]Region Östergötland, Local Health Care Services in Central Östergötland, Sweden; [6]Linköping University, Department of Biomedical and Clinical Sciences, Linköping, Sweden; [7]Clinicum and Innovations Centrum, Linköping, Sweden

Background
Accurate identification of patients at risk in the Emergency Department (ED) is crucial in order to avoid delays in treatment which may result in poor outcomes. Our aim was to study the association of the decision in ED to admit patients with chest pain and/or breathlessness in the ED to a ward with risk stratification by RETTS or NEWS and level of the surrogate biomarkers Copeptin, MR-proADM and MR-proANP of vasoregulatory hormones.
Methods
Patients presenting at the ED with chest pain and/or breathlessness were enrolled. Vital signs were recorded and patients were triaged accordingly to Rapid Emergency Triage and Treatment System (RETTS). NEWS (national early warnings score) was retrospectively calculated from the vital signs. Levels of Copeptin, MR-proADM and MR-proANP on presentation were analyzed.
Results
334 patients were included. The median age was 64 year. 167 (50%) of them were male. 210 (63%) patients complained of chest pain, 65 (20%) of breathlessness and 59 (18%) of chest pain and breathlessness. Of those 176 (52.7%) patients were admitted to a ward and 158 (47.3%) patients were discharged from ED. In binary logistic models age, gender, vital parameters, NEWS class and Copeptin were associated with admission to award from ED, whereas there was no association with RETTS, MR-proADM or MR-proANP. Assessed by receiver operating characteristic (ROC) curves constructed with: age, gender and vital signs for prediction of admission from ED, addition of copeptin did not significantly increase the area under the curve (AUC).
Conclusions
Age, vital signs, NEWS and copeptin, are related to the decision of admission to a ward from ED for patients with chest pain and/or breathlessness.

Patients susceptible to an adrenal crisis show marked differences in urinary cortisol excretion and glucocorticoid sensitive pathways

Annet Vulto[1], Martijn van Faassen[2], Michiel Kerstens[1] & Andre van Beek[1]
[1]University Medical Center Groningen, Endocrinology, Groningen, Netherlands; [2]University Medical Center Groningen, Laboratory Medicine, Groningen, Netherlands

Background
Adrenal crisis (AC) is a life threatening medical situation caused by an absolute or relative cortisol deficiency. A biological predisposition may be of importance, because some patients never experience an AC, whereas others are admitted repeatedly to the hospital for an AC. Differences in cortisol pharmacokinetics (PK) and/or pharmacodynamics (PD) may underlie this vulnerability.
Objective
To study PK and PD data of glucocorticoid sensitive pathways in patients with or without an AC.
Design
An exploratory analysis of well-characterized patients with secondary adrenal insufficiency who participated in a randomized controlled trial investigating the effects of two different hydrocortisone (HC) doses corrected for body weight.
Methods
Analysis of variables was performed on the lower HC dose (0.2–0.3 mg/kg body weight/day) as this was considered to better reflect the state of (relative) hypocortisolism. Variables of interest were also analyzed on the higher dose (0.4–0.6 mg/kg body weight/day). Plasma cortisol and cortisone, 24 hour urinary steroid profile, as well as the glucocorticoid sensitive tryptophan-kynurenine, and renin-aldosterone pathways were determined by LC-MS/MS. In addition, quality of life (QoL) was measured by means of questionnaires. A P-value <0.05 was considered significant. Considering the exploratory study design, a P-value <0.1 was considered to be of interest.
Results
Out of the 52 patients included in this study, 9 (17%) suffered from at least one AC. No differences in baseline characteristics were observed between patients with (AC+) and without (AC-) an adrenal crisis. On the lower HC dose the 24 hour urinary excretion of cortisol and cortisone were found to be lower in AC+ (P = 0.01 and P = 0.04, respectively). No differences in

plasma half-life and other PK parameters of (free) cortisol were observed. Kynurenine was higher in AC+ (P = 0.03), as was 3-OH-kynurenine and the kynurenine-tryptophan ratio (both P = 0.06). In addition, perceived pain (P = 0.08), general fatigue (P = 0.04) and anxiety (P = 0.06) were higher in the AC+ group. On the higher HC dose, the 24 hour urinary excretion of cortisol and cortisone remained lower (both P≤0.01) in the AC+ group, whereas differences in the kynurenine pathway and quality of life were no longer present. A higher plasma aldosterone concentration was found in the AC+ group on the higher HC dose.
Conclusion
Patients susceptible to an adrenal crisis demonstrate lower urinary excretion of cortisol and cortisone as well as differences in the kynurenine pathway and QoL on a standardized lower hydrocortisone substitution dose when compared to patients who never experienced an adrenal crisis.

Histopathology and post-surgical outcomes of surgically treated patients for primary aldosteronism

Lucie S Meyer[1], Laura Handgriff[1], Martin Reincke[1], & Tracy Ann Williams[1,2]
[1]Medizinische Klinik und Poliklinik IV, Klinikum der Ludwig-Maximilians-Universität München, Munich, Germany; [2]Division of Internal Medicine and Hypertension, Department of Medical Sciences, University of Turin, Turin, Italy

Background
Unilateral forms of primary aldosteronism (PA) are usually surgically treated to remove the source of aldosterone excess. After adrenalectomy, aldosteronism persists in a subset of patients indicating abnormal aldosterone production from the unresected gland.
Objective
To retrospectively analyze histopathology and post-surgical outcomes in a 3-year prospective cohort of patients diagnosed with unilateral PA (2016 to 2018).
Methods
Histopathology was evaluated by the international HISTALDO consensus and postsurgical outcomes were assessed by the PASO criteria.
Results
The cohort comprised 60 adrenals categorized as classical or nonclassical histopathology of unilateral PA. The classical group (solitary aldosterone-producing adenoma or nodule) comprised 45 cases (75% of 60). More than half of these adrenals (26 of 45) displayed aldosterone-producing lesions in the adjacent cortex. The nonclassical group comprised 15 adrenals (25% of 60) characterized by multiple aldosterone-producing micro/nodules or aldosterone-producing diffuse hyperplasia. A high proportion of the classical histopathology group achieved complete biochemical success compared with the nonclassical group (97.6% versus 66.7%, P = 0.002). The ratio of the aldosterone concentration in the contralateral adrenal vein to the peripheral vein was increased in the nonclassical group relative to the classical group (3.8 [1.7–6.5] vs 2.0 [1.1–3.1], P = 0.004).
Conclusion
Adrenals with nonclassical histopathology of unilateral forms of PA are associated with disease persistence and abnormal aldosterone production from the unresected adrenal.

Long-term follow-up in primary aldosteronism: the major determinant of the haemodynamic phenotype is volume load

Eeva Kokko[1], Aapo Mutanen[1], Manoj Choudhary[1], Antti Tikkakoski[1], Onni Niemelä[1], Marianna Viukari[2], Niina Matikainen[2], Jukka Mustonen[1], Pasi Nevalainen[1] & Ilkka Pörsti[1]
[1]Tampere University, Finland; [2]Helsinki University, Finland

Background
Aldosterone excess causes volume retention and cardiovascular damage. We evaluated the long-term haemodynamic changes in patients with targeted treatment of primary aldosteronism (PA) (n = 40) in comparison with essential hypertension (EH) (n = 40) and untreated normotensive controls (n = 40).
Methods
PA patients were subjected to adrenal vein sampling and allocated to adrenalectomy (n = 20) or spironolactone-based treatment (n = 20) and followed for 2.8 years (median). In the PA and EH groups, age (55 and 50 years, respectively), sex distribution (30 and 31 males), body mass index (BMI) (31 and 29 kg/m^2), and smoking status (6 and 3 present, 25 and 23 never, respectively) were corresponding. The normotensive controls had similar sex distribution and smoking status but were younger (44 years) with lower mean BMI (26 kg/m^2). Supine haemodynamics were recorded using whole-body impedance cardiography and continuous radial tonometric pulse wave analysis.
Results
The average initial number of antihypertensive medications in the PA and EH groups was 3 vs 1, and the final number was 3 vs 2, respectively, with all major classes of antihypertensives in use. Aortic systolic and diastolic blood pressures (BP) were similarly elevated in the PA and EH groups, and the values were correspondingly reduced by treatment. However, BP remained higher in both hypertensive groups than in normotensive controls. The PA and EH groups presented with similar treatment-induced reductions in systemic vascular resistance without changes in cardiac output. The foremost initial haemodynamic change in the PA patients was about 1 litre (10%) excess of extracellular water volume versus the EH and NT groups (P < 0.001) that was completely normalised by treatment. Before treatment aortic forward wave amplitude (FWA) and backward wave amplitude were correspondingly elevated in the two hypertensive groups. However, when compared with normotensive controls, the treatment-induced decrease in FWA was more pronounced in PA patients (4.1±1.4 vs 0.2±1.4 mmHg, P = 0.043) but not in EH patients (–2.1±1.2 vs 0.2±1.4 mmHg, P = 0.170). In two models of linear regression analysis, extracellular water volume (β=0.255, P = 0.007, R^2 of the model 0.338) and PA (β=0.289, P = 0.013, R^2 0.353) were independent explanatory factors for FWA.
Conclusions
Patients with PA presented with corresponding BP, systemic vascular resistance, and cardiac output, but clearly higher extracellular water volume than patients with EH. Targeted treatment of PA eliminated the volume excess and reduced aortic forward wave amplitude. These findings support the view that systematic evaluation of the volume status would benefit the clinical diagnostics and treatment of PA.

Pheochromocytoma crisis precipitated by invasive coronary angiography in a patient with ventricular tachycardia and raised troponin

Nikita Jolapara[1], Jonathan Lazari[2], Hassan Ibrahim[1] & Carol Whelan[3]
[1]Basildon University Hospital, United Kingdom; [2]Royal Surrey County Hospital, United Kingdom; [3]Royal Free Hospital, United Kingdom

A 63-year-old female with cardiovascular risk factors presented with tremor, sweating, lower back discomfort, nausea and dyspnoea. ECG showed sinus tachycardia with lateral ST-depression. High-sensitivity troponin was dynamically elevated (72 ng/l to 112ng/l on one-hour repeat). Computed tomography aortogram ruled out aortic dissection but identified a 6.6cm lesion in the left adrenal gland. Ventricular tachycardia was detected on cardiac monitoring. Differential diagnoses included acute coronary syndrome and a pheochromocytoma (with arrhythmia and myocardial injury). Invasive coronary angiography demonstrated non-obstructive coronary artery disease. Post-procedure, the patient developed a pheochromocytoma crisis. This was managed with intravenous phentolamine. Our case serves as an important reminder that invasive procedures in these patients can induce potentially life-threatening hyperadrenergic episodes. Pheochromocytomas are usually benign tumours, arising from the chromaffin cells in the adrenal medulla or a paraganglion. The vast majority are hormonally active, secreting catecholamines. The resulting hyperadrenergic state causes the classic triad of symptoms; paroxysms of tremor, headache and diaphoresis. However, presentation can be varied and may mimic other conditions. They are rare, with an estimated annual incidence of 2 – 8 per million population, although this is likely an underestimation based on post-mortem studies and increasing pre-symptomatic diagnosis rates. Whilst most are sporadic cases, at least a third occur as part of a familial syndrome (e.g. von Hippel-Lindau, MEN-2, neurofibromatosis-1). Treatment is firstly medical, but in the absence of metastatic disease, cure can be achieved with surgical resection. Prior to surgery, patients need to be adequately alpha-blocked, typically for 7–14 days with phenoxybenzamine. Lifestyle advice to increase sodium and fluid intake is important pre-operatively to prevent hypotension after resection. Beta-blockers are contraindicated initially as unopposed beta-blockade can trigger

a hypertensive crisis, but can be commenced after adequate alpha-blockade. Suggested treatment of a hypertensive crisis is with intravenous phentolamine boluses followed by infusion as required for maintenance of responsee. There have been a number of published case reports showing pheochromocytomas presenting with chest pain, ECG changes and raised cardiac biomarkers mistakenly being investigated and treated as acute coronary syndromes (ACS). [*e.g.* 5–7] Given the rarity of pheochromocytomas and how common coronary heart disease is, this presentation understandably can lead to delays in the correct diagnosis. Our case report is therefore an important reminder that in those patients with confirmed or suspected pheochromocytomas, invasive procedures such as coronary angiography can trigger hyperadrenergic crises.

Cushing's syndrome presenting with dilated cardiomyopathy: A case report

Beril Turan Erdogan[1], Mehdi Houssein[1], Ozgur Ozcelik[1], Neslihan Cuhaci Seyrek[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Yildirim Beyazit University Faculty of Medicine, Ankara City Hospital, Department of Endocrinology and Metabolism

Background
Cardiovascular complications of Cushing's syndrome (CS) include; hypertension, left ventricular hypertrophy, and myocardial ischaemia. Also, CS can cause structural and functional changes in the heart, leading to dilated cardiomyopathy in rare cases. Here, we present a case with dilated cardiomyopathy related to Cushing's syndrome.
Case
A 31-year-old male patient applied to the cardiology department with shortness of breath that worsened with exertion for a year. Globally advanced hypokinetic and globally dilated heart was found in echocardiography with ejection fraction (EF) 20%. His medical treatment was arranged by cardiology department and referred to endocrinology clinic due to the 25 kg weight gain in one year, increased appetite and purple striae on the abdomen and shoulder. Laboratory tests revealed that; ACTH was <5 pg/ml, cortisol: 24.3 μg/dl, night cortisol: 24.7 μg/dl. After 1 mg dexamethasone suppression test (DST) and, 2 day 2 mg DST cortisol levels were found 18.9 μg/dl and 31.79 μg/dl, respectively. Because these findings suggest the CS, abdominal MRI was performed and revealed that a mass lesion (adenoma?) with a smooth contour, 37 × 28 mm in size, showing heterogeneous signal loss in the outer phase in the left adrenal gland. No pathological finding was found in pituitary MRI. With these findings, the patient was diagnosed with adreanal Cushing Syndrome. Viral myocarditis, lupus or autoimmune myocarditis was ruled out by negative viral respiratory panel, and negative autoimmune panel respectively. Absence of hilar adenopathy excluded sarcoidosis. Cardiac MRI conducted for cardiac exclusion of mixoma and revealed no findings that were consistent with the mixoma. After the exclusion of other reasons of cardiomyopathy the patient was diagnosed with dilated cardiomyopathy. In the control echocardiography 2 months after heart failure treatment, EF was found 40%. Metyrapone therapy was started gradually to lower the risk of surgery by lowering the patient's preoperative cortisol load. The cortisol level was found to be 17.4 μg/dl, 2 hours after the first metyrapone treatment. 10 days after metyrapone treatment, when the cortisol level decreased by 14.8 μg/dl, left adrenal gland excision was performed. Postoperative cortisol was found to be 1.8 μg/dl and 3.2 μg/dl. Pathology result was compatible with nodular diffuse hyperplasia.
Conclusion
Dilated cardiomyopathy and left ventricular failure are rare presentations of CS. Since cardiomyopathy can be reversed following successful treatment of Cushing's syndrome it is important to consider this diagnosis in patients with both heart failure and signs of CS.

Severe hypercholesterolemia with primary sclerosing cholangitis

Himmet Durmaz[1], Unzile Arifoglu[2], Caglar Keskin[2], Husniye Baser[1], Meral Akdogan Kayhan[3], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Ankara Yildirim Beyazit University Faculty of Medicine, Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara City Hospital, Department of Gastroenterology, Ankara, Turkey

Introduction
Hypercholesterolemia may develop due to primary and secondary causes. Diabetes mellitus, hypothyroidism, nephrotic syndrome and liver diseases are among the most common causes of secondary hyperlipidemia. Here, we will present a case with severe hyperlipidemia due to primary sclerosing cholangitis(PSC).
Case
A 36-year-old male patient was admitted to our outpatient clinic due to severe hypercholesterolemia. It was learned in his history that he had increased liver enzymes for 3 years. He was diagnosed with PSC 4 months ago and liver transplantation was planned. The patient was using ursodeoxycholic acid 2x500 mg treatment. On physical examination, blood pressure was 120/70 mmHg, heart rate was 78 beats/minute and he had icteric appearance. Xanthoma, xanthelasma, arcus cornea was not observed. In laboratory tests, AST, ALT, ALP, GGT, total bilirubin, total cholesterol, LDL, triglyceride, VLDL, HDL were 111 U/l, 108 U/l, 1037 U/l, 301 U/l, 17 mg/dl, 574 mg/dl, 499 mg/dl, 348 mg/dl, 70 mg/dl, 5 mg/dl, respectively. The patient had no other comorbid diseases other than PSC. There was no history of early cardiovascular disease or sudden death in family members. It was learned that the patient's LDL value was 102 mg/dl 5 years ago. The cause of hypercholesterolemia in the patient was considered depending on the PSC. Statin therapy was not considered due to impaired liver function tests. We planned to start cholestyramine 12 grams per day.
Conclusion
PSC is a liver disease with biliary obstruction. Lipid disorder due to biliary obstruction is associated with lipoprotein X (LpX). LpX is a abnormal low density lipoprotein. It is unable to exert negative feedback on the cholesterol synthesis rate limiting enzyme hydroxymethyglutaryl coenzyme A (HMG-CoA) reductase. In contrast, the presence of LpX increases the activity of HMG-CoA reductase in the liver with increased hepatic cholesterol synthesis. Patients with biliary obstruction have increased LDL and decreased HDL. Hypercholesterolaemia improves with removal of obstruction or liver transplantation. LDL apheresis, statins and cholestyramine decrease cholesterol levels in patients with PSC.

A case of non-familial pheochromocytoma presenting one of the identical twin at young age

Kubra Turan[1], Esra Copuroglu[1], Muhammed Sacikara[2], Narin Nasiroglu Imga[2], Altug Tuncel[3], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Yildirim Beyazit University Faculty of Medicine, Ankara City Hospital, Clinics of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara City Hospital, Clinics of Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara City Hospital, Clinics of Urology, Ankara, Turkey

Background
Pheochromocytomas are rare tumors originating from chromaffin cells and characterized by excessive catecholamine synthesis. They are usually benign lesions. Hypertension(HT), tachycardia, sweating and headache are frequently observed. We aimed to present a high malignancy suspected pheochromocytoma case diagnosed in a young age female.
Case presentation
A 20-year-old female patient was admitted to the emergency department due to high blood pressure, tinnitus and headache. The patient was hypertensive (220/110 mmHg) and had tachycardia (130/bpm). For the etiology of HT, renal doppler USG was performed. An extra-renal solid mass lesion (pheochromocytoma?) was reported. She was referred to our clinic. Surrenal MRI revealed a lesion in the left paraaortic area with 40 × 37 mm enhancement in the area corresponding to the adrenal region. 24-hour urinary normetanephrine and metanephrine levels were found 10 times higher than upper limit of the reference range. Laparoscopic partial adenomectomy was performed by the urologist. After surgery, blood pressure was return to normal range without any medication. In histopathology, Ki 67 proliferation index was reported as 20%. Periadrenal adipose tissue invasion, atypical mitosis, lymphovascular invasion and capsule invasion were found positive. Calculated PASS score was reported 6/21 and it was evaluated as high suspicion of malignancy. Genetic analysis (VHL, MEN, SDH) result was negative. The patient had an identical twin. Pheochromocytoma symptoms of the identical twin were not present**.** In the literature some cases of identical twins which have concominant pheochromocytoma were reported. We performed pheochromositoma screening tests for identical twin and no pathology was found.
Conclusion
Although pheochromocytoma is most common in the 4th and 5th decades, it can be seen in all age ranges. The majority of patients are sporadic, there are

also hereditary forms. Genetic background should be investigated in patients diagnosed with pheochromocytoma at the young age. Although our case was diagnosed with pheochromocytoma at a young age, her genetic tests was not showed any mutation.

Effect of dexamethasone's and triptorelin's treatment in 9-year-old girl with congenital adrenal hyperplasia due to 21- hydroxylase deficiency-case report

Beata Sawicka, Hanna Borysewicz-Sanczyk & Artur Bossowski
Medical University in Bialystok, Department of Pediatrics, Endocrinology and Diabetology with the Cardiology Division, Bialystok, Poland

Congenital adrenal hyperplasia due to 21-hydroxylase deficiency is the most common disorder, in which lack of the enzyme causes deficiency aldosterone and cortisol. The result of this deficiency is an increased level of ACTH. The classic form appears in early childhood and may be associated with the development of abnormal genitalia. Clinically older patients present the GnRH-independent precocious puberty with rapid growth and advanced bone age. We present the case of 9-year-old girl, who was treated of the congenital adrenal hyperplasia due to 21- hydroxylase deficiency. When the girl was 5 years old, she was diagnosed because of precocious puberty. The height and weight were over 97 percentile, bone age – 11 years, advanced puberty by Tanner stages: Th1, Pub 3, Ax 1, enlarged clitoritis. In laboratory tests the patient had normal cortisol level in serum and elevated adrenal androgens. Congenital adrenal hyperplasia was confirmed in steroid profile in urine. The hydrocortisone had been administered orally in dosages of 8-12 mg/m^2/day in three divided doses. The side effect of that therapy was hypertension. The result of using hydrocortisone was slow down progression of bone age. When the girl was 7.5 years old, because of progress precocious puberty, the test with GnRH was performed. Central precocious puberty was treated with triptorelin to achieve gonadotropin inhibition. Due to insufficient improvement after treatment with hydrocortisone the using therapy with dexamethasone (0.5 mg daily orally) caused decreased level of androgens, slowed growth during first year of treatment and normalization steroid profile in urine.

Results

1). The preferred glucocorticoid for chronic treatment of the congenital adrenal hyperplasia due to 21- hydroxylase deficiency is hydrocortisone. 2). For the purpose of prevented hyperandrogenism in children and adolescents it is important to treat the patient by antiandrogenic drugs. 3). Sometimes, precocious puberty should be treated centrally in children.

Evaluation of subclinical cardiovascular disease by carotid intima media thickness, epicardial adipose tissue thickness, serum endocan, and nesfatin-1 levels in patients with primary hyperparathyroidism

Muhammet Kocabas[1], Yakup Alsancak[2], Mustafa Can[1], Ilker Cordan[3], Hatice Çalışkan Burgucu[1], Mellia Karakose[1], Fatma Hümeyra Yerlikaya Aydemir[4], Mustafa Kulaksizoglu[1] & Feridun Karakurt[1]
[1]Meram Tıp Fakültesi Hastanesi, The Department of Endocrinology and Metabolism, Turkey; [2]Meram Tıp Fakültesi Hastanesi, Department of Cardiology, Turkey; [3]Edirne Sultan Murat 1. State Hospital, The Department of Endocrinology and Metabolism, Turkey; [4]Selçuk Üniversitesi Tıp Fakültesi Mediko Sosyal, The Department of Biochemistry, Turkey

Background

Primary hyperparathyroidism (PHPT) is known to be associated with cardiac and metabolic morbidities. Chronic hypercalcemia in PHPT patients has been reported to be associated with an increased risk of mortality, particularly due to cardiovascular disease, during long-term follow-up. Endocan is secreted by vascular endothelial cells and is involved in the regulation of important endothelial functions. Endocan secretion increases in a variety of endothelium-related pathological conditions such as atherosclerosis, inflammation, infections, and tumor progression. Nesfatin-1 was found to be expressed in the hypothalamus and involved in regulating food intake. Nesfatin-1 has also been found to have some cardiovascular effects such as regulation of blood pressure and heart rate, role in cardiomyocyte metabolism, and protection against ischemia / reperfusion injury.

Objective

The aim of our study was to evaluate the clinical relevance of serum endocan and nesfatin-1 levels, EAT thickness and CIMT as markers of increased CVD risk in patients with PHPT.

Materials and methods

In this case-control study, 44 patients with clinical evidence of PHPT, and 40 healthy control subjects were enrolled from October 2019 to October 2020. Serum concentrations of endocan and nesfatin-1 were measured by ELISA.

Results

CIMT values were statistically significantly higher in the PHPT group compared to the control group (P = 0.001). EAT thickness values were higher in the control group compared to the PHPT group, but there was no statistically significant difference (0.454). Serum endocan level was measured as 824.8±351 pg/ml and 826.68±373.65 pg/ml in PHPT patients and control group, respectively. Serum nesfatin-1 level was measured as 148.8±4.5 pg/ml and 149.14±5.66 pg/ml in PHPT patients and control group, respectively. There was no difference between the two groups in terms of serum endocan and nesfatin-1 levels (P = 0.963 and P = 0.510, respectively). In correlation analysis, a negative correlation was found between PTH and LDL cholesterol levels (P = 0.001). No significant relationship was found between other parameters.

Conclusions

No significant difference was found between PHPT patients and healthy controls in terms of serum endocan and nesfatin-1 levels. CIMT, which is a marker of CVD risk, was found to be increased in mild PHPT patients and consequently, CVD risk is high in these patients, but no relationship was found in terms of serum endocan and/or nesfatin-1 levels.

Keywords: primary hyperparathyroidism, carotid intima media thickness, epicardial adipose tissue thickness, endocan, nesfatin-1, cardiovascular disease risk.

Comparison of patients with normocalcemic and hypercalcemic primary hyperparathyroidism

leyla akdoğan, Sefika Burcak Polat, Cevdet Aydin, Berna Ogmen, Oya Topaloglu, Reyhan Ersoy & Bekir Cakir
Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey

Objective

Primary hyperparathyroidism (PHPT) is the most common cause of hypercalcemia. A group of patients who were followed up with a diagnosis of PHPT had normal calcium levels with high parathyroid hormone (PTH) levels. For the diagnosis of normocalcemic PHPT, secondary causes of hyperparathyroidism such as vitamin D deficiency should be excluded. In this study, the data of 318 PHPT patients who were operated were retrospectively analyzed, and biochemical and clinical characteristics of hypercalcemic and normocalcemic patients were compared.

Methods

The data of patients who were admitted to our hospital's endocrinology clinic between January 2012 and January 2019, diagnosed with PHPT and operated according to guidelines (all symptomatic patients and asymptomatic patients with at least one operation indication) were retrospectively evaluated. A total of 318 patients were divided into two groups as hypercalcemic and normocalcemic according to the corrected calcium level. The two groups were compared according to clinical and biochemical properties.

Results

Female gender was dominant in both groups (P = 0.07). The mean age was similar in both groups (P = 0.36), while it was 54.0 ± 10.3 in the hypercalcemia group, and 55.4 ± 12.8 in the normocalcemia group. As expected, serum corrected calcium (Ca), PTH levels and urinary Ca excretion were higher in the hypercalcemia group (P < 0.01). While phosphorus (P) level was lower in the hypercalcemia group (P < 0.01), urinary P excretion was similar between the two groups (P = 0.77). There was no difference between the two groups in alkaline phosphatase, creatinine, and vitamin D levels. Percentage of localization with preoperative ultrasonography and mean adenoma size were similar. Also, there was no difference in adenoma features (echogenicity, cystic appearance) and localization, thyroid nodules and thyroiditis prevalence on ultrasonography. The positive result obtained on neck MRI and MIBI scanning was similar. There was no difference between the two groups in terms of stone incidence and osteoporosis prevalance (P = 0.72 and P = 0.08, respectively).

Conclusion
In our cohort, corrected Ca and PTH levels and urinary Ca excretion were high in the hypercalcemic group, as expected. But, the phosphorus level was significantly lower in the hypercalcemia group. In the normocalcemic group, the PHPT phenotype was found to be similar to the hypercalcemic group. These findings suggest that the frequency of surgical indications is similar in normocalcemic PHPT patients to that in hypercalcemic PHPT patients.

Vitamin D deficit in type 2 diabetes patients during the winter in Northern Gran Canaria with and without supplementation

Alba Hernández Lázaro[1], Paula María Fernandez-Trujillo-Comenge[1], Ricardo de Leon-Durango[1], Agnieszka Kuzior[2], Manuel Esteban Nivelo Rivadeneira[1], Carmen Acosta-Calero[2], Claudia Arnas-Leon[2], Sara Quintana-Arroyo[2], Paula Gonzalez-Diaz[3] & Francisco Javier Martinez-Martin[2]
[1]Hospital Universitario de Gran Canaria Dr. Negrin, Endocrinology and Nutrition, Las Palmas de Gran Canaria, Spain; [2]Hospitales San Roque, Endocrinology and Nutrition, Las Palmas de Gran Canaria, Spain; [3]Centro de Salud de Arucas, Primary Healthcare, Arucas, Spain

Introduction
Vitamin D deficiency is associated with higher risk of COVID-19, and type 2 diabetic patients are a vulnerable group. We described an alarming rate of vitamin D deficiency (81.0% < 30 ng/ml plasma calcifediol) in unsupplemented type 2 diabetes patients during the 2020 spring lockdown in Northern Gran Canaria. During the winter period (December 2020 to February 2021) some restrictions for social gatherings and a nightly curfew have been enforced but there was no mandatory lockdown.
Objectives
To assess the prevalence of vitamin D deficiency in type 2 diabetic patients from Northern Gran Canaria during the winter period (December 2020 to February 2021).
Methods
Plasma calcifediol levels were sampled in an unselected type 2 diabetic population, along with age, gender and vitamin D supplementation status.
Results
Data were obtained from 227 consecutive patients, 133 female (58.6%), mean age 59.7 ± 14.7 years. 103 (45.4%) were taking vitamin D supplements. Mean plasma calcifediol was 31.2 ± 13.0 ng/ml; but it was lower than recommended (<30 ng/ml), in 50.2% of the patients, deficient (<20 ng/ml) in 20.3% and severely deficient (<12 ng/ml) in 5.3%. In supplemented patients, calcifediol was mostly adequate (mean 41.1 ± 10.7 ng/ml, with 15.5% < 30 ng/ml, 3.9% < 20 ng/ml, none < 12 ng/ml and none > 80 ng/ml) but low in unsupplemented patients (mean 23.0 + 8.2 ng/ml, with 79.0% < 30 ng/ml, 34.7% < 20 ng/ml and 9.3% < 12 ng/ml). Plasma calcifediol was significantly higher in supplemented patients (mean difference 18.1 ng/ml, unpaired *t*-test, $P < 0.0001$) and the proportions of low, deficient and severely deficient patients were significantly lower (Fisher's exact test, $P < 0.0001$, $P < 0.0001$ and $P = 0.0006$, respectively). Female patients had slightly higher plasma calcifediol than males (mean difference 4.1 ng/ml, unpaired t-test, $P = 0.019$). There was an inverse correlation between age and plasma calcifediol (coefficient -0.091, $P = 0.004$).
Conclusions
Even without a mandatory lockdown, the prevalence of low calcifediol levels during the winter months in our unsupplemented type 2 diabetic population is extremely high. However, when taking vitamin D supplements their vitamin D status is satisfactory with < 4% deficient patients and none severely deficient. Their use was effective to prevent the deprivation associated with voluntary lockdown, social gathering restrictions and low insolation during wintertime.

AEP801

A case report of Primary hyperparathyroidism presenting as a brown tumor in the mandible

Gonzalo Miranda
Hospital Real de San Andrés, Cercado de Lima, Peru

Brown tumor (BT) is a rare bony benign lesion caused by excess osteoclast activity and hemosiderin deposition because of uncontrolled primary or secondary hyperparathyroidism. 71-year-old man with no significant pathological history, twelve months before admission presented with growing mandibular brown tumor and bone pain in lower limbs. He was referred to Endocrinology unit. Physical examination found left facial paralysis, absence of horizontal branches and left jaw ascending. A total parathyroidectomy was performed without implantation of a parathyroid fragment into the forearm muscle. PTH was monitored intraoperatively, and the PTH level decreased. A histopathological examination of the mass confirmed the diagnosis of parathyroid adenoma with a tumor result of giant cells of 1.8 × 5 × 4 cm with necrotic and hemorrhagic areas and serum PTH level continued to decrease after surgery. Surgical resection of a brown tumor is generally not recommended and should only be considered if the patient wants quick resolution, if the bony lesion is compromising body functions or promoting facial deformation, or if the lesion fails to regress after 1–2 years. The 10-year duration of our case was too long, reflecting the inadequacy of preventing and managing brown tumors in underdeveloped countries like Peru where is from our patient. In developed countries, PHPT is mostly diagnosed by routine biochemical screening without clinical signs suggesting the disease, so the classical manifestations of PHPT are very uncommon. The case of an older adult patient with an unusual presentation of primary hyperparathyroidism by a mandibular-level brown tumor is present as an initial manifestation, which should be considered in differential diagnosis when evaluating a patient with a bone tumor at the maxillary level presenting with multifocal osteolytic bone lesions, although bone metastases and multiple myeloma still should be considered first.

Hypovitaminosis D in patients with SARS-CoV2: Correlation with inflammatory markers and severity of the disease

Federica Saponaro[1], Maria Franzini[2], Chukwuma Okoye[3], Rachele Antognoli[3], Fabio Monzani[3], Alessandro Celi[1], Riccardo Zucchi[1], Aldo Paolicchi[2] & Alessandro Saba[1]
[1]Department of Surgical, Medical, and Molecular Pathology and Critical Care Medicine, University of Pisa, Pisa, Italy; [2]Department of Translational Research and New Technologies in Medicine, University of Pisa, Pisa, Italy; [3], Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

In March 2020, the infection due to **COVID-19** spread as a pandemic emergence showing a mutable phenotype ranging from asymptomatic to lethal severe acute respiratory syndrome coronavirus 2 **(SARS-CoV-2).** Among multiple biological and environmental investigated factors, **vitamin D status was proposed as a credible candidate**, since hypovitaminosis D could be identified as a modifiable risk factor and a potential tool in SARS-CoV-2 prevention or ancillary treatment.
The aim of this study is to analyse the relationship between vitamin D status and a complete biochemical panel of immune system markers (pro and anti-inflammatory factors), in a cohort of patients with SARS-CoV-2. This was a **retrospective, observational study** conducted on available serum samples from consecutive patients with COVID-19 related pneumonia, admitted from March to May 2020 in two Hospital Units (Pulmonary and Geriatric Unit) in Pisa.
A total of 93 patients were included in the study, they were mainly males ($n = 64$, 68.8%) with a mean age of 68±16 years (median 69 i.r 57–80). Mean 25OHD was 17.3±10.7 ng/ml, with a median of 16.5 ng/ml (i.r. 7.9–23.2). Eighty-three patients had 25OHD levels ≤ 30 ng/ml (89%), 61 patients (65%) had 25OHD levels £20 ng/ml and 27 patients (29%) had 25OHD £10 ng/ml (severe vitamin D deficiency). Inflammatory markers were measured in all patients and compared between patients with 25OHD levels >20 ng/ml and those with ≤ 20 ng/ml. The latter showed significantly higher IL-6 [20.8 (10.9–45.6) vs 12.9 (8.7–21.1) pg/ml $P = 0.02$], CRP [10.7 (4.2–19.2) vs 5.9 (1.6–8.1) mg/dl $P = 0.003$], TNFα [8.9 (6.0–14.8) vs 4.4 (1.5–10.6) pg/ml $P = 0.01$], D-dimer [0.53 (0.25–0.72) vs 0.22 (0.17–0.35) mg/l $P = 0.002$] and IL-10 [3.7 (1.8–6.9) vs 2.3 (0.5–5.8) pg/ml $P = 0.03$] (Figure 1 panel A-E). In the overall group, an inverse correlation was found between 25OHD and IL-6 ($r = –0.22$, $P = 0.03$), between 25OHD and CRP ($r = –0.21$, $P = 0.04$), between 25OHD and D-dimer ($r = –0.43$, $P = 0.001$), between 25OHD and IL-10 ($r = –0.25$, $P = 0.02$) (Figure 2 panel A-D). These correlations remained statistically significant in a multivariate linear regression analysis, adjusted for age and gender [β=-0.64, $P = 0.04$ IL6; β=-0.17, $P = 0.03$ CRP; β=-0.017, $P = 0.001$ D-Dimer; β=-0.11, $P = 0.02$ IL-10]. In conclusion, hypovitaminosis D is related to the negative prognostic inflammatory status in patients with SARS-Cov2.

Physical activity and female sexual dysfunction: too much of a good thing?

Elisa Maseroli[1], Giulia Rastrelli[1], Vincenza Di Stasi[1], Sarah Cipriani[1], Irene Scavello[1], Tommaso Todisco[1], Veronica Gironi[2], Giovanni Castellini[2], Valdo Ricca[2], Flavia Sorbi[3], Massimiliano Fambrini[3], Felice Petraglia[3], Mario Maggi[4] & Linda Vignozzi[1]

[1]Department of Experimental Clinical and Biomedical Sciences "Mario Serio", University of Florence, Florence, Italy; [2]Psychiatric Unit, Department of Neuroscience, Psychology, Drug Research and Child Health, University of Florence, Florence, Italy; [3]Gynecology Unit, Department of Biomedical, Experimental and Clinical Sciences "Mario Serio", University of Florence, Florence, Italy; [4]Endocrinology Unit, Department of Experimental Clinical and Biomedical Sciences "Mario Serio", University of Florence, Florence, Italy

Background
Research on the relationship between physical activity (PA) and female sexual dysfunction (FSD) is lacking.
Aim
To investigate the clinical, psychological, and sexual correlates of PA in women with FSD.
Methods
A non-selected series of n = 322 pre- and post-menopausal patients consulting for FSD was retrospectively studied. Regular involvement in PA and its frequency (<1 hour/week: sedentary, 1–3 hours/week: active, 4–6 hours/week: very active, >6 hours/week: extremely active) were investigated with a specific question.
Outcomes
FSDs, including HSDD (Hypoactive sexual desire disorder) and FGAD (Female genital arousal disorder), were diagnosed according to a structured and clinical interview. Participants underwent a physical examination and a clitoral Doppler ultrasound, and were asked to complete the Female Sexual Function Index (FSFI), Female Sexual Distress Scale-Revised (FSDS-R), Body Uneasiness Test (BUT), and Middlesex Hospital Questionnaire (MHQ).
Results
At multivariate analysis, women engaging in PA (67.4%, n = 217) scored significantly higher in several FSFI domains - including desire, arousal and lubrication - and showed lower sexual distress and lower resistance of clitoral arteries, as compared to sedentary women. A significant, inverse association between PA and HSDD was observed. Mediation analysis demonstrated that the negative association between PA and HSDD was partly mediated by body image concerns (BUT Global severity index), psychopathological symptoms (MHQ total score) and sexual distress (FSDS-R score). These latter two factors also partly mediated the association between PA and a reduced risk of FGAD, whilst a lower BMI was a full mediator in the relationship between PA and FGAD. Finally, extreme PA was associated with significantly worse scores in several psychosexual parameters (i.e. sexual satisfaction and histrionic/hysterical symptoms), even compared to a sedentary lifestyle.
Clinical Implications
Women consulting for FSD may gain benefits on desire, arousal, lubrication and sex-related distress from regular PA; however, physicians should remain alert to the downsides of excessive exercise.
Strengths & Limitations
The main strength lies in the novelty of the findings. The main limitations are the cross-sectional nature, the clinical setting, the small sample size of the different PA groups, and the use of self-reported instruments for the evaluation of PA.
Conclusion
In women with FSD, PA was associated with better sexual function and clitoral vascularization, lower sexual distress and reduced odds of HSDD and FGAD; the benefits of PA on sexuality were mediated by both psychological and organic determinants; excessive PA was related with a poor overall sexual function and with a low sexual satisfaction.

Effects of Christian Orthodox versus intermittent fasting on plasma irisin concentrations in overweight adults

Spyridon Karras[1], Theocharis Koufakis[1], Lilian Adamidou[2], Georgios Dimakopoulos[3], Paraskevi Karalazou[4], Katerina Thisiadou[4], Kali Makedou[4] & Kalliopi Kotsa[1]

[1]Division of Endocrinology and Metabolism, First Department of Internal Medicine, Medical School, Aristotle University of Thessaloniki, AHEPA University Hospital, Thessaloniki, Greece; [2]Department of Dietetics and Nutrition, AHEPA University Hospital, Thessaloniki, Greece; [3]Medical Statistics, Epirus Science and Technology Park Campus of the University of Ioannina, Ioannina, Greece; [4]Laboratory of Biological Chemistry, Medical School, Aristotle University of Thessaloniki, AHEPA University Hospital, Thessaloniki, Greece

Irisin is an adipomyokine produced during physical activity and implicated in the browning of adipose tissue. Existing evidence suggests an inverse relationship between irisin plasma levels and adverse metabolic outcomes; however, the exact impact of diet on irisin levels remains unclear. We aimed to assess the effects of two dietary patterns, Christian Orthodox fasting (OF) and 16:8 time-restricted eating (TRE), on irisin concentrations among overweight, metabolically healthy, subjects. Plasma irisin, glycemic indices, lipid parameters, calcium homeostasis markers, and anthropometry were measured in 29 Orthodox fasters and 14 age- and body mass index (BMI)-matched TRE controls (mean age and BMI 48.8 years and 28.7 kg/m^2, respectively) at three time points: before the implementation of the energy-restricted diets (baseline), at the end of the dietary intervention (7 weeks) and 5 weeks after participants returned to their standard dietary habits (12 weeks from baseline). At 12 weeks, the OF group had higher irisin concentrations than both its baseline values (64.3 ± 54.4 vs 43.6 ± 42.2 ng/ml, P = 0.01) and those of the TRE group at the same time point (64.3 ± 54.4 vs 44.2 ± 26.6 ng/ml, P = 0.04). Glycemic, lipid, and anthropometric markers were not found to correlate with irisin levels. Parathyroid hormone (PTH) concentrations at 12 weeks correlated with irisin levels (P = 0.04), with lower values of irisin expected for higher PTH. Our findings suggest favorable long-term effects of OF on irisin status. The interaction between irisin, PTH, and nutrition deserves further investigation.

Self-management behavior of the patients with type 2 diabetes: A cross-sectional survey in the eastern european population (Belarus)

Andrei Yaroma[1] & Larissa I. Danilova[2]

[1]Belarusian Medical Academy of Postgraduate Education, Department of Psychotherapy and Medical Psychology, Minsk, Belarus; [2]Belarusian Medical Academy of Postgraduate Education, Department of Endocrinology, Minsk, Belarus

Background
The prevention of complications and improvement of metabolic control and state of health in diabetes cannot be effective only with medications. And now we need to develop different approaches – not only up to date pharmacological treatment of diabetes, but change the Self-Management Behavior among patients with Type 2 Diabetes.
Aims
To assess the current status of diabetic self-management behavior and the factors responsible for such knowledge among type 2 diabetes patients in Minsk, Belarus.
Methods
A correlational, exploratory, quantitative research design was utilized. We used the Diabetes Self-Management Questionnaire (DSMQ) and a questionnaire with free questions related to diabetes to investigate patients with T2DM from August to December 2020 in Minsk, Belarus.
Results
We enrolled a total of 206 patients in the present study. The median score of self-management behavior was 5.48 (10 maximum point), the interquartile range was 4.64–6.04 points. An analysis of subscale was: "Glucose Management" was 7.33 (6.00; 8.00) (P -value: < 0.001); "Dietary Control" 5.00 (3.33; 5.83) (P-value: < 0.001); "Physical Activity" 4.44 (2.22; 5.56) (P -value: < 0.001); "Health-Care Use" 5.56 (3.33; 6.67) (P -value: < 0.001). Answers for the 16th item "My diabetes self-care is poor" were: "Applies to me very much" 27.20%; "Applies to me to a consider-able degree" 4.76%; "Applies to me to some degree" 33.80%; "Does not apply to me" 34.27%. Further, a correlation was made between the onset of the disease, the patient's age, the degree of cognitive impairment, the average mean of hemoglobin A1c and DSMQ subscales.
Discussion
Self-Management Behavior in Patients with Type 2 Diabetes was negatively correlated with: the duration of the course of diabetes; the patient's age; the degree of cognitive impairment; the existing disorders of carbohydrate metabolism.

Conclusion
There are a number of reasons that could affect on changes in Self-Management behavior. It is likely that the maximum Self-Management behavior changes are available to the patient in the early stages of the onset of type 2 diabetes. Given the limited capacity of any national health care system, it is worth paying attention to the possibility of making maximum efforts to change Self-Management behavior among patients in whom the period of diagnosis of diabetes mellitus is from 1 to 2 years.

Rapid onset of severe diabetes in adult patients with prior, mild SARS-COV-2 infection

Francesca Pecori Giraldi[1,2]
[1]University of Milan, Dept. Clinical Sciences & Community Health, Milan, Italy; [2]Istituto Auxologico Italiano, Milan, Italy

COVID-19 is affecting Northern Italy since early 2020 and long-term consequences of the pandemia are progressively coming to light. Over the past months, a marked increase in the number of adults with rapid-onset severe diabetes has been observed at the Diabetes Clinic thus prompting an evalutation into possible links with COVID-19. Of note, diabetes and hyperglycaemia are known to worsen during COVID-19 and there are several reports of new-onset hyperglycaemia during SARSCoV2 infection, possibly due to the links between SARS-CoV-2 and pancreatic islet damage. Aim of the present study was to review charts of adult patients with newly diagnosed, severe diabetes recorded after the first pandemic wave.
Methods
Data relating to diabetes and SARS-CoV-2 infection was reviewed in patients attending the Diabetes Clinic from September 2020 to March 2021.
Results
Out of 120 patients who attended the clinic in the 7-month span, four (2 men and 2 women, age 51–71 years) presented with recent-onset, severe diabetes. None had previous history for hyperglycaemia or diabetes. Features of uncontrolled hyperglycaemia (e.g., weight loss, glycosuria, polyuria) had developed over the prior 2–3 months; patients were normal-weight or midly overweight and did not report significant changes to their eating habits. HbA1c ranged from 10.7% to 14.1%, fasting glucose from 300 to 410 mg/dl. Testing for autoantibodies common to Type 1 diabetes proved negative. Two patients had previously presented mild symptoms of COVID-19 and tested positive for SARS-Cov-2 whereas the other two reported close contacts with SARS-CoV-2 positive individuals during past months. None of the patients had been hospitalized or required any treatment for COVID-19-related symptoms.
Conclusions
This report describes an increased incidence of rapid-onset, uncontrolled hyperglycaemia in adults with no known risk factor for diabetes in the aftermath of the first COVID-19 pandemic wave. Severe diabetes developed months after mild or asymptomatic SARS-CoV-2 infection and mandates the need for an increased awareness among physicians given the sheer number of individuals who came and will come in contact with SARS-CoV-2.

Significance of technology in diabetes care during pandemic in our county hospital

Azhar Al-Shaibany
Our Lady's hospital/ Navan, Meath, Ireland, General Medicine/ Endocrinology unit, Navan, Ireland

Introduction
In last two decades, new technological advances have permitted the use of novel approaches to the management of diabetes. Continuous Glucose Monitoring (CGM) has been linked to improved HbA1c and overall quality of life. The evidence, however, is limited to retrospective studies. This audit was designed to evaluate the effectiveness and impact of CGM before and after on HbA1c and quality of life in clinical practice setting during pandemic in our county for 12 patients in our local Diabetes Day Centre (DDC).
Methods
Data of diabetes patients identified from medical notes of DDC in Our Lady's hospital of Navan for patients commenced on DEXCOM CGM since we started using CGM in 2019. Total number of patients recruited for this audit is12. All patients have type I diabetes mean age of participant is 38 years for 10–12 months duration.
Patients Contacted by phones to answer the following questions:
- Frequency of hypoglycemia (<4 mmol) episodes before and after getting CGM?
- HbaA1C before and after CGM? Collected from our lab system.
- Lifestyle quality after getting CGM system?
- Satisfaction: Are patients satisfied with DEXCOM CGM (less hypoglycemia, less stress in diabetes control, more confidence)? With rating (0–10) Score.

Table 1 Hypoglycemia before and after, Hba1c before and after CGM

Number	Hypoglycemia before CGM	Hypoglycemia after CGM	HbAlc before CGM (mmol/mol)	HbAlc after CGM (mmol/mol)	Life quality after CGM	Satisfaction score 0–10
1	up to few limes aclay,	Twice a month	92	78	improved	7
2	up to 5 times a month	Nil	94	64	improved	10
3	Once a month	Once a month	74	70	Improved	10
4	Once a clay	Once a month	66	55	Improved	10
5	Tree times/clay	3 times/week	88	73	Improved	10
6	4 times/week	One time/week	66	58	improved	9
7	Once every week	Once every 3 months	80	64	improved	8
8	Up to 8 per week	Up to 2 per week	59	70	improved	10
9	Once per month	No hypoglycemia	113	91	improved	8
10	Almost every day	No Hypoglycemia	91	101	improved	10
11	Once per month	No hypoglycemia	85	70	improved	8
12	Once every week	No Hypoglycemia	50	Not done	improved	

Results
Among 12 patients with type I diabetes who were commenced on CGM, it shows:
- All patients have no or very little hypoglycemia after CGM with hypoglycemia confidence.
- 90% of patients had reduced overall HbA1c after CGM and less diabetes distress.
- All patients noted remarkable improvement in quality of life.
- All patients satisfied with CGM technology and more than half of patients have 100% satisfaction and others more than 80% satisfaction.

Figure 1 Satifaction score of patients on technology.

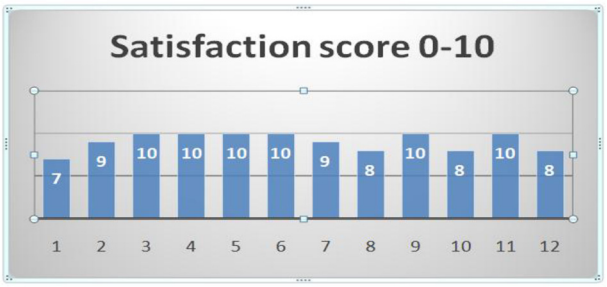

Figure 2 Average HbA1c pre and post CGM.

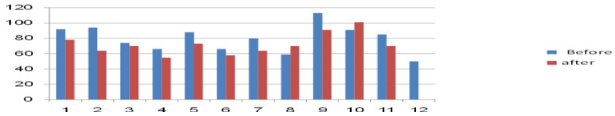

Conclusion
Obviously, it is highly recommended to consider CGM a common and useful tool in diabetes care who was at high risk of dysglycemia. It showed significant improvement in less time spent for day and nocturnal hypoglycemia. Patients feel safer and more confident during pandemic where the diabetes care facilities are very limited. It provided remarkable

glycemic control and positive effects on HbA1c levels. Less dysglycemia, as a result, improved life quality.

Comparison of the clinical efficacy of Semaglutide between DPP4-inhibitor-naive and DPP4-inhibitor-experienced patients in a real world setting in Spain

Roberto Miguel Sierra Poyatos[1,2], Jersy Jair Cardenas Salas[1,3], Bogdana Luiza Luca[1], Nancy María Sanchez Gomez[1], Naiara Modroño Mostoles[3], Begoña Sánchez Lechuga[1], Eva Cruces Vega[3], Maria Jesus Silva Rodriguez[1,3], María De La Paz Gómez Montes[3], Diego Meneses González[1], Teresa Montoya Alvarez[3], María de los Angeles Velez Romero[1], Alicia Estrella Santos[1], Maite Ortega Juaristi[1], Maria De Los Angeles Gonzalo Redondo[1] & Clotilde Vazquez Martinez[1,2,3,4]

[1]Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain; [2]General Hospital Villalba, Collado Villalba, Spain; [3]Hospital Universitario Infanta Elena, Valdemoro, Spain; [4]Hospital Universitario Rey Juan Carlos, Móstoles, Spain

Introduction

Glucose and weight control effectiveness in patients with Type 2 diabetes (T2D) in treatment with DPP4 inhibitors (DPP4i) that switch to semaglutide is scarce. We aim to assess it in a real-world setting of DPP4i-experienced patients and compare it to DPP4i-naive patients.

Methods

Patients with T2D that were prescribed Once-Weekly semaglutide in 4 hospitals in Madrid-Spain were identified. Patients with another new glucose-lowering-agent prescription and GLP1-experienced patients were excluded. A total of 250 patients were included. The Changes at 6 months of follow up (Paired T-test, Exact McNemar), and comparison between groups (T-test and Chi^2) were analysed. A multiple linear regression model to assess HbA1c change in both DPP4i groups (naive vs experienced) adjusted by age, T2D duration, BMI, baseline-HbA1c, insulin use, SGLT2-inhibitors use and semaglutide dose was perfomed.

Results

Baseline weight and BMI was higher in DPP4i-naive group and HbA1c was higher in DPP4i-experienced group. A higher proportion of patients in the DPP4i-naive group had a baseline-HbA1c <7% compared to DPP4i-experienced. There were no other baseline differences (Table 1). At 6 months of follow up boths groups achieved significant reductions in HbA1C, Glucose, weight, BMI and fat mass, but there were no differences between groups. The proportions of patientes that achieved a HbA1c <7% was higher in the DPP4i-naive group (Table-2). Only patients in the DPP4i-naive group achieved a signifficant reduction in insuline dose. After adjusment, the HbA1c reduction in the DPP4i-experienced group was 0.36% lower than in DPP4-naive (IC95%: 0.14% to 0.59%).

Conclusions

Switching to semaglutide is an effective glucose and weight lowering treatment in DPP4i-experienced patients with T2D.

Table 1 Baseline Characteristics

	DPP4i-Naïve n = 153	DPP4i-experienced n = 97
Age(years)	60.1±11.0	62.0±9.5

Peripheral serotonin and its interaction with other hormones, in male Wistar rats with obesity and obesity-induced diabetes, studied by using of LP533401

Ivaylo Bogomilov[1], Ivona Daskalova[2], Vesela Mihneva[2], Rumen Nikolov[3] & Nadka Boyadjieva[3]

[1]Military Medical Academy-Sofia/Medical University Sofia, Endocrinology/ Pharmacology, Sofia, Bulgaria; [2]Military Medical Academy-Sofia, Endocrinology, Sofia, Bulgaria; [3]Medical University-Sofia, Pharmacology, Sofia, Bulgaria

Background and aims

95% of serotonin is produced in the periphery. Serotonin system in the periphery regulates multiple physiological aspects. In previous researches that we made, using the Tph1 inhibitor - LP533401 (peripheral serotonin inhibitor) it shows that this agent could be use for treatment of obesity and obesity-induced diabetes in male Wistar rats. With current study we aimed to look more detailed in to fine mechanisms of action of serotonin related with other hormones such as ghrelin and leptin.

Materials and methods

We used forty Wistar rats separate in 2 groups- rats with induced obesity and diabetes and healthy rats (control group). Each of this groups was separated in other 2 - one with daily intraperitoneal injection of LP533401 (0.5 mg/kg) and one without. In 4 weeks period, we were tracking different factor-blood glucose level, insulin secretion, rats weight, blood levels of ghrelin and leptin. We measured the level of ghrelin and leptin in the beginning of the study and in the beginning of every week just before the meal.

Results

After application of LP533401, the blood levels of ghrelin starts to change. In the group with diabetic and obese rats using LP544401, the levels of ghrelin decreased of 5.4% for the first week till 12.2% in the fourth week (P<0.05), and with 9,4% (in total) in the control group. No significant dynamic in the groups without daily intraperitoneal injection of LP533401. Also there were significantly reduction of hyperglycemia and peripheral insulin resistance and reducing body weight in the obese and diabetic rats group, but also in the control group using LP533401. In the beginning of the study, the levels of leptin were around 3 times higher in the diabetic and obese rats' groups both using LP533401 or not. During the study, the leptin level in the diabetic and obese rats group using LP533401 decrease with 54.4% (P <0.05). In the diabetic and obese rats group in which we were not using LP533401, the levels of leptin raised with 5.4%.

Conclusion

Using LP533401 inhibitor significantly decrease fasting blood level of ghrelin in rats with induced obesity and diabetes, which corresponded with their weight loss and reduction of hyperglycemias. The level of leptin in the group whit diabetic and obese rat using LP533401, also decrease significantly together with their weight loss, which leads us to the conclusion for decreasing of leptin resistance in this group.

Post-transplant dyslipidemia in two cases

Nurcan Ince[1], Bugra Durmus[2], Ozgur Ozcelik[2], Ahmet Dirikoc[1], Cevdet Aydın[1], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakır[1]
[1]Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Bilkent City Hospital, Ankara, Turkey, Department of Endocrinology and Metabolism, Ankara, Turkey

Introduction
Lung transplantation was associated with a 32% prevalence of hypercholesterolemia and a 41% prevalence of hypertriglyceridemia. The prevalence of dyslipidemia in liver transplant recipients is 43% and 31% –51%. In this report, we present 2 cases who developed dyslipidemia after transplantation.
Case 1
The blood test of a 73-year-old male patient who had lung transplantation about 3 years ago revealed Triglyceride (TG) 475 mg/dl (<150), LDL-Cholesterol: 382 mg/dl (<100), HDL 53 mg/dl (>40), Total cholesterol 431 mg/dl (<200) and HbA1C: 8.3. Six months ago, he was diagnosed with diabetes mellitus by his primary physician. He was on everolimus, prednisolone, and mycophenalate sodium therapy, and was referred to us. There were no cutaneous findings related to hyperlipidemia. After the diet and blood sugar regulation, the tests were repeated; TG was 422 mg/dl and LDL was 366 mg/dl. He had elevated liver function test (LFT) levels, and hepatitis panel and liver auto antibodies were negative. Atorvastatin 1× 10 mg was initiated on 14/02/2020. TG was 210 mg/dl (<150), and LDL cholesterol level was 123 mg/dl (<100).
Case 2
A 65-year-old female patient underwent liver transplantation from a cadaver on 12/09/2019 due to toxic hepatitis and on 25/09/2019 due to hepatic vein thrombosis after transplantation. Receiving tacrolimus and mycophenolic acid treatments after transplantation, she developed refractory dyslipidemia after the second transplant. Tests performed in February 2020 showed levels of Triglyceride 474 mg/dl (<150), LDL-Cholesterol 512 mg/dl (<100), Total Cholesterol 815mg/dl (<200) and HDL cholesterol 11 mg/dl (>50). Pravastatin 1 × 40 mg was initiated in February 2020 and intermittent lipid apheresis was performed. In April 2020, ezetimibe 1 × 10 mg was added to her treatment. In May 2020, LDL level was determined 186 mg/dl.
Discussion
Maintaining or improving allograft function after transplantation and reducing cardiovascular risk are main objectives during follow-up. Interventions for dyslipidemia have the effect of reducing cardiac events in clinical studies specific to transplant population.

AEP812

Psychological factors in type 2 diabetes mellitus: A cross-sectional survey in the eastern european population (Belarus)

Andrei Yaroma[1] & Larissa I. Danilova[2]
[1]Belarusian Medical Academy of Postgraduate Education, Department of Psychotherapy and Medical Psychology, Minsk, Belarus; [2]Belarusian Medical Academy of Postgraduate Education, Department of Endocrinology, Minsk, Belarus

Background
It has often been argued that important psychosocial factors such as depression, anxiety and emotional stress can influence self-help behavior and therefore negatively affect glycemic control. In turn, the reduced quality of life due to chronic illness is a mediated cause of poor glycemic control. Also, attention is drawn to the prevalence of cognitive impairments and dementia.
Aims
1) to assess the psychological status of patients with diabetes; 2) to describe subgroups of patients with anxious and depressive reactions; 3) to assess quality of life. To assess the current status of diabetic self-management behavior and the factors responsible for such knowledge among type 2 diabetes patients in Minsk, Belarus.
Methods
Questionnaires were used to assess cognitive impairment (MoCA), depressive disorders (PHQ-9), anxiety disorders (GAD-7), quality of life (RU-ADDQol).
Results
We examined a total of 206 patients in the present study. The prevalence of cognitive decline was 79.07±3.10% (136/172) (25 and below points) in patients with type 2 diabetes. The average score was 19.00 (18.00; 25.00). The average value of depressive reactions on the PHQ-9 scale in the study group was 11.00 (8.00; 13.00). Mean of anxious reactions on the GAD-7 scale in the study group was 8.50 (5.75; 11.00). The average value of the quality of life on the RU-ADDQol scale in the study group was –3.21 (–3.68; –2.84); the average value for men is –2.63 (–3.12; –2.42), for women –3.39 (–3.74; –3.04). The differences are statistically significant between men and women (W-statistic: 4144.50, p-value: <0.001). The lowest score was obtained for the parameter motivation (–4.11), freedom to eat (–4.48), financial situation (–4.18), feelings about future (–3.87). We also analyzed the correlation of the level of glycated hemoglobin with the level of cognitive decline, depressive and anxiety reactions, and the level of quality of life.
Discussion
The prevalence of cognitive impairments, anxiety and depressive reactions in the population of patients with type 2 diabetes mellitus is higher than among a similar sample of healthy people. Psychological factors (cognitive impairment, anxiety and depressive reactions) negatively affect metabolic parameters, motivation and limit the ability to adapt to type 2 diabetes. In addition, mental factors were directly correlated with poor glycated hemoglobin levels and quality of life.
Keywords: behavior, RU-ADDQol, diabetes/quality of life, depression, anxiety, psychology, type 2 diabetes mellitus, eastern europe.

Three faces of the metabolic syndrome in children

Amalia Ioana Arhire
Bucharest, Endocrinology, Diabetes and Nutrition Department, Bucharest, Romania

Introduction
As the incidence of pediatric obesity is increasing, so is the incidence of metabolic syndrome in the pediatric population. We present the management of 3 such cases.
Case report
Three 14 (D.D), 15 (C.A.), 16 (C.M) year-old males presented for weight and metabolic management.DD had a medical history weight gain since 2 years old, obesity, dyslipidemia, hyperuricemia. C.A., obese since 2018, with hypertriglyceridemia and insulin resistance (HOMA-IR of 3.71). C.M., obese since 2015, with a Bethesda II 1.5 cm thyroid nodule (right lobe), hyperuricemia since 2017. All three had important first degree antecedents of type 2 diabetes, hypertension and metabolic syndrome. The clinical examination showed in all three boys normal pubertal Tanner stage (P4–5G4), D.D: BMI 35.5, 1.68 m (+2SD), 44% fat, 179% obesity degree, BP 130/80 mmHg and a waist circumference: 113 cm, C.A.: BMI 30.2, 1.82 m (+2.5DS), 22.9% fat, 137% obesity degree, BP 147/78 mmHg, important acanthosis nigricans, waist circumference: 106.5cm and C.M.: BMI 35.4, 1.83 m (+2DS), 38.7%fat, 161% obesity degree, BP 145/88mmHg, waist circumference: 120 cm.
Laboratory
Dyslipidemia with HDL: 35/26/39, TG: 71/250/190, insulin resistance in C.M.-HOMA-IR: 5.8, type 2 diabetes in C.A: HbA1c= 7.4%, blood glucose 135, hepatic cytolysis in C.A. (TGO= 118, TGP= 182) and D.D. (TGP= 48.6, TGO= 26 UI/l,) 25-OH vitamin D – between 17 and 25 ng/dl and hyperuricemia 10.53 in D.D., 7.4 in C.A. and 8.4 mg/dl in C.M. The abdominal ultrasound: severe liver steatosis, BP monitoring showed 1st degree hypertension in all three patients. The basal metabolic rate (indirect calorimetry) - low in D.D. (85%), correlated with the low muscle mass, normal in the other 2 boys – 94 and 99%. We began a hypocaloric Mediterranean diet (400 calories daily deficit), moderate physical activity (45–60 minutes), low sodium intake. All three received Omega 3(2000 mg), 2000 UI vitamin D, vitamin E and hepatic protectors for the liver cytolysis. After 1 month of diet and 2% of body fat loss the BP, cytolysis and fasting glucose normalized.
Conclusion
The metabolic syndrome is a frequent condition in adults with increasing prevalence in children and teenagers, but there is no common definition and treatment of the conditions associated with this syndrome. A new guideline for the metabolic syndrome in the pediatric population is needed to manage and monitor the effects of this syndrome and avoid the serious health risks in our children and teenagers.

Awareness of normal weight, overweight and obese patients about complications, risk factors and prevention of obesity

Ahmet Dirikoc[1], Birgul Genc[2], Didem Ozdemir[1], Berna Evranos Ogmen[1], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Ankara Yildirim Beyazit University, Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey

Background
We aimed to determine the awareness of obese, overweight and normal weight patients about the complications, causes and prevention of obesity.
Methods
Patients who admitted to our clinic during a four months period were included. Demographical features, familial histories of obesity, smoking, alcohol use, chronic diseases, medications, medical nutrition therapy and exercise habits were determined. Answers of agree, not agree or no idea were obtained for 40 questions regarding the definition, consequences, risk factors and prevention of obesity. Patients were grouped as normal, overweight and obese according to the WHO criteria.
Results
Data of 352 patients (282 female and 70 male) were analyzed. There were 51(14.5%) normal weight, 72 (20.5%) overweight and 229 (65.0%) obese patients. Median ages were 49, 44 and 33 in obese, overweight and normal patients, respectively (P <0.001). Education level was lower and familial history of obesity was higher in obese patients (P <0.001). The rates of agreeing that obesity may cause insulin resistance, type 2 diabetes, cardiovascular disease, hypertension, dyslipidemia, fatty liver, sleep apnea, asthma, gastrointestinal problems, depression, mental problems, limitation of movement and mortality varied between 69.60% and 92.61%. Only 130 (36.93%), 138 (39.20%) and 191 (54.26%) patients agreed that obesity is associated with cholelithiasis, pancreatitis and cancer, respectively. The rate of patients who thought that obesity may cause death, sleep apnea and asthma were significantly higher in obese compared to normal weight patients. Approximately half of the patients agreed that obesity in family, eating too much, skipping meals, and engaging in other activities during eating are risk factors for obesity. Rates of agreement about risk factors for obesity were similar in three groups. More than 2/3 of patients agreed with how a healthy diet should be, and believed in the benefit of exercise. The rate of those who agreed that 4–6 meals/day and not to miss snacks are important for a healthy diet was highest in the obese group (72.92%, P = 0.043). There was no significant difference between groups in terms of other questions regarding a healthy diet.
Conclusion
While awareness about some of the obesity associated complications are high, awareness about others such as gall bladder disease, pancreatitis and cancer are low. Obese patients have higher awareness that obesity can cause death, sleep apnea and asthma. The knowledge about risk factors of obesity related with eating habits was relatively low. It is important to raise awareness of both obese and non-obese patients for the prevention and appropriate treatment of obesity.

AEP815

Correlation between the wrist circumference and waist circumference in patients with and without diabetes

Salomi Shaikh[1], Asma Shaikh[2], Shazia Siddiqui[2] & Shayaan Shaikh[2]
[1]D.Y.Patil School of Medicine, India; [2]K.G.N.Diabetes and Endocrine Centre, India

Introduction
Contemporary literature highlights the importance of wrist circumference as an easy-to-use marker of general and abdominal obesity
Methods
We measured the wrist circumference and the waist circumference in a heavy volume outpatient department of a specialised endocrine centre in 467 subjects with and without diabetes over a period of one month. Patients with known medical conditions, that were confounding and influencing anthropometric parameters like body weight, including thyroid related disorders, genetic disorders were excluded. A dedicated nurse assistant was trained to eliminate the observer bias. The measurements were by standard protocols using calibrated instruments. Descriptive statistics and Pearson r was used for the statistical analysis.
Results
We evaluated 467 patients (with diabetes n = 252, without diabetes n = 215). The mean body weight (kg) in patients with diabetes 72.43 kg (±14.44, 95% CI 70.64 to 74.22) was more than those without diabetes 67.73 kg (±15.38, 95% CI 65.6 to 69.8), P = 0.0007. The mean age of the cohort was 46 years (±17, 95% CI 44 to 47). The mean age (years) of diabetics was more (51 ± 0.78, 95% CI 49.54 to 52.63) than the non-diabetics (39.8±1.43, 95% CI 37.01 to 42.63), P <0.0001. There was a significant positive correlation between the wrist circumference and the waist circumference, irrespective of diabetes (Pearson r 0.50, 95% CI 0.4388 to 0.5686 P <0.0001). The mean wrist circumference (cm) was significantly higher in the diabetics (16 ± 1.4, 95% CI 16.24 to 16.59) than the non-diabetics (15.94±1.33, 95% CI 15.77 to 16.12), P = 0.0003.
Conclusion
The results of our study suggest that wrist circumference is a useful index for assessing obesity irrespective of the diagnosis of diabetes. It is easy, quick, and convenient to measure than the waist circumference. This might make wrist circumference as a routine measurement in daily clinical practice. The results of our study need corroboration with larger epidemiological studies, involving varied population with multi-ethnic population.

24-week impact of dapagliflozin treatment on body weight, body composition, and cardiac risk indicators of patients with type-2 diabetes mellitus

Pinar Akhanli, Sema Hepsen, Ismail Emre Arslan, Hakan Duger, Hayri Bostan, Muhammed Kizilgul, Bekir Ucan & Erman Cakal
University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Endocrinology and Metabolism, Turkey

Aims
We aimed to reveal the impacts of dapagliflozin, a sodium glucose transporter inhibitor (SGLT2i), on the body weight and body composition, cardiovascular risk indexes, and carotis intima-media thickness (CIMT).
Methods
Body weights, body compositions measured by means of bioelectrical impedance, and CIMT in the baseline, the 12th, and the 24th week of 42 patients with type-2 diabetes mellitus receiving SGLT2i treatment along with medication were measured. Visceral adiposity index (VAI), lipid accumulation product (LAP), and atherosclerotic index of plasma (AIP) were measured according to lipid measurements and anthropometric values.
Results
Mean change in total body weight and total fat mass was –2.96 and –1.97 kg, respectively (P <0.001). There was a reduction in total fat mass of 1.23 kg (from 31.4 to 29.3 kg, P <0.001) and in body fat percentage of 2.5% (from 35.8% to 34.4%, P <0.001) in the first 12 weeks. A mild increase was observed in both total fat mass and body fat percentage between the weeks of 12 and 24, which was not statistically significant (P = 0.783, P = 0.925 respectively) whereas there was a statistically significant reduction in hsCRP, AIP, and CIMT values (P = 0.006, P = 0.035, P = 0.007, respectively). No change observed in VAI and LAP values (P = 0.985, P = 0.636).
Discussion
We detected in our study that dapagliflozin causes a weight loss in the 24-week follow-up period. The rate of weight was explicit particularly in the first 12 weeks and it was observed with the reduction in total fat mass and body fat percentage. Apart from the studies on SGLT-2 inhibitors, we detected an increase in total fat mass and body fat percentage in spite of the fact that there was no reduction in weight in the follow-ups after the 12th week. According to our ideas, that our patients made less physical activity as a consequence of Covid-19 pandemic process, which had started during our follow-ups must have caused this situation. However, adding dapagliflozin to the current treatment was associated with the reduction in cardiovascular risk factors like hsCRP, CIMT, and PAI.
Conclusions
We have observed that dapagliflozin not only contributes to weight and fat loss but also has positive impacts on cardiovascular and atherosclerotic indicators.

Vitamin B12 deficiency in type two diabetes patients using metformin at kenyatta national hospital

Ellen Njagi[1], Erastus Amayo[2], Fredrick Otieno[2], Jessie Githanga[3] & Julius Kuria[3]
[1]Calderdale and Huddersfield NHS Foundation Trust, United Kingdom; [2]University of Nairobi, Internal Medicine, Nairobi, Kenya; [3]University of Nairobi, Pathology, Nairobi, Kenya

Background
Metformin is most frequently prescribed first line therapy for individuals with type 2 diabetes. Continuous use of metformin is associated with vitamin B12 deficiency, yet the prevalence of this side effect and subsequent clinical implications has not been estimated.
Objective
To determine the prevalence of vitamin B12 deficiency and the variables associated with it in patients with type 2 DM on metformin at Kenyatta National Hospital.
Design
A cross-sectional, descriptive study.
Setting
Diabetes out-patient clinic of Kenyatta National Hospital, Nairobi, Kenya.
Subjects
A total of 190 patients with type 2 diabetes on metformin for more than one year attending the out- patient clinic, were enrolled into the study.
Results
Of the patients studied the peak age was around 50–59 years, and majority (61%) were women. The mean duration of metformin use was 5.6 years. Eight percent (n =14) of diabetic patients had confirmed B12 deficiency. With vitamin B12 levels < 208 pg/ml, 18% (32) of the study population had lower/normal levels 208–300 pg/ml and 74%patients had normal levels > 300 pg/ml. No significant correlation between vitamin B12 levels and dosage and duration of metformin use, Hb, MCV or peripheral neuropathy was found.
Conclusion
Vitamin B-12 deficiency is rare in diabetics treated with metformin at an average dose of 1gram per day. A possibility that an individual's diet, duration of exposure to metformin, and dosage may have been responsible for the low prevalence of Vitamin B12 deficiency.
Keywords: metformin, type 2 diabetes, vitamin B12.

Relevance of non-invasive central pressure measurements with vascular stiffness indicators to predict future cardiovascular risk in children with type 1 diabetes

Klaudyna Noiszewska & Artur Bossowski
Medical University in Bialystok, Dep of Pediatric, Endocrinology and Diabetes, with a Cardiology Unit, Poland, Poland

Introduction
Modern diabetology is focused on preventing late complications of diabetes and to find research tools to detect discrete changes, with the possibility of early entry with treatment. Type 1 diabetes (DM1) causes oxidative stress, affects the cardiovascular system and increases vascular stiffness. The non-invasive measurement of central blood pressure (CBP) together with augumentation and aplification indicators, more accurately reflects the condition of blood vessels and can be useful in monitoring patients with DM1.
Aim
Evaluation of central blood pressure parameters in children with DM1
Materials and methods
The study was conducted in 101 children selected for age, weight and height, without hypertension (mean age 13 years). They were divided into a control group (A) of healthy children (n = 21) and patients with DM1 with short <5 years ((B) n = 37) and long > 5 years ((C) n = 43) duration of the disease, under the care of the Diabetes Clinic and the Department of Pediatrics, Endocrinology and Diabetology udsk in Bialystok. Based on HbA1c levels, all DM1 patients were divided into 2 groups with good HbA1c <7.5% (D) and insufficient HbA1c > 7.5% (E) metabolic control. Three CBP measurements were taken at 5-minute intervals using the Centron Diagnostic and then averages were calculated. The statistical analysis was performed using the Stat12.5 (U Mann-Withney test).
Results
Peripheral and central blood pressure were comparable in patients with type 1 diabetes mellitus and control group. The Augumentation rate was significantly higher in children with DM1 who had short-term patients (0.62 vs 0.56, P = 0.02). Statistical significance was not demonstrated in cbp parameters between groups of children with diabetes mellitus, while both vascular stiffness indicators showed a positive trend with regard to vascular elasticity in the group of children with DM1 long-suffering (AUG 0.62 vs 0.58, AMP 1.65 vs 1.76). In patients with HbA1c, >7.5% hba1c correlates with CBP.
Conclusions
Vascular stiffness rates of Augumentation and Aplification showed improvement during therapy and were higher in the group of children with DM1<5 years, perhaps as a residue after ketoacidosis at the time of diagnosis of the disease. Significant vascular changes may not occur early in DM1 in children with good metabolic control.

AEP819

The impact of endocrine-disrupting chemicals on the prevalence of diabetes

Hassan Heshmati
Endocrinology Metabolism Consulting, LLC, Anthem, United States

Introduction
Endocrine-disrupting chemicals (EDCs) are a heterogeneous group of exogenous chemicals or chemical mixtures that interfere with the action of hormones and cause adverse effects. Humans are constantly exposed to hundreds of EDCs mainly through air, water, and food. Pregnant women are exposed to multiple EDCs that can cross the placenta and enter the fetus. The developing fetus and neonate are more sensitive than adults to perturbation by EDCs. The prevalence of diabetes has risen dramatically over the last several decades.
Methods
A systematic search of literature was conducted using the search terms endocrine-disrupting chemicals, obesogens, prenatal exposure, type 1 diabetes, type 2 diabetes, and vulnerable populations.
Results
The number of EDCs has markedly increased over the past 60 years. The potential contribution of several EDCs (e.g., bisphenol A, dioxins, phthalates, polychlorinated biphenyls, and organochlorine pesticides) to the development of diabetes has been proposed by several epidemiological studies. Prenatal and early-life exposures to EDCs can promote the development of type 1 diabetes by increasing the risk of autoimmunity and affecting ńcell development and function. EDCs with androgenic activity (e.g., bisphenol A) may interfere with β-cell function, impair insulin secretion by accelerating insulitis, and cause type 1 diabetes. Several EDCs called obesogens may promote the development of type 2 diabetes through weight gain and the resulting insulin resistance. The higher burden of diabetes in the vulnerable populations of the USA (e.g., Latinos, African Americans, and low-income individuals) may be partly due to a higher exposure of these populations to diabetogenic EDCs.
Conclusion
Exposure to EDCs may be a significant component of the environmental origin of diabetes. Promotion of public knowledge and initiation of preventive measures, especially in the vulnerable populations, will help minimizing the exposure to EDCs and the resulting diabetes.

Ethnicity and its influence on post-oral glucose tolerance test glucagon-like peptide-1 responses

Shiau Chin Chong[1], Norlela Sukor[1], Sarah Anne Robert[2], Kim Fong Ng[3] & Nor Azmi Kamaruddin[1]
[1]The National University of Malaysia Medical Centre, Endocrinology, Kuala Lumpur, Malaysia; [2]The National University of Malaysia Medical Centre, Pharmacy, Kuala Lumpur, Malaysia; [3]Hospital Sultanah Aminah Johor Bahru, Cardiology, Johor Bahru, Malaysia

Introduction
Glucagon-like peptide-1 (GLP-1) plays an important role in the pathophysiology of type 2 diabetes mellitus (T2DM). Results from some

studies on post-OGTT GLP-1 responses involving East Asians with abnormal glucose tolerance states tend to differ from the West. This may be attributed to the different diabetic phenotypes found in East Asians.
Aim
To examine post-OGTT GLP-1 responses in subjects with normal glucose tolerance (NGT) and T2DM among three major ethnic groups in Malaysia.
Methods
A total of 120 Malaysians consisting of Malays (n = 41), Chinese (n = 43) and Indians (n = 36), were categorised based on their glucose tolerance states following a 75g OGTT. There were 58 NGT and 62 T2DM subjects. Plasma total GLP-1 concentrations were measured at 0, 30 and 120 minutes during OGTT.
Results
Overall, T2DM had higher GLP-1 responses to OGTT compared to NGT. GLP-1 levels were positively correlated with insulin levels and HOMA-IR. Among NGT, Malays had lower post-OGTT GLP-1 levels than Chinese and Indians whereas Chinese and Indians had comparable GLP-1 levels. Among T2DM, Malays appeared to exhibit higher GLP-1 levels at 30 minutes post OGTT than Chinese and Indians. There was a significant ethnic difference in incremental GLP-1 levels at 120 minutes in T2DM group (P = 0.024), where the levels were higher in Malays than in Chinese and Indians. Indians were the most insulin resistant while Malays were the most insulin sensitive.
Conclusions
Insulin resistance was associated with compensatory increased GLP-1 secretion in T2DM. Malays with NGT had lower post-OGTT GLP-1 responses. In contrast, Malays with T2DM had higher GLP-1 responses compared to Chinese and Indians to compensate for their prevailing insulin sensitivity.
Comparisons of post-OGTT GLP-1 responses by ethnicity and glucose tolerance states.

Gender differences in ghrelin levels in patients with type 2 diabetes mellitus

Veranika Lobashova[1], Alla Shepelkevich[2] & Yulia Dydyshko[3]
[1]Republic Centre of Medical Rehabilitation and Balneotherapy, Minsk, Belarus; [2]Belarusian State Medical University, Minsk, Belarus; [3]Belarusian State Medical University, Endocrinologic, Minsk, Belarus

Introduction
Ghrelin has an important role in insulin resistance, glucose and lipid metabolism and cardiovascular morbidity and mortality. It is still unclear whether insulin and glucose per se play a direct inhibitory role in ghrelin secretion. The decrease in ghrelin levels after an oral glucose load is modulated by sex, status of obesity, and level of insulin resistance. The aim of our study was to evaluate gender differences in ghrelin levels in type 2 diabetes mellitus patients.
Methods
109 women and 32 men with type 2 diabetic mellitus were included to the study. The age of the participants was 62 (59–68) years old, mean body mass index – 32.2 (29.0–35.7) kg/m^2 with no statistical gender differences in parameters (U=1587.5; P = 0.173, U=1689.0; P = 0,373). The serum levels of ghrelin were analyzed by the sandwich ELISA method.
Results
Fasting concentration of ghrelin in diabetic patients was 0,78 (0.57–0.98). The level of ghrelin in women with type 2 diabetes mellitus was 0.79 (0.55–0.96), in men with type 2 diabetes mellitus was 0.78 (0.64–1.06). The results revealed no gender differences in ghrelin levels (U=1410.0; P = 0.100).
Conclusion
The study did not reveal gender differences in fasting ghrelin concentrations in type 2 diabetes mellitus patients.

Influence of physician-related factors on the "Glycemic Happiness" of persons with T2DM: Interim analysis of an observational survey

Sanjay Kalra[1], Ashok Kumar Das[2], Gagan Priya[3], Nareen Krishna Polavarapu[4], Kumar Gaurav[4], Amey Mane[4], & Colette Stephen Pinto[4]
[1]Bharti Hospital, Endocrinology, Karnal, India; [2]Pondicherry Institute of Medical Sciences, Puducherry, India; [3]Fortis Hospital, Chandigarh, India; [4]Dr. Reddy's Laboratories Limited, Hyderabad, India

Background
Apart from long-term complications associated with diabetes(T2DM), the psychological impact also significantly contributes to poor outcomes in persons living with diabetes. An observational survey was undertaken to assess various physician-related factors that can help define "glycemic happiness" for persons living with T2DM.
Methods
A prospective, multicentric, cross sectional, observational survey involving 40 physicians from 40 tertiary care centers in India. Interim analysis of 12 centers is presented here. Survey (Box 1) was based on a simple questionnaire developed by an expert panel and administered by designated personnel at study centers.
Results
Of the 12 responses from physicians obtained to date, all of them feel that physician's belief in one-self to make a difference in life of person with T2DM and satisfaction from being able to help the person with T2DM can influence glycemic happiness of person with T2DM. In addition, 10 (83.33%) and 6 (50%) agree that professional satisfaction and physical/mental exhaustion at work can affect glycemic happiness of person with T2DM respectively.
Conclusion
Apart from good glycemic control, glycemic happiness of persons with T2DM can be influenced by physician's belief in his role in T2DM management, professional satisfaction and ability to cope with physical and emotional professional demands.
Funding
Dr Reddy's Laboratories

Box 1. Questionnaire of the Glycemic Happiness Survey – Physician Component

- Do you feel happy and satisfied that you chose to be a diabetes care professional?
- Do you get satisfaction from being able to help T2DM patients?
- Do you feel you can make a difference in life of with T2DM patients through your work?
- Do you get physically and emotionally exhausted at work?
- Do you feel you are losing enthusiasm at work?
- Do you feel you are in control dealing with complex problems of T2DM management?
- Do you feel worn out by your job as a care provider?
- Do you feel overwhelmed because Diabetic patients load seems endless?
- Do you feel depressed by the traumatic stress of T2DM patients whom you try to help?
- Do you feel less empathetic and connected with your colleagues and friends?

Introduction
Glucagon-like peptide 1 receptor agonists (GLP-1RA) and sodium-glucose cotransporter-2 inhibitors (SGLT2i) are the two novel classes of anti-diabetic agents with compelling efficacy, in terms of glucose-lowering and cardio-renal protection. Euglycemic diabetic ketoacidosis (EDKA) is a serious rare adverse effect of SLT2i while the use of GLP-1RA has been scarcely linked with acute pancreatitis in humans.
Case presentation
We present the case of a 50-year old, overweight man who was admitted to the Emergency Department due to diffuse abdominal pain radiating to the back, nausea, appetite loss and bile vomiting. He had a 20-year history of Type 2 Diabetes (T2D) and was on triple anti-diabetic regimen with dulaglutide, empagliflozin and metformin which he continued to take, despite a marked decrease in food intake over the last 5 days. Clinical examination was remarkable for rapid heart rate, Kussmaul breathing, signs of extracellular volume depletion (dry skin and mucosa) and breath smell of acetone. Initial laboratory work-up revealed metabolic acidosis (pH 7.053) with increased anion gap (22.3 mmol/l), ketonaemia (4.9 mmol/l) and ketonuria (4+ in urine dipstick), in the setting of mild hyperglycaemia (glucose 204 mmol/l) and normal renal function (eGFR 126 ml/min/1.73 m^2). Meanwhile, computed tomography of the abdomen revealed misty mesentery and significant stomach dilation; therefore, a nasogastric tube for drainage was placed. EDKA was managed with intravenous administration of 5% dextrose solution, fixed-rate insulin infusion, 0.9% normal saline and potassium. Following the above protocol, b-hydroxybutyric acid gradually decreased, blood glucose level was maintained stable (130–180 mg/dl), and acidosis was reversed within 12 hours (pH 7.330). However, serum and urine amylase demonstrated a gradual increase during the first 24 hours (peak levels of 654 U/l and 1423 U/l respectively). Gastroenterology review established the diagnosis of acute pancreatitis, thus intravenous esomeprazole and metoclopramide were initiated. The patient demonstrated rapid clinical improvement and feeding restarted after 48 hours. As for the cause of acute pancreatitis, all other etiologies (lithiasis, alcohol, autoimmune, trauma) were excluded and it was attributed to GLP-1RA use.
Conclusions
The possibility of EDKA due to SGLT2i must be kept in mind when evaluating a patient with long standing T2D and unexplained metabolic acidosis. Acute pancreatitis due to GLP-1RA exists in humans, although several studies did not verify an increased risk. This case highlights that all anti-diabetic agents must be applied in a patient-tailored way, accompanied by appropriate sick day rules.

Diabetes care during COVID-19 pandemic using a telehealth approach

Rajeev Chawla[1], Shubhaa Chawla[1], Shalini Jaggi[2], Aastha Chawla[1], Siddhant Trehan[3] & Rohit Kumar[1]
[1]North Delhi Diabetes Center, Delhi, India; [2]Lifecare Diabetes Centre - Dr Shalini Jaggi Best Diabetes Clinic, New Delhi, India; [3]Sri Jayadeva Institute of Cardiovascular Sciences and Research, Bengaluru, India

Introduction
COVID-19 pandemic has rapidly changed the landscape of diabetes care to quickly adapt to continue providing optimal care to patients with diabetes in an efficient and effective manner
Methods
We describe a retrospective assessment of patients with diabetes, with and without COVID-19 infection, during the lockdown period March 2020 to February 2021 managed through a dedicated comprehensive dedicated telehealth platform. The virtual health applications comprised of telephone consultations and video telehealth consultations
Results
The total patients who were managed by teleconsultation were 765 (30 T1DM), (440 males). 250 patients were COVID-19 with type 2 diabetes, and 15 patients were type 1 diabetes. The mean age (years) was 60 (±14, minimum 10, maximum 88, 95% CI 58 to 62). There were 49% (375/765) patients with age less than 60 years. The mean number of teleconsultations per patient were 1.5 (±0.97, minimum 1, maximum 6, 95% CI 1.4 to 1.7). There were 235 patients who sought at least 1 repeat virtual consultation, of which 145 had two virtual consultations. The mean number of virtual consultations were comparable in patients with (1.6±0.94, 95% CI 1.3 to 1.8) or without COVID-19 (1.4±0.97, 95% CI 1.2 to 1.6), $P = 0.41$ ns. The mean age was comparable in patients with (58±15.5, 95% CI 54.47 to 63.04) or without COVID-19 (60.45±12.81, 95% CI 57.91 to 62.9), $P = 0.47$ ns. The mean number of virtual consultations were comparable in elderly >60 years (1.4±0.78, 95% CI 1.2 to 1.5) and in age group <60 years (1.6±1.1, 95% CI 1.3 to 1.8), $P = 0.22$ ns. The mean number of virtual consultations were similar in males (1.4±0.77, 95% CI 1.2 to 1.5) and in females (1.6±1.1, 95% CI 1.3 to 1.9), $P = 0.11$ ns.
Conclusion
Digital – virtual diabetes clinic has a potential to provide efficient method of consultative service. Virtual electronic consultation mitigated the lockdown induced disruption in diabetes care activities and appears to be a reliable approach. Beyond the pandemic, we suggest that annually per patient, two virtual consultations would complement the two in person consultations, that would suffice to maintain the continuity of care and deliver optimal diabetes care

Mucormycosis in a patient with newly diagnosed diabetes mellitus and diabetic ketoacidosis

Kubra Turan[1], Esra Copuroglu[1], Ali Abbas Tam[1], Caglar Keskin[2], Didem Ozdemir[1], Nilufer Onak Kandemir[3], Mecit Sancak[4], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Yildirim Beyazit University Faculty of Medicine, Ankara City Hospital, Clinics of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara City Hospital, Clinics of Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara City Hospital, Clinics of Pathology, Ankara, Turkey; [4]Ankara City Hospital, Clinics of Otolaryngology, Ankara, Turkey

Background
Mucormycosis is an opportunistic fungal infection that can be aggressive and mortal. Diabetic ketoacidosis(DKA) is a risk factor for mucormycosis. We present a case with mucormycosis presenting with newly diagnosed diabetes mellitus and DKA.
Case presentation
A 34-year-old male patient presented with confusion and vomiting. He had no comorbiditiy. On admission the patient was afebrile, hypotensive (85/55 mm/hg) and had tachycardia (120/bpm). Laboratory investigations revealed hyperglycemia (673 mg/dl), severe metabolic acidosis (pH:6.86, bicarbonate:2.6 mmol/l) and urinary ketones. The patient was intubated due to cardiac arrest and followed up in the intensive care unit for 15 days. After that, the patient with newly diagnosed diabetes was admitted to our clinic for blood glucose regulation. During follow up, he described a feeling of swelling in the left half of the face and blurred vision. There was an erythematous appearance on the left eyelid. Diagnostic nasal endoscopy showed widespread crusting filling left nasal cavity and necrosis in the adjacent septum and middle meatus which was suggestive of mucormycosis. Paranasal sinus CT revealed mucosal thickening in the left frontal sinus, left anterior-posterior ethmoidal cells, sphenoid sinus in the left compartment and in the left maxillary sinus, causing almost complete loss of ventilation. Mucosal thickening was observed in the left compartment of the sphenoid sinus and the ethmoidal cells on the left. Left frontal and left sphenoethmoidal recesses were obliterated. Left precentral fatty tissue and left pterygopalatine fossa, around the sphenopalatine foramen were dirty. Orbital CT was normal. Cranial MRI showed 22 × 10 mm flair hyperintensity accompanied by effacement in the sulcus in left frontal lobe, frontobasal-orbitofrontal level, cortical-subcortical located in the medial part. In this location, frontal bone integrity was not clearly differentiated, and signs of inflammation were observed in the adjacent frontal sinus. The patient was operated urgently. Histopathology confirmed the diagnosis of mucormycosis. Liposomal amphotericin-B treatment was started. The patient was discharged with intensive insulin treatment after five weeks.
Conclusion
Mucormycosis is an invasive and progressive disease which requires immediate diagnosis and treatment including surgical debridement. Although uncontrolled and long standing diabetes is a well-known important risk factor for this opportunistic infection, it is rare to see it in patients with newly diagnosed diabetes. Our case is important in terms of showing that this infection can also occur in newly diagnosed diabetes.

The promising role of Agouti related peptide in the differentiation of ACTH-independent Cushing syndrome

Mario Detomas, Barbara Altieri, Martin Fassnacht & Ulrich Dischinger
University Hospital of Würzburg, Department of Internal Medicine, Division of Endocrinology and Diabetes, Würzburg, Germany

Background
Agouti related peptide (AgRP) is a neuropeptide, produced by the hypothalamus and by the adrenal glands. AgRP is an antagonist of proopiomelanocortin (POMC) and its principal role is to stimulate appetite. Although current evidences suggest that AgRP levels are influenced by glucocorticoids, it is still not clear, whether they depend on adrenocorticotropic hormone (ACTH) or cortisol. One of the aims of this study was to address this issue. Furthermore an analysis of AgRP in the differentiation of Cushing´s disease (CD), ectopic Cushing syndrome (ECS), adrenocortical adenoma (ACA), and adrenocortical carcinoma (ACC) was performed.
Methods
We performed a retrospective analysis of AgRP levels in blood samples of 103 patients with proven Cushing syndrome (CS), including 44 with ACTH-dependent CS (n = 33 CD, n = 11 ECS) and 59 ACTH-independent CS (n = 21 ACA, n = 38 ACC). Levels of AgRP were measured with ELISA. Considering the AgRP fluctuating levels throughout the day, the analysis was performed on midnight serum samples for all patients. Correlation with midnight cortisol levels, basal ACTH, and in ACC with tumor burden and overall survival (OS) were investigated.
Results
Considering the entire cohort, a negative AgRP-ACTH correlation (rs = –0.60, $P < 0.001$) and a moderate positive AgRP-cortisol correlation (rs = 0.25, $P = 0.02$) was identified. Levels of AgRP did not differ between CD and ECS [median 0.39 (0.23–0.57). ng/ml vs 0.43 (0.34–0.65) ng/ml, respectively, $P = 0.99$]. Concerning the ACTH-independent CS, ACC were characterized by significant higher levels of AgRP compared to ACA [median 1.38 (0.22–8.71) ng/ml vs 0.45 (0.25–0.79) ng/ml, respectively, P = 0.035] with a mean ACC/ACA fold change of 4.7. Furthermore, AgRP levels were significantly higher in ACC in comparison to both CD ($P < 0.0001$) and ECS ($P = 0.014$). Among ACC, AgRP levels were higher in patients with a higher tumor burden (considered as two or more site of metastasis) compared to those with a lower tumor burden ($P = 0.025$). No difference in terms of OS was observed between patients with low AgRP levels (considered as <1.38 ng/ml) in comparison to those with high AgRP levels (≥1.38 ng/ml) (median survival 14 vs 15 months, respectively, P = 0.47).
Conclusions
AgRP seems to play an intriguing role in the pathophysiology of cortisol-secreting ACC and could be an interesting marker in the differentiation of the ACTH-independent CS. On the other hand, the analysis of AgRP seems not to be beneficial in the differentiation of ACTH-independent CS. Further analyses on a larger population are necessary to confirm our results.

Germline variants of the MEN1 gene in 132 subjects with clinical indication of genetic diagnosis, born in Argentina

Patricia Fainstein-Day, Maria Lorena Viale, Maria Pia Serra & Andrea Kozak
Hospital Italiano de Buenos Aires, Endocrinology, Buenos Aires, Argentina

Multiple Endocrine Neoplasia type 1 (MEN1) is an autosomal dominant inherited disease with a high degree of penetrance. The three most common locations of tumors are the parathyroid glands, the gastro-duodenum pancreas and/or the anterior pituitary gland. The gene involved in this disease is MEN 1, a tumor suppressor gene located on chromosome 11q13. The objective of our work was to describe the genotype of patients with MEN 1 born in Argentina.
Subjects and Methods
We studied 132 possible carriers of MEN1 born in Argentina: 56 index cases (31 women; mean age 40.42 years (SD 16.2); r: 2–75 years) and 76 asymptomatic first-degree relatives (41 women; age 33.70 (SD 19.1); 2–69 years). The coding region (exons 2–10), the promoter, exon 1 and, the flanking intronic regions of the MEN1 gene were sequenced by the Sanger method. MLPA was used in patients with no mutation findings.
Results
We found mutations throughout the entire gene, in the coding regions, the flanking intronic and splicing sites as reported in the literature. Forty mutations were found in 56 patients (71.4%). The prevalence of mutations was 92% in familial cases and 54.5% in sporadic cases. Of the 31 different pathogenic variants, 11 (38.7%) were reading frame alterations (38.7%) (9 microdeletions, 1 microduplication and 1 microinsertion), 7 (22.6%) were nonsense variants, 7 nonsense (22.6%), 3 mutations in splicing sites (9.7%) and 2 large deletions (6.4%). We found nine novel pathogenic variants.
Conclusions
The genetic diagnosis of this population of 76 with MEN1 allowed us to confirm the diagnosis in 71.4% of the patients and to identify 38% of the first-degree relatives as asymptomatic carriers. Carriers of the mutation may be studied annually according to international guidelines that would improve their survival through early diagnosis of tumors.

Duodenal neuroendocrine tumor (siNET) and Rothmund-Thomson syndrome: a new association of a rare genetic disorder

Miguel Paja Fano[1,2], Adela L. Martínez-Martínez[1], Andoni Monzón[1], Josune Rodríguez-Soto[1], Ignacio Merlo[1], María J García-Barcina[3], Sonia Merino[3] & M. Carmen González-Serrano[4]
[1]OSI Bilbao-Basurto; Basurto University Hospital, Endocrinology, Bilbao, Spain; [2]Basque Country University, Medicine, Spain; [3]OSI Bilbao-Basurto Basurto University Hospital, Genetic Medicine, Spain; [4]OSI Bilbao-Basurto; Basurto University Hospital, Hepatobiliary Surgery, Spain

Rothmund-Thomson syndrome (RTS) usually presents with physical stigmata (poikiloderma, ectodermal dysplasia, juvenile cataracts…) and it´s associated with malignancies in patients with homozygous or compound heterozygous mutations in the *RECQL4 helicase* gene (RTS-II). Neoplasms include osteosarcoma in childhood and skin cancer later in life, with occasional malignancies affecting other tissues (leukemia, lymphoma and gastrointestinal adenocarcinomas). To our best knowledge, its association with neuroendocrine tumors has not been reported. We present one patient with this association. A 33-year-old woman was admitted in February 2020 for diarrhoea (4–5 stools/day) with urgency and mucus. At six she had been diagnosed with RTS-II after detecting osteosarcoma of the right femur, treated with amputation and chemotherapy with no evidence of disease in check-ups. In 2015, an ultrasound showed two liver lesions in segment VI and biopsy of the larger one was reported as a benign hepatocyte proliferation. In 2018, a cutaneous squamous cell carcinoma on the left heel had been resected and a CT scan showed a tumor in the duodenal setting, with two endoscopic US-guided FNAC obtaining insufficient cytological material for diagnosis. Colonoscopy disclosed a 1.8 cm tubule-villous adenoma with high-grade dysplasia and gastroscopy showed a tumor located posterior to the duodenal bulb, about 15 mm in diameter. Endoscopic biopsy showed a well-differentiated NET (G2). Biochemistry revealed dissociated cholestasis and elevation of chromogranin A (3,001ng/ml; NV<100) with slightly elevated glucagon (153 pg/ml; NV<100). SPECT-CT with Tektrotyd confirmed the uptake of the lesion, as well as of adjacent adenopathies, without hepatic involvement. Operated on May 2020, a hard lesion on the posterior aspect of the duodenal bulb and adjacent adenopathies were resected. Intraoperative ultrasound showed more than 10 liver lesions in both lobes, whose biopsy confirmed their metastatic nature. Pathology diagnosed a well-differentiated NET of 2 cm, infiltrating up to muscularis propria, with lymphatic invasion and lymph nodes affected. Ki-67:15%. Genetic study discovered two variants of the RECQL gene in compound heterozygosis: c.1620+1G>C (NM_004260.3) and c.2547_2548delGT (NM-004260.3). After surgery, two sessions of transarterial chemoembolization with adriamycin were performed. Seven months later, a SPECT-CT with Tektrotyd shows uptake in non-treated hepatic segments and regional periduodenal adenopathies. CgA levels have reduced to 923 ng/ml. In conclusion, this is the first reported case of NET in a patient with RTS. Duodenal malignancy was previously reported in association with RTS-II. Increased awareness of the risk of gastrointestinal malignancy in patients with RTS could improve detection and outcomes in these patients.

Papillary thyroid cancer in adolescents after neuroblastoma in childhood: Description of the two cases

Sofia Enikeeva[1], Maria Pankratova[1], Konstantin Slashchuk[2], Maria Kareva[1] & Valentina Peterkova[1]
[1]Endocrinology Research Centre, Pediatric Endocrinology, Moscow, Russian Federation; [2]Endocrinology Research Centre, Radiology, Moscow, Russian Federation

Background
It is known that the thyroid gland is sensitive to the damaging effects of irradiation, and patients who have received radiotherapy for tumor treatment require regular thyroid screening subsequently. A few cases of thyroid cancer after receiving 131I-metaiodobenzylguanidine (MIBG) therapy in the treatment of neuroblastoma in childhood have been described (HM van Santen et al 2012; SC Clement et al, 2013). Here, we report the two cases of papillary thyroid cancer in adolescents after treatment of neuroblastoma in childhood without applied of 131I-MIBG therapy.
Patient findings
A 14-year-old girl, treated neuroblastoma at the age of 11 months, and a 17-year-old girl, treated at the age of 9 months, were both diagnosed with papillary thyroid cancer at 12 and 13 years, respectively. In both cases surgery and chemotherapy have been used to treat neuroblastoma in childhood (without 131I-MIBG therapy). Thyroid cancer was discovered in nonpalpable nodules by thyroid ultrasound. Papillary thyroid carcinoma with capsular invasion was detected after surgical treatment in both, with lymph node metastasis in the second patient, what required 131I-therapy.
Conclusions
In this cases the development of thyroid cancer in adolescents is not associated with the treatment of neuroblastoma with 131I-MIBG in childhood, as described in previous articles. The development of several types of cancer is possibly associated with the presence of the hereditary tumor syndromes and requires further diagnostic molecular genetic research.

DOI: 10.1530/endoabs.73.AEP829

AEP830

Clinical case of insulinoma in patient with germline mutation in the ADCY1 gene

Marina Yukina, Evgeny Vasilyev, Nurana Nuralieva & Ekaterina Troshina
Endocrinology Research Centre, Moscow, Russian Federation

Introduction
The clinical cases of insulinoma patients with well-studied hereditary syndromes due to mutations in the *MEN1, VHL, TSC1,* and *TSC2* genes are repeatedly described in the literature. At the same time, the hereditary nature of the pathology is highly probable in young patients with primary multiple lesions without mutations in these genes. In such cases, one can assume the presence of germline mutations in genes with the described somatic mutations accompanying tumorigenesis and insulin hypersecretion.
Objectives
To search for novel germline mutations associated with insulinoma.
Methods
Based on the literature data, we have compiled a genetic panel that includes 10 genes. *MEN1, VHL, TSC1,* and *TSC2,* and candidate genes, which were reported to contain changes in the tissue of sporadic insulinoma (*KRAS, YY1, CDKN2A, MLH1, ADCY1, CACNA2D2*). Targeted sequencing of these genes was performed in a 38-year-old woman with insulinoma of pancreatic head (the disease manifested at the age of 26 years with hyperglycemia). The diagnosis was confirmed by results of histological and immunohistochemical studies (tumor size: 10×4 mm, ki67 – 4%, Grade 2). The concomitant pathology included gastric polyp, kidney cyst, autoimmune thyroiditis; heredity was burdened by diabetes mellitus.
Results
we revealed the heterozygous variant *c.789+114A>G (rs536921599)* of unknown significance in the *ADCY1* gene (NM_021116.4) in intron 2. The *ADCY1* gene encodes adenylate cyclase 1, which is not expressed by normal pancreatic tissue. This protein is regulated by the concentration of calcium and calmodulin. When the gene is mutated, sensitivity to calcium concentration is likely to be lost, which leads to overstimulation of insulin secretion (regardless of glucose level) and proliferation of pancreatic β-cells. The variant found in the patient has not been described in the literature. Germline biallelic or compound heterozygous mutations in *ADCY1* are known to lead to hereditary hearing loss (autosomal recessive inheritance). The patient and her relatives have no pronounced hearing impairment. No changes were found in the rest of the genes included in the panel. We continue the monitoring of the patient.
Conclusion
we revealed the germline variant *c.789+114A>G* in the *ADCY1* gene, which is involved in regulation of insulin secretion and pancreatic β-cells proliferation, in patient with insulinoma. The identified variant is possibly a novel genetic marker of tumor: we plan to clarify its clinical significance. Identification of genetic predictors of insulinoma will allow predicting the course of the disease and developing optimal tactics for managing the patients.

AEP831

Paraneoplastic Cushing syndrome: Diagnostic and management challenge

Sana Abid, Ines Bayar, Bilel Ben Amor, Hanene Sayadi, Héla Marmouch & Inès Khochteli
Fattouma Bourguiba hospital, Endocrinology department, Monastir, Tunisia

Introduction
Paraneoplastic Cushing syndrome (CS) due to ectopic ACTH secretion is a rare syndrome usually associated with severe hypercortisolism which is responsible for life-threatening comorbidities. These tumors are often difficult to locate. Among all ACTH-secreting thoracic tumors,well differentiated neuroendocrine tumors located in the bronchi are the most common and account for 20% to 40% of all cases.
Case
A 36-year old man,was admitted on June 2020 for exploration of a CS. His medical history dates back to July 2019 with the diagnosis of insulin-requiring diabetes and a resistant severe hypertension with symptomatic hypokalaemia, all associated with morphological changes suggesting a CS. The drug history excluded an exogenoous exposure to glucocorticoids. Clinical examination revealed *facio-truncular obesity*, thin arms and legs,muscular atrophy, «moon face», buffalo neck, steroid acne on the trunk, fragile and poorly healing skin,large violaceous striae over the abdomen and axillary area, spontaneous bruising.Biochemical findings confirmed the diagnosis of CS: urine free cortisol was elevated (3880 µg/24 h□over 53 times of normal); the circadien cortisol secretion was disturbed. Adrenocorticotropic hormone (ACTH) level was high (254.5 ng/ml□five times normal). Clinical assessement for complications(in addition to diabetes and hypertension) found a left ventricular hypertrophy, dyslipidemia, functional hypogonadism,diffuse bone demineralization, *chronic hypocalcemia*, hypercoagulability,anxious and depressive symptomatology with insomnia. Based on the rapid deterioration of our patient's general condition,severity of clinical manifestations,a negative nocturnal 8 mg-DST(cortisol level: 421 µg/l)and a negative pituitary imaging,an ectopic CS was suspected.Thus,a chest CT-scan had shown a solid peripheral nodule of the postero-basal segment of the right lung of 20 mm with heterogeneous enhancement on injection of iodinated contrast agent, suggesting a neoplasic origin. Due to the unavailability of octreoscan preoperatively as well as the severity of clinical and biological signs resisting to medical treatment, the patient was operated. He underwent a video-assisted thorocoscopic surgery with total resection of the tumor. Histological examination revealed a low grade pulmonary neuroendocrine tumor measuring 17 mm. *Tumor* cells were positive for chromogranin, synaptophysin and ACTH on *immunohistochemistry*. Post-operative evolution was marked by improvement of diabetes and hypertension,normokaliemia and adrenal insufficiency was obtained within the second week.Octreoscan performed after the surgery did not show a metastatic localisation or residual tumor. We observed that *physical* features were ameliorated at 3 months and resolved at 6 months.
Conclusion
Ectopic ACTH secreting tumors are rare and severe. The ideal treatment is their excision. In addition to symptomatic treatments, hypercortisolism must be controlled rapidly as a pre-operative management or if surgery is impossible. However, these tumors carry an excellent prognosis especially localized and well-differentiated bronchial tumors.

AEP832

The management of pituitary macro adenoma in a patient with multiple myeloma-a diagnostic and treatment dilemma and a 2 year journey

Gideon Mlawa, Mariza Monteiro, Priscilla Asare, Ahmad Imran, Saqib Shafique & N Stojanovic
Queen's Hospital, United Kingdom

Introduction
Multiple myeloma is a haematological malignancy arising from plasma cells. It accounts for 10% of all haematological malignancies. Myeloma usually occurs in people over the age of 65, however, we have noted an increase occurrence of people with a younger age.
Case Report
A 68 year old male, with background of hypertension and right total hip replacement, was referred to the outpatient haematology; as his blood results

revealed IgGK monoclonal bands(18 g/l) following a GP appointment. Further testing also confirmed Bence-jones protein in the urine sample. A skeletal survey was requested, which showed some soft lucencies in the skull. Subsequently, a CT head was organised, however this did not show any skull lucencies. Despite the absence of skull lucencies on the CT head, lytic lesions in C1 vertebral body were present as well as an incidental finding of macroadenoma pituitary adenoma compressing the optic chiasm. This was confirmed with an MRI scan. Further discussions were made with neurosurgeons, who also noted the incidental pituitary adenoma. In spite of this, the neurosurgeons were strongly convinced that this was likely a pituitary plasmacytoma given the patients latest diagnosis of multiple myeloma. Therefore, neurosurgeons suggested to start the patient on treatment for multiple myeloma. The patient responded very well to the chemotherapy however, he later developed some blurring of his vision which prompted an optician review. This confirmed bitemporal visual field defects with no reduction in pituitary tumour size on MRI. As a result, the patient underwent transsphenoidal surgery with improvement in visual field.
Discussion
A common diagnostic criteria for multiple myeloma include: □10% clonal plasma cells on bone marrow examination or presence plasmacytoma following biopsy, hypercalcemia, renal failure, anaemia, and lytic bone lesions. Pituitary adenomas are often misdiagnosed. Sella and Parasellar plasmacytomas are rare tumours, that can progress to multiple myeloma or even be present in the midst of a diagnosis of multiple myeloma. The clinical presentation of patients with sellar or intrasellar plasmacytoma are headaches due to the mass effect or visual disturbances. Due to the mimicry nature and similarity in clinical presentations accurate diagnosis is essential for successful management.
Conclusion
This case delayed definitive treatment of non-functioning pituitary adenoma for almost 2 years. This highlights the importance of having the correct diagnosis, to avoid delayed treatment.

Treatment of severe symptomatic hyponatraemia using hypertonic saline; real world findings from 2017–2020 in two university hospitals in the UK

Muhammad Fahad Arshad*[1,2], Ahmed Iqbal*[1], James Weeks[2], Ines Fonseca[2], Alia Munir[2] & William Bennet[2]
[1]The University of Sheffield, United Kingdom; [2]Sheffield Teaching Hospitals NHS Foundation Trust, United Kingdom; *These authors contributed equally to this work

Introduction & aim
Hypertonic saline (HTS) is an effective treatment for severe symptomatic hyponatraemia. European Society of Endocrinology (ESE) published guidelines to standardise HTS administration in 2014, however, evidence behind the guidelines is limited by virtue of being largely derived from small retrospective studies and expert opinion. The aim of this study was to evaluate the 'real-world' safety and efficacy of these guidelines.
Methods
This was a retrospective, observational, cohort study. We examined use of HTS for severe symptomatic hyponatraemia at two University hospitals between 2017–2020 that had uniformly adopted ESE guidance. Patients were identified via a centralised pharmacy database and data was collected to record demographic and clinical variables in addition to treatment details. The primary outcome was rate of overcorrection after first and second HTS boluses (defined as rise in sodium >5 mmol/l), and at 24 and 48 hours (rise in sodium >10 and 18 mmol/l) respectively. Secondary outcomes were inpatient mortality rate, all-cause mortality rate at 12 months, and rate of osmotic demyelination syndrome (ODS).
Results
In total 112 patients (Females: Males = 61:51) met the inclusion criteria for the study. Their mean age ± SD was 66.4 ± 16.0 years with mean body mass index ± SD of 24.8 ± 5.6 kg/m^2. Mean serum sodium ± SD at baseline was 113.8 ± 6.4 mmol/l. Less than 1/5th of the patients were administered treatment to mitigate overcorrection (dextrose infusion/desmopressin). *Primary outcome:* Overcorrection rates after first and second boluses were 22.6% and 34.6%, respectively, while overcorrection rates at 24 and 48 hours were 44.9% and 19.6%, respectively. *Secondary outcomes*: 7.1% patients died during the same admission, while the mortality at 12 months was 18.7%. No cases of ODS were reported. A bivariate regression analysis including various categorical and continuous variables was unable to define characteristics of a high-risk group. Finally, a significant correlation was noted between paired serum and venous blood gas sodium (n = 36, Spearman's correlation r = 0.956; P<0.001), although the latter was, on average, 1.9 mmol/l lower than for serum.
Conclusion
This is the first study to comprehensively evaluate ESE guidelines in a real-world setting. Rate of overcorrection at various endpoints is significantly high without long-term sequelae. We recommend liberal use of overcorrection treatments, especially in the first 24 hours, to keep the sodium rise within the suggested cut-offs. Accounting for a correction factor of ~2 mmol/l, a venous gas sodium check between the first two boluses is useful in practice.

Perception of the speciality of endocrinology and nutrition among students training for the medical internship examination

Lourdes García-Blasco[1], Pedro Pinés Corrales[1], Irene Bretón Lesmes[2], Felicia Hanzu[3] & Javier Escalada San Martín[4]
[1]Hospital General Universitario de Albacete, Endocrinology, Albacete, Spain; [2]Hospital General Universitario Gregorio Marañón, Endocrinology, Spain; [3]Hospital Clinic, Endocrinology, Barcelona, Spain; [4]Clínica Universitaria de Navarra, Endocrinology, Spain

Introduction
The choice of a specialty in medicine is a decision that is imposed on new graduates. The aim of our study was to assess the perception of the specialty of Endocrinology and Nutrition among a large sample of medical students in their final year of their degree or prior to taking their Medical Internship Examination in order to know if they would choose Endocrinology and Nutrition for their specialised training, as well as the most and least attractive factors of the specialty.
Materials and methods
We designed an anonymous survey with seven questions that was distributed via telematics among the students of one of the main Spanish academies dedicated to preparation of exam that allow access to specialised medical training.
Results
A total of 2193 responses were obtained. Of these, 63.1% corresponded to "junior doctors" (who would take their exam in 2021) and 36.9% to final-year medical students (who would take their exam in 2022). 2.6% of the students surveyed considered the speciality of Endocrinology and Nutrition as their first choice for their specialised training at the time of the survey. Those students who rated the specialty of Endocrinology and Nutrition as their first choice considered the importance of the teaching of the subject in their decision with average value of 7.8 (SD: 2.2) being 10 extremely important. The most attractive aspect of the speciality among the students is that "it has a logical pathophysiological basis" (53.6%) followed by "the work is dynamic, varied and with great scientific soundness of its benefits" (28.0%). The least attractive aspect of the speciality among the students is that "it has few interventional techniques" (44.9%). Finally, students considered the most attractive part of the speciality to be hypothalamic-pituitary pathology (26.6%), diabetes mellitus (22.0%), thyroid pathology (17.8%), clinical nutrition (11.1%) and adrenal pathology (9.7%). Among students intending to choose Endocrinology and Nutrition for their specialised training, the most attractive part of the specialty was diabetes mellitus (35.1%), clinical nutrition (17.6%), hypothalamus-pituitary pathology (15.8%), thyroid pathology (14.0%) and obesity and dyslipidaemias (14.0%).
Conclusions
The teaching of the subject is an important factor in the choice of speciality. It would be interesting to increase and show the different interventional techniques in Endocrinology and Nutrition.

Preliminary evidence of the role of circulating testosterone levels in a cohort of women with SARS-CoV-2 infection

Giulia Rastrelli[1], Vincenza Di Stasi[1], Francesco Inglese[2], Massimiliano Beccaria[2], Martina Garuti[2], Domenica Di Costanzo[2], Fabio Spreafico[2], Graziana Francesca Greco[2], Antonietta Pecoriello[2], Tommaso Todisco[1], Sarah Cipriani[1], Elisa Maseroli[1], Irene Scavello[1], Claudia Glingani[3], Massimo Franchini[3], Mario Maggi[4], Giuseppe De Donno[2] & Linda Vignozzi[1]
[1]Department of Experimental and Clinical Biomedical Sciences "Mario Serio", University of Florence, Florence, Italy; [2]Intensive Care Respiratory Unit, Carlo Poma Hospital, Mantova, Italy; [3]Department of Hematology

and Transfusion Medicine, Carlo Poma Hospital, Mantova, Italy; [4]Department of Experimental and Clinical Biomedical Sciences "Mario Serio", Endocrinology Unit, University of Florence, Careggi Hospital, Florence, Italy

Purpose
Objective of this study was to assess the association between testosterone (T) levels and biochemical markers in a cohort of female patients admitted for SARS-CoV-2 infection in a respiratory intensive care unit (RICU).
Methods
A consecutive series of 17 women affected by SARSCoV-2 pneumonia and recovered in the RICU of the Hospital of Mantua (Italy) were analyzed. Biochemical inflammatory markers as well as total testosterone (TT), calculated free T (cFT), sex hormone–binding globulin (SHBG), and luteinizing hormone (LH) were determined.
Results
TT and cFT were significantly and positively associated with PCT, CRP, and fibrinogen as well as with a worse hospital course. We did not observe any significant association between TT and cFT with LH; conversely, both TT and cFT showed a positive correlation with cortisol. By LOWESS analyses, a linear relationship could be assumed for CRP and fibrinogen, while a threshold effect was apparent in the relationship between TT and procalcitonin, LDH and ferritin. When the TT threshold value of 1 nmol/l was used, significant associations between TT and PCT, LDH or ferritin were observed for values above this value. For LDH and ferritin, this was confirmed also in an age-adjusted model. Similar results were found for the association of cFT with the inflammatory markers with a threshold effect towards LDH and ferritin with increased LDH and ferritin levels for values above cFT 5 pmol/l. Cortisol is associated with serum inflammatory markers with similar trends observed for TT; conversely, the relationship between LH and inflammatory markers had different trends.
Conclusion
Opposite to men, in women with SARS-CoV-2 pneumonia, higher TT and cFT are associated with a stronger inflammatory status, probably related to adrenal cortex hyperactivity.

Lithium-induced hypercalcaemia

Sana Ali, Mariza Monteiro, Danny Lunda Ngandu, Daria Crepostnaia, Shirin Patel Md.Humayun Kabir, Alan Mitchell, Muhammed Saleem, Suhier Elshowaya, Hassan Rehmani & Gideon Mlawa
Queen's Hospital, United Kingdom

Introduction
Lithium remains a first-line treatment for several mental disorders. Hypercalcaemia has been associated with long-term lithium treatment, yet it is often unrecognized. The manifestations of hypercalcaemia can develop insidiously and mimic psychiatric disturbances.
Cases
Case Report 1 – A 53-year-old Caucasian gentlemen referred by his GP following routine bloods with an adjusted calcium of 3.46 mmol/l (2.2–2.6), PTH of 8.7 pmol/l (1.6–6.9), and a lithium level of 0.56 mmol/l (0.4–1). The patient was asymptomatic and clinically well. With a background of depression and right-sided hydrocele, this patient was on the following medications: lithium, atorvastatin, folic acid, mirtazapine, olanzapine and venlafaxine. An ultrasound of the parathyroid showed a small hypoechoic ovoid lesion adjacent to the inferior pole of the right lobe of the thyroid measuring 7 mm × 4 mm, suspicious for a small parathyroid adenoma. He was treated with IV fluids and given IV pamidronate prior to discharge. Additionally, his lithium dose was reduced and sodium valproate was initiated. Case Report 2 – A 73-year old Caucasian gentlemen was admitted with confusion and acute kidney injury on a background of Chronic Kidney Disease. Prior to admission, he described being generally unwell for the last two months, with poor oral intake and appeared significantly unkempt. His past medical history was notable for primary hyperparathyroidism secondary to a parathyroid adenoma, type 2 diabetes mellitus with retinopathy, severe depression with previous psychotic symptoms and hypertension. He was taking lithium, sitagliptin, venlafaxine, aspirin, and gliclazide. Blood tests results revealed an elevated calcium at 3.25 mmol/l (2.20–2.60), a raised PTH of 71.1 pmol/l (1.3–6.8) and a lithium level of 1.16 mmol/l (0.4–1). This patient's lithium was stopped, and he was treated with IV fluids and pamidronate. His AKI resolved and his discharge calcium was 3.11 mmol/l.
Discussion
While primary hyperparathyroidism usually arises from parathyroid adenomas, in patients on lithium, drug-induced hypercalcaemia should be considered and ruled out. Lithium is thought to cause hyperparathyroidism by altering the set points of extracellular calcium-sensing receptor (CaSR). This promotes excess parathyroid release. Thus, consistently elevated PTH levels may lead to hypercalcaemia.
Conclusion
Lithium-induced hypercalcaemia is likely more common than reported. Many patients are asymptomatic, with diagnosis only becoming apparent on routine blood tests. These cases and previously reported cases highlight that either reduction of lithium dosing or cessation of lithium can be effective management strategies. Regular measurement of serum calcium, PTH, as well as thyroid function test upon commencing lithium treatment is advisable.

How has the covid-19 pandemic affected training in endocrinology and nutrition

Ana Zugasti[1], María Ballesteros-Pomar[2], Irene Breton[3], Javier Escalada San Martín[4], Miguel Angel Rubio Herrera[5], Cristina Tejera[6], Pedro Pinés Corrales[7], Felicia Hanzu[8], Elena Dios[9]
[1]Complejo Hospitalario de Navarra, Pamplona, Spain; [2]Complejo Asistencial Universitario León, León, Spain; [3]Hospital Gregorio Marañon, Madrid, Spain; [4]Clínica Universidad de Navarra, Pamplona, Spain; [5]Hospital Universitario Clínico San Carlos, Madrid, Spain; [6]Complejo Hospitalario Universitario Ferrol, Ferrol, Spain; [7]Hospital General Universitario Albacete, Albacete, Spain; [8]Hospital Clinic Barcelona, Barcelona, Spain; [9]Unidad de Gestión de Endocrinología y Nutrición. Instituto de Biomedicina de Sevilla (IBiS), Consejo Superior de Investigaciones Científicas, Universidad de Sevilla. Hospital Universitario Virgen del Rocío, Spain

Introduction
The pandemic has altered the day-to-day running of hospitals and most of the material and human resources have been made available for COVID-19 care. So have the residents in Endocrinology and Nutrition (MIR), who have been working on the front line, and this has led to alterations in their training programme. In addition, this unexpected and stressful work situation has had psychological consequences. The Spanish Society of Endocrinology and Nutrition (SEEN) wanted to evaluate how the pandemic has affected the residents in our speciality in Spain.
Material and methods
From 9 to 22 November, all MIR in were invited to participate anonymously. A survey was created using Google Forms and the MIR members of SEEN and heads of departments and tutors were contacted. Surveys were collected with demographic data (age, sex, year of training), location and size of hospital, alteration of internal and external rotations and training, participation in teleconsultation, infection by COVID, participation in COVID teams and emotional involvement.
Results
Eighty-seven surveys were received: -67.8% female. MIR: 81.6% 3–4th year (60% 4th). -Size: 88.5% >500 beds. Cancellation of rotations: 70.1% in own speciality, 43.7% in their own centre, 37.9% another centre. Participation in teleconsultation: 93.1%. Training courses, congresses: 97.7%. Perception of training impact: 78.1%. COVID infection: 21.8% and quarantine: 28.7%. Participation in COVID teams: 83.9% (53.5% for more than two months). Feeling supported by tutor: 67.8% A lot - Quite a lot. Affected mood: 75.8% A lot - Quite a lot.
Conclusions
This study shows the disruption that the residents have suffered in their training programmes, due to the health care collapse generated by the pandemic. In 4th- year residents, the loss of important rotations in the speciality could affect their future professional activity. The psychological impact of the pandemic should not be forgotten. The positive aspects to be highlighted are having had experience in Teleconsultation and having participated in multidisciplinary teams in an exceptional pandemic situation. New training scenarios (online, virtual reality, etc.) that can replace or complement the classic models should be considered to ensure the correct training of the residents. Assuming that, after the 3rd wave, the impact on training and rotations may have been even greater than described with these data, the SEEN requests that consideration be given to extending

the residency period for those who have lost more than 3 months due to participation in COVID teams.
Keywords: resident, training, COVID-19.

Context
The occurrence of different subtypes of endogenous Cushing's syndrome (CS) in single individuals is extremely rare. We here present the case of a female patient who was successfully cured from adrenal CS 4 years before being diagnosed with Cushing's disease (CD).
Case Description
A 50-year-old female was diagnosed with ACTH-independent CS and a left-sided adrenal adenoma in January 2015. After adrenalectomy and histopathological confirmation of a cortisol-producing adrenocortical adenoma, biochemical hypercortisolism and clinical symptoms significantly improved. However, starting from 2018, the patient again developed signs and symptoms of recurrent CS. Subsequent biochemical and radiological workup suggested the presence of ACTH-dependent CS along with a pituitary micoradenoma. The patient underwent successful transsphenoidal adenomectomy, and both postoperative adrenal insufficiency and histopathological workup confirmed the diagnosis of CD. Exome sequencing excluded a causative germline mutation, but showed somatic mutations of the β-catenin protein gene (*CTNNB1*) in the adrenal adenoma, and of both the ubiquitin specific peptidase 8 (*USP8*) and the glucocorticoid receptor (*NR3C1*) genes in the pituitary adenoma.
Conclusion
Our case illustrates that both ACTH-independent and ACTH-dependent CS may develop in a single individual even without evidence for a common genetic background.

Neuroendocrine neoplasm of the pancreas as a manifestation of familial isolated pituitary adenoma: A case report

Eva Coopmans[1], Esther Korpershoek[2], M.F. van Velthuysen[2], Adrian F. Daly[3], Albert Beckers[3], Aart Jan Van der Lely[1], Sebastian Neggers[1], Hans Hofland[1], Richard Feelders[1] & Wouter W de Herder[1]
[1]Erasmus University Medical Center Rotterdam, Endocrinology section, Rotterdam, Netherlands; [2]Erasmus University Medical Center Rotterdam, Department of Pathology, Rotterdam, Netherlands; [3]University of Liège, Department of Endocrinology, Liège, Belgium

Context
Germline mutations in the aryl hydrocarbon receptor-interacting protein (*AIP*) have been identified in patients with pituitary adenomas, most frequently presenting as somatotropinomas in the setting of familial isolated pituitary adenoma (FIPA). Our current understanding of *AIP* related tumorigenesis indicates that it leads to isolated pituitary adenomans, while other associated tumors have not typically been considered part of the clinical spectrum. pancreatic neuroendocrine neoplasms (panNENs)
Case description
We report a unique case of an advanced pancreatic neuroendocrine neoplasm (panNEN) in a patient from a 3-member kindred. Germline DNA revealed a heterozygous pathological *AIP* variant c.910C > T (p.R304*) in the affected family members; no germline multiple endocrine neoplasia type 1 (*MEN1*) or cyclin-dependent kinase inhibitor 1B (*CDKN1B*) variants were seen. The tumor DNA sequencing confirmed the *AIP* c.910C > T (p.R304*) change in a liver metastasis, accompanied by loss of heterozygosity at the *AIP* locus. Furthermore, the liver metastasis showed an additional somatic variant in *MEN1* c.1289_1291del (p.E430del).
Conclusions
Genetic testing and tumor histopathology in this FIPA kindred suggest that in this case, the panNEN might represent a rare new *AIP*-associated malignancy.

Markers of humoral and cell-mediated immune response in primary autoimmune hypophysitis: A pilot study

Sabrina Chiloiro[1], Antonella Giampietro[1], Flavia Angelini[2], Pier Paolo Mattogno[2], Tommaso Tartaglione[3], Liverana Lauretti[2], Alfredo Pontecorvi[1], Laura De Marinis[1] & Antonio Bianchi[1]
[1]Endocrinology, Università Cattolica del Sacro Cuore, Rome, Italy; [2]Neurosurgery, Università Cattolica del Sacro Cuore, Rome, Italy; [3]Radiology, Istituto Dermopatico dell'Immacolata, IRCCS, Rome, Italy

Introduction
Primary autoimmune hypophysitis (PAHs) is a rare inflammatory disease of the pituitary gland. Although largely investigated, the pathogenesis of PAH is not completely clarified. We aimed to investigate the immune response in PAHs.
Material and methods
Serum anti-pituitary and anti-hypothalamus antibodies (respectively APAs and AHAs) were investigated though an indirect immunofluorescence on monkey hypophysis and hypothalamus slides, serum cytokines though an array membrane and cell-mediated immunity though the white blood cells count.
Results
Nineteen PAH cases entered the study. APA or AHA were identified in all cases. APA were detected in 13 patients (68.4%) and AHA in 13 patients (68.4%). Ten patients (52.6%) were simultaneously positive for both APA and AHA. The prevalence of APAs and AHAs was higher as compared to those observed in 50 health controls (respectively 14% $P < 0.001$ and 24% $P = 0.004$) and in 100 not-secreting pituitary adenoma (NFPAs) (respectively 22% $P = 0.002$ and 8% $P < 0.001$). Similarly, the prevalence of simultaneous positivity for APA and AHA (52.9%) was higher as compared to the those detected in patients affected by NFPAs (0%; $P < 0.001$) and in health controls (16% $P = 0.002$). No differences were identified between PAHs and controls at qualitative and quantitative analysis of serum cytokines and white blood cells count.
Conclusions
This study suggest that APA and AHA may be detected in an high percentage of PAH cases and that their simultaneous identification may be useful for the differential diagnosis between PAH and NFPAs, in an appropriate clinical context.

Natural course and surveillance of non-functioning pituitary microadenomas

Rishi Iyer, Rakshit Kumar & Anand Velusamy
Guy's and St Thomas' NHS Foundation Trust, Department of Endocrinology, London, United Kingdom

In the current era of multi-modal imaging being performed for various pathologies, incidental non-functioning pituitary microadenomas (NFPAs) are being increasingly identified. The available literature and guidance is limited on the long-term surveillance and monitoring and hence there is a wide variation in clinical practice across the UK. We conducted a

retrospective study in our institution to compare the outcome in our cohort to the current literature.
Method
Keyphrase "pituitary adenoma" was used to select 1700 patients over a 10-year period (2010–20) from pituitary MDM, radiology database and electronic patient records. Macroadenomas, functioning tumours, Rathke's cleft cysts, MEN syndrome and patients with < 2 pituitary screening (imaging and biochemistry) were excluded. Retrospective analysis was conducted on 43 patients with a mean age of 51 ±13 years (32F and 11M). NFPA diameter ranges were 1 – 5 mm in 24 (56%) and 6 - £10 mm in 19 patients (44%).
Results
Mean follow up period was 28.5 months (range 3 – 96) equating to 102 patient years. Although 20% of cases progressed in size (0.72 mm/year), overall net growth was negative (- 0.13 mm/year) as 80% regressed or remained unchanged. The maximum dimension reached during surveillance was 11mm in 1 NFPA from a baseline of 10mm.
Surveillance summary
1 – 10 mm: Regression in 30%, unchanged 50% and progression in 20%.
1 – 5 mm: Regression in 25%, unchanged in 60% and progression in 15%.
6 – 10 mm: regression in 30%, unchanged in 40% and progression in 30%.
Conclusion
Compared to the largest meta-analysis of 14 multi-centre observational studies that consisted of 229 NFPAs, our single centre case series of 43 NFPAs demonstrated 20% (vs 10%) progression, 30% (vs 7%) regression and 50% (vs 83%) unchanged with stable size. None of the NFPAs in our series came into contact with the optic chiasm and all the patients remained eupituitary throughout. Our study further reaffirms the benign course of NFPA if £10 mm, however, further up to date multi-centre data collation is essential for predictive modelling based on size and age at presentation and standardisation of follow up and discharge protocols.

The first comprehensive study of the clinical response of a cohort of acromegalic patients with somatostatin responsive headache

Sonia Kaniuka-Jakubowska[1,2], Miles J Levy[3], Aparna Pal[2], Dayakshi Abeyaratne[2,4], William Drake[5], Nikolaos Kyriakakis[6], Robert D Murray[6], Steve M Orme[6], Shailesh Gohil[3], Antonia Brook[7], Graham Leese[8], Márta Korbonits[9] & John Wass[2]
[1]Medical University of Gdansk, Department of Endocrinology and Internal Medicine, Gdask, Poland; [2]Oxford University Hospitals NHS Foundation Trust, Department of Endocrinology at the Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford, United Kingdom; [3]Leicester Royal Infirmary, University Hospitals of Leicester NHS Trust, Department of Endocrinology, Leicester, United Kingdom; [4]National Hospital of Sri Lanka, Diabetes and Endocrinology Unit, Colombo, Sri Lanka; [5]St Bartholomew's Hospital, Barts Health NHS Trust, Department of Endocrinology, London, United Kingdom; [6]Leeds Centre for Diabetes & Endocrinology, St James's University Hospital, Leeds Teaching Hospitals NHS Trust, Department of Endocrinology, Leeds, United Kingdom; [7]Royal Devon and Exeter Hospital, MacLeod Diabetes and Endocrinology Centre, Exeter, United Kingdom; [8]NHS Tayside, Department of Endocrinology, Dundee, United Kingdom; [9]Barts and The London School of Medicine, Queen Mary University of London, Charterhouse Square, Centre for Endocrinology, William Harvey Research Institute, London, United Kingdom

It is known that acromegaly may be associated with headache as a significant co-morbidity. Amongst all acromegaly headache patients, there is a unique group with specific types of severe headache that fail to improve despite acromegaly therapy and are resistant to conventional analgesics, however, immediately respond to subcutaneous short-acting (SA) somatostatin analogue (SSA) treatment. We have surveyed 8 tertiary specialist UK centres and identified 18 patients (6 females) on the basis of their presentation with SSA-responsive acromegaly associated headache. The phenotype was mostly chronic migraine (78%) and International Headache Society pituitary-tumour associated headache (22%). All patients reported a daily, persistent headache (apart from those on long-acting (LA) SSA) with intense severity (mean 9 on 0–10 pain scale). No headache cessation after surgery was observed (although in 27.8% improvement was reported). All patients presented with macroadenoma, mostly after incomplete resection (94.1%) and headache ipsilateral to remnant tissue (93.8%). All patients failed to respond to conventional analgesic treatment. However, they all observed headache relief after SA-SSA injection within minutes, lasting up to 6 hours. The frequency of SA-SSA injections was higher when taking SA-SSA alone (n = 8), than in combination treatment with SA- and LA-SSA (n = 10) for disease control (mean 10.4 [range 3–6] SA-SSA alone; vs mean 3.7 [range 0–7] SA with LA-SSA). Headache was long-lasting, persisted up to 33 years after diagnosis (mean 18 [range 6–33]), and only 4 patients were in headache remission. 77.8% of patients achieved biochemical control, although 71.4% of this group still had headache despite normal IGF-1. Elapsed time after radiotherapy in patients with headache remission was higher than in patients still struggling with headache (median 21 vs 10 years). Headache, as a significant co-morbidity in a specific group of patients with acromegaly can be persistent, severe, unrelieved after surgery, and not correlated with biochemical control, while reacting to SA-SSA, which appears to have a modulatory role with its still unknown mechanism.

The stimulatory effects of glucagon on cortisol and GH secretion occur independently from FGF-21

Ilyas Akkar[1], Zuleyha Karaca[1], Serpil Taheri[2], Kursad Unluhizarci[1], Aysa Hacioglu[1] & Fahrettin Kelestimur[3]
[1]Erciyes University, Endocrinology, Kayseri, Turkey; [2]Erciyes University, Molecular Biology, Kayseri, Turkey; [3]Yeditepe University, Endocrinology, Istanbul, Turkey

Aim
Glucagon stimulation test (GST) is used to assess hypothalamo-pituitary-adrenal (HPA) and GH axis with an incompletely defined mechanism. Glucagon has physiological effects on body weight and metabolic parameters and some of these effects are suggested to occur via fibroblast growth factor-21 (FGF-21) which is a circulating hepatokine. FGF-21 was also shown to affect HPA and GH axis in rodents. The aim of the present study was assess if glucagon acted through FGF-21 to stimulate the cortisol and GH secretion. Secondary outcome was to determine the relationship of FGF-21 with variable GH responses to GST in obesity.
Material and methods
A total of 26 healthy participants were included in the study. 11 participants were obese (Body Mass Index (BMI) > 30 kg/m^2) and 15 had a normal weight (BMI <25 kg/m^2). Basal pituitary and target hormone levels were measured and glucagon stimulation test (GST) was performed. During GST, glucose, insulin, cortisol, GH and FGF-21 responses were measured.
Results
Glucagon resulted in significant increases in FGF21, glucose, insulin, cortisol and GH levels. Serum glucose levels showed variations during GST. Peak GH and area under curve $(AUC)_{(GH)}$ responses to GST in the obese group were lower than those of the normal weight group with a different pattern of response. Cortisol responses were similar in two groups. Obesity was associated with significantly increased glucose and insulin responses and slightly decreased FGF-21 response to glucagon. But neither cortisol nor GH response to the GST was related to FGF-21, deeper hypoglycemia may be related to increased GH response to GST in lean individuals.
Conclusion
Obesity was associated with blunted and delayed GH, but preserved cortisol responses to GST. This is the first study, at least according to our knowledge, to show that glucagon stimulates the HPA and GH axis independently from FGF21. The delayed GH response to GST in obesity does not seem to be related to FGF-21.

The relative's viewpoint on acromegaly in remission : A psychosocial dimension of a chronic disease

Rachel Fourneaux[1], Vermalle Marie[1], Frederique Albarel[1], Isabelle Morange[1], Thomas Graillon[2], Vincent Amodru[1], Thomas Cuny[1], Henry Dufour[2], Thierry Brue[1] & Frederic Castinetti[1]
[1]Aix Marseille University, Endocrinology, Marseille, France; [2]Aix Marseille University, Neurosurgery, Marseille, France

Aim of the study
A relative can be an asset in dealing with chronic illnesses such as acromegaly where quality of life is altered even after remission. However, it has been shown that quality of life of caregivers can also be impacted. Our

main objective was to explore the consequences of acromegaly in remission in the patient-relative dyad in a matter of quality of life and self-esteem.
Methods
In this French monocentric observational study, to better characterize the perception of the disease by the relative, patient's body image (Stunkard figurines) and self-esteem were evaluated from the patient's point of view and from the relative's (n = 27 dyads, including 77.7% partners and 22.2% children) using the same questionnaires with modified instructions. Both evaluations were correlated in an original approach to try to understand the differences of the perception of acromegaly in remission seen by the partner when he/she was asked to think of what would be the answer given by the patient. The patient and the relative were also asked to fulfil quality of life, anxiety/depression and coping strategies questionnaires.
Results
The relative had an overall accurate estimation of the patient's body image (P = 0.171 in comparison with the patient). However, there were individual variations between the patient's and the relative's answers for self-esteem and body perception from an individual viewpoint. The relative's quality of life was not altered and was significantly higher in the social domain than for the patient. As expected, patients had a significantly lower quality of life and body satisfaction than the French population: in multivariate analysis, self-esteem was associated with an impaired psychological quality of life score. Finally, the adaptation strategy preferentially adopted by the relative was positive thinking. Problem solving came in second position, and seeking social support in third.
Conclusions
Our study is the first to analyse the consequences of acromegaly of the patient-relative dyad in a matter of quality of life and self-esteem. Despite inter-individual changes between the patient's and the relative's view, our results show that the relative appeared to have an accurate estimation of the patient's body image. However, the relative was not fully aware of the consequences of body changes on the patient's self-esteem. The relative should thus be educated in all the steps of the management of acromegaly, and be encourages not to postpone seeking social support.
Funding
This work was financed by an unrestricted educational grant received from IPSEN.

Importance of proper diagnosis and treatment challenges in a 16-year-old patient with ectopic posterior pituitary and panhypopituitarism - a rare case report

Mihaela Stanciu[1,2] & Ruxandra Paula Ristea[2]
[1]'Lucian Blaga' University of Sibiu, Faculty of Medicine, Department of Endocrinology, Sibiu, Romania; [2]Academic Emergency Hospital of Sibiu, Endocrinology, Sibiu, Romania

Background
Posterior pituitary ectopia is a rare congenital condition that consists of the abnormal position of the distinctly hyperintense signal suggestive of the posterior pituitary gland on magnetic resonance imaging. The classical features include the ectopic location of the posterior pituitary gland, pituitary stalk abnormalities and associated clinical manifestations related to isolated growth hormone deficiency. In rare cases, some patients suffering from this condition may develop panhypopituitarism.
Case report
The present paper aimes to present a rare case of a late-diagnosed ectopic posterior pituitary with an absent pituitary stalk and panhypopituitarism, in a 16-year-old male patient with severe mental retardation, under the care of a non-compliant mother. The initial physical examination showed short stature, mild facial dysmorphism, absence of both expressive and receptive language, micropenis and cryptorchidism. Laboratory investigations showed multiple anterior pituitary deficiencies: growth hormone deficiency (GHD), with a corresponding low insulin-like growth factor-1 (IGF-1), low free-thyroxine-4 (FT4), low follicle-stimulating hormone (FSH), and luteinizing hormone levels (LH), low total testosterone level, low serum cortisol level, hyperprolactinemia and severe 25-hydroxivitamin D deficiency. The radiographic anatomy of the hand estimated a bone age between 6 and 7 years. A pituitary magnetic resonance imaging revealed the absence of the pituitary stalk, hypoplastic anterior pituitary and the ectopic location of the posterior pituitary near the mammillary bodies. Initially, the patient was treated with prednisolone 5 mg/day, levothyroxine 50 mg/day, and cholecalciferol 1000 IU/day. At the 3-month follow-up, no significant improvement could be observed, due to lack of compliance from the patient's mother regarding treatment administration. The decision to add human growth hormone and later on human chorionic gonadotropin to the current treatment was taken. Parent counseling was provided. At the 6-month follow-up, a slight improvement in the patient's height and general condition was observed.
Conclusion
Taken together, our findings support the theory that in rare cases, an absent infundibular stalk is associated with panhypopituitarism. Based on the clinical and hormonal findings, magnetic resonance imaging for hypothalamic-hypophyseal abnormalities was the key investigation to determine the underlying cause of these aspects. If diagnosed early and with adequate treatment adherence, the therapy can ensure normal psychiatric and somatic development in pediatric patients. Parent compliance is crucial for successful outcomes.

Hemorragic degeneration after covid-19 infection in microprolactinoma

Nurcan Ince[1], Mehdi Houssein[2], Nagihan Bestepe[2], Himmet Durmaz[1], Didem Ozdemir[1], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Ankara, Turkey, Department of Endocrinology and Metabolism,, Ankara, Turkey; [2]Ankara Bilkent City Hospital, Ankara, Turkey, Department of Endocrinology and Metabolism,, ankara, Turkey

Introduction
Pituitary apoplexy is seen in 1.5–27.7% of pituitary adenomas. Common etiologies include hypertension, diabetes mellitus, radiotherapy, contrast-enhanced MR, surgery, drugs, anticoagulant, antithrombotic, estrogen, head trauma and pregnancy. SARS-CoV-2 had spread rapidly, and caused COVID-19 pandemic. Although it mainly causes respiratory problems, there may also be extrapulmonary involvement. COVID-19 infection is associated with hemorrhagic complications, cardiac and renal infarction and cerebrovascular hemorrhage. In this report, we present a patient who was followed up with microprolactinoma and developed hemorrhagic degeneration in adenoma after Covid-19 infection.
Case
A 26-year-old female patient was found to have serum prolactin of 94.19 mg/l (4.79–25.3) in the tests performed due to menstrual irregularity and complaints of galactorrhea by provocation. Control prolactin was 104 mg/l, and macroprolactin was negative. Other anterior pituitary hormones, kidney and liver function tests were normal. A 4 × 6 mm microadenoma was detected on pituitary gland in pituitary MRI. Cabergoline 0.5 mg/week was initiated in March 2019 with the diagnosis of microprolactinoma. The pituitary MRI taken in February 2021 revealed a 7 × 5.5 mm lesion in the adenohypophysis with the presece of hemorrhagic degeneration. There were no complaints of severe headache, nausea, vomiting, or visual impairment during system inquiry. Anterior pituitary hormone levels were normal. Medical history showed that she was diagnosed with Covid-19 in September 2020. She used hydroxychloroquine sulfate 2 × 200 mg (5 days) and enoxaparin sodium 2 × 0.6 mg (10 days) and then acetylsalicylic acid for 10 days. It was thought that hemorrhagic degeneration might be due to the antiaggregant/antithrombotic treatment she had received or the Covid-19 infection itself.
DISCUSSION
Case reports of pituitary apoplexy following Covid-19 infection have been presented in the literature. It is unclear whether this infection occurs as a contributing factor to pituitary apoplexy or coincidentally. It is possible that coronavirus infection could cause an acute hemorrhagic infarction of the gland. This risk increases with anticoagulant and antiaggregant treatments used during Covid-19 infection. Although bleeding into adenomas is spesific to macroadenomas, it should be kept in mind that it may also occur with microadenomas.

Two thyrotropin secreting pituitary adenoma cases diagnosed after response to the somatostatin analogue

Gulsum Karahmetli[1], Mehdi Houssein[2], Belma Ozlem Tural Balsak[2], Berna Ogmen[1], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakır[1]
[1]Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Ankara, Turkey, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Bilkent City Hospital, Ankara, Turkey, Department of Endocrinology and Metabolism, Ankara, Turkey

Introduction
Pituitary adenomas secreting TSH (TSHoma) are a rare cause of hyperthyroidism. They account for approximately 0.5–3 % of functioning pituitary tumours and much less than 1% of all cases of hyperthyroidism. TSHoma should be considered in all hyperthyroid patients, especially those with diffuse goitre and no extrathyroidal signs of Graves' disease.
Case 1
A 30-year-old female applied to the internal medicine department with complaints of palpitations, diarrhea, sweating and weight loss. In repeated examinations, high levels of TSH, fT3 and fT4 were detected, TSH, fT3 and fT4 values examined in 3 different centres and again found to be high.The serum sex hormone-binding globulin concentration was slightly elevated. In family screening, no thyroid dysfunction was detected. In pituitary MRI, 5 mm adenoma was detected.The serum α-subunit level was 2.4 ng/ml (normal < 1.2), and the α-subunit/*TSH molar* ratio (α-subunit × 10/*TSH*) was 4.3 (normal < 1).We performed an analysis for mutations in the *THRB* gene; no mutations found. The serum TSH concentration didn't increase in response to the thyrotropin-releasing hormone, while a fall in serum TSH concentrations was detected in response to administered T3. Since the tests showed discordance, a short course of long-acting (LAR) somatostatin analogue (SSA) was administered. Thyroid function tests returned to normal with LAR-SSA therapy and strengthened the diagnosis of TSHoma. Surgery was planned.
Case 2
A 35-year-old male patient was referred to the endocrinology department when elevated TSH, fT3 and fT4 values were detected in the smoking cessation outpatient clinic. Repeated examinations in the same centre and two different centres showed high TSH, fT3 and fT4 levels. No thyroid dysfunction was found in first-degree relatives.The serum sex hormone-binding globulin concentration was normal,and the serum ńsubunit level was 0.7 ng/ml (normal<0.5). In pituitary MRI, 7 mm adenoma was detected. The serum TSH concentration didn't increase in response to the thyrotropin-releasing hormone,while a fall in serum TSH concentrations was detected in response to administered T3. Since the tests showed discordance,a short course of LAR-SSA was administered. Thyroid function tests returned to normal with LAR-SSA therapy and strengthened the diagnosis of TSHoma. Surgery was planned.
Conclusion
Most *TSHomas* are detected as pituitary *macroadenomas***.** The presence of a microadenoma on MRI is not specific for a TSH-secreting tumour and can be seen as an incidental finding in 10 per cent of normal individuals. The rutin tests used for the differential diagnosis of TSHoma and Thyroid hormone resistance sometimes may be discordant. In such cases, performing the LAR-SSA test strengthen the diagnosis.

EGFR (Epidermal Growth Factor Receptor) expression in tumor microenvironment of pituitary adenomas – pathogenic and therapeutic implications

Ana Silvia Corlan[1], Cimpean Anca Maria[2] & Raica Marius[2]
[1]University of Medicine and Pharmacy Victor Babes Timisoara, Endocrinology, Timisoara, Romania; [2]University of Medicine and Pharmacy Victor Babes Timisoara, Microscopic Morphology/ Histology, Timisoara, Romania

Background
Pituitary adenomas are general benign tumors. However, gross invasion at time of operation is observed in up to 35% of pituitary adenomas. The new WHO classification describes pituitary tumor subtypes along with histological markers, such as Ki67 > 3%, that may suggest a potential for aggressive clinical behavior. The expression of EGFR in tumor microenvironment of pituitary adenomas ant its correlation with tumor behavior have been poorly characterized.
Materials and methods
Our study included 92 selected cases (10 normal pituitary glands, 82 pituitary adenomas extracted through transsphenoidal approach). We used standard morphological stain- hematoxylin-eosin to determine the tinctorial classification and the growth pattern of the adenomas. We used the immunohistochemical method to obtain the hormonal profile; we determined the mRNA for the well known growth factors (VEGF, VEGF165b, PDGF A, PDGF B/PDGFR BETA, EG-VEGF) through ISH, respectively the RNA scope technique. We also characterized S100 -positive folliculo-stellate cells and tumor associated macrophages.
Results
We identified 2 types of cells, with positive immunohistochemical reaction to EGFR in pituitary tumors with negative reaction to EGFR. In some adenomas, we identified, at the periphery of the tumor, an important accumulation of tumor associated macrophages. In these cells,we identified a strong expression of the receptor EGFR. We identified a strong expression of EGFR in folliculostellate cells with a homogenous or granular cytoplasmatic pattern.Both adherent and gap junctions are between folliculostellate cells and between folliculostellate cells and endocrine cells. These cells are also positive for GFAP (glial fibrillary acidic protein), suggesting that this cell type may represent an astrocyte – or microglia – like cell type. Our observations support older findings, notably the increased activity of folliculostellate cells under pathological conditions, their phagocytic activity and their capacity to secrete angiogenic growth factors, suggesting that folliculostellate cells may be involved in basement membrane remodeling, tumoral neoangiogenesis and tumoral expansion.
Discussions and conclusions
The role of folliculostellate cells expressing EGFR in pituitary adenomas has not been studied until now. Clearly, the tumor microenvironment is a major component of pituitary adenomas that holds promise for targeted therapies. We need to better characterize the composition of this microenvironment ,influencing the tumor behavior and the response to therapy

Pituitary diseases registry study in latvia. Part 2

Ingvars Rasa[1] & Maija Gurevica[2]
[1]Riga East Clinical University Hospital (RECUH), Outpatient Clinic, Riga, Latvia; [2]Aura, Outpatients Centre, Riga, Latvia

Introduction
Pituitary diseases result in clinical consequences and increased mortality due to tumors mass effects and also due to pituitary hypersecretion and insufficiency. Pituitary tumors registry enables identification of diagnostic and prognostic markers. The registry improves long-term clinical outcomes, pituitary diseases care and management.
The aim of this study
Our registry study is designed to create a unified database of pituitary disease patients in Latvia for the first time.
Materials and methods
We collected 3 yrs data from pnts medical records with pituitary diseases and tumors from Clinical University Hospital Outpatient Clinic and from 4 Outpatients Clinics in Riga and in Jelgava, which were the workplaces of both authors. Prospective cohort analysis was performed based on demographic data, MRI and lab. data, data on medications, doses, and regimens, information on co-morbidities and concomitant medications. We collected pnts with pituitary diseases and tumors: prolactinomas, CNFA, acromegalies, empty sella syndr., Cushing's disease (CD), Ratke's pocket cysts, meningiomas, craniopharyngioma, pituitary aplasia or hypoplasia, TSH-omas, germinoma, glioma, chondrosarcoma, pericytoma.
Results
355 pnts (71.7% women) with pituitary diseases were registered from July 2016 to July 2019. The mean age was 43.4 yrs (range 18–83 yrs). Prolactinomas were the most common adenomas (40.8%), followed by CNFA (28.5%), acromegaly (16.1%) and than empty sella syndrome (5.1%), CD (2.3%), Ratchet pocket cysts (2.3%), meningiomas (1.4%), craniopharyngiomas (1.1%), pituitary aplasia and hypoplasia (0.8%), TSH-omas (0.6%), germinoma (0.3%), glioma (0.3%), chondrosarcoma (0.3%), pericitoma (0.3%). Patients in this cohort most often received drug therapy with any medication alone or in combination (octreotide LAR, lanreotide, bromocriptine, cabergoline, pegvisomant) in 50.5% of cases. The majority of 94.7% of patients (n = 336) had 1 or more co-morbidities. The most common group of comorbidities was the thyroid disease group (n = 289). The next - the cardiovascular diseases group (n = 273), vitamin D deficiency 76.2% (n = 256), dyslipidaemia 59.2% (n = 199), various types of diabetes mellitus/carbohydrate metabolism disorders 36.3% (n = 122), non-alcoholic steatohepatosis (NASH) 19.3% (n = 65), osteoarthritis 17.9% (n = 60), primary/secondary osteoporosis/osteopenia 7.1% (n = 24), gallstone disease 10.4% (n = 35), etc. The majority of pnts (81.7%) were treated with 1 or more concomitant medications.
Conclusions
As a result of this study, a unified database of pnts with pituitary diseases has been created, and data on 14 different pituitary diseases has been collected in register, which allows analyzing the population characteristics

of the pituitary diseases, the applied treatment schemes for the treatment of pituitary diseases; types of neurosurgery, medications data.

A case of pituitary xanthogranuloma diagnosed with diabetes insipidus

Kubra Turan[1], Unzile Arifoglu[2], Narin Nasiroglu Imga[2], Belma Tural Balsak[2], Denizhan Divanlioglu[3], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]

[1]Yildirim Beyazit University Faculty of Medicine, Ankara City Hospital, Clinics of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara City Hospital, Clinics of Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara City Hospital, Clinics of Neurosurgery, Ankara, Turkey

Background

Pituitary xanthogranulomas are extremely rare tumors of the sellar region. A cystic mass lesion was found in the pituitary MRI of our patient diagnosed with central diabetes insipidus (DI). We aimed to present a case who was operated for a pituitary mass and diagnosed with sellar xanthogranuloma.

Case presentation

37-year-old female patient was applied to our outpatient clinic with complaints of polydipsia, polyuria and headache for 8 months. The anterior pituitary hormone levels were in normal. Plasma osmolarity: 291 mOsm/kg, urine osmolarity: 130 mOsm/kg, urine density: 1006 and serum electrolytes were in normal range. Pituitary MRI revealed a cystic mass lesion with prominent hyperintense mucoid content in T1-weighted sequences with a diameter of approximately 10 × 11 mm and completely obliterating the neurohypophysis in the posterior of the adenohypophysis. Also the cystic mass lesion showed expansion towards the posterior suprasellar system. Her visual field examination was found normal. The patient was admitted to our clinic for the water deprivation test. Complete central DI was diagnosed. Desmopressin treatment was started on. The clinic and laboratory findings of DI were improved after desmopressin treatment. The patient was evaluated by neurosurgery department. Transsphenoidal surgery was performed for the mass lesion in the pituitary. The pathology result was reported as sellar xanthogranuloma. Desmopressin therapy was continued in the postoperative period. Clinical and laboratory findings were found normal under desmopressin treatment. Pituitary MRI performed 3 months after the operation, no finding of residual-recurrent adenoma was detected in the sellar region.

Conclusion

Sellar xanthogranulomas are very rare seen intracranial tumors. They have not any typical radiological feature. Patients can present with clinical signs such as headache, visual disturbance, vomiting, DI and hypopituitarism.

AEP851

A man with adenocarcinoma metastasis to the pituitary gland presenting with panhypopituitarism and double vision

İnan Anaforoglu[1], Sevgi Sahin[2], Erdogan Suleymanlar[3], Ayca Ersen Danyeli[4] & İlhan Elmacı[5]

[1]Mehmet Ali Aydınlar University Acıbadem Maslak Hospital, Endocrinology, İstanbul, Turkey; [2]Mehmet Ali Aydınlar University Acıbadem Maslak Hospital, Nephrology, İstanbul, Turkey; [3]Acıbadem Maslak Hospital, Radiology, İstanbul, Turkey; [4]Mehmet Ali Aydınlar University Acıbadem Maslak Hospital, Pathology, İstanbul, Turkey; [5]Mehmet Ali Aydınlar University Acıbadem Maslak Hospital, Neurosurgery, İstanbul, Turkey

A 76 year old man known to have coronary heart disease, hypertension and chronic kidney disease due to hypertensive nephropathy admitted to the nephrology clinic with fatigue, nausea and dizziness. His creatinine level was detected to be increased (from 1.5 to 2.5 mg/dl) and was he was hospitalized. The cranial magnetic resonance imaging (MRI) performed after neurology consultation for dizziness showed a pituitary mass. When asked, the patient described bitemporal hemianopsia for 2 months and double vision for the last 3 days. During eye examination bitemporal hemianopsia and VI. nerve palsy were detected. Pituitary MRI showed a 18.2 × 18.6 × 17 mm, bilobular, heterogenous mass with cystic and necrotic areas invading and expansing sella turcica. The lesion also compressed optic chiasma and stretched out pituitary stalk. ıt was interpreted as a macroadenoma but a metastasis could not be excluded. Pituitary hormones revealed panhypopituitarism; cortisol 1.92 mg/dl, ACTH<5 pg/ml, TSH 0.207 uIU/ml, triiyodothyronin 3.46 pmol/l (3.5–6.5), thyroxin 9.31 pmol/l (11.5–22.7), IGF-1 48.8 ng/ml (35–216), LH 0.389 mIU/ml (3.1–34.6), total testosteron< 7.00 ng/dl (86.4–788), PRL 43 ng/dl. The patient was started L-thyroxin subsequently methyl-prednisolon. The patient underwent pituitary biopsy; the tumor, within a desmoplastic stroma, was composed of malignant epithelial cells forming large glandular structures with intraluminal mucin. The neoplastic cells were positive for Cytokeratin 7 and TTF1, was negative for Cytokeratin 20, CDX2, Thyroglobulin, Synaptophysin, Chromogranin and CD56. The tumor was consistent with an adenocarcinoma metastasis. Positron emission tomography-fluorodeoxycortisol (PET-FDG) was performed to reveal the possible primary source of the tumor. PET-FDG showed bone metastases at the dorsal, lumbar vertebrae, left scapula, right acetabulum and left hip (SUVmax: 8.6) and a thyroid nodule at right lobe with normal FDG uptake. Cyber-knife neurosurgery was made to the pituitary lesion of the patient. The pituitary gland is an unusual location for any metastatic spread. Metastases to the pituitary gland represent 0.4% of all intracranial metastatic tumors. Symptoms and signs of pituitary metastases include diabetes insipitus, visual damage, ophtalmoplegia, headache, fatigue, weight loss, nausea and cognitive deterioriation. Anterior pituitary deficiency is common and hyperprolactinemia can be seen.

AEP852

Rare hypophysis tumor arising in a case with diabetes incipidus: Granular cell tumor

Nurcan Ince[1], Muzaffer Serdar Deniz[2], Muge Keskin[2], Ahmet Dirikoc[1], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]

[1]Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Ankara, Turkey, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Bilkent City Hospital, Ankara, Turkey, Department of Endocrinology and Metabolism, Ankara, Turkey

Introduction

Pituitary gland tumors constitute approximately 10–15% of primary brain tumors, and posterior pituitary tumors are extremely rare. Granular cell tumor (GCT) is a low grade non-neuroendocrine neoplasm. Here, we will present our case who was found to have GCT during follow-up of diabetes insipidus (DI).

Case

A 23-year-old male patient applied to our outpatient clinic for routine control. 12 years ago, he was diagnosed with growth hormone deficiency and central hypothyroidism during tests performed for short stature, and used growth hormone and levothyroxine treatments, and it was learned that these treatments were discontinued after puberty, and he had been using desmopressin for partial DI for 10 years. He was using desmopressin 240 mg/day at presentation. His height and weight were 165 cm and 60 kg, his blood pressure was 120/80 mm Hg, and his pulse was 72 beats/min. Systemic examination was normal. Serum Na level was 142 mEq/l, serum osmolality was 291 mOsm/kg, spot urine osmolality was 693 mOsm/kg, and urine density was 1020 (Table 1). On the neurohypophysis lodge, a high-signal lesion area (granular cell tumor?) was observed with magnetic resonance imaging in T1A and T2A series with 1.4 × 1 × 0.6 cm dimensions, which created convexity at the base of the sella contour. When the pituitary images of previous years were examined, it was reported that neurohypophysis was normal in 2010 and 2016, tubular structure showing loss of signal in all sequences in the neurohypophysis (vascular structure?) was observed in 2013, and in 2019, it was determined that a lesion (lipoma?, terotoma?, dermoid cyst?) was detected in the neurohypophysis lodge, which showed suppression (?) in a fat-suppressed sequence of 13 × 7 mm in size, and did not form a distinct opacification pattern in dynamic study. He was evaluated in a multidisciplinary council and follow-up was planned.

Discussion

DI was seen in 3–5% of GCT cases. In our case, no tumor was observed on neurohypophysis at the time of diagnosis, but GHT was detected during follow-up. We are of the opinion that periodic pituitary imaging in DI cases may increase the possibility of detecting rare tumors such as GHT.

AEP853

Giant invasive prolactinoma –a dramatic quick response to medical therapy

Sing Yang Sim & Ma'en Al-Mrayat
University Hospital Southampton NHS Foundation Trust, United Kingdom

Giant prolactinomas are rare tumours, accounting for only 2–3% of all prolactin (PRL)-secreting tumours which can pose therapeutic challenges. It has a higher preponderance in men with a male to female ratio of about 9:1. A 70year old gentleman initially presented to the ophthalmology department with blurred and reduced colour vision. He denied any headache, galactorrhoea or gynaecomastia however he noticed reduced libido and difficulties with erections. His past medical history included hypertension, Type 2 Diabetes and renal stones. He reported no family history of endocrine disease or tumours. On examination, his weight was 92 kg, with a BMI of 31.A mild temporal left visual field defect was noted with normal eye movements. In view of the visual defect he had a brain MRI which demonstrated a large mass centred on the body of the sphenoid extending laterally into both cavernous sinuses the sphenoid wings and roof of the orbits with extension into the ethmoid air cells and left frontal air cells. The mass elevated the chiasm, floor of the third ventricle and anterior frontal lobes. He was subsequently referred to the pituitary service and initial biochemistry showed a random cortisol of 237 nmol/l, FSH 2.0 iu/l ,LH 1.1 iu/l, TSH 1.42 mu/l (0.34–5.6), T4 8.5 mu/l (7.7–15), IGF-1 17.4 nmol/ (5.3–29), ACTH 23 ng/l (0–46), Testosterone 2.1 nmol/l (10.0–27.6), prolactin (post dilution) : 411, 237 mu/l (55–276), Renal, calcium and liver function profiles were normal. In liaison with neurosurgery he was commenced on cabergoline at a dose of 500 micrograms once weekly with views to increase to 500micrograms twice weekly as tolerated. He was also started on hydrocortisone given the indeterminate cortisol level and a short synacthen test was arranged. He was also started on levothyroxine 50 micrograms once daily for secondary hypothyroidism. He responded very well to medical therapy and his prolactin levels dramatically improving to 6911 mu/l.An interval pituitary MRI at 6 weeks showed modest reduction in the bulk of the macroprolactinoma with resolution of chiasmal compression. His subsequent prolactin levels were suppressed to latest of 97 mU/l and serial MRI scans showed progressive shrinkage of the giant tumour.

Conclusion

Dopamine agonists remain the first line treatment for giant macroprolactinoma in tumour size reduction and normalization of prolactin levels. Neurosurgical interventions are associated with high morbidity and mortality and best reserved when medical therapy is ineffective or not tolerated. Patients should be managed in Tertiary Centres within an MDT setting.

Examination of pituitary adenomas and non-adenoma lesions

Bülent Vatansever[1], Merve Soyhan[1] & Cigdem Ozkan[2]
[1]İzmir Bozyaka Education and Research Hospital, İnternal Medicine, İzmir, Turkey; [2]İzmir Bozyaka Education and Research Hospital, Endocrinology, İzmir, Turkey

Introduction

Pituitary adenomas generate 10–15% of primary brain tumors. Most of these adenomas are benign and orginate from the epithelial cells of the adenohypophysis. Pituitary adenomas can occur in all age groups, but most common in the third and sixth decades. In this study, we are investigated the demographic characteristics of pituitary adenomas and non-adenoma lesions that admission to the Bozyaka Education and Research Hospital Endocrinology and Metabolic Diseases outpatient clinic between 2018–2019.

Materials and methods

93 patient who have pituitary adenomas and non-adenoma lesions that admission to the Bozyaka Education and Research Hospital Endocrinology and Metabolic Diseases outpatient clinic between 2018–2019; detailed anamnesis, pituitary hormone results and pituitary MR images were retrospectively analyzed.

Results

The mean age of patients was 44, 7 (range 19–93). Of 93 patients, we were seen 70% were female (n:66) and 29% were male. (n:27) We were found that microadenoma 56% (n:53), macroadenoma in 31% (n:29), empty cella 2% (n:2), partial empty cella 6%(n:6), craniopharyngioma 3% (n:3), rathke cleft cyst 1% (n:1) of the patients who admitted to the study. Among the patients diagnosed with macroadenoma, the mean age of male patients was 58, 3 (n:13), and the mean age of female patients was 48.9 (n:16). The mean age of female patients who diagnosed with microadenoma was 38 (n:44), and the mean age of male patients who diagnosed with microadenoma was 46, 1. (n:9). When the patients were evaluated according to hormone secretion function; 68% (n:64) of the patients examined were prolactinoma, 6,4% (n: 6) acromegaly, 13,9% (n:13) were nonfunctional adenoma. Majority of the patients (%77,9) who diagnosed with prolactinoma were female. (n: 53)

Conclusion

When both macroadenoma and microadenoma were evaluated, we found that the average age in men was higher than in women. As a result of the study, we determined microadenomas were more common in women and noticed at an younger, however; observed less frequently in men, but diagnosed in older ages. When pituitary lessions were evaluated according to hormone secretion function, prolactinoma was the most common. As a result of our study, the majority of patients followed up with the diagnosis of microadenoma with medical treatment (n:43) while the majority of patients diagnosed with macroadenoma are followed together with surgical and medical treatment.(n:16). In this study, we aimed to make demographic analysis of patients with pituitary adenoma and non adenoma lesions who applied to our hospital. The results of our study were found to be consistent with the literature.

An unusual presentation of a metastatic typical bronchial carcinoid

Maria Lavinia Popa[1], Găloiu Simona Andreea[1,2], Ingrid Adriana Iordan[3] & Catalina Poiana[1,2]
[1]"C.I. Parhon", National Institute of Endocrinology, Bucharest, Romania, Pituitary and neuroendocrine pathology, Bucharest, Romania; [2]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, Endocrinology, Bucharest, Romania; [3]Focus medical center, Oncology, Bucharest, Romania

Introduction

Lung Neuroendocrine tumors (NETs) range in aggressiveness from low-grade typical carcinoid (TC) and intermediate-grade atypical carcinoid (AC) to the high-grade large cell neuroendocrine carcinoma (LCNEC) and small cell lung carcinoma (SCLC). TC have excellent prognosis post-surgery and European Neuroendocrine Tumor Society (ENETS) recommands no adjuvant therapy for these well diferentiated tumors.

Case report

A 67-year old, hypertensive woman was referred to our Institute for assessement of thyroid function, accusing exertional dyspnea and chronic hypokalemia. She has a recent history of thyreotoxicosis, treated with antithyroid drugs for a few months. Also, two months before presentation, she underwent a cardiac tamponade with emergency pericardial drainage by left anterolateral thoracotomy. The patient is oncologically monitored for a typical bronchial carcinoid, surgically treated 9 years ago. Her oncologist yearly recommended computer tomography of chest and abdomen, who revealed at the last assessement a left adrenal mass and two hepatic lessions. Soon after that, she performed a FDG-PET CT, which did not show a metabolic active lesion. Her physical examination was normal, except a slightly elevated blood pressure, 140/90 mmHg, and an grade I WHO thyroid goiter. Biochemistry confirmed the hypokalemia (plasma K= 2.9 mmol/l, normal range 3.5–5). Thyroid function was normal, spontaneously. TSH receptor antibodies and ATPO were negative. Thyroid ecography revealed a hypoechoic, pseudonodular echogenicity. Her plasma metanephrines and normetanephrines, basal cortisol, cortisol after 1mg overnight supression test, ACTH, prolactin and PTH, were also in the normal range values. Plasma Aldosteron level was high (377 pg/ml, normal range 18.8–256.7) and plasma renin level supressed (0.68 pg/ml, normal range 2.64–27.66), but taken under antihypertensive agents known to interfere with these hormons and under hypokalemia. Her neuroendocrine markers were as follows: Cromogranin A level was 116.9 ng/ml (normal range 20–100), serotonin level was 78 ng/ml (normal range 80–400), neuron specific enolase level was 15.01 mg/l (normal range 0–18.3) and urinary 5 hydroxiindolacetic acid level was in the normal range. Octreoscan showed single hepatic and pericardial lesions with somatostatin receptor expression, suggestive for secondary determinations of typical pulmonary carcinoid. She was discharged with the recommendation to increase the dose of antialdosteronic diuretic, potassium supplements, repeat thyroid function after 8 weeks and a recommendation of a hepatic biopsy, followed by resection of the lesion if secondary hepatic determination confirmed. Also, a somatostatin analog therapy was initiated.

Conclusion

For the optimal management of NETs, a detailed anamnesis is necessary and requires decision-making within a multidisciplinary team.

A rare case of glucagonoma presented with high serum amilase and lipase

Oya Topaloglu[1], Oyku Tayfur Yurekli[2], Onur Metindogan[3], Mehmet Arda Inan[4], Mehmet Ali Sendur[5], Osman Ersoy[2], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Ankara Yildirim Beyazit University, Faculty of Medicine, Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Yildirim Beyazit University, Faculty of Medicine, Ankara City Hospital, Department of Gastroenterology, Ankara, Turkey; [3]Gazi University Medical Faculty, Department of General Surgery, Ankara, Turkey; [4]Gazi University Medical Faculty, Department of Pathology, Ankara, Turkey; [5]Ankara Yildirim Beyazit University, Faculty of Medicine, Ankara City Hospital, Department of Medical Oncology, Ankara, Turkey

Introduction
Glucagonoma is an extremely rare type of functional pancreatic neuroendocrine tumor that is characterized by distinctive clinical manifestations such as diabetes mellitus, weight loss, deep vein thrombosis, and necrolytic migratory erythema which represents the hallmark clinical sign of glucagonoma syndrome. Here, we report the case of a 53-year-old male patient who presented with high amilase and lipase levels. In further investigation a pancreatic tumor was determined and after pancreatic surgery it was diagnosed as glucagonoma.
Case
A 53-year-old male patient was examined routinely in cardiology. In the laboratory analysis, amilase and lipase were detected as above the upper limit of normal [amilase: 212 (Normal range: 30–118 U/l), lipase: 224 (Normal range: 12–53 U/l)]. He did not have any symptoms or signs associated with pancreatitis. Glycosylated A1c was 6.5%. In his past history he did not have diabetes mellitus. In the family history, he reported that his mother had diabetes. He referred to our outpatient clinic for prediabetes. Furtherly, 75 gr oral glucose tolerance test was performed. It was evaluated as impaired fasting glucose (0.min glucose: 115 mg/dl, 120.min glucose: 93 mg/dl). In the investigation of pancreatic enzyme abnormalities, abdominal ultrasound was performed. In the ultrasound, Grade 2 hepatosteatosis and a heterogenous weakly hypoechoic solid mass located in proximal pancreatic body which was 20x14.5 mm in diameter were detected. In abdominal MRI, a 21x16 mm mass located in posterior part of the pancreatic body which was mildly hyperintense in T2A and hypointense in T1A images was reported, and in contrasted images the tumor was found as prominent minimally according to parachyme, and had also diffusion restriction. For the investigation of neuroendocrine tumor, Ga-68 DOTA-PEPTIDE PET/CT was performed and it demonstrated a high pathologic Ga-68 enhancement in the pancreatic mass (SUVmax: 21.92). Then, the patient was operated. Distal pancreatectomy and splenectomy was performed. The histopathology was reported as grade 1 glucagonoma. Postoperatively, he had diabetes mellitus, he was under insulin treatment. His postoperative amilase, lipase values were normal. The postoperative glucagon value was 248 (normal range: 25–250 pg/ml).
Conclusion
Glucagonoma is a rare pancreatic neuroendocrine tumor. Most common presentation is the skin lesions. Our patient was diagnosed after investigation of biochemical abnormality. He presented atypically as he did not have most typical presentations like most patients in the literature.

SHBG as a Q1 marker of NAFLD and metabolic impairments in women referred for oligomenorrhea and/or hirsutism and in women with sexual dysfunction

Vincenza Di Stasi[1], Elisa Maseroli[1], Giulia Rastrelli[1], Irene Scavello[1], Sarah Cipriani[1], Tommaso Todisco[1], Sara Marchiani[1], Flavia Sorbi[2], Massimiliano Fambrini[2], Felice Petraglia[2], Mario Maggi[3] & Linda Vignozzi[1]
[1]Andrology, Women's Endocrinology and Gender Incongruence Unit, Department of Experimental Clinical and Biomedical Sciences "Mario Serio," University of Florence, Florence, Italy; [2]Gynecology Unit, Department of Biomedical, Experimental and Clinical Sciences "Mario Serio," University of Florence, Florence, Italy; [3]Endocrinology Unit, Department of Experimental Clinical and Biomedical Sciences "Mario Serio," University of Florence, Florence, Italy

PCOS (Polycystic Ovary Syndrome) is one of the most common endocrine disorders and NAFLD (Nonalcoholic Fatty Liver Disease) is one of its most dangerous metabolic consequences. The diagnosis of NAFLD is not a practical task and the condition is at risk of being overlooked. The use of simpler but still reliable surrogate markers is necessary to identify women with a high likelihood of NAFLD. The aim of this study was to evaluate the clinical correlates of NAFLD Liver Fat Score (NAFLD-LFS) in women with oligomenorrhea and/or hirsutism. Furthermore, the study aimed to evaluate whether, among the hormonal parameters evaluated in such women, possible hallmarks of NAFLD may be identified. To this purpose, 66 women who attended our Outpatient Clinic for oligomenorrhea and/or hyperandrogenism were included in the study. In order to validate the results obtained in the first cohort, a second independent sample of 233 women evaluated for female sexual dysfunction (FSD) was analyzed. In cohort 1, NAFLD-LFS positively correlated with metabolic and inflammatory parameters. Among the hormone parameters, NAFLD-LFS showed no significant relationships with androgens but a significant negative correlation with SHBG (Sex Hormone Binding Globulin) ($P < 0.0001$) that therefore appeared as a candidate hallmark for pathologic NAFLD-LFS. The ROC analysis showed a significant accuracy (81.1%, C.I. 69.1–93.0, $P < 0.0001$) for SHBG in identifying women with a pathological NAFLD-LFS. In particular, a SHBG 33.4 nmol/l was recognized as the best threshold, with a sensitivity of 73.3% and a specificity of 70.7%. In order to validate this SHBG as a marker of metabolic impairment possible related with the presence of NAFLD, we tested this threshold in cohort 2. FSD women with SHBG <33.4 nmol/l had worse metabolic parameters than women with SHBG ≥33.4 nmol/l and a significantly higher NAFLD-LFS even after adjusting for confounders (B=4.18 [2.05; 6.31], $P = 0.001$). In conclusion, this study provides a new evidence in the diagnostic process of NAFLD, showing that the measurement of SHBG, which is routinely assessed in the workup of women referred for possible PCOS, could identify women at higher metabolic risk, thus detecting those who may deserve further targeted diagnostic assessment.

Infertility revealing a classical form of congenital adrenal hyperplasia in a 39 years old man

Ilboudo Alassane[1], Sagnan Yempabou[1], Guigui Mathilde[2], Dubreuil Sophie[2], Lamaziere Antonin[3], Anne Bachelot[2], Philippe Touraine[2] & Courtillot Carine[2]
[1]CHUSS, Medecine, Bobo-Dioulasso, Burkina Faso, Paris, France; [2]IE3M Service d'Endocrinologie et Médecine de la Reproduction, Endocrinologie, Paris, France; [3]Hôpital Saint-Antoine, Service de Métabolique, Peptidomique et Dosage des Médicaments, Paris, France

Classical forms of congenital adrenal hyperplasia (CAH) are generally diagnosed in neonates (salt wasting form) or in early childhood (pure virilizing form). Here, we report the case of a 39 years old man from Sri Lanka in whom a classical CAH has been diagnosed during the exploration of infertility with azoospermia, along with extremely low gonadotropins contrasting with a normal level of testosterone. Hormonal tests revealed high serum 17-hydroxyprogesterone levels (255 ng/ml) and an extremely low level of cortisol with no response to the ACTH stimulation test and high levels of ACTH. The genetic study of CYP21A2 gene found 3 different mutations (c.1066C>T, c.166G>A, c.126C>T), 2 of which are associated with the classical form of 21 hydroxylase deficiency. The patient has never received glucocorticoids, and has never presented signs of adrenal insufficiency or adrenal crisis, suggesting the role of adrenal steroid precursors in the activation of glucocorticoid receptors.

Superoxide dismutase activity of testicular organs after intervention with fermented soy milk on hyperlipidemic rats

Muhammad Luthfi Adnan[1], Dini Islamiana[1], Hilmi Ardian Sudarto[1] & Miranti Dewi Pramaningtyas[2]

[1]Universitas Islam Indonesia, Sleman, Indonesia; [2]Universitas Islam Indonesia, Departement of Physiology, Sleman, Indonesia

Background
Oxidative stress in hyperlipidemic conditions can affect superoxide dismutase (SOD), a natural antioxidant in the body. One of the organs affected by increased oxidative stress due to hyperlipidemic conditions is the testicular organ. Increased oxidative stress in the testicular organ can damage to sperm cell and increase the risk of infertility. Soy milk is a beverage product made from soybeans which are widely consumed as an alternative to cow's milk. Fermented soy products can improve nutritional quality and have beneficial effects on health.
Aim
The aim of this study was to determine SOD inhibition rate in the testicular organs of hyperlipidemic rat after intervention with fermented soy milk.
Method
The subjects are three-month-old rats (*Rattus norvegicus*) male Wistar strain with body weight 200–300 grams divided into 3 groups (Negative Control (NC), Positive Control (PC), and Intervention group). PC and intervention group were given quail egg yolk for 2 weeks with a dose of 5 ml for hyperlipidemic induction while group of NC were only given fed ad libitum. After hyperlipidemic induction, the intervention group was given fermented soy milk (5 ml) from *Lactobacillus bulgaricus* and soybean. All rats then terminated to taken the testicular organ to measure the level of SOD inhibition rate. All data were statistically analyzed with One-Way ANOVA and Bonferroni Post-Hoc test. Values were considered significant at $P<0.05$.
Results
Mean of SOD inhibition rate (%) in rats was 82.03±1.62 in NC group, 17.97±2.06 in PC group, and 70.31±2.38 in intervention group. The One-Way ANOVA test showed significant differences activity between group with $P<0.001$ and the Bonferroni Post-Hoc test $P<0.001$.
Conclusion
Intervention with fermented soy milk can increase superoxide dismutase inhibition rate in the testicular organs of hyperlipidemic rats.
Keywords: fermentation food, hyperlipidemia, soy milk, superoxide dismutase, testicular organ.

Insight on the intracrinology of menopause: androgen production within the human vagina

Sarah Cipriani[1], Ilaria Cellai[1], Vincenza Di Stasi[1], Paolo Comeglio[1], Elisa Maseroli[1], Tommaso Todisco[1], Chiara Corno[1], Sandra Filippi[2], Flavia Sorbi[3], Massimiliano Fambrini[3], Felice Petraglia[3], Irene Scavello[1], Giulia Rastrelli[1], Gabriele Acciai[1], Fabio Villanelli[4], Giovanna Danza[4], Erica Sarchielli[5], Giulia Guarnieri[5], Annamaria Morelli[5], Mario Maggi[4] & Linda Vignozzi[1]
[1]Andrology, Women's Endocrinology and Gender Incongruence Unit, Department of Experimental and Clinical Biomedical Sciences "Mario Serio," University of Florence, Florence, Italy; [2]Interdepartmental Laboratory of Functional and Cellular Pharmacology of Reproduction, Department of Neurosciences, Psychology, Drug Research and Child Health (NEUROFARBA), University of Florence, Florence, Italy; [3]Gynecology Unit, Department of Experimental and Clinical Biomedical Sciences "Mario Serio," University of Florence, Florence, Italy; [4]Endocrinology Unit, Department of Experimental and Clinical Biomedical Sciences "Mario Serio," University of Florence, Florence, Italy; [5]Section of Human Anatomy and Histology, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy

In this study, we investigated steroidogenic gene mRNA expression in human vagina and verified the ability of human vagina smooth muscle cells (hvSMCs) to synthesize androgens from upstream precursor dehydroepiandrosterone (DHEA). As a readout for androgen receptor (AR) activation, we evaluated the mRNA expression of various androgen-dependent markers. hvSMCs were isolated from vagina tissues of women undergoing surgery for benign gynecological diseases. In these cells, we evaluated mRNA expression of several steroidogenic enzymes and sex steroid receptors using realtime reverse transcription-polymerase chain reaction. Androgen production was quantified with liquid chromatography tandem-mass spectrometry (LC-MS/MS). In vaginal tissues, AR mRNA was significantly less expressed than estrogen receptor α, whereas in hvSMCs, its mRNA expression was higher than progestin and both estrogen receptors. In hvSMCs and in vaginal tissue, when compared to ovaries, the mRNA expression of proandrogenic steroidogenic enzymes (HSD3β1/β2, HSD17β3/β5), along with 5α-reductase isoforms and sulfotransferase, resulted as being more abundant. In addition, enzymes involved in androgen inactivation were less expressed than in the ovaries. The LC-MS/MS analysis revealed that, in hvSMCs, short-term DHEA supplementation increased Δ4-androstenedione levels in spent medium, while increasing testosterone and DHT secretion after longer incubation. Finally, androgenic signaling activation was evaluated through AR-dependent marker mRNA expression, after DHEA and T stimulation. This study confirmed that the human vagina is an androgen-target organ with the ability to synthesize androgens, thus providing support for the use of androgens for local symptoms of genitourinary syndrome in menopause.

Disorders of steroid metabolism in women of reproductive age with polycystic ovary syndrome

Olga Glavnova[1], Ludmila Velikanova[2], Natalia Vorokhobina[2], raviliy Galakhova[2], Ekaterina Malevanania[2] & Irina Matezius[2]
[1]The Research Institute of Obstetrics, Gynecology, and Reproductology named after D.O. Ott; [2]North-Western State Medical University named after I.I. Mechnikov

Background of study
PCOS is a heterogeneous disease characterized by endocrine, metabolic and reproductive disorders. PCOS plays an essential role among the causes of chronic anovulation, menstrual irregularities, hirsutism and anovulatory infertility. Diagnostic problems appear to be extremely urgent due to the wide range of clinical and laboratory manifestations. The study of urine steroid profile by gas chromatography-mass spectrometry will improve the assessment of steroid metabolomics, and will allow for the increase in the percentage of PCOS detection, particularly at the early stages of the disease, to provide prompt treatment.
Aims of study
To study the metabolomics of androgens, progestinsand glucocorticoids by gas chromatography-mass spectrometry in obese and non-obese women with polycystic ovary syndrome
Study design, materials, and methods
53 women of reproductive age with PCOS were examined. The first group included 30 women aged 22 to 29 years with normal body weight. The second group comprised 23 obese patients aged 25 to 33 years with an average body mass index (BMI). Steroid urine profiles (SPM) were studied by means of gas chromatography-mass spectrometry (GC-MS) with optimization of the sample preparation schedule. 69 steroids were identify by this method.
Results
In women with PCOS and obesity, urinary excretion of androsterone and dehydroepiandrosterone metabolites (16-oxo-androstenediol and androstenediol-17β) was increased. In patients of normal body weight with PCOS an increase in urinary excretion of androstenedione metabolites, dehydroepiandrosterone and its metabolites, 17-hydroxypregnanolone and pregnanolone, 5-en-pregnenes was revealed. In addition, the reduction in the ratio of cortisoltetrahydro derivatives combined with cortisone to 11-oxo-pregnanthriol, pregnanthriol and 17-hydroxypregnanolone was detected, which is associated with21-hydroxylase enzyme and 3β-hydroxysteroid dehydrogenasedeficiency, which is indicative of hyperandrogenism mixed genesis. An increase in urinary excretion of 5α-tetrahydrocortisone and cortolones, the signs of decreased activity of 11β-hydroxysteroid dehydrogenase type 1 were found out in PCOS patients regardless of body mass index, which indicates functional hypercortisolism.
Conclusion
Determining simultaneously the number of androstenedione and DHEA metabolites, progestins, α- and β-glucocorticoid metabolites in the study of SPM by GC-MS method suggests new opportunities for the diagnosis and differential diagnosis of various presentations in PCOS.

Predictive factors of final height in children with congenital growth hormone deficiency in Tunisian children

Dorra Dorraelguiche[1], Manel Jemel[2], Anis Grassa[1], Radhouane Gharbi[2], Hajer Kandara[2] & Ines Kammoun[2]
[1]National Institute of Nutrition and Food Technology, Endocrinology,

Tunis, Tunisia; [2]National Institute of Nutrition and Food Technology. Tunis Manar University, Endocrinology, Tunis, Tunisia

Introduction
Growth hormone deficiency (GHD) is a rare cause of statural retardation in children. The diagnosis is evoked in front of a bundle of anamnestic, clinical and radiological arguments. Treatment consists of substitution by recombinant GH with the aim of restoring normal size. There is interindividual variability in the response to treatment. We therefore proposed to study the response to treatment as well as the predictive factors of this response in the Tunisian population.
Methods
This is a retrospective study including 34 patients who were followed at the National Institute of Nutrition in Tunis for congenital GH deficiency and who completed their treatment.
Results
The assessment of statural response was based on total statural gain at the end of treatment and final height, thus investigating factors predictive of good response to treatment for each of these two parameters. The mean total statural gain was 31.62 ±19 cm with extremes ranging from 3 to 75 cm corresponding to a mean statural gain of 1.17 ±0.8DS. Age of discovery was negatively correlated with total statural gain (r = –0.64; P <0.001).Total statural gain was 28.6±19.6 cm for boys versus 36.66±19.96 cm for girls with no significant difference (P = 0.150). Height, BMI at baseline (P = 0.04; P <0.001 respectively) were correlated with total statural gain, and baseline IGF1 (SD) and thyroid insufficiency were correlated with statural gain (P = 0.025; P = 0.017 respectively). Bone age at baseline was negatively correlated with statural gain(cm)(r = –0.67, P <0.001). For the standard deviation (SD) assessment of statural gain, only general disease history was correlated with this parameter(P = 0.005). Final height was 158.3±7.09 cm in boys and 144.79±14 cm in girls with a significant difference (P = 0.001). The parameters correlated to the final height were: general disease history(P = 0.002), combined deficit (0.015), existence of corticotropic insufficiency(P = 0.027), thyroid insufficiency (P = 0.048), number of deficits greater than 1(P = 0.027) and pathological aspect on hypothalamic-pituitary MRI (P = 0.01).
Discussion/Conclusion
The response to treatment in our population was close to the results of the literature series. Factors predictive of a good response to treatment vary from one individual to another and from one population to another. These factors can be integrated into a true predictive model allowing for an adaptation of treatment.

Are there a gender difference in growth hormone (GH)-deficiency in Tunisian Children?

Dorra Dorraelguiche[1], Manel Jemel[2], Grassa Anis[1], Radhouane Gharbi[2], Hajer Kandara[2] & Ines Kammoun[2]
[1]National Institute of Nutrition and Food Technology, Endocrinology, Tunis, Tunisia; [2]National Institute of Nutrition and Food Technology. Tunis Manar University, Endocrinology, Tunis, Tunisia

Introduction
Congenital GH deficiency is more common in boys than in girls. Several differences have been noted between the 2 genders. We proposed to study these differences for epidemiological, auxological and anthropometric characteristics.
Methods
This is a retrospective study including 75 patients followed for congenital GH deficiency in the endocrinology department at the National Institute of Nutrition in Tunis.
Results
In our population, 46 patients (63%) were male. The average age of discovery was 112 ± 54 months or 9 ± 4.5 years for males and 93 ± 45 months or 7 ± 3 years for females (P = 0.137). The delay of diagnosis was on average 32 ± 32 months for males and 12 ± 19 months for females but without significant difference (P = 0.243). The mean target height of our patients was 165.45 ± 9.89 cm, 170.6±5.07 cm for boys and 156.09±9.78 cm for girls (P <0.0001). The mean weight at diagnosis was 19.72 kg ± 8.38 with a mean height of 114.56 ± 20.09 cm. The most frequent initial height in girls (41%) was less than - 4 DS versus (30%) in boys for a height between –2 and –3 DS. Initial height in DS was on average –2.33 ±1.2 DS for girls and –2.58 ±0.5 DS for boys with a significant difference (P = 0.043). The mean weight at diagnosis was 19.72 ± 8.38 kg. Underweight less than –2SD was noted in 20% of cases. There was no significant difference between the two sexes for BMI in SD (P = 0.168).
Discussion/Conclusion
This difference between the 2 genders has also been found in the literature. This is interesting to know especially for a better knowledge of the characteristics of these children which leads to a better management.

Steroid Cell Tumor of the Ovary - A case presenting with hirsutismus

Muhammed Sacikara[1], Kubra Solmaz[1], Gulsum Karaahmetli[1], Husniye Baser[2], Cevdet Aydın[2], Sevgi Ayhan[3], Nazmiye Dincer[4], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara City Hospital, Clinics of Endocrinology and Metabolism, Turkey; [2]Ankara Yildirim Beyazit University Faculty of Medicine, Clinics of Endocrinology and Metabolism, Turkey; [3]Ankara City Hospital, Clinics of Gynecologic Oncology, Turkey; [4]Ankara City Hospital, Clinics of Pathology, Turkey

Introduction
Steroid cell tumors (SCTs) are a rare subgroup of sex-cord tumors of the ovary that account for less than 0.1% of all ovarian tumors. They are classified into three categories based on the cell origin: stromal luteoma, Leydig-cell tumor, and not otherwise specified (NOS). NOS tumors are the most common subtype and comprise the largest proportion of cases (60%).The clinical presentations are not specific, including abdominal pain, distention and bloating. However, the more significant presentations are those associated with the hormonal activity and virilizing properties of the tumor. The cornerstone of SCT-NOS treatment is surgery.
Case
A 55-year-old female came to our hospital in November 2020 with months' history of increasing facial and truncal hair. She also had hypertension and diabetes mellitus. In the medical history of the patient, she had been operated for papillary thyroid cancer, sleeve gastrectomy, total abdominal hysterectomy and left salpingo-oophorectomy 30 years ago. Physical examination revealed obesity (body mass index, 37.3 kg/m^2).She had a Ferriman–Gallwey score of 24. Abdominal ultrasound identified a 40 × 20 mm solid, right ovarian mass.Biochemical data shows the levels of folicle stimulating hormone and luteinising hormone were as high as 52.1 U/l and 33.3 U/l, respectively. Serum adrenocorticotropic hormone, cortisol, estradiol, serum prolactin, dihydroepiandosterone sulfate were found within reference intervals.Total and free serum testosterone levels were found to be as high as 450 ng/dl (normal 7–49 ng/dl) and 19.99 (normal<4.2 pg/ml), respectively. Magnetic resonance imaging with contrast confirmed the ultrasound findings and detected no adrenal gland enlargement or tumor.The right salpingo-oophorectomy was done, and the specimen was sent to our department for histopathological examination. On surgical staging laparotomy, it was found that there was an enlarged (3×3×2 cm) right ovary with both solid and cystic component and normal ovarian contour.Microscopically, mitotic activity 2–3/10, mild atypia, and no significant necrosis. Immunohistochemistry revealed a result of MelanA(+), ER (+), CD56(+), Calretinin (+), Inhibin-α (+), ki-67 (5–6%+). Histological features were consistent with SCTs-NOS type.At post-operative follow-up, her total serum testosterone and serum free testosterone level had gone down to 13 ng/dl and 0.73 pg/ml, respectively.
Conclusion
SCTs, NOS, are rare ovarian tumors which can be difficult to diagnose. Careful history and physical examination, in addition to laboratory values and imaging studies, are helpful in making the diagnosis.They are usually benign, unilateral and are characterized by hyperandrogenism and virilization. SCTs should be considered in differential diagnosis among women presenting with symptoms of virilization.

Effectiveness of iodine supplementation during pregnancy in western Poland – a single center study

Dorota Filipowicz[1], Aniceta Ada Mikulska[2], Marta Karaźniewicz-Łada[2], Ewelina Szczepanek-Parulska[1], Franciszek Główka[2] & Marek Ruchala[1]
[1]Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Medicine, Poznań, Poland; [2]Poznan University of Medical Sciences, Department of Physical Pharmacy and Pharmacokinetics, Poznań Poland

Introduction
Twenty-four years after implementing the national salt iodization programme in Poland in 1997, the country is considered as adequate iodine supply. However, most reports do not take into consideration pregnant or lactating females. Additional intake of 150–200 µg KI per day, independently on levothyroxine (LT4) treatment, is a recommended dose for pregnancy and lactation due to Polish endocrinological guidelines. The study aim was to evaluate iodine supply in the group of pregnancies and relate the results to maternal thyroid parameters.
Material & methods
95 mother-child pairs (healthy, hypothyroid and euthyroid with autoimmune thyroiditis with or without LT4 treatment) were recruited at planned admission to the obstetric ward of tertiary reference gynaecological hospital. The venous blood serum was obtained from mothers before delivery, where thyrotropin (TSH), free triiodothyronine (fT3) and free thyroxine (fT4) and antibodies against thyroid peroxidase (a-TPO) and thyroglobulin (a-Tg) were measured by ECLIA. A single random urine sample was obtained from mothers to measure ioduria (UIC) by a validated ion-pair HPLC-UV method. Additionally, urine creatinine was measured by ELISA and iodine/creatinine ratio (UIC/Cr) was calculated.
Results
71% declared iodine supplementation intake in dose 150–200 mg/daily. The median UIC was 105 µg/l (Q25-Q75, 69–171). According to WHO 68% were iodine-deficient < 150 µg/l (including 10% with deficits < 50 µg/l), 22% were adequately supplied (150–249 µg/l), 9% had more than adequate supplies (250–499 µg/l) and 1 patient had excessive supply (> 500 µg/l) on concomitant high-dose LT4 treatment. The median UIC/Cr ratio was borderline adequate 151 µg/g (Q25-Q75, 64–282), but the higher percentage of patients (41%) had results < 100 g/l and 25% between 100 and 200 g/l. Additionally, in the group not-treated with LT4, women who supplemented iodine had higher fT3 (4.3 vs 3.7, $P = 0.03$) pmol/l.
Conclusions
Despite recommendations one-third of recruited women did not supplement iodine during pregnancy. Most females were iodine-deficient independently from iodine supplementation. Iodine intake may improve maternal thyroid function. During the construction of future guidelines, an increase of the recommended dose of iodine supplementation in pregnancy should be considered, taking into consideration concomitant LT4 treatment.

17-β Hydroxysteroid Dehydrogenase Type 3 Deficiency with Novel Mutation in Iranian Family

Fatemeh Saffari[1] & Ali Homaei[2]
[1]Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Qazvin university of medical sciences, Children Growth Research Center, Research Institute for Prevention of Non-Communicable Diseases, Qazvin University of Medical Sciences, Qazvin, Iran, Qazvin, Iran

Introduction
Deficiency of 17- beta hydroxysteroid dehydrogenase 3 (17-HSD 3) is a rare autosomal recessive disorder which causes sexual ambiguity in fetuses with 46XY karyotype. Pathogenic mutations in the 17βHSD-3 gene (MIM# 264300) are associated with impaired sexual development of the 46, XY fetus. Here, we describe the clinical and genetic findings of a large family with several 46xy cases with a new mutation in 17-β-HSD3 gene in Qazvtn,Iran.
Case reports
Proposita was a 11-year-old girl who was referred for examination due to the infertility of her aunts. The external genitalia were completely female and had a short vaginal pouch. The testicles were not found on examination. She had palpable gonads in her inguinal area and at the age of two underwent bilateral orchiectomy. Other physical examinations were normal. In pelvic sonography, uterine and ovarian were not seen. Her peripheral blood karyotype was 46xy. Three of the patient's aunts and the patient's mother's aunt also had had similar findings (Fig.1)

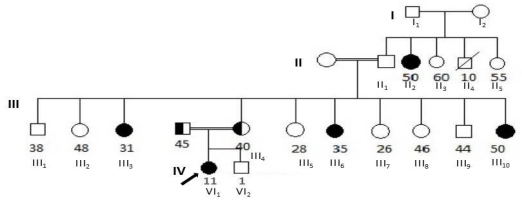

Figure 1: Pedigree

Method and Material
To determine the molecular etiology, whole-exome sequencing (WES) was performed.
Results
We identified a novel homozygous missense variation (c.731T>A, p. Ile244Lys) in HSD17B3 gene. This alteration changes Isoleucine to Lysine in exon 10. This variation – which has not been reported before – is predicted to be a variant of unknown significance (VUS) based on computational analysis.

Case report of complete androgen insensibility syndrome in an adult female

Daniela-Georgiana Amzar[1], Balas Melania[1], Golu Ioana[1], Vlad Mihaela[1], Stoian Dana[1] & Laura Cotoi[2]
[1]Victor Babeş University of Medicine and Pharmacy, Endocrinology, Timişoara, Romania; [2]Victor Babeş University of Medicine and Pharmacy, PHD School, Timişoara, Romania

Introduction
Complete androgen insensibility syndrome (CAIS) is an androgen receptor defect disorder associated with vaginal and uterine agenesis in women with a 46,XY karyotype. The syndrome affects sexual development before birth and during puberty. The major clinical issues surrounding this syndrome include timing of gonadectomy, hormone replacement, vaginal dilation, and attention to psychological issues.
Case presentation
A 25-year-old woman presented in February 2021 in the Endocrinology Clinic with primary amenorrhea. She had no significant past medical history or family history. Clinical evaluation found absent axillary hair and pubic hair, normal external genital organs and normal development of breasts. Biochemical and hormonal evaluation found normal levels of potassium and sodium and the hormonal evaluation found an elevated testosterone of 679.68 ng/dl (15 to 70 ng/dl), estradiol 32 pg/ml (45.4–854), progesterone 0.42 ng/ml (0.18 – 2.84), LH 9.9 mUI/ml (1–11), FSH 0.27 mUi/ml (1.7–7.7), prolactin 7.8 ng/ml (4.7–23.3), normal thyroid and cortisol function. Gynecological examination and ultrasound were performed identifying normal external genitalia and normal length but blind-ended vagina, absence of uterus and suggestion of the presence of gonads located in the pelvis of 21/15 mm. A pelvic magnetic resonance imaging (MRI) exam was performed to plan a laparoscopic gonadectomy and showed two soft tissue structures suggestive for gonadal tissue located in the right along the external iliac artery and along the left external iliac artery. A pericentimetric cyst was found adjacent to each gonad. Apart from the vagina, no development of Müllerian duct structures was observed. Surgery was planned for removal of gonadal tissue, as this condition is associated with an increased risk of testicular germ cell tumor. A complete psychological evaluation was performed before surgery. Hormonal treatment by progesterone will be introduced after surgery.
Conclusion
Complete androgen insensitivity syndrome is a rare genetic disease. Patients with complete AIS should undergo post pubertal gonadectomy and lifelong hormone replacement therapy is advised. Attention to psychological considerations in such patients is important to maximize long-term success.

Frequency of euthyroid sick syndrome before and after renal transplantation in patients with end stage renal disease and its association with oxidative stress

Tugce Akman[1], Oya Topaloglu[2], Alparslan Altunoglu[3], Salim Neselioglu[4], Ozcan Erel[4], Bekir Cakir[2] & Osman Ersoy[1]
[1]Ankara Yildirim Beyazit University, Faculty of Medicine, Ankara City Hospital, Department of Internal Medicine, Ankara, Turkey; [2]Ankara Yildirim Beyazit University, Faculty of Medicine, Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara City Hospital, Department of Nephrology, Ankara, Turkey; [4]Ankara Yildirim Beyazit University, Faculty of Medicine, Ankara City Hospital, Department of Biochemistry, Ankara, Turkey

Aim
Euthyroid Sick Syndrome (ESS) is a thyroid disease appeared in critical and noncritical illnesses. ESS can be seen in patients with end stage renal disease (ESRD). In this study, we aimed to evaluate the frequency of ESS before and after renal transplantation in patients with ESRD, and its association with oxidative stress by evaluating thiol-disulphide levels.
Material and Method
In this study, free triiodothyronine (fT3), free thyroxine (fT4) and thyroid stimulating hormone (TSH) levels were recorded before and after renal transplantation in patients with ESRD. ESS was diagnosed in patients with unresponsive TSH to low fT3 and/ or fT4 levels, Thiol and disulphide parameters of patients before and after transplantation were also recorded.
Results
One- hundred twenty one patients were included in the study. Of these, 69 (57%) were males and 52 (43%) were females. The mean age was 45±12.61 years. ESS was detected in 39 (32%) of 121 patients. Of 39 patients, 24 (61%) had ESS before transplantation and 15 (39%) after transplantation. Frequency of ESS was 19.8% in patients followed with ESRD. Sixteen of 24 (66.7%) patients with ESS before transplantation reached to normal thyroid functions after transplantation. After transplantation, patients with ESS had significantly higher urea and creatinine (respectively, P = 0.025 and P = 0.009), and lower fT4, fT3, total protein, and albumin (P = <0.001; for all parameters) compared to patients without ESS. Patients with ESS before transplantation had also significantly higher creatinine levels compared to patients without ESS (P = 0.034). Free T4 and fT3 levels were significantly low (P <0.001 for both). Thiol- disulphide levels of 20 patients with ESS at any time compared with 68 patients without ESS. We found that native thiol and total thiol were low significantly in patients with ESS (respectively, P = 0.025 and P = 0.044).
Conclusion
Our study is the initial study evaluating the oxidative stress and antioxidation status in etiology of ESS in patients with renal transplantation. Presence of markedly low level of antioxidation in these patients supports the possible role of oxidative stress in etiology of ESS.

Comparative analysis of five different ultrasonographical risk-stratification systems in the preoperative diagnosis of malignant and benign thyroid nodules

Fatma Dilek Dellal[1], Abbas Ali Tam[2], Şefika Burçak Polat[2], Mustafa Omer Yazicioglu[3], cevdet aydin[2], Didem Ozdemir[2], Afra Alkan[4], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara City Hospital, Endocrinology and Metabolism, Turkey; [2]Ankara Yildirim Beyazit University, Faculty of Medicine, Endocrinology and Metabolism, Turkey; [3]Ankara City Hospital, General Surgery, Turkey; [4]Ankara Yildirim Beyazit University, Faculty of Medicine, Biostatistics, Turkey

Background
Our aim was to compare the effectiveness of five different risk-stratification systems using the ultrasonographical features of thyroid nodules in determining malignant histopathology.
Methods
The preoperative ultrasonography (US) features of 6925 nodules of 3030 patients who underwent thyroidectomy between 2007 and 2014 were analyzed retrospectively. The nodules were classified according to Kwak-TIRADS (Thyroid imaging reporting and data system), European Thyroid Association-TIRADS (EU-TIRADS), Korea-TIRADS, American Society of Clinical Endocrinologists (AACE), American Thyroid Association (ATA).1362 nodules (1042 patients) that could be scored in all of these systems were included. Malignancy rate, specificity, sensitivity, positive predictive value (PPV) and negative predictive value were calculated.
Results
In the nodules with high risk scored,malignant histopathology rate were 50%, 27.7%, 32.2%, 29.9%, 31.9% in Kwak-TIRADS, EU_TIRADS, Kore-TIRADS, AACE, ATA, respectively (Table 1). Area under curve (AUC) was higher than 0.5 for all systems (P <0.001,Table 2). When determining optimal cut-off for each system, sensitivity, specificity, PPV, and NPV were about 60%, 75%, 27–30% and 92%, respectively (Table 2). EU-TIRADS had significantly lower AUC (corrected P<0.05). AUC of Korea-TIRADS was lower than that of ATA (corrected-P<0.001). AUCs of Kwak-TIRADS, AACE, and ATA were similar and significantly higher than the others (Table 2).
Conclusion
Risk-stratification systems have variable efficiency in predicting malignancy risk since they are operator dependent and require experience in that field. The sensitivity was found to be lower than the previous studies which might be due to retrospective evaluation of US reports rather than real time risk scoring.

Table-1.Distribution of benign and malignant nodules according to risk-stratification systems

	Benign (n = 1179) n (%[1]/%[2])	Malignant (n = 183) n (%[1]/%[2])
Kwak-TIRADS		
Possibly benign	137 (97.9/11.6)	3 (2.1/1.6)

Advanced differentiated thyroid carcinoma (aDTC), herein defined as locally unresectable and/or metastatic, is one of the most common late-stage endocrine neoplasias. However, available data about its natural history are limited. ERUDIT is a multicenter, observational, retrospective study of patients diagnosed with aDTC in Spain and Portugal. The study describes its natural history from the initial diagnosis until the advanced stages, focusing on specific characteristics of this subpopulation, its treatment, response patterns, and medical specialties involved in its management. The objective of this communication is to describe the diagnostic demographics and clinical characteristics of relapsing DTC patients, the efficacy of rescue therapies used, and the prognostic factors associated to disease evolution. Clinical records from patients ≥18 y-o diagnosed with aDTC (including poorly differentiated DTC) with first evidence of advanced disease documented between January 2007 and August 2017, were retrospectively reviewed until death or lost to follow-up. 213 aDTC patients were identified in 23 sites with median age at initial DTC diagnosis 63 y-o and 59% being females. Of these, 46% progressed or relapsed to aDTC (87% metastatic, being lung in 41% of cases) after receiving initial treatment (surgery ± 131radioiodine [RAI]) for their early DTC (eDTC). Median (95% CI) relapse/progression-free survival [(RP)FS] and overall survival (OS) from the initial treatment were 2.3 (1.8–2.9) years and 10.4 (8.1–16.0) years, respectively. Notably, significant OS differences (log-rank P<0.0001) were seen according to surgical outcome, favouring R0/R1 resections compared to R2. Post-relapse rescue therapies, when indicated, were mainly RAI (57%) and surgery (13%). Specifically, 23% of the patients treated with RAI received up to 3 courses with median dose of 150 mCi each and cumulative dose of 620mCi. Persistent structural disease was frequently reported after RAI (average 15% after three doses). Initial R2 surgical outcome, receiving <600 mCi, not receiving any RAI or requiring stimulation with hrTSH, and resulting in incomplete biochemical/structural response to it, were all negative prognostic factors for eDTC to relapse to aDTC. Endocrinology was the leading medical specialty responsible for patient monitoring (63%), while two thirds of the patients were evaluated by multidisciplinary committees. Almost half of this cohort become aDTC tumours after relapsing from previously treated eDTC with median [(RP)FS] of 2.3 years while 57% being still RAI-treatable. From this group, yet 15% showed persistent disease after three RAI doses among other poor prognostic factors. This suggests identifying early unfavorable course in some DTC patients is maybe possible from initial stages.

AEP872

A rare cause of malignant pleural effusion: Poorly differentiated thyroid carcinoma

Burcak Helvaci[1], Gulsum Karaahmetli[2], Muhammet Sacikara[1], Neslihan Cuhaci Seyrek[2], İrem Serifoglu[3], Cevdet Aydin[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara City Hospital, Endocrine and Metabolism, Ankara, Turkey; [2]Yildirim Beyazit University Faculty of Medicine, Ankara City Hospital, Endocrine and Metabolism, Ankara, Turkey; [3]Ankara City Hospital, Pulmonology, Ankara, Turkey

Purpose
Poorly differentiated thyroid carcinoma (PDTC); is a rare type of thyroid cancer with a high risk of recurrence, metastasis, and death. Pleural effusion due to thyroid cancer has seldom been reported. In this report, we present a case with PDTC related malignant pleural effusion.
Case
A 66-year-old male patient presented with neck swelling and shortness of breath. At another center, thyroid ultrasonography revealed a multinodular goiter and an irregularly circumscribed lymphadenopathy on the left level IV. He had multiple lung metastases in thorax computed tomography (CT). Positron emission tomography/computed tomography (PET-CT) detected "hypermetabolism in malignant nodules in the thyroid, multiple metastatic lymph nodes in the neck and bilateral metastatic lung nodules." Cytology of lymph nodes at the right level 3,4,6–2a junction was malignant. The patient underwent bilateral total thyroidectomy, bilateral central lymph node dissection, and right modified radical neck dissection with a final pathologic diagnosis of "poorly differentiated thyroid carcinoma, right lateral and central tumor positive lymph node." Upon persistence of dyspnea, thoracentesis was performed for a left-sided pleural effusion, which in the end had exudative characteristics. [blood thyroglobulin (Tg): 23960 ng/ml, Tg with pleural fluid dilution > 30000 ng/ml]. Cytology confirmed carcinoma infiltration. In the follow-up, mediastinal, lung, and pleural metastases in addition to effusion in the left hemithorax persisted. We performed pleurodesis after the initial tube thoracostomy. During follow-up pleural fluid cell-block was performed due to continued pleural effusion and reported as carcinoma metastasis. 200 mCi RAI treatment was given after preparation with recombinant thyroid stimulating hormone (TSH). After the comparative PET-CT revealed progression, transthoracic lung biopsy performed and reported as carcinoma metastasis. After these results tyrosine kinase inhibitör (sorafenib) was initiated to the patient.
Conclusion
The most common sites of distant metastasis of PDTC are the lungs and bones. It constitutes about 85% of deaths related to the disease. Less than 1% of malignant pleural effusions are associated with thyroid cancers. Pleural fluid thyroglobulin level and immunohistochemical staining may enhance the diagnostic process.

Changes in thyroid hormones and free triiodothyronine-to-free thyroxine ratio in euthyroid patients with obesity in terms of different glucose metabolism statuses

Sema Hepsen, Pinar Akhanli, Muhammed Erkam Sencar, Hakan Duger, Hayri Bostan, Muhammed Kizilgul, Ismail Emre Arslan & Erman Cakal
University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey

Purpose
Thyroid hormones are known to have an essential role in the regulation of energy homeostasis and glucose metabolism. Considering to literature data, variations of thyroid hormones within normal ranges change in obesity and type 2 diabetes mellitus (T2DM) in opposite ways. This study aims to evaluate thyroid hormone levels and fT3/fT4 ratio in different glucose metabolism statuses of euthyroid patients with obesity.
Methods
This retrospective observational study evaluated thyroid hormones and fT3/fT4 ratio of 209 patients with obesity grouped according to their glucose metabolism status.
Results
131 (62.7%), 41 (19.6%), and 37 (17.7%) patients had normal glucose tolerance (NGT), prediabetes, and T2DM, respectively. Serum fT4 level was higher in patients with T2DM compared to patients with NGT (P =0.009), although no difference was observed in TSH and fT3 levels among groups. Baseline characteristics, laboratory test results, and thyroid hormone levels of the subjects are presented in Table 1. FT3/fT4 ratio was determined to be lower in patients with T2DM than patients with NGT (P = 0.012). HbA1c was independently and positively associated with fT4 (β= 0.345, r^2=0.119, P = 0.003) and negatively associated with fT3/fT4 ratio (β= –0.371, r^2=0.138, P = 0.001).
Discussion
Serum fT4 level increased and fT3/fT4 ratio decreased in patients with T2DM independently of obesity. The interaction of T2DM with thyroid hormones may overcome obesity-related changes in thyroid functions in our cohort.

Table 1. Baseline characteristics, laboratory parameters, and thyroid hormones of the subjects

	Patients with NGT (n = 131)	Patients with prediabetes (n = 41)	Patients with DM (n = 37)	P value NGT vs DM	P value NGT vs prediabetes	P value Prediabetes vs DM
Age, years	34 (27–44)	39 (31–46)	48 (38–53)	<0.001	0.045*	0.005

Nodular goiter (NOD) observed pre- and post-nuclear powerplant accident (NPP) – Experience in a single institution close to the NPP site

Takao Kunori & Hiroshi Yoshida
Iwaki-City Medical Center, Surgery, Iwaki, Japan

Background
An increase of pediatric thyroid cancer has been reported in Fukushima area. While there is no adult survey to date except NPP workers. Our institute is located 40 km from the NPP and has been playing a major medical role in this area (population 340,000). We analyzed patients with NOD whether there is any difference in cytological findings between pre- and post-NPP accident. Patients and methods:1,065 new patients (2005–2020) with NOD were examined; pre(A), 780 patients (46%) and post (B), 907patients. Cytological diagnosis was made 1,802 times. Ultra-sonogram (US) and hormonal assay were performed in each patient. Follow-up study was performed in 316 patients (28%).
Results
1) Yearly assay number: 318 FNAB was performed between 2007 and 2008 (a peak) then decreased to 154 between 2015 to 2016 (4 years after NPP accident, lowest). 2) Age: Period A, 59±15 years; B, 61±14 (P <0.004). 3) Gender: Proportion of female, A, 637 (82%) B, 739 (82) (NS). 4) Level of serum thyroglobulin (Tg): A, 708±3,109 (median 98) ng/ml, B, 400±1.178 (median 95) (P<0.01). 3. Size (diameter): A, 25±73mm (median 20). B, 23±13.3 mm (median 21) (NS). 5) Tg/size: A, 21.4±68 (Med 5.2) B, 15.6±40,2 (Med 4.8). (NS). 6) Cytological classification: Class 2, A, 454 (46%), B, 544 (55%); class 3, A, 27 (42%), B, 38 (59%); class 4, A 5 (42%), B, 7 (58%); class 5, A, 46 (70%), B, 20 (30%) (Kai2< 0.004). 7) Cytological diagnosis: Papillary carcinoma, A, 45 (65%), B, 24 (35%); Cellular atypia, A, 15 (32%), B, 32 (68%); Follicular neoplasm, A, 23 (49%), B, 34 (60%); Adenomatous goiter (AG), A, 152 (37%), B, 271 (63%); Benign goiter A, 197 (50%), B, 106 (50%); Cyst, A, 166 (57%), B, 124 (43%); Chronic thyroiditis, A, 46 (63%), B, 27 (37%) (Kai2, P <0.0001).
Discussion
There was no increase of NOD patients nor carcinoma diagnosis after NPP accident. Although AG was more frequently diagnosed in period B, the increase started early years of period A. Tg level decreased in period B corresponding to lesser size, possibly due to early detection by widespread US.
Conclusion
There was no apparent effect of NPP accident in adult NOD around our institution.

Management of thyrotoxicosis induced by PD1 or PD-L1 blockade

Alessandro Brancatella, Isabella Lupi, Nicola Viola, Daniele Sgrò, Lucia Montanelli, Chiara Sardella, Eleonora Molinaro, Paolo Piaggi, Rossella Elisei, Claudio Marcocci, Ferruccio Santini, Francesco Latrofa
University of Pisa, Pisa, Italy

Background
Thyrotoxicosis is a common immune-related adverse event in patients treated with PD1 or PD-L1 blockade. A detailed endocrinological assessment, including thyroid ultrasound and scintigraphy is missing, as are data on response to treatment and follow-up. Aim of the study was to better characterize the thyrotoxicosis secondary to immune checkpoint inhibitors, gaining insights into pathogenesis and informing management.
Methods
We conducted a retrospective study of 20 consecutive patients who had normal thyroid function before starting immunotherapy and then experienced thyrotoxicosis upon PD1 or PD-L1 blockade. Clinical assessment was combined with thyroid ultrasound, scintigraphy, and longitudinal thyroid function tests.
Results
Five patients had normal scintigraphic uptake (Sci+), no serum antibodies against the TSH receptor, and remained hyperthyroid throughout follow-up. The other 15 patients had no scintigraphic uptake (Sci-) and experienced destructive thyrotoxicosis followed by hypothyroidism (n=9) or euthyroidism (n =6). Hypothyroidism was more readily seen in those with normal thyroid volume than in those with goiter (P = 0.04). Among Sci- subjects, a larger thyroid volume was associated to a longer time to remission (P <0.05). Methimazole (MMI) was effective only in Sci+ subjects (P<0.05).
Conclusion
Administration of PD1 or PD-L1 blocking antibodies may induce two different forms of thyrotoxicosis that appear similar in clinical severity at onset: a type 1 characterized by persistent hyperthyroidism that requires treatment with MMI, and a type 2 characterized by destructive and transient thyrotoxicosis that evolves to hypo- or euthyroidism. Thyroid scintigraphy and ultrasound help differentiating and managing these two forms of iatrogenic thyrotoxicosis.

Cabral, Lisbon, Lisbon, Portugal; [4]Endocrinology, Metabolism and Diabetes Clinic of Lisbon, Lisbon, Portugal; [5]Institute of Scientific Investigation Bento da Rocha Cabral, Lisbon, Portugal; [6]Genetic Laboratory and Ecogenetic and Human Health Group, Environmental Health Institute- ISAMB, Faculty of Medicine, University of Lisbon;, Lisbon, Portugal; [7]Endocrinology, Diabetes and Metabolism Service, Santa Maria, North Lisbon Universitary Hospital Centre, Lisbon, Portugal; [8]University Clinic of General Practice, Faculty of Medicine, Lisbon University, Lisbon, Portugal; [9]Institute of Preventive Medicine and Public Health, Environmental Health Institute– ISAMB, Faculty of Medicine, University of Lisbon, Lisbon, Portugal

Background and objectives
TAS2R38 is a bitter taste gene that can influence food consumption depending on its single nucleotide polymorphisms (SNPs) leading to aminoacid substitutions in the receptor protein P49A (proline/alanine), A262V (alanine/valine) e V296I (valine/isoleucine). Subjects with at least one PAV (proline-alanine-valine) copy are bitter tasters, while AVI homozygotes are non-tasters. Other variants have intermediate bitter tasting: AAV<AAI<PAI. TAS2R38 is expressed in thyroid and other organs. This study evaluates TAS2R38 gene polymorphisms influence in thyroid function, metabolism and body composition.
Methods
DNA of 167 individuals (79% female) 24.6% eutrophic, 43.7% overweight and 31.7% obese was genotyped by *endpoint analysis*. From these, 79 had thyroid functional disease (hypothyroidism n = 41) compared with 88 controls. Anthropometric parameters BMI (kg/m^2), fat mass (%), total fat mass (kg), total lean mass (kg) determined by DEXA; metabolic/hormonal parameters by standard methods: triglyceridaemia (mg/dl), HDL (mg/dl), LDL (mg/dl), glycaemia (mg/dl), TSH (mcUI/ml), T3 (ng/dl), T4 (ng/dl), FT4 (ng/dl). Leptin (ng/ml) by ELISA. Statistics: ñ and ANOVA, significance for P <0.05.
Results
There were differences (p<0.001) in the distribution of diplotypes between subgroups being respectively for hypothyroidism-hyperthyroidism-controls (%): PVV/AVI (65.4; 64.3; 0); AVV/AVV (19.2; 10.7; 0); PVI/PVI (7.7; 7.1; 31.6); PVV/AVV (3.8; 7.1; 0); AAV/AAV (3.8; 0; 15.8); PVV/AAI (0; 0; 46.1); PVV/PAI (0; 0; 5.3); AVV/AVI (0; 3.6; 0); PAV/AAV (0; 0; 1.3); PVV/PV (0; 7.1;0). Diplotypes were associated with fat mass (P = 0.025); leptin (P = 0.019) and triglyceridaemia (P = 0.048). For PVV/AVI and PVV/AAI diplotypes, average values were respectively: fat mass 37.45±6.67 and 34.45±7; leptin: 56.80±37.32 and 50.85±54.16; triglyceridaemia: 99.64±49.76 and 94.52±55.97. Significant association between the SNP A262V and hyper/hypothyroidism (P <0.001); total lean mass (P = 0.012) and fat mass (P = 0.03), triglyceridaemia (P = 0.05) and TSH (P = 0.025). The SNP V296I was associated with total lean mass (P = 0.014). Metabolic and anthropometric variables associated with hyper/hypothyroidism: total fat mass (P = 0.02); BMI (P = 0.002), glycaemia (P = 0.035), triglyceridaemia (P = 0.05), TSH (P = 0.008), FT4 (P = 0.027). No significant differences for other parameters.
Conclusions
The distribution of TAS2R38 diplotypes differed between the control and hyperthyroidism or hypothyroidism samples. The haplotype AVI (SNP A262V) associated with metabolic and body composition parameters and with less bitter sensitivity may be a clue for dysfunctional thyroid. This could be due to exogenous factors such as higher ingestion of bitter goitrogenic compounds inducing hypothyroidism or, on the other hand, predisposition to hyperthyroidism via higher resistance to antithyroid effects of unknown endogenous factors in individuals with the AVI variant. In conclusion, TAS2R38 gene influences thyroid function witch modulates metabolism and body composition.

Papillary thyroid microcarcinomas that metastasize to lymph nodes

Ahmet Dirikoc[1], Abbas Ali Tam[1], Nurcan Ince[1], Didem Ozdemir[1], Oya Topaloglu[1], Afra Alkan[2], Aylin Kılıcyazgan[3], Reyhan Ersoy[1] & Bekir Cakır[1]
[1]Ankara Yıldırım Beyazıt University Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Yıldırım Beyazıt University Faculty of Medicine, Department of Biostatistics and Medical Informatics, Ankara, Turkey; [3]Ankara Yıldırım Beyazıt University Faculty of Medicine, Department of Pathology, Ankara, Turkey.

Background
We aimed to determine clinicopathological features that can predict lymph node metastasis (LNM) in papillary thyroid microcarcinomas (PTMC).
Methods
Medical records of 872 patients with papillary thyroid cancer >1 cm (PTC >1 cm) and 1184 patients with papillary thyroid microcancer (PTMC) (£1 cm) were reviewed retrospectively. Demographical, clinical and histopathological features of (PTC >1 cm) and PTMC were compared. Association between clinicopathological features and LNM in PTMC was investigated.
Results
The median age of patients with PTMC was significantly higher than patients with PTC>1 cm (49 vs 46 years old, P <0.001). Multifocality, capsular invasion, vascular invasion, extrathyroidal extension (ETE) and LNM were more frequent in patients with PTC>1cm compared to patients with PMTC (P <0.001 for each). In PTMC group, those with LNM had significantly higher proportion of multifocality, capsular invasion, vascular invasion and ETE compared to those without LNM (P = 0.007, <0.001, P = 0.011 and P <0.001, respectively). Multifocality and ETE were significant factors for LNM with logistic regression analysis. Multifocality increased the risk of LNM by 1.737 times (95% CI: 1.079–2.979) and ETE increased the risk by 3.528 times (95%: 1.914–6.503). Primary tumor diameter □5.75 mm was predictive for LNM with a sensitivity of 0.782 and a specificity of 0.517 in PTMC.
Conclusion
LNM should be investigated more carefully in patients with PTMC in the presence of tumor diameter□5.75 mm, multifocality or ETE.

Serum endocan level and its correlation with clinicopathologic features in patients with Papillary Thyroid Cancer

Musa Kursad Sener[1], Mellia Karakose[2], Muhammet Kocabas[2], Taha Ulutan Kars[3], Cihad Solak[4], Fethi Yönet[5], Mehmet Emin Gerek[4], Fatma Hümeyra Yerlikaya Aydemir[6], Mustafa Kulaksizoglu[2] & Feridun Karakurt[2]
[1]Cihanbeyli State Hospital, The Department of Internal Medicine, Konya, Turkey; [2]Necmettin Erbakan University Meram Medical School, The Department of Endocrinology and Metabolism, Konya, Turkey; [3]Necmettin Erbakan University, School of Medicine, Department of Internal Medicine, Division of Hematology, Konya, Turkey; [4]Konya Numune State Hospital, The Department of Internal Medicine, Konya, Turkey; [5]Nigde Omer Halisdemir University Research and Training Hospital, The Department of Internal Medicine, Konya, Turkey; [6]Selcuk University Medical School, The Department of Biochemistry, Konya, Turkey

Background
Papillary thyroid cancer (PTC), has a slow progression and good prognosis and is often treatable, but may show recurrence and metastasis. Age, sex, histopathologic variants of PTC, lymphatic or vascular invasion, lymph node involvement are among the factors affecting the occurrence of metastasis. Endocan is produced in vascular endothelial cells, epithelial cells lining the distal tubules of the kidney, submucosal glands of bronchus and lungs. In recent studies, the role of endocan in many cancers has been identified. Serum endocan levels can be used in the early diagnosis of cancers because of the aforementioned characteristics. In addition, many studies have suggested that it can be a molecule of prognostic importance in various cancers. The aim of this study was to compare preoperative serum endocan levels of patients diagnosed with PTC by thyroid FNAB and endocan levels of patients with no malignancy after thyroid FNAB.
Materials and Methods
This study included 48 patients with PTC who underwent total thyroidectomy and 40 age- and sex-matched healthy controls between November 2018 and May 2019. Serum samples were obtained from the patients before surgery. Serum endocan levels of the patients and controls were measured and the results were compared. The relationship between endocan levels and clinicopathological factors was investigated
Results
PTC patients had higher mean serum endocan level than control subjects (45.1 ± 9.6 vs 37.7 ± 8.3 pg/ml, P < 0.001) (Table 1). In PTC patients, there was no relationship between serum endocan levels and histopathologic variant, lymphatic or vascular invasion, surrounding thyroid tissue invasion, lymph node metastasis, surgical margin status, TNM stage and ATA risk stratification group, age and tumor size.
Conclusions
PTC patients had higher mean serum endocan level than control subjects. In PTC patients, there was no relationship between serum endocan levels and

histopathologic variant, lymphatic or vascular invasion, surrounding thyroid tissue invasion, lymph node metastasis, surgical margin status, TNM stage and ATA risk stratification group, age and tumor size. This study suggests that serum endocan level can be used as an adjunct test in the diagnosis of PTC in patients with thyroid nodules.

Table 1. Comparison of demographic and laboratory findings of patients and controls

Parameter	Patient group	Control group	*P*
Gender (M / F)	38/10	36/4	0.167
Age	48.5±14.1	48.7±15.8	0.932
Weight (kg)	70.7±9.6	72.5±8.9	0.372
Height (cm)	164.8±6.8	165.5±6.5	0.622
BMI (kg/m^2)	25.9±2.6	26.3±2.2	0.426
TSH (IU/ml)	2.1±1.3	2.2±1.3	0.846

Association of thiol/disulfide homeostasis with Bethesda classification of thyroid nodules and thyroid cancer

Muhammet Cuneyt Bilginer[1], Abbas Ali Tam[2], Sevgul FAKI[3], Bağdagül Yüksel Güler[4], Ozcan Erel[5], İbrahim Kilinç[6], Didem Ozdemir[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Karadeniz Technical University School of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Yildirim Beyazit Universty School of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey; [3]University of Health Sciences Turkey, Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [4]University of Health Sciences Turkey, Gulhane Faculty of Medicine and Gulhane Training and Research Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [5]Ankara Yildirim Beyazit Universty School of Medicine, Department of Medical Biochemistry, Ankara, Turkey; [6]University of Health Sciences Turkey, Ankara City Hospital, Department of General Surgery, Ankara, Turkey

Background
Ultrasonography and fine needle aspiration biopsy are frequently used in the diagnosis of thyroid cancer. However, supportive data might be required in case of diagnostic difficulty. In this study, we investigated whether there is a relationship between thiol/disulfide homeostasis and cytological and histopathological diagnosis of thyroid nodules.
Materials and methods
A total of 119 participants were included in the study (81 euthyroid nodular goiter patients and 28 age and body mass index matched healthy volunteers). The patient group consisted of individuals scheduled for thyroidectomy. Thyroidectomy indications were giant nodule, cytological diagnosis and patient preference. Patients with diseases that would affect thiol/disulfide homeostasis were excluded. Cytological findings, histopathology results were evaluated. Native thiol, total thiol, and disulfide concentrations were measured, and disulfide/native thiol, disulfide/total thiol and native thiol/total thiol ratios were calculated. Thiol/disulfide levels were analyzed with automated spectrophotometric method.
Results
There was no significant difference in oxidative stress parameters between different Bethesda categories. However, the increasing Bethesda categories were weakly positively correlated with the disulfide/native thiol (r: 0.241, p: 0.030) and disulfide/total thiol (r: 0.250 p: 0.024). The disulfide concentration was 16.07±9.28 µmol/l in histopathologically benign, 19.85±11.28 µmol/l in malignant, and 14.87±7.62 µmol/l in the control group (P<0.001, f=11.724). Disulfide/native thiol was calculated as 3.58±2.0 in the benign group, 5.50±2.85 in the malignant group, and 3.41±1.70 in the control group (P <0.001, f=8.415). Disulfide/total thiol was significantly higher in the malignant compared to benign and control groups (4.96±2.24, 3.27±1.80 and 4.96±2.24, respectively, P <0.001, f=9.49).
Conclusion
Oxidative stress parameters were significantly higher in thyroid cancer. A weak positive correlation was detected between Bethesda categories and the disulfide/native thiol ratio and the disulfide/total thiol ratio. In case of diagnostic difficulties, additional benefit can be obtained from thiol/disulfide measurement.

Subacute thyroiditis at the time of SARS-CoV-2 pandemic

Alessandro Brancatella[1], Nicola Viola[1], Grazia Rutigliano[2], Daniele Sgrò[1], Ferruccio Santini[1] & Francesco Latrofa[1]
[1]Endocrinology Unit, Clinical and Experimental Medicine, University of Pisa, Pisa, Italy; [2]Pathology Unit, University of Pisa, Pisa, Italy

Background
Subacute thyroiditis (SAT) has been related to acute respiratory syndrome coronavirus 2 (SARS-CoV-2). We evaluated the incidence and the severity of SAT due to SARS-CoV-2.
Methods
A cross-sectional, retrospective study was conducted at the Endocrinology Unit of University-Hospital of Pisa, Italy. All patients experiencing SAT arisen within a period of 15 days earlier and yet untreated, assessed from January 2016 to December 2020, were included in the study. SAT cases from 2016 to 2019 (n = 152) were defined as "pre-SARS-CoV-2", while 2020 SAT patients were classified as "pos-SARS-CoV-2" (n = 13) or "neg-SARS-CoV-2" (n = 24) according to positive or negative test for SARS-CoV-2 at SAT onset or within a period of 45 days earlier.
Results
While in the years 2016–2019 most SAT cases were observed in the 3rd quarter, in 2020 there were two peaks, in the 2nd and in the 4th quarters, superimposable to the two main outbreaks of SARS-CoV-2. Compared to the same quarters of the years 2016–2019, in the 2nd and the 4th quarters of 2020 we observed higher levels of free thyroxine (FT4), C-reactive protein (CRP) and thyroglobulin (Tg). Compared to pre-SARS-CoV-2, pos-SARS-CoV-2 had higher FT4 (28·1 vs 24·1 nmol/l), CRP (8·0 vs 3·6 mg/l) and Tg (155 vs 60 µg/l) (P<0·05 for all) and resulted more frequently in hypothyroidism at 3 months (9/10 vs 30/152) (P <0·001). Neg-SARS-CoV-2 patients showed a clinical picture intermediate between pre-SARS-CoV-2 and pos-SARS-CoV-2 patients.
Interpretation
Most SAT cases in 2020 were associated with SARS-CoV-2 infection and were more severe than those previously observed.
Funding
This study was supported by "Fondi di Ateneo", University of Pisa.

Follicular thyroid carcinoma in a developing country : A retrospective study of 10 years

Abdul Aziz, Muhammad Qamar Masood, Saadia Sattar, Saira Fatima & Najmul Islam
Aga Khan University Hospital, Karachi, Pakistan

Introduction
The most common endocrine tumor is thyroid cancer. Follicular Thyroid Carcinoma (FTC) accounts for 5%–10% of all thyroid cancers. Patients with FTC frequently present with more advanced stage diseases and a higher occurrence of distant metastases because of the propensity of vascular invasion. FTC are mainly treated with surgery while radioactive iodine therapy (RAI) is main adjuvant therapy as per ATA guidelines. In many developing countries surgical facilities and RAI are in short supply therefore understanding the trends of FTC may help developing countries to plan and use resources more effectively.
Methodology
It was a retrospective observational study of FTC patients of age 18 years and above conducted at Aga Khan University Hospital, Karachi from 1st January 2010 to 31st December 2019.
Results
There were total of 404 patients of thyroid carcinoma out of which forty (10.1%) were FTC. 50% of the patients were in age group of 41–60 years and female to male ratio was 1.5 : 1. 60% presented with complain of neck swelling followed by bony, lung metastasis (20%) and compressive symptoms (20%). The pre-operative thyroglobulin level was done in six out of eight metastatic patients (75%) in which it was elevated. This emphasizes

the importance of checking thyroglobulin level in unusual presentation (bone pain, fractures) of patient having neck swelling also. On FNAC, 50% (20 patients) had Bethesda category III-IV nodules while 10% (4 patients) had Bethesda category II. In sixteen patients FNAC was not done as they presented with compressive symptoms or metastasis. Fifty percent had total thyroidectomy and 50% had subtotal followed by completion thyroidectomy plus ten patients had lymph node dissection out of which seven had histopathological lymph node involvement. On histopathology twenty three patients (57.5%) had minimally invasive while seventeen (42.5%) had widely invasive FTC. In our study 65% of the patients had clinical stage 1 disease while 25% had stage 2 and 10% had clinical stage 4. Seventeen patients (42.5%) had received RAI 30–100 mCi while ten patients (25%) received more than 100 mCi.
Conclusion
FTC demographic and clinicopathological presentation are same in Pakistan as compared to other countries. Surgery followed by RAI are the main stay of treatment. Thus understanding the trend of FTC and proper planning and utilization of the resources will help the developing countries in effectively treating the FTC.

Clinical and pathological features of thyroid cancer in adolescents and young adults

Nagihan Bestepe[1], Ahmet Dirikoc[2], Husniye Baser[2], Omer Yazicioglu[3], Aysegul Aksoy Altinboga[4], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Yildirim Beyazit University Faculty of Medicine, Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara City Hospital, General Surgery, Ankara, Turkey; [4]Yildirim Beyazit University Faculty of Medicine, Pathology, Ankara, Turkey

Introduction
Thyroid cancer is the most common endocrine malignancy and its overall incidence has increased significantly in the last 30 years. Cancer in adolescents and young adults (AYA) is defined by the National Cancer Institute as diagnoses occurring among those aged 15 to 39 years. Thyroid cancer is the second most common cancer in the AYA population. In this study, we aimed to compare clinical, ultrasonographical, cytological and histopathological features of thyroid carcinoma in patients AYA with older counterparts.
Materials and methods
The medical records of patients who underwent thyroidectomy between December 2006 and September 2016 and were diagnosed with thyroid cancer histopathologically were retrospectively reviewed. Patients were subdivided into two age groups: 15–39 (Group1) and ≥ 40 years old (Group 2). Thyroid functions, ultrasonographic features of malignant nodules, cytological and histopathological findings were compared in patients with AYA patients and ≥ 40 years.
Results
The study included 229 (22.6%) AYA patients and 784 (77.4%) patients aged ≥ 40 years. Thyroid functions, thyroid autoantibody positivity and thyroidectomy indications were similar. There were 305 (21.4%) and 1121 (78.6%) malignant foci in Group 1 and 2, respectively. Preoperative US features were similar in the two groups. Cytological results were distributed similarly in two groups (P = 0.512). Of all cancer types, 93.1% in Group 1 and 93.5% in Group 2 were papillary thyroid cancer (P = 0.772). Follicular cancer was found in 2.6% of Group 1 and 2.1% of Group 2 (P = 0.544). Medullary cancer constituted 1% of Group 1 and 1.1% of Group 2 (P = 0.895). Anaplastic cancer was found in 0.4% of Group 1 and 0.4% of Group 2 (P = 0.940). Lymph node metastasis was detected in 9.2% of group 1 and 7.4% of group 2 (P = 0.246). Distant metastasis was not detected in group 1, and it was found in 3 (0.4%) patients in group 2 (P = 0.366). There was not any significant difference in capsular and vascular invasion and extracapsular extension between groups.
Conclusion
Previous studies have found that although AYA patients are more likely to be diagnosed with locoregional lymph node involvement compared to older patients, they are less likely to be diagnosed with distant metastases. In our study, the rate of diagnosis of lymph node metastasis was higher and the rate of distant metastasis was lower, but the difference was not statistically significant.

AEP883

Transient thyrotoxicosis induced by bone metastasis from differentiated thyroid cancer : a case report

Ekram Hajji, Abir Ezzin, Soumaya Tahri, Manel Nouira, Raja Sfar & Kaouther Chatti
CHU Sahloul, Nuclear Medicine Department, Sousse, Tunisia

Introduction
Thyrotoxicosis due to functioning metastases in differentiated thyroid cancer (DTC) is exceedingly rare. The mechanism remains unknown despite several hypotheses. We report on a case of transient thyrotoxicosis due to functioning bone metastasis of follicular thyroid carcinoma.
Case report
We present a case of female patient of 68-years-old diagnosed with follicular thyroid carcinoma revealed by a lytic lesion of the right iliac bone. She had undergone total thyroidectomy followed by treatment with 100 mCi of iodine 131.The post-therapeutic whole-body scan showed intense uptake in the right iliac bone and residual thyroid gland uptake. Bone scintigraphy and SPECT/CT fusion images showed focal, intense uptake in the right iliac bone. Thoracic computed tomography and skeletal scintigraphy revealed bilateral multiple nodules in her lungs. Initially, TSH levels after 4 weeks of stopping levothyroxine treatment in preparation for treatment with I-131were high (> 60 mU/l; normal range, 0.25–5 mU/ml). The patient had undergone partial surgical resection of approximately 50% of the volume of the right iliac tumor mass.The bone metastasis was much too extensive and hypervascular to permit complete resection. After surgical management, the patient complained of symptoms of hyperthyroidism. The hyperthyroidism was confirmed by laboratory tests. Thyroid stimulating hormone (TSH) remained suppressed and free T4 remained elevated after I-131 therapy without thyroid hormone supplementation. The levothyroxine remained discontinued. TSH returned to adequate levels 8 months after surgery. TSH levels increased to 128 mU/l. Levothyroxine treatment was restarted at a suppressive dose of 175 µg/ml.
Conclusion
Thyrotoxicosis caused by thyroid follicular metastases is principally the consequence of multiple metastatic localizations, with a large tumoral volume. It must be evoked when there is no increase of the TSH after a thyroidectomy, or during the period of interruption of the suppressive treatment.

A tru-cut biopsy proven rare thyroid neoplasia in a giant nodule with a benign fine needle aspiration cytology

Leyla Akdoğan[1], Konul Ahmadova[1], Nagihan Bestepe[2], Sefika Burcak Polat[1], Imdat Dilek[3], Cevdet Aydin[1], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Ankara, Turkey, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Bilkent City Hospital, Ankara, Turkey, Department of Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Ankara, Turkey, Department of Hematology, Ankara, Turkey

Introduction
Extramedullary plasmacytoma (EMP) is a plasma cell neoplasm of extraosseous tissues. Less than 5% of all plasma cell neoplasms develop extramedullary. EMP is most common in the upper respiratory tract and oral cavity. The thyroid gland is one of the extremely rare regions. It is more common in men and the average age at diagnosis is 55. Primary thyroid plasmacytoma is one of the rare thyroid neoplasms. It often manifests as a rapidly growing mass in the neck and cause symptoms due to mass pressure. Pathological evaluation is particularly important. At the diagnosis of thyroid plasmacytoma, multiple myeloma must be ruled out. Here we present our case of thyroid plasmacytoma diagnosed by tru-cut biopsy.
Case
A 71-year-old female patient, with hypothyroidism and multinodular goiter since 2014, presented with a 6-month history of dyspnea and neck swelling. She had type 2 diabetes mellitus, hypertension, and coronary artery disease. Thyroid gland was grade 3, fixed nodules were bilateral palpable. Thyroid function tests were euthyroid on levothyroxine treatment and thyroid autoantibodies were positive. An ultrasound scan of the thyroid revealed an enlarged thyroid with thyroid nodules on the right and left lobes, extending to the isthmus with a significant increase in size compared to previous controls. Fine needle aspiration cytology was benign. Due to suspicion of

thyroid lymphoma, tru-cut biopsy was performed which suggested plasma cell neoplasia and plasmacytoma. Hematology consultation was made, as a result of the tests, multiple myeloma and other plasma cell disorders were excluded. The patient was evaluated as extramedullary plasmacytoma. In the council of endocrinology and metabolism, hematology, general surgery, nuclear medicine and radiation oncology departments operation was preferred. Bilateral total thyroidectomy was performed, histopathology reported as plasma cell neoplasm. Radiotherapy was not considered to be given to the patient as she had no residue in the examinations performed in the postoperative period. The patient has been followed in remission for one year.
Conclusion
Primary thyroid plasmacytoma is a rare thyroid neoplasm. Clinical examination and imaging methods are usually not determinative in diagnosis, pathological evaluation is at the forefront of diagnosis. Even if fine needle aspiration biopsy is benign, patients should be evaluated for tru-cut biopsy in case of clinical suspicion. In the begining, multiple myeloma must be ruled out. Regular follow-up of the patient is necessary, as conversion to multiple myeloma may occur rarely.

Thyro-cutaneous fistula a rare presentation of thyroid lymphoma

Sevgul Faki[1], Himmet Durmaz[2], Serdar Deniz[1;2], Belma Tural Balsak[2], Merve Pamukçuoğlu[3], Oya Topaloğlu[2], Reyhan Ersoy[2] & Bekir Çakir[2]
[1]Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Yildirim Beyazit University, Department of Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara City Hospital, Department of Haematology, Ankara, Turkey

Background
Primary thyroid lymphoma (PTL) is defined as a lymphoma involving only the thyroid gland or the thyroid gland and adjacent (regional) neck lymph nodes. Primary lymphomas of the thyroid are uncommon tumours, representing approximately 5% of the thyroid neoplasms and 2% of extranodal lymphomas. The most characteristic presentation is that of a rapidly enlarging neck mass often associated with dysphagia [5]. The majority of patients are euthyroid and one third of patients have compressive symptoms. The mass is usually fixed to surrounding tissues and half the patients have unilateral or bilateral cervical lymph node enlargement. Abscess formation in the background of thyroid lymphoma with thyro-cutaneous fistula is further rare. Reaching the final diagnosis can be delayed if insufficient biopsy material is obtained and ıt may be difficult to distinguish thyroid lymphoma from anaplastic carcinoma and thyroiditis. The present study describes the case of a patient who was presentad with Abscess formation suggesting the possibility of anaplastic carcinoma and finaly diagnosd by diffuse large B-cell lymphoma.
Case
A 73-year-old female presented with anterior neck pain, hoarseness and rapidly expanding mass with Abscess formation on here neck. the patient was admitted to our clinic for preoperative thyroid surgery suggesting the possibility of anaplastic carcinoma due to fine needle aspiration cytology of suspicious for malignancy. Her serum TSH was *elevated to* 47 mU/l and anti TPO was very high. Here neck ultrasound showed a significantly enlarged, diffuse parenchymal inhomogeneity and ill defined border of the thyroid gland. We performed Tru-cut biopsy and histological diagnosis was Diffuse large B-cell lymphoma of the thyroid gland. After 18FDG-positron emission tomography/computed tomography (PET/CT) scanning the patient reseaved 6 regimen of chemotherapy R-CHOP (rituximab, cyclophosphamide, doxorubicin [hydroxydoxorubicin], vincristine [Oncovin], prednisone with antibioticsand she has a good physical condition.
Discussion
Thyroid abscess is a rare clinical situation. It is most commonly associated with pyriform sinus fistula. Abscess formation in the background of thyroid cancer with thyro-cutaneous fistula is further rare. PTL is an uncommon malignancy of the thyroid. PTL occur most commonly in elderly women and are commonly of B- cell origin. Fine needle aspiration has become the procedure of choice for the initial pathological diagnosis of thyroid nodule. However, studies have also shown inconsistent results in the diagnosis of lymphoma of the thyroid. But clinical and radiological suspicion and cytomorphological features can help reaching the correct diagnosis in such cases.

Hematological changes before and after radioactive iodine therapy

leyla akdoğan[1], Sefika Burcak Polat[1], Fatma Neslihan Cuhaci Seyrek[1], Abbas Ali Tam[1], Elif Ozdemir[2], Cevdet Aydin[1], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Ankara, Turkey, Department of Nuclear Medicine, Ankara, Turkey

Objective
Radioactive iodine (RAI) therapy is widely used in both diagnosis and treatment of benign and malignant thyroid diseases. It is generally a well tolerated therapy. Bone marrow suppression is often a temporary side effect with a decrease in white blood cells and platelets up to 6–10 weeks. In this study, we aimed to examine hematological changes in patients who received RAI treatment for benign or malignant diseases of the thyroid.
Methods
The records of patients who applied to our endocrinology clinic between January 2016 and January 2019 and received RAI treatment for benign or malignant etiologies were evaluated retrospectively. The demographic data of the patients and data on thyroid disease, additional diseases, and the drugs used were recorded, the patients were grouped according to the etiology and the RAI dose they received. Blood count parameters measured before RAI treatment within 7 days, after RAI treatment and at the last control of the patient were recorded and compared in these patients.
Results
In the study, data of total 202 patients, including 158 women (77.5%) and 44 men (21.6%), were evaluated. 168 of these patients (82.4%) had received RAI treatment due to malign, and 34 benign (16.7%) etiologies. The median age they received RAI was 45 (20–84), while the median dose of RAI was 75 mCi (10–200). Pre-treatment and first control interval was median 44 (18–93) days, and the median time between pre-treatment and last control was 35 (4–56) months. In comparison of hematological parameters before and after treatment, the median leukocyte count was 7.72 (3.89–19.93) × 10^9/l before treatment, while it was significantly reduced 6.27 (0.86–14.5) × 10^9/l at the first control after treatment and 6.78 (3.58–10.8) × 10^9/l at the last control. Similarly, a decrease in neutrophil and lymphocyte counts was detected after treatment. While the median hemoglobin value was 13.95 (8.8–17.2) g/dl before RAI treatment, it was 13.5 (7.8–17.3) g/dl and 13.5 (6.7–17.6) g/dl at the first and last control after treatment, respectively. The median platelet count was 283 (149–563) × 10^9/l, and it was 250.5 (134–507) × 10^9/l at the first post-treatment control and 266.5 (116–539) × 10^9/l at the last control. While the median value of mean platelet volume(MPV) was 10.8 (8.5–13.8) fL before treatment, it was 10.15 (7.6–13.1) fL and 8.2 (6.6–11.1)fL, respectively, in controls.
Conclusion
In our study, a significant decrease was found in the leukocyte, neutrophil, lymphocyte, platelet counts, hemoglobin levels and mean platelet volumes in the post RAI treatment period. According to these findings, it can be thought that the decrease in hematological parameters continues not only in the acute period but also in the chronic period after RAI.

Effect of iodine 131 in the treatment of Graves' disease on thyroid mass and clinical signs of hyperthyroidism

Ekram Hajji, Raja Sfar, Soumaya Tahri, Tarek Kamoun, Manel Nouira, Najla Ayechi & Kaouther Chatti
CHU Sahloul,Sousse, Nuclear Medicine, Sousse, Tunisia

Introduction
Radioiodine I-131 (RAI) therapy of Graves' Disease (GD) affects biological thyroid function, clinical signs of hyperthyroidism (SCH), but also the mass of the thyroid (MT). The aim of our study is to assess the effect of RAI on GD and TM according to biological thyroid function after 6 and 12 months.
Methods
This is a prospective study of 86 patients (mean age 43 ± 11, sex ratio 2.07) referred for RAI therapy of GD. The biological thyroid function was assessed after 6 months and one year of RAI. The patient's weight, heart rate and thyroid mass were evaluated at 6 months and 12 months. According to the biological thyroid function at 6 and 12 months, the patients are divided into two subgroups: the subgroup of patients who persist in hyperthyroidism

(GI) and the patients who achieved remission (eu- or hypo-thyroidism) (GII). We compared the change in weight, heart rate, and thyroid mass after RAI between the two subgroups.
Results
Follow-up after RAI was possible in 66 patients at 6 months and 63 after a year. Hyperthyroidism persists or recurs in 29% of patients at 6 months and 20% at 12 months. We noted weight gain ($p < 0.0001$ at 6 and 12 months), reduction in heart rate ($P = 0.003$ at 6 months and $P < 0.0001$ at 12 months) and reduction in TM ($P < 0.0001$ at 6 and 12 months) for all patients. Weight gain was significant for both subgroups at 6 and 12 months, but less significant for GI ($P = 0.001$ vs $P < 0.0001$ at 6 months and $P = 0.047$ vs $P < 0.0001$ at 12 months). At 6 months, the reduction in heart rate was significant for GII ($P = 0.002$) but not significant for GI ($P = 0.47$). At 12 months, the reduction in heart rate was significant for both subgroups, but less significant for GI ($P = 0.008$ vs $P = 0.005$). The reduction in MT was significant for both subgroups at 6 and 12 months, but less significant for GI ($P = 0.001$ vs $P < 0.0001$ at 6 months and $P = 0.007$ vs $P = 0.0001$ at 12 months).
Conclusion
RAI therapy improves SCH and reduces thyroid mass even for the subgroup of patients with persistent hyperthyroidism, but less significantly than the subgroup of patients who achieved remission at 6 and 12 months.

Thyroid diseases and mastopathy in normally cycling women

Irina Vasyhina[1] & Larisa A. Danilova[2]
[1]The Republican Research Center for Radiation Medicine and Human Ecology, Endocrinology, Belarus; [2]Belarusian Medical Academy for Postgraduate Education, Belarus

Objective
To evaluate the combined pathology of the thyroid and mammary glands in normally cycling women
Materials and Methods
We have examined normally cycling 265 women aged 18 to 56 years. The modeling was performed using the SPSS 17.0 statistical software package.
Results
the combined pathology of the thyroid and mammary glands was detected in 149 women (56.2%) of the number of examined women. Isolated pathology of the thyroid gland in the age group from 18 to 35 years old was defined in 29 people (23.0%); isolated breast pathology - in 36 (28.6%); combined pathology of the thyroid and mammary glands - in 49 women (38.9%). In the group from 36 to 44 years old, isolated thyroid pathology was diagnosed in 14 women (14.9%); isolated pathology of the mammary gland - in 13 (13.8%), combined pathology of the thyroid and mammary glands - in 63 women (67%). In the group of 45 years and older, isolated pathology of the thyroid gland was diagnosed in 5 women (11.1%); isolated breast pathology - in 1 (2.2%); combined pathology of the thyroid and mammary glands - in 37 women (82.2%). The incidence of combined pathology of the thyroid and mammary glands in all age groups is higher than the isolated pathology of the thyroid gland (group 1 - $\chi^2 = 7.43$; $P < 0.05$; group 2 - $\chi^2 = 52.06$; $P < 0.001$; group 3 - $\chi^2 = 44.72$; $P < 0.001$). The incidence of combined pathology in groups from 36 to 44 years old and 45 years and older is higher than isolated breast pathology (group 2 – $\chi^2 = 54.45$; $P < 0.001$; group 3 – $\chi^2 = 57.76$; $P < 0.001$). The incidence of concomitant pathology is significantly higher in group 3 (compared with women in group 1 - ($\chi^2 = 10.17$; $P = 0.001$).
Conclusions
The incidence of combined pathology of the thyroid and mammary glands in all age groups is higher than the isolated pathology of the thyroid gland.

Emergency total thyroidectomy in a COVID 19 patient with Graves' disease and pancreatitis induced by methimazole

Melania Balas[1], Flore Varcus[2], Daniela-Georgiana Amzar[1], Ioana Golu[1], Iulia Plotuna[1], Andreea Borlea[1], Ana Silvia Corlan[1] & Mihaela Vlad[1]
[1]University of Medicine and Pharmacy V.Babes Timisoara, Endocrinology, Timisoara, Romania; [2]University of Medicine and Pharmacy V.Babes Timisoara, Surgery, Timisoara, Romania

Introduction
The use of antithyroid drugs is associated rarely with severe hepatotoxicity. Recently, due to several cases reported in the literature, acute pancreatitis was added as a severe potential adverse effect induced by methimazole. The physiopathology of methimazole induced pancreatitis is not fully understood (intrinsic toxicity or idiosyncratic drug reaction were proposed as possible mechanisms). If adverse effects occur and no other treatment options are available (other antithyroid agent, radioiodine therapy), the rapid correction of hyperthyroidism can be obtained by surgery (thyroidectomy).
Case presentation
A 69-year-old woman was diagnosed with Graves' disease in January 2021, with severe thyrotoxicosis, without ophthalmic involvement. The patient started methimazole treatment with high doses (30 mg/day) gradually tapered over the following weeks. Three weeks later she presented to the Emergency Department with severe abdominal pain, nausea, vomiting, inappetence, palpitations, and sweating. She had no fever and was negative for coronavirus (RT-PCR test). She reported no history of hypertriglyceridemia, alcohol or other medication. The laboratory tests confirmed acute pancreatitis (serum lipase was elevated 6 times the upper limit of normal) and liver dysfunction (transaminases were elevated 10 times the upper limit). Alkaline phosphatase (ALP), gamma-glutamyl transferase (GGT) and total bilirubin were significantly increased. All the imagistic investigations (abdominal ultrasound, computed tomography, echoendoscopy) confirmed the diagnosis of acute pancreatitis, without signs of gallstones or tumors. Thyroid ultrasound revealed normal thyroid volume (15 ml), marked hypoechoic parenchyma, increased vascularization. The hormonal data showed a very suppressed TSH associated with normal FT3 and slightly increased FT4. Methimazole was interrupted and Propranolol was administered in high doses (80 mg/day). After i.v. fluids, pain medication and proton pump inhibitor administration, patient's condition improved. After five days, transaminases, lipase, ALP and GGT levels decreased significantly. On the sixth day, the repeated RT-PCR for COVID 19 was positive. She was transferred to the special COVID 19 Department, where she was evaluated (thoracic CT showed only minor lesions, with "ground-glass" appearance affecting less than 10% of the lungs) and treated with i.v. perfusions, pain medication, anti-inflammatory drugs, heparine and propranolol. Radioactive iodine therapy was unavailable. On the same day she underwent emergency total thyroidectomy, without any complications. She was discharged after 6 days, on oral anticoagulants and levothyroxine.
Conclusion
As severe thyrotoxicosis may be associated with more serious complications from COVID-19, urgent thyroidectomy is a valid option in patients with severe adverse effects to antithyroid drugs (pancreatitis).

Radiofrequency ablation for benign thyroid nodules: 600 patients - five years follow-up single center experience

Vyacheslav Solovov
Samara Oncology Center, Interventional Radiology, Samara, Russian Federation

Purpose
The objective of this study was to evaluate the efficacy and safety of ultrasound (US)-guided radiofrequency ablation (RFA) for treating of benign thyroid nodules of long-term follow-up.
Material and methods
The retrospective analysis included the results of treatment of 600 patients with benign tumors of the thyroid gland in the Samara Oncology Center. 108 (18%) patients had autonomously functioning thyroid nodules and 492 (82%) had symptomatic ones. The mean volume of nodule was 33.1 (1.5–179.5) ml.
Results
RFA reduced nodular volume by 68% after 6 months, 85% after 60 months and it was an effective method for treating nodule-related clinical problems and hot nodules. 54 (9%) patients with nodule volume more than 75 ml underwent 2–10 sessions of RFA. Cosmetic results were excellent in 95% of patients. No serious complications such as thyroiditis, voice change, and hematomas were observed.
Conclusion
Long-term follow-up showed that RFA was effective and safe for treating benign thyroid nodules.

SARS-Cov-2 related subacute thyroiditis in Belarusian patients with the previous autoimmune thyroiditis

Maxim Lushchyk[1], Larissa I. Danilova[1], Natallia Dudzik[2], Irina Bourko[1], Galina Korolenko[3], Elena Kuzmenkova[4] & Artur Grigorovich[5]
[1]Belarusian Medical Academy of Postgraduate Education, Endocrinology Department, Minsk, Belarus; [2]Belarusian Medical Academy of Postgraduate Education, Thyroid disease Unit, Minsk, Belarus; [3]10th Minsk City Clinical Hospital, Endocrinology Department, Minsk, Belarus; [4]Republican Centre of Medical Rehabilitation and Watertherapy, Republican Endocrine Consultative Centre, Minsk, Belarus; [5]Brest Regional Endocrinological Dispensary, Brest, Belarus

Introduction & Background
A COVID-19 pandemic smashed the world not only by it`s severity, but also by the tremendous amount of comorbidities, many of them having autoimmune basis. Thyrotoxicosis as one of the above - could result either from SARS-CoV-2 directly infecting the thyroid gland, as described in other viral infections, or can develop due to immune overactivation during the severe viral load. Subacute thyroiditis (SAT) is a self-limiting inflammatory disease of viral or post-viral origin, characterized by general symptoms, neck pain and thyroid dysfunction, lasting for a period of weeks or months—followed by hypothyroidism with subsequent restoration of euthyroidism. The pathogenesis of SAT started after SARS-Cov-2 infection is thought to be similar to the association with the other viral conditions.
Aim
In our study we aimed to analyze the variety of clinical, laboratory and ultrasonic data in the observed cases of subacute thyroiditis associated with SARS-Cov-2 infection.
Materials and methods
We have analyzed 8 cases of late-onset subacute thyroiditis in 6 Belarusian female and two male patients. All our patients have had a history of mild to severe SARS-Cov-2 infection, that required admission to the clinic. In a short period (from 2 to 7 weeks) after the discharge from the hospital they returned to an out-patient department with complaints for a tachycardia and a pain on the frontal area of the neck.
Discussion
The pathogenesis of subacute thyroiditis emerging in a short time after SARS-Cov-2 infection is thought to be similar to the association with the other viral-induced thyroid conditions. The viral etiology is supported by the onset of SAT after an upper respiratory infection and its occurrence during viral outbreaks. In our observed cases – only two of the females (2/6) had the diagnosis of autoimmune thyroiditis before the pandemic period, in other cases – ultrasound features of autoimmune thyroiditis and slightly decreased fT4 and fT3 levels were revealed during the exams.
Conclusion
An analysis of more cases is definitely needed to answer the question "Does antecedent autoimmune thyroiditis lead to a higher risk of SARS-Cov-2-associated subacute thyroiditis?" Current recommendation remains as a proposal of more thorough observation of thyroid out-patients with all forms of autoimmune disorders in case of reported SARS-Cov-2 reconvalescence.

Evaluating the role of circulating dendritic cells in methimazole-treated pediatric Graves' disease patients

Aleksandra Starosz[1], Karolina Stożek[2], Marcin Moniuszko[1], Kamil Grubczak[1] & Artur Bossowski[2]
[1]Medical University in Bialystok, Department of Regenerative Medicine and Immune Regulation, Medical University of Bialystok, Poland; Poland, Poland; [2]Medical University in Bialystok, Department of Pediatric, Endocrinology and Diabetes, with a Cardiologfy Unit, Poland, Poland

Graves' disease (GD) is hyperthyroidism associated with organ-specific autoimmune 14 inflammation. GD occurs more frequently in adults than in children, however, pediatric patients are 15 a therapeutic challenge due to cycles of remissions and relapses requiring constant monitoring at 16 every stage of treatment administered. Dendritic cells (DCs) are considered a link between innate 17 and adaptive immunity. DCs as antigen-presenting cells (APCs) are involved in antigen 18 presentation to T lymphocytes, thereby, initiate shift towards effector cells. In accordance, DCs 19 participates also in the modulation of tolerance to specific antigens. To date, the data on DC role in 20 Graves' pathological processes are scarce. Therefore, here we evaluated frequencies and role of 21 circulating DCs in GD pediatric patients treated with methimazole. Flow cytometric analysis was 22 implemented to evaluate mDC1, mDC2 and pDC cells and their correlation with clinical GD-related 23 parameters. We found significantly higher levels of DC subsets in patients at admission. 24 Furthermore, methimazole treatment seemed to effectively reduce subsets of DCs which, in 25 addition, were found to differentialy correlate with thyroid function. Our study shed a new light on 26 DCs role in pediatric GD pathomechanism. Further studies are required for mechanistic assessment 27 of DCs exact role in disease progression and influence on thyroid function.

Two cases of rare thyroid cancer• Hyalinizing trabecular tumor and Warthin like papillary carcinoma.

Stavroula Psachna[1], Evangelia Vogiatzi[1], Dimitrios Ioannidis[1], Dimitrios Lilis[1], Maria Drakou[1], Christina Zoumpouli[2], Nikolaos Goutas[3] & Antonis Polymeris[1]
[1]Attica General Hospital "Sismanoglio - Amalia Fleming", Endocrinology - Diabetes Mellitus - Metabolism Department, Greece; [2]Sismanoglio Hospital, Department of Pathology, Greece; [3]The National and Kapodistrian University of Athens, Laboratory of Forensic Medicine and Toxicology, Greece

Background
Following the 4th edition of WHO classification of thyroid tumors several pathologic entities were reclassified, mainly as a means of de-escalating addressed therapy. We herein present two rare types of thyroid cancer, hyalinizing trabecular tumor (HTT) and Warthin-like papillary carcinoma (WL-PTC).
Cases presentation
A 64-year-old female patient presented with an ultrasonographic 1.92 × 1.11 cm isoechoic thyroid nodule with intranodular vascularity. Fine–needle aspiration (FNA) cytology showed atypia of undetermined significance (TBS III). Three years later FNA was repeated due to nodule enlargement and the cytology was reported as suspicious of malignancy (TBS V). A total thyroidectomy was performed and the pathology report revealed HTT. Substitution levothyroxine therapy was started. Three months postoperatively the patient was in an excellent condition with undetectable thyroglobulin levels and negative antithyroglobulin antibodies. The second patient, a 54-year-old woman with a known history of Hashimotos' disease, presented with an ultrasonographic 13 mm-thyroid nodule, with irregular margins and microcalcifications. The subsequent FNA cytology showed papillary thyroid carcinoma (PTC), probably a tall cell variant (TSB VI). The patient underwent a total thyroidectomy and the pathology revealed a WL-PTC. Ablation radioiodine treatment was offered and suppression levothyroxine treatment was started.
Discussion
Both variants have a female preponderance with a middle-aged occurence and are usually associated with lymphocytic thyroiditis. HTT incidence is not known, but it is considered to be a rare thyroid neoplasm with a characteristic trabecular growth pattern and hyalinization. In FNA thyroid samples HTT shares nuclear features of PTC, so that it is usually diagnosed only after thyroidectomy. Cell membrane and cytoplasmic positivity for Ki67 and somatic GLIS rearrangement, especially PAX8-GLIS3, are characteristic of HTT. The majority of these tumors is noninvasive and considered to be benign, nevertheless distant metastases have been reported. WL-PTC is a rare histological variant of papillary carcinoma with a similar prognosis to the classical PTC. Histopathologically it resembles the Warthin tumor of salivary glands. While at first it was considered a subtype of the oncocytic variant of PTC, it is now reclassified as a separate PTC variant.
Conclusion
Despite their rareness, both HTT and WL-PTC might be clinically encountered. They are generally considered to have a benign clinical behavior. More information regarding long-term courses is needed, in order to properly treat such patients and avoid unnecessary therapies

Radioactive iodine therapy with recombinant human TSH (rhTSH) for well-differentiated thyroid cancer had no difference in GO outcome; case report

Sevgul Faki[1], Serdar Deniz[1], Burçak Cavnar Helvacı[1], Çağlar Keskin[1], Burçak Polat[2], Nilay Yüksel[3], Şeyda Türkölmez[4], Oya Topaloğlu[2], Reyhan Ersoy[2] & Bekir Çakir[2]

[1]Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Yildirim Beyazit University, Faculty of Medicine, Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara Yildirim Beyazit University, Faculty of Medicine, Ankara City Hospital, Department of Ophthalmology, Ankara, Turkey; [4]Ankara Yildirim Beyazit University, Faculty of Medicine, Ankara City Hospital, Department of Nuclear Medicine, Ankara, Turkey

Background
The risk of cancer is relatively higher in Graves' patients presenting simultaneously with thyroid nodules. Radioiodine (RAI) therapy recommended in intermediate-high risk differentiated thyroid carcinoma may be associated with worsening of a pre-existing Graves' orbitopathy (GO) or developing a new onset. The impact of RAI therapy in patients with differentiated thyroid cancer on the course of a pre-exisiting GO has not been specifically investigated. we report a sever GO patient treated by recombinant Tsh (RhTSH) for intermediate-risk of papillary thyroid cancers (PTC).
Case
A 47-year-old man, presented to our center with exophthalmos and ptosis of eyes. His thyroid function tests and thyroid autoantibodies were as follows: TSH; 0.01 (0.4–4 uIU/ml), FT3; 5.41 (1.6–4.9 pg/ml), FT4; 1.74 (0.78–1.76 ng/dl); anti TPO was positive TSH-R Ab; 1.249. On the ultrasonographic examination of the thyroid gland the paranchyme was heterogeneous and in the right lobe 11.2 × 8.9 mm heterogeneous, iso-hyporechogenic nodule and pathologic lymphadenopathy were detected in levels 4 of neck. US-guided fine-needle aspiration biopsy was performed and the cytological examination were suspicious for papillary thyroid cance of the nodule and malign sitology of the lymph node. Computed tomography scan of orbita demostrated bilateral anterior bulging of bulbus oculi clearly and bilateral enlargement of medial, inferior and superior rectus muscles and also swelling of the optic nerve. In addition to antithyroid and beta blocker, for severe ophthalmopathy intravenous pulse therapy with high doses of methylprednisolone as 500 mg tapered in 24 weeks duration, followed by 250 mg for 24 weeks. He underwent thyroidectomy and a dissection of the santral and right lateral lymph nodules was conducted. The diagnosis were PTC with < 5% of hobnail variant and mestatic lymph nodules was confirmed. Once stabilized of GO under oral methylprednisolone and became euthyroid he reseved 150 mCi RAI with rhTSH with no changes in GO after One month observation.
Discussion
The risk of cancer is relatively higher in Graves' patients in the presence of an accompanying nodular disease. Moreover, some authors reported that thyroid cancer associated with GD seemed to be more aggressive. RAI therapy is recommended in high-risk differentiated thyroid carcinoma, but it might worsen or induce a new onset of GO. Glucocorticoid treatment should be given especially in patients who will receive high doses of RAI. RAI with rhTSH had no difference in GO outcome at first month.

Are the outcomes that matter most to persons with thyroid dysfunction in Malaysia the same as in other populations in developed countries?

Cheow Peng Ooi[1,2], Abdul Hanif Khan Yusof Khan[1], Rosliza Abdul Manaf[1], Sharifah Mohd Nor[1], Norlela Sukor[2], Norlaila Mustafa[2] & Nor Azmi Kamaruddin[2]

[1]Universiti Putra Malaysia, Department of Medicine, Faculty of Medicine and Health Sciences, Serdang, Malaysia; [2]Pusat Perubatan Universiti Kebangsaan Malaysia, Endocrine Unit, Department of Medicine, Faculty of Medicine, Kuala Lumpur, Malaysia

Background
The burden of disease in thyroid dysfunction (TD) is modifiable. Social domain of quality-of-life is a vital aspect of the biopsychosocial approach to management. Treatment decisions are increasingly guided by quality-of-life issues, creating a need to monitor the quality-of-life within clinical practice. Thyroid-specific patients reported outcomes scale/tool (ThyPro) was developed and used predominantly in populations in developed countries. Whether this tool can capture the important social domains of quality-of-life in patients with chronic multi-morbid TD in diverse cultures, e.g., South-east Asia, is uncertain. We aimed to compare the findings from our quality-of-life qualitative research project of persons with TD in Malaysia to those in the ThyPro tool study.
Methods
The questionnaires of a Malay language version of the semi-structured qualitative survey in Malaysia, part of the larger research: A CORE OUTCOME SET FOR THYROID DYSFUNCTION[1], were developed from interactive discussions with patients who have thyroid dysfunction. A mixed-method approach was used to collect the data: face-to-face in-depth interviews in the endocrine clinic and online survey using the same set of questionnaires. The responses were analyzed using Braun and Clark's thematic analysis[2] framework guided by the question: What are the perceptions and experiences of thyroid care that matter most to patients with TD? The findings were then compared with the items in the ThyPro scale.
Findings
There was no significant difference in the baseline demographic characteristic of our subjects in comparison to the ThyPro cohort (Table 1). The only marked difference is that our study participants have TD of prolonged duration compared with the recent onset in the ThyPro cohort. Major themes that emerged from our analysis are emotional security, functional ability, self-care (including psychosocial and socioeconomic well-being), and quality of physician-patient relationships (Details in Table 2). Symptoms of hyperthyroidism and hypothyroidism impacted upon all the above themes. All the items in the ThyPro scale are present in our cohort. However, health-service factors emerged as an important parameter in our population and are absent from the ThyPro scale.
Conclusion
Our study can capture all the items in patients with recent and chronic TD, unlike the ThyPro scale that captures only outcomes in patients with recent TD. Further robust research is required to determine whether the additional important patient-reported outcomes in populations with varying duration of TD and diverse cultures impact the development of core outcome set for thyroid dysfunction.

A case report of metastatic adrenocortical carcinoma

Dayssem Khelifi, Iadh Ksira & Hedi Krifa
Department of neurosurgery, Sahloul University Hospital, Tunisia

Introduction
Adrenocortical carcinoma is a rare neoplasm with local development, rarely metastatic in the spine. We report a case of metastatic dorsal spinal cord compression due to adrenocortical carcinoma.
Observation
A 38-year-old lady with no notable medical history, complained of generalised weakness, severe abdominal pain and spasms. Abdominal computed tomography showed a large right adrenal renal mass measuring 127 * 118 mm infiltrating the tendon center of the diaphragmatic pillar pushing back up the liver and down the kidney with loss of the fatty border. She did not have any signs of hypercortisolism or virilisation. Serum potassium level, oestradiol, testosterone, serum cortisol and 24 h urinary metanephrine were within normal limits. Per operatively, the tumour was free from the kidney and entire adrenal mass was removed with adequate resection margin. Histological examination made the diagnosis of malignant adrenocortical carcinoma. Three days after surgery, she complained of rapidly progressive and continuous back pain, and a sudden heaviness in both limbs. Physical examination revealed proximal paraplegia of the two lower limbs, pyramidal syndrome and hypoaesthesia with a T3 sensory level. A spinal magnetic resonance imaging was performed in emergency visualizing a progressive spinal cord compression secondary to the epidural component of the T3-T4 mass. Decompressive laminectomy and resection of endoluminal tumor material were performed urgently. Histological examination was in favor of spinal metastasis from adrenocortical carcinoma.
Conclusion
Spinal metastasis of adrenocortical carcinoma is exceedingly rare with only few cases having been reported previously. This case highlights the rapid and agressive nature of non-secreting adrenocortical carcinoma causing metastatic dorsal spinal cord compression.

Screening for subclinical Cushing's Syndrome in Malaysians with metabolic syndrome: A single center, cross-sectional study

Eunice Lau[1,2] & Zanariah Hussein[1]
[1]Putrajaya Hospital, Endocrinology, Federal Territory of Putrajaya, Malaysia; [2]University of Malaya Medical Centre, Endocrinology, Kuala Lumpur, Malaysia

Background
Patients with Subclinical Cushing's Syndrome (SCS) share many similarities with those of metabolic syndrome. Several studies have shown variable prevalence of SCS in patients with diabetes and obesity of up to 9% suggesting that it may be more common in these patients. Our study aims to explore the prevalence of SCS in Malaysians with metabolic syndrome and examine any possible predicting factors.
Methods
This is a cross-sectional single center study at a tertiary referral hospital of 147 patients in outpatient diabetes and obesity clinics who fulfil the criteria for metabolic syndrome and do not have any discriminatory features of Cushing's syndrome (facial plethora, easy bruising, proximal myopathy and reddish or purple striae measuring > 1 cm). Patients were screened with the 1 mg overnight dexamethasone test (ODST), followed by the 48-h 2 mg low dose dexamethasone test (LDDST), using cut-offs of 50 nmol/l for both tests.
Results
Six patients had a non-suppressed ODST result and only 1 patient had both non-suppressed ODST and LDDST. Hence, the prevalence of SCS was 0.7% in this study. There were no statistically significant differences between suppressors and non-suppressors on ODST testing.
Conclusion
Based on the results of this study we do not recommend routine screening for SCS in patients with metabolic syndrome in absence of clinical suspicion.

Bilateral primary adrenal lymphoma: a case report

Sawsen Essayeh, Bel Hadj Sliman Chayma, Sabrina Ayari, Najla Bchir, Zouaoui Chedia & Haroun Ouertani
The Military Hospital of Tunis, Endocrinology-Nutrition, Tunis, Tunisia

Introduction
Primary adrenal lymphoma (PAL) are rare extranodal lymphomas and account for<1% of all non-Hodgkin lymphomas, with characteristic clinical features including high incidence of bilateral involvement, predominantly diffuse large B-cell histology, and low incidence of extra-adrenal disease at diagnosis. We report a case of 50-year-old patient affected by bilateral B-cell adrenal lymphoma.
Case presentation
A 50-year-old woman was admitted for exploration of suspicious bilateral adrenal incidentalomas. History of the disease dates back to February 2020, marked by the onset of recurrent urinary tract infection. Abdominal ultrasound showed two right and left adrenal masses measuring respectively 9 and 10 cm. There were no hyperpigmentation, no touchable lymph nodes, no abdominal mass, untouchable liver and spleen and no breast nodule at physical examination. Computed Tomography (CT) showed oval hypodense right and left adrenal masses, with limited contours measuring respectively 66 * 90 mm and 100 * 81 mm, with average spontaneous density of 43UH and 42UH, and absolute washout at 33% and 27%, slightly enhanced after injection of contrast product, heterogeneous with necrosis and without calcifications. Biology revealed microcytic hypochromic anemia with normal ferritinemia, elevated levels of erythrocyte sedimentation rate at 80 mm (reference: 25 mm/h), C-reactive-protein (CRP) at 51 mg/l (reference<6) and lactate dehydrogenase (LDH) at 400 UI/l (0–247). Morning plasma cortisol was low at 133 nmol/l (185–624 nmol/l), Adrenocorticotropin (ACTH) was increased at 470 pg/ml (reference<46 pg/ml). The patient was treated with hydrocortisone. Serum catecholamines, plasma renin activity, aldosterone, testosterone and dehydroepiandrosteone sulfate (DHEA-S) were normal. β-microglobulin was slightly elevated at 3.51 mg/l (1.42–3.21 mg/l). Serum tumor markers were normal. Thoraco-abdomino-pelvic CT showed right thyroid nodule with no other lesions especially no lymphadenopathy. Biopsy of left adrenal mass revealed a diffuse lymphomatous proliferation partially necrotic. Cells are large with a rounded or ovoid nucleus strongly nucleolated. Immunohistochemestry showed that cells were CD20(+), Pax5(+), CD3(−) and CK(−). Cell proliferation index (Ki67) was 90%. The diagnosis of diffuse large B-cell lymphoma was made. The patient presented an acute adrenal decompensation related to macrophage activation syndrome. Broad-spectrum antibiotics and dexamethasone were administrated with a good clinical course. After chemotherapy, the patient presented a tumor lysis syndrome with septic shock and acute respiratory distress syndrome and she died.
Conclusion
PAL is rare and prognosis is generally poor. More studies are needed in the future to identify the predictors of good clinical and radiological response to therapy.

Successful spontaneous pregnancy and successful delivery in a patient with severe 11-beta hydroxylase deficiency

Ahmet Suat Demir[1], Şafak akın[2], Damla Tufekci[1], Yasemin Emur Gunay[1], Muhammet Cuneyt Bilginer[1], Ozge Ucuncu[1], Hulya Coskun[1], Irfan Nuhoglu[1] & Mustafa Kocak[1]
[1]Karadeniz Technical University Faculty of Medicine, Department of Endocrinology and Metabolism, Trabzon, Turkey; [2]University of Health Sciences, Gulhane Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey

Objective
11-Beta Hydroxylase deficiency (11ß0HD) is a rare form of congenital adrenal hyperplasia, resulting in glucocorticoid deficiency, virilization and hypertension. In the literature, there are rare case reports of successful pregnancy in a patient with genetically confirmed classic 11ß0HD.
Case
Our patient, now age 31, was diagnosed at birth with ambiguous genitalia. There was no family history of any intersex disorder. Deafness was detected when she was 8 months. She was commenced on hydrocortisone. She had a homozygous CYP11B1 gene mutation [NM_000497.3, p.L299P (c.896T>C)]. She underwent surgery, when she was four and 24. She has

had hypertension for 19 years. She has used spironolactone intermittently. She had a spontaneous pregnancy four years ago. She was commenced methylprednisolone 4 mg in morning and dexamethasone 0.5 mg in evening in the first six months of her pregnancy. In the last 3 months, she used hydrocortisone 30 mg/day. Laboratory results are shown in Table 1. During the pregnancy her blood pressure was normal and ultrasound showed a female foetus. Elective caesarean section was performed at 34 weeks of gestation. She delivered a healthy female baby, with a birth weight of 2.750 g and with normal external genital. Her blood pressure was 160/100 mmHg six months after delivery and amiloride treatment was given. In the genetic examination of the family, the mother, father, two brothers and daughter were heterozygous positive for 11-Beta Hydroxylase deficiency, and her husband was normal. Now, she is taking hydrocortisone 20 mg/day.

Conclusion

There is limited knowledge in current literature regarding pregnancies in patient with 11ßOHD. Information on the disease is limited to case reports only.Our patient is the first report of a spontaneous successful pregnancy and successful delivery with 11ßOHD in Turkey.

Acquired hypoaldosteronism as classified by circulating aldosterone levels: characteristics

Jorge Gabriel Ruiz Sánchez[1,2,3], Mario Pazos[1], Xavier Pérez Candel[1], Martín Cuesta Hernández[1], Emilia Gomez Hoyos[4], Maria Paz De Miguel Novoa[1], Victoria Saez de Parayuelo[1], Alfonso Calle[1] & Isabel Runkle[1]
[1]Hospital Clinico Universitario San Carlos, Endocrinología y Nutrición, Madrid, Spain; [2]Instituto de Investigación Sanitaria San Carlos (IdISSC), Madrid, Spain; [3]Hospital Universitario Fundación Jiménez Díaz, Endocrinología, Madrid, Spain; [4]Hospital Clínico Valladolid, Endocrinología y Nutrición, Valladolid, Spain

Acquired Hypoaldosteronism may be caused by low circulating aldosterone levels (AD), resistance to mineralocorticoid action (MR), or a combination of both (CB). We describe the clinical/biochemical characteristics of these three types of hypoaldosteronism.

Methods

Retrospective review of a series of 177 patients with acquired hypoaldosteronism assessed by the Endocrinology Department of a tertiary teaching hospital from 2012 to 2019. We analyzed serum and urine markers of cases in which serum aldosterone (PAC) and direct renin concentration (PRC) levels were available coinciding with hyperkalemia: serum Potassium (SK) ≥5 mmol/l. Cases were classified as follows: AD: PAC <90, MR: PAC >200, or CB: PAC 90–200. PAC, PRC by Radioimmunoassay, in pg/ml. Serum/urine electrolytes in mmol/l. Mean ± S.D.

Results

51 cases analyzed, 27 (52.9%) male, age 73 ± 12 years. 30/51 were hypovolemic, 25 of whom (83.3%) presented hyponatremia. 30/51 were hyponatremic, 25/30 presenting hypovolemia. Hypovolemia was associated to hyponatremia (P<0.001). 17/32 in whom acid-base status was evaluated presented hyperchloremic metabolic acidosis (HMA). Results by group given in Table 1. No correlations were found between PAC and SK or trans-tubular-potassium gradient (TTKG) in any group, nor when all patients were grouped together (ALL). In ALL, there was a negative correlation between TTKG and urine sodium (UNa) (r= **–0.333,** P=**0.041**), TTKG and UNa/urine potassium (UK) ratio (r= **–0.725**, P<**0.001**), PAC and UNa (r= **–386**, P=**0.007**), PAC and Serum sodium (SNa) (r= **–346,** P=**0.013**), and PAC and UNa/UK ratio (r= **–0.355,** P=**0.014**).

Conclusions

In our series of patients, most hypovolemic patients presented hyponatremia. In the absence of concomitant measurement of circulating aldosterone levels, discerning the pathogenesis of hypoaldosteronism is difficult. However, higher UNa and UNa/UK levels were observed in cases of aldosterone deficit. Furthermore, marked hyponatremia may suggest mineralocorticoid resistance.

Table 1. Clinical/Biochemical characteristics of the types of acquired hypoaldosteronism.

	AD (n=28)(54.9%)	MR (n=9)(17.6%)	CB (n=14)(27.5%)	P

Acute respiratory distress syndrome in a patient with new onset Addison's disease

Tasneem Ladha, Zaib Hilal, Dhruti Hirani, Maura Moriarty, Vassiliki Bravis & Tannaz Vakilgilani
Imperial College Healthcare NHS Trust, St Mary's Hospital Endocrinology, London, UK

Primary adrenal insufficiency, Addison's disease, is a rare endocrine disorder. Early diagnosis is often difficult and the presentation is commonly only recognised after a life threatening adrenal crisis. Fortunately, with appropriate early treatment further complications are uncommon in the acute setting. This case concerns a 19-year-old man who presented with lethargy, dyspnoea on exertion and a one month history of hyperpigmentation. He had a history of nocturnal enuresis for which he was taking desmopressin. On examination he had tanned skin, buccal pigmentation and borderline hypotension. Admission bloods revealed hyponatraemia and hyperkalaemia. After establishing a working diagnosis of first presentation with Addison's disease, treatment was started including fluid resuscitation and intravenous hydrocortisone. The diagnosis of primary adrenal insufficiency was supported by inadequate response on short synacthen test and positive adrenal cortex antibodies. Two days after admission he developed sudden onset respiratory distress and hypoxia. Bi-basal crepitations were present. CTPA reported bilateral predominantly central ground glass and confluent opacities with no evidence of pulmonary embolus. Of note there was CT evidence of right heart strain. An echocardiogram showed good systolic function with estimated ejection fraction 60–65%. Pulmonary artery pressures were elevated. COVID-19 throat swab was negative. Troponin was mildly elevated though ECG showed sinus tachycardia with no ischaemic changes. He rapidly improved with CPAP for several days. Further endocrine investigations confirmed the diagnosis of primary adrenal failure (0900 h ACTH levels 688 ng/l (reference range <30 ng/l), aldosterone levels <60 pmol/l (reference range 90–700 pmol/l), grossly atrophic adrenals on CT). He was successfully converted to oral therapy prior to discharge. The reason he developed acute respiratory distress syndrome (ARDS) following treatment of adrenal insufficiency remains unknown. A literature review conducted to identify links between cases of Addison's disease and ARDS reports few cases. One (1) presented a very similar, though more severe, history and course of

illness. For our patient, previous desmopressin use may have been a contributor, exacerbating the rapid changes in fluid balance as steroid deficiency was corrected. This case highlights a rare, though potentially life-threatening, complication of acute adrenal crisis and the necessity for increased awareness of such cases among treating physicians.

Addison's disease and type 2 diabetes

Wajdi Safi, Dhoha Ben Salah, Sidina Mohamed Elmoctar, Mohamed Abdallahi Mohamed Ahmed, Nadia Charfi, Fatma Mnif, Nabila Rekik, Mouna Mnif, Faten Hadj Kacem & Mohamed Abid
Hedi Chaker Hospital, Endocrinology, Sfax, Tunisia

Introduction
Recent studies in patients with Addison's disease (AD) have shown that this condition, even if treated, is fraught with significant morbidity. In this context, we report a retrospective study which concerned 32 patients with AD in order to determine the deleterious effects of long-term glucocorticoid substitution, mainly on the occurrence of type 2 diabetes.
Results
In the 32 patients followed during this study, the average fasting blood sugar level at the discovery of the disease was 4.8 mmol/l. After an average of 17 years of follow-up (range 5 and 38 years) 25% of the patients had developed type 2 diabetes. At the last consultation, almost half of the patients (42.8%) were on insulin with a dose average of 0.66 IU/kg per day. Diabetes was unbalanced in 85.7% of cases with an average fasting glucose of 9.22 mmol/l and an average HBA1c of 10.01%. The impact assessment showed retinopathy and diabetic nephropathy in 25% of patients for each.
Discussion
In the literature, a higher risk of glucose intolerance or even diabetes has been noted during treated AD. This is because patients treated with hydrocortisone have higher cortisol concentrations than physiologically, especially in the afternoon. This reduces glucose tolerance, insulin sensitivity and secretion in these patients. This effect is proportional to the dose of hydrocortisone without correlation with the duration of the disease.
Conclusion
Adjustment of replacement therapy during Addison's disease is an issue in view of the morbidity and mortality associated with overdose. Regular monitoring and a personalized therapeutic approach are necessary to improve the prognosis of his patients.

EP8

Very large adrenal nodule and Cushing syndrome – when histology differs from the clinical suspicion

Mariana Lavrador, Carolina Moreno, Luísa Barros & Isabel Paiva
Centro Hospitalar e Universitário de Coimbra, Endocrinology Department, Coimbra, Portugal

Introduction
The malignancy risk of an adrenal nodule is based on clinical symptoms (rapid onset of hypercortisolism and hyperandrogenism; mass symptoms) and imaging characteristics. These suspicious criteria include boundary irregularities, heterogeneity, dimension>6 cm and density>20 HU (CT). However, these are not absolute criteria.
Case report
We report the case of a 43 years-old female patient with a history of alopecia, decrease in muscular strength, secondary amenorrhea, and easy bruising with 4 years of evolution. Arterial hypertension, diabetes *mellitus* and dyslipidemia were diagnosed 1 year after. A 20 kg weight gain during the previous 6 months and the appearance of abscessed skin lesions 2 months ago were also refered. Physical examination showed exuberant hypercortisolism. Analytical study revealed the presence of an ACTH-independent Cushing Syndrome: morning and midnight ACTH levels <5 pg/ml (9–52); morning and midnight serum cortisol of 19 and 18 µg/dl (5–25); urine-free cortisol of 841 µg/24 h (10–80); salivary midnight cortisol of 1.7 µg/dl (<0.1); and cortisol of 19 µg/dl after low-dose dexamethasone suppression test. The patient performed an adrenal CT that revealed, in the left adrenal gland, the presence of an 8.3×6.3 heterogeneous nodule with cystic areas, calcifications, without cleavage plan with stomach and spleen and without infiltrative aspects. Based on the high suspicion of adrenal carcinoma, the patient started therapy with ketoconazole 400 mg a day and was referred to adrenalectomy. Histological exam showed a 9 cm adrenal cortex neoplasm with score 1 in modified Weiss criteria (necrosis, reticulin pattern, and Ki<5%). This was compatible with a benign tumour. The patient maintains follow-up under replacement therapy with hydrocortisone, anti-hypertensive and anti-hyperglicemic drugs in progressive reduction. The patient also presents significant improvements in her morphotype, with a relevant weight loss of 27 kg in 5 months.
Conclusion
Imaging results (dimension> 8 cm, heterogeneity and calcifications) raised the suspicion of carcinoma. ACTH independency was also suggestive, as cortisol is the most frequent hormonal secretion associated with malignancy, as well as the age and female sex. However, the slow progression of the disease was a factor that disfavour this hypothesis. Although these imaging signs are more often associated with an aggressive behaviour, only histological results define the exact type of the lesion.

Pheochromocytoma of urinary bladder: a case report

Maatougui jasser[1], Raboudi Mehdi[1], Chayma Besrour[2], Zouaoui Chadia[2], Khiari Ramzi[1], Ouertani Haroun[2] & Ghozzi Samir[1]
[1]The Military Hospital of Tunis, Urology, Tunis, Tunisia; [2]The Military Hospital of Tunis, Endocrinology, Tunis, Tunisia

Background
Paraganglioma of the urinary bladder is rarely encountered. Its clinical signs and symptoms are usually nonspecific.
Case presentation
We report a case of a 48-year-old woman who presented with recurrent hematuria for last 2 months with a recently detected hypertension. Computed tomography (CT) revealed a lobulated mass arising from the posterior wall of the urinary bladder and protruding into the vesical lumen measuring 3 cm with inhomogeneous postcontrast enhancement. Transurethral resection of the mass has instantly produced a hypertensive peak (200/110 mmHg) leading to an interruption of operation. Pathology of the specimen found a pheochromocytoma. Our patient denied a history of dizziness, sweating, and palpitations during micturition. Hormonal evaluation showed a normal level of both plasmatic and urinary metanephrine and normetanephrine. Metastatic workup was negative. Both adrenal glands were normal at CT. MIBG scan showed an increased localized activity in the bladder. After preoperative stabilization of hypertension and medical preparation, a complete transurethral resection of the tumor was performed. This case was discussed at a tumor board meeting and surveillance was decided. The patient has been disease-free for 9 months.
Conclusion
In patients with unusual, striking symptoms and an increase in blood pressure with micturition, diagnosis of pheochromocytoma of the urinary bladder must be considered. Imaging will help in confirming the diagnosis and localizing the tumor. Surgical removal is the treatment of choice.

Adrenal tumors and mixed secretions

Elleuch Mouna, Hana Charfi, Ben Salah Dhoha, Safi Wajdi, Rekik Nabila, Mnif Fatma, Charfi Nadia, Mnif Mouna, Hadj Kacem Faten & Abid Mohamed
Hedi Cheker, Endocrinology, Tunisia

Introduction
Adrenal tumors represent an increasingly common problem in modern endocrine practice. The diagnostic approach can be challenging and occasionally reveals surprising features like mixed hormonal secretion: aldosterone-and-cortisol producing adenoma. This rare situation can also impact on the therapy and the post-operative management. In this context, we report 5 patients who are followed in the Endocrinology department in Hedi Chaker hospital, sfax, Tunisia for adrenal mixed tumors.

Purpose
The aim of our study was to describe the clinical and data of these patients and monitor their evolution after appropriate treatment.
Methods
A retrospective study of patients who have cortico and or medullary mixed tumors.
Results
We objected Aldosterone- and cortisol-co-secreting tumors in four cases and corticomedullary mixed tumors in one case. All patients were female aged between 42 and 76 years old, and the average age was 59 years old. No particular family medical history was found. All patients had hypertension and type 2 diabetes. Obesity was described in one case and overweight in the others. Two patients were referred to our departement for adrenal incidentaloma, 2 for recent and resistant hypertension and 1 for hypokaliema. Medical examination revealed high blood pressure in one patient and cushing manifestation in one patient. No neuromuscular signs nor paroxysmal seizures were noted. Laboratory finding revealed hypercortisolism in all patients associated to hyperaldosteronism in 4 cases and catacholamine excess in one case. Adrenalectomy was performed to all patients without incidents. Histopathological study revealed 1 case of corticomedullary adenoma, 3 cases of mixed adrenocortical adenoma and one case of myelolipoma associated with mixed adrenocortical adenoma. After a follow up of 7 years, patient with corticomedullary adenoma showed multiple cardiovascular incidents. These incidents were myocardial infarction, ischemic stroke and peripheral arterial occlusive disease. An Uncontrolled diabetes was also noted during her monitoring. In the other patients with co-secetion cortisol and aldosterone, 3 patients had steady evolution after 1.5 years of follow up. However, one patient developed contralateral adrenal adenoma.
Conclusion
Mixed adrenal adenoma are rare. The clinical suspicion of cortisol co-secretion by an APA and corticomedullary adenoma can be confirmed bay hormones tests. In addition, a more detailed histological and molecular work-up of such lesions may inform us on additional ways of development of adrenal autonomy.

A 14 cm nonfunctioning left adrenocortical carcinoma in an adult man: a case report

Maatougui jasser[1], Raboudi Mehdi[1], Chayma Besrour[2], Zouaoui Chadia[2], Khiari Ramzi[1], Ouertani Haroun[2] & Ghozzi Samir[1]
[1]The Military Hospital of Tunis, Urology, Tunis, Tunisia; [2]The Military Hospital of Tunis, Endocrinology, Tunis, Tunisia

Background
Adrenocortical carcinoma is a rare endocrine malignancy, with an unfavorable prognosis. Radical adrenalectomy is the gold standard for localized disease.
Case presentation
We report a case of a 47-year-old male with left abdominal pain and sensation of discomfort. Our patient didn't present classical tumor symptoms, such as cachexia or night sweats. Computed tomography revealed a left heterogeneous retroperitoneal enhancing adrenal mass measuring 17 cm, with high density (30 Hounsfield units), smooth margins, and a wash-out <60%. Hormonal evaluation was negative, with normal ACTH and cortisol level. Suppression test was negative. Measurement of plasma renin activity and serum aldosterone levels showed no abnormalities. Plasmatic metanephrine and normetanephrine was also normal, excluding a pheochromocytoma. Open left adrenalectomy was performed by sub-costal approach. Pathology confirmed the diagnosis of adrenocortical carcinoma with positive microscopic surgical margins. Metastatic workup was negative. This case was discussed at a tumor board meeting. Adjuvant treatment by mitotane was not recommended. The patient has undergone a regular follow-up and has been disease-free for 6 months.
Conclusion
Adrenocortical carcinoma is a diagnosis challenge. Surgery remains the main treatment. A multidisciplinary management should be offered in those cases.

Clinical, imaging and laboratory features of patients with adrenal incidentaloma referred to a tertiary medical center in recent years and a comparison with a historical institutional cohort

Hadar Yaacov[1], Gloria Tsvetov[1,2], Sigal Levy[3,4] & Dania Hirsch[1,2]
[1]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [2] Rabin Medical Center – Beilinson Hospital, Department of Endocrinology, Petach Tikva, Israel; [3]The Academic College of Tel Aviv Yaffo, Statistical Education Unit, Tel Aviv Yaffo, Israel; [4]Tel Aviv, University, Sackler Faculty of Exact Sciences, Tel Aviv, Israel

Background
The term adrenal incidentaloma (AI) refers to the existence of an asymptomatic adrenal mass that was detected at random in an imaging test performed not in order to evaluate the adrenal glands. In recent years, the use of imaging tests has increased, and the resolution of the imaging studies has been improved. This trend may affect the characteristics of AIs at the time of diagnosis.
Objective
Investigating the demographic, clinical, imaging and laboratory characteristics of patients with AI who were referred to the Endocrine Institute at the Rabin Medical Center in the recent years and comparing the findings with data collected from consecutive patients referred to the same institute between 1995 and 2005.
Research Methods
The research was conducted at the Endocrine Institute at Rabin Medical Center. The study's design is retrospective-comparative. Demographic, clinical, imaging and laboratory features of 191 consecutive patients who were referred to the Endocrine Institute with AI over the years 2005–2016 years were retrieved from the computerized files, analyzed and compared with 100 patients referred for investigation between 1995 and 2005.
Results
The patients' average age at diagnosis was 61.6 (median 62), and female patients constituted 62.3% of the cohort (119/191). The average size of the mass at presentation was 23 ± 12.2 mm (mean 20). Most patients (169/191, 88.5%) underwent an additional imaging test during a follow-up of 4.5 ± 3.3 years. In 52 patients (27.2%), a change in the diameter of the mass at the end of the follow-up period was reported. The Incidence of left AIs was higher more than twice than right adrenal masses (59.1% vs. 28.3%) and bilateral masses were demonstrated in 12.5%. The rate of functional tumors was 14.6% and most of them (25/28, 89%) were cortisol-secreting. A known diagnosis of a malignancy at time of the detection of AI was present in 29.3% of the patients, diabetes in 35.6%, hypertension in 59.1% and obesity in 30.9%. Adrenalectomy was performed in 17 patients (8.9%) of whom a primary adrenal malignancy was diagnosed in two. In comparison to the results from the previous study on patients diagnosed with AI during the years 1995–2005, we did not find differences in the age of the patients and their underlying conditions or the characteristics of the adrenal mass.
Conclusion
The clinical features of patients diagnosed with AI and the imaging characteristics of the adrenal mass have not been changed significantly in recent years.

[1]Hospital CUF Descobertas, Endocrinology Department, Portugal; [2]Hospital CUF Descobertas, High Risk Obstetrics Department; [3]Hospital CUF Descobertas, Internal Medicine Department; [4]Hospital CUF Descobertas, Anaesthesiology Department; [5]Hospital CUF Descobertas, Neonatology Department; [6]Hospital CUF Descobertas, Surgery Department

Introduction
Pheochromocytoma(PHEO) occurs in pregnancy with an estimated incidence of 0.007%. Its rarity and overlapping presentation with other pregnancy-related hypertensive disorders make the diagnosis really challenging. If left unrecognized, may result in increased maternal and fetal mortality. There are no guidelines on approaching PHEO during pregnancy. This case highlights the difficulties encountered in managing this condition in pregnancy.

Clinical case
A 33-year-old previously healthy female(G3P2) with clinical features of pulsatile headache and palpitations triggered by physical efforts, without hypertension, starting 4 months before conception, treated with antidepressants. She had a gestational diabetes *mellitus* history since the 11th week of gestation (WG) which was managed with diet and metformin. Until the 2nd trimester of pregnancy she was normotensive, however, her headaches worsened at 24thWG and related hypertensive peaks were reported (180/100 mmHg) from this time. Methyldopa was initiated at a starting dose of 250 mg, twice daily with a necessary increase to three times daily. Nevertheless, the clinical picture's worsening prompted further investigation at 36thWG. Laboratory data revealed elevated plasma metanephrine of 201 pg/m(<65) and normetanephrine of 1735 pg/ml (<196); elevated total urinary metanephrine of 10 605 µg/24 h(<785). MRI showed a right adrenal solid mass of 4.6×5.5 cm. She was admitted to the hospital and treated with phenoxybenzamine (increasing doses, 20 mg/day) followed by propranolol(40 mg/day) and nifedipine(10 mg, SOS). Methyldopa was suspended. Maternal dyspnea, chest pain, orthostatic hypotension accompanied by fetal distress emerged. On the sixth day of adrenergic blockade, at 38thWG, she went into spontaneous labour. A multidisciplinary decision (Endocrinology, Internal Medicine, Obstetrics, Anaesthesia, Surgery and Neonatology) was made to perform a caesarean section. Hypertensive peak (220/120 mmHg) was controlled with boluses of IV isosorbide-dinitrate. The newborn had an Apgar score of 10/10 (1`/5`) and was transferred to the intensive care unit (ICU) for surveillance. He was discharged 3 days after birth, without complications. Twenty days after delivery, the patient underwent an uncomplicated laparoscopic adrenalectomy. In the postoperative period she remained in the ICU for 11 days due to difficult to manage hypertensive peaks. Histopathology examination confirmed PHEO.
Conclusions
PHEO should be considered in pregnant patients presenting atypical/resistant hypertension despite treatment. Moreover, methyldopa may cause false high values in urine metanephrine levels, hampering the diagnosis. There are few reports in literature describing the antepartum difficulties in the management of these patients. We emphasize hypotension, decisions concerning timing/method of delivery and the appropriate surgical timing. A multidisciplinary team's commitment is of utmost importance.

Severe adrenal hemorrhage in a hypertensive patient, with high plasma aldosterone and metanephrines

Paula Maria Fernandez-Trujillo-Comenge, Alba Hernández Lázaro, Ricardo de León Durango, Agnieszka Kuzior, Manuel Esteban Nivelo-Rivadeneira, Ana Delia Santana-Suarez & Francisco Javier Martinez-Martin
University Hospital of Gran Canaria Dr. Negrin, Endocrinology and Nutrition, Las Palmas de Gran Canaria, Spain

Introduction
Severe hemorrhage is a rare and potentially lethal manifestation of adrenal gland nor usually associated with primary aldosteronism.
Material and methods
Review of the patient's clinical record and of the relevant literature.
Case report
A 47-year-old male with personal history of asthma, untreated stage II hypertension, obesity, dysphagia associated with diffuse esophageal spasm and head trauma with subdural hematoma (several years ago) came to the Emergency Room of our Hospital with sudden periumbilical pain radiating to the left renal fossa, after a strenuous exercise. He showed malaise, peripheral hypoperfusion, diaphoresis and high blood pressure. His renal function was previously normal but plasma creatinine in the ER was 1.6 mg/dl and the estimated glomerular filtration rate was 46.5 ml/min/1.73 m^2. The abdominal CT scan revealed a large (8 × 12 × 19 cm) retroperitoneal hematoma apparently flowing from the left adrenal which showed active bleeding, with a possible underlying lesion. The patient suffered anemization requiring successive blood transfusions plus continuous perfusion with solinitrine and urapidil to control blood pressure. The physical examination showed the persistence of high blood pressure and a painful left hemiabdomen with a rigid left flank. In the context of hemorrhagic shock, the lab tests showed: plasma aldosterone 657 pg/ml (PRA not available), potassium 3.48 mEq/l, metanephrine 165 pg/ml and normetanephrine 619 pg/ml. After hemodynamic stabilization aldosterone was 130 pg/ml, PRA 0.4 ng/ml/min and ARR 32.5; metanephrine 26 pg/ml and normetanephrine 76 pg/ml, with normal ionogram, TSH 4.18 µUI/ml and cortisol 16 µg/dl. A PET-CT scan ruled out adrenal malignancy. The patient developed hypertensive encephalopathy with hypertensive retinopathy, and persistence of the renal insufficiency associated to nephroangiosclerosis. He is presently being treated with carvedilol, doxazosin and amlodipine, with acceptable blood pressure control. A follow-up abdominal MRI showed partial persistence of the hematoma, and absence of an underlying adrenal lesion. Primary aldosteronism has not been ruled out, and a confirmation test after carvedilol withdrawal is scheduled.
Conclusion
Adrenal hemorrhage is infrequent, and has not usually been reported as a complication of primary aldosteronism. The rapid normalization of the plasma aldosterone and metanephrines after haemodynamic stabilization is also noteworthy, and reminds us that the diagnostic workup of primary aldosteronism and pheochromocytoma/paraganglioma must wait until the patient is stable.

Hiding in plain sight – a case of adrenal Cushing

Mihaela Rosu, Felicia Baleanu, Georgiana Taujean & Laura Iconaru
CHU Brugmann, Université Libre de Bruxelles, Brussels, Belgium, Department of Endocrinology, Bruxelles, Belgium

Bariatric surgery is increasingly deployed world-wide in patients with significant weight excess in order to mitigate the deleterious effects of associated metabolic and cardiovascular comorbidities. Pre-operative evaluation systematically investigates for possible causes of secondary obesity due to endocrine pathologies. In our hospital a standard blood test panel comprising the anterior hypophysis, the adrenal and the thyroid is requested as well as an endocrinological evaluation thereafter. We report the case of a 39-year old male patient with morbid obesity and relatively new-onset diabetes and hypertension. At the time of presentation (October 2020), he weighed 128 kg at a height of 173 cm, BMI 42.7 kg/m^2. The patient reported a weight gain of 37 kg during first half of 2020. The same year he was diagnosed with hypertension and a worsening of his diabetes. The hormonal profile revealed a cortisol in the normal range (212 nmol/l), a suppressed ACTH (1.7 ng/l), all other hormonal axes were in the normal range. A redo analysis confirmed the initial findings and at that moment the patient remembered being investigated several years ago for an adrenal mass, with unclear hormonal profile at the time but labelled as incidentaloma, hence probably hormonally inactive. An abdominal CT-scan in December 2020 demonstrated a mass in the left adrenal gland. Furthermore, both the low dose and the high dose dexamethasone suppression test showed no effect on the morning cortisol level (311 nmol/l and 375 nmol/l, respectively). A diagnosis of adrenal Cushing was established and the patient was referred for surgery. The mass was laparoscopically removed and the histological examination demonstrated a benign adenoma. Post-surgery a substitutive therapy with hydrocortisone adapted for the weight was instituted and an endocrinological follow-up was organized. No data concerning the weight curve at the time of writing this abstract was available. The current case emphasizes the importance of screening all candidates for weight-loss surgery for endocrinological cases of obesity as the therapeutic approach radically changes and missing a curable endocrinological cause may complicates the evolution post-surgery and hinders the results in terms of weight loss. The particularity of this case is the fact that the existence of the adrenal mass was already known but somehow flew under the radar all the while the predisposition to progress to a secretory state is well described in the medical literature.

Functional retroperitoneal paragangliomas: a case report

Wafa Benothman, Asma Ben Abdelkrim, Asma Gorchène, Ghada Saad, Amel Maaroufi, Maha Kacem, Molka Chaeib, Yosra Hasni & Koussay Ach
CHU Farhat Hached, Endocrinology Department, Sousse, Tunisia

Introduction
Paragangliomas (PGs) are rare tumors arising from sympathetic and para-sympathetic paraganglia with an incidence of 15–20%. We report a case of a pre-operative diagnosis of retroperitoneal PGs evoked on anatomic imaging confirmed by biochemical evaluation.

Observation
A 55-year-old female was referred to the endocrinology department for investigation of a paroxistic hypertension. For her personal medical history, she had a 15-year history of hypertension with hypertrophic obstructive cardiomyopathy (HCM). She was treated with calcium channel blockers, and angiotensin 2 receptor blockers but her hypertension was never controlled. She was receiving high doses of propranolol for her HCM. An abdominal computed tomographic (CT) scan done 3 years ago for abdominal pain revealed retroperitoneal mass; lymphoma was suspected and a biopsy was indicated but the patient was lost to follow-up. There was no significant family history. The patient complained of paroxysms of headache, sweating and palpitations associated with abdominal pain for over 15 years. On examination, she had a blood pressure of 220/120 mmHg with orthostatic hypotension. 24-h blood pressure measurement has confirmed the presence of paroxism up to 270/140 mmHg. Biochemical testing revealed an elevated plasma normetanephrines with normal metanephrines level. The abdominal CT examination revealed two left hypervascular retroperitoneal masses (43 mm and 65 mm) with left adrenal gland and abdominal aorta contact, consistent with PGs. MIBG scintigraphy revealed an uptake in the retroperitoneal space corresponding to the location of the masses. On the basis of all findings, the diagnosis of functional retroperitoneal non-metastatic PGs is made. Surgery is postponed after septal alcoholization for HCM.
Conclusion
Our case highlights the importance of including extra-adrenal PGs in the differential diagnosis of retroperitoneal tumors, despite their rarity. Definitive diagnosis requires a histopathological assessment and genetic testing as PGs were detected before the age of 50 years.

Biopsy in the diagnosis of bilateral pheochromocytoma

Barbora Havlinova[1], Eliska Mosnerova[2], Filip Gabalec[2], Jiri Horacek[2] & Jan Cap[2]
[1]University Hospital Hradec Kralove and Charles University, Faculty of Medicine in Hradec Kralove, 4th Department of Internal Medicine – Hematology, Hradec Kralove, Czech Republic; [2]University Hospital Hradec Kralove and Charles University, Faculty of Medicine in Hradec Kralove, 4th Department of Internal Medicine – Hematology, Hradec Kralove, Czech Republic

Pheochromocytoma is a rare neuroendocrine tumour usually formed in the adrenal medulla. Percutaneous biopsy has been associated with life-threatening haemorrhage, hypertensive crisis, capsular disruption with tumour implantation and death. We present a case of a 63 years old woman with non-specific clinical signs which included high blood pressure, headache, tachycardia and abdominal pain. She was treated for rheumatoid arthritis. Bilateral expansion of adrenal gland with delayed wash-out, on the right site 45 × 20 × 40 mm with cystic necrosis and 25 mm on the left site. In the liver there were unclear foci, not typical for a cyst or haemangioma. The radiological diagnosis was not clear. Therefore for fear of malignancy percutaneous biopsy under ultrasonic control was performed before the knowledge of metanephrine levels. Plasma metanephrines were available later. The level of metanephrine level was 0.45 nmol/l (normal range 0.06–0.31) and of normetanephrine was 4.64 nmol/l (normal range 0.1–0.61), respectively. Other screening tests done to exclude the other tumours that are connected to the inherited syndrome were negative. No mutation in RET proto-oncogene was found. Bilateral laparoscopic adrenalectomy was performed after pre-treatment with alpha-1 blocker Doxazosin. In this case, fortunately, complications related to the biopsy of pheochromocytoma did not occur. However, tumours suspected to be a pheochromocytoma or paraganglioma should not have a biopsy, unless it is absolutely necessary to confirm a diagnosis.

Clinical and endocrinological characteristics of adrenal incidentaloma in Algiers Center

Mouna Mezoued, Merrouche Amina, Mansour Fatiha & Azzouz Malha
Bologhine Hospital, Endocrinology, Algiers, Algeria

Adrenal incidentaloma (AI) is an adrenal mass discovered accidentally during abdominal or chest imaging techniques not aimed to adrenal gland assessment. Guidelines suggested confirming the benignity of AI radiologically and excluding hormonal dysfunctions. This study was designed to evaluate the clinical, endocrinological and histological characteristics of adrenal incidentalomas (AI).
Methods
Retrospective study of patient addressed to the endocrinology department at Algiers Hospital (Bologhine) for assessment of an incidentaloma from 2014 to 2018. In all, sixty patients were followed, involving 45 females and 15 males.
Results
Means age of population is 52 ± 30 years. Endocrinological evaluations demonstrated that 45% of total AI were non-functioning adenomas, 18% are cortisol production adenoma, including 13% with subclinical Cushing's syndrome. 15% as pheochromocytomas, and 1.66% as aldosterone-producing adenomas. The mean nodule size of AI based on computed tomography was 3.7 cm. 60% of the nodules are size under 4 cm, 11% size between 4 and 6 cm, and 28% upper 6 cm. it is noted that 88% of pheochromocytomas and 100% of adrenal carcinoma have a size of more than 4 cm. When to Compared to non-functioning adenomas (NFAs), tumor diameters were significantly larger in adrenocortical carcinomas (ACCs), pheochromocytomas, cortisol-producing adenomas (CPAs), myelolipomas, cysts,($P < 0.01$).
Conclusion
The occurrence of incidentally discovered adrenocortical carcinomas and pheochromocytomas is not rare. These data shows that an endocrine evaluation should be performed in all adrenal incidentalomas and Evaluation of the mass size and CT characteristics are asimple and effective methods to differentiate malignant lesions.

Correction of androgen deficiency in a woman with primary adrenal insufficiency. Clinical case

Nurana Nuralieva, Marina Yukina, Ekaterina Troshina & Yulia Absatarova
Endocrinology Research Centre, Moscow, Russian Federation

Introduction
There is no consensus about the necessity of dehydroepiandrosterone (DHEA) replacement in women with adrenal insufficiency (AI).
Methods
The woman aged 44 with medical compensation of autoimmune 1-AI, 1-hypogonadism, osteoporosis took DHEA (tablets of 50 mg in every morning) during 4 months. Concomitant therapy: hydrocortisone, fludrocortisone, drospirenone+estradiol, colecalciferol, calcium carbonate.
Results

	Units	Baseline	Day		Month

Aldosterone antagonist responsive hypokalaemia, hypercortisolism and colonic pseudo-obstruction

Suganya Giri Ravindran, Kaenat Mulla, Rahat Tauni & Razak Kehinde
Watford General Hospital, UK

Hypokalemia is a common and potentially fatal electrolyte disturbance, especially in hospitalised patients. Therefore, prompt assessment and management is vital to avoid serious complications. We report a case of 77 Year old gentleman with a background of Alzheimer's presenting with abdominal distension, intermittent diarrhoea and shortness of breath. He had normal blood pressure with no signs of Cushing syndrome but was found to have hypokalaemia. Plain imaging revealed dilated markedly distended bowel loops. CT pulmonary angiogram found bilateral pulmonary embolism, which was treated with apixaban. CT imaging also revealed colonic pseudo-obstruction and fat rich left adrenal nodule. Due to Type 1 respiratory failure, he required three days of intubation and ventilation. Hypokalaemia worsened requiring intravenous potassium replacement. His breathing and diarrhoea improved, but he had persistent hypokalaemia despite oral and intravenous potassium replacement. Flexi-sigmoidoscopy and partial thickness colonic biopsy was unremarkable. He was deemed unfit for colectomy due to his comorbidities. Endocrine biochemistry revealed raised 24 h urinary cortisol, non-suppressed cortisol after overnight dexamethasone suppression test and low renin and aldosterone. He had inappropriately normal 24 h urinary potassium, normal serum bicarbonate and magnesium. Addition of spironolactone and eplerenone normalised potassium levels. He has clinically improved and further testing is being performed to establish an endocrine diagnosis. The cause of hypokalemia in this case is unclear. The differentials include gastrointestinal or renal loss and the latter could be due to possible hypercortisolism. Irrespective of the cause, clinicians should consider treating hypokalaemia before a cause could be established in situations where hypokalaemia could be contributing to a potentially life threatening condition. It is also important to emphasize that patients have physiological hypercortisolism during periods of illness and hence endocrine testing must be repeated when the stress of illness is over.

Recurrence of ACTH-secreting bronchial carcinoid: a therapeutic challenge

Maria Batool[1], Vincent Young[2], John Mcdermott[1] & Seamus Sreenan[1]
[1]Connolly Hospital Blanchardstown, Dublin, Ireland; [2]St James's Hospital, Ireland

A man presented at age 32 with clinical features of Cushing's syndrome and biochemical investigations were consistent with ectopic ACTH. The only potential source on imaging was a 5 mm right lung nodule on chest CT but which was too small to biopsy. Medical therapy was not successful at controlling his Cushing's features so he was referred for thoracotomy. Following lobectomy, the lung nodule was found to be a carcinoid tumour. Post operatively, the patient's symptoms improved. He remained well for many years. 11 years later he represented with similar symptoms and recurrence of ACTH-dependent Cushing's syndrome was confirmed. A CT thorax, abdomen and pelvis revealed no abnormality but an octreotide scan suggested recurrence of disease a right infrahilar lymph node. He underwent lobectomy with lymphadenectomy for recurrent typical carcinoid in his mediastinal glands. Postoperatively, his symptoms improved. To date he has not shown any signs of recurrence and is doing very well. This case highlights the major diagnostic and therapeutic challenges associated with ectopic ACTH-secreting lesions. In addition, it points out the importance of long-term follow-up even after surgical resection and apparent cure of this condition.

Deficiency or insufficiency of vitamin D and the frequency of hypocalcemia episodes and the circadian rhythm of serum calcium level

Elena Kovaleva[1], Anna Eremkina[1], Alina Aynetdinova[1] & Natalia Mokrysheva[2]
[1]Endocrinology Research centre, Department of Parathyroid Disorders, Moscow, Russian Federation; [2]Endocrinology Research centre, Director, Moscow, Russian Federation

Introduction
Vitamin D deficiency is considered as a major public health concern. Due to vitamin D's crucial role in the intestinal calcium absorption, its deficiency may result in hypocalcemia and in a spectrum of associated clinical manifestations.
Aim
To assess the effect of 25(OH) vitamin D level (25(OH)D) on the frequency of hypocalcemia episodes and the daily profile of serum calcium and 24-h urinary calcium levels.
Methods
The interventional, prospective, comparative study of 10 healthy volunteers (women/men – 9/1) was performed. We have analyzed the daily profiles of serum calcium (total (Ca_{total}) and albumin-corrected calcium (Ca_{corr})) and 24-h urinary Ca levels. The descriptive statistics are represented by medians and the first and third quartiles in Me (Q1; Q3) and by absolute and relative frequencies.
Results
Episodes of hypocalcemia were registered in patients with low vitamin D levels: in 3.33% for Ca_{total} and in 5.8% for Ca_{corr}. No clinical symptoms was observed. The frequency of hypocalcemia decreased to 0% for Ca_{total} and to 2.5% for Ca_{corr} after vitamin D supplementation, while we did not detect any difference in Me serum Ca and 24-h urinary Ca levels. However, the summary number of reference calcium values increased as 25(OH)D level was reached more than 30 ng/ml: from 90.8 to 100% for Ca_{total} and from 94.2 to 97.5% for Ca_{corr}. Analysis of Ca_{total} and Ca_{corr} deviations during the day showed a less variability of the calcium profile after vitamin D treatment. This study also revealed circadian character of daily serum calcium profile with the presence of maximum (0940–1740) and minimum (2340–0740) values during the day.
Conclusion
Target 25(OH)D levels more than 30 ng/ml are needed for effective calcium absorption. We confirmed the decreased frequency of hypocalcemia and the less variability of serum calcium levels during the day, as well as an increased number of reference calcium values after vitamin D supplementation.

Severe hypercalcemia due to vitamin D intoxication in patients with chronic hypoparathyroidism: Five cases report

Kardi Asma, Ibtissem Oueslati, Meriem Yazidi, Fatma Chaker & Melika Chihaoui
La Rabta Hospital, University of Tunis El Manar, Faculty of Medicine, Endocrinology, Tunis, Tunisia

Introduction
Current standard treatment of primary hypoparathyroidism is based on calcium and activated vitamin D supplementation. Iatrogenic severe hypercalcemia due to vitamin D intoxication is an uncommon complication rarely described in literature. Herein we report 5 cases of severe hypercalcemia secondary to vitamin D intoxication.
Observations
Three men and two women with chronic hypoparathyroidism were included in this study. Their mean age was 56 years with extremes of 18 and 76 years. All patients were admitted in our department for a severe hypercalcemia secondary to vitamin D intoxication. Calcium bicarbonate was prescribed at the dose of 1500 mg per day in all of them. One patient was overdosed in active vitamin D, while the other patients presented dosing error in this drug. Four patients had abdominal pain and asthenia. However, one patient had confusion and agitation. The five patients had dehydration signs with acute renal failure. Electrical changes of hypercalcemia were present in three of them. The mean calcium level was 156 mg/l with extremes of 130 and 182 mg/l. Hemodialysis was indicated in one patient who had neurological symptoms. His calcium level decreased from 182 mg/l to 134 mg/l. All of patients received normal saline rehydration with a duration of 2–3 days and an infusion of 3 l/24 h. The mean of calcemia declined from 147 mg/l to 113 mg/l and reached normal levels in three patients after rehydration. Intravenous corticosteroids were prescribed in two patients and helped to normalize calcium level. Bisphosphonates were not prescribed in any patient.
Conclusion
Iatrogenic hypercalcemia due to vitamin D intoxication can present a life-threatening condition indicating urgent and appropriate management. Intravenous saline rehydration, intravenous corticosteroids and eventually hemodialysis should be considered in this situation. Furthermore, education of patients with chronic hypoparathyroidism on their doses of vitamin D as well as symptoms of hypercalcemia is the cornerstone of severe hypercalcemia prevention.

Primary Hyperparathyroidism with SVT and hypertensive crises; to proceed or not to proceed with surgery?

Hassan Ibrahim, Christo Albor, Solat Hasnain, Ayaz Hussain & Jawad Bashir
Basildon University Hospital, Basildon, UK

57 year old lady was admitted in hospital with hypertensive urgency (BP 205/107 mmHg) as first presentation of hypertension. There was no other past medical history. During admission, her BP was controlled over 24 h with combination therapy of amlodipine (10 mg OD) and doxazocin (2 mg OD). Routine blood tests revealed raised serum calcium (levels) and PTH (levels) consistent with diagnosis of primary hyperparathyroidism (PHPTH). Her hypercalcaemia was treated with IV fluids and IV pamidronate infusion. All subsequent investigations confirmed the final diagnosis of primary hyperparathyroidism (Corrected Calcium=2.97 mmol/l, PTH=30 pmol/l, urinary calcium=4.39 mmol/l, Vitamin D=55 nmol/l). Parathyroid imaging (US parathyroid and SESTAMIBI) revealed bilateral parathyroid adenomas. Whilst awaiting elective parathyroidectomy she required she had another hospital admission with supraventricular tachycardia (SVT). ECG revealed sinus tachycardia (heart rate 142 bpm) which resolved without use of rate control medical therapy after a period of observation, use of vagal manoeuvres and IV fluids. Due to two admissions with hypertensive urgency, supraventricular tachyarrhythmia (SVT) and multiple glandular parathyroid adenomas, a possibility of underlying genetic cause for PHPTH was raised. One of the worries with episodic tachyarrhythmia and hypertensive crises is possibility of pheochromocytoma associated with multiple endocrine neoplasia (MEN). There was no family history of note but for perioperative safety she was screened for pheochromocytoma. Multiple screening tests for pheochromocytoma were reported as borderline positive with the conclusion of inability to exclude pheochromocytoma.

Plasma metanephrine (results)		
Plasma Metadrenaline	**656** pmol/l	(80–510)
Plasma Normetadrenaline	**2582** pmol/l	(120–1180)
Plasma 3-methoxytyramine	<120 pmol/l	(<120)
Urinary metanephrine:		
Normetanephrine	**4.56** umol/day	(<3.7)
Metanephrine	**1.55** umol/day	(<1.3)
24 h Urine 3-methoxytyramine	0.82 umol/day	(<2.6)
30 min supine plasma metanephrine		
Plasma Metadrenaline	375 pmol/l	(80–510)
Plasma Normetadrenaline	**2100** pmol/l	(120–1180)
Plasma 3-methoxytyramine	<120 pmol/l	< 120

A pituitary hormonal profile and MRI pituitary was requested revealing eupituitary hormonal status with an incidental finding of 4 mm microadenoma. The case was discussed in local MDT and the outcome was to continue conservative management of PHPTH with cinacalcet until pheochromocytoma has been ruled out completely. Both MEN-1 and MEN-2 are associated with PHPTH. If a patient is having episodic adrenergic crises with inconclusive metanephrines analysis then excluding pheochromocytoma is important for perioperative safety. This case highlights the diagnostic work up in such cases.

Fahr's syndrome secondary to hypoparathyroidism revealed by generalized pustulosis (about 2 cases)

Amal Elkhomri, Nassim Essabah Haraj, Siham El Aziz, Fouzia Hali, Soumiya Chiheb & Asmaa Chadli
CHU Ibn Rochd, Endocrinology-Diabetology and Metabolic Diseases Department, Casablanca, Morocco

Introduction
Amicrobial skin pustulosis is one of the exceptional manifestations of hypoparathyroidism. We report 2 observations of a Fahr syndrome secondary to hypoparathyroidism revealed by generalized pustulosis.
Observations 1
24 year old woman, with no history of thyroid surgery, The patient was admitted for generalized covering more than 90% of the body surface. Biology objected to hypocalcemia at 57 mg/l, hyperphosphatemia at 66 mg/l and parathyroid hormone at 2.9 pg/ml. Fahr's syndrome was confirmed on a brain tomodensitometry conveyed bilateral calcifications of the central gray nucleus. The ophthalmologic examination revealed a bilateral posterior subcapsular cataract.
Observations 2
A 47-year-old woman, without the notion of thyroidectomy. The patient was admitted for a diffuse pustular rash. Biology objected : hypocalcemia at 39 mg/l, hyperphosphatemia at 69 mg/l and parathyroid hormone at 3 pg/ml. The brain tomodensitometry conveyed bilateral calcifications of the central gray nucleus. The diagnosis of Fahr syndrome on hypoparathyroidism was retained. The two patients were treated with intravenous calcium 8 g/d and with alfacacidol 3 µg/d magnesium 600 mg/d orally. The evolution of the 2 patients was marked by the disappearance of more than 95% of the lesions, concomitant with the correction of calcium levels.
Conclusion
The dermatological expression of Fahr syndrome secondary to hypoparathyroidism has been rarely reported in the literature, which should be considered in the presence of any skin pustulosis.

Challenges in diagnosis and treatment of Parathyroid Carcinoma – case report

Joana Reis Guiomar[1], Carolina Moreno[1,2], Miguel Melo[1,2], Lúcia Fadiga[1], Diana Alexandra Festas Silva[1] & Isabel Paiva[1]
[1]Coimbra Hospital and University Center, EPE, Endocrinology, Diabetes and Metabolism Department, Coimbra, Portugal; [2]University of Coimbra, Faculty of Medicine, Portugal

Introduction
Parathyroid carcinoma (CaPa) is an extremely rare cause of primary hyperparathyroidism. Patients with CaPa usually present severe hypercalcemia with abrupt bone and renal diseases, neurologic manifestations and gastrointestinal symptoms. However, sometimes the presentation is insidious with nonspecific symptoms and mild hypercalcemia. Surgery is the only curative treatment and after surgery close monitoring of calcium levels are necessary due to high risk of severe hypocalcemia by 'hungry bone syndrome'. Progressive disease is common with local recurrence and distant metastases.
Case Report
A 63-year-old woman with nonspecific bone pain for 7 years and progressive serum calcium elevation went to the hospital with an acute back pain without any sings of traumatic injury. Personal and family history was unremarkable. Laboratory investigations showed serum total calcium level of 4.24 mmol/l (NR 2.2–2.5 mmol/l), parathormone levels (PTH) 1387 pg/ml (NR 15–68.3 pg/ml), phosphate 0.51 mmol/l (NR 0.81–1.55 mmol/l), magnesium 0.61 mmol/l (NR 0.66–1.07 mmol/l), 25-hydroxyvitamin D 25 ng/ml (n>29). Ultrasonography of the neck showed a nodular lesion, with 25 mm at the lower pole of the left thyroid lobe with Tc-99m sestamibi scintigraphy confirming increased uptake in the same location. Genetic tests were negative for MEN1 and HRPT2/CDC73. She underwent surgical resection. The histologic examination confirmed the diagnosis of parathyroid carcinoma with capsular invasion and thyroid tissue involvement. Despite the efforts to prevent 'hungry bone syndrome', a severe hypocalcaemia was observed in the immediate postoperative period indicating the need to prolong medical treatment. Three months after surgery there was evidence of local recurrence and left thyroid lobectomy was completed. New local recurrence was observed two years after, and the patient underwent resection of the lesion. However, a progressive increase in PTH and calcium levels were observed six months after the last surgery, despite imaging investigations not revealing any evidence of residual or metastatic disease. It was decided to keep the patient under surveillance, as the patient is asymptomatic under calcimimetic therapy (cinacalcet 90 mg), with stabilization of the serum total calcium level.
Conclusion
Parathyroid carcinoma is an extremely rare tumour with challenges in diagnosis and treatment that are often difficult. All these are associated with delayed diagnosis, ineffective treatments, and consequently with poor prognosis. In the presence of hypercalcemia and elevated PTH level, parathyroid carcinoma, although a rare condition, should be considered.

Surgical difficulties during parathyroid surgery

Mohamed Masmoudi, Thabet Wadii, Rihab Lahmar, Mehdi Hasnaoui & Mighri Khalifa
Tahar Sfar Hospital Mahdia, ENT Department, Mahdia, Tunisia

Introduction
Parathyroid surgery is indicated essentially in primary and secondary hyperparathyroidism. This surgery may present some difficulties even in experienced hands. Our aim is to describe the difficulties that can occur during parathyroid surgery.
Material and methods
A retrospective study including 81 cases of hyperparathyroidism, operated between 2001 and 2018.
Results
The mean age was 53.2 years. Our study included 67 cases of secondary hyperparathyroidism and 14 cases of primary hyperparathyroidism. All patients, having secondary hyperparathyroidism, underwent subtotal 7/8 parathyroidectomy. In the majority of cases (80.6%), the parathyroid glands were found in their usual locations, without intraoperative challenges. Intrathymic localization was noted in 5 cases (thymectomy was done in these 5 cases). Two parathyroid glands were superposed in 5 cases. Parathyroid glands were located in the recurrent laryngeal nerve's entry point into the larynx, in 3 cases. In cases of primary hyperparathyroidism, intraoperative difficulties were noted in 4 cases: prevertebral parathyroid gland (1 case), latero-tracheal parathyroid gland (2 cases) and parathyroid gland located between the trachea and the oesophagus (1 case).
Conclusion
Preoperative imaging has an important role in the guidance of the surgical procedure. Nevertheless, a good knowledge of the surgical anatomy of the parathyroid and thyroid glands is essential to overcome the difficulties that can occur during parathyroid surgery.

EP28

Giant maxillary tumor as initial presentation of primary hyperparathyroidism: a case report

Priscilla Alves, Carlos Lima & Angela Leal
Federal University of Sergipe, Medicine, Aracaju, Brazil

Case
Male, 44 y.o., with rigth maxillary tumor of progressive growth for 1 year with local and low back pain. Imaging exams: CT/MRI skull and face: right axial expansive lesion (62×52×46 mm), heterogeneous, multiloculated with bulging of the right orbit inferomedial wall, with a neoplastic aspect. CT pelvis: bone lesions with soft tissue densities in pelvis, heterogeneous L4, with height reduction. Biopsy of the lesion suggesting a brown tumor. Investigation continued with PTH: 998 pg/ml and calcium: 10.4 mg/dl (8.5–10.5 mg/dl), scintigraphy: parathyroid-hyperfunctioning left lower parathyroid and bone-hypercapture, with emphasis on the skull, right scapula, some costal arches, T8, L4, sacroiliac regions, iliac crystals, left pubic branch, left ischium, trochanter of the right femur, proximal third of the left tibia and medial and malleoli right side, DXA Z-score RD -8.0DP. The patient was admitted with severe hypercalcemia (calcium: 14.6 mg/dl), phosphorus 2.4 mgdl, without neurological symptoms. Parathyroidectomy was performed with histological result of adenoma and a significant reduction in PTH levels (29.9 pg/ml) in the immediate postoperative period. In the

6 months of follow-up, he has normalization of calcemia and PTH, significant pain improvement, and gradual reduction of the tumor.
Discussion
Brown tumor appears in hyperparathyroidism, due to the action of PTH, leading to a replacement of bone tissue by dense connective tissue well vascularized, with fusiform and giant cells, areas of hemorrhage with a large amount of hemosiderin pigments and bone trabeculae, forming a very demineralized and fragile area, with a higher risk of fracture. In the initial evaluation of a lesion suggestive of a brown tumor, it is essential to measure the levels of calcium and PTH. Majority of cases of HPT are caused by adenomas (80 to 85%) and the minority due to hyperplasia of the four glands (15%), with 2 to 4% of multiple adenomas and less than 0.5% caused by carcinoma. Differentiation of adenoma and carcinoma by histological/immunohistochemical study takes into account degree of lesion invasion, number of mitoses, trabecular pattern and evaluation of a panel of markers (parafibromine, galactin-3, PGP9.5 and Ki67).
Final comments
It is necessary to emphasize the importance of screening methods and early diagnosis of a systemic disease such as hyperparathyroidism, which can evolve with serious complications, increasing morbidity and mortality.

Atypical parathyroid adenoma : a case report

Chayma Besrour, Imen Rojbi, Marwa Majdoub, Youssef Lakhoua, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Hospital Charles Nicolle, Endocrinology-Diabetology, Tunis, Tunisia

Introduction
The atypical parathyroid adenoma is a histological diagnosis. It is a parathyroid tumor with atypical histological features different from an adenoma and not similar enough to be considered as a carcinoma.It has an uncertain malignant potential.
Observation
We report the case of a 55 year-old woman, referred to us by her rhumatologist after discovering a severe hypercalcemia when exploring her for osteoporosis. The biology found a high level of calcium 3.68 mmol/l, and a very important level of parathormone PTH 1325.62 pg/ml (20 fold the normal level), confirming the diagnosis of primary hyperparathyroidism. The cervical ultra sound revealed a left hyperechoic, heterogeneous parathyroid mass, measuring 2.05 × 3.97 × 3.18 cm in diameter and a normal thyroid gland, and the Sestamibi-scintigraphy showed a large left inferior parathyroid adenoma. In front of this large mass, the severe hypercalcemia and the very high level of PTH, the malignancy was suspected and we completed the exploration by dosing two biomarkers of malignancy,the alkaline phosphatase (ALP) which was at 420 U/l (3 fold normal level) and the BHCG was high at 4.09 mUI/ml. Before referring the patient to surgery, she received an intravenous bipohosphonate therapy to control the hypercalcemia, then she underwent a parathyroidectomy and a lobo-isthmectomy with no post operative complications and the level of calcium normalized to 2.25 mmol/l and the PTH level dropped to 152 pg/ml. On the examination of the removed tissue, the histo-pathological exam concluded to an atypical parathyroid adenoma.
Conclusion
The atypical parathyroid adenoma is a very rare tumor, and the diagnosis is still a challenge, the outcome of patients is not well known yet, there for the surveillance is important and must be regularly.

EP30

Sporadic multiple parathyroid gland disease in young woman with primary hyperparathyroidism

Ekaterina Bibik[1], Anna Eremkina[1] & Natalya Mokrysheva[2]
[1]Endocrinology Research Centre, Parathyroid Glands Pathology, Moscow, Russian Federation; [2]Endocrinology Research Centre, Director, Moscow, Russian Federation

Background
Most cases of primary hyperparathyroidism (PHPT) is caused by a single benign adenoma, multiple parathyroid neoplasms (MPN) occur less often in 10–15%, parathyroid carcinoma accounts for <3%. MPN can be sporadic or develop due to inherited genetic syndromes (most commonly multiple endocrine neoplasia syndrome type 1 (MEN-1) that usually manifest at a young age. The preoperative examination of patients with MPN is important for achieving acceptable cure rates.
Aim
To describe the young patient with severe sporadic PHPT and giant parathyroid neoplasms.
Clinical case
34-year old woman presented with tooth damage, permanent neck ache, pains in lower extremities and general weakness. She had an episode of renal colic and previous fracture of metatarsal bone. There were no other diseases and no family history of endocrinopathies. Lab tests revealed severe PHPT: albumin-adjusted calcium level 3.0 mmol/l (reference range 2.15–2.55), PTH 403.7 pg/ml (16–65), 24-h urinary calcium 11.0 mmol (2.5–8). Other estimated parameters were osteocalcin 100.9 ng/ml (11–43), b-CTx 1.31 ng/ml (0.01–0.69), GFR 120 ml/min/1.73 m^2. We detected a significant decrease in bone mineral density (BMD) in all areas, maximal in Radius (−4.9 s.d., *Z*-score). CT scans confirmed the osteitis fibrosa cystica, Th12-vertebral fracture, as well as bilateral nephrolithiasis. Ultrasound and SPECT/CT showed multiple tumors in right (6.6×4×16 mm) and both left parathyroid glands (27×22×59 mm and 15×12×39.3 mm). The tumor of the left lower parathyroid gland covered the carotid artery. Clinical data allowed to suspect MEN-1 or the parathyroid cancer. Diffusion-weighted MRI was additionally completed (ADC 1.6–1.7×10^{-3} mm^2/s). Genetic testing excluded *CDKN*, *CDC73*, *MEN1* mutations. The patient underwent the removal of three identified tumors. Morphological examination diagnosed benign adenoma of the both left and hyperplasia of the right parathyroid glands. Post-surgery hypocalcemia (serum calcium 1.67 mmol/l, PTH 57 pg/ml) and severe hungry bone syndrome were managed with alfacalcidol, calcium carbonate and cholecalciferol. The follow-up one year after surgery revealed increased PTH (80.25 pg/ml) with normocalcemia (2.4 mmol/l) and adequate 25(OH) D level, but 7-day stimulation test with alfacalcidol confirmed the PHPT persistence (serum calcium 2.57 mmol/l, PTH 113 pg/ml). The ultrasound showed the residual tissue between brachiocephalic and left carotid arteries (14 × 19 × 20 mm). Given the patient's refusal to reoperate and significant improvement of target organs, we decided to continue the active observation and cholecalciferol treatment.
Conclusion
MPN remains a quite difficult condition with high rate of recurrent or persistence PHPT. It requires extensive preoperative diagnostics and explorative surgery. The long-term follow-up is mandatory in such patients.

EP31

Recurrent and persistent primary hyperparathyroidism due to secondary parathyromatosis

Everardo Josué Díaz-López[1], Alejandro Ramírez-Izcoa[1], José Vinicio Velecela Abambari[2] & Adalberto Infante-Amorós[3]
[1]Hospital Clínico Quirúrgico Hermanos Ameijeiras, Endocrinología, Honduras; [2]Hospital Clínico Quirúrgico Hermanos Ameijeiras, Endocrinología, Ecuador; [3]Hospital Clínico Quirúrgico Hermanos Ameijeiras, Endocrinología, Cuba

Introduction
Parathyromatosis is a potential cause of recurrent hyperparathyroidism, of rare etiology, described as multiple nodules of hyperfunctioning benign parathyroid tissue, it constitutes less than 1% of the cases of recurrent hyperparathyroidism and since its description in 1975, less than 40 cases have been reported Worldwide. The presentation in primary hyperparathyroidism is extremely rare, with around 20 cases reported in the English literature. In the databases reviewed, no cases published in Cuba or in the rest of Latin America were found.
Case report
43-year-old female patient, with 18-years history of recurrent and persistent primary hyperparathyroidism due to secondary parathyromatosis that debuted with a brown cell tumor; currently with multiple spontaneous fractures, bone deformations and the onset of of stage II chronic kidney disease secondary to bilateral nephrolithiasis and moderate right hydronephrosis. Parathyroidectomy of 6 glands was performed prior to the identification of the lesions by imaging studies, at four surgical times in a period of 18 years, associated with right hemithyroidectomy due to incidental finding of papillary thyroid carcinoma. In the last admission with serum parathyroid hormone of 1000 pg/ml, serum calcium of 3.9 mmol/l, serum phosphorus of 0.73 mmol/l. A radioguided left lower parathyroidectomy was performed, obtaining a 4.8 × 2.7 cm gland. The pathological study reported parathyroid tissue with proliferation of oxyphilic cells with lesion limited to the

capsule. After the intervention, parathyroid hormone levels decreased by 40% (610 pg/ml) but remained high, with normalization of serum calcium and phosphorus. He continues to be monitored for external consultation.
Conclusion
The treatment of choice is cytoreduction of all identifiable parathyroid tissue remains, while treatment aimed at removing all disseminated nodules is rarely successful, patients are initially controlled with subtotal parathyroidectomy, however reintervention is often necessary, as noted in this case, cinacalcet is a medical option. Parathyromatosis is a rare cause of recurrent and persistent hyperparathyroidism. Preoperative diagnosis continues to be a challenge even with the advent of new technologies, even after 40 years of being described. Its pathophysiology continues to be studied and discussed. Lack of knowledge about this entity can result in unsuccessful attempts to control and eradicate the disease. It is important that it be considered especially in patients with persistent hyperparathyroidism.

EP32

Secondary hyperparathyroidism associated with exostosis in a 10-year-old girl: a case report

Anca Maria Andrei[1], Natalia Mitru[1], Sorana Vasilescu[1], Diana Preda[1,2] & Alexandra Mirica[1,2]
[1]Grigore Alexandrescu Emergency Hospital for Children, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background
Secondary hyperparathyroidism is a condition that can occur as a result of low vitamin D level. Parathyroid hormone (PTH) has the role of stimulating bone resorption by two mechanisms: direct activation of osteoblasts and indirect stimulation of osteoclast. Exostosis or bone spur is a benign tumor that consists in overgrowth of a pre-existing bone. Exostoses can affect any bone, however they are most commonly located on the bones of the joints such as: the ribs, hips, knees, ankles, shoulders and elbows. Their exact cause is not known, however, they appear mostly during the active growth stages and as a result of bone lesion. They can cause chronic pain or can be asymptomatic and discovered incidentally.
Case presentation
We herein report the case of a 10-year-old Caucasian girl who presented to the orthopaedic ward complaining of leg pain during walking. The radiologic investigation showed a lateral exostosis above the right knee. The patient's family physician referred her to our endocrinology clinic. Her pubertal stage was Tanner IV for breast growth and Tanner IV for pubic hair development. Biochemical investigations showed elevated PTH level 91.4 pg/ml (normal range, 15–68 pg/ml), low vitamin D level 23.5 ng/dl (normal range, >30 ng/ml), normal calcemia, urinary calcium/creatinine ratio <0.2 mg/dl (normal range, <0.14 mg/dl) and normal thyroid hormone levels. The diagnosis established was secondary hyperparathyroidism due to vitamin D insufficiency. The patient received replacement therapy with cholecalciferol (2000 IU) under which the levels of PTH turned within normal range.
Conclusion
This case illustrates the unusual association of exostosis located above the knee in a patient with secondary hyperparathyroidism caused by low vitamin D level. Although there is only the possibility of a casual association, this case is noteworthy to report because of its interesting features. We highlight the importance of vitamin D replacement in childhood, for it can prevent secondary hyperthyroidism along with its consequences.

Hyperparathyroidism complicating a pre-existing diagnosis of Familial Hypocalciuric Hypercalcemia (FHH)

Alamin Alkundi & Rabiu Momoh
William Harvey Hospital, Kent, UK

Familial hypocalciuric hypercalcemia is a rare clinical condition of persistently elevated serum calcium and reduced urinary calcium levels with an autosomal dominance inheritance pattern to the three out of four large types of this condition known. This rare condition goes largely undiagnosed as patients are largely asymptomatic and where symptoms are present, other causes of hypercalcaemia are considered first. Hyperparathyroidism, superimposing on FHH, is an even rarer occurrence. We present the case of an adult male with an initial provisional assessment of FHH, which was later confirmed with a genetic study. He went on to develop hyperparathyroidism (with evident parathyroid hypertrophy on Sestamibi parathyroid scan done). This occurred on his pre-existing familial hypocalciuric hypercalcemia and surgical consideration (subtotal parathyroidectomy) was offered. It remains to be established if this is an incidental occurrence or if there is a causal relationship between FHH and an onward development of parathyroid hypertrophy or adenoma(ta).

Severe hyperinsulinemia and osteoporosis in a lean patient with Jacobsen syndrome

Georgios Boutzios[1], Sofia Chatzi[1], Athina Karampela[1], Myrto Miliou[1], Loukia Koutsogeorgopoulou[1], Eleni Koukoulioti[1], Markos Psifis[2] & Androniki Drakou[2]
[1]Medical School, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece; [2]Laiko General Hospital, Orthopaedics, Athens, Greece

Introduction
Jacobsen syndrome (JS) is a rare gene disorder caused by a terminal deletion of the long arm of chromosome 11. The estimated prevalence of Jacobsen syndrome is 1/100.000 births. It is most commonly presented with psychomotor and physical growth retardation, dysmorphic facial features, thrombocytopenia or pancytopenia. It is also characterized by congenital heart defects, and kidney, gastrointestinal tract, genitalia, CNS and skeletal deformities.
Case presentation
We herein report an unusual case of a 19-year-old male, non-smoker, with a medical history of moderate cognitive disorder, facial deformities, lower limb skeletal malformation and hearing impairment, who was referred to the outpatient clinic due to severe osteoporosis and hyperinsulinemia. His BMI was 21.5 kg/m^2. The OGTT showed glucose levels within normal range and increased insulin levels, 46.4 pmol/l and 238.8 pmol/l at time 0' and 30', respectively. Spine (L1–L4) and total body mass density were measured 0.875 g/cm^2 and 0.877 g/cm^2 with *Z*-score of –2.7 and –2.0, respectively, finding which documented the presence of severe osteoporosis. Thyroid and adrenal function tests, vitamin D and PTH levels, liver function tests, autoantibodies specific for celiac disease and 24-h urine calcium were within normal limits. A genetic analysis was performed and revealed a de novo deletion in 11q24.1-qter, compatible with JS. The patient was placed on bisphosphonates along with calcium and cholecalciferol supplementation as a treatment for his severe osteoporosis.
Conclusion
We present this case to alert the medical community on the possible association of Jacobsen syndrome with severe osteoporosis and hyperinsulinemia in a young male.

DOI: 10.1530/endoabs.73.EP34

EP35

Coexistence of multiple cystic parathyroid adenomas and thyroid carcinoma

Maria Boudina[1], Eleni Syndouka[2], Aimilia Fotiadou[1], Mariana Stamati[1], Chrysanthi Zouli[1], Elpiniki Argyropoulou[1], Theodosios S. Papavramidis[3] & Alexandra Chrisoulidou[1]
[1]Theagenio Cancer Hospital, Department of Endocrinology; [2]Theagenio Cancer Hospital, Department of Radiology; [3]1st Propedeutic Department of Surgery Faculty of Medicine, School of Health Sciences, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background
Cystic parathyroid adenoma is a rare entity (<0.01% of all cervical masses) that leads to primary hyperparathyroidism in 9% of cases. Parathyroid scintigraphy is essential for the diagnosis although there are pitfalls with false negative results. Parathyroidectomy is the treatment of choice but its success depends on the exact preoperative localization of the parathyroid lesions. 4D-CT is a very helpful diagnostic tool in such cases.

Case presentation
A 43-year-old man presented with a history of recurrent episodes of nephrolithiasis. Cervical ultrasound was indicative of multiple isoechoic thyroid nodules and 3 cystic hypoechoic lesions behind the middle and lower part of both thyroid lobes. The biochemical examinations indicated primary hyperparathyroidism. Thyroid function tests, calcitonin and urine metanephrines were in normal range. CBI scintigraphy showed one parathyroid adenoma behind the lower part of the left thyroid lobe. Since there was no accordance between the two diagnostic procedures, cervical MRI followed, demonstrating 7 small lesions, indicative of parathyroid adenomas or lymph nodes. A 4D-CT Scan revealed 3 mixed solid and cystic lesions ranging from 2 to 2.8 cm, posteriorly to both thyroid lobes. The patient underwent total thyroidectomy because of multinodular goiter and parathyroidectomy according to the 4D-CT. The histological examination demonstrated the coexistence of 1 right and 2 left mixed cystic parathyroid adenomas and a unifocal right lobe papillary thyroid carcinoma invading the thyroid parenchyma. There was a significant decrease in PTH levels after the excision of the adenomas.
Conclusions
Simultaneous mixed solid and cystic multiple parathyroid adenomas and papillary thyroid carcinoma is an extremely rare entity. Functional imaging has low sensitivity in displaying cystic lesions. It is worth noting that 4D-CT is a very important preoperative diagnostic tool in cases of discrepant functional (Sestamibi) and structural (ultrasonography) imaging.

Cerebral calcifications revealing familial pseudohypoparathyroidism
Dayssem Khelifi, Wided Debbabi, Issam Kharrat & Slim Samet
Ibn Jazzar Hospital, Tunisia

Introduction
Pseudohypoparathyroidism (PHP) is the first example of hormonal resistance observed in human pathology characterized by a great variability of clinical and genetic expression. We present a case of PHP in a Tunisian family.
Observation
The index case is a 31-year-old man. He was burn out of a consanguineous marriage (distant consanguinity) followed since the age of 15 for convulsive seizures. Three months earlier, complex partial seizures became reccurent and refractory to medication. The brain MRI revealed the presence of calcifications of the central gray nuclei. Serum biochemical analysis presented severe hypocalcemia (1.15 mmol/l), hyperphosphatemia (2.76 mmol/l) and an elevated serum parathyroid hormone level (320 pg/ml) (normal range 10–60 pg/ml). On general physical examination, there was a short stature, facial dysmorphia, android obesity, bradymetacarpia of fourth and fifth fingers bilaterally, bradymetatarsia and subcutaneous ectopic calcifications. Signs of latent tetany in the form of Chvostek's and Trousseau's sign were present. Renal function and 25 (OH) vitamin D levels were normal with no biological signs of malabsorption. The ophthalmologic examination showed a bilateral subcapsular cataract.Thyroid profile revealed normal T3, T4 levels with slightly elevated TSH levels (8.5 uIU/ml), suggestive of TSH resistance. Patient was diagnosed as PHP type 1a. He was treated with oral calcium (3 g/day) and calcitriol (1 µg/day). He responded to the treatment, and is presently asymptomatic with maintenance of normal calcium levels and no recurrent epileptic seizures. Family investigation revealed the presence of the same abnormal regulation of calcium and phosphate homeostasis in his sister and his younger brother (older brother would be unharmed), and the discovery of asymptomatic hypocalcemia in the mother and maternal uncle. The biomolecular study of the Gs protein is in progress.
Conclusion
PHP is a rare, deeply impairing disorder of calcium metabolism, characterized by end-organ resistance to the action of paratyroid hormone. This group of disorders is caused by different and complex genetic and epigenetic defects. There is an urgent need to improve knowledge on the natural history of the diseases, to better understand the bridges between these clinically heterogeneous and to develop new therapies.

EP37

Bisphosphonate-related osteonecrosis of the jaws in persistent primary hyperparathyroidism
Wiem Ben Elhaj, Ibtissem Ben Nacef, Imen Rojbi, Youssef Lakhoua, Nadia Mchirgui & Karima Khiari
Charles Nicolle Hospital, Department of Endocrinology, Tunisia

Background
Primary hyperparathyroidism (PHPT) results from inappropriate overproduction of parathyroid hormone from one or more of parathyroid glands with consequent hypercalcemia. Medical therapy by bisphosphonates is indicated for patients contraindicated for surgical treatment or those with therapy failure. We report the observation of a patient receiving zoledronic acid for persistent PHPT and who developped bisphosphonate-related osteonecrosis of the jaws (BRONJ).
Case report
A 54-year-old man, who had diabetes mellitus presented with symptomatic PHPT manifested by joint pain with chondrocalcinosis, and elevation in serum PTH to 720.4 pg/ml and total calcium to 3.2 mmol/l levels. Neck ultrasonography, sestamibi scan, cervico-thoracic Magnetic Resonnance Image were negative. Exploratory cervicotomy was indicated and parathyroidectomy of 3 glands was released. The fourth parathyroid gland was not found. Histological findings revealed hyperplasia of three parathyroid glands. He was presented with reccurence after 3 years. Cervical computed tomography and sestamibi scan were negative and a second mediastinal operative procedure was planned, however, no ectopic parathyroid gland was found. Because of persistence of severe hypercalcemia associated to renal lithiasis, he was medically managed with intravenous zoledronic acid for 6 years. One day, he came with left gingival pain. He was referred to maxillofacial surgeon who noted gingival redness and swelling with pus discharge and necrotic bone exposure. Finally, he was diagnosed with BRONJ. A review of the dental history indicated that he extracted one tooth 2 months ago. Subsequent treatment consisted of antibiotic and recurretage of the extraction socket without improvement. Bisphosphonates were discontinued immediately after the diagnosis and sequestrectomy was performed. A histological reported sclerotic and necrotic bone. The patient maintained on palliative treatment consisting of local wound dressings, antibiotics, and antimicrobial rinses. Although surgery appeared to give some initial relief painful symptoms returned and the patient was proposed to hyperbaric oxygen.
Conclusion
BRONJ has been well documented in a patient with persistent primary hyperparathyroidism who received 6 years of bisphosphonates. It presents a serious adverse effect and often related to a site of previous dental treatment. Therefore, patients should be informed of an increased potential risk for osteonecrosis and the importance of conservative therapy.

Vitamin D deficiency and primary hyperparathyroidism
Aicha Bouzid[1], Azzouz Malha[2] & Djamila Meskine[1]
[1]Medical University of Algiers, Endocrinology & Metabolism laboratory Algiers 1, EPH Bologhine, Algiers, Algeria; [2]Medical University of Algiers. EPH BOLOGHINE, Algiers, Algeria

Introduction
The association between vitamin D deficiency and primary hyperparathyroidism(PHP) has clear implications. Co-existing vitamin D deficiency may cause the serum calcium level to fall into the normal range, which can lead to diagnostic uncertainty. The objective of this study is to assess the vitamin D status of patients followed for primary hyperparathyroidism.
Materials and methods
This is a retrospective study conducted at the endocrinology department of EPH Bologhine in Algiers between 2013 and 2017, involving 21 patients followed for primary hyperparathyroidism. The diagnosis of PHP was made in the presence of normal or elevated serum calcium in relation to inappropriate PTH with elimination of secondary hyperparathyroidism. The 25OHD assay was performed in 16 patients.

Results
The mean age of the patients was 56.5 years. These were 20 women and only one man diagnosed with a familial form. HPP was asymptomatic in 47.6%. The mean serum calcium was 2.98 mmol/l. The mean PTH was 475 ng/l. The mean 25OHD level was 14.42 ng/ml. 87.5% of patients had 25OHD <30 ng/ml, 81.2% had 25OHD <20 ng/ml) and 25OHD <10 ng/ml was found in 43% of patients. Osteodensitometry was performed in 13 patients, it was normal in 2 patients, osteoporosis was found in 69.2% (9 cases) and osteopenia in 15.4 cases.
Discussion
Vitamin D deficiency and insufficiency seem to be more prevalent in patients with primary hyperparathyroidism than in geographically matched populations. Regardless of the clinical severity of primary hyperparathyroidism, the disease seems to be more severe in those with concomitant vitamin D deficiency.
Conclusion
Vitamin D insufficiency is very common in patients with primary hyperparathyroidism. Vitamin D deficiency is associated with high blood calcium and high PTH levels. Recent recommendations from learned societies propose a systematic dosage of 25OHD in all patients with primary hyperparathyroidism.

Osteoporosis, as a manifestation of multiple myeloma disease in women post menopause

Natalya Volkova, Ilya Davidenko, Irina Dzherieva, Lilia Ganenko, Alexander Zibarev, Yulya Sorokina, Igor Reshetnikov, Yuliya Degtyareva & Maria Merenkova
Rostov State Medical University, Rostov, Russian Federation

Osteoporosis is a systemic skeletal disease characterized by a decrease in bone strength and an increased risk of fractures. In the structure of osteoporosis, secondary osteoporosis is 5% in women and 20% in men. Clinicians need to exclude the secondary nature of osteoporosis, since under the 'mask' of mineral metabolism disorders, more rare and dangerous diseases can arise. A 65-years-old women presents with complaints of three low-traumatic fractures in the last year. From the anamnesis: in 2018 she consulted a traumatologist with complaints of back pain and increased fatigue. Dual-energy X-ray absorptiometry (DXA): compression fractures of the 2nd and 3rd lumbar vertebrae, a decrease in bone mineral density (BMD) in the lumbar part of vertebral column (*T*-score −2.5). A diagnosis of postmenopausal osteoporosis was made, therapy with zoledronic acid was recommended, however, due to the high cost of the drug, calcium and vitamin D therapy was chosen. In March 2020, a low-traumatic fracture of 2 ribs was developed (VIII rib on the left, IX rib on the right). In July 2020, there was a fracture of the scaphoid on the right. Due to persistent complaints, the patient consulted an endocrinologist. Physical examination: BMI-27 kg/m^2, BP-135/80 mmHg, HR-68 beats per minute, pale skin and visible mucous membranes, musculoskeletal system without visible deformation, muscle tone is normal, risk of falls on the Morse scale is high (55 points). She denies taking medications that affect BMD. DXA was performed: BMD was reduced in the lumbar part of vertebral column (*T*-score – −2.5), in the area of the femoral neck (*T*-score – −2.6). Was calculated the FRAX: the risk of major osteoporotic fracture was 22% ten-year risk of hip fracture-4.3%. Due to the presence of atypical localization fractures an additional examination to exclude secondary causes of osteoporosis was performed: primary hyperparathyroidism, vitamin D deficiency were excluded. However, anemia (hemoglobin-95 g/l) and accelerated ESR (40 mm/h) were detected, which in combination with osteoporosis can be clinical manifestations of paraproteinemia, so the patient was referred to a hematologist. After an additional examination a diagnosis of multiple myeloma was made. The patient is currently receiving chemotherapy. Differential diagnosis of osteoporosis must be carried out in the early stages of the disease in order to exclude secondary osteoporosis and identify pathologies accompanied by a violation of mineral metabolism. Identification of reliable causes of osteoporosis allows prescribing timely etiotropic therapy, which ultimately improves the prognosis of such patients.

Shoulder pain, polyuria and lytic lesions: novel presentation of primary hyperparathyroidism or multiple myeloma?

Kaenat Mulla, Suganya Giri Ravindran, Rahat Tauni & Julia Ostberg
Watford General Hospital, UK

Traditionally, patients diagnosed with primary hyperparathyroidism present with mild hypercalcaemia and tend to be asymptomatic. Symptomatic patients tend to have severely high calcium and exhibit the classic 'bones, stones, abdominal moans and psychic groans.' We present a case of a 92-year-old Caucasian gentleman presenting with recurrent falls, postural hypotension and trauma to head and shoulder. X-ray imaging showed small non-specific lucencies in the cervical and upper thoracic vertebral bodies, clavicles and left upper humerus along with an old left clavicular fracture. He was normocalcaemic (2.52 mmol/l) on admission, had normocytic anaemia and had a mild acute kidney injury (AKI) on chronic kidney disease (CKD). The computer tomography (CT) chest, abdomen and pelvis showed multiple punched out lytic lesions within the skeleton bones and an 13 mm elongated nodule behind the right lobe of thyroid. Presence of similar lucencies in shoulder imaging from 2015 and 2016 ruled out the possibility of metastatic disease. Biochemistry revealed raised parathyroid hormone at 35.6 pmol/l (1.6–6.9) and vitamin D deficiency of 24 nmol/l. On two occasions during the admission, his calcium was found to be mildly elevated (2.73 mmol/l). Tests for myeloma screen were inconclusive. He had urinary bence jones protein (BJP), raised kappa and lambda free light chains and no immunoparesis. He was managed with vitamin D and is awaiting further tests, such as sestamibi scan. He will be followed up in endocrine clinic to discuss results. Any bone lesion detected in a patient above the age of 40 years, should have further investigations for myeloma and/or metastatic disease. The differentials in this case are primary hyperparathyroidism as suggested by long standing bone lesions, high PTH and a potential parathyroid lesion or plasma cell neoplasia as suggested by BJP in the urine with kappa light chains. Literature search suggests that lytic lesions, specifically brown tumours can be seen in patients with primary hyperparathyroidism. The diagnosis is still unclear, nevertheless a uniquely delayed presentation of potential primary hyperparathyroidism or both the conditions.

Calcium metabolism in Latvian patients with granulomatosis with polyangiitis (GPA) at the time of diagnosis – 2013-2018 data

Ieva Ruza[1,2] & Aiga Plegermane[2]
[1]Riga Eastern Clinical University Hospital, Latvia; [2]Riga Stradins University, Latvia

Key words
GPA, granulomatosis, serum, 24 h urine, calcium.
Introduction
Granulomatosis with polyangiitis (GPA) is a very rare systemic disease of unknown etiology that is defined by the formation of granulomas in different organ systems. Due to this pathology, there may be an increase in serum and 24 h urine calcium that can have a clinical impact on the course of the disease.
Aim
The goal of this study was to assess the changes in total serum calcium and 24 h urine at the time of diagnosis in new cases of GPA from 2013 till 2018.
Materials and methods
In a retrospective study, medical records of all patients who were screened due to suspected GPA (*n*=48) in the Riga Eastern University Hospitals' 'Clinic of Tuberculosis and Lung Diseases' between the 1st of January 2013 and 31st of December 2018 were analyzed. For further analysis, only patients with first-time histologically and/or clinically confirmed diagnosis of GPA (*n*=30; 15 men and 15 women) were selected, and only the data from the first episode was evaluated. The information was obtained from patients' case files and medical records in the centralized hospital information system.
Results
On average, there were 5 (ranging from 3 to 10) new GPA cases (approximately 50% women and 50% men) per year in Latvia. Patients' age ranged from 29 to 77 years with mean age of 56 ± 13.4 years. The highest number of newly diagnosed GPA was in the age group of 50–59 years (*n*=12; 7 women and 5 men). Serum calcium level was evaluated only in 9 of 30 patients, hypercalcaemia was detected in one case (*n*=1) – 2.57 mmol/l [2.1–2.55]. 24 h urine calcium level was evaluated only in two cases (*n*=2), no hypercalciuria was found.
Conclusions
Most patients lack serum and/or 24 h urine calcium levels evaluated at the time of the diagnosis of GPA. Hypercalcaemia was observed in one case. Due to small number of cases and the lack of serum and urine calcium

evaluation at the time of diagnosis, substantial statistical analysis was not possible. Doctors should be reminded and encouraged to perform an early basic calcium metabolism screening in GPA patients.

Impact Of Vitamin D Supplementation On Phospho-Calcium Metabolism

Catarina Ivo, David Veríssimo, Vitória Duarte, João Silva, Luís Lopes, Dolores Passos, João Jácome de Castro & Mafalda Marcelino
Armed Forces Hospital, Endocrinology Department, Portugal

Introduction
It has been estimated that prevalence of vitamin D deficit (25(OH)D) in the world is between 20 and 100%, depending on age group, ethnicity and region. In European population, the prevalence is around 40%. The Endocrine society guidelines recommend the supplementation of vitamin D when vitamin D deficiency is confirmed. The objective of this work is to evaluate the effect of 25(OH)D supplementation on phospho-calcium metabolites: calcium (Ca), phosphorus (Ph) and parathormone (PTH).
Methods
Retrospective study of 185 individuals diagnosed with 25(OH)D deficit in routine analyses and to whom supplementation was prescribed. Individuals with hyperparathyroidism (HPTP) were excluded. We analysed the age, sex, glomerular filtration rate (GFR), Ca, Ph, 25(OH)D and PTH baseline, at 6 and 12 months(M) after supplementation. Two levels of deficiency of 25(OH)D were defined: deficiency if 25(OH)D<20 ng/ml and insufficiency if 20 ng/ml≤ 25(OH)D <30 ng/ml. The various formulations of 25(OH)D were prescribed, according to the recommended dosage. Statistical analysis was performed in Excel® with significance level *P*=0.05.
Results
185 patients, 51.9% female with a mean age of 69 years and mean GFR 91.6 ml/min. In the pre-supplementation phase 74.6% had 25(OH)D deficiency and 25.2% had insufficiency. 26.5% of patients were supplemented with calcifediol and 73.5% with cholecalciferol. The mean values of analysed metabolites at 0, 6 and 12 months were respectively: 25(OH)D 16 ng/ml, 30 ng/dl and 29.95 ng/dl (*P<0.001*); Ca 9.47 mg/dl, 9.55 mg/dl and 9.57 mg/dl (*P=0.208*); Ph 3.34 mg/dl, 3.5 mg/dl and 3.22 mg/dl (*P=0.178*); PTH 88.1 pg/ml, 74.4 pg/ml and 82.4 pg/ml (*P=0.077*). We did a sub-analysis of patients with renal failure (GFR<60 and 60<GFR<90 ml/min) with similar results, without statistical significance (GFR<60 ml/min: Ca *P=0.49*; Ph *P=0.55*; PTH *P=0.19* and 60<GFR<90 ml/min: Ca *P=0.32;* Ph *P=0.28;* PTH *P=0.29).*
Conclusion
In this study it was found that vitamin D supplementation is an effective therapy in the treatment of this deficiency. After 12 months of 25(OH)D supplementation, there was no significant statistical variation in the phospho-calcic metabolites. Renal failure did not influence the results obtained in this study. These results are in line with those previously published in the literature.

Pregnancy outcomes after successful chemotherapy for choriocarcinoma in a diabetic woman: A case report

Ghofrane Hakiri, Zohra Hadj Ali, Manel Dridi, Yosra Htira & Faika Ben Mami
Institut De Nutrition, Section C, Tunis, Tunisia

The pregnancies conceived after chemotherapy for trophoblastic neoplasia should be followed with clinical surveillance due to higher rates of some pregnancy complications especially when associated with diabetes mellitus. We report the case of a 30-year-old nulliparous woman, obese, had been diagnosed with type 2 diabetes mellitus for 10 years,without micro or macrovascular complications, treated by conventional insulin therapy,with a history of low-risk gestational choriocarcinoma complicating a hydatidiform mole,treated with 11 sessions of Methotrexate chemotherapy in remission for four months. Pregnancy was allowed to proceed by an obstetrics–gynecology specialist after a 3-month preconception program with optimization of insulin therapy and switching to Asparte and Detemir insulin analogues, allowing a decrease in glycated hemoglobin (HbA1c) from 8.4% to 7.7%. Folic acid and iron supplementations were also carried out as well as progestin and salicylic acid. The patient was hospitalized once every three months in order to carry out the assessment of the impact of her diabetes by monitoring of glycemic control as attested by (HbA1c) and fasting blood glucose (FBG), as well as an ophthalmological examination and the search for albuminuria.In the gestational diabetes unit,the patient maintained a strict regimen of capillary blood glucose measurements six times a day weekly as well as dietary avoidance of fat.Blood glycemic control required high doses of insulin (1.2 UI/kg per day) to maintain the HbA1c and FBG levels in the range of 7% and 0.98 mg/dl, respectively.The cardiac and ophthalmologic examinations showed normal findings at each visit.No rise of albuminuria was detected.However, the patient had gained weight more than recommended (11 kg).All measurements of beta-hCG titer showed normal findings throughout pregnancy. Pregnancy progressed favorably up to a term of 27 weeks of gestation when the patient was hospitalized in a gynecology–obstetrics department because of a threat of premature delivery. The contractions were stopped and an obstetrical ultrasound showed a progressive pregnancy with fetal hypotrophy with an estimated weight of 830 g and hydramnios. After a regularly monitored pregnancy, the patient gave birth by caesarean section at 37 weeks of gestation and 2 days. The newborn weighed 4.050 g and had normal Apgar score at 1 and 5 minutes, respectively and was devoid of serious metabolic complications. No similar case has been described in the literature, hence the originality of our case.

The second Moroccan mobile application for type 1 diabetes self-care : towards a new pedagogical dynamism in T1DM self-management

Nada Derkaoui, Salma Ben Yakhlef, Rami Imane, Ouafae Elmehraoui, Messaoudi Najoua, Siham Rouf & Hanane Latrech
Mohamed VI University Hospital Center of Oujda, Endocrinology Diabetology and Nutrition Department, Oujda, Morocco

Introduction
Mobile health technology has been highly beneficial for people with diabetes, offering a plethora of educational patterns especially during COVID-19 pandemic. Diabetes self-management education through telehealth technologies is important in promoting health practices and in reducing the risk of complications. Nevertheless, the challenge is to elaborate a digital application in light of sociocultural background and economic status.
Material and methods
We imagined and developed a new smartphone application named : 'Ana wa Soukari' in simplified Arabic, using mapped sections with pictured characters, and providing individualized blood glucose prescription chart helping the patient manage rapid insulin doses. The purpose of our study is to evaluate the clinical and biological effectiveness of the second Moroccan mobile application 'Ana wa Soukari' on type 1 diabetes mellitus self-management.
Results
Here we present our preliminary results. A total of 9 patients initially received the application 'Ana wa soukari' on their smartphones. The mean age of our patients was 12.7 years (6–20). 33% of them were male and 66% were female. The patients were diagnosed with type 1 diabetes for a mean of 3.39 years. Only one patient had diabetes for more than 5 years. 55% of the patients were initially admitted in our endocrinology diabetology department for poor glycaemic control, and 45% were admitted for a newly diagnosed diabetes mellitus. All of them had initially received therapeutic education in its usual form. None of them had a degenerative complication of diabetes. The mean HbA1c level was 8.51% (6.4%–12.4%). The mean number of hypoglycaemic events before the application was used dropped from 4.3 events per week to 2.1 per week after one week using the application.The patients thought the content was suitable for the young diabetic patients and understandable, and found that the application was perfectly complementary to therapeutic education in its classic form besides giving them the possibility of adapting their insulin doses according to each meal and physical activity.
Conclusion
Our preliminary results bring out the need for a longer study to explore the efficacy of 'Ana wa Soukari' to optimize outcomes in young people with type 1 diabetes mellitus and give a greater opportunity for computer-aided diabetes education to play a significant role in Diabetes self-management.

Initial daily insuline dose and body mass index

Amal Mehrzi, Htira yosra, Emna Bornaz, Ben Hadj Ali Zohra & Ben Mami Feyka
Tunisian Institute of Nutrition, The C Department of Diabetology and Nutrition, Tunisia

Introduction
Insulin therapy can lead to obesity which can affect the comorbidities of the type 2 diabetes. Should we consider the body mass index (BMI) before prescribing it?
Methods
Our study is prospective, randomized and comparative.We recruited patients with type 2 diabetes hospitalized for a switching to insulin in the C department of diabetology and nutrition at the National Nutrition Institute in Tunis, during 6 months.We divided the patients according to their BMI and compared the corresponding averages of the initial daily insuline dose using the Welch test.
Results
We included 50 patients with type 2 diabetes, hospitalized for a switching to insulin, 54% were men, 46% were women, with an average age of 59 years (± 11), the averge duration of diabetes was eight years (± 7), the average BMI was 29 (95% CI 27–31), the average waist size was 101 cm (95% CI 97–105), 28% of patients were normoponderal, 34% were overweight, 22% had stage 1 obesity, 6% had stage 2 obesity, 10% had morbid obesity. We measured the average of the initial daily insuline dose for each of these groups, it was 0.52 IU/kg/d (95% CI 0.4–0.6) for normoponderal patients, 0, 46 IU/kg per day (95% CI 0.4–0.5) for overweight patients, 0.34 IU/kg per day (95% CI 0.3–0.4) for those with stage 1 obesity, 0.36 IU/kg per d (95% CI 0.2–0.5) for those with stage 2 obesity, 0.36 IU/kg/d (95% CI 0.3–0.4) for those with morbid obesity.We found a statistically significant difference between these avearges only for the normoponderal group and the group with stage 1 obesity ($P = 0.041$).
Conclusion
According to this study, the initial daily insuline dose of the normoponderal patient is lower than the obese one**.**

Diabetic ketoacidosis: role of the patient 'Expert' in the management!

Sara Ijdda, Ekondzoula Joel Rudy, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
University Hospital Center Mohamed VI, Department of Endocrinology, Diabetes, Metabolic Disease and Nutrition, Marrakech, Morocco

Introduction
The emergence of the concept of the expert patient has changed the paternalistic doctor–patient relationship. The 'knowing' patient is an active actor, his level of knowledge acquired during therapeutic education programs (ETP), allows him a certain autonomy in the management of his pathology. We focus through a case report of ketoacidosis on the useless intervention of an 'expert' patient to prevent it.
Case report
A 25-year-old patient, type 1 diabetic since the age of 6, having received in our departement as part of therapeutic education, a training in functional insulin therapy, which she stopped for lack of funds. She was admitted to the visceral surgery departement for surgical management of appendicitis. The postoperative course was marked on the second day by the installation of hyperglycemia at 3.3 g/l with ketosis. On biological assessment, natremia was 140 mg/l, kalaemia 4.3, alkaline reserves 12 meq/l, with good renal function and significantly improved creatinine reactive protein. We noted that the patient had been put by the healthcare team, only on rapid insulin boli since admission. In addition, she reports having unsuccessfully requested from caregivers to give her her basic insulin regimen for fear of falling into ketoacidosis. Our treatment consisted of introduction of the correction regimen and then, the return of her previous insulin regimen with good progress.
Discussion/conclusion
In the case of a chronic disease, in this case diabetes, the patient's quality of life will be 'impacted' by the therapeutic choice. In particular, compliance with this choice will be all the greater the more the patient has participated in the decision. By observing his body and his reactions to the disease, the patient-expert accumulates experiential knowledge (derived from knowledge of the disease *in vivo*) that can complement the physician's clinical knowledge and guide its decisions. The behaviour of this patient-expert does not aim to question the legitimacy of the physician, since this legitimacy is institutionalized, but raises the question of the acceptability and credibility of this legitimacy.

Glycemic control of patients on human insulin and those on insulin analogues, is there a difference ?

Amal Mehrzi, Haifa Abdesslem, Eya Safi, Kamilia Ounaissa, Rym Ben Brahim, Rym Yahyaoui, Imen Sebai & Chiraz Amrouche
Tunisian Institute of Nutrition, The Day Hospital Department, Tunisia

Introduction
The objective of our study was to compare the glycemic control between patients on human insulin and those on insulin analogues.
Methods
We conducted a prospective, randomized and comparative study. By recruiting patients with diabetes hospitalized in the day hospital departement at the National Nutrition Institute in Tunis during 8 months. The glycemic control of patients on human insulin and those on insulin analogues was evaluated by comparing the averages of their fasting glucose level and glycated hemoglobin.We used the *t*-test for independent samples.
Results
We included 50 patients with diabetes, 80% with type 2 diabetes and 20% with type 1 diabetes, 60% were women and 40% were men,the average age was 49 years (± 16), the average duration of diabetes was 10 years (± 7), insulin-treated for an average duration of 5 years (± 6), 74% were on human insulin and 26% were on insulin analogues, the average body mass index was 28 (95%CI26-29), the average fasting glucose level was 10 mmol per liter (95%CI9-11), the average glycated hemoglobin was 9.5%(95%CI9-10). The average of fasting glucose level for patients on human insulin was 10 mmol/l (95% CI 8.6–11.4) and for those on insulin analogs 10.4 mmol/l (95% CI 8.4–12.3), we found no statistically significant difference between these two averages (P=0.66). The average of glycated hemoglobin for patients on human insulin was 9.67% (95%CI 9.1–10.1) and for those on insulin analogues 9.2% (IC95% 8.5–10%),we found no statistically significant difference between these two averages($P = 0.34$).
Conclusion
In this study, we found no statistically significant difference between the glycemic control of patients on human insulin and those on insulin analogues. More studies are needed to validate these results.

Relationship between vitamin D levels and visceral fat thickness, insulin resistance, inflammation and thyroid parameters in patients with obesity

Volodymyr Pankiv
Ukrainian Research Centre of Endocrine Surgery, Transplantation of Endocrine Organs and Tissues, Clinical Endocrinology, Kyiv, Ukraine

Background
Low serum vitamin D concentrations have been associated with autoimmune thyroiditis. Obesity is characterized by lower vitamin D levels and higher risk to develop autoimmune diseases. The aim of the study was to investigate the possible relation of serum vitamin D concentrations to visceral fat thickness (VFT), insulin resistance (IR), inflammation (serum monocyte chemoattractant protein-1 – MCP-1) and thyroid parameters in obese patients.
Materials and methods
A total of 45 non-diabetic, obese patients aged 20–59 years without a history of thyroid pathology were recruited. Biochemical markers, insulin, 25(OH) D, thyroid parameters (thyroid stimulating hormone – TSH, free thyroxine – fT_4, free triiodothyronine – fT_3, thyroid peroxidase antibodies – TPO-Ab, thyroglobulin antibodies – Tg-Ab) and VFT were measured. Serum MCP-1 evaluated the inflammation. A HOMA-IR cut-off value of 3.0 defined IR.
Results
Most patients had vitamin D deficiency (46.7%) and insufficiency (48.9%). Vitamin D level was negatively associated with BMI ($P = 0.038$) and VFT ($P = 0.006$). Vitamin D deficiency correlated with autoimmune thyroiditis prevalence ($P = 0.032$) and was a risk factor for its occurrence ($P = 0.023$).

At 20 ng/ml cut-off value, vitamin D was negatively correlated with MCP-1 (P = 0.007). Also, MCP-1 was positive correlated with HOMA-IR (P = 0.039), TPO-Ab levels (P = 0.015) and with autoimmune thyroiditis (P = 0.028). MCP-1 was a risk factor for vitamin D deficiency (P < 0.001). The final logistic model of a multivariate analysis, performed with autoimmune thyroiditis as the dependent variable and age, BMI category, 25(OH)D category, and TSH levels as the independent ones, showed that patients with autoimmune thyroiditis were more likely to have deficiency of 25(OH)D (P = 0.023) and higher TSH (P < 0.001) levels.
Conclusion
This investigation supports an interaction between vitamin D and systemic inflammation in obese patients. Systemic inflammation is related to the frequency of autoimmune thyroiditis. Vitamin D deficiency is the single independent factor associated with autoimmune thyroiditis in patients with obesity.

Internet searches for diet and obesity in the COVID-19 era: a study in Greece and Lithuania

Lina Zabuliene[1], Athanasios Tselebis[2] & Ioannis Ilias[3]
[1]Faculty of Medicine, Vilnius University, Institute of Clinical Medicine, Vilnius, Lithuania; [2]Sotiria Hospital, Department of Psychiatry, Athens, Greece; [3]Elena Venizelou Hospital, Endocrinology, Athina, Greece

Introduction
Internet searches mirror – to a degree – real-life behaviors and are influenced by chronic situations or abrupt events. From 2019 onwards the advent of the COVID-19 pandemic has changed profoundly daily habits, particularly during periods of protracted lockdown and following stay-at-home orders.
Aim
In this study we aimed to assess Google Trends internet searches for diet and obesity over time and vis-à-vis searches for COVID-19 in Greece (GR; a typical mediterranean country) and Lithuania (LT; a typical northern European country); both countries have comparable per capita income and Gini indexes (measuring income inequality).
Methods
We collected data on Google Trends internet searches (by means of relative search volumes; RSVs) in GR and LT regarding 'diet/obesity' and 'coronavirus/COVID-19' (in English, Lithuanian and Greek) from 2016 onwards. Statistical assessment was done with analysis of covariance, linear regression, evaluation of autocorrelation and cross correlation.
Results
A positive time trend – particularly in 2020 – was noted for RSVs regarding 'diet' both in LT and GR (in English), whereas a negative time trend was noted regarding 'dieta = diet' and 'nutukimas = obesity' (in Lithuanian). The periodicity of RSVs did not reach statistical significance. Searches regarding 'diet' and 'obesity' were positively correlated in LT and GR. Mostly negative cross-correlations regarding RSVs for 'diet/obesity' and 'coronavirus/COVID-19' were noted in both countries, with the exception for searches regarding 'nutukimas = obesity' vs 'COVID-19' in LT (r at lag 0 = +0.341, P = 0.013).
Discussion
Being locked in at home is stressful and with limited physical activity. Comfort food consumption and increased food intake were reported during lockdown for COVID-19; this may lead to weight gain. More than half of the population in GR and LT are overweight or obese. Our results show a growing interest for diets over time (that was not necessarily coupled with an interest in obesity) which was dampened to a degree by searches for COVID-19. Other factors – that were not assessed here – may also play a role: in Asia, a study has shown national Google Trends internet searches for diet and obesity to reflect the country's economic indices; this finding was subsequently not verified in GR.

Metabolic disorders in children who are obese A study of 84 cases

Sidina Mohamed Elmoctar, Dhoha Ben Salah, Mouna Elleuch, Khouloud Boujlben, Mouna Mnif, Nabila Rekik, Fatma Mnif, Nadia Charfi, Faten Haj Kacem & Mohamed Abid
Hedi Chaker Hospital, Route El Ain, Sfax, Tunisia, Endocrinology, Sfax, Tunisia

Introduction
Metabolic syndromeis the association in the same individual of a number of cardiovascular risk factors, namely abdominal obesity, dyslipidemia, high blood pressure and glucose intolerance. The objective of this study is to analyze the clinical and paraclinic characteristics of obese and overweight children in order to look for the elements of metabolic syndrome in these children
Methods
We carried out a retrospective and analytical study, we included children admitted for explorations of obesity to the department of endocrinology of the Hédi Chaker Hospital in Sfax between January 2015 and December 2019. Obesity was defined by a BMI greater than the 97th percentile according to the French reference curves. Abdominal obesity was retained if waist circumference is greater than 90° percentile depending on age and sex according to the American reference curve for children of European origin. The metabolic syndrome was defined according to the child-adapted NCEP-ATPIII.
Results
The study population consisted of 84 children, 44 boys and 40 girls. 71.4% of patients come from an urban area. Family history of obesity was recorded in 84.5% of cases. The average weight at first consultation was 72.68 kg (20–125 kg), average waist circumference was 98.7 cm (65–145 cm) and Average BMI was 31.55 kg/m^2. Obesity was primary in 96.4% of cases, 1st class in 21% of cases and 2nd class in 79% of cases. The obesity complications were cardiovascular in 4.8%, mechanical in 4.8% of cases, respiratory 7.1% of cases. and metabolic in 22% of cases. according to the criteria of NCEPATPIII adapted for the child 22.2% of patients had a metabolic syndrome. this metabolic syndrome was noted in 20.6% of boys and in 24% of girls, HTA was present in 4 patients (4.8%). Android fat distribution was present in 69 patients (82%). The mean HDL cholesterol was 1.12 mmol/l, and the mean triglycerides was 1.1 mmol/l. Twenty four percent of patients who hada family history of obesity and none of the patients without family history of obesity had a metabolic syndrome. In our series, metabolic syndrome was 6% in children under 10 years, 25% in children 10–15 years, and 36.4% in children above 15 years.
Conclusion
In our study, 22% of all children included had a metabolic syndrome. this high prevalence requires the research of this pathology in at-risk children, particularly children who are obese and aged above 10, to prevent complications in adulthood.

Outcome of intensive treatment for obesity at our hospital

Bunzo Matsuura[1], Hidenori Senba[1], Hironobu Nakaguchi[1], Sayaka Kanzaki[2], Masumi Miyazaki[2], Kyoko Watanabe[2], Teruki Miyake[2], Shinya Furukawa[2] & Yoichi Hiasa[2]
[1]Ehime University Graduate School of Medicine, Lifestyle-related Medicine & Endocrinology, Toon, Japan; [2]Ehime University Graduate School of Medicine, Gastroenterology & Metabology, Toon, Japan

Since 2006 at our hospital, lifestyle modification, such as diet and exercise, for obese patients has been provided through a team approach with a physician, dietician, nurse, physical therapist and psychologist. From 2016, a surgeon and anesthesiologist were added to the team for metabolic/bariatric surgery. The aims of this study are to clarify the effectiveness and problems of lifestyle modification for short-term intensive management (for 3 months) and long-term management (for over 2 years), and to clarify the characteristics of patients who transferred for surgical treatment. The diet menu is as follows: intake energy is (resting energy expenditure + exercise energy) × 0.9, and nutrients/total energy is 55–60% carbohydrates, 15–20% protein and 20–25% fat. The exercise is performed as follows: regular exercise more than 3 times per week or more than 5000 steps per day, and if possible, more than 10000 steps per day. Until now, 150 obese patients (mean age of 50 years and mean body mass index (BMI) of 36) have received medical management, and the mean BMI significantly decreased by 1.2 over 3 months. Thirty patients (20%) have transferred for surgical treatment. Seventeen patients had diabetes with a BMI of 31–48 and HbA1c 8–9% despite intensive therapy. Five with a BMI of 41–60 had bilateral knee osteoarthritis and required total knee replacement, three with a BMI of 38–51 had severe sleep apnea, and one with a BMI of 44 had infertility. The complete (HbA1c < 6% without diabetic medication) and partial (HbA1c < 6.5% with some medication) remission of diabetes was achieved in 70% and 30%, respectively. Serum C-peptide levels were significant higher in patients with the complete remission of diabetes than that in patients with the partial remission. In conclusion, diabetic patients need a lower BMI

for metabolic/bariatric surgery compared with non-diabetic patients, and baseline serum C-peptide level has a major influence on outcome in Japan.

The association of depression with adipose tissue inflammation related to obesity

Said Lhamyani[1], Adriana Mariel Gentile[1], Maria Isabel Cabrera Gonzalez[2], Laura Sanchez Marin[3], Antonia Serrano[3], Francisco José Tinahones[4,5], Gabriel Olveira[1,6] & Rajaa El Bekay[1,5]

[1]Unidad de Gestión Clínica Intercentros de Endocrinología y Nutrición, Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Regional Universitario de Málaga/ Universidad de Málaga., Malaga, Spain; [2]Universidad de Malaga. Campus Teatinos., Malaga, Spain; [3]Unidad de Gestión Clínica de Salud Mental, Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Regional Universitario de Málaga, Universidad de Málaga, Malaga, Spain; [4]Unidad de Gestión Clínica Intercentros de Endocrinología y Nutrición, Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Clínico Virgen de la Victoría/Universidad de Málaga., Malaga, Spain; [5]Centro de Investigación Biomédica en Red de obesidad (CIBERorn), Spain; [6]Centro de Investigación Biomédica en Red de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), CB07/08/0019, Spain

Background and aim

Major depressive disorder (MDD) is one of the common mental disorder that affect more than 350 million subjects. MDD has been reported to be associated with systemic inflammation and obesity. However, there are no data that relate adipose tissue (AT) inflammation to MDD. The analysis of inflammatory markers in AT could pave the way to clarify the potential association between MDD and obesity. For this reason, the aim of our study was to analyze the expression of inflammatory adipokines in human and mice AT in relation with obesity and MDD.

Materials and methods

IL-6, IL-1b, ADIPOQ, TNF-a, MCP-1, ITGAM and PLAUR expression levels were measured by real-time qPCR from subcutaneous (SAT) and visceral (VAT) adipose tissue of depressive and no depressive normoweight subjects (n = 10) and depressive and no depressive morbid obese (n = 10) and from male obese mice fed a high fat diet (HFD, n = 7) and male lean mice fed a standard diet (S.D., n = 7).

Results

in this study, we observed that in both SAT and VAT the expression levels of *IL-6, IL-1b, TNF-a, MCP-1, ITGAM and PLAUR* increased significantly in no depressive normoweight and no depressive obese compared with no depressive normoweight, while *ADIPOQ* expression was lower in these groups compared with no depressive normoweight. Additionally, in obese subjects, the expression levels of IL-6 were higher in depressive subjects compared with no depressive subjects whereas ADIPOQ expression was lower in depressive subjects compared with no depressive in SAT and VAT. The expression levels of *Il-6, il-1b, Tnf-a, Mcp-1, Itgam and Plaur* increased significantly from obese mice HFD compared with lean mice S.D. in VAT and SAT while, Adipoq expression decreased with obesity.

Conclusion

Our results suggest the potential involvement of VAT and SAT inflammation in MDD, inducing complex mechanisms which are strongly linked with obesity. This work was supported by grants from the Spanish Ministry of Health (FIS), PI18/00785 and Miguel Servet II" [CPII13/00041], and co-funded by Fondo Europeo de Desarrollo Regional–FEDER, and from the Consejería de Innovación and co-funded by Fondo Europeo de Desarrollo Regional–FEDER (CTS-7895) S.L. was a recipient of a post-doctoral grant Plan Andaluz de Investigación, Desarollo e Inovación (DOC-01138) from Consejería de Economía, Conocimiento, Empresas y Universidad.

Evaluation of the effect of lockdown order during Covid-19 pandemic on the clinical and metabolic parameters of obese patients in Turkey

Damla Tufekci[1], Hulya Coskun[1], Egemen Unal[2], Yasemin Emur Gunay[1], Ahmet Suat Demir[1], Muhammet Cuneyt Bilginer[1], Ozge Ucuncu[1], Irfan Nuhoglu[1] & Mustafa Kocak[1]

[1]Karadeniz Technical University Faculty of Medicine, Karadeniz Technical University Faculty of Medicine, Department of Endocrinology and Metabolism, Trabzon, Turkey, Trabzon, Turkey; [2]Yildirim Beyazit University Faculty of Medicine, Department of Public Health, Ankara, Turkey, Turkey

Aim

Lockdown order during COVID-19 pandemic caused a sedentary life-style and disruptions in eating and sleeps patterns of obese patients. In this study, it is planned to evaluate the clinical and metabolic effects of this period on obese patients.

Methods

This study included 44 obese patients who were followed up in Endocrinology and Metabolic Diseases Clinic of Karadeniz Technical University. In this study, metabolic parameters (fasting plasma glucose, insulin, homa-IR, lipid profile) and obesity-related problems during the lockdown (weight gain, dietary habits, exercise situations) experienced by obese patients, who were followed up in our clinic, were compared between the 6 months period before the March 11, 2020 the date of the first case of COVID-19 seen in Turkey and the period patients started to apply for the first time after the pandemic started to slow down. During the outpatient clinic applications of the patients; whether the patients followed up their weight, physical activity status, any change in their dietary habits, whether they needed to apply to the hospital and had any infection during the lockdown order was questioned and blood samples were taken for biochemical analysis.

Findings

72.7% of the study group was women. Average age of subjects was 39.89 ± 13.92 years. Subjects' average body mass index (BMI) was 36 kg/m^2 and 27.3% (n = 12) of the subjects were morbidly obese. Dietary compliance before and during COVID-19 pandemic was found as 27.3% and 13.6%, respectively (P: 0.109). The ratio of exercise at home was 29.5% before the COVID-19 pandemic and increased to 31.8% during the pandemic (P: 0.999). 68.2% of the participants stated that they tracked their weight and 52.3% stated they had an increased appetite. The behavior of not tracking the weight during the pandemic was more common in morbidly obese participants (P = 0.027). An increase was observed in weight (P<0.001) and BMI (P<0.001) measurements of participants during the lockdown order. During the pandemic; diet (P: 0.609) and exercise (P: 0.633) were not found associated with weight increase. After the lockdown order; a significant increase was found in glucose (P: 0.001), insulin (P< 0.001), homa-IR (P<0.001) and cholesterol (P<0.001) values of the participants.

Conclusion

This study shows lockdown order during COVID-19 pandemic caused weight increase and related disruptions in insulin resistance and lipid parameters regardless of dietary and exercise habits in obese patients who have not had COVID-19 infection.

Effects of a single-centre lifestyle modification programme on anthropometric, metabolic, and cardiovascular risk factors in adults with severe obesity

John Brazil[1], Francis Finucane[1], Irene Gibson[2,3], Chris Collins[4], Brian Maguire[5], Mary Hynes[5], Mustafa Bakir[1], Denise Dunne[2,3], Siobhan Foy[1], Suzanne Seery[3], Paul Bassett[2] & Colin Davenport[1]

[1]HRB Clinical Research Facility, Galway University Hospital, Bariatric Medicine Service, Centre for Diabetes Endocrinology and Metabolism, Galway, Ireland; [2]Croi, the West of Ireland Cardiac Foundation, Heart and Stroke Centre, Galway, Ireland; [3]National Institute for Prevention and Cardiovascular Health, Galway, Ireland; [4]Department of Upper Gastrointestinal Surgery, Galway University Hospital, Galway, Ireland; [5]National University of Ireland, Galway, School of Psychology, Galway, Ireland

Background

Structured lifestyle modification programmes are offered as first line treatment to patients referred to bariatric specialist services. We sought to describe changes in anthropometric and metabolic characteristics in a cohort of bariatric patients following completion of an eight-week, multidisciplinary group-based lifestyle intervention focussed on diet and physical activity.

Methods

We conducted a prospective cohort study of all patients who completed the programme from 2013 to 2019. Weight, body mass index, blood pressure, HbA1c, lipid profile and functional capacity (Incremental shuttle walk test) at baseline and follow-up were compared in per-protocol analyses.

Results
Of 1122 patients enrolled in the program, 877 (78.2%) attended for follow up measures. Mean age was 47.3 ± 11.9 years and 66.9% were female. BMI decreased from 47.0 ± 7.8 to 46.2 ± 7.8 kgm^{-2} (P<0.001), weight decreased from 131.6 ± 25.5 to 129.5 ± 7.8 kg (P<0.001) and the number of patients achieving HbA1c <53 mmol/l increased from 79.4% to 83.6% (P = <0.001). There were also improvements in blood pressure, lipid profiles and functional capacity: MET (metabolic equivalents of thermogenesis) max 5.6 ± 2.1 vs 7.0 ± 2.8 (P = <0.001).
Conclusions
Adults with severe and complicated obesity referred from a hospital-based bariatric service who completed eight weeks of supervised, group-based structured lifestyle modification had improvements in anthropometric and metabolic characteristics consistent with a reduction in cardiovascular risk.

Association of Vitamin D deficiency with obesity in middle-aged subjects with or without Type-2 diabetes in India

Dr. Neetu Mishra & Yoogita Dhas
Symbiosis International (Deemed University), Symbiosis School of Biological Sciences, Pune, India

Background
The prevalence of type 2 diabetes has been increasing all over the world. Various risk factors have been identified for the generation of type 2 diabetes include; ageing, family history of diabetes, general obesity, central obesity, physical inactivity, and sedentary lifestyle. Obesity, particularly central obesity is associated with insulin resistance (IR), 'beta-cell' dysfunction, partly through increased free fatty acids (FFAs) and lipotoxicity. Approximately 1 billion individuals worldwide, nearly 15% of the world's population, are vitamin D deficient or insufficient (less than 20 ng/ml or between 20 and 30 ng/ml, respectively). Vitamin D deficiency become a very common among all age groups worldwide and the highly prevalent in obese people.
Material and methods
The study was conducted in 90 control and 90 type 2 subjects with Type 2 diabetes mellitus patients of both genders aged 30–50 years. We obtained ethics approval from Institutional Ethics Committee, Symbiosis International (Deemed University), Pune, India before blood sample collection. The data regarding BMI, among control and T2DM subjects were collected. We have used WHO cut-offs to define overweight and obesity, whereas IDF cut-offs to define central obesity using different indicators such as WC and WHR. 'American Diabetes Association (ADA)' cut-offs were used for categorizing dyslipidemia Serum 25(OH)D, fasting plasma insulin (FPI), fasting plasma glucose (FPG), HbA1c, and lipid profile were measured by standard methods.
Results
In the control group, an almost equal percentage of subjects had normal BMI (41.11%) or were overweight (42.22%), while in the T2DM group majority of subjects were overweight (48.89%). Data indicated that T2DM subjects had significantly higher BMI, WC, HC, WHtR, blood pressure, TG, and VLDL-c than controls. The proportion of waist circumference WC>90cm was seen significantly higher among T2DM male subjects than control male subjects, while there was no significant difference for the proportion of WC>80 cm in female subjects. Also, among the study groups, there was no significant difference observed in the proportions of waist hip ratio WHR>0.88 in male and WHR≥0.80 in female subjects. Among lipid profile parameters there was a significant difference observed in the proportions for TG and HDL (in females) among control and T2DM groups. 'Spearman's rank-order correlation' was utilized to evaluate the correlation of '25(OH)D' with anthropometric and biochemical variables among control, T2DM, and total study subjects.
Conclusion and significance
Vitamin D could be associated with obesity and insulin resistance.

Self-esteem among obese patients in Sfax, southern Tunisia

Yosra Mejdoub[1], Nouha Ketata[1], Dhoha Ben Salah[2], hanen maamri[1], Mondher Kassis[1], Sourour Yaich[1], Mouna Elleuch[2], Faten Hadj Kacem[2], Jamel Damak[1], Jihen Jdidi[1] & Mohamed Abid[2]

[1]Hedi Chaker University Hospital, University of Sfax, Tunisia, Community Health and Epidemiology Department, Tunisia; [2]Hedi Chaker University Hospital, University of Sfax, Tunisia, Endocrinology Department, Tunisia

Introduction
Self-esteem is widely viewed as a person's overall evaluation about self-worth or personal value and is considered an essential indicator for positive mental health and psychological well-being. This study sought to explore the level of self-esteem and identify the factors associated with low self-esteem in this population.
Methods
It was a cross-sectional study conducted in Sfax, Southern Tunisia from June to July 2020. We included all obese adults aged 19 to 64 years consulting at the basic health centre of Sfax and having a BMI greater than or equal to 30 kg/m^2. We excluded pregnant and nursing women and patients with severe decompensated organic disease and psychiatric disorder. We used the Rosenberg Self-Esteem Scale. Statistical analysis was performed using SPSS.24.
Results
A total of 150 obese patients were included in the study. There were 115 women giving a male to female ratio of 0.3. The mean age was 50 ± 12.5. There were 82 cases (54.7%) in stage I, 31 cases (20.7%) in stage II and 37 cases (24.7%) in stage III of obesity. Overall, 84 patients (56%) were from urban areas. History of associated illness was noted in 90 cases (60%). There were 12 current smokers (8%) and 62 patients (41.3%) were exercising physical activity. Overall, 69 patients (46%) had obesity for more than 10 years. The mean score of self-esteem was 26.9 ± 2.9. Of all patients, 139 cases (92.7%) had a low or very low self-esteem score. Prevalence of depression, anxiety, extreme self misperception, severe social phobia and bulimia were 26%, 75.3%, 29.3%, 38.7% and 10%, respectively. There was no significant association between low self-esteem and depression, anxiety, self misperception or social phobia. Besides, exercising physical activity was statistically associated with good self esteem (OR = 0.1; P = 0.01).
Conclusion
Obese patients demonstrated lower levels of self-esteem. Health-focused conversations between practitioners and obese patients about weight status and self-esteem, and appropriate follow up counseling can help improve self-esteem and mental health among obese patients.

The association between obesity and type 1 diabetes: prevalence and complications

Mohamed Aymane Loukili, Abdessamad Malki, Anouar Jamal, Siham Rouf & Hanane Latrech
Mohammed VI university hospital center, Endocrinology Diabetology, Oujda, Morocco

Introduction
An increasing number of type 1 diabetics (T1DM) are being identified as having characteristics of metabolic syndrome and obesity. The aim of our work is to assess the prevalence of overweight and degenerative complications in a population with type 1 diabetes.
Material and methods
This is a descriptive and retrospective study concerning 377 type 1 diabetics hospitalized in the endocrinology-diabetology department over a 6-year time period.
Results
The mean age was 21.4 ± 11 years. A total of 44.6% had active diabetes for more than 5 years with an average of HbA1c 10.7 ± 5.2%. 44.4% of patients were admitted for uncontrolled diabetes with dietary errors in 26.4% of cases. The mean BMI was 20.3 ± 4.3 kg/m^2, it was inversely correlated with HbA1c (P = 0.001), 21.9% had a BMI > 25 kg/m^2 with a sex ratio M/W = 0.3, including moderate obesity in 3.4% and severe obesity in 0.9%. Hypertension was observed in 13.7% of cases, ischemic heart disease in 2%. 18% of patients had diabetic retinopathy, and 12% had diabetic nephropathy.
Discussion–conclusion
Patients with T1DM have more characteristics usually associated with T1DM patients with overweight, known as 'double diabetes'. This association seems to be an independent and important risk factor for the development of macrovascular and microvascular complications. Long-term studies are required to confirm the specific dietary patterns in this population.

Overweight and obesity in a Tunisian population of medical students

Eya Safi, Yosra Htira, Khadija Ben Naceur, Oueslati Insaf, Manel Dridi, Mehrez Achwak & Feika Ben Mami
National Nutrition Institute, Tunisia

Introduction
Over the past decades, the prevalence of overweight, especially obesity, has steadily increased. This global scourge has affected all populations including that of medical students. The objective of our work was to determine the prevalence of this pathology in the population of future physicians and to study the factors associated with it.
Methods
This is a cross-sectional study including 120 medical students, recruited at the Faculty of Medicine of Tunis between November 2019 and March 2020.
Results
The average age of the students was 21.82 ± 2.09 years old. A female predominance was noted witha sex ratio (M/F) = 0.54. The average BMI was 21.4 kg/m^2 with extremes ranging from 16.87 to 35.67 kg/m^2. Overweight (BMI> or equal to 25 kg/m^2) was present in 30% of the cases of which 30 were pre-obese, 5 had class I obesity and only 1 student had class II obesity. The mean waist circumference was 79.73 ± 10.74 cm and abdominal obesity was noted in 36 students (30%). This excess weight was significantly associated with the female sex (P = 0.002). It was also significantly associated with college year repetition, noted in 36 students (P = 0.018) and was unrelated to the year of medical study. This overweight was significantly more noted in smokers (n = 36) (P = 0.049) and regular alcohol users (n = 37) (P <0.001). It was more common in students who used drugs without this being significant (P = 0.59). We did not find a significant association between the use of anxiolytics and antidepressant medication and overweight. The mean of the perceived stress scale (PSS) was higher in the presence of overweight (31.61 ± 5.85 versus 29.99 ± 5.61) without this being significant.
Conclusion
Overweight was common in our student population. Identification of potentially associated factors is necessary in order to reduce the prevalence of this pathology, a source of both physical and psychological disability.

DOI: 10.1530/endoabs.73.EP58

EP59

Overweight impact on the progression of non-alcoholic fatty liver disease and liver fibrosis

Nadiia Gavryliuk[1], Ihor Hospodarskyy[1], Oksana Prokopchuk[1] & Michail Havrylyuk[2]
[1]Ternopil, Department of Clinical Immunology, Allergology and General Patient Care, Ternopil, Ukraine; [2]Ternopil, Department of Internal Medicine No.1, Ternopil, Ukraine

Background
Currently, the overweight and obesity influence on human organs and systems is being studied all over the world, which are based on the violation of metabolic processes of fat and carbon metabolism, hyperglycemia with glucose toxicity, insulin resistance, obesity and metabolic syndrome. NAFLD progresses not only from steatosis to steatohepatitis (NASH), but is accompanied by liver fibrosis with transformation into cirrhosis and hepatocellular carcinoma in 20% of NASH patients. It is fibrosis that determines the further prognosis in patients and the risk of their death.
Objectives
To study the impact of overweight and obesity on liver fibrosis in NAFLD patients.
Methods
The object of the study was 59 patients without concomitant pathology with different body mass index and signs of steatosis and fibrosis according to ultrasound examination in combination with changes in the lipid profile or impaired glucose tolerance. for everyone Anthropometric examinations (weight, height, BMI), laboratory and instrumental examinations, biochemical studies to determine the functional state of the liver, liver elastometry and serum markers to determine liver fibrosis and steatosis (FIB4, NAFLD) were performed for each patient.
Results
Among the examined patients, there were 28 men (24.35%) and 31 women (26.95%) with an average age of 48.71 ± 2.37 and 51.1 ± 1.78. All patients were divided into groups depending on their body weight: Group I – normal weight (18.5–24.9 kg/m^2), II – overweight (25–29.9 kg/m^2), III – obesity I degree (30–34.9 kg/m^2). A direct relationship was established between weight and gender (r = 0.30, P < 0.05), which confirms the tendency to overweight in women. Going to the lipid profile, a direct relationship was established between BMI and very low density lipoproteins and triglycerides (r = 0.324, P <0.05 and r = 0.318, P <0.05). Observed growth rates of ALT, AST indices in the biochemical blood test with an increase in body weight (r = 0.679, P <0.05; r = 0.674, P <0.05). A direct strong relationship was found between BMI and the mean value of liver elastography data (r = 0.74, P <0.05), non-invasive FIB4 test (r = 0.88, P <0.05) and NFS (r = 0.89, P <0.05).
Conclusion
Overweight and obesity are the foundation for the fibrotic processes development in the liver, and its significant increase leads to pronounced fibrotic changes (F2–F3 according to METAVIR).

A death case of type 1 diabetes mellitus due to COVID-19

Kader Ugur[1], İlknur Karatas[2], Ramazan Fazıl Akkoç[3] & Süleyman Aydın[4]
[1]Firat University, Elazig, Turkey, Department of Internal Medicine (Endocrinology and Metabolism Diseases), Faculty of Medicine, Elazig, Turkey; [2]Firat University, Elazig, Turkey., Department of Internal Medicine, Faculty of Medicine, Elazig, Turkey; [3]Firat University, Elazig, Turkey., Department of Anatomy, Faculty of Medicine, Elazig, Turkey; [4]Firat University, Elazig, Turkey., Department of Medical Biochemistry and Clinical Biochemistry (Firat Hormones Research Group), Faculty of Medicine, Elazıg, Turkey

Introduction
The prevalence and mortality of the new type of coronavirus (SARS Cov-2) are high in patients with metabolic disease, especially in diabetes circumstances. Therefore, this study aims to present the changes in the clinical and biochemical parameters of a patient with Type 1 diabetes who died due to Covid-19.
Case
The case is a 24-year-old female patient who has been followed up in our hospital with the diagnosis of Type 1 diabetes, Celiac disease, and osteoporosis due to secondary hypogonadism for years. Again, this patient had been receiving treatment for chronic renal failure and hypertension due to diabetic nephropathy for 2 years. She was using inhaler ß2 agonists and corticosteroids for 1 year because of her asthma bronchiale. In addition, the case was underdeveloped compared to her peers and was 140 cm tall and 40 kg in weight. Initially, the patient was admitted to our hospital with a blood glucose level of 1050 mg/dl and a diagnosis of diabetic ketoacidosis (Table 1). In addition, since the patient was accompanied by dyspnea and nasal discharge, it was consulted with the clinic of infectious diseases. Her blood and urine cultures were taken and sent for Covid-19 PCR. The ground-glass images in the Thorax CT result were compatible with pulmonary edema and pulmonary embolism. Appropriate fluid replacement and intravenous insulin infusion treatment were initiated until the infection results were obtained. Despite all the treatments, target values determined for diabetes could not be achieved for this patient. We were able to reduce blood glucose by a maximum of 250 mg/dl. Additionally, the patient's electrolyte and blood gas were monitored. In its follow-up, treatment-resistant fever 39.5 °C was measured. Despite all efforts, the O2 saturation of the patient fell below 70 mmHg. As soon as Covid-19 was diagnosed, she was taken to the Covid-19 intensive care unit, and her glucose follow-up was followed up continuously and she was intubated. However, our patient died 1 day later.
Conclusion
As a result, it was observed that blood glucose regulation is more difficult in patients with new types of coronavirus infection.

Table 1. Laboratory findings of patient

eGFR (ml/min/ 1.73 m^2)	15
Glucose (mg/dl)	1050
HbA1c (%)	>15
WBC (10e3/µl)	6.56
Lymphocyte (10e3/µl)	0.85
Hgb (g/dl)	7.5
AST (U/L)	24
ALT (U/L)	8

Urea (mg/dl)	157
Creatinine (mg/dl)	3.89
Sedimentation (mm/h)	102
CRP (mg/l)	35.6
Ferritin (ng/ml)	1030
D-Dimer (mg/l)	0.4
Fibrinogen (mg/dl)	754
PO2/FiO2	118
Procalcitonin (mg/l)	0.38

The diabetic foot : a descriptive study

Mouna Elleuch, Rami Mejdoub, Hadj Kacem Faten, Safi Wajdi, El Arbi Kawthar, Trabelsi Ons, Mnif Mouna, Mnif Fatma, Charfi Nadia, Rekik Nabila & Abid Mohamed
UH Hèdi Chaker, Endocrinology and Diabetology, Sfax, Tunisia

Introduction
The diabetic foot represents a public health problem with very important direct and indirect expenses. Multidisciplinary care and monitoring is essential. The aim of this Study was to describe the management of the diabetic foot in the endocrinology department.
Materials and methods
It was a retrospective study carried out in the Endocrinology and Diabetology department of the Hédi Chaker university hospital. It concerned patients with diabetic foot hospitalized between January 2010 and December 2018 regardless of the reason for hospitalization.
Results
Our study covered 130 patients with a mean age of 59 years and a sex ratio of 5 M/1 W. Our population comprised 83.7% of type 2 diabetic including 56.1% under insulin therapy and 16.3% of type 1 diabetic. The impairment was bilateral in 25.4% of cases. The mean duration of diabetes was 13.08 years. The insulin therapy was indicated for 70.8% of patients. We have found ulceration in 24.8% of cases and a perforating foot ulcer in 28% of cases. Neuropathy and arteriopathy were reported in 88.5% and 67% of patients, respectively. The infection was objectified in 42.2% of cases. The lesion recurred in 41.6% of patients. Amputation was reported in 39.1% of cases, of which 29.6% were major. The mortality rate was 4.9%.
Conclusion
Our results highlight the major impact of diabetic foot. Thus, a national care program is essential.

Characteristics of non-alcoholic steatohepatitis in patients with type 1 diabetes: a study of 8 cases

Dhoha Ben Salah, Mohamed Abdellahi Mohamed Ahmed, Mouna Elleuch, Kawthar El Arbi, Mouna Mnif, Nabila Rekik Majdoub, Nadia Charfi, Hadj Kacem Faten & Abid Mohamed
Chu Hedi Chaker /Service Endocrinologie/ Sfax, Sfax, Tunisia

Introduction
Non alcoholic steato-hepatitis (NASH) is the most common chronic liver disease in developed countries rare in type 1 diabetes it is associated with an increased risk of complications in patients with type 1 diabetes mellitus (T1DM). The aim of this study is to clarify the characteristics of NASH in patients with T1DM.
Materials and methods
we conducted a retrospective descriptive study in non-alcoholic type 1 diabetes patients diagnosed with ultrasound of hepatic steatosis, hospitalized in the endocrinology department of the Hedi-Chaker University Hospital in Sfax between 2000 and 2020.
Results
8 medical records were analyzed, of which 6 women and 2 men, a sex ratio of 1 in 3, the average age was 27.25 years (16 -67 years), the average weight was 56.12 kg (41- 72 kg), with average BMI of 21.6 kg/m^2 (15- 28 kg/m^2). One patient has overweight. The average waist circumference was 82.3 cm (65–111 cm), 4 patients had dyslipidemia, no history of hypertension, no atherosclerosis was found. Only 2 patients had metabolic syndrome. History of: T2DM in 5 patients, android obesity in 1 single patient and dyslipidemia in 1 other patient, no family history of T1DM neither autoimmune pathologywas found. The metabolic assessment of our patients was as follows: the mean blood glucose level was 18.7 mmol/l (10.9–32), the mean HBA1c rate was 11.6% (7–14), the average creatinine rate of 66.4 µmol/l (41–117), with an average GFR of 130 ml/min (57–231). The average lipid level: total cholesterol: 5.7 mmol/l, triglycerides: 2.03 mmol/l, HDL: 1.25 mmol/l, LDL: 2.4 mmol/l. Thehepaticassessment was:meanASAT rate was 422 Iu/l (22-1430), the mean ALAT rate was 245.7 Iu/l (17-1420). The hepatic steatosis index measured was an average of 30.5 (23–40.7). The total daily insulin dose averaged 64.3 IU (20–106), equivalent of 1.14 IU/Kg (0.44–1.56), 5 patients receive insulin doses greater than 1 IU/kg per day. 2 patients were under mixed treatment (metformin + insulin). Diabetes duration average was 10 years (4–19). The duration of onset of NASH compared to the diagnosis of diabetes was on average 7 years (1–16). Degenerative complications related to diabetes were as follows: 2 patients had retinopathy, 2 patients had neuropathy and only one had nephropathy.
Conclusion
NASH should be researched and well monitored in type 1 diabetics especially in view of android obesity and high transaminase rate; the diagnosis of this liver disease should lead to the achievement of a metabolic and cardiovascular assessment.

Pain in diabetic patients with lower limb amputation

Soumaya Elarem, Aymen Haj Salah, Ikram Haddada, Amira Jemni, Wafa Said, Mouna Sghir & Wassia Kessomtini
taher Sfar Hospital, Mahdia, Tunisia

Introduction
The aim of our study was to search the causes of pain in diabetics followed for a lower limb amputation in physical medicine and rehabilitation (PMR) department.
Patients and methods
A retrospective study carried out between 2018 and 2020 on diabetic patients referred to PMR department for lower limb amputation.
Results
Forty-two patients were included in the study. Their mean age was 61.4 ± 15.7 years with a sex ratio of 3.2. Most patients (65%) were type 2 diabetics with a history of 15 years of diabetes, 52.4% were hypertensive and 40% had obliterating arteriopathy of the lower limbs (OALL). Infectious origin (gangrene) was the most common cause of amputation (90.5%), followed by vascular origin (4.4%). The mean delay to PMR consultation after amputation was 7.9 ± 9.5 months. Amputations involved the leg (84.4%), the thigh (13.3%) and the foot in 4.4% of cases. They were unilateral in 73.3% of cases. Re-amputation was necessary in 6 cases. Patients experienced neuropathic pain in 57.6% of cases and a sensation of non-painful phantom limb in 84.4% of cases. Neuromatous pain was noted in 6.7% of cases and overlying joint pain (in the knee or hip) was found in 17.8% of patients. Half of the patients (50.3%) received their prosthesis and 8% of them presented with a painful conflict prosthesis requiring some corrections.
Conclusion
Pain in amputees can have several aspects to consider and seek by the clinician to ensure adequate management.

Critical Ischemia and albuminuria: positive correlations for prognosis of amputation in diabetic patients

Aikaterini Andreadi[1,2], Ilenia D'Ippolito[1,2], Sofia De Taddeo[1,2], Alessio Maiorino[1,2], Maria Romano[2], Valeria Ruotolo[2], Alessandro Minasi[2], Laura Giurato[2], David Della Morte – Canosci[1], Alfonso Bellia[1,2], Luigi Uccioli[1,2] & Davide Lauro[1,2]
[1]University of Rome 'Tor Vergata', Department of System's Medicine, Division of Endocrinology and Metabolic Diseases, Rome, Italy;

[2]Fondazione Policlinico Tor Vergata, Department of Medical Sciences, Unit of Endocrinology and Diabetology, Rome, Italy

Background
Diabetic nephropathy complicated by albuminuria along with low estimated glomerular filtrate rate (eGFR) are a typical feature of Type 2 Diabetes (T2D) and it's related to a significant increase in mortality and chronic complications in diabetic patients However, data from the literature are still not conclusive regarding the direct association between albuminuria and risk of amputation for ischemic limb vascular disease, in diabetic patients. Therefore, in the present study we aimed to explore this association in a cohort of elderly diabetic patients treated with surgery for critical ischemic limb vascular disease.
Material and methods
We enrolled hospitalized patients for the management of the diabetic foot with critical ischemia of the lower limbs from February to November 2019 at the Unit of Endocrinology and Diabetology. The study cohort had the following characteristics: 1) 118 patients in total (82 men/35 female); 2) mean age 67.15 years (± 11.49 years s.d.); 3) mean average duration of T2D 19.59 years (± 11.83 years s.d.); 4) mean of body mass index (BMI) 28.64 kg/m^2 (± 5.55 kg/m^2 s.d.); 5) mean of HbA_{1c}: 8.4%–68 mmol/mol (± 1.87%- mmol/mol s.d.); 6) mean eGFR 84.24 ± 42.01 ml/min s.d. Patients were divided in 3 groups considering the surgical approach: 1) 78 patients treated with revascularization of the lower limb; 2) 34 patients treated with conservative medical treatment of the lesson; 3) 16 amputee patients, 10 out of 16 had already performed at least one procedure of revascularization during hospitalization. Linear regression model was used to find association between different groups and investigated outcomes. A $P<0.05$ was considered statistically significant.
Results
Macroalbuminuria were significanlty increased in patients who had a major amputation limb intervention (distal or proximal), when compared to non-amputated patients. In the same cohort, PCR values increased while eGFR values reduced in the amputee when compared to the non-amputee patients. Conversely, no significant difference was present comparing blood glucose values between the groups. Interesting, a trend for an increase on triglycerides level ($P = 0.06$) was present in amputee compared to non-amputees patients.
Conclusions
The present study reports as diabetic patients with critical ischemia of the lower limbs, and with chronic kidney disease, specifically with renal failure and increased levels of macroalbuminuria, have a significant increase in the risk of amputation. In addition, there was a specific correlation between major amputation and a high degree of marker of inflammations. Further studies in a larger population are needed to confirm present results.

EP65

Glycemic control and microvascular complications in patients with type 1 diabetes and treated celiac disease

Rahma Khalaf, Zohra Hadj Ali, Yosra Htira & Faika Ben Mami
National Institute of Nutrition, Tunis, Tunisia

Background
Celiac disease (CD) occurs in patients with type1 diabetes (T1DM) ranging the prevalence of 4.4–11.1% versus 0.5% of the general population. The mechanism of association of these two diseases involves a shared genetic background.
Aim
To investigate whether in type1 diabetes (T1DM) patients the concomitance of treated celiac disease (CD) impacts glycemic control and the prevalence of microvascular complications.
Methods
This retrospective study was performed in 20 patients with type 1 diabetes mellitus and treated celiac disease (CD) admitted to section C of National Nutrition Institute from 2017 to 2020. Age at CD diagnosis, gender, type 1 diabetes duration, glucose control (HbA1c) and insulin requirement before and after diagnosis of CD, status of microvascular complications and concomitant autoimmune diseases were evaluated. The control group consisted of 20 patients with T1DM and negative CD serology matched for age, gender, T1DM duration.
Results
Of the study population, 70% were females and 30% had concomitant autoimmune diseases (hypothyroidism). Mean age and mean duration of diabetes at CD diagnosis was 28 years, 9.5 years respectively. HbA1c levels at the moment of CD diagnosis were 10% and at the most recent visit 10.22% indicating no difference. A gluten free diet had little effect on insulin dosage (from 0.8 UI/Kg per day to 0.9 UI/Kg per day). Prevalence of diabetic retinopathy was higher in T1DM+CD group compared with controls (30% vs 10%, $P<0.05$) whereas no difference in the prevalence of diabetic nephropathy (10%) and diabetic peripheral neuropathy (5%) was found between the two groups.
Conclusion
The co-occurrence of T1DM + CD has no impact on glycemic control. However patients with T1DM + CD have higher prevalence of diabetic retinopathy than those with T1DM alone.

Risk of pancreatitis in type 2 diabetes

Faten Haj Kacem, Ameni Salah, Mouna Elleuch, Dhouha Ben salah, Mouna Mnif, Fatma Mnif, Nabila, Nadia Charfi & Mohamed Abid
UHC Hedi Chaker, Endocrinology, Sfax, Tunisia

Introduction
Pancreatitis is an inflammatory condition of the pancreas, which has known an increased incidence over the last years. Gallstones and alcohol abuse are the most common causes. But many risk factors are associated with pancreatitis, including Type 2 diabetes who has an estimated risk of pancreatitis at nearly three times the risk of non-diabetics. The aim of our work is to study the relationship between these two entities.
Methods
This is a retrospective study involving 14 patients with type 2 diabetics who presented with acute or chronic pancreatitis during their hospitalization in the endocrinology department of the Hedi Chaker Sfax University Hospital, during the period from 2009 to 2020.
Results
The average age of our patients was 55.8 ± 16.6 years with a slight male predominance (gender retio H/F = 1.3). Diabetes was recently discovered in 6 cases and old in the rest of cases with a median length of 5 years. The reason for hospitalization was a diabetic imbalance or an acute metabolic complication in most cases. Digestive symtoms (epigastric pain, vomiting and diarrhea) were noted in 12 cases, a severe form with signs of extracecullary dehydration was noted in one case, whereas pancreatitis was asymptomatic in one case. The assay for amylase and/or lipase was high in all cases. Abdominal CT scan revealed an aspect of acute pancreatitis in 9 cases (stage A in 3 cases, stage C in 1 case, stage D in 1 case and stage E in 4 cases) and an aspect in favor of chronic calcifying pancreatitis in 1 case. In our series a lithiasic origin was noted in 4 cases, alcoholism was noted in 6 cases and hypertriglyceridemia was noted in 3 cases. However, pancreatitis was related to hypercalcemia due to primary hyperparathyroidism in one case.
Discussion–conclusion
Type 2 diabetes is an additional risk of pancreatitis and biliary disease and can also be a major complication of chronic pancreatitis. Further studies are required to identify causal factors that may account for the observed increased risk of pancreatitis associated with diabetes.

Boerhaave syndome and 'Diabetic Ketoalkalosis' in a patient with type 1 diabetes mellitus: a case report

Maria Batool, Ashling Ni Chinneide, Roxana Tudor, Tommy Kyaw Tun, Seamus Sreenan, Mayilone Arumugasamy & John McDermott
Connolly Hospital Blanchardstown, Dublin, Ireland

A 20-year-old woman, with type 1 diabetes, presented to Emergency Department complaining of abdominal pain and vomiting for 3 days. She reported intermittent non-compliance with insulin therapy. Physical examination revealed epigastric tenderness. Blood glucose was 34.6 mmol/l, blood ketones 7.8 mmol/l, creatinine 131 µmol/l and CRP 31.47 mg/l (< 10). Despite clinical and initial laboratory features suggesting diabetic ketoacidosis, pH was 7.52 (7.32–7.43), pCO_2 5.9 kPa (4.6–6.4), HCO_3^- 33.5 mmol/l (22–26), potassium 3.4 mmol/l (3.4–4.5), chloride 73 mmol/l (normal 98–107) and anion gap was 16. As the ketoacidosis improved with treatment, the woman complained of retrosternal burning pain. Chest X-ray

suggested a pneumomediastinum, which was confirmed on CT thorax and barium swallow identified an oesophageal leak. A diagnosis of Boerhaave Syndrome was made. A laparoscopic esophagectomy and jejunostomy was successfully performed. We report a case of 'diabetic ketoalkalosis', where gastrointestinal pathology with metabolic alkalosis masked an underlying diabetic ketoacidosis. Alkalosis in patients with DKA is a rare phenomenon. This is the first case to our knowledge of diabetic ketoalkalosis in the setting of Boerhaave syndrome. The metabolic alkalosis in this patient was a clue to the presence of significant underlying GI pathology, which ultimately required surgical intervention.

Temporal mandibular involvement in external necrotizing otitis

Monia Ghammem, Lobna Chouchane, Mouna Bellakhdher, Rihab Lahmar, Wassim Kermani & Mohamed Abdelkafi
ENT and Neck Surgery Department Farhat Hached Hospital, Susa, Tunisia

Aims
To describe the epidemiological and clinical characteristics of temporal-osteomyelitis mandibular complicating necrotizing otitis externa and discuss how to take it in load.
Materials and methods
This is an 18-year retrospective study [2010–2017], conducted in our ENT department, collecting 74 hospitalized patients for management of necrotizing otitis externa.
Results
The average age was 67 with a sex ratio of 1.13. All patients were diabetic. Otalgia was the master symptom. A chewing pain with a limitation of the mouth opening was found in 3 patients. Clinical examination confirmed the diagnosis of otitis externa. The palpation was painful on palpation compared to TMJ in all patients. Trismus was present in 4 patients. A biological inflammatory syndrome was present in all patients. Otitis externa was bacterial in 4 patients with Pseudomonas and mycosic in 2 patients. A CT of the rocks confirmed the achievement of TMJ with signs in favor of temporo-arthritis mandibular in all patients. Facial mass MRI performed in addition to computed tomography in one case confirmed the extension of infection to the para pharyngeal space and showed condyle involvement mandibular and infiltration of the external pterygoid muscle. Treatment was medical in all cases.
Conclusion
Temporal-mandibular osteomyelitis is a rare complication of necrotizing otitis externa. The spread of infection may be secondary to tympanal osteitis or occur through congenital dehiscence of the external auditory canal. Pain, limitation of opening oral and pre-tragic swelling are the main clinical signs. The treatment is mainly medical, based on antibiotic therapy.

Assessment of insulin injection technique among diabetic patients

Bel Hadj Sliman Chayma, Zouaoui Chadia, Sawsen Essayeh, Bchir Najla & Ouertani Haroun
Military Hospital of Tunis, Endocrinology-Nutrition, Tunis, Tunisia

Introduction
Diabetes is a chronic disease and a public health problem. Insulin Injection is used as a treatment for type 1 diabetes and insulin-requiring type 2 diabetes. A well-made injection is the key to a good glycemic balance. However, many studies showed that diabetic patients did not master the injection technique, reflecting an empirical random or non-existent therapeutic patient education(TPE). Our objectives were to assess our patients' knowledge of injection technique, to identify factors associated with glycemic balance and pain.
Methodology
This is a cross-sectional and descriptive study involving 50 diabetic patients (DT1: 40%, DT2:60%) insulin-treated recruited from the endocrinology department of the military hospital of Tunis, based on a questionnaire inspired by validated questionnaire proposed by Francophone Society of Diabetes(SFD) for the evaluation of the acquired knowledge of diabetic patients. The assessment of pain was carried out by the visual analogue scale(VAS).
Results
Our population was predominantly male (sex ratio 1.27). The mean age was 56.4 ± 19.4 years. The mean duration of diabetes was 13.3 with an average HbA1c of 10.2%. Insulin therapy averaged 7.4 ± 5.5 years (22% bed time, 36% basal, 42% basal/bolus). The mean number of daily injections was 3 with extremes ranging from 1 to 6. Thirty-three patients received an education mainly on themes of 'insulin conservation' (78.8%) and 'choice of injection site' (63.6%). Deficiencies mainly concerned the rotation of injection sites (20%), the search of lipodystrophies (14%), the practice of skin fold (48%), the reuse of needles (86%), and the unsafe waste disposal (94%). Glycemic balance was associated with rotation of injection sites($P = 0.01$) and the practice of skin fold($P = 0.01$). The presence of pain and its intensity were associated with the average number of injections per needle ($P = 0.04$ and $P = 10$€respectively).
Conclusion
The role of caregivers is essential in the TPE of diabetic patients. However, they must be trained in this mission and guided through a pre-established program.

Hospital admission, a good time to optimize treatment and rethink the diagnosis

Elizabeth Lorenzo Hernández[1], Lidia Cobos Palacios[1], Viyey Kishore Doulatram Gamgaram[2] & Ricardo Gómez Huelgas[1]
[1]Hospital Regional Universitario de Málaga, Medicina Interna, Spain;
[2]Hospital Regional Universitario de Málaga, Endocrinología y Nutrición, Spain

Introduction
Prediabetes and type 2 diabetes prevalence in children and teenagers has been rising lately, according to obesity increase in this population. Diabetes is the first cause of kidney failure in this individuals. These clinical entities are associated with hypertension and dyslipidemia, leading to an increased risk for cardiovascular disease. In this case, as a result of the presence of a diabetic complication, the differential diagnosis of the cause of diabetes is reconsidered.
Case report
33-year-old-woman diagnosed with hypertension, obesity and type 1 diabetes developed at the age of 14. She currently has no glycemic control (last HbA1c determination 2 years ago: 12%) and her diet is based on refined carbohydrates and processed food products. She is supposed to follow a treatment regimen consisting of insulin Glargine once a day and insulin Aspart at meals, but she acknowledges treatment nonadherence. She is admitted to the hospital because of fever, swelling and purulent drainage of second and fourth fingers of her left foot, being finally hospitalized for intensive intravenous antibiotic therapy and surgical drebidement. During the hospital admission she has normal glucose levels without insulin treatment, just following a balanced diet. Due to this unexpected well-controlled glucose levels, her diabetes diagnosis is reconsidered. Her disease history was checked: she was diagnosed with tuberculous meningitis at the age of 4 so she was under treatment with high-dose corticosteroids for several months. It led to iatrogenic Cushing syndrome, reduced growth and eventually short height. She received treatment with growth hormone during childhood and developed diabetes during puberty. She started treatment with oral antidiabetic drugs but due to uncontrolled glycemias she is finally treated with insulin regimen. In order to clarify her type of diabetes, some tests are done: glucose 175 mg/dl, HbA1c 8.7%, serum insulin level 7.1 (3–25 mUI/ml), C-peptide 2.63 (0.81–3.85 ng/ml), ACTH 16.1 (5–50 pg/ml), serum cortisol 9.8 (5–25 mg/dl), PCR-us 2.31. Anti-insulin, anti-tyrosine phosphatase y anti-glutamate antibodies were negative. Considering this results, she is finally diagnosed with type 2 diabetes. During the hospitalization she receives diabetes self-management education and at hospital discharge she is recommended to follow a treatment with Metformin twice a day and Losartan daily.
Conclusions
It is important to reconsider established diagnosis when a disease does not follow the expected progression and clinical manifestations. Nowadays, type 2 diabetes is a common disease in children and teenagers and its proper diagnosis is essential for an adequate treatment.

Needs and expectations of Tunisian diabetic patients in terms of therapeutic education

Mouna elleuch[1], Hamdi Frikha[1], Dhoha Ben Salah[1], AbdelMouhaymen Missaoui[1], Insaf Nasri[2], Fatma Mnif[1], Nadia Charfi[1], Mouna Mnif[1], Hadj Kacem Faten[1] & Abid Mohamed[1]
[1]Hedi Chaker Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Hedi Chaker Hospital, Department of Family Medicine, Sfax, Tunisia

Background
Faced with the increase in the number of diabetic patients in Tunisia, an inventory of their needs as well as their expectations is necessary to help the medical staff deliver appropriate means of therapeutic education of the patient.
Aim
We aim to assess Tunisian diabetic patients' understanding of the disease, evaluate its impact on several aspects of their life, and classify their needs and expectations.
Methods
We used a semi structured qualitative interviews analyzed using SPSS. Tunisian adults (≥18 years) living with type 1 diabetes mellitus (DM) or type 2 DM able to describe their situation in Arabic were included.
Findings
We have collected 55 patients, 7 with type 1 DM and 48 with type 2 DM. Only half of interviewees think they have a good understanding of diabetes and its complications while two thirds of them think that they were not well educated concerning anti-diabetic therapies. For over 45% of patients, diabetes has badly impacted their life quality. In terms of satisfaction, 76% of interviewees were satisfied with the procured medical care while only 50% were satisfied with the financial and psychological support they receive. Interestingly, we found that over two thirds of diabetic patients find that they get an unsatisfactory therapeutic education. This goes hand in hand with the fact that two thirds of the interviewees were unaware of the existence of therapeutic educational programs. Regarding patients' expectations, we found that most of our patients consider getting information about the disease as their first priority. In the second place, our patients were expecting to be more informed about dietary and therapeutic issues. Thirdly, they expressed their need to be educated about preventive measures against diabetes complications. Education about economic, legal, psychological and social aspects of the disease came as a last tier concern. Finally, collected data suggest that whether a patient is treated in public or private sector had a significant influence on his priorities.
Conclusion
These findings highlight a need to develop and promote context-specific, patient-oriented therapeutic educational programs.

Insulin Pen first demo effectiveness in Novel insulin pen users in Central Indian Population

Bharat Saboo
Prayas Diabetes Center, Diabetology, Indore, India; [2]Prayas for Care of Diabetes Society, Diabetology, Indore, India

Introduction
Insulin remains the cornerstone of therapy in a substantial number of patients with type 2 diabetes mellitus (T2DM). Inadequate knowledge regarding insulin pen usage is likely to influence its acceptance and adherence, and outcome of therapy, underscoring need to teach proper injection pen technique to T2DM patients
Methods
In 2019–2020 we conducted survey of 328 respondents (male: 202, female: 126), novel Insulin pen user patients who were enrolled as outpatient in a Diabetes clinic during last one years (2019–2020), to assess the ability to use insulin pen after one demonstration by an insulin advisor.
Results
Out of 328 respondents 34% were not able to use insulin pen injections after first demonstration. the inability to use insulin pen was more in rural patients 63%, in females 58% as compared to males 42%, was more in lower educational status and was more in basic phone users 72% as compared to smart phone users 38%.
Discussion
This study shows that there is a pressing need to develop strategies to teach patient in a better way to self-administer insulin via insulin pen. We can predict based on educational status and other parameters mentioned in study to give more elaborate training to those groups in need. And there is a further need to study the efficacy and adaptability of various ways of teaching patients about the insulin pen.
Keywords
Diabetes, insulin injection, insulin pen, patient knowledge.
DOI: 10.1530/endoabs.73.EP72

Case of Mucopolisaccharidosis Type 4A (Morquio 4A)

Ahmet Suat Demir, Yasemin Emur Gunay, Damla Tufekci, Irfan Nuhoglu, Hulya Coskun, Ozge Ucuncu, Muhammet Cuneyt Bilginer & Mustafa Kocak
Karadeniz Technical University Faculty of Medicine, Department of Endocrinology and Metabolism, Trabzon, Turkey

Introduction
Mucopolysaccharidosis type 4A (Morquio 4A) is an autosomal recessive lysosomal storage disease caused by a mutation in the gene encoding galactosamine 6 sulphatase (GALNS). It's main clinical features include short stature, skeletal dysplasia,cloudy cornea,hearing loss and dental anomalies. Herein, a case of Morquio 4A, a rare cause of short stature is presented.
Case report
A 41 year old female patient was admitted to our clinic for short stature. On physical examination height 95 cm,body weight 24 kg, kyphoscoliosis, short neck, pectus carinatum,genu valgum,nasal root flattened,coarse forehead and abnormal gait were detected. There was hearing loss and decrease in vision. There was no previous history fractures. Her parents were relatives and had normal height. Four of her ten siblings were short, two of whom died in the fifth decade. Laboratory tests were normal. DEXA with *Z* score for L1–L4 and femoral neck were −3.1, −1.7, respectively; BMD was 0.590 g/cm^2 and 0.600 g/cm^2 for L1–L4 and femoral neck respectively. Diffuse loss of height in the vertebrae (platyspondyle), sharpening of the anterior vertebrae,shortening of the long bones,enlargement of the metaphysis,diffuse decrease in bone density,irregularity in the epiphyses (epiphyseal displasia) were observed in bone survey examination. These findings were thouht to be compatible with mucopolysaccharidosis type 4A (Morquio 4A). *N*-acetylgalactosamine 6 sulfatase enzyme activity in leukocyte was<0.1 nmol/mg 17 h (>68). In the genetic analyses, homozygous mutation encoding the C.1157+2T>6(p?) nucleotid was detected in the GALNS (NM-001323544.1) gene. The patient was diagnosed with Morquio 4A (MIM#253000). Vitamin D and calcium were initiated for bone health. Enzyme therapy was planned.
Conclusion
Although Morquio 4A is a rare cause of short stature,it should recognise especially in those with a family history. Carriers of this disease should be determined by advising genetic counseling to the families of these patients. These patients may have many vital organs involvement other than bone,follow up and treatment with a multidisciplinary approach is required. Although there is an enzyme replacement therapy there is no curative therapy yet.

Epidemiological aspects of differentiated thyroid carcinoma metastases

Hana Charfi, Hamza Fatma, Khrouf Bechir, Jardak Issam, Maaloul Mohamed, Kallel Faouzi, Amouri Wissam, Charfeddine Salma, Chtourou Khalil & Guermazi Fadhel
Habib Bourguiba Hospital, Nuclear Medicine, Tunisia

Introduction
Differentiated thyroid cancer (DTC) is the most common thyroid cancer with a relatively high survival rate. Distant metastasis (DM) is not a frequent event in DTC but has an adverse impact on mortality of patients.
Purpose
The aim of this study was to determine the most frequent metastases and their prognosis after adequate treatment.
Methods
A retrospective study of patients who had DTC metastases and were treated in the nuclear medicine departement in Hbib Bourguiba hospital, Sfax, Tunisia.

Results
A total of 26 patients had remote metastases, 19 of whom had metastasis at the time of initial diagnosis. Metastasis locations in descending frequency order were : lungs (42.3%), mediastinum (15.3%), lungs + bones (15.3%), lungs + mediastinum (7.7%), liver (7.7%), eye (3.8%) and lungs + other locations (7.7%). For pulmonary metastases, it was a miliary lung in 64.7% of cases, a single or multiple pulmonary nodule in 17.4% each. Bone metastases were unique in 2 patients and multiple in the rest. In order of frequency : Sternum : 2 cases, pelvis : 2 cases, lumbar spine : 2 cases, femur : 2 cases, shoulder : 1 case, Skull :1 case. All of our patients had radioactive iodine ablation and 8 of them had additional therapies : surgery was performed to one patient with unique mediastinum meatastases, one with both mesdiastinum ang lung metastases and 2 patients with lungs and bones metastases. Radiotherapy was performed to 4 patients (3 cases of mesdiastinum ang lung metastases and one case of lungs + bones + liver metastases). Two cases of death were reported (mediastinum metastases, lungs and bones metastases). Recovery was observed in 15 patients whilst eight had a stable health state. High thyroglobulin level remained stable in one case of lungs metastases.
Conclusion
The most common sites of metastatic differentiated thyroid cancer are the neck lymph nodes, while distant metastases typically involve the lungs, the bones, and less frequently the brain. Uncommon metastatic sites include the liver, adrenal gland, kidney, pancreas, and skin. The epidemiological aspects of thyroid metastases in rare sites are largely unknown and their identification could have a significant impact on patients management.

Systemic diseases and diabtes

Imen Chabchoub[1], Mouna Elleuch[2], Hadj Kacem Faten[2], Dhoha Ben Salah[2], Nadia Charfi[2], Nabila Mejdoub[2], Fatma Mnif[2], Mouna Mnif[2] & Abid Mohamed[2]
[1]Hedi Chaker Hospital, internal medicine, Sfax, Tunisia; [2]Hedi Chaker Hospital, Endocrinology and Diabetes, Sfax, Tunisia

Introduction
The association of type 1 diabetes with other autoimmune diseases is well known due to a common genetic terrain of varied clinical expressions. However, the occurrence of systemic diseases in diabetic patient, whatever the type of diabetes, is poorly studied. The objective of this study is to describe autoimmune and inflammatory diseases associated with diabetes.
Materials and methods
It ' s a retrospective, descriptive study of the observations of diabetic patients followed up in our department, who have been diagnosed with an associated systemic disease based on clinical, immunological and/or histological data.
Results
We involved 22 patients: 20 women and 2 men with an average age of 49.9 years at the time of diagnosis of diabetes. They were type 2 diabetes in 19 cases (86.3%), type 1 diabetes in 1 case (4.5%), corticosteroid-induced diabetes: 1 case and gestational diabetes: 1 case. The discovery of diabetes is made in front of polyuropolydipsia in 14 cases, weight loss in 6 cases and fortuitous in 3 cases. Oral antidiabetic drugs (OADs) were prescribed in 18 patients and insulin therapy was immediately initiated in 3 cases. Metabolic syndrome was noted in 41% of patients. Vascular complications of diabetes were noted in 68% of cases. Associated systemic diseases were Rheumatoid Arthritis: 12 cases (54.5%), Sjogren's Syndrome: 4 cases (18%), Hashimoto's autoimmune thyroiditis: 2 cases (9%). Primary biliary cirrhosis, Horton's disease, Behçet's disease, antiphospholipid syndrome and Still's disease were objected in 1 case respectively. Diabetes preceded the systemic disease in 8 cases for an average duration of 11 years, succeeded it in 8 cases for an average duration of 11 years and occurred concomitantly in 6 cases. Diabetes was unbalanced at the time of relapses of the systemic diseases in 81.8% of cases.
Conclusion
Each of the two pathologies can influence the evolutionary course of the other, while underlining the effect of the outbreaks of systemic diseases on the imbalance of diabetes by the inflammation they generate or by the prescribed therapeutics.

Hepatogenous diabetes: is it real?

David Veríssimo, Catarina Ivo, Vitória Duarte, Joao Silva, Luis Lopes, Dolores Passos, J Jácome Castro & Mafalda Marcelino
Hospital das Forças Armadas, Serviço de Endocrinologia, Portugal

Introduction
Diabetes mellitus (DM) due to cirrhosis is described as hepatogenous diabetes (HD). Despite being frequently described in the literature, it is not recognized as an entity by the ADA/EASD.
Case report
Woman, 70 years old, previous history of autoimmune hepatitis with Child-Turcotte-Pugh A cirrhosis (CTP-A) since 2018, arterial hypertension and overweight (BMI 29.1 kg/m^2). No personal or family history of DM. Medicated with bisoprolol 5 mg, candesartan 8 mg, furosemide 20 mg, spironolactone 25 mg. Normal glycemic profile until May 2019, when was admitted in the Emergency Department with polydipsia, polyuria and loss of 10 kg in 2 months. No infectious complications or medication changes were noticed. The patient was diagnosed with hyperosmolar syndrome, with glycemia of 629 mg/dl, ketonemia 0.2 mmol/l, without acidosis (pH 7.43), HbA1c 14.2%. No increase in inflammatory parameters, amylase, lipase and no renal dysfunction was detected. Liver profile was according to the patient's baseline (AST 79 UI/L; ALT 43 UI/L; ALP 136 UI/L; total bilirubin 0.95 mg/dl). An optimal response to insulin therapy was observed, with discharge after 15 days. During hospitalization, an abdominal CT was performed, which excluded pancreatic lesions or masses. No changes in iron or cortisol metabolism were observed and anti-Langerhans islet antibodies, anti-insulin, anti-GAD studies were negative. During follow-up, after discharge, she maintained an excellent metabolic control (HbA1c 6.2%) medicated with metformin/empagliflozin 850/5 mg twice a day and 34 U/day of glargine insulin.
Discussion
The present case describes a newly diagnosed Diabetes in a patient with cirrhosis, suggesting a HD. The patient had no personal or family history of DM and did not show the progressive worsening usually observed in type 2 Diabetes. Infection, use of hyperglycemic medication, autoimmune and other causes for secondary DM were excluded. Although the prevalence of HD is related to the severity of cirrhosis, this prevalence may reach 20.5% in CTP-A, with an increase of 4.4% just 1 year after diagnosis. Liver dysfunction appears to cause hyperinsulinemia by decreasing insulin clearance and combined with an increase in inflammatory mediators, causes tissues' insulin resistance and pancreatic islets Œcells' toxicity. These changes lead to a deterioration in glucose metabolism that follows the worsening of cirrhosis. Treatment can be challenging in advanced stages of cirrhosis, due to dysfunctional liver metabolism, which can cause greater susceptibility to hypoglycemia and worse metabolic control.

Does sars-cov 2 causes diabetes?

Ihtisham Malik
Midland Regional Hospital, Mullingar, Ireland

Does COVID cause diabetes?

Malik I , Rafi A , Sheehy M, Healy U & Hoashi S
Diabetes and Endocrine Centre, Regional Hospital Mullingar, Co Westmeath; [2]UCD School of Medicine, Co Dublin

Little is known on the impact of acute COVID-19 infection on causation of diabetes. We report on a 36 years old man from Nigeria who presented with diabetic ketoacidosis (DKA) with typical osmotic symptoms of polyuria and polydipsia, fatigue and weight loss over 2 weeks. He tested positive for SARS-COV2 by PCR. The initial laboratory results: Random glucose 30.6 mmol/l, capillary blood ketones 7.4 mmol/l, pH 7.22, bicarbonate 7.5 mmol/l. Despite insulinopaenic state, at presentation, he was insulin resistant requiring several upward adjustment of IV insulin therapy, requiring over 200 units IV Actrapid infusion in the first 24 h i.e. 8–9 units per hour. At 2 weeks, basal bolus subcutaneous insulin requirement was 1.2 U/kg per day. Currently, 6 weeks after diagnosis, insulin requirement was lower at 0.52 U/kg with drop in HbA1c from 125 to 67 mmol/mol. Retrospectively, random C-Peptide 0.41 µg/l (1.1–4.4) and repeated 6 weeks 0.9 µg/l, Islet cell Ab 14 U/ml (<28), AntiGAD Ab 24 IU/ml (<17) repeated 6 weeks 11 IU/ml.

Discussion
New presentation of DKA with acute COVID-19 in a young Nigerian man. Initially insulin resistant despite insulinopaenia but resolution of insulin resistance by 6 weeks, and persistence of ketonemia despite normal acid base. Initially elevated Anti GAD Ab but six weeks later normalised. Is it latent autoimmune diabetes, or ketosis prone diabetes, or a hybrid pleiotropic metabolic effects of COVID-19 infection from as yet undefined mechanism?

Influence of diabetes mellitus on mortality in patients hospitalized with COVID-19

Raul Rodriguez Escobedo, Fernando García Urruzola, Soraya Lanes Iglesias, Carlos Alonso Felgueroso, Gema Martinez Tames, Alba Gutierrez Hurtado, Tomas Gonzalez Vidal, Elias Delgado & Edelmiro Luis Menendez Torre
Hospital Universitario Central de Asturias, Spain; [2]Grupo ENDO, Instituto de Investigación Sanitaria del Principado de Asturias – ISPA, Spain

Introduction
Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection has generate a pandemic disease around the world. It has been documented that diabetes mellitus (DM) acts as a risk factor among people hospitalized with coronavirus disease (COVID-19). The objective of this study is to test if DM may unfavorably influence the outcome of COVID-19.
Methods
Data from Hospital Universitario Central de Asturias (Spain) of patients older than 55 years hospitalized with COVID-19 between 3 March 2020 and 30 September 2020 were collected. We compared patients with previous diagnoses of type 2 DM and no diabetes patients. We analyzed the percentage of deaths according to glycosylated hemoglobin (HbA1c) in the last 365 days before admission. Analysis was performed by using GraphPad Prism, 8.0.1 version. Statistical differences were evaluated by Chi-square and Chi-square with Yates correction.
Results

		n	Age	Sex (M/F)	Death (%)	P

	No DM	203	72.72		48 (23.65)	
Female	DM	44	79.61		8 (18.18)	0.5778
	No DM	156	75.40		23 (14.74)	
		n	Age	Sex (M/F)	Death (%)	P
HbA1c < 7		63	72.66	45/19	11 (17.46)	0.9868
HbA1c < 7		19	74.79	7/12	4 (21.05)	

Discussion
Our results suggest that diabetes mellitus could be a risk factor of death in patients hospitalized with COVID-19, even if there is no statistical association. According to our study, an innapropiate glycemic control could increase the risk of death. It is necessary to perform new researches to confirm these results. In conclusion, COVID-19 is a new reason to encourage our patients to achieve therapeutic goals.

Diabetics hospitalized for COVID-19: descriptive study

María Del Carmen Andreo-Lopez, Enrique Redondo, Sara León Utrero, Mª del Carmen Serrano Laguna, Elena López-Mezquita Torres & Pablo J López-Ibarra Lozano[1]
Granada, Hospital San Cecilio, Granada, Spain

Introduction
The SARS-Coronavirus-2 pandemic affects 248 469 people with 28 341 deaths in Spain as of June 28, 2020. Severe infection is more prevalent in patients with advanced ages, cardiovascular risk factors (CVRF) and chronic diseases (diabetes mellitus, cardiovascular disease and asthma). Having diabetes implies vulnerability to serious complications and death from coronavirus; although, not all diabetics have the same level of risk. The oldest is present over 65 years of age. This study analyzes the profile of diabetics and baseline characteristics of those admitted for SARS-Coronavirus-2 in a third-level hospital in Granada (Andalusia, Spain).
Material and methods
Retrospective descriptive study. 102 diabetics admitted for COVID-19 treated with Glargine U100, between March 12-May 15, 2020 at Hospital Universidad San Cecilio. We reviewed electronic medical records to collect variables: gender, age, CVRF, type of diabetes, glycosylated hemoglobin (HbA1c), angiopathic complications, and home treatment.
Results
54% men. 97% diabetes mellitus 2, 2 debuts, and 0.03% diabetic due to high-dose corticosteroid therapy. Over 65 years, 76.47%. 92% associated comorbidities with diabetes: hypertension (82.35%, 60.7% were taking ACEI or AIIRA), dyslipidemia, hyperuricemia or angiopathic complications. 27.45% microangiopathic, the most frequent: 23.5% chronic kidney disease and 32.35% macroangiopathic: 13.7% cerebrovascular disease and 14.7% ischemic heart disease. At home, 36.27% were insulin dependent. 50.1% HbA1c (up to 1 previous year) lower than 7.5%. Mortality 17.65%, 88.8%> 65 years. Among the deceased, 100% hypertensive, 83% took angiotensin converting enzyme inhibitors or angiotensin receptor blockers, 100% some comorbidity and average HbA1c around 7.5%.
Conclusions
The most frequent diabetic profile hospitalized for COVID-19 has been DM 2 over 65 years with CVRF and/or angiopathic complications. It is deduced from the average HbA1c value among the deceased that diabetes per se is not a determining factor in the severity and/or mortality of the infection.

COVID-19-associated syndrome of inappropriate anti diuretic hormone secretion in type 2 diabetic patient: A case report

Asma Kardi, Ibtissem Oueslati, Fatma Chaker, Meriem Yazidi & Melika Chihaoui
La Rabta Hospital, University of Tunis El Manar, Faculty of Medicine, Endocrinology, Tunis, Tunisia

Introduction
Hyponatremia secondary to the syndrome of inappropriate anti diuretic hormone (SIADH) secretion is one of the most frequently observed electrolyte abnormalities in coronavirus disease -2019 (COVID-19). Herein, we report a new case of SIADH in a type 2 diabetic patient with COVID-19 pneumonia.
Observation
A 79-year-old man with type 2 diabetes mellitus was admitted for a poor general condition. On physical examination, he had a tachycardia and alveolar sounds. No other abnormalities were found. On biological investigations, he had a blood glucose level of 15 mmol/l, a serum sodium of 122 mmol/l, a potassium level of 4.1 mmol/l, a serum urea level of 0.17 g/l, a serum creatinine level of 7 mg/l, a C-reactive protein (CRP) of 53 mg/l, white blood cells of 3380 elements/mm^3, and lymphocytes of 660 elements/mm^3. Corrected natremia was 124.7 mmol/l and the plasmatic osmolarity was 270 mOsmol/l. Chest computed tomography-scan revealed a suggestive aspect of a moderate COVID-19 pneumonia. RT-PCR nasopharyngeal swab test was positive. The diagnosis of SIADH was established and the patient was put on a fluid restriction. The outcome was marked by the elevation of the natremia reaching 133 mmol/l.
Conclusion
Hyponatremia due to SIADH was reported in patients with COVID-19 infection. Its pathophysiological mechanism involves many factors associated with infection such as cytokine storm, stress, and pain. However,

it is important to rule out other etiologies of hyponatremia in order to ensure the appropriate management.

Covid-19 and dexamethasone treatment as a cause of Hyperosmolar Hyperglycaemic State in a patient with unknown diabetes mellitus before. A case report

Marjeta Kermaj, Ina Mihaj, Ira Xhemollari, Marsela Xhindi & Agron Ylli
UHC 'Mother Tereza', Endocrinology, Tirane, Albania

Introduction
COVID-19 can precipitate hyperglycaemic emergencies like Hyperosmolar Hyperglycaemic State (HHS) in patients with or without DM. It is currently hypothesized that COVID-19 may have a diabetogenic effect in addition to the stress-related response of glucose metabolism in severe illness. Dexamethasone reduces mortality in people with COVID-19 who require ventilation or oxygen therapy but can impair glucose metabolism. We present a case with HHS precipitated by COVID-19 infection and corticoid treatment in a patient without prior history of Diabetes Mellitus.
Case presentation
We present a clinical case of a woman 85 years old, obese that was admitted to the emergency unit in coma. Medical history: She has been treated for high blood pression and bronchial asthma for 30 years but not known before for diabetes mellitus. No family history of diabetes. In early December 2020, she was diagnosed with COVID-19. Because of severe Covid-19 form, she was treated with antibiotics, oxygen therapy and dexamethasone 8 mg/day for 10 days. After one month, she was improved but she complained progressive fatigue and weakness, polyuria-polydipsia, anorexia. Every symptom was attributed to Covid-19 and it was hoped that over time they would disappear. But symptoms have been aggravated during the last 2 weeks and she was presented in emergency unit in coma. Laboratory examinations: Hyperglycaemia (1280 mg/dl),high level of urea and creatinine (222.4 mg/dl and 2.88 mg/dl) respectively, high level of cardiac enzymes (LDH693,Ck566 u/l, Troponin1, 86 ng/ml),High PCR16 mg/dl, high D-dimer418 mg/dl(<198) normal level of SGPT,SGOT. Na+153 mmol/l, K+4.3 mmol/l. WBC32000 with high neutrophils and low lymphocytes. Mild normochromic normocytic anaemia. HGA: Ph7.4 but O2 saturation83%. High plasma osmolarity = 402 mOsm/kg. Imaging examinations: Head-CT: without acute intracranial lesions. Lungs CT: Interstitial opacities in absorption with invadation of less than 10% of lung tissue, aspect in favour of post Covid-19 changes. After the examinations, it was concluded that, the situation was related to HHS precipitated by COVID-19 infection and corticoid treatment in a patient without prior history of Diabetes Mellitus. Initially she was treated in Intensive Unit Care with iv liquids, oxygen therapy, anticoagulants, antibiotics, insulin therapy. After 3 days, stabilised, she was transferred in the Endocrinology Department for further treatment. After 10 days in a good general condition, she was discharged from the hospital with endocrinologist follow-up under insulin therapy.
Conclusion
COVID-19 together with dexamethasone treatment can precipitate Hyperosmolar Hyperglycaemic State, a life threatening situation, in a patient without diabetes. All physicians must be aware about this situation, to prevent it.

New onset type 1 diabetes during COVID 19 pandemic : experience of a single tertiary care Center

Tahri Abir, Salma Ben Yakhlef, Wahiba Abdellaoui, Siham Rouf & Hanane Latrech
Mohammed VI University Hospital, Medical School, Mohammed the First University, Endocrinology, Oujda, Morocco

Introduction
After the emergence of the COVID 19 pandemic, many publications have interested in type 2 diabetes mellitus with a dearth of papers regarding type 1 diabetes mellitus (T1DM), especially new-onset type 1 diabetes which entails a special concern. We report herein the experience of a single tertiary care Center.
Methods
A retrospective observational study including New-onset T1D patients between March 2020 and December 2020 comparing with the same period of the year 2019. Data were collected from patient charts, and teleconsultation reports.
Results
Between Mars 2020(Lockdown Covid-19) until December 2020, 29 patients have been admitted to our Department. The pediatric population represent 65.5% of them and the sex ratio H/F is 1.27. Compared to the same period of the last year we observed an increase of 22%. Severe ketoacidosis (DKA) was observed in 28% of patients in 2020 and 17.4 of patients in 2019 (P<0.001). The mean baseline Hba1c was: 12.72% (± 1.6). The follow-up was ensured using teleconsultation and the therapeutic adjustment was made daily for 2 weeks after discharge. No episode of decompensation or severe hypoglycemia was noted during follow-up and the mean Hb1Ac at 3 months was 7.2%
Conclusion
Several papers report an increase in the number of New-onset T1D diabetes and the severity of ketoacidosis DKA during the COVID-19 pandemic. The potential bidirectional link between COVID 19 and T1DM is being investigated. Telemedicine seems to be an effective approach for the management of patients with New-onset T1D.

Assessment of biochemical indicators in laboratory diagnostics of metabolic syndrome

Olga Moskalenko, Olga Smirnova & Eduard Kasparov
[1]Nauchno-Issledovatel'skiy Institut Meditsinskikh Problem Severa, Krasnoyarsk, Russian Federation

Metabolic syndrome (MS) is one of the most pressing problems of modern medicine. MS is a symptom complex of impaired carbohydrate metabolism, abdominal obesity, dyslipidemia, hypertension with an increased risk of developing cardiovascular diseases and type 2 diabetes mellitus. The main reasons for the increase in the incidence of MS are a decrease in physical activity and a high-calorie diet. The prevalence of MS in different countries is 25–30% and varies depending on the criteria used. The aim of our study was to assess the role of blood biochemical parameters in the diagnosis of MS. Materials and methods. 60 patients with MS and 45 apparently healthy volunteers were examined on the basis of the therapeutic department of the Federal Research Center "Krasnoyarsk Science Center" of the Siberian Branch of the Russian Academy of Sciences. The glucose level was determined by the glucose oxidant method, the lipid profile was assessed using standard test systems. Insulin level was determined by enzyme immunoassay using the DRG test system. All examined persons signed an informed consent to participate in the study, approved by the ethics committee of the Federal Research Center "Krasnoyarsk Science Center" of the Siberian Branch of the Russian Academy of Sciences. Statistical data processing was carried out using the Statistica for Windows 8.0 software packages with the determination of the median (Me) and interquartile range (C25–C75). The statistical significance of differences was determined using the Mann–Whitney rank test, P <0.05. Results In patients with MS, the HOMA-IR index increased by almost 2 times (P = 0.003) relative to the control group, which is a predictor of the risk of developing vascular and diabetic complications in them. The non-esterification fatty acids (NEFA) content was increased in all patients with MS (P = 0.001), while the NEFA value was 2 times higher than normal values (P = 0.004). There was an increase in the content of insulin (P = 0.002) and glucose (P = 0.003) in the fasting blood in patients with MS in comparison with the control group. Conclusion The study confirmed that early diagnosis of vascular and diabetic complications in patients with MS requires a combined determination of the HOMA-IR index and the content of NEFA. These indicators were sensitive in all patients with MS.

DOI: 10.1530/endoabs.73.EP83

EP84

Assessment of the quality of life, anxiety-depressive disorders in patients with metabolic syndrome

Olga Moskalenko & Olga Smirnova
Nauchno-Issledovatel'skiy Institut Meditsinskikh Problem Severa, Krasnoyarsk, Russian Federation

The prevalence of MS in different countries is 25–30% and varies depending on the diagnostic criteria used. The severity of the clinical manifestations of MS affects the quality of life (QL) of patients, while the indicators of physical and mental health decrease. The problem of QL of patients suffering from overweight and obesity is relevant and socially significant. Obesity leads to anxiety-depressive disorders, neurosis-like conditions, which contributes to a worsening of the prognosis of the underlying disease. The aim of the work was to assess QL, the level of anxiety, depression in patients with metabolic syndrome.
Research methods
60 patients with MS and 35 apparently healthy volunteers who did not have concomitant diseases and were not obese were examined. The study was carried out on the basis of the therapeutic department of the Federal Research Center "Krasnoyarsk Science Center" of the Siberian Branch of the Russian Academy of Sciences. Examination of patients, determination of anthropometric parameters (waist circumference, body weight, BMI) with an assessment of the quality of life (questionnaire SF-36, Russian version, Institute of Clinical and Pharmacological Research, St. Petersburg). The level of anxiety and depression was determined according to the hospital scale of anxiety and depression HADS (The hospital Anxiety and Depression Scale Zigmond A.S., Snaith R.P.). The statistical significance of differences was determined using the Mann–Whitney rank test, $P<0.05$.
Results
Indicators of the QL level were significantly higher in healthy individuals than in patients with MS (P = 0.001). Our study revealed a decrease in the average level of the parameters 'physical functioning' by 18.3% (P = 0.003), 'role functioning' by 32.1% (P = 0.002), 'general health' by 12.3% (P = 0.001), 'vitality' by 15% (P = 0.03), 'emotional functioning' by 51.1% (P = 0.03). The level of anxiety and depression in patients with MS corresponded to the subclinical level, the level of depression exceeded the value of the control group by 19% (P = 0.04).
Conclusion
QL in obese patients is one of the most important factors in the integrative assessment of patients' condition, the higher the patient's body weight, the worse his physical condition and the more pronounced concomitant diseases. Patients with MS are characterized by a decrease in quality of life indicators, subclinically expressed anxiety/depression.

Assessment of obesity in patients with toxic hepatitis

Oksana Prokopchuk , Ihor Hospodarskyy, Nadiia Gavryliuk & Svitlana Danchak
Ternopil National Medical University, Department of Clinical Immunology, Allergology and General Patients' Care, Ternopil, Ukraine

Background
Over the last years obesity has become an important medical and social problem in almost all countries of the world. The social significance of the problem is determined by the disability threat of patients and reduction of overall life expectancy due to the frequent comorbidities development. According to scientific data and modern ideas, there are a number of factors that affect not only the course of toxic hepatitis, but also the therapy effectiveness. The bulk is due to obesity.
Objectives
Examination of patients with toxic hepatitis for obesity detection as one of the hepatic fibrogenesis triggers.
Methods
To achieve this goal, 24 patients with toxic liver disease were examined. The body mass index (BMI, Kettle index) was calculated using anthropometric indicators. Due to the formula BMI is a person's weight in kilograms divided by the square of height in meters. BMI is an inexpensive and easy screening method for weight category—underweight, healthy weight, overweight, and obesity. For all our patient which are 20 years old and older, BMI is interpreted using standard weight status categories (classification of BMI adopted by the WHO (1997). The value of BMI in the range of 18.5–24.9 kg/m^2 should be considered optimal – normal or healthy weight; reduced BMI or underweight ≥ 18.5; overweight – 25.0–29.9; obesity I degree – 30.0–34.9; obesity II degree – 35.0–39.9; grade III obesity – ≥ 40 (kg/m^2).
Results
The examination revealed that the following changes were observed in BMI: 42% of patients were with normal weight, 21% were overweight, obesity I degree was detected in 25% of patients and 13% of patients were with obesity II degree.
Conclusions
Obesity of varying degrees was found in 58% of patients with toxic hepatitis. These data should be taken into account when choosing and prescribing adequate treatment. Last, but not least, nutrition should always be considered. Given that obesity can be a trigger of hepatic fibrogenesis in patients with toxic hepatitis this issue requires further research to identify the possible impact of concomitant non-alcoholic fatty liver disease on the course of toxic hepatitis.

Bariatric surgery: a shift in metabolic control

David Veríssimo, Catarina Ivo, Vitória Duarte, Joao Silva, Luis Lopes, Dolores Passos, J Jácome Castro & Mafalda Marcelino
Hospital das Forças Armadas, Serviço de Endocrinologia, Portugal

Introduction
Obesity is a chronic disease that is associated with several comorbidities, decreased quality of life, and increased mortality rate. Bariatric surgery is the most effective therapy for obese patients with class III and class II with metabolic diseases. Its effectiveness is not only related to the weight reduction, but also to the improvement of the metabolic profile. The aim of this study is to characterize the effects of gastroplasty with Roux-en-Y (gastric bypass – BG) and vertical gastrectomy (gastric sleeve – SG) in reducing obesity and associated comorbidities.
Methods
Prospective study of patients with class III and class II obesity with metabolic diseases who underwent BG or SG between May 2017 and May 2020. Clinical observation at 0, 6, 12, 18 and 24 months.
Results
43 patients, 53.5% male, mean age 49+9 years, mean BMI 41.9+2.9 kg/m^2, 67.4% submitted to BG and 32.6% to SG. The average excess weight lost percentage was 74.3+16.3% at 6 months (n = 43), 84.3+20.9% at 12 months (n = 39), 79.3+22% at 18 months (n = 28) and 73.3+24% at 24 months (n = 22). No difference between patients undergoing BG or SG (P-value = 0.2) or between men and women (P-value = 0.114) was observed. Mean abdominal circumference reduction was 20.6+5.5% at 24 months and body fat mass percentage reduction was 27.7+17.2%, with no difference between procedures (P-value = 1 and 0.114). 53.5% of patients had Diabetes mellitus or pre-diabetes, 60.8% achieved total remission at 24 months after surgery and 21.7% partial remission (pre-diabetes). 58% had arterial hypertension, 52% achieved remission and 40% reduced the number of antihypertensive drugs. 86% had altered lipid metabolism, 46% achieved remission and 5% reduced the number of drugs. 60% of patients suffered from obstructive sleep apnea syndrome, with remission achieved in 46% of patients and a 54% reduction in severity. 85.7% of the patients had steatosis on preoperative abdominal ultrasound, with 60% having hepatomegaly. In the reevaluation at 12 months, 53.2% maintained steatosis and 7.6% hepatomegaly.
Conclusion
Bariatric surgery is a treatment option that provides excellent results in reducing weight, abdominal circumference and percentage of fat mass. The underlying modification of the metabolism allows the correction of comorbidities associated with obesity, with remission in a large number of patients.

Social phobia and predictive factors in obese adults

Dhouha Ben Salah, Ameni Salah, Yosra Mejdoub, Wajdi Safi, Mouna Elleuch, Sourour Yaich, Jihen Jdid, Jamel Dammek, Faten Haj Kacem & Mohamed Abid
UHC Hedi Chaker, Endocrinology, Sfax, Tunisia

Introduction
In Tunisia, obesity is a public health problem. In fact, it has been considered as a complex disease including alteration of the nutritional, somatic and psychological functioning of the individual. Various psychological disorders have been associated with it such as social phobia (SP). In this context, our study was conducted to determine the psychological profile in terms of SP in obese adults.
Methods
This was a cross-sectional descriptive study. We included obese adults aged 19 to 64 who consulted in the basic health districts of Sfax, South Tunisia,

and who had a body mass index (BMI) greater than or equal to 30 kg/m^2. Data was collected using a validated anonymous questionnaire: Liebowitz Social Anxiety Scale (LSAS).
Results
A total of 150 adults were included with an average age of 47.1 ± 12.5 years. Females accounted for 76.7% with a sex ratio H/F = 0.3. The mean BMI was 35.9 kg/m^2 (s.d. = 5.6). Eighty-two subjects (54.7%) had grade I obesity, 31 subjects had grade II (20.7%) and 37 subjects (24.7%) had grade III. Abdominal obesity was present in 142 people (94.7%). The study of the psychological profile revealed that 33.59 and 58 patients had respectively a mild, a moderate and a severe intensity of SP according to the LSAS questionnaire. the study of the factors which condition the severity of SP had shown that it was correlated with age (31% of the subjects of the age group [19,34] had severe SP vs 39% of the group [35,49] vs 41% of the group [50,64], $P = 0.01$). On the other hand it was not correlated with gender, the grade of BMI, the practice of a physical activity or the somatic impact of obesity.
Conclusion
The prevalence of SP was significant in our study population. As a result, the establishment of a national care program for obese patients including psychologists is mandatory.

Rooibos tea (Aspalathus linearis) upregulates hepatic sex hormone-binding globulin production

Laura Briansó Llort[1,2], Carmen Pheiffer[3,4], Lidia Fuertes Rioja[1], Lorena Ramos Perez[1], Cristina Hernandez[1,2], Rafael Simo Canonge[1,2] & David Martinez[1,2]
[1]VHIR – Vall d'Hebron Institut de Recerca, Diabetes and Metabolism Research Unit, Barcelona, Spain; [2]UAB, Cerdanyola del Vallès, Spain; [3]South African Medical Research Council, Biomedical Research and Innovation Platform, Cape Town, South Africa; [4]Stellenbosch University, Division of Medical Physiology, Cape Town, South Africa

Sex hormone-binding globulin (SHBG) is a circulating plasma glycoprotein produced by the liver, which in the blood binds estrogens and androgens with high affinity and regulates its bioavailability. Low plasma SHBG levels are associated with obesity, metabolic syndrome and non-alcoholic fatty liver disease. Importantly, epidemiological studies have demonstrated that low plasma SHBG levels is a risk factor for developing type 2 diabetes and cardiovascular disease. In the last years, we have described the molecular mechanisms by which several nutritional factors including high carbohydrate diets, olive oil, red wine (resveratrol) and caffeine regulate hepatic SHBG production. In the present work we have studied the effects of Rooibos tea on hepatic SHBG production since Rooibos (*Aspalathus linearis*), a South African herbal tea, has been shown to possess anti-diabetic and cardiovascular protective effects. For this objective, we performed *in vitro* and *in vivo* studies. The results showed that Rooibos treatment increases SHBG production in HepG2 cells. These results were corroborated *in vivo* using *SHBG* transgenic mice. Our results showed for the first time that Rooibos consumption increases hepatic SHBG production. These results suggest that the anti-diabetic and cardiovascular beneficial effects of Rooibos may be explained by increasing hepatic SHBG production.

The prevalence of masked hypertension in the obese

Safi Wajdi[1], Hadj Kacem Faten[1], Rebai Mohamed[2], Charfeddine Salma[2], Hana Charfi[1], Ben Salah Dhoha[1], Chabchoub Imen[1], Mnif Fatma[1], Charfi Nadia[1], Mnif Feki Mouna[1], Rekik Nabila[1], Kammoun Samir[2] & Abid Mohamed[1]
[1]HEDI Cheker, Endocrinology, Tunisia; [2]Hedi Cheker, Cardiology, Tunisia

Introduction
Obesity is a social scourge. Masked arterial hypertension (HTAM) is a relatively recently described entity that poses a diagnostic problem and places the patient with it at an increased risk of cardiovascular events. In this context we report a prospective study of 50 patients to determine the prevalence and predictive factors of HTAM.
Methods
Descriptive study of obese patients treated in the Endocrinology and Diabetology Department of the Hédi Chaker Sfax University Hospital, Tunisia. These patients had body mass index (BMI) > = 30 kg/m^2 with no history of hypertension. They all had normal blood pressure for the last 2 years of their chek ups.
Results
We recruited 50 patients whose mean age was 46.52 years with extremes ranging from 22 to 64 years. The average BMI was 36.03 kg/m^2. An android distribution of fat was objectified in all of our patients. The collection of blood pressure figures in consultation showed an average SBP of 120 ± 8.8 mmHg and an average DBP of 75 ± 7.3 mmHg. The prevalence of HTMA in our series was 36%, occurring in predominantly non-dipper subjects (38%). These results were statistically somewhat higher compared to those in the literature (between 17.1 and 30.9%). Sleep apnea syndrome, smoking, metabolic syndrome as well as high normal blood pressure values were factors associated with AMT in our patients.
Conclusion
It seems essential to perform outpatient screening for HTAM in obese patients. The induced morbidity and mortality and the cardiovascular risk would be significant and fully justify it.

Vitamin D deficiency, associated factors and possible adverse outcomes in a tertiary care institute in Sri Lanka

Ishara Ranathunga, Manilka Sumanatilleke & Noel Somasundaram
National Hospital of Sri Lanka, Endocrinology, Colombo, Sri Lanka

Background and objectives
Around 50% of the population is affected with vitamin D insufficiency worldwide. The increasing prevalence is attributed to change in lifestyle, reduced exposure to sunlight and other environment factors. Vitamin D has multiple actions in the body including calcium homeostasis and has impact on several biologic processes with several clinical implications including obesity, diabetes mellitus, and metabolic syndrome, cancer, cardiovascular disease and immune function. Studies on factors associated with vitamin D deficiency and its complications in local setting are lacking. We have studied the vitamin D status, associated factors and outcome of patients.
Methods
A descriptive cross sectional study was conducted from March/ 2019 to March/ 2020 at the Endocrinology Unit of the National Hospital of Sri Lanka. Consecutive sampling was done recruiting all patients who have had vitamin D assessment as part of the routine medical care. Interviewer administered questionnaire was used collect data. Vitamin D sufficiency, insufficiency and deficiency was defined on levels of >50 ng/ml, 20–30 ng/ml, <20 ng/ml respectively. Categorical and numerical variables were analysed using Chi-square and independent sample t-tests respectively.
Results
153 subjects who meets the inclusion and exclusion criteria were recruited in to the study over a period of one year. Out of the study population, majority were females (85.6%). The population mean age was 52.1 (s.d. ± 14.38) years and ranged from 18 to 89 years. The mean weight was 59.4 (s.d. ± 15.70) kg and BMI was 31.3 (s.d. ± 7.54) kg/m^{-2}. Out of the whole population 58.8% had vitamin D deficiency while 31.4% suffered from vitamin D insufficiency. Only 9.8% had the values within the normal range. The mean vitamin D status of the population is 9.8 ng/ml. Pearson chi square was significant in the frequency of fish/ meat intake/per week, screen time per day with vitamin D category. Multiple Linear Regression Analysis was carried out to determine the predictors of vitamin D status. Out of the possible factors skin colour had a significant association with vitamin D insufficiency and deficiency ($F = 4.355$, $P<0.05$).
Conclusions
Majority of the patients who has undergone vitamin D level assessment in the study setting had Vitamin D levels in the deficient or insufficient range. The skin color, frequency of fish/ meat intake/per week and screen time per day had a positive association with the vitamin D status. Further large scale studies to recognize potential causes and outcomes are needed in the future.

Primary hypertriglyceridemia : an early and severe form

Faten Haj Kacem, Ameni Salah, Sidina Med Elmokhtar, Mouna Elleuch, Dhouha Ben Salah, Fatma Mnif, Mouna Mnif, Nabila Rekik, Nadia Charfi & Mohamed Abid
UHC Hedi Chaker, Endocrinology, Sfax, Tunisia

INTRODUCTION
Type IV hypertriglyceridemia (HTG IV) or endogenous HTG is a rare inheriteddisorder of the lipoprotein metabolism due to increased hepatic triglyceride synthesis(TG). Although HTGIV is not usually expressed until adulthood, it might be unmasked earlier. We report the case of an early and severe HTGIV complicated with chronic pancreatitis.
Case report
A 6-year-old childwith no particular history was hospitalized in the paediatric department of the UHC Hedi Chaker sfax, Tunisia for an acute pancreatitis (amylasemiawas 264 IU/l). The appearance of the fasting serum was lactescent. The triglyceride level was high at 5.4 g/l with VLDL at 74% without chylomicrons, cholesterol levelwas normal at 1.65 g/l. The diagnosis of primary HTG type IV was retained after exclusion of secondary causes. Dietary modifications were initiated and then at the age of ten a pharmalogical treatment (fibrates) was added. Despite treatment, TG levels were always high and the child has several episodes of acute pancreatitis. At the age of 18, he was hospitalized in the endocrinology department of the UHC hedi Chaker Sfax, Tunisia for paroxysmal abdominal pain and polyuropolydipsic syndrome. A weightloss of 5 kg in 1 year has been noted. The biological assessment showed a blood sugar level of 21 mmol/l with a glycated hemoglobin at 14.7%, without acute metabolic complication. The liver profile was normal but a high lipasemia level of 3 times the upper limit was noted, hence an abdominal CT scan was done revealing an appearance of acute cephalic pancreatitis with atrophy of the pancreatic tail. The diagnosis of diabetes secondary to chronic pancreatitis complicating HTG IV was most likely, but antibodies directed to the pancreas were requested as well.
Discussion–conclusion
Primary HTG can be discovered at an early age. His management is difficult : dietary restrictions remains the mainstory of therapy supplemented by TG levellowering medications. Close monitoring is alsomandatory due to the risk of complications.

Managing hypertension can be a night-mare!

Muhammad Shoaib Zaidi
King Saud University Medical City, University Diabetes Center, Riyadh, Saudi Arabia

Introduction
Hypertension is a frequent finding amongst people having either Type1 or Type 2 diabetes. In Type 2 diabetes, hypertension is present in a great number of persons, at the time of diagnosis but it's occurrence is low with the diagnosis of Type 1 diabetes.
Case presentation
A 34 years old Saudi male, non-smoker, had been following up at our University Diabetes Center since February, 2020. He had Type1 diabetes for 23 yrs, hypertension for 2 yrs, chronic kidney disease G4A2 and vitamin D deficiency with secondary hyperparathyroidism. The patient had a strong family history of hypertension & diabetes. There was no previous history of ketoacidosis or any other illness. Systemic review unremarkable. The patient had Stage 2 Hypertension, as per office & home BP readings, despite being compliant to all antihypertensives. He was on Basal bolus insulin, Angiotensin receptor blocker, B-blocker,Calcium channel blocker, hydrochlorthiazide,Spironolactone and Cholecalciferol replacement. Exam-BP 160/90 mmHg with no postural drop, pulse 72/m,regular, RR 20/m,afebrile,O2sat 99%. BMI 32.93 kg/m^2. Rest of the general and systemic exams unremarkable.
Investigations
(25.11.20) Normal CBC(Hb% 14 g/dl),liver & thyroid parameters. BUN 10 mmol/l(10–6.4),Creatinine 239 µmol/l(62–115),eGFR(EPI)–29 ml/min, Albumin:Creatinine 161.33 mg/g(0–30),HbA1c 8.2%(4.3–5.8),Bone profile(corrected S.Ca++2.41 mmols/l(2.1–2.55),25-OH Cholecalciferol 27 nmol/l(75–250),PTH 18.24 pmol/l(1.6–6.9). Rest normal). Aldosterone:Cortisol 0.07(0.1–3.7). CXR & ECG normal. Echocardiogram-mild concentric left ventricular hypertrophy & moderate LA enlargement. US renal arteries doppler-normal. The patient was referred to the Nephrology clinic for further management.
Conclusions
Chronic kidney disease in people with diabetes increases the chances of resistant hypertension. Resistant hypertension runs parallel to the worsening renal parameters i.e.eGFR and albuminuria.

Corticosteroid-induced diabetes during pregnancy: case report

Fatiha El Miski, Imane El Abbassi, Btissam Ouafidi, Moukhlis Sabah, Amine Lamrissi, Karima Fichtali & Said Bouhiya
Ibn Rochd University Hospital of Casablanca, Gynecology and Obstetrics Department, Casablanca, Morocco

Introduction
Glucocorticoids are among the most widely used treatments for controlling inflammatory or autoimmune diseases. However, their metabolic side effects are not negligible, particularly on carbohydrate metabolism. Corticosteroid-induced diabetes is an identity frequently found in the clinic. Its occurrence during pregnancy can affect the maternal and foetal prognosis. After the illustration of a clinical case, we will discuss the definition, risk factors and treatment of cortico-induced diabetes during pregnancy.
Observation
Q.B 36 years old, followed since 2003 for lupus nephropathy class 2 under corticotherapy and Immurel with the notion of several relapses and self-medication, known hypertensive under dual therapy, 6G2P with a history of 3 miscarriages and 3 neonatal deaths. Patient admitted to our department for Added Preeclampsia on a pregnancy of 26SA+6 days, with proteinuria at 5.5 g /24 h on the biological assessment. The use of corticosteroids was accompanied by a frank glycemic imbalance with postprandial hyperglycemia greater than 2 g/l and normal glycated hemoglobin at 5.5% which defines corticosteroid-induced diabetes. The patient was put on Lantus in the evening and rapid insulin therapy. Glycemic imbalance, the presence of hypertension, the existence of renal impairment and corticosteroid therapy at a dose higher than 20 mg/d were all factors that affected the foetal prognosis and fetal death in utero was declared at tenth day of hospitalization.
Conclusion
The beneficial effects of glucocorticosteroids are sometimes outweighed by significant deleterious effects such as corticoid-induced diabetes. The diagnostic criteria and therapeutic objectives are close to those for type 2 diabetes, its occurrence during pregnancy increases foetal and neonatal morbimortality, and diabetes in general, its management remains disparate due to the absence of evidence-based recommendations.

Diabetic pregnancy and gestational diabetes: high-risk gestational situations

Moukhlis Sabah, Bouab Maryem, Fatiha El Miski, Btissam Ouafidi, Amine Lamrissi, Karima Fichtali & Said Bouhiya
Ibn Rochd University Hospital of Casablanca, Gynecology and Obstetrics Department, Casablanca, Morocco

Introduction
Pre-pregnancy diabetes and gestational diabetes are gestational risk situations. The objective of our study is to evaluate the course of these pregnancies in order to improve their management.
Patients and methods
Descriptive retrospective study, including 175 patients with diabetic pregnancy followed in the department of gynecology and obstetrics of the Ibn Rochd University Hospital in Casablanca between October 2019 and September 2020.
Results
The study included 175 patients with an average age of 28.8 years, 30% had gestational diabetes and 70% had pre-gestational diabetes. The mean pre-gestational BMI was 26.9 kg/m^2. For gestational diabetes, the mean gestational age of discovery was 21.7 SA, with 71.4% fasting blood glucose levels versus 21.4% for oral glucose tolerance test (OGTT). Concerning pre-gestational diabetes, 24.5% of patients had type 1 diabetes and 43.5% had type 2 diabetes, of which 4.5% had planned their pregnancy. The average

HbA1c was 7.9%. For treatment, 75% of the patients were on insulin and 25% were undergoing hygienic and dietary rules. Glycemic control was perfect in 50.4% of patients, 70.3% of whom had pre-gestational diabetes and 29.7% had gestational diabetes. Concerning the obstetrical complications observed pregnancy-related hypertension in 15.5%, pre-eclampsia in 5%, macrosomia in 13%, threat of premature delivery in 4.5%, malformations and hydramnios in 3.5%. Discontinued pregnancies were observed in 2.9% with no significant difference in complications between patients with and without hypertension.
Discussion
The management of diabetic pregnancy remains a challenge, including pregnancy planning, detecting gestational diabetes, and achieving and maintaining glycemic control to prevent complications.

Upper limb infections in diabetic patients

Sara Ijdda, Sana Rafi, Ghizlane El Mghari, & Nawal El Ansari
[1]University Hospital Center Mohamed VI, Departement of Endocrinology, Diabetes, Metabolic Disease and Nutrition, Marrakech, Morocco

Introduction
The diabetic is characterized by his vulnerability to infections of the upper limb compared to the general population realizing the tropical diabetic hand. So this is a very serious problem, especially in emerging countries in tropical regions. The aim of this work is to study the clinical, therapeutic and progressive aspects of infections of the upper limb in diabetic patients.
Materials and methods
This is a cross-sectional study spread over 6 years, including diabetic patients with lesions of the upper limb who consulted in the emergency room of the Mohamed VI university hospital in Marrakech, Morocco.
Outcomes
We saw 44 diabetic patients with upper limb infection. The majority of our patients had peripheral neuropathy. The average time between consultation and onset of lesions was 15.3 days. The lesions involved several parts of the upper limb: the hand in 30 cases, the arm in 8 cases, the entire upper limb in 6 cases. Various lesions were observed, phlegmon: 17 cases, panaris: 6 cases, necrotizing fasciitis: 7 cases, erysipele: 8 cases, gangrene: 4 cases, ulceration: 1 case, anthrax: 1 case. Bacteriological study of pus was only carried out on 13 lesions. Therapeutic management consisted of intensifying insulin therapy, with strict glycemic control. Triple probabilistic intravenous antibiotic therapy was initiated and then adapted to the results of the antibiogram in patients who received a bacteriological sample. As for surgical management, drainage represented 78.6% of cases, including 5 necrosectomies in 41%.
Discussion/conclusion
Lesions of the upper limb in the diabetic concern patients most often from a low socio-economic level. The lack of intrinsic coordination between the medical and surgical structures in the management of lesions of the limbs, is not likely to favor the vital prognosis of both the limb and the patient. In some cases, these injuries have been the cause of death. Indeed, the treatment of diabetes and lesions of the limbs is not confined to a drug prescription only, but requires above all patient education; it is the cornerstone of treatment, with goals to be established consistently.

Analysis of HMBS gene in Chinese patients with acute intermittent porphyria

Ru Li[1], Yi Ren[2] & Jing Yang[2]
[1]ShanXi Medical University, Taiyuan, China; [2]The First Hospital of Shanxi Medical University, Department of Endocrinology, Taiyuan, China

Background
The reported HMBS mutations of acute intermittent porphyria(AIP) have been increasing gradually in China. We aim to explore its mutation characteristic in China and improve the understanding of its molecular heterogeneity.
Material/methods
We searched the literature about Chinese AIP patients with HMBS mutation in the PubMed,CNKI,Wanfang and CQVIP database, and 3 AIP patients with HMBS mutation in our hospital were included. We analyzed the characteristic of these mutations in mutation site, type and frequency. The pathogenicity of all exon mutations were predicted by Mutation Taster.
Results
Totally, 66 unrelated AIP families were enrolled in this study, and 50 mutations were detected, including 17 missense mutations, 15 frameshift mutations, 11 splicing mutations, 6 nonsense mutations and 1 codon mutation. Exon mutations were mainly concentrated in exon 11 and 14(50%). Most of the mutations had the family specificity, but there were 8 mutations occurred in multiple families. P.R173W was the most common mutation, which occurred in 8 unrelated families. The predicted effects of c.913C>A, c.1071delT and c.1078_1132del were polymorphisms, but the others were pathogenicity. C.160delA could not be predicted by Mutation Taster because it was located in the junction of exons and introns.
Conclusion
This is the first comprehensive analysis of HMBS mutation in China. Genetic analysis revealed that missense mutation accounted for the largest proportion and the p.R173W was the most common mutation. In addition, the pathogenicity prediction of bioinformatics software can only provide reference value, so further functional verification test is necessary.

DOI: 10.1530/endoabs.73.EP96

Immüne checkpoint inhibitors induced an autoimmune diabetes

Meriç Dökmetaş[1], Emre Sedar Saygili[2], ömer fatih ölmez[3], Hatice Sebile Dökmetaş[4] & Fatih Kılıçlı[3]
[1]Istanbul Medipol University, Internal Medicine; [2]Hospital of Çanakkale Mehmet Akif Ersoy; [3]İstanbul Medipol University, Oncology; [4]İstanbul Medipol University, Endocrinology and Metabolism

Diabetes caused by immune checkpoint inhibitors is extremely rare. A 48-year-old male patient with a diagnosis of squamous cell cancer in the external auditory canal and operated on received adjuvant radiotherapy. When relapse was seen, 6 cycles of 5-fluorouracil, carboplatin, and cetuximab were administered. The patient was admitted to the hospital with nausea, vomiting, and abdominal pain 10 days after the second cycle infusion, when pembrolizumab was started when the cranial MRI showed progression 6 months later. Serum glucose: 717 mg/dl (70–100), creatinine: 1.5 mg/dl (0.7–1.2), sodium: 132 mmol/l (136–145), potassium (K): 5.5 mmol/l (3.5–5.1), amylase 55 U/l (13–53), blood pH: 7.02 (7.35–7.45), pCO_2: 29 mmHg (35–45), HCO_3: 8 mEq/l (22–26), lactat: 1.9 mmol/l (0.5–1.6), urinalysis; ketons: ++++, glucose: ++++. Treatment was started with the diagnosis of diabetic ketoacidosis and the desired c-peptide due to possible immune checkpoint inhibitor-induced diabetes mellitus: <0.001 ng/ml, anti-insulin antibodies: 1.5 U/l (0–10), GAD antibodies: 718 IU/ml (0–10) were found. TSH required for other possible immune-related adverse events: 1.6 µIU/ml (0.2–4.2), free T4: 1 ng/dl (0.9–1.7), anti thyroid peroxidase: 11 IU/ml (0–34), anti thyroglobulin: 11 IU/ml (0–115), cortisol: 16 µg/dl (6–18), and no other immunocheckpoint-related endocrinopathy was detected. The patient who responded to ketasidosis treatment was discharged with insulin therapy. The treatment was not stopped because the patient's response to pembrolizumab treatment was good. The side effects of these drugs, whose immune checkpoint inhibitors act by blocking the inhibitory mechanisms on the immune system, are also autoimmune events that occur as a result of excessive immune response. There were no other more common autoimmune side effects in our patient, who was diagnosed with autoimmune diabetes. While using these drugs, patients should be followed up carefully for other possible side effects, as well as for autoimmune diabetes.

Novel toxicological method to investigate the increased ROS in mouse kidney stem cell mitochondria by doxorubicin

Minsu Lee, Sunhwa Jeong, Jimin Lee, Donglin Yi & Eui-Bae Jeung
Laboratory of Veterinary Biochemistry and Molecular Biology, College of Veterinary Medicine, Chungbuk National University, Cheongju, Chungbuk, Republic of South Korea

Mitochondria play a key role in hormone biosynthesis and involve in renal cell proliferation by producing about 90% of cellular energy and controlling cell apoptosis. Doxorubicin is commonly used for many tumor treatments. However, its clinical utility is limited by the adverse reactions, which are

known to be nephrotoxic. The mechanism by which doxorubicin induced kidney damage is still not completely understood, however nephrotoxicity by doxorubicin might be related to mitochondrial dysfunction. In this experiment, the following mitochondrial toxicity test was performed after doxorubicin was treated to mouse kidney stem cells. First, we identified IC_{50} values for doxorubicin in mouse kidney cells. We investigated that mRNA expression level of Mn-SOD, the neutralizer of reactive oxygen species (ROS), in the mitochondria increased in a concentration-dependent manner of doxorubicin. To confirm the relationship between mitochondrial toxicity and ROS, MitoSOX red assay was performed. The results showed that the ROS level increased according to the ascending concentration of doxorubicin. Further experiment should be conducted for assessing the apoptosis pathway induced by doxorubicin. This research was supported by grants (20183MFDS525) from the Ministry of Food and Drug Safety in 2021.

Hyperandrogenia and non-alcoholic liver fatty disease: what is the prevalence?

Nisrine Bouichrat, Messaoudi Najoua, Salma Ben Yakhlef, Marouan Karrou, Siham Rouf & Hanane Latrech
Mohamed VI University Hospital Center, Oujda, Department of Endocrinology-Diabetology and Nutrition, Oujda, Morocco

Introduction
Non-alcoholic liver fatty disease is one of the metabolic consequences found in patients followed for hyperandrogenia, especially those with polycystic ovary syndrome. Studies have suggested that hyperandrogenia is considered as an additional risk factor in synergy with obesity and insulin resistance in the development of non-alcoholic liver fatty disease. The aim of our work was to study the prevalence of non-alcoholic liver fatty in patients consulting for hyperandrogenia and to identify these predicting factors.
Material and methods
This is a retrospective descreptive study involving 98 patients followed for hyperandrogenia in Endocrinology-Diabetology-and-Nutrition Department of the Mohammed VI University Hospital Center of Oujda, Morocco. All patients were provided with a complete clinical examination and laboratory analysis, and the abdominal ultrasound was performed in only 25 patients.
Results
We collected 98 patients having a hyperandrogenia with an average age at 24.6 ± 6.2 years old. Abdominal ultrasound showed non-alcoholic liver fatty in 8 patients, varying in age from 23 to 41 years with an average of 30.5 ± 6.3 years old. The mean BMI of these patients was elevated above 32.1 ± 10.2 kg/m^2, obesity was noted in 50% of cases, and overweight in 12.5%. Abdominal obesity was objectivated in 75% of cases, with an increased average waist circumference at 110.7 ± 28.4 cm. Insulin resistance was present in 50% of cases. Dyslipidemia was reported in all patients, with hypoHDlemia in 87.5% of patients, hypertriglyceridemia in 25% and hypercholesterolemia in 12.5%. 50% of patients with non-alcoholic liver fatty had polycystic ovary syndrome, 37.5% had idiopathic hirsutism and 12.5% had Cushing disease.
Discussion–conclusion
The present study shows a high prevalence of non-alcoholic liver fatty (NALF) in overweight and obese patients with lipid and carbohydrate metabolism disorders notably those with insulin resistance, especially patients followed for polycystic ovary syndrome (PCOS). This is in agreement with the data reported in the literature, which find an increased prevalence of NALF in women with PCOS. Further, that obesity and insulin resistance (IR) seem to be the main contributing factors to NALF. In particular, IR is linked to impaired suppression of lipolysis in adipose tissue, leading to higher levels of free fatty acids in the liver, and steatosis. Hence the interest of systematic screening for non-alcoholic liver fatty at diagnosis and during follow-up, in patients followed for hyperandrogenia, especially those with PCOS, to avoid the risk of progression to cirrhosis or even hepatocellular carcinoma in the absence of early and adequate management.

Obesity in Bardet–Biedl syndrome

Aicha Bouzid[1], Ztaitou Khaoula[2], Djamila Meskine[1] & Azzouz Malha[2]
[1]Medical University of Algiers, Endocrinology & Metabolism laboratory Algiers 1, EPH Bologhine, Algiers, Algeria; [2]Medical University of Algiers. EPH Bologhine, Algiers, Algeria

Introduction
Bardet–Biedl syndrome (BBS) is a rare autosomal recessive ciliopathy characterized by rod-cone dystrophy, learning difficulties, polydactyly, obesity, genital malformations, and renal abnormalities. We report the case of a young patient followed for this syndrome, which is revealed by early obesity.
Observation
This is a 23-year-old patient from a consanguineous marriage with a personal history of well-substituted peripheral hypothyroidism. Received in consultation for obesity. the history revealed excessive weight gain and an eating disorder such as polyphagia and active search for food. On clinical examination, the patient presented with pronounced obesity with a body mass index (BMI) of 37.2 kg/m2, BP = 160/100 mmHg, deformation of the fingers of the hands and feet type axial polydactyly, syndactyly and brachydactyly. There is a difficulty in adapting to the dark followed by a gradual decline in visual acuity, retinitis pigmentosa in the fundus. Cardiovascular: Arterial hypertension well controlled under ARB 2 with normal heart echo. Renal: Moderate renal failure with an estimated renal clearance of 53.9 ml/min, ultrasound shows bilateral renal atrophy with loss of cortico-medullary differentiation. the Patient was put under hygieno-dietetic rules with a monitoring protocol.
Discussion
Despite normal birth weight, most individuals with BBS experience rapid weight gain in early childhood, with high rates of overweight/obesity sustained through adolescence. The diagnosis of SBB is retained in the face of obesity associated with polydactyly, retinitis pigmentosa and renal impairment. The obesity observed in our patient is almost constant and genetic, early and difficult to treat. Although the mechanisms for obesity in BBS remains incompletely understood, disruption of the hypothalamic leptin-melanocortin signaling pathway is evident. THe molecular mechanistic pathways leading to renal disease in BBS remain unelucidated. It has been suggested that aberrant mTOR signaling may contribute to the development of cystic kidney disease. Another theory proposes that ciliary dysfunction leads to aberrant non-canonical Wnt signaling and planar cell polarity, which may contribute to the development of cysts. At least 25 causative genes have been identified in BBS. Previous reports document that truncating variants in BBS genes predict greater risk for severe chronic kidney disease and increased cardiovascular disease markers compared to missense variants.
Conclusion
Obesity and renal failure are common manifestations in the autosomal recessive Bardet–Biedl (BB) syndrome. Bardet–Biedl syndrome is currently treated symptomatically focusing in particular on aggressive management of diabetes, hypertension, and metabolic syndrome

DOI: 10.1530/endoabs.73.EP100

EP101

Type 2 diabetes mellitus and vitamin D deficiency among women of reproductive age

Ivan Pankiv
Bukovinian State Medical University, Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine

Background and aim
Vitamin D may affect glucose homeostasis, vitamin D levels having been found to be inversely related to glycosylated hemoglobin (HbA1c) levels in type 2 DM. With the scarcity of the regarding data in Ukraine, the aim of this study was to assess the relationship between hypovitaminosis D and glycemic control in type 2 DM women of reproductive age.
Material and methods
To test the hypothesis that 25(OH)D levels may be lower in a cohort of type 2 DM women and that 25(OH)D levels may be related to glucose control in this group of patients, 25(OH)D and HbA1c levels were measured in 90 women with type 2 DM and in 55 persons of control group. In a group of 90 type 2 DM patients, aged 20–45 years, mean age 36.2 ± 1.3 years, 25(OH) D levels and HbA1c levels were measured. The study was conducted during the summer.
Results
HbA1c levels were higher in the group of type 2 DM patients than in the control group, HbA1c levels being 7.8 ± 0.19% and 5.2 ± 0.07% in the patient and control groups, respectively ($P < 0.01$, Student's t-test). In the group of type 2 DM patients, 25(OH)D levels were lower than in the control group, 25(OH)D levels being 17.42 ± 0.98 ng/ml and 24.03 ± 1.04 ng/ml in the patient and control group, respectively ($P < 0.05$). In the group of type 2 DM women, 17 of 90 (18.9%) as opposed to 3 of 55 (5.5%) in the control group had vitamin D levels ≤ 10 ng/ml ($P = 0.0067$). 25(OH)D levels were

found to be inversely associated with HbA1c levels in the group of diabetic type 2 women ($P = 0.007$, $r = 0.054$). When the analysis was performed in all participants, type 2 DM patients and controls, it was found that 25(OH) D levels were inversely associated with HbA1c levels ($P < 0.01$, $r = 0.082$).
Conclusion
Vitamin D levels appeared to be lower in type 2 DM women of reproductive age than in the control group. Vitamin D levels being related to glycemic control in type 2 DM. These findings may have therapeutic implications as cautious vitamin D supplementation may improve glycemic control in type 2 DM.
Keywords: diabetes mellitus type 2, glycemic control, vitamin D, women of reproductive age.

You name it & she had it'

Muhammad Shoaib Zaidi
King Saud University Medical City, University Diabetes Center, Riyadh, Saudi Arabia

Introduction
Metabolic syndrome is the concurrence of the metabolic risk factors for both diabetes and cardiovascular disease, namely, hypertension, hyperglycemia, dyslipidemia and abdominal obesity.
Case presentation
We report a case of 59 years old morbidly obese, Saudi lady, who had been following up at our outpatient diabetes clinic, since last many years. She had Type2 diabetes for 34 yrs, hypertension, advanced proliferative diabetic retinopathy (S/P laser), ischemic heart disease, chronic kidney disease 5-A3, dyslipidemia, osteoarthritis knees & obstructive sleep apnea (on O2 inhalation, 4 l/m & BiPAP). The patient was non-compliant to medications, diet, exercise & follow-ups. No hypoglycemic episodes at home. She had decreased hearing from both ears. There was a past history of left breast abscess (status post incision & drainage twice), recurrent urinary tract infections, acute right hemispheric stroke, following acute coronary syndrome (5 years ago, status post percutaneous coronary intervention & stenting), ischemic neuritis right ear & cataract extraction. There was a positive family history of Type 2DM and obesity. She was allergic to Ceftriaxone & Strawberries & was on Basal bolus insulin regime, Linagliptin, dual anti-platelets, statin, Hydralazine, calcium carbonate, 1 alphacalcidol & a proton pump inhibitor. On evaluation lastly on 10.11.20, the patient had moderate bilateral pedal edema (L > R) & absent vibration sensation at left ankle. Her available records had indicated the following trends for her physical & biochemical values, from 2015 to 2020:BMI (41.33–53.24 kg/m^2), HbA1c (14.1–6.5%), eGFR (44–10 ml/min), Albumin/Creatinine ratio (643–1119.58 mg/g).
Conclusions
Our case depicts the legacy effect of uncontrolled diabetes (with microvascular & Macrovascular sequelae) and the tendency for recurrent infections. It's also apparent that as the patient's renal function progressively deteriorated, her blood glucose started coming under control, due to reduced insulin clearance thru the affected kidneys.

From type 2 diabetes to cardiac arrest

Viyey Kishore Doulatram Gamgaram[1], Araceli Pineda Cantero[2], José Abuín Fernández[1], Lidia Cobos Palacios[2] & Gabriel Olveira Fuster[1]
[1]Hospital Regional de Málaga, Endocrinología y Nutrición, Spain;
[2]Hospital Regional de Málaga, Medicina Interna, Spain

Introduction
Gastrointestinal adverse effects such as nausea and vomiting are widely described for GLP-1 receptor agonists (arGLP-1). We highlight Semaglutide, a drug that needs to start its administration at a reduced dose, to be able to increase the dose later with better tolerance and adherence of the patient. Not doing it this way can lead the patient to have serious adverse effects such as incoercible vomiting or profuse diarrhea that entails serious ionic alterations.
Case report
A 70-year-old man, living independently, diagnosed with type 2 diabetes mellitus and grade 2 obesity, treated with Empagliflozin 10 mg and Semaglutide 1 mg. He presented symptoms of general malaise, frequent vomiting, hyporexia and weight loss of 25 kg in the last 6 months (coinciding with the initiation of Semaglutide at an initial dose of 1 mg subcutaneous weekly). He suffers from worsening with incoercible vomiting and instability, so he goes to the emergency room, where he suffers a tonic–clonic crisis and cardiorespiratory arrest. Advanced cardiopulmonary resuscitation maneuvers were started and the patient proceeded to oropharyngeal intubation, recovering a pulse after 3 min, and he was transferred to the ICU. In the blood test extracted, severe hypocalcemia (< 5 mg/dl) and hypomagnesemia (1.2 mg/dl) stand out, the rest without relevant alterations, with these values in range in previous tests. In the study of hypocalcemia and hypomagnesemia, parathyroid hormone (PTH) 404 pg/ml, 1,25-(OH)2 Vit D 32 pg/ml is observed, with a calcium excretion fraction < 0.01 and a magnesium excretion fraction 0.7%. After correction of calcium and magnesium levels, a new determination of PTH 57.5 pg/ml is performed, where normalization is observed. During the diagnostic process, occult neoplasia, thyroid disease, severe deficiency or resistance to vitamin D and resistance to PTH were ruled out. Given the patient's history and the initiation of treatment with Semaglutide at 1 mg weekly, a dose higher than that indicated in the technical data sheet (0.25 mg weekly), we consider that serious gastrointestinal effects occurred in the patient, the deficiency etiology of hypocalcemia and hypomagnesemia being the most probable cause.
Conclusion
arGLP-1, and specifically Semaglutide, are excellent drugs for the control of patients with DM2, but they require that we know in depth the possible adverse effects and the appropriate form of administration of each of them.

Weight gain and insulin therapy in patients with type 2 diabetes mellitus

Mehrez Achwak, Yosra Htira, Manel Dridi, Zohra Hadj Ali & Faika Ben Mami
National Institute of Nutrition of Tunis, Department C, Tunisia

Introduction
Traditionally, there has been a stepwise introduction of glucose-lowering interventions, with the final 'step' of insulin therapy being administered 10–15 years after diagnosis. Both patients and physicians are often reluctant to start insulin because of fears of painful injections, hypoglycemia, and weight gain. The aim of our study was to assess the effectiveness of initial basal insulin therapy on glycaemic control in type 2 diabetic patients and to study the effects of this treatment on body weight.
Methods
We conducted a retrospective study including patients with type 2 diabetes previously on oral agents, followed up in our department 6 months after initiating insulin therapy.
Results
97 patients were included with a mean age of 59 ± 9.5 years. More than half of patients were women (61%). The duration of diabetes was meanly 9.5 ± 6.2 years. The mean glycated hemoglobin (HbA1c) before starting insulin therapy was 10.8% ± 2.2. Six months after initiating insulin, the mean HbA1c was 9.2% ± 1.6 and the mean weight gain was 4.2 kg ± 4.9. The majority (89%) were taking metformin in association with insulin. Higher doses of insulin therapy were associated with a greater weight gain and a better glycemic control with a significant $P = 0.01$. Weight gain was significantly smaller when metformin was associated to initial insulin therapy ($P = 0.02$).
Conclusion
Insulin therapy is associated with both a better glycemic control and a greater weight gain. Use of metformin in combination with insulin is commonly recommended as a way to limit weight gain in patients with type 2 diabetes. For lasting weight control, lifestyle interventions need to continue throughout the course of treatment.

Hypertriglyceridemia and glycemic control among patients with type 2 diabetes

Manel Dridi, Yosra Htira, Achwek Mehrez, Zohra Haj Ali & Fayka Ben Memi
National Institute of Nutrition, C Departement, Tunisia

Introduction
Moderate hypertriglyceridemia is exceedingly common in diabetes, and there is growing evidence that it contributes to residual cardiovascular risk in statin-optimized patients. Added to lipid lowering drugs and lifestyle intervention, an optimal glycemic control is necessary. The aim of our study was to compare triglyceride levels in diabetic patients before and after initiating insulin therapy.
Methods
We conducted a retrospective study including patients with type 2 diabetes on insulin therapy for more than one year. We compared the triglyceride levels before and one year after initiating insulin therapy.
Results
Our study enrolled 97 patients. The mean age was 59 ± 9.5 years. Women represented 61% of the patients. The duration of diabetes was meanly 9.44 ± 6.31 years. The mean glycated hemoglobin was 10.7% ± 2.24. A total of 61% patients were receiving lipid-lowering medications. Hba1c was significantly correlated with high triglyceride levels (P = 0.032). The mean triglyceride level decreases on insulin therapy but not significantly (1.78 g/l ± 0.98 before switching to insulin therapy vs 1.26 g/l ± 0.46)
Conclusion
Elevated triglyceride levels were associated with inadequate glycemic control; thus, suppressing triglyceride levels may attain more optimal glycemic control in patients with type 2 diabetes mellitus.

Initiation of insulin therapy in obese patients with type 2 diabetes mellitus

Mehrez Achwak, Yosra Htira, Manel Dridi, Ghofran Hakiri, Zohra Hadj Ali & Faika Ben Mami
National Institute of Nutrition of Tunis, Tunisia

Introduction
Weight gain represents a considerable challenge in type 2 diabetes mellitus patients with insulin therapy and a frequent cause of delay in initiation of treatment with insulin. The aim of our study was to describe the features of diabetic obese patient when switching to insulin therapy.
Methods
It was a retrospective study which enrolled 61 patients with type 2 diabetes divided in two groups: patients with a normal Body Mass Index (BMI) < 25 kg/m^2 and obese patients with BMI > 30 kg/m^2. All patients were on oral **hypoglycemic medications** and were admitted in our department to switch to insulin therapy.
Results
In obese patients' group: the mean age was 55.5 ± 8.2 years, the duration of diabetes was meanly 8.2 ± 5.6 years, the mean initial weight was 84.3 kg ± 10.1 and the mean glycated hemoglobin was 10.4% ± 1.96. In the other group, the mean age was 60.6 ± 8.2 years, the duration of diabetes was meanly 10.6 ± 7.1 years, the mean initial weight was 60.8 kg ± 7.33 and the mean glycated haemoglobin was 11.6% ± 2.1. Hypertension and dyslipidemia were more frequent in the obese patients' group (74% and 71% respectively). These two comorbidities were found in half of patients with BMI < 25 kg/m^2. Polymedication were more frequent among obese patients (71% vs 36.7%). Obese patients were receiving lower dose of insulin than normal weighted patients (0.35 UI/kg ± 0.13 VS 0.43 UI/kg ± 0.16). Weight gain was smaller in obese patients compared to the other group (4.55 kg ± 8.7 vs 8.77 kg ± 12.06).
Conclusion
Earlier and lower doses of insulin therapy was indicated in obese patients while weight gain was less noticed in this population. Weigh control and lifestyle intervention are needed for optimal diabetes control especially for obese patients.

Initial daily insuline dose and diabetic retinopathy

Amal Mehrzi, Yosra Htira, Emna Bornaz, Zohra Ben Hadj Ali & Feyka Ben Mami
Tunisian Institute of Nutrition, The C Department of Diabetology and Nutrition, Tunisia

Introduction
Diabetic retinopathy is a serious complication of type 2 diabetes, which compromise the visual function and impair the quality of life of these patients. A rapid lowering of blood glucose especially when starting insulin therapy can worsen this retinopathy. We studied the variation of the initial daily insuline dose in the presence of diabetic retionopathy.
Methods
Our study is prospective randomized and comparative. We recruited patients with type 2 diabetes hospitalized for a switching to insulin in the C department of diabetology and nutrition at the national nutrition institute in Tunis, during 6 months, we compared the average of the initial daily insuline dose calculated on the day of discharge between the group with diabetic retionopathy and the group not affected using the Mann Whitney test.
Results
We included 50 patients with type 2 diabetes, 54% were men and 46% were women, with an average age of 59 years (± 10.7), the averge duration of diabetes was eight years (± 7).32% (95% CI 20–46) had diabetic retinopathy. The average of initial daily insuline dose was 0.42 IU/kg/d (95% CI 0.4–0.5) in the group not having diabetic retinopathy and it was 0.47 IU/kg/d (95% CI 0.4–0.6) in the affected group. No significant difference was found (P = 0.58).
Conclusion
This study did not show a variation in the initial daily insuline dose in the presence of diabetic retinopathy. Long-term ophthalmological follow-up of patients with retinopathy is necessary to judge the effect of a rapid lowernig of glucose serum level on this complication.

Impact of diabetes mellitus on baseline SpO2 levels and Chest CT severity score in patients affected with COVID-19

Aniket Inamdar
Samarpan Clinic, Internal Medicine, Omerga, India

Coronavirus disease 2019 (COVID 19) caused by severe acute respiratory syndrome corona virus 2 (SARS – CoV-2) which predominantly affects lungs and leads to COVID 19 pneumonia. India is second worst affected country in the world after U.S having more than 10 Million COVID 19 cases till date. Diabetes is frequently associated with severe COVID-19 infection and with a worse prognosis. This retrospective study aims to evaluate the impact of diabetes mellitus on baseline SpO2 levels on admission and Chest CT severity score in patients affected with COVID-19 infection.
Materials and methods
In this observational study 157 symptomatic COVID-19 patients were included at a dedicated COVID hospital in Rural India from July 22, 2020 to Oct 12, 2020. The COVID19 positivity was defined on the basis of RT PCR. Baseline SpO2, HRCT Chest scans, inflammatory markers such as CRP, Ferritin and D-Dimer were done at the time of admission. A semi-quantitative CT severity score was calculated based on the extent of lobar involvement (0:0%; 1: < 5%; 2: 5–25%; 3: 26–50%; 4: 51–75%; 5: > 75%; range 0–5; global score 0–25). Data were compared using Mann Whitney U test.
Results
In this study baseline SpO2 levels were 90.24 ± 4.61 (Mean ± S.D.) in patients with diabetes and 92.72 ± 4.09 (Mean ± S.D.) in patients without diabetes. Patients with diabetes had lower baseline SpO2 levels which were statistically significant (P: < 0.001). CT severity score in patients with diabetes was higher than patients without diabetes with t value of −1.833 (P: 0.069).
Conclusions
This study data suggests the potential role of simple and cost effective measurement like baseline SpO2 on room air for predicting the severity of lung involvement in SARS-CoV-2 patients with diabetes mellitus. This observational study shows COVID-19 patients with diabetes had significantly lower SpO2 levels. This study also shows that CT severity score was higher in diabetics compared to non-diabetics. COVID-19 infection with diabetes is more likely to cause more severe pneumonia with severe hypoxia. CRP and other inflammatory markers were also elevated in diabetics. This could be also due to people with diabetes have a dysregulated innate and adaptive immune response and their already having chronic low-grade inflammation which makes them more susceptible to more severe pulmonary disease. Further large scale studies are needed to validate the clinical implications of this study.

Is total body fat more strongly correlated with lipid profile than the body mass index in type 2 diabetes?

Chtioui Sara, Rafi Sanaa, El Mghari Ghizlane & El Ansari Nawal
[1]Mohammed VI University Hospital Center, Department of Endocrinology, Diabetology and Metabolic Diseases, Marrakech, Morocco

Background
In type 2 diabetes, abnormalities of lipid metabolism and tissue distribution are common and associated with an increased risk of cardiovascular disease. The aim of this work was to study the relationship between the impedancemetric parameters and the lipid profile in a population of type 2 diabetics followed in the Endocrinology Department MED VI of Marrakech.
Methodology
Body fat was assessed using a body composition analyzer. Serum triglyceride, total cholesterol and low and high density lipoprotein cholesterol levels (LDL-c and HDL-c) were determined by standard enzymatic procedures. Relationships between age, impedancemetric parameters with several metabolic elements including serum lipid levels and HBA1c were analyzed in both sexes separately.
Results
The correlation of the lipid profile was higher with body fat compared to the Body Mass Index(BMI):LDL-C $r = 0.32$ vs 0.26, HDL-C $r = -0.46$ vs -0.43, total cholesterol $r = 0.15$ vs $r = 0.08$.
Conclusion
To sum up, in light of our study, compared to BMI, body fat measured by impedancemetry more accurately reflects the lipid profile in type 2 diabetics.

Ketosis-prone diabetes presenting with an atypical phenotype (A + /β +)

Damla Tufekci, Yasemin Emur Gunay, Ahmet Suat Demır, Muhammet Cuneyt Bilginer, Hulya Coskun, Irfan Nuhoglu, Ozge Ucuncu & Mustafa Kocak
Karadeniz Technical University Faculty of Medicine, Endocrinology and Metabolism, Trabzon, Turkey

Introduction
In clinical practice, differentiating between the types of diabetes is not always possible. In recent years, there has been an increase in the cases of Type 2 diabetes triggered by diabetic ketoacidosis in young-adult age individuals, and this condition is known as ketosis-prone diabetes (KPD). In this report, we present a case of autoantibody-positive KPD who had an adequate pancreatic reserve and an atypical phenotype due to having a normal body weight, in whom the presence of ketosis could not be confirmed by laboratory tests.
Case presentation
A 33-year-old female patient presented to an Internal Diseases clinic with complaints of frequent urination, increased water consumption, and weight loss. In that clinic, the patient was diagnosed with diabetes mellitus (DM) due to increased blood glucose (413 mg/dl) and HbA1c (9.5%) levels, and the patient was initiated on an intensive insulin therapy although no blood gas or urine test was performed. After one month, the patient presented to our Endocrinology clinic. Her body height was 152 cm, weight was 56 kg, and body mass index was 24 kg/m^2. Her sister and niece had been previously diagnosed with Type 1 DM. The C-peptide level, which was measured due to the lack of insulin resistance findings, uncontrolled weight loss, and the young age of the patient, was sufficient (6.02 µg/l). Moreover, the islet cell antibody and the anti-glutamic acid decarboxylase antibody, which were assessed twice, were positive with a high titer (> 250.00 IU/ml). Basal insulin and metformin treatment was initiated, considering that the patient might need insulin due to autoantibody positivity. Throughout the follow-up, no decrease has been detected in her C-peptide level. Additionally, the patient is still being followed up, with her blood sugar regulated and her HbA1c level being at the target range.
Conclusion
Ketosis-prone diabetes (KPD) is an atypical form of diabetes whose frequency has increased in recent years. There are four variants of KPD defined in the literature. In one of these, the beta-cell reserve is preserved but the islet cell antibody is positive. In such patients, the progressive beta-cell loss may develop, which may require lifelong insulin therapy. More over autoantibody positivity is a strong determinant of subsequent insulin need, and in such cases, patients should be re-evaluated with clinical and laboratory findings and treatment revisions should be performed as needed.
Key words
Ketosis-prone diabetes, insulin autoantibodies

'Not everything is as it seems' – a case report of Ketosis-Prone diabetes

Guilherme V. de Assunção, Liliana Fonseca, Vania Benido Silva, Maria Teresa Pereira, Joana Vilaverde, Jorge Dores & Maria Helena Cardoso
Centro Hospitalar e Universitário do Porto, Endocrinology, Diabetes and Metabolism, Porto, Portugal

Introduction
Ketosis-Prone Diabetes (KPD) is a heterogeneous condition that shares clinical characteristics of type 1 and type 2 diabetes. It is usually a challenging diagnosis because patients are prone to develop diabetic ketoacidosis (DKA) without having the classic clinical phenotype of autoimmune type 1 diabetes.
Case report
A Caucasian 26-years-old female with known history of renal transplant, morbid obesity (BMI 41.5 kg/m^2), hypertension and dyslipidemia was diagnosed with pregestational diabetes during her first pregnancy. During the actual pregnancy, insulin was required to achieve controlled blood glucose levels and maintenance of this therapy was necessary after delivery. Some months after, she was brought to the emergency room due to polydipsia, polyuria, blurred vision, mild asthenia and paresthesias of the upper extremities. The arterial pH was 6.99, glucose 657 mg/dl and bicarbonate and aniogap were unmeasurable. Urinalysis was positive for ketonuria (high unmeasurable value). Laboratory tests revealed no evidence of infection, cardiac ischemia, renal or liver dysfunction. The patient was admitted with severe DKA and promptly received appropriate treatment. Low C-peptide levels (0.19 ng/ml [RR:1.1–4.4 ng/ml]) and HbA1c 12.3% were document. Beta-cell specific autoantibodies were all negative. She was discharged with a basal-bolus insulin regimen. One month after her C-peptide level was 1.76 ng/ml and HbA1c was 11.8%, her insulin needs were much lower and at that time she initiated GLP-1 receptor agonist.
Discussion
This case report presents us a young obese woman with dysmetabolic traits that clearly suggests a Type 2 DM. The therapeutic non-compliance determined this severe hyperglycemic presentation that usually is a typical expression of insulinopenia and Type 1 diabetes. The autoimmunity against Ɓcell was negative and after glucotoxicity the presence of pancreatic insulin reserve was proven. The presented case of KPD should alert clinicians to this entity. Although the presentation is similar to Type 1 diabetes the evolution appears to resemble Type 2 DM. This has impact on misclassification and mistreament of patients.

Coefficient of variation

Soichi Takeishi & Tatsuo Inoue
Inuyama Chuo General Hospital, Diabetes, Inuyama-City, Japan

We studied how to achieve 'target coefficient of variation (CV)' ['TCV']. In a cross-sectional study, we analyzed 24-h glucose levels measured using CGM (iPro2) in 150 patients with type 2 diabetes. We analyzed 51 time in range (TIR) (reference ranges [RRs]: mean glucose level (M) ± M ÷ 100 × 10, M ± M ÷ 100 × 11…M ± M ÷ 100 × 60 mg/dl [we referred to the underlined numbers as 'percentages which compose margins' (P)]). We analyzed 'optimal cutoff values' (C) of TIR to predict CV below target, corresponding to 51 TIR × 26 TCV (15, 16…40%), using ROC analysis. Of the 51 RRs, the RR for which TIR had the largest AUC for each TCV was referred to as optimal RR (ORR). Table shows the P of ORR (PO) and C of TIR for ORR (CTO) for each TCV. TCV correlated to PO ($r = 0.82$ $P < 0.001$, PO = 1.09 × TCV + 6.6) ($n = 26$). In 26 TCV, the CTO was 80.8 ± 10.7, the sensitivity of CTO was 97.1 ± 2.4, and the specificity of CTO was 97.2 ± 2.5. If ORR is used as an alarm threshold in a personal CGM and TIR for ORR > 80% is achieved, CV below the target may be achieved.

Infections revealing type 2 diabetes

Abdessamad Malki, Mohamed Aymane Loukili, Anouar Jamal, Siham Rouf & Hanane Latrech
Mohamed VI University Hospital Center, Oujda, Department of Endocrinology and Diabetology, Oujda, Morocco

Introduction
Type 2 diabetes is a field of immunosuppression predisposes to infections in all its locations. The mode of revelation by degenerative or infectious complications is frequent. The aim of our work is to study the epidemiological, clinical and therapeutic aspects of infections that reveal type 2 diabetes.
Material and methods
This is a retrospective study, including 35 type 2 diabetic patients, hospitalized in an Endocrinology–Diabetology department over a 6-year time period, and in whom an infectious complication was the factor revealing type 2 diabetes.
Results
The mean age of our patients was 53.7 ± 14.9 years, with a female predominance at 68.6%. The mean HbA1c at the diagnosis of diabetes was 12.5 ± 3.1%, decompensation revealed 57.14% of patients, and 62.9% of patients reported a cardinal syndrome. The infections were: skin infections in 47% (intertrigo, fungal infections in skin folds, onychomycosis, erysipelas, diabetic foot), urinary tract infections in 40% (cystitis, acute pyelonephritis), pleuropulmonary infections in 25.71% and vaginal infection in only 1 case. All of the patients received large specter antibiotic therapy, adapted to each case after the results of the antibiogram. 34.2% of patients treated by insulin alone, and 5.7% by oral antidiabetics, 34.2% were treated on combined therapy insulin + oral antidiabetic medication. Macroangiopathic complications were present in 17.14% of cases, including coronaropathy (8.57%), ischemic stroke (2.85%), peripheral arteriopathy (2.85%).
Discussion–conclusion
Infections revealing type 2 diabetes are frequent, a systematic screening for diabetes in patients with severe or recurrent infections is required.

Homozygous LMNA p.R582H in dunnigan-type familial partial lipodystrophy

Mouna Mezoued[1], Bessaid Khadidja[1], Azzouz malha[1] & lascols olivier[2]
[1]Algeria, Endocrinology, Algeria; [2]Pôle de Biologie Médicale et Pathologie, France

Dunnigan-type familial partial lipodystrophy (FPLD2) is a rare genetic disease associated with loss of subcutaneous adipose tissue and metabolic involvement such as diabetes, hyperlipidemia, and hepatosteatosis. We aimed to present a rare FPLD2 caused by an atypical Lamin A/C gene (LMNA) mutation. We report a case of an Algerian 31 year-old female with a lamin A specific pathogenic variant in exon 11, denoted LMNA (c.5454G > A; p.R582H), present in the homozygous state. The patient consulted for a male morphotype, with a personal and a family history of diabetes including a sister with a similar pattern. First she noticed well-defined muscles in her arms and legs around puberty and gradual disappearance of subcutaneous fat. Although the patient was unable to define a clear period of time when subcutaneous fat disappeared. At 21 years, she was diagnosed diabetes militus currently on 1.6 IU/kg of insulin without achieving glycemic target. Physical examination revealed generalized fat loss with lunar fascia, with massive muscles of the arms and thighs, but also visibility of veins and absence of subcutaneous tissue, with curled fingers. Her body mass index (BMI) was 24 kg/m^2, her gonadal axis does not find any cycle disorders nor hirsutism. Her biological assessment find several desorders such as HbA1c above 12% and elevated triglyceride at 3000 mg/dl. Hepatic, Cardiac and neurological regular assessments were normal. In conclusion, lipodystrophy is a very heterogeneous disease with a current classification based on clinical and morphometric features, LMNA undergoes alternative splicing to produce two nuclear laminar proteins – lamin A and C. Multiple missense mutations associated with FPLD2, most of which are located in exon 8 at the codon position 482, have been reported, The mutation c.5454G > A; p.R582H in homozygous state is rarely found.

Metabolic disorders at a young age

Irina Savasteeva
Gu 'Respublikanskiy Nauchno-Prakticheskiy Tsentr Radiatsionnoy Meditsiny I Ekologii Cheloveka', Gomel, Belarus

Risk factors were assessed, including lipid spectrum studies, among young patients. The survey included 225 men and 327 women. All examined patients had no clinical signs of diseases of the cardiovascular system and type 2 diabetes mellitus. The median age was 33.35 (31.15; 35.52) years. Obesity was 1.6 times more common among young men than among women ($\chi 2 = 4.67$; P = 0.03). The relative risk of developing (RR) obesity in (men/women) was 1.79 (1.23 ÷ 2.60); $P = 0.0007$. Type 2 diabetes mellitus was not diagnosed in those examined. Impaired glucose tolerance (IGT) have been identified among women and men. IGT in men occurred 2 times more often than in women ($\chi 2 = 4.94$; $P = 0.03$), RR (men/women) was 2.12 (1.14 ÷ 3.92); $P = 0.01$. The incidence of type IV dyslipidemia in men was 3.12 times higher than in women ($\chi 2 = 18.20$; $P = 0.00001$), RR in men (in relation to women) was 3.64 (2.04 ÷ 6.64); $P = 0.0003$. This study demonstrates the high risk of metabolic disorders in men already at a young age.

Vitamin D as a biomarker of long of hospital stay in geriatric department – preliminary study

Justyna Nowak[1], Marzena Jabczyk[2], Bartosz Hudzik[1,3] & Barbara Zubelewicz-Szkodzińska[2]
[1]Medical University of Silesia, Department of Cardiovascular Disease Prevention; Faculty of Health Sciences in Bytom, Bytom, Poland; [2]Medical University of Silesia, Department of Nutrition Related Prevention; Faculty of Health Sciences in Bytom; [3]Medical University of Silesia, 3rd Department of Cardiology, Faculty om Medical Science in Zabrze, Silesian Center for Heart Diseases

Introduction
Inadequate low serum of 25(OH) vitamin D leads to skeletal effect (rickets, osteoporosis, osteomalacia) and furthermore exhibits nonskeletal effects – increase the risk of cardiovascular diseases, type 2 diabetes, mental illness and many others. Vitamin D deficiency is associated with a severe morbidity burden and low functional performance among elderly patients. A long length-of-stay (LOS) among elderly patients is related to revere morbidity burden and low functional performance too.
Aim
The aim of the study was to determine the association between concentration of 25(OH)D and duration of hospitalization at Geriatric Department.
Material and methods
To the study was enrolled 152 patients above 60 years, hospitalized in Geriatric Department in hospital in Piekary Slaskie (Poland). The study was conducted between 2013 and 2015. Each patient provided consent before included to the study. Blood samples were collected after overnight fasting. The serum level of 25-hydroxyvitamin D (ng/ml) was measured by enzyme-linked immunosorbent assay (ELISA).
Results
Mean age of the study group was 76.24 ± 7.47 years. The mean 25(OH) D level among study group was 14.61 ± 5.96 ng/ml. The mean time of hospitalization was 10.25 ± 3.95 days (minimum was 2 days and maximum was 22 days). We observed correlation between serum level of 25-hydroxyvitamin D and long of hospitalization geriatric patients ($r = -0.25$; $P = 0.0085$). We also observed that mean time of hospitalization among group patients with deficiency of vitamin D (defined as 25OH D below 20.0 ng/ml) was a little longer in comparison to group of patients with suboptimal vitamin D (defined as 25 OH D between 20.0–30.0 ng/

ml), but this different was no statistically significant (10.46 ± 4.29 days vs 9.55 ± 2.70 days; $P = 0.6463$). Also we divided patients into three group with serum level of 25-hydroxyvitamin D of below10.0 ng/ml (first group), 10.0–20.0 ng/ml (second group) and 20.0–30.0 ng/ml (third group). The mean time of hospitalization was the highest among the first group of patients (12.15 days) and lower into second and third group (respectively 9.77 and 9.55 days), but this was no statistically different ($P = 0.0981$).
Conclusion
25(OH)D should be considered as a potential biomarker of long length-of-stay among elderly patients hospitalized in Geriatric Department. More researches are needed to confirm this thesis.

Retropharyngeal abscesses in diabetic adults

Monia Ghammem, Lobna Chouchane, Mouna Bellakhdher, Heyfa Belhadj Miled, Wassim Kermani & Mohamed Abdelkefi
ENT and Neck Surgery Department Farhat Hached Hospital, Susa, Tunisia

Aim
identify the clinical presentation of retropharyngeal abscesses in adults and the therapeutic management modalities.
Materials and methods
We illustrate two cases of retropharyngeal abscess in two elderly subjects collected in the ENT department of the Farhat Hached hospital in Sousse.
Observations
1-/It is about a 70-year-old man, diabetic (DNID) who consulted us for intense cervicalgia, torticollis, and odynophagia. The physical examination found an apyretic and eupneic patient. Oropharynx examination: Halitosis, bulging of the posterior wall with thick pus issue. In profile cervical radiography: thickening of the retropharyngeal space with the presence of an air opacity in relation to the cervical vertebral bodies (C2–C4). The patient had drainage under general anesthesia endoorally with triple antibiotic therapy: Claforan – Fosfomycin- Flagyl. The bacteriological samples did not isolate any germs. A control MRI at J10 of treatment showed: extensive thickening of the soft parts prevertebral retropharyngeal affected by the adjacency of vertebral bodies from C3 to C5 without signs of discitis. The development was favorable. 2-/it is about a patient, 57 years old, diabetic (DNID) who consulted us for mixed high dysphagia associated with cervicalgia and a limitation of the mobility of the cervical spine and the left upper limb. The clinical examination found: torticollis, monoplegia of the left upper limb, tight trismus, a bulge in the posterior wall of the pharynx. Cervical MRI: an important pre-vertebral abscess collection spanning 11 cm responsible for a significant mass effect on the aerodigestive chain and spondylodiscitis advanced to C3–C4 stage. The patient had an endobuccal floating with a safety tracheotomy in front of significant glottic edema and has been given triple antibiotic therapy. The evolution was favorable with regression of trismus, resumption of oral feeding, and regression of the Left upper limb deficit. Decanulation was made at J10.
Conclusion
The pharyngeal abscess must be suspected before any neck stiffness, trismus or dysphagia, associated or not with febrile syndrome especially in immunocompromised persons such as diabetic.

The traditionnel bath: it's time to put an end to this dangerous ritual for diabetics!

Sara Ijdda, Ekondzoula Joel Rudy, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
University Hospital Center Mohamed VI, Departement of Endocrinology, Diabetes, Metabolic Disease and Nutrition, Marrakech

Introduction
In Morocco, the Moorish bath is an important social ritual. All categories of society frequent it very regularly. The traditionnel bath can lead in the diabetic, by the means of acute decompensations, serious falls and burns, with heavy functional, social and psychological consequences. Through this observation, we report the risks associated with the Moorish bath, and we underline the value of educating diabetic patients and making them aware of the dangers of frequenting Moorish baths.
Case report
A 78-year-old patient, known to be diabetic for 20 years on oral antidiabetics, admitted to the intensive care unit for burns of the 2 lower limbs following a fall in a heated Moorish bath, in a context of consciousness disorders without idea on capillary glycemia, this incident had taken place during the afternoon without notion of taking the meal of the lunch. On clinical examination, the patient was conscious, hemodynamically and respiratory stable, apyretic, with a glycemic cycle of blood glucose levels around 3 g/l without ketosis. The skin surface area burned to the second degree was estimated at 18%. The patient received rehydration and appropriate daily dressings. He was put on a hyperglycemia correction regimen adapted to his cardiac and renal functions, then on a basic regimen of intensified insulin therapy. The course was marked by the installation of functional renal failure with necrosis of both feet. The patient died with suspicion of pulmonary embolism.
Discussion
Diabetic patients are usually complicated patients, due to the strong presence of systemic micro and macro vascular damage affecting multiple organs. Also, diabetes is well known to be associated with decreased healing ability. The Moorish bath can cause serious burns in these patients by several mechanisms: diabetic retinopathy, a source of reduced visual acuity that can be responsible for falls, neuropathy with skin insensitivity, as well as the significant effort deployed in the activities of the Moorish bath which could induce hypoglycemia.
Conclusion
In our society, the traditionnel bath is a synonym for hygiene and cleanliness, but it can be responsible for serious accidents in diabetic patients. Our observation elucidates the risks of the Moorish bath in these particularly vulnerable patients, hence the importance of prevention which involves educating diabetic patients or even banning the use of Moorish baths.

Gluten free diet in real life

Imen Akkari, Harbi Raida, Mrabet Soumaya & Ben Jazia Elhem
Hospital Farhat Hached, Gastroenterology, Tunisia

Introduction
The only currently available treatment of coeliac disease is a gluten-free diet (GFD). It improves outcomes, and reduces health-care costs. However, adhering to a gluten-free diet is difficult for many people. The aim of this study is to evaluate the diet adherence in real life and his impact on disease evolution.
Patients and methods
This is a descriptive transversal study carried out over a period of 10 years. All patients with celiac disease were included.
Results
Forty one patients were included; the average age of patients was 36 years (17–75 years) with a sex ratio (M/F) equal to 0.46. The follow-up was assessed in 35 patients; the monitoring rhythm was 3 to 6 months according to the clinical state of the patient at the last visit. Diet adherence was limited to a few months after the introduction of the gluten-free diet in 37.1% of patients. Seventeen patients adhered to the diet during the follow-up period. A Non–observance to GFD was described in 5 patients. The main cause was the cost of it. Clinical improvement was noted in 20 patients after a mean delay of 3 months. Some cases of relapses (28.6%) were noted due to a poor gluten-free diet adherence. A normalization of celiac serology was noted in 44% of cases after an average delay of 34 months. Histologically, subtotal or total atrophy persisted in 10 patients.
Conclusion
Heightened awareness by patients can help maximize successful treatment, Routine follow-up is necessary to reinforce the need for a GFD, provide social and emotional support. Finally the role of associations should be encouraged to resolve financial problem.

COVID-19 in diabetic and non-diabetic patients hospitalized to private medical center: a retrospective analysis

Olena Antonyuk, Sofiia Shatylo & Inna Kuchynska
Oberih, Kyiv, Ukraine

Keywords diabetes, COVID-19, medical care
COVID-19 belongs to the global problem and health systems are faced with severe challenges. Diabetic patients are in the group of risk, especially among elderly people. The aging of the population leads to the comorbidity of diabetic patients with a high risk of death in the case of severe COVID-19 complications. Never doubt it could be fatal for diabetic patients more often than among non-diabetic. Patients with chronic diseases try to avoid visiting medical centers for check-ups or regular tests or consultations concerning social distancing strategies. As a result, a lot of them are hospitalized to COVID departments too late than advisable with severe respiratory disorders. Using glucocorticoids in critically ill patients can lead to decompensation of diabetes which could be potentially life-threatening. We analyzed a group of 393 patients treated in the medical center in Kyiv from September till December of 2020 in 3 infectious departments. Information was received from the database of the clinic, and 100% of patients signed an agreement on using their personal data. No personal data (including name and others) was published. The average duration of in-patient treatment was for 8.78 days. 19 patients died (4.83%). In the group of critically ill diabetes was significantly more often than in the control group. The average duration of treatment was higher in the 1st department due to intensive care wards where were treated critically ill patients. The reason of death was SARS, sepsis, respiratory and heart insufficiency. All of the patients had COVID-19 which was proved laboratory and/or instrumentally (in a small number of cases CT was not performed due to severity of the condition with intensive oxygen supply with higher risks of transportation in the clinic. For such patients, we used ultrasound of lungs for control in dynamics. Some patients reported rapid progression of respiratory insufficiency in the absence of low-grade fever and they tried not to visit a doctor. As a result, the start of intensive care was termed latter. Patients were treated by multiple specialty teams of health professionals including infectionists, internists, anesthesiologists, endocrinologists, specialists in rehabilitation, and sometimes neurologists, cardiologists, nephrologists. It was important to react rapidly in the case of acute kidney injury (including urgent dialysis), acute coronary syndrome (with further stenting of coronary arteries in specialized cardiosurgical centers).
Conclusion
COVID-19 challenges are extremely important for analysis as we are focusing on the improvement of health care.

Macrovascular complications in adult-onset type 1 diabetes

Hadj Kacem Faten[1], Khouloud Boujelben[1], Allymamod Bibi Twaheerah[1], Charfeddine Salma[2], Charfi Nadia[1], Mnif Fatma[1], Mnif Mouna[1], Rekik Nabila[1], Kamoun Samir[2] & Abid Mohamed[1]
[1]Hedi Chaker Hospital, Department of Endocrinology, Diabetology, Sfax, Tunisia; [2]Hedi Chaker Hospital, Department of Cardiology, Sfax, Tunisia

Introduction
Type 1 Diabetes (T1D) diagnosed during adulthood is a form of diabetes which is underdiagnosed and underreported. Lower incidence of cardio metabolic risk factors such as atherogenic dyslipidemia, high blood pressure and obesity have been reported in T1D patients compared to type 2 diabetes. In this study, we aimed to determine the prevalence of and predictive factors for macrovascular complications during T1D diagnosed in adulthood.
Patients and methods
Patients over 20 years diagnosed with diabetes were included. Data from 166 patients were analyzed. Levels of antibodies to glutamic acid decarboxylase (anti-GAD), protein tyrosine phosphate (IA2) and islet cell (ICA) were quantified in all patients. T1D was diagnosed in patients testing positive for at least one of autoantibodies.
Results
The mean age was 31.81 years (range: 20–64 years). In our study, 95 were male (57.2%), and 71 (42.8%) were female. The median disease duration was 7.34 ± 6.73 years. The mean of basal metabolic index (BMI) was 21.05 kg/m^2. Underweight was found in 23.5% of cases and 63.9% of patients had normal BMI. Overweight and obesity were observed in 9% and 3.6% of patients, respectively. The incidence for the composite macrovascular outcome was 7.8%. Hypertension occurred in 6% of patients after a mean diabetes duration of 16.5 ± 7.23 years (range:10–35 years). About half of those patients were grade 1 hypertensive, while 40% and 10% were grade 2 and 3 hypertensive, respectively. Coronary artery disease was observed in 2.4% of patients after a mean diabetes duration of 13.5 ± 13.77 years (range: 3–32 years). Only 3 patients (1.8%) developed peripheral arterial occlusive disease after a mean duration of 21.3 ± 15.5 years (range:10–39 years). A higher incidence of macrovascular complications among T1D adults was significantly observed in patients with longer disease duration ($P < 0.5$). Moreover, macrovascular complications are more prevalent among adults who were hypertensive and smokers ($P < 0.05$). No significant correlation was identified between obesity and macrovascular complications.
Conclusion
This research provides insights into the association between T1D diagnosed during adulthood and macrvascular complications and highlights the importance of a screening approach in order to enhance therapeutic outcome.

The activity of inflammatory markers in patients with nonalcoholic fatty liver disease and type 2 diabetes

Zvenigorodskaya Larissa, Petrakov Alexander, Nilova Tamara, Galina Varvanina & Shinkin Mikhail
Moscow Clinical Research and Practice Center named after Loginov, Moscow Department of Health, Moscow, Russian Federation

Purpose of research
To determine the level of insulin content, the content of nitric oxide metabolites, Malondialdehyde, the activity of lipoprotein-associated phospholipase A2 (FLA2), in the blood serum of patients with NFLD with type II D and impaired glucose tolerance.
Material and methods
The study included 74 patients with non-alcoholic fatty liver disease. 30 of them have diabetes of the second type, and 34 patients have impaired glucose tolerance. The average age of patients is 55.6 ± 2.2 years. Body mass index is 34.85 ± 1.79 kg/m^2. Phospholipase A2 was determined by chemiluminescent immunological analysis on the device 'Siemens'. Fatty acids were determined by enzyme method using test-systems (England). Metabolites of nitric oxide were determined by the method Metel'skaia V. A., Malonicdialdehyde (MDA) was determined by the method of Andreeva.
Research result
Insulin levels were determined in all 74 patients. Hyperinsulinemia was observed in 30 patients with low glucose tolerance. 34.65 ± 4.16 mkme/ml. Readings in the control group total 8.3 ± 1 mkme/ml. In patients with diabetes, the insulin content was 6.28 ± 0. 4 ($P = 0.001$), which caused the expression of phospholipase A2 3 times in diabetes and twice with low glucose tolerance. In non-alcoholic fatty liver disease activity of nitric oxide and its content increased. The level of metabolites increased in parallel with the activity of alanine Aminotransferase. The content of malonic aldehyde in patients with diabetes increased and made up 24.12 + - of 1.64 mmol/l. patients with low tolerance to glucose the content of MDA made up 16.91 ± 3.87. Monitoring indicators equal to 9.94 ± 1.62 µmol/l, $P = 0.001$. A negative correlation between insulin and Malon aldehyde was revealed. ($r = -0.31$). The interrelation of the lipid peroxidation and leading to phospholipase mechanism of damage to the lipid membranes of hepatocytes FLA2 and MDA $r = -0.53$; $P = 0.001$; between NO and FLA2 = 0.625. $P = 0.001$.
Summary
High activity of inflammation markers in patients with NAND with type 2 diabetes is a diagnostic and prognostic criterion for the activity of the inflammatory process in the liver with a high risk of complications. Hyperglycemia induces the production of free radicals, reduces the activity of nitric oxide synthase and disrupts the sensitivity of insulin receptors.

Nutritional medical practice for assessment and therapeutic intervention patients with colorectal cancer

Jose Alvaro Romero Porcel, Eyvee Arturo Cuellar Lloclla & Estefania Jimenez Licera
Hospital De Valme, Seville, Spain

Introduction
Candidate patients for colorectal cancer surgery may present malnutrition due to the tumor pathology itself. This must be corrected preoperatively in order to achieve good surgical results.
Methods and objectives
Objectives
Determine the nutritional status in our population and to know the type of nutritional support necessary.

Methods
Descriptive study including preoperative patients for scheduled surgery for colorectal carcinoma and excluding those who require neoadjuvant treatment or urgent surgery, during a period of 12 months (May 2019 to April 2020). In the month prior to the intervention, they are evaluated in a nutrition consultation, indicating the nutritional support, according to their condition.
Results
123 patients, aged 68.8 ± 10.19 years old, were studied, 59.3% were men. The Global Subjective Assessment was 51.2% type A (well nourished), 39% type B (moderate malnutrition or risk of malnutrition) and 8.9% type C (severe malnutrition). The anthropometric variables analyzed were weight in men (presented at the time of consultation) of 82.40 kg ± 17.14 and BMI of 28.92 ± 5.31 kg/m^2, in women weight of 69.52 ± 14.71 and BMI of 28.90 ± 5.32 kg/m^2. Abdominal circumference of 105.8 ± 12.1 cm. Regarding the analytical values, they presented Albumin of 3.66 ± 6.13 g/dl and Transferrin of 270.4 ± 61.7 mg/dl. The results indicated a high prevalence of abdominal obesity and mild protein malnutrition. 4.4% of the patients received complete home enteral nutrition, generally due to intestinal subclusive symptoms (from the consultation assessment until the day of the intervention). In 91.1%, oral nutritional supplements were indicated as presurgical preparation during the 5 days prior to surgery.
Conclusion
The PCCR colorectal cancer patients, preoperatively after scheduled surgery, presented a low prevalence of severe malnutrition, which required total enteral nutrition until the intervention. The prevalence of abdominal obesity was high. Studies are needed to assess the surgical impact of the improvement in nutritional status in these patients.

Does the initial daily insuline dose vary with the duration of diabetes ?

Amal Mehrzi, Yosra Htira, Emna Bornaz, Zohra Ben Hadj Ali & Feyka Ben Mami
tunisian Institute of Nutrition, The C Department of Diabetology and Nutrition, Tunisia

Introduction
Uncontrolled patients with oral antidiabetics may require injectable treatment including insulin. We studied the variation of the initial daily insuline dose with the duration of diabetes.
Methods
We conducted a prospective randomized study. We recruited patients with type 2 diabetes hospitalized for a switching to insulin in the C department of diabetology and nutrition at the National Nutrition Institute in Tunis, during 6 months. We correlate the initial daily insuline dose and the duration of diabetes using the Spearman test.
Results
We included 50 patients with type 2 diabetes, 54% were men and 46% were women, with an average age of 59 years (± 11), the averge duration of diabetes was 8 years (± 7). We found no statistically significant correlation between the initial daily insuline dose and the duration of diabetes ($r = 0.006$, $P = 0.966$).
Conclusion
Our results showed that the initial daily insuline dose prescribed for type 2 diabetes is independent of the duration of diabetes. This proves that the recommendations concerning the doses prescribed when switching to insulin can be used for all insulin-dependent patients with type 2 diabetes, regardless of the duration of diabetes.

Relationship between phase angle and urinary tract infection in hospitalized cancer patients

Bianca Tabita Muresan Oltean, Ana Jiménez Portilla, Jessica Ruiz Berjaga, Ana Artero Fullana, Mario López Merseguer, Beatriz Voltas Arribas, Martín Núñez Abad, Juan Manuel Mascarós Martínez, Carlos Camps Herrero & Carlos Sánchez Juan
Consorci Hospital General Universitari de València, València, Spain

Background
Bioelectrical impedance analysis (BIA) has been widely used in the evaluation of body composition. Phase angle (PhA) is obtained from the direct measurements of resistive (Rz) and reactive (Xc). Pha and can be interpreted as an indicator of fluid distribution, electric resistance and cellular membrane capacitance of the human body, and is associated with nutritional status. Its screening, and an early intervention in patients with a low PhA, may help to prevent malnutrition. However, there are no studies on its role in urinary tract infection. We aim to establish the association between PhA and urinary infections in hospitalized cancer patients.
Methods
Prospective observational study carried out in hospitalized cancer patients at the General University Hospital of Valencia, from November 2019 to March 2020. BIA and other anthropometric parameters were evaluated within the first 48 h after admission. PhA was measured using a bioelectrical impedance (Akern®). Inpatient were followed-up through daily medical oncologist reports, and urinary infections were registered during hospitalization.
Results
A total of 100 cancer patients were evaluated. The mean age was 66.1 years and 66 were males. Most patients (74%) had an advanced stage disease, mostly lung (29%) and gastrointestinal tumors (32%). Mean weight and BMI was 68 kg and 24.73 kg/m^2 respectively. During admission, 10% developed a urinary infection. PhA was significantly lower in patients who developed an urinary infection (OR 0.531; CI 95%: 0.293 – 0.022; $P = 0.022$).
Conclusions
A low PhA is associated with a higher risk of urinary infections in hospitalized cancer patients. An adequate nutritional evaluation is essential to detect patients with a low PhA. A timely implementation of nutritional support during hospitalization could avoid urinary infection risk.

Hyperprogression of Merkel cell carcinoma during immunotherapy

Ivana Bozic-Antic[1], Marko Jovanovic[2], Ana Petkovic[3], Marjan Micev[4], Bojana Popovic[1], Sanja Ognjanovic[1], Isailovic Tatjana[1], Dusan Ilic[1], Tamara Bogavac[1], Milica Opalic[1], Valentina Elezovic-Kovacevic[1] & Djuro Macut[1]
[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, University Clinical Center of Serbia, Department for Neuroendocrine Tumors and Hereditary Cancer Syndromes, Belgrade, Serbia; [2]Institute of Oncology and Radiology of Serbia, Belgrade, Serbia, Belgrade, Serbia; [3]Department for Radiology and Magnetic Resonance Imaging, University Clinical Centre of Serbia, Belgrade, Serbia, Belgrade, Serbia; [4]Department for Pathohistology, University Clinical Centre of Serbia, Belgrade, Serbia, Belgrade, Serbia

Introduction
Merkel cell carcinoma-MCC) is a rare, aggressive, neuroendocrine skin tumor with a poor prognosis. Chemotherapy (CT) and/or local/locoregional radiotherapy (LRRT) are first-line MCC therapies, but disseminated/locally advanced MCCs often become resistant to this treatment. The use of programmed cell death receptor1/programmed cell death ligand 1 (PD-1/PD-L1) monoclonal antibodies is a new type of therapy for MCC. While PD-1 monoclonal antibody (pembrolizumab) is registered for the treatment of various types of aggressive tumors, PD-L1 monoclonal antibody (avelumab) is registered exclusively for the treatment of locally advanced/metastatic MCC. Significant efficacy of these drugs has been shown by prolonged stabilization or partial regression (PR) of the disease in 30–60% of patients with MCC.
The aim
A case report of a patient with locally advanced MCC who developed tumor hyperprogression during immunotherapy.
Case presentation
A 47-year-old patient was diagnosed with MCC (Ki67 index 97%) in the subcutaneous tissue of the left pectoral and axillary region, size 9×10×10 cm. The tumor was inoperable, and the diagnosis was made by biopsy. Treatment started with 4 cycles of HT (etoposide–platinum), followed by LRRT and 2 more cycles of HT, and the effect of therapy was PR (tumor reduction by 90%). One month later, the disease progressed – several confluent tumors with a total size of 5×2×2 cm were diagnosed outside the field of LRRT (left hemitorax and hemiabdominal region). Pembrolizumab was administered in 3 doses, after which the disease progressed: multiple confluent tumors in the left hemitorax and hemiabdomen, size 11×7×9 cm. Retreatment with the same HT was performed in 3 cycles, which was complicated by significant myelotoxicity (pancytopenia grade III–IV) and sepsis. Because

of this adverse event, further application of HT is abandoned, although PR of tumors has occurred (three tumors, size: 4×3 cm, 4×4 cm and 2×1.5 cm). After 3 doses of avelumab, a rapid tumor growth was registered (one tumor size 9×7 cm-increase by 120% in comparison to pre-avelumab size and second tumor size 12×8 cm-increase by 90%). An emergency LRRT was performed in order to stop the further tumor growth, which threatened to exulcerate. Three months later, the patient died.
Conclusion
Unlike pseudoprogression, which occurs due to immune cell infiltration of the tumor and is followed with tumor shrinkage (relatively common during immunotherapy), tumor hyperprogression during immunotherapy is a rare phenomenon and has not been described in patients with MCC.

Advanced metastatic disease in a low-grade pulmonary neuroendocrine tumor: a case report with partial response to targeted therapy

Calin Cristiana[1], Roxana Dusceac[1,2], Burcea Iulia-Florentina[1,2] & Poiana Catalina[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Pituitary and Neuroendocrine Pathology, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucureşti, Romania

Background
It has been well recognized that grade heterogenity exists within well-differentiated neuroendocrine tumors (WD-NETs). Targeted therapy plays an important role in metastatic disease control.
Case presentation
We present the case of a 58-year-old male patient who was diagnosed with a pulmonary tumor on computer tomography (CT) and underwent a posterobasal left lobectomy. On immunohistochemical staining, synaptophysin and chromogranin A were positive, and the Ki-67 index was 10%, thus the tumor was graded as G2. Treatment with interferon alfa was administered for 7 months, followed by somatostatin analogues (Octreotide). Tumor markers increased suddenly withing a year from diagnosis. Bone scintigraphy identified multiple hypermetabolic lesions, also confirmed on 18F-FDG PET CT and Ga68-DOTATOC PET CT, along with hepatic and splenic high-uptake lesions. Octreotide dose was increased from 30 mg to 60 mg every 28 days. The patient also underwent at this point 2 peptide receptor radionuclide therapy (PRRT) sessions with Lu-177-DOTATATE but at reevaluation with Ga68-DOTATOC PET CT, multiple liver metastasis, with no SSR expression appeared. Percutaneous liver biopsy of the avid nodules showed tumor cells similar to the primary tumor, with a Ki 67% index of 12%. Treatment with Everolimus was initiated in order to decrease hepatic tumor burden, but it produced mild to moderate adverse effects (e.g. rash, fever), which in the end led to dose reduction. During reassessment, the CT scan showed slight progression of the liver metastasis and the tumor markers increased due to tumor necrosis.
Conclusion
Prognostic parameters should be established for WD-NET in order to prevent progression of the disease. Furthermore, in cases of progressive disease, different anti-tumor agents are necessary in order to ensure progression-free survival.

DOI: 10.1530/endoabs.73.EP127

EP128

A neuroendocrine tumour presenting with double vision

Hessa Boharoon[1] & Florian Wernig[2]
[1]Imperial College Health Care Hospital, Endocrine, UK; [2]Imperial College Healthcare NHS, UK

Carcinoid tumours are low grade neoplasms usually arising from neuroendocrine cells of the bronchial and gastrointestinal tracts. Carcinoid tumours metastasise in 50–75% of patients, most commonly to lymph nodes, liver, and bones, but intra-orbital metastases have only rarely been reported. Here, we describe a patient who presented with an intra-orbital neuroendocrine tumour which was successfully treated with surgery and radiotherapy. A 70-year-old female patient presented with diplopia and was found to have a right orbital tumour which was excised by craniotomy. Surprisingly, the histology revealed a neuroendocrine tumour of small bowel origin. Subsequent imaging identified a small bowel primary tumour for which she underwent surgical removal. The histological diagnosis was a grade 1 neuroendocrine tumour (Ki-67 proliferation index of 2%) with 6/14 lymph nodes involved and extra-nodal spread and the histological features matched those of the orbit. Further disease recurrence in the bowel necessitated repeat bowel surgery and ileocaecal tumour resection. Follow-up Gallium-68 DOTATATE PET scanning showed a DOTATATE-avid recurrence of her orbital diseases more than 5 years after her original surgery. She underwent successful Gamma Knife radiosurgery and remains free from recurrence 12 months later. Neuroendocrine metastases to the orbit are extremely rare, but can have a significant impact on patients' quality of life. Treatment options for orbital neuroendocrine tumour metastases include surgical excision, orbital exenteration, radiotherapy, as well as chemotherapy. As demonstrated in this case, metastatic neuroendocine tumours of the orbit can lead to local recurrence many years after surgical excision and/or radiotherapy. Therefore, longterm surveillance imaging is mandatory to allow early detection of recurrent disease.

Luque[1,2,3,4] & Manuel D. Gahete[1,2,3,4,4]
[1]Maimónides Institute of Biomedical Research of Córdoba (IMIBIC), Córdoba, Spain; [2]University of Córdoba, Department of Cell Biology, Physiology and Immunology, Córdoba, Spain; [3]Reina Sofia University Hospital, Córdoba, Spain; [4]CIBER Pathophysiology of Obesity and Nutrition (CIBERobn), Córdoba, Spain; [5]Reina Sofia University Hospital, Department of Hepatology and Liver Transplantation, Córdoba, Spain; [6]CIBER Hepatic and Digestive Diseases (CIBERehd), Córdoba, Spain; [7]Reina Sofia University Hospital, Unit of Hepatobiliary Surgery and Liver Transplantation, Córdoba, Spain

Obesity is emerging as a prevalent cause of chronic liver damage, which can lead to the development of metabolic-associated fatty liver disease (MAFLD), nonalcoholic steatohepatitis (NASH), or even hepatocellular carcinoma (HCC). Increasing evidence suggests a profound dysregulation of the splicing machinery (spliceosome and splicing factors) in these pathologies; however, the role of PRPF8, a pivotal spliceosome element, has not been described in chronic liver pathologies. Thus, we aimed to analyze the expression of PRPF8 in different liver cancer cohorts, and to characterize its putative role in tumor development/progression. PRPF8 expression (mRNA and protein) was analyzed in a retrospective cohort (n = 172 samples) and validated in two *in silico* cohorts (TCGA and CPTAC) of HCC samples with different aetiologies and their adjacent non-tumor control samples. Functional and molecular consequences of *PRPF8* silencing (using specific siRNAs) were evaluated in liver-derived cell lines (HepG2, Hep3B and SNU-387) and in Hep3b-induced xenograft tumors. Moreover, RNAseq and eCLIP data generated in HepG2 cells were analyzed. This study shows that PRPF8 expression is elevated (at the mRNA/protein levels) in HCC samples from different aetiologies in all the cohorts analysed. PRPF8 levels were associated with: i) increased tumor aggressiveness (tumor size, patient survival, etc.), ii) the expression of HCC-related splicing variants and, iii) the alteration of critical genes related to cancer-associated pathways. *PRPF8* silencing reduced *in vitro* aggressiveness of liver cancer cell lines (reducing proliferation, migration, tumorospheres-/colonies-formation, while increasing apoptosis), and decreased xenograft tumour growth *in vivo*. CLIPseq data in HepG2 demonstrated that PRPF8 binds preferentially to exons of protein-coding genes, and RNAseq analysis showed that *PRPF8*-silencing altered numerous splicing events, mainly exon skipping, of multiple genes. Integrated analysis of CLIPseq and RNAseq and *in vitro* experiments revealed that *PRPF8*-silencing modulates fibronectin (FN1) splicing, promoting the exclusion of exon 40.2, which is paramount for binding to integrins. Consistently, *PRPF8* silencing reduced FAK/AKT phosphorylation and blunted stress-fibres formation. Finally, HepG2 cells exhibited lower invasive capacity in membranes treated with media from PRPF8-silenced cells compared to that observed with media from scramble-treated cells. Altogether, our data demonstrate that PRPF8 is overexpressed and associated with aggressiveness in alcoholic, viral and metabolic-associated HCC. Indeed, PRPF8 seems to play key roles in chronic liver disease progression and hepatocarcinogenesis by modulating FN1 splicing, which leads to FAK/AKT activation and stress-fibers formation.

Bilateral pheochromocytoma in MEN 2A

Chayma Besrour, Imen Rojbi, Marwa Majdoub, Youssef Lakhoua, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Hospital Charles Nicolle, Endocrinology-Diabetology, Tunis, Tunisia

Introduction
Pheochromocytoma is rare neuroendocrine tumor arising from the chromaffin cells of the adrenal medulla. It can be even sporadic or take part of inherited syndromes.
Observation
We report the case of a young 32 year-old woman followed by her oncologist for medullary thyroid cancer treated with surgery and radiotherapy. On the examination of the removed tissue, there was a bilateral cancer, measuring 30 mm in diameter on the right lobe and 40 mm in diameter on the left lobe of the thyroid, associated to a parathyroid hyperplasia. As part of the assessment of the extent of extra-thyroidal extension of the cancer, the CT-scan showed a multiple bilateral adrenal masses, with a spontaneous density > 10 UH, 15 mm in diameter on the right gland, and two masses on the left gland ; 13 mm and 8 mm respectively. The patient was asymptomatic with normal tension and absence of any abnormalities in the examination. First, the adrenal insufficiency was eliminated, then the hormonal exploration revealed a pheochromocytoma (urinary normetanephrine 436 nmol/creat, urinary metanephrine 618 nmol/creat, two-fold and five-fold the upper normal limit respectively). The 123I-MIBG-Scintigraphy was in favor of a bilateral pheochromocytoma without any other locations. The patient was presented for bilateral adrenalectomy. Meanwhile, the genetic diagnosis of the mutations in the RET proto-oncogene (chromosome 10) is being tested.
Conclusion
This case describes a condition named multiple endocrine neoplasia type 2A (MEN 2A), where medullary thyroid cancer is present in 98-100% of cases, parathyroid hyperplasia in 5–10% and pheochromocytoma in 50% ; among them more than 60% are bilateral. The MEN 2A is a genetic condition which follows an autosomal dominant inheritance pattern. Our patient didn't have any similar cases in her family which make her a part of less than 5% of people with MEN 2A thought to have a novo mutation. Genetic screening of family members of MEN 2A is an early detection tool allowing to predict phenotypic characteristics and the association to other endocrinopathies, by detecting the specific RET mutation.

Endocrine monitoring after severe hypercalcemia due to primary hyperparathyroidism. In search of lost…MEN 2A?

Laura Teodoriu[1], Maximilian Hogea[2], Viorel Scripcariu[3,4], Bianca Ioan[5], Letitia Leustean[1,5], Christina Ungureanu[1,5], Cipriana Stefanescu[6] & Cristina Preda[1,5]
[1]University of Medicine and Pharmacy Gr. T Popa, Endocrinology, Iasi, Romania; [2]Regional Institute of Oncology, Urology, Iasi, Romania; [3]Regional Institute of Oncology, Surgery, Iasi, Romania; [4]University of Medicine and Pharmacy Gr. T Popa, Surgery, Iasi, Romania; [5]Emergency Clinical Hospital of St. Spiridon, Endocrinology, Iasi, Romania; [6]University of Medicine and Pharmacy Gr. T Popa, Nuclear Medicine Department, Iasi, Romania

The association between primary hyperparathyroidism and pheochromocytoma is present in multiple endocrine neoplasia type 2A (MEN 2A) along with medullary carcinoma or it can be a simple simultaneousness. The presence of the genetic mutation is mandatory in order to have a positive diagnosis of MEN. We report the case of a female patient 63 years old admitted in our department for a large adrenal incidentaloma (10 cm) with no clinical signs of adrenal dysfunction. An adrenal biopsy was already performed in the urology department and the histological result was positive for pheochromocytoma. The medical history of our patient revealed the presence of primary hyperparathyroidism 12 years ago. At the time, the severe hypercalcemia (14 mg/dl total plasmatic calcium) was the trigger for the diagnosis. After we normalize the calcium and we identify the parathyroid adenoma (ultrasound and sestamibi scan) the right inferior parathyroidectomy was performed along with subtotal thyroidectomy for multiple thyroid nodules. After the surgery our patient did not follow any treatment or medical control. The family medical history was negative for medullary carcinoma, pheochromocytoma and hyperparathyroidism. In our department hormonal tests showed: upper limit for plasmatic metanephrines, over 1000 ng/ml chromogranin A, normal PTH and slightly increase calcitonine 12 pg/ml (NV:0–10 pg/ml). The patient is currently on alpha-blocker medication as pre-surgical protocol requires. After surgery a calcitonine stimulation test is planned in order to check for medullary carcinoma. If this test is positive the genetic testing for RET mutation is necessary. This case report emphasizes the importance of medical follow-up after severe hyperparathyroidism no matter patient's age. The voluminous pheochromocytoma shows a long evolution. Lack of hypertensive crisis and other specific symptoms are explained by the intratumoral consumption of catecholamine. A close monitoring is necessary for the possible thyroid involvement (medullary carcinoma) and also for the parathyroid and adrenal function.

The prevalence of common risk factors for depression development in diabetes mellitus of the type 2

Yana Navmenova & Elena Makhlina
1SI "The Republican Research Center for Radiation Medicine and Human Ecology", Endocrinology, Gomel, Belarus

Objective
To evaluate the frequency of common risk factors for depression development in patients with the diabetes mellitus of the type 2 (DM 2).
Materials and methods
163 patients with DM 2 at the age of 40–65 years old, period of DM is 11.18 [4.28; 22.33] years. The evaluation of the anxiety and depression level was carried out with the use of the Hospital anxiety and depression scale *(HADS);* a questionnaire was carried out with the use of specially developed form to reveal common risk factors for depression development. A study group was divided into 2 subgroups depending on the level of depression in accordance with the HADS: group 1 included patients with DM 2 and depression (n = 46) and group 2 included patients with DM 2 without depression (n = 117).
Results
1. There are more patients that live alone (23.9% in comparison with 9.4% consequently,C= 0.04) and person with disability status (69.6% in comparison with 47.9% consequently, C= 0.03), among patients with DM 2 and depression, than among patients with DM 2 without depression.
2. The disability status is associated with the risk for depression development in DM 2 (OR = 2.41; P = 0.01; 95% CI 1.16–4.19)

Severe hypertriglyceridemia in young adults

Wiem Gherissi, Hadj Kacem Faten, Dhoha Ben Salah, Asma Zargni, Nabila Mahjoub Rkik, Mona Mnif, Fatma Mnif, Nedia Charfi, Mona Elleuch & Mohamed Abid
Hedi Chaker Hospital, Endocrinology, Sfax, Tunisia

Introduction
Severe hypertriglyceridemia (sHTG) (plasma triglycerides > 10 g/l) is a rare but pernicious and understudied condition.
Objective
Our objective was to evaluate the etiology, characteristics, and complications of sHTG.
Methods
It's a retrospective study including 10 patients with (sHTG) diagnosed between 1998 and 2020, at the department of endocrinology at Hedi Chaker-hospital Sfax-Tunisia.
Results
Notable male predominance was noted (sex ratio = 4), the mean age was 30.1 years (18–40). Family history of metabolic disorders was reported: dyslipidemia (50%), HTA (80%), diabetes (60%). Past history of Diabetes was reported for 5 patients: diabetes type 2, diabetes type 1, and diabetes

secondary to chronic pancreatitis, maternally inherited diabetes in 60%, 20%, 20%, and 20% respectively. 6 patients were being followed for dyslipidemia, 2 of them had chronic pancreatitis due to sHTG in pediatric age. 70% of patients had body mass index (BMI) between 25 and 30 kg/m^2. Also, alcohol consumption was reported in 3 cases with mean consumption of 55 g/per day. All of diabetic patients had a poorly controlled diabetes during hospitalization with mean HBA1c of 11.6%. Symptoms reported were: vomiting (6 patients), epigastria pain (7 patients), and weight loss (7 patients). Eruptive xanthoma was notable only for one patient. The mean fasting Plasma TG level was 19.92 g/l (10.5 to 34). Extremely severe hypertriglyceridemia TG > 30 g/l was reported in 2 cases. Abdominal imaging findings included acute pancreatitis signs (7 cases) in addition to hepatic steatosis. Necrotizing pancreatitis occurred in about 71% of acute pancreatitis cases. Lipoprotein electrophoresis helped to determine the causes of dyslipidemia in our study. Dyslipidemia type IV was the most common etiology (6 patients) and dyslipidemia type IIB was observed in 30% of cases. However, dyslipidemia type V was notable only for 1 patient. All patients received a fibrate (range of dose from 160 to 320) as either monotherapy or part of combination lipid-lowering therapy. We report a case of rhabdomyolysis induced by high dose of fibrate 320 mg/day associated with statin 20 mg/day. These therapeutic strategy including diet and intensification of diabetes treatment contributed to a decrease in the average triglyceride level of 72.8%.

Conclusion

These findings highlight the importance of early identification and successful treatment of severe HTG and its underlying disorders to reduce the risk of recurrent pancreatitis.

Autoimmune polyglandular syndrome type 3: a case report

Chayma Besrour, Imen Rojbi, Rihab Laamouri, Youssef Lakhoua, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Hospital Charles Nicolle, Endocrinology-Diabetology, Tunis, Tunisia

Introduction

Autoimmune polyglandular syndrome (APS) is a rare endocrinopathy, characterized by the coexistence of two or more glandular autoimmune diseases that can appear at different intervals of time.

Observation

Herein the case of a young woman descendant of first degree consanguineous marriage, diagnosed since the age of six with celiac disease (CD) where gluten-free diet was not respected due to poor socio-economic conditions, and an important retardation regarding the pondero-statural development was present. She consulted at the age of 33 year-old for recent onset of diabetes mellitus (DM), the anti-GAD antibodies were positive at 36 UI/ml, in favor of the diagnosis of latent autoimmune diabetes in adults (LADA). The biological exploration of the hypophyseal function revealed a primary hypothyroidism (TSH > 100 µU/ml), with negative TPO antibodies. And on the cervical ultrasound, the thyroid gland appeared to be atrophic.

Conclusion

This association of auto-immune thyroiditis to other auto-immune disorders represent the autoimmune polyglandular syndrome type 3 (APS 3: APS3A with DM, APS 3C with CD), it is an autoimmune condition that affects the body's endocrine glands. The cause is still unknown, but multifactorial mecanisms are to be involved (genetic and environmental).

Multiple endocrine neoplasia type 1 presenting with foreneck swelling

Fen-Yu Tseng[1,2] & Wan-Chen Wu[1]
[1]National Taiwan University Hospital, Internal Medicine, Taipei, Taiwan; [2]Taitung Christian Hospital, Internal Medicine, Taitung, Taiwan

Introduction

Multiple endocrine neoplasia type 1 (MEN-1) is a hereditary condition with neoplastic lesions in multiple endocrine organs, which most frequently involves pituitary, parathyroid gland, and pancreas.

Case report

A 53 y/o male visited endocrine clinic with the chief complaint of foreneck swelling for 1 month. He had history of renal stone for years. He had normal fT4 (1.13 ng/dl, reference 0.93–1.7), normal TSH (0.3 µIU/ml, reference 0.27–4.2), elevated PTH (125.3 pg/ml, reference 18.4–80.1) and elevated serum calcium (11.9 mg/dl, reference 8.6–10.2). Thyroid echo revealed a cystic lesion at the right thyroid lobe but no definite parathyroid lesion. Aspiration from the cystic lesion got 17 ml chocolate-colored fluid. Levels of PTH and thyroglobulin in the washout fluid were > 3000 pg/ml and 211 ng/ml respectively. Cytology revealed sheet of follicular cells with macrophages and colloid. Sestamibi parathyroid scan with SPECT revealed focal hot spots at left upper and right lower thyroid beds, and a large cold area at right lobe of thyroid. Pituitary and adrenal endocrine survey revealed hormone levels within normal reference ranges. A 0.4 cm hypoenhanced nodule in posterior portion of the pituitary gland was identified by MRI. Further studies to screen possible pancreatic neoplasms and parathyroidectomy are scheduled.

Conclusions

Hemorrhagic thyroid cyst is one of common causes of foreneck swelling. With detailed history taking and logically reasoning, the patient with foreneck swelling was finally diagnosed as MEN-1. Patients with MEN-1 may have manifestations of various endocrine disorders in different lifetime. Genetic study and long-term follow-up are warranted.

EP136

Clinical implications for the variations in the BMI in the clinical trial population with obstructive sleep apnea and narcolepsy evaluated for excessive sleepiness with Solriamfetol: a rapid review

Shailesh Trivedi[1] & Akta Trivedi[2]
[1]Anand Hospital, Baroda, India; [2]Anand Neurology Hospital, Baroda, India

Introduction

Solriamfetol is a dopamine and norepinephrine reuptake inhibitor, indicated to improve wakefulness in adult patients with excessive daytime sleepiness associated with narcolepsy or obstructive sleep apnea (OSA). Decrease in the body weight as an adverse effect of < 2% incidence in both the narcolepsy and OSA patients has been reported. We hypothesise that the baseline Body Mass Index (BMI) may be a an independent predictive marker for the decrease in the body weight in narcolepsy and OSA

Methods

We conducted a rapid review in accordance with PRISMA guidelines for the published randomised controlled clinical trials that document BMI in studies for Solriamfetol, across PubMed and Cochrane library. We eliminated duplication by excluding publications for subgroup and post hoc analysis

Results

A total of eight clinical trials were identified and four unique studies that included BMI as baseline demographic parameter were included for narrative synthesis. The BMI range varied from 18 to < 45 kg/m^2, across dose groups. The mean BMI was 32 (s.d. ± 2.5, minimum 28, maximum 33, range 5.4, 95% CI 28 to 36). The patients in the OSA group had a higher BMI (33 kg/m^2) which was 19.1% greater (5.35 kg/m^2) than the patients with narcolepsy (28 kg/m^2). We evaluated four Phase 3 trials, three for 12 weeks and one open label trial evaluating the safety and efficacy for long term (50 weeks)

Conclusions

OSA patients tend to be more obese. Baseline BMI appears be an important determinant for appropriate patient selection to initiate and predict the decrease in body weight. Mechanistically, dual reuptake inhibition properties of solriamfetol distinguishes it from the amphetamine stimulants by its lack of release of monoamines, which may have varied long term outcomes for excessive sleepiness in patients with narcolepsy and OSA. Periodic body weight monitoring would add value to the emerging clinical evidences especially for varied doses of solriamfetol.

Extra-digestive manifestations of celiac disease

Imen Akkari, Harbi Raida, Mrabet Soumaya & Ben Jazia Elhem
Hospital Farhat Hached, Gastroenterology, Tunisia

Introduction

Celiac disease is an autoimmune enteropathy secondary to gluten intolerance developing in genetically predisposed patients. The atypical presentation is the most common form of the disease. The aim of this work is to report the various extradigestive manifestations associated with celiac disease.

Patients and methods
This is a descriptive transversal study carried out over a period of 10 years. All patients with celiac disease were included.
Results
Forty one patients were included; the average age of patients was 36 years (17–75 years) with a sex ratio (M/F) equal to 0.46. The typical clinical presentation including chronic diarrhea and/or weight loss was observed in 29 patients, it was atypical in 10 patients and suspected in 2 asymptomatic patients with type1 diabetes. The extra-digestive manifestations associated with celiac disease were: anemia (83% of cases), amenorrhea (73% of cases), sterility (2.4% of cases), delayed puberty (2.4% of cases), coetaneous signs (12% of cases), psychiatric disorders (12% of cases), myalgia (9.7% of cases), hypocalcaemia (51% of cases), hypo albuminemia (73% of cases)), cytolysis (9.7% of cases), and cholestasis (7.3% of cases). All patients received a gluten-free diet and symptomatic treatment of extra-digestive manifestations. The evolution was marked by a clinical and biological improvement in 75% of cases.
Conclusion
Asymptomatic and atypical presentations are frequent in celiac disease, justifying a disease screening in order to start early the gluten free diet and improve the prognosis of the disease.

Functional hypoglycemia: clinical and biological characteristics

Elyes Kamoun[1,2], Sabrine Mekni[1,2], Imen Rojbi[1,2], Nadia Mchirgui[1,2], Youssef Lakhoua[1], Ibtissem Ben Nacef[1,2] & Karima Khiari[1,2]
[1]Hospital Charles Nicolle, Tunis, Tunisia; [2]Medical School of Tunis, Tunis, Tunisia

Introduction
As hypoglycemia is a common symptom, an organic cause is always the first diagnosis looked for as it can be associated with a specific medical or surgical treatment. Diagnosis of functional etiology isn't as precise, as the whipple triad can be incomplete. We herein report a serie of confirmed etiology for functional hypoglycemia.
Methods
This is a descriptive retrospective study including 20 cases of functional hypoglycemia. The etiology was assessed either by using the Homeostatic Model Assessment for Insulin Resistance (HOMA-IR) or by performing an oral glucose tolerance test (OGTT).
Results
Four patients had gastric emptying disorders, three men and one woman. Mean age was 49 years, 3 patients had a history of pyloroplasty and vagotomy, and one patient had partial gastrectomy. Neurogenic signs were noted in all patients, and 3 patients had neuroglycopenic symptoms such as headaches in 3 patients and loss of conscience in one. In 3 cases, body mass index (BMI) was normal, one patient was overweight. None of the patients changed weight. All patients had an early postprandial hypoglycemia, with hypoglycemia at 60 min in 2 cases and at 120 min in 2 cases at OGTT, with a mean glycemia of 0.52 ± 0.07 g/l. They were put under dietary measures with approvement of symptoms. Ten patients had a risk state of diabetes mellitus, 7 men and 9 women. Mean age was 37 ± 12 years. Twelve had family history of type 2 diabetes. Three patients had a normal BMI, 7 were overweight and 6 were obese. All patients had neurogenic symptoms and 12 had neuroglycopenic signs. Hypoglycemia was late post prandial in 13 cases and without clear timing in 3 cases. Mean glycated hemoglobin was 5.62 ± 0.48% in the 10 cases it was assessed. Kidney, liver and thyroid parameters were normal. Hyperinsulinism and insulin resistance was confirmed with a HOMA-IR at 6.35 ± 3.65 in 11 cases, and in the 5 cases with no confirmed insulin resistance, there was an inadequate insulin response to OGTT with a mean hypoglycemia at 210 min, mean glycemia at 0.6 ± 0.06 g/l and insulin 5 times more than basal insulin. Prediabetes was confirmed in 7 cases. All patients had dietary measures with improvement of hypoglycemia.
Conclusion
Functional hypoglycemia remains an important diagnosis to think of in the situation of spontaneous hypoglycemia, as investigations differ from organic etiologies and first line treatment is dietary intervention that can improve and treat efficiently the symptoms.

Vitamin D status and the association with metabolic risk factors in polycystic ovarian syndrome patients attending a tertiary hospital of Morocco

Salma Ben Yakhlef, Nisrine Bouichrat, Wahiba Abdellaoui, Siham Rouf & Hanane Latrech
Mohammed VI University Hospital, Mohammed I University, Department of Endocrinology- Diabetology, Oujda, Morocco

Introduction
Polycystic ovary syndrome (PCOS) is the most common female endocrine disorder with a prevalence of 8– 13% in women of reproductive age. Accumulating evidence suggests that vitamin D deficiency might have multiple impacts on the disease process ; and is involved in the pathogenesis of metabolic syndrom in PCOS. This notion is carried by the fact that the vitamin D receptor gene regulates about 3% of the human genome. The purpose of this study is to elucidate vitamin D status and the potential association with metabolic factors in polycystic ovarian syndrome patients followed-up in our center
Patients and methods
This is a retrospective data analysis of 51 PCOS patients, attending the endocrinology department of Oujda's Mohammed VI university hospital. The levels of 25OHD in the serum were determined using Architect chemiluminescent immunoassay technology, and Insulin resistance was estimated by the HOMA-IR. For all statistical tests, *P* value below 0.05 was pictured as statistically significant
Results
A total of 51 patients were involved in the study. The mean age was 24.83 ± 5.62 years. The majority of PCOS subjects (69.2%) were found to be vitamin D deficient,; with an average vitamin D concentration of 13.54 ± 7.14 ng/ml. Serum 25-hydroxyvitamin concentrations less than 10 ng/ml were classified as severe vitamin D deficiency and were found in 25% of cases. Overweight was noticed in 67.3% with a mean body mass index (BMI) of 26.12 ± 5.86 kg/m^2 and a mean waist circumference of 91.25 ± 17.61 cm. All PCOS patients underwent a 75-g oral glucose tolerance test, and the association between vitamin D status and HOMA-IR was statistically significant ($P < 0.001$), whereas the association between vitamin D status and BMI ranges was not statistically significant ($P = 0.52$). 25-hydroxyvitamin D concentrations were positively correlated with high-density lipoprotein cholesterol ($P < 0.05$).
Conclusion
Vitamin D deficiency is highly prevalent among women with PCOS, with an increasing evidence that vitamin D deficiency is associated with multiple metabolic risk factors in PCOS syndrome. In order to prove these findings, large intervention trials with vitamin D supplementation are warranted in PCOS women.

Thrombosis and coeliac disease

Imen Akkari, Harbi Raida, Mrabet Soumaya & Ben Jazia Elhem
Hospital Farhat Hached, Tunisia

Introduction
The occurrence of thromboembolic events in celiac disease has been reported in the literature, especially in adults. The objective of our study is to determine the prevalence and clinical characteristics of thrombosis in celiac disease and to clarify the role of thrombophilic factors.
Patients and methods
This is a retrospective series of four observations of thrombosis among a cohort of 41 patients with celiac disease revealed in adulthood. Laboratory workup for acquired or constitutional thrombophilia was performed in all four cases.
Results
Between 2000 and 2014, celiac disease was diagnosed in 41 patients, among whom 5 cases of thrombosis were collected, for an overall prevalence of 12%. They were 4 women and 1 man with an average age of 43 years [18–61]. No patient had a family history of thrombosis. Thrombotic manifestations preceded the diagnosis of celiac disease in two cases. Two patients presented with two concomitant thrombotic locations: one had deep vein thrombosis of the left lower limb associated with portal thrombosis, the other had intracardiac thrombus and extensive portal thrombosis. The thrombosis was mesenteric-portal in the third case, cerebral in the fourth

case and hepatic in the fifth case. Risk factors for thrombosis were identified in the five patients and could all be linked to celiac disease: hyperhomocysteinemia (n = 2), antiphospholipid antibodies (n = 1) and protein C and S deficiency (n = 2) linked to vitamin K deficiency,. The outcome in the three patients was good under anticoagulant treatment and a gluten-free diet.
Conclusion
The diagnosis of celiac disease should be made in case of unexplained thrombotic manifestations even in the absence of digestive signs. Risk factors for thrombosis can be acquired during this disease. These factors must be investigated, corrected, or even indicate thromboembolic prophylaxis.

Wermer syndrome: different phenotypes for the same disorder

Imen Halloul, Asma Ben Abdelkerim, Safa Khaldi, Ghada Saad, Maha Kacem, Molka Chaieb, Amel Maaroufi, Yosra Hasni & Koussay Ach
Farhat Hached University Hospital, Department of Endocrinology and Diabetes, Sousse, Tunisia

Introduction
Werner syndrome (WS) is a rare genetic disorder that displays clinical features suggestive of accelerated aging. Also known as adult progeria, it is caused by mutations in the *WRN* gene, which encodes a RecQ DNA helicase. Primary characteristics of this syndrome are progeroid changes of hair, bilateral cataract, atrophic skin, soft-tissue calcification, bird-like face, abnormal voice and many others features. Here we report 5 patients that presented with different phenotypes of this syndrome showing the heterogenicity of this genetic disorder.
Case report
All of our 5 patients were born from consanguineous parents. The first 2 patients are brother and sister. The older sister was 22-year-old and followed for short stature and hypogonadism. She had a bird-like face with an atrophic skin. She developed over the years bilateral cataract and adrenal insufficiency. She was treated with hormonal replacement therapy and hydrocortisone. As for her brother, the diagnosis of WS was evoked at the age of 10, when he consulted for short stature and bird-like face. A hypothyroidism and adrenal insufficiency were also diagnosed later. The second family consist of 2 brothers aged 34 and 32, who consulted for short stature, hypogonadism and hypothyroidism. Both presented with pinched facial appearance, pitched voice, skin atrophy, diabetes mellitus (DM), dyslipidemia and cataract. And the last patient, is 36-year-old male patient who was first followed for hypothyroidism and DM. Considering the association with hypogonadism, short stature and atypical facial features, the WS was probable. All the 5 patients were treated with hormonal replacement to compensate for the different deficiencies. Unfortunately, the genetics test was not available to confirm this disorder.
Conclusion
WS is a rare syndrome but it must be evoked, considering its association with different malignancies such as thyroid follicular carcinomas, malignant melanoma, meningioma, soft tissue sarcomas, primary bone tumors and leukemia. They also develop premature atherosclerosis, which is the second cause of death for those patients. The discordances between the signs and the age of diagnosis may be attributed to numerous factors, such as differential expressions and regulations of the WRN protein in various cell types and tissues, rates of cell turnover, and variations in the replicative potentials of various types of stem cells. The role of the genetic tests is becoming more and more necessary to unsure the proper diagnosis and to eventually lead a standard follow-up of the different comorbidities.

K^+-dependent Na^+/Ca^{2+} -exchangers 3 aggravates experimental colitis in mice

Eui-Bae Jeung, Dinh Nam Tran, Donglin Yi & Kang Min Kim
Chungbuk National University, Laboratory of Veterinary Biochemistry and Molecular Biology, College of Veterinary Medicine, Cheongju, Chungbuk, Republic of South Korea

Calcium signaling plays a regulatory role in the events of cellular proliferation. In immunocytes such as T cells, B cells, mast cells and many other cell types, Ca^{2+} signals show to control the proliferation, differentiation, and function. Furthermore, Ca^{2+} has been shown to act as a second messenger to regulate innate immune cell function and activation. Here, we found that loss of Nckx3, a potassium-dependent Na^+/Ca^{2+} exchanger, up-regulated of innate immune response-associated genes in the duodenum. In addition, Nckx3 KO mice showed an increase in inflammatory bowel disease- and tumorigenesis-related genes. In DSS-induced experimental colitis mice models, Nckx3 KO mice attenuated the severity of colitis. There were higher in the cumulative injury score, histopathology and evident at both the levels of mucosal inflammation and crypt injury in the DSS-treated Nckx3 KO mice than in the wild-type mice. Together, these results highlight that Nckx3 plays a critical role in the innate immune and immune response, may be central to the pathogenesis of inflammatory bowel diseases.

Pituitary stalk interruption syndrome: a clinical case report

Alexandra Mirica[1,2], Vitan Luiza[3], Diana Monica Preda[1] & Diana Loreta Paun[2,4]
[1]Spitalul Clinic de Urgenţă pentru Copii Grigore Alexandrescu, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucureşti, Romania; [3]Hospital CF2, Bucureşti, Romania; [4]Parhon Hospital Bucharest, Bucureşti, Romania

Introduction
Pituitary stalk interruption syndrome (PSIS) is a rare entity characterized by a triad of thin or interrupted pituitary stalk, aplasia or hypoplasia of the anterior pituitary and absent or ectopic posterior pituitary seen on magnetic resonance imaging (MRI). We are presenting the clinical case of a child who presented for short stature.
Case presentation
We present the case of a 4 year and 8 months old child who presented for short stature in our outpatient department. He was the first child born to a non-consanguinous young couple, with a normal gestational period. The parents denied any significant pathological history. The child was born full term by caesarean section, Apgar score 9, birth weight of 3.7 kg and a prolonged physiological jaundice treated with phototherapy. In the neonatal period he presented episodes of hypoglycemia, considered secondary to a transient adrenal insufficiency, treated until the age of 6 months with hydrocortisone, later being lost from monitoring. He has been well with no chronic medical problems, no hospitalizations, and no surgeries, until this evaluation. Physical examination showed no facial dysmorphia, with a height at −3.5 s.d., with a normal weight, with stage 1 Tanner of pubertal development, micropenis, with both testicles present in the scrotum. Hormonal analysis showed normal thyroid stimulating hormone (TSH), freeT4, prolactin and a normal fasting morning cortisol: 10 µg/dl (n = 5–25 µg/dl). Furthermore growth hormone (GH) stimulation test (clonidine) was abnormal with a value < 1 ng/ml (normal > 7 ng/ml), together with low IGF1 value. The bone X-ray of the hand was 1 year old (bone age). In addition, MRI brain revealed anterior pituitary hypoplasia and absent pituitary stalk with normal neurohypophysis.
Conclusions
We present the case of a pituitary stalk interruption syndrome in a 4 year child, in which case hormonal replacement therapy was started.

Co-existing microprolactinoma and meningioma – a rare case

Ifrah Mahmood[1], Ankita Singh[1] & Tahir Omer[2]
[1]Northampton General Hospital, General Medicine, Northampton, UK; [2]Northampton General Hospital, Diabetes And Endocrinology, Northampton, UK

Introduction
Meningiomas and pituitary tumours are two most prevalent benign tumours of the CNS but neither are common and without a history of radiotherapy their concomitant existence is extremely rare. Meningiomas comprise 15–25% of all intracranial neoplasms while prevalence of benign pituitary adenomas is 10–23%. We report a rare case of co-existing Brain tumours.
Case
51 year old lady presented with deteriorating vision in left eye with deteriorating visual acuity. No other significant medical or family history. Examination revealed significant right hemianopia. The CT scan showed

a suprasellar tumor of 32×31×13 mm. Short synacthen test and pituitary hormones were all normal. IGF-1 Prolactin 605 mIU/l. MRI suggested it to be a meningioma rather than a primary pituitary tumour which was confirmed by histopathology obtained by Transfrontal Debulking surgery followed by Radiotherapy for residual disease which she tolerated really well. Few months later she complained of some headaches, some weight gain, secondary amenorrhoea & galactorrhoea. Blood test for prolactin, LH, FSH, Oestradiol, TFTs, IGF1 and Cortisol was arranged and showed Prolactin 2225 mIU/l and normal other hormones. MRI was difficult to interpret due to recent surgery but showed no interval change from previously and she was started on Cabergoline following which her symptoms improved.
Conclusion
In our case the cause of rise in prolactin level post-surgery was unclear. Radiation induced hypopituitarism could be one of the causes but the fact that all other pituitary hormones were stable makes it less likely. A co-existing microprolactinoma is more likely. The diagnosis of co-existing brain tumours is not easy to make based only on MRI, but it is important to distinguish between them as the treatment strategy for these tumours are different. Post-surgical evaluation in cases of suprasellar meningiomas with regular monitoring of the pituitary function might be beneficial.

EP145

A case of Cushing syndrome misdiagnosed as treatment with antiepileptic drug

Mehmet Sözen, Berrin Çetinarslan, Zeynep Cantürk, Alev Selek, Emre Gezer & Damla Köksalan
Kocaeli University Faculty of Medicine, Endocrinology and Metabolism, Turkey

Introduction
The most common causes of pseudo Cushing syndrome are alcoholism, chronic kidney disease, neuropsychiatric diseases, pregnancy, uncontrolled diabetes, and drugs. We present a patient who was operated on suspected Cushing syndrome based on abnormal results in overnight dexamethasone suppression tests.
Case presentation
A 49-year-old female patient was referred to our clinic for reoperation due to persistant cushing syndrome after first pituitary surgery in another center. Cortisol had been found to be 10.2 µg/dl after overnight 1 mg dexamethasone suppression test (DST) performed in aforementioned center with suspicion of cushing syndrome in the patient with type 2 diabetes mellitus and obesity. Basal morning ACTH and cortisol had been found 44 pg/ml and 12.7 µg/dl respectively. The cortisol response to 48-h, 2 mg/day low-dose DST was 6.24 µg/dl. 24-h urinary free cortisol (UFC) had beenfound to be normal. Heterogeneous contrast enhancement was observed in the right half of the pituitary gland, and no mass lesion had been detected in pituitary magnetic resonance imaging,. She was diagnosed with bilateral cushing disease in inferior petrosal sinus sampling and operated. On the first postoperative day morning cortisol was 14 µg/dl. At the 3rd month control, the cortisol levels after 1 mg DST was 4.4 µg/dl. The patient was referred to our clinic with the diagnosis of persistant cushing disease. Beside facial plethorea and abdominal obesity (body mass index 41.2 kg/m^2) her physical examination was unremarkable. Past medical history revealed carbamazepine use for 10 years due to epilepsy. Recurrent tests performed in our clinic showed that, midnight serum cortisol was 1.79 µg/dl, and 24-hour UFC was 150 µg/day (43-403). No pathological signal change was observed in the control pituitary MRI. When the pathological specimens were re-evaluated in the pathology department no adenoma was identified, it was observed that the normal reticulin structure was preserved, Ki67 proliferation index was < 1%, and diffuse strong cytoplasmic staining was observed with GH, ACTH and PRL. Telangiectasias of the face were evaluated in favor of rosacea disease by the dermatology clinic. We concluded that there was no clinical evidence of Cushing's syndrome and that failed dexamethasone suppression tests were due to the effect of carbamazepine.
Conclusion
Some drugs such as carbamazepine induce CYP3A4 activity and may lead to false positive dexamethasone suppression test results. The results must be properly evaluated to avoid misdiagnosis.

EP146

A case of primary amenorrhea revealing a macroprolactinoma

Dayssem Khelifi, Imen Rojbi, Ibtissem Ben Nacef, Youssef Lakhoua, Nadia Mchirgui & Karima Khiari
Charles Nicolle Hospital, Department of Endocrinology, Tunisia

Introduction
Primary amenorrhea should be considered in any patient who has not experienced periodic menstruation by 16 years regardless of the presence of normal growth and development of secondary sexual characteristics.
Observation
17-year-old patient, who exhibited normal secondary sexual characteristics, normal auxiliary and pubic hairs, normal breast development since the age of 12 with the non-appearance of menstruation beyond 16 years. No history suggestive of hypothyroidism, repeated infections, raised intracranial pressure was there. No history of difficulty in walking, deformity of extremities and nothing contributory from developmental and birth history. No similar history in family was present. Physical examination revealed Height: 162 cm, Weight: 74 kg, BMI: 28.24 kg/m^2. Secondary sexual characteristic: Pubic hair P 4, Breast development B 4. No signs of hirsutism and no clitoromegaly was seen and other systemic examinations were normal. The hormonal profile of the patient revealed hypogonadotropic hypogonadism, hyperprolactinemia at 2390 ng/ml and MRI showing a pituitary macroadenoma of 25 × 16 mm. It is extending into the left cavernous sinus. The *patient* was already *treated* with *dopamine agonists* with a decrease in the level of prolactin and the size of the pituitary adenoma.
Conclusion
The prolactin adenoma in our patients probably set in during puberty after the normal development of secondary sexual characteristics and stopped puberty development before the onset of menstruation.

A challenging case of Cushing's disease complicated with diverticular rupture and multiple thrombotic phenomena following trans-sphenoidal surgery

Piyumi Wijewickrama[1], Noel P Somasundaram[2], Manilka Sumanatilleke[1] & Sathyajith Ambawatte[3]
[1]NHSL, Endocrinology, Colombo, Sri Lanka; [2]NHSL, Colombo, Sri Lanka; [3]Ministry of Health, Colombo, Sri Lanka

Background
Cushing's syndrome (CS) occurs due to cortisol overproduction. Endogenous hypercortisolemia can be secondary to Adrenocorticotropic hormone (ACTH) dependent as well as independent causes (1). Early identification and prompt definitive management is crucial to minimize mortality. Successful management of CS becomes extremely challenging due to multiple associated complications, especially the thrombotic events which are even more prominent in post-operative period needing close monitoring. We report a case of Cushing's disease (CD) in a young female managed with trans-sphenoidal surgery, followed by a challenging post-operative period due to multiple thrombotic phenomena, ultimately succumbed.
Case presentation
A 32-year-old Sri Lankan female presented with overt features of CS and diagnosed to have CD with pituitary microadenoma. Pre-operatively she was medically managed with Ketoconazole. She underwent trans-sphenoidal surgery and despite achieving normalization of post-operative day2 cortisol, she developed multiple complications including diverticular rupture and ischemic colitis, needing hemicolectomy, followed by parieto-occipital infarction, which ultimately lead to her death despite aggressive management.
Conclusion
This case highlights important and aggressive complications associated with CS giving rise to a challenging post-operative course. Diverticular rupture had been rarely described in association with hypercortisolemia, due to multiple mechanisms, and this case adds to the existing literature (2). Post-operative ischemic colitis and stroke which lead to the death of this patient are seen with procoagulant state associated with CS, with a high risk during the immediate post-operative period. Venous thrombo-embolism is the most commonly reported thrombotic phenomenon while acute mesenteric ischemia as seen in our patient is only rarely reported (3). This emphasizes the need to consider thromboprophylaxis for patients with CS in the immediate post-operative period, although clear guidelines regarding this do not exist.

Double localization of a cerebral germinoma, a case study

Bessaid Khadidja
El Djazair, Algeria

Introduction
Germ cell tumour are embryonic tumour localized mainly at the gonads level, their cerebral localization is rare with less than 1% of intracranial neoplasia.
Observation
We have reported a 20 years old girl case without pathological history who had progressive diabetes insipidus for one year associated with spaniomenorrhea, the MRI revealed an aspect suggesting a pineal stem germinoma (12 mm of major axis), with a second localization at the pituitary stalk (12 mm of major axis) and a disappearance of the spontaneous hyper signal of the post-pituitary gland, measurement of tumour markers: was positive for the B HCG at 8.33 u UI/ml (normally < 2 m UI/ml) and normal for the other markers, which confirmed the diagnosis of pure germinoma without biopsy.
Discussion
Germinomas of suprasellar and pineal dual localization remain rare and present only 5–10% of germinomas with only 15 cases reported in the literature, the clinical expression is polymorphic and imaging provides a highly evocative radiological semiology, the treatment is mainly based on radiotherapy and sometimes on a combination of radio and chemotherapy this last alternative was our therapeutic choice with a good clinical and biological evolution.

Apparently non secreting adenoma: a new challenge

Diana-Georgiana Lazar[1], Sabina Elena Oros[1,2], Anda Dumitrascu[1], Daniela Alexandrescu[1], Andreea Raluca Petria[1] & Sergiu Stoica[3]
[1]National Institute of Endocrinology 'C.I. Parhon', Bucharest, Romania; [2]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania; [3]Monza Hospital, Bucharest, Romania

Introduction
Silent corticotroph adenoma represent an uncommon subtype of nonfunctioning adenoma, immunoreactive for ACTH, without clinical or biochemical evidence of hypercortisolism and unclear pathogenesis. Usually, they present with local mass effect (visual deterioration being the most common) and endocrine dysfunctions. They carry a more aggressive behavior, particularly upon earlier recurrence.
Case presentation
A 47-year-old, obese male patient, recently diagnosed with pituitary macroadenoma, came to our clinic for emergency endocrine evaluation, accusing suddenly visual field dysfunction and headache 7 days before admission with the left temporal hemianopsy development. At admission, IGF-1, thyroid and adrenal hormone status within normal, mild hyperprolactinemia and hypogonadotrophic hypogonadism. A second opinion on CT and IRM cerebral scans certified pituitary macroadenoma with suprasellar and intrasellar extension, optical chiasm compression and pituitary apoplexy. Ophthalmological examination confirmed right quadranopsy-superior temporal and left temporal hemianopsy. Transphenoidal adenomectony was performed. The immunohistochemistry exam showed positive staining for ACTH, Ki67 proliferation index-4%, p53 positive in rare tumor cells, positive cytokeratin CAM 5.2 and cromogranin with variable intensity in the tumor cells. Visual dysfunctions have markedly improved post surgery. He was discharged with hydrocortisone, levothyroxine and testosterone replacement therapy and periodic follow-up.
Particularities
Silent corticotroph macroadenoma probably grew aggressively. Despite the local mass effect and visual deterioration that are the most common manifestations, our patient didn't complain about sexual dynamic disorder. Age at diagnose is also peculiar with peak incidence in the 3rd decade, being more frequent in women. The presence of tumor proliferation markers such as ki67 and p53 associate an aggressive pattern and a poor prognosis.
Conclusions
Management of silent corticotroph macroadenoma is complex. Surgery remains the main therapeutic approach. This patient needs to be monitored closely for quick hypopituitarism onset and careful follow-up due to frequent and early recurrences. Rarely, they can change to a more aggressive phenotype or possibly transform to Cushing disease and multimodal therapy is necessary.

A rare etiology of hypopituitarism in adulthood

Madhi Wiem[1], Ines Kammoun[1], Malek Kaabar[1], Radhouane Gharbi[1], Neji Sonia[2], Hiba Allah Chatti[1], Hajer Kandara[1] & Manel Jemel[1]
[1]National Institute of Nutrition, Endocrinology – Diabetology, Tunis, Tunisia; [2]National Institute of Neurology, Radiology, Tunis, Tunisia

Introduction
Rathke Cleft Cysts (RCC) are common benign cystic lesions in the sellar region. These cysts are often small, intrapituitary and asymptomatic. Voluminous forms are rare and can be symptomatic by compressing the adjacent structures. We report the case of pituitary insufficiency related to RCC.
Observation
A male patient aged 49 years old, diagnosed with type 2 diabetes since 8 years treated with metformin and glimiperide, was addressed to the endocrinology department for additional exploration of frequent hypoglycemic episodes occurring despite stopping glimepiride. The patient was also presented with hormonal findings of central hypothyroidism. Patient complained of headache and erectile dysfunction. No Polyuria-polydipsia syndrome was found. Exploration of the other pituitary axes concluded to central hypogonadism and central adrenal insufficiency. The patient was treated with hydrocortisone and levothyroxine. The pituitary MRI showed a posterior intrasellar expansive process, extended to the suprasellar space and compressing the optic chiasma. Fundus and visual field examination were normal. The patient underwent endoscopic endonasal transsphenoidal surgery. Pathological examination was in favor of RCC. After surgery, hypopituitarism was persistent.
Discussion
Symptomatic RCC represent 5 to 15% of operated sellar region tumors. This pathology is often diagnosed in children. Our case is particular because of the appearance of symptoms in adulthood and the atypical radiological presentation, mimicking a tumor of the post pituitary gland.

Fasting glucose and other metabolic features of 17 Brazilian women with microprolactinomas

Mariana Botelho[1], Rafaela Sousa[1], João Nascimento[1], Adilson Lamounier Filho[2], Erika Naliato[3] & Alice Violante[1]
[1]Universidade Federal do Rio de Janeiro, Brazil; [2]Universidade Federal do Espírito Santo – UFES, Brazil; [3]Teresopolis Medical Association, Ricardo A T Castilho Center of Studies, Teresopolis, Brazil

Introduction
Among other organic functions, Prolactin (PRL) can influence metabolism.
Aim
To evaluate basal glucose metabolism in women with prolactinoma, according to menstrual cycle, presence of hyperprolactinemia, and dopamine agonist (DA) treatment.

Material and methods
Cross-sectional study of 17 women with microprolactinoma and 11 healthy controls. Variables evaluated: PRL, FSH, LH, estradiol, GH, IGF1, fasting glucose and insulin, Homeostatic Model Assessment (HOMA), HOMA-beta, body mass index (BMI), waist, hip, and waist-to-hip ratio (WHR). Group comparison between controls and patients with: (I) normal (NPRL, $n = 6$) and elevated PRL (EPRL, n = 11), (II) eumenorrhea (EU, $n = 10$) and oligomenorrhea (OLIGO, $n = 7$), and (III) bromocriptine (BC), cabergoline (CAB, $n = 5$) or no DA (NDA, $n = 7$) treatment.
Results
(I) Comparisons between NPRL, EPRL and controls: WHR was higher in NPRL (0.89 ± 0.04) than controls (0.80 ± 0.09; $P = 0.0292$). GH levels were lower in EPRL (0.50 ± 0.38 ng/ml) than controls (1.76 ± 1.17 ng/ml; $P = 0.0275$). (II) Comparisons between EU, OLIGO, and controls: PRL levels were higher in OLIGO (83.74 ± 54.04 ng/ml) than controls (13.82 ± 5.74 ng/ml; $P = 0.0017$). WHR was higher in EU (0.87 ± 0.05) and OLIGO (0.87 ± 0.05) than controls ($P = 0.0380$). GH levels were lower in EU (0.50 ± 0.43 ng/ml) than controls ($P = 0.0210$). (III) Comparisons according to DA treatment: CAB had higher PRL levels (77.08 ± 57.18 ng/ml) than controls ($P = 0.0085$). BC had lower fasting glycemia than CAB (77.0 ± 7.6 vs. 89.4 ± 3.6 mg/dl; $P = 0.0220$) and NDA (89.4 ± 5.2 mg/dl; $P = 0.0021$). HOMA-beta was higher in BC ($P = 0.0347$). GH levels were lower in NDA (0.41 ± 0.32 ng/ml) than controls ($P = 0.0439$). There were no other significant differences in variable comparisons between groups. Linear regression models did not show influence of GH on clinical-biochemical parameters of the patients. The influence of PRL and estradiol suggested by linear regression models was not confirmed by multivariate analyses, which only corroborated the influence of BC treatment on fasting glycemia ($r^2 = 0.6159$; $P = 0.0020$).
Conclusions
Patients with EPRL, NPRL, eumenorrhea, and oligomenorrhea had changes in WHR and GH levels. Treatment with BC was the main influence on fasting glucose. The authors emphasize the need for metabolic evaluation of patients with microprolactinoma and, despite the small sample size, our data indicate special attention to GH assessment, aiming at early detection of GH deficiency.

Management of malignant insulina

Nerea Egaña Zunzunegui, Cristina Elias Ortega, Inmaculada Venegas Nebreda, Ismene Bilbao Garay, Maite Aramburu Calafell, Cristina García Delgado, Jorge Rojo Alvaro, Maite Perez de Ciriza Cordeu, Alfredo Yoldi Arrieta & Miguel Maria Goena Iglesias
Donostia Unibertsitate Ospitalea, Donostia, Spain

Introduction
Malignant insulinoma is a rare pancreatic neuroendocrine tumor that accounts for only 10% of all cases of insulinoma. The clinical picture is characterized by the presence of severe hyperinsulinemic hypoglycaemic syndrome in a patient with pancreatic tumor with locoregional and/or distant metastases. Therapeutic management is challenging due to the need to control both hypoglycemic syndrome and tumor growth. Curative surgery is rarely applicable due to widespread metastases. We analyze clinico pathological characteristics, treatments and prognosis of 3 patients diagnosticated from 2009 to 2015.

	CASE 1	CASE 2	CASE 3
SEX	Female	Female	Male
AGE	37	37	77
TUMOR SIZE	4.5	5	5
METASTASIS	Hepatic + lymph node	Hepatic + lymph node	Hepatic + lymph node
GLUCOSE	10	42	38
INSULINE	86	38	40
C PEPTIDE	7.7	8.7	9.5
PROINSULINE	> 100	> 100	> 100
KI67	20%	> 20%	5-10%
HYPOG TREATMENT	Diazoxide + Dexameta	Diazoxide	Diazoxide + Dexameta
SURGERY	No	No	No
S. ANALOGS	Lanreotide LAR	Lanreotide LAR	Lanreotide LAR
2º LINE	Hepatic mets embolizat	Everolimus	Everolimus
3º LINE		Temozola + Capecita	Sunitib
SURVIVAL	22 months	26 months	29 months

Surgery was the first choice of treatment in all the cases but it was dismissed from surgeon. Glycaemic control was the therapeutic challenge in these patients. In case 2 the hypoglycemic was controlled with diazoxide and lanreotide LAR. The others needed corticosteroid therapy and high doses of diazoxide to avoid hypoglycemia. After somatostatin analog Everolimus was the first line treatment. Case 1 refused this therapy and case 2 took only for one month because of bad tolerance. Hepatic metastases embolization improve the glycemic control in case 1. Lu- DOTATE was not available in our center.
Conclusion
Surgery is the unique curative treatment but is rarely applicable due to the widespread metastasis at diagnosis. The hypoglycemic syndrome is often refractory and decreased quality of life of these patients, in addition to medical treatment, debulking surgery or locoregional therapies can improve the symptoms control.

Hydrocephalus associating Hakim-Adams syndrome as unusual manifestation of pituitary adenoma

Begoña Pla Peris, Pablo Abellán Galiana, Jacobo Blanco, Mayet Roxana Padilla Segura, Margarita González Boillos, Javier Maravall, Susana Pérez Naranjo & Agustín Ángel Merchante Alfaro
Hospital General Universitario de Castellón, Endocrinology and Nutrition, Spain

Introduction
Non-functioning secretory pituitary adenomas are usually characterized by the lack of associated hormone overproduction. The absence of symptoms of excess hormone production results in a delayed diagnosis: sometimes as an incidental diagnosis, sometimes due to compressive symptoms with visual involvement or neurological symptoms as headache. However, hydrocephalus associating Hakim-Adams Syndrome caused by foramen of Monro obstruction secondary to pituitary adenoma is an unusual manifestation.
Case presentation
We present the case of a 64-year-old man admitted to Emergency Department for a gradual development of gait disturbance and primarily urinary incontinence for the past three months, as well as the onset of cognitive impairment (disorientation, frequent medication forgetfulness, driving disability). He had a previous medical history of hypertension and chronic daily headaches. He had recently consulted Neurology, being diagnosed of atypical parkinsonian syndrome and having started the combination of levodopa and carbidopa medication, with no apparent improvement. At physical examination he presented decreased alertness, memory loss and postural instability. His walk was characterized by short and shuffling steps on widely spaced legs and loss of balance. Head magnetic resonance (MR) revealed a 44 × 48 × 35 mm pituitary Knosp 3a macroadenoma with suprasellar extension, compressing the optic chiasma and associating a remarkable hydrocephalus, particularly of the right ventricle resulting from obstruction of the foramen of Monro. Visual field revealed paracentral scotomas. On admission, laboratory findings showed prolactin levels 9.2 ng/ml [2.6–13.1], TSH and T4L levels 0.40 mUI/l [0.380–5.330] and 0.58 ng/dl [0.54–1.24], respectively; IGF-1 levels 82.6 ng/ml [67–141] and testosterone levels < 0.10 ng/ml [1.75–7.81]. LH 0.42 UI/l [1.2–8.6] and FSH 2.93 UI/l [1.27–19.26]. Cortisol and ACTH not valuable due to treatment with dexamethasone when MR images were assessed by neurosurgery on

admission to the emergency room. Sodium levels 135 mmol/l [134–145], without any clinical symptoms suggestive of diabetes insipidus. Due to COVID-19 pandemic and overcrowding hospital the patient had to be transferred to a free-Covid hospital for surgery, with pathological pattern and immunohistochemical analysis pending.

Conclusion

Hydrocephalus as a complication of pituitary adenomas is infrequent. Pituitary tumours rarely become large enough to cause an obstruction at the foramen of Monro. This case is an illustration of this unusual clinical manifestation: hydrocephalus caused by foramen of Monro obstruction associating the classical picture of Hakim-Adams Syndrome in a patient misdiagnosed with atypical parkinsonian syndrome. The considerable overlap of symptoms for atypical parkinsonian syndromes with symptomatic hydrocephalus makes clinical diagnosis challenging and may lead to delay in diagnosis.

Coexistence of papillary thyroid carcinoma and primary hyperparathyroidism in a patient with acromegaly.

Elyes Kamoun, Ibtissem Oueslati, Fatma Chaker, Meriem Yazidi & Melika Chihaoui
La Rabta Hospital, University of Tunis El Manar, Faculty of Medicine, Endocrinology, Tunis, Tunisia

Introduction

Acromegaly is an endocrine disorder resulting from an excess of growth hormone (GH). The cause is almost always a pituitary adenoma, and it affects through the insulin-like Growth Factor 1 (IGF-1) the cellular proliferation, increasing therefore the risk of malignancy. Herein, we describe a case of coexistence of papillary thyroid carcinoma and primary hyperparathyroidism in a patient with acromegaly.

Case report

A 58-year-old woman was referred to our department for suspicion of acromegaly. Her past medical history included diabetes mellitus, hypertension and dysmorphic syndrome for last 4 years. On physical examination, she had a blood pressure of 120/80 mmHg, an acrofacial dysmorphia, a goiter with a firm left nodule. On laboratory investigations, she had a glycated hemoglobin of 8.28%, a calcemia level of 121 mg/l, a serum phosphate level of 22 mg/l, a PTH level of 209 pg/ml (nr: 15-68), an IGF-1 level of 646 ng/ml (3 times normal), GH level at 18.93 mUI/l. The pituitary hormonal evaluation revealed a corticotropin deficiency, without gonadotropin nor thyrotropin deficiency. The pituitary magnetic resonance imaging showed a 28 mm macroadenoma invading the cavernous sinuses. Cervical ultrasound found a 57 × 44 × 73 mm goitre with a 70 mm left nodule classified TIRADS 5. Parathyroid imaging investigation (ultrasound, CT-scan and scintigraphy) didn't individualize any adenoma or hyperplasia. She had a total thyroidectomy and a parathyroidectomy of the right inferior gland containing an adenoma and parathyroidectomy of the right superior gland. The histopathological examination confirmed the diagnosis of papillary thyroid carcinoma and parathyroid adenoma.

Discussion and conclusion

This case highlights the importance of the screening for malignancies associated with acromegaly and the evaluation of other endocrine neoplasia. The coexistence of parathyroid and anterior pituitary tumors is part of either multiple endocrine neoplasia type 1 or type 4. In addition, papillary thyroid carcinoma is reported as a part of the clinical presentation of multiple endocrine neoplasia type 4. Genetic investigations are mandatory to assess the responsible mutation.

Functional pituitary gonadotroph adenoma in male patients: a case study

Nanik Ram[1], Sajjad Ali Khan[1], Bhagwan Das[2] & Najmul Islam[1]
[1]Aga Khan University Hospital, Department of Medicine, Section of Diabetes Mellitus, Metabolism and Endocrinology, Karachi, Pakistan; [2]Cancer Foundation Hospital, Karachi, Pakistan

Background

Pituitary gonadotroph adenomas are common but very rarely do they secrete biologically active luteinizing hormone (LH) and follicle-stimulating hormone (FSH). There have been case studies reporting high sex hormones (testosterone/estrogen) in the presence of high or normal LH and FSH.

Case presentation

Here we report two cases who presented with visual disturbance and headache at a tertiary care hospital, Karachi, Pakistan. Brain imaging of both patients revealed a pituitary macroadenoma. Hornonal workup of our patients is shown below.

Hormonal workup of case 1 and case 2

Laboratory Parameters	Case 1		Case 2		Normal values
	Pre-Surgery	Post-Surgery	Pre-Surgery	Post-Surgery	
FSH	36.66	4.97	13.61		1.4–15.4 MIU/ml
LH	7.09	0.99	4.45		1.2–7.8 MIU/ml
Testosterone	952.7	176.8	> 1500	20.14	193–740 ng/dl
Cortisol	2.60	7.40	12.60	11.10	4.3–22.4 ng/dl
FT4	0.69	1.65	0.84	0.88	0.89–1.76 ng/dl
Prolactin	12.40		36.80		3–14.7 ng/ml
GH	< 0.50	0.06	0.13		2.0–5.0 ng/ml

Figure Legend: FSH, Follicle stimulating hormone; FT4, Free Thyroxine; LH, luteinizing hormone; MIU/ml, milli-international units per milliliter; ng/dl, nanogram per deciliter; ug/dl, microgram per deciliter; GH, Growth hormone; Both patients underwent transsphenoidal resection of the tumor and tissue histopathology confirmed pituitary adenoma. Postoperatively, improvement in hormonal profile was observed along with the resolution of visual disturbances and headaches.

Conclusion

Thus, functional gonadotroph adenoma should be considered in the presence of elevated testosterone/estrogen and normal or elevated follicle-stimulating hormone (FSH)/ luteinizing hormone (LH). Early diagnosis leads to a better outcome.

EP157

Psychological effects of cabergoline in a patient with a giant prolactinoma.

Hiba-Allah Chatti, Ibtissem Oueslati, Fatma Chaker, Meriem Yazidi & Melika Chihaoui
La Rabta Hospital, University of Tunis El Manar, Faculty of Medicine, Endocrinology, Tunis, Tunisia

Introduction

Psychological disorders may be expected in patients with hyperprolactinemia. Indeed, they generally have poor quality of life, anxiety, depression and certain personality troubles. Dopamine agonists are the first-line treatment of prolactinoma. Recently, an increasing number of reports emphasized on dopamine agonists psychological side effects. Effectively, some patients develop de novo psychiatric symptoms or have exacerbation of pre-existing conditions during dopamine agonist therapy. We report the case of a patient with prolactinoma who developed a psychiatric disorder after cabergoline therapy initiation.

Observation

A 42-year-old woman was referred to our department for pituitary apoplexy. Her past medical history revealed a type 2 diabetes mellitus. She presented with headaches and disturbed vision. Pituitary MRI showed a giant pituitary adenoma with hemorrhagic necrosis extending to the sphenoid sinus and optic chiasm, and complicated by hydrocephalus. On physical examination, she had a body weight of 75 kg, a body mass index of 27 kg/m^2, a blood pressure of 120/70 mmHg. Biological investigations revealed hyperprolactinemia (2975 ng/ml) with gonadotropic deficiency. After ruling out a neurosurgical indication, the patient was put on dopamine agonist therapy (Cabergoline 1 mg/ week). One day after treatment initiation, the patient developed an acute delirium with temporo-spatial disorientation and a suicide attempt. No further treatment was needed, just a close follow up. One week after, neurological and psychological condition was stabilized.

Conclusion

Patients with hyperprolactinemia receiving dopamine agonists may develop changes in mood and behavior regardless of prior psychiatric history.

Larger prospective controlled clinical studies are needed to delineate the prevalence of these psychiatric complications and to assess their appropriate management.

EP158

Rapid decrease of a pituitary mass with gonadotrophic and thyrotrophic insufficiency – the case for lymphocytic hypophysitis?

Monica Livia Gheorghiu[1,2], Bunea Irina Andreea[1], Sofia Maria Lider Burciulescu[1], Dumitrascu Anda[1] & Aldea Ramona[3]
[1]C.I. Parhon National Institute of Endocrinology, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucureşti, Romania; [3]Spitalul Municipal Câmpulung, Câmpulung, Romania

Background
Lymphocytic hypophysitis is an unusual inflammation of the pituitary gland affecting mostly women. Its pathogenesis is still poorly understood and the presentation and clinical course vary largely. Serum prolactin levels may be low, normal, or elevated. Unlike what is observed in clinically nonfunctioning pituitary adenomas, there is not a clear hierarchy of anterior pituitary hormone deficiencies. Hypophysitismay resolve spontaneously, may relapse, and in some cases may be refractory to treatment.
Case presentation
A 47-year-old woman with history of sudden secondary amenorrhea at the age of 46 andsubsequent hot flashes, discovered galactorrhea incidentally after 6 months. Her initial evaluation revealed mild hyperprolactinemia 1532 uIU/ml (127–637), significantly low FT4 5.7 pmol/l (12–22), T4, FT3 and T3 0.8 nmol/l (1.3–3.1), mildly increased TSH 5.61 uIU/mLand increased TPOAb. Levothyroxine (LT4) 50 µg was introduced, but T4 and T3 remained low despite normal TSH, indicating central hypothyroidism, interestingly without any clinical signs. Gonadotrophic insufficiency was documented: FSH 5.4 uUI/l, LH 0.92 IU/L, E2 < 5 pg/ml. MR imaging revealed aninhomogeneous, hypodense, contrast enhancing 1.1 cm sellar mass in contact with the optic chiasm, and left deviation of pituitary stalk. Cabergoline (CAB) 0.5 mg/week was added, with rapid PRL decrease to subnormal values, but amenorrhea persisted. At presentation in our clinic, the patient had only amenorrhea with nogalactorrhea, headaches, visual impairment orpolyuria. On LT4 35 µg/day and CAB 0.25 mg/week, TSH: 4 uIU/ml, FT4 10.5 pmol/l (9–19), T3: 72.8 ng/dl (80–200), morning cortisol 12.33 µg/dl (6–22), low PRL, IGF1 83.15 ng/ml (60–240), low FSH, LH and estradiol (2.74 IU/l, 0.92 IU/l, 20.52 g/ml, respectively). A rapid GnRH test showed partialresponse of LH (4.66 IU/l), with an estradiol increase to 110.7 pg/ml. Repeated imaging (at 3 months) showed a significant shrinkage of the more inhomogenousand hypodense pituitary mass. This rapidly decreasing infiltrative-like pituitary mass associated with partial pituitary failure, possibly due to pituitary stalk compression (gonadotrophic&thyrotrophic insufficiency and mild hyperprolactinemia) suggests a possible lymphocytic hypophysitis. Confirmation could be obtained only by pituitary biopsy or surgery, which were not recommended yet.
Conclusions
Lymphocytic hypophysitis is a rare inflammatory disease of the pituitary gland which is frequently a diagnosis of exclusion. It can be associated with atypical pituitary insufficiency and with spontaneous remission of the pituitary mass. Of note, central hypothyroidism may present with low FT4/T4 and low, normal or even mildly elevated TSH.

Diabetes insipidus

Hadj Kacem Faten[1], Gorchene Asma[2], Dhoha Ben Salah[1], Sidina Mohamed Elmoctar[1], Fatma Mnif[1], Nadia Charfi[1], Mouna Mnif[1], Nabila Rekik Majdoub[1], Mouna Elleuch[1] & Abid Mohamed[1]
[1]Hedi Chaker Hospital, Sfax, Tunisia; [2]Hospital farhat hached, Sousse, Tunisia

Background
Diabetes Insipidus is a complex and heterogeneous clinical syndrome affecting water balance, resulting in large volumes of dilute urine. Determining the mechanism and etiology of diabetes insipidus, as well as differentiating it from other pathologies that cause polyuria and polydipsia has always been a challenge since water deprivation test is not always conclusive and antidiuretic hormone can not be reliably measured in the circulation.
Aim
The aim of this study is to analyze the most common causes of diabetes insipidus, and thus determine the different etiologies of this disorder.
Methods
This study was conducted using SPSS including patients who had been diagnozed with diabetes insipidus, hospitalized between 2012 and 2020 in the Endocrinology Department of Hedi Chaker university hospital, Sfax, Tunisia.
Results
A total of 20 patients were included in this study. The average age was 60 years old. 13 of them were women and 7 were men. All of our patients had polyuria and polydipsia. Only 6 of them had signs of intracranial hypertension. No signs of dehydration was found in any of our patients. The average polyuria was quantified at 7.8 l/24 h. While average polydipsia was estimated at 7.2 l /24 h. An elevated plasma osmolarity was found in only two patients, estimated at 318 and 328 mOsm/l respectively. The average urinary osmolarity was 208 mOsm/l. Only 7 of our patients undertook a water deprivation test, it was well-tolerated in 5 of them, and poorly tolerated in 2, due to extreme thirst. The water deprivation test was in favor of central diabetes insipidus in 4 patients and inconclusive in 3 others. Central diabetes insipidus was found in 19 patients, while nephrogenic diabetes insipidus was found in only one patient. A lack of posterior pituitary hyperintensity on sagittal T1-weighted imaging was found in 7 out of the 19 cases of central diabetes insipidus. Neuro-surgery was the most common cause of central diabetes insipidus, found in 10 patients, while empty sella syndrome was found in 3 patients, head trauma in 2 patients, craniopharyngioma in 1 patient, and idiopathic central diabetes insipidus in 3 patients. While the nephrogenic diabetes insipidus was linked to lithium.
Conclusion
The patient history, MRI scan and water deprivation test usually suffice to establish the cause of diabetes insipidus, but some situations remain unclear and not devoid of discrepancy. Copeptin test may offer a promising accuracy regarding diagnosing the etiologies of diabetes inspidus.

A pituitary TSH and GH co-secreting adenoma presenting with thyrotoxicosis, but no symptoms of acromegaly: a case report

Rea Nagy[1], Anna Vágvölgyi[1], Nikolette Szucs[2], Balint Scheich[3], Gergely Nyari[4], Tibor Hortobagyi[4], Pal Barzo[5] & Zsuzsanna Valkusz[1]
[1]University of Szeged Faculty of Medicine, Department of Internal Medicine, Szeged, Hungary; [2]Semmelweis University Faculty of Medicine, Department of Internal Medicine and Oncology, Budapest, Hungary; [3]Semmelweis University Faculty of Medicine, I. Department of Pathology, Budapest, Hungary; [4]University of Szeged Faculty of Medicine, Department of Pathology, Szeged, Hungary; [5]University of Szeged Faculty of Medicine, Department of Neurosurgery, Szeged, Hungary

TSH producing pituitary adenomas are a rare cause of thyrotoxicosis. These tumors account for only 1–2% of the pituitary adenomas. Co-secretion occurs in 30% of thyrotropinomas and requires careful investigation and subsequent follow up.
A 43-year-old male presented with hand tremor and tachycardia. He was found to have elevated TSH, free T4 (FT4) and free T3 (FT3), but did not get treatment for years. In 2019 he developed atrial fibrillation. TSH was 7.65 mIU/l (0.55–4.78 mIU/l), FT4 was 28.5 pmol/l (11.5–22.7 pmol/l), FT3 was 13.69 pmol/l (3.5–6.5 pmol/l). In early 2020 he underwent an MRI of the brain, which showed a 25×18×18 mm pituitary macroadenoma. Basal growth hormone (GH) level was 0.99 ng/ml, and during an oral glucose tolerance test it remained 0.48 ng/ml at 60 min and decreased below 0.4 ng/ml at the other time points. In May 2020 he had transsphenoidal surgery. Histology showed plurihormonal hypophysis adenoma with extensive GH and focal prolactin (PRL) and TSH expression with immunohistochemistry, consistent with type 3 plurihormonal adenoma. Following the surgery he continued to have elevated TSH and FT3 levels and required beta-blocker therapy for symptom control. Thiamazole therapy was also attempted, but the patient did not tolerate it. Somatostatin analog therapy was also considered, but was not started. He continued to have heat intolerance, palpitations, anxiety and generalized weakness. On the 4-month postoperative sella MRI there was no significant change in the size of the pituitary tumor (25×16×15 mm). His TSH, FT4 and FT3 level increased to 9.4 mIU/l (0.27–4.2 mIU/l), 33.0 pmol/l (12.0–22.0 pmol/l) and 14.7 pmol/l (3.1–6.8 pmol/l) respectively. Basal GH level was 0.48 ng/ml, and during an oral glucose tolerance test it decreased below 0.4 ng/ml at all time points. In December

2020 he had a reoperation of the persistent tumor. Histology revealed GH immunohistochemistry positive hypophysis adenoma, but TSH positivity could not be verified. 6 days after surgery his TSH decreased to 0.03 mIU/l, FT3 to 3.0 pmol/l and FT4 to 18.6 pmol/l. One month after the surgery his TSH level was 0.81 mIU/l, FT3 was 2.6 pmol/l and FT4 was 6.3 pmol/l, therefore he was started on thyroid hormone supplementation. No other pituitary hormonal derangements were observed. First-line treatment of thyroptopinomas is pituitary adenomectomy followed by irradiation in the case of surgical failure. Our case highlights the importance of attempting definitive cure by removal of the tumor to avoid long-term effects of pituitary irradiation.

Predictive factors of macroprolactinoma aggressiveness: case report and review of literature

Hind Asbar, Sana Rafi, Ghizlane EL MGHARI & Nawal El Ansari
[1]Mohammed VI University Hospital of Marrakesh, Department of Endocrinology, Diabetes, Metabolic Diseases and Nutrition, Mohammed VI University Hospital, Marrakesh, Marrakesh, Morocco

Introduction
Prolactinomas are the most frequent pituitary tumors. They are usually benign with a good response to conventional medical treatment by dopaminergic agonists (DA). However in some cases, prolactinomas are defined as invasive or aggressive according to clinical, radiological, biological and histopatholgical arguments. The aim of our case report is to discuss potential predictors of aggressiveness in prolactine secreting pituitary tumors.
Case report
A 56 year-old female patient, was admitted in hospital for a giant pituitary adenoma revealed by opto-chiasmatic syndrome. MRI showed a giant macroadenoma measuring 54 × 50 × 54 mm with latero supra and infrasellaire extension and lytic lesions of sphenoid bone and clivus. Hormonal explorations showed a hyperprolactinemia of 48 658 ng/ml (monomeric prolactin represented 95% of total prolactin ruling out a macroprolactinemia) with a secondary gonadal and corticotropic defiencency. Partial transcranial adenomectomy was performed then cabergoline was started at 1 mg/week. Histological assessment confirmed a macroadenoma with a Ki67 of 5%. Follow up imaging and biological assessement are in progress.
Discussion
Aggressive pituitary tumors (APTs) are defined as radiologically invasive tumors with an unusually rapid tumor growth rate, or relevant tumor growth despite optimal standard therapies. The World Health Organization 2017 classification of pituitary tumors abandoned the previous term 'atypical pituitary adenoma' and categorizes prolactinomas into PRL-producing adenomas and APTs or carcinomas in case of metastases. Invasiveness alone is insufficient to define APTs, but is still considered as a key component of aggressiveness. APTs typically evolve from macroadenomas with lactotroph and corticotroph tumors predominating. In our case, the giant prolactinoma with invasive radiological signs and lytic bone lesions were suggestive of aggressiveness. However, radiological and biological evolution after surgical and correctly conducted medical treatment will settle the diagnosis.
Conclusion
Prolactinomas are the most frequent secreting pituitary tumors. Their treatment is well established due to their good response to DA. However, some cases can be invasive with a rapid growth pattern. Predictive factors of aggressiveness are not well defined but tumor size, early radiological signs of invasiveness as well as histological assessement may be suggestive of such entity.

Pituitary macroadenoma and Covid-19 infection

Sona Maghakyan[1,2] & Elena Aghajanova[1,2]
[1]Muratsan University Hospital, Endocrinology, Yerevan, Armenia; [2]YSMU, Endocrinology, Yerevan, Armenia

Introduction
SARS-CoV-2 is a novel coronavirus rapidly spread throughout the world.. As it is already known, several endocrine organs do express ACE2, namely, pancreas, thyroid, testis, ovary, adrenal glands, and pituitary We report a patient diagnosed with pituitary incidentaloma and Covid-19. We would like to introduce our experience in treating patient with pituitary incidentaloma and covid-19.
Materials and methods
A 71-yowoman with a history of pituitary macroadenoma was admitted to Heraci University hospital with bilateral pneumonia related to coronaviral infection. According to the patient at the age of 43 after the second delivery (she had 2 pregnancies, 2 deliveries) an olfactory disorder was developed and then 2 years later she was treated by neurologists for trigeminities for many years. In March 2020 she had severe headaches, abrupt deterioration of vision, diplopia,. Brain MRI was performed and it revealed pituitarycystic macroadenoma with compression of chiasmus opticus, spread to cavernous sinuses. Lab results revealed TSH = 10.05 µIU/ml (*n* 0.27–4.2), FT4 = 0.780 ng/dl (*n* 0.93–1.7), level of cortisol, ACTH, prolactin were in normal laboratory ranges, as well as HbA1C, glucose and blood electrolites, Pituitary macroadenoma (incidentaloma) and primary hypothyroidism were diagnosed and L-thyroxin 50 mkg together with cabergolin 0.5 mg twice a week (before surgery) were prescribed. In October 2020 patient had following complaints- high temperature, general weakness, shortness of breath. SARS COV-2 PCR test positive. She got treatment at home by GP -Levofloxacin 500 mg 7 days, Dexamethasone 6 mg 4 days, Enoxaparin, Ibuprofen. She was admitted to the hospital on the 12th day of the illness with BMI = 25.3, SpO2 85%(O2-), 96%(O2 +), BP = 120/80 mmHg, Ps = 85 bpm, T = 38.5°C. Chest CT-bilateral pneumonia with a typical viral etiology, mild lesions up to 15%.

	Result	*n*
Lymphocytes	0.62%	(1.00–3.70)
ESR	41Mm/hr	(2–15)
CRP	6.234 mg/dl	(< 0.5)
AST	65.9 mmol/l	(< 35)
ALT	86.5 mmol/l	(< 40)
glucose	8.9–7.0–6.2 mmol/l	(4.2–6.1)
Prolactin	0.860 ng/ml	(6–29.9)
TSH	2.43 µIU/ml	(0.27–4.2)
FT4	1.11 ng/dl	(0.93–1.7)

Treatment underwent – infusion therapy, Dexamethasone 12 mg with dose decrease to 4 mg, Heparin 10000 U daily, Aspirin, Quamatel, Spironolactone, Galvus 50 mg, L-thyroxin 50 mkg, Oxigen
Results.
The patient improved on treatment. She has no temperature since the 2nd day. Saturation without oxygen was 90% from the 6th day. The patient was advised to continue L-thyroxine therapy with the same dose, remove cabergoline and check prolactin in 6 weeks. Monitoring of glucose level was recommended. After stabilization, surgical treatment of macroadenoma is recommended.

Analysis of clinical and biological features of non-functioning pituitary adenomas: A retrospective study

Hadj Kacem Faten, Khouloud Boujelben, Ghariani Imene, Gdoura Salma, Charfi Nadia, Mnif Mouna, Mnif Fatma, Rekik Nabila, Abid Mohamed
Hedi Chaker Hospital, Department of Endocrinology, Diabetology, Sfax, Tunisia

Introduction
Non-functioning pituitary adenomas (NFPA) present approximately 15% to 30% of all pituitary adenomas. They are most commonly misdiagnosed, until they are large enough to lead to mass effect and hypopituitrasm. The present study was carried out with the aim of studying the clinical and biological characteristics of patients who are followed for NFA.
Patients and methods
This is a retrospective study of 35 patients presenting with NFPA, at the department of endocrinology at Hedi Chaker hospital Sfax-Tunisia, from January 2000 to December 2017.

Results
There were twenty males (57.14%) and fifteen (42.85%) females. The average age of patients was 49.23 years (16–75 years). The majority (48.57%) were aged between 40 and 60 years-old. Approximately 31.4% of patients were smokers. Headache was a major complaint for 28 patients (88%). Most of the patients reported to present moderate headache (57.14%, n = 16). Severe and mild headache were reported in 39.2% (n = 11) and 3.5% (n = 1), respectively. Holocranial headache was present in 32.1% of patients, followed by the bitemporal (35.7%) and frontal (9.5%) regions. Visual symptoms were identified in 74.28% of our study group. Blurring and progressive loss of vision were present in 53.8% and 73% of cases, respectively. Intracranial hypertension occurred in 6 cases (17.14%). Most tumors were macrodenomas, 32 (91.4%) vs 3(8.6%) microadenomas. Endocrine evaluation revealed central hypothyroidism in 34.28% of patients, presenting all a macroadenoma, with a mean level of thyroxine hormone (T4) and thyroid-stimulating hormone (TSH) of 6.95 pmol/l and 1.56 µUI/l, respectively. Adrenal insufficiency was observed in 37.65% of patients with a mean basal cortisol level of 56 µg/l. Prevalence of hypogonadotropic hypogonadism (HH) was 55% on males with a mean testosterone level of 1.12 ng/ml (range.0.02–2.8 ng/ml). On the other hand, 53.3% of the female group presented HH with an average level of oestradiol of 11.4 pg/ml (8–17.7 pg/ml). Disconnection hyperprolactinemia was found in 28.57% of patients with a mean value of 35.29 ng/ml.
Conclusion
NFPA present a heterogeneous group of pituitary tumors that range from being totally asymptomatic to inducing visual disorders and pituitary dysfunction secondary to mass effect. While NFPA are benign tumors, their management require treatment and regular monitoring and follow up.

EP164

Is hypoprolactinemia also associated with sexual dysfunction?

Zuleyha Can Erdi[1] & Cigdem Ozkan[2]
[1]University of Health Sciences Izmir Bozyaka Education and Research Hospital, Internal Medicine, Izmir, Turkey; [2]University of Health Sciences Izmir Bozyaka Education and Research Hospital, Endocrinology and Metabolism, Izmir, Turkey

Our knowledge about sexual dysfunction during the treatment of patients with prolactinoma is limited. The sexual dysfunction may not improve or turn out a different form as in our patient. Delayed ejeculation (DE) is a complex form of male sexual dysfuntion, characterized by a considerable delay in ejaculation or an inability to complete ejaculation. Both organic and psychogenic etiologies can cause DE, however the pathophysiology is indefinite. In this case, we present a male patient who had developed delayed ejeculation during his follow-up period. A 33-year-old male patient was admitted to our outpatient clinic with complaints of loss of libido, impotence and premature ejaculation. His hormone profile showed hyperprolactinemia, prolactin level was determined as > 200 ng/ml and magnetic resonance imaging (MRI) of the pituitary revealed a macroadenoma. The patient diagnosed as a prolactinoma and cabergoline was started 1 mg per week. Four months after cabergolin, prolactin level was 0.63 ng/ml (2.64–13.13). The patient's loss of libido regressed, but initially described delayed ejaculation rather than pre-existing premature ejaculation. He presented with different patterns of sexual dysfunction in his follow-up period. The effects of prolactin on the male reproductive system have not been clearly elucidated yet. Hyperprolactinemia disrupts the pulsatile secretion of GnRH and cause sexual dysfuntion. Recovery of sexual dysfunction is expected after treatment with dopamine agonists. However, the long-term suppression of the stimulating pathways in the hypothalamus and the psychological reasons caused by the initial complaints in the patients may be effective in persisting sexual dysfunction. Delayed ejeculation is a multifactorial condition that can be both organic and psychogenic, and the pathophysiology is unclear. Hypoprolactinemia was found to be associated with metabolic syndrome and worse glycemic and lipid control. In a study a higher prevalence of erectile dysfunction was found in patients with hypoprolactinemia, but no difference was found in the prevalence of DE. As a conclusion, there isn't enough data in the literature regarding sexual dysfunction in patients with prolactinoma during the follow-up period. In our patient, the psychological reasons caused by the initial complaints may also lead to development of delayed ejaculation. With this case presentation, we aimed to highlight the need to increase the number of studies on sexual dysfunction in the follow-up of patients with prolactinoma.

Key words: Prolactinoma, erectil dysfunction, sexual dysfunction, delayed ejeculation, cabergolin

Hypopituitarism in young patients: clinical aspects and diagnosis

Hadj Kacem Faten, Oumeyma Trimeche, Dhoha Ben Salah, Hamdi Frikha, Mahdi Chaabouni, Fatma Mnif, Nabila Rekik Majdoub, Mouna Mnif, Nadia Charfi, Mouna Elleuch & Abid Mohamed
Hedi Chaker Hospital, Sfax, Tunisia

Introduction
Hypopituitarism is the partial or complete loss of anterior pituitary function that can result from acquired or congenital causes. Understanding its clinical aspects in children could lead to early diagnosis and therefore better outcome.
Objective
The aim of this study is to evaluate the characteristics of presentation, and etiology of Hypopituitarism in children.
Methods
This descriptive retrospective database study was conducted at the Hedi Chaker university hospital, Sfax, Tunisia after collecting medical records of patients having in common anterior hypopituitarism.
Results
We collected the data of 20 patients with an average age of 10 years (between 1 and 18 years), SR was 4. In 70% of the cases, the discovery circumstance was other physicians suspecting the disease and therefore referring the patients to us. Family history showed an autoimmune disease in 10% of the cases and only 5% had a family member with hypopituitarism. 35% of our subjects had fetal distress, 5% had neonatal hypoglycemia, 10% had micropenis and 10% had a history of head trauma. Up to 75% of the individuals of our study group had growth retardation, 25% had puberty delay and 10% presented intellectual deficiency. The mean BMI was 20 ± 3.8 kg/m^2 and the mean height Standard Deviation was 1.5 ± 1.6. For those with growth retardation the mean age of the growth curve abruptness was 5 ± 2 years. The physical examination revealed that 25% of the individuals had dysmorphic appearance, 15% had depigmentation. The most common deficiency found was GH deficiency (80%) as well as gonadotropic deficiency (70%) whereas corticotropic deficiency was present in only 20% of the cases and thyrotropin deficiency in 15%. PRL was low in 10% of the cases, and high in 25%. No global hypopituitarism was found in our study group however 15% had partial hypopituitarism, the rest had only one pituitary hormone deficiency. MRI was conducted in 19 patients and was abnormal in 55% of the cases showing hypoplasic pituitary (15.7%), pituitary interruption syndrome (15.7%), hyperplasic pituitary (5.2%), primary empty sella syndrome (5.2%) and hypophysitis (10.5%). The most common causes of hypopituitarism found in our database were congenital causes (66.7%) followed by hypophisitis (11.1%) and hyperplasic pituitary (5%).
Conclusion
Diagnosis of hypopituitarism is important, because unrecognized pituitary dysfunction significantly affects the physical and psychological well-being of people.

Acromegaly: clinical and para-clinical study by gender

Marwa Jemaa, Nadia Khessairi, Wafa Grira, Yasmine Mouelhi, Meriem Yazidi & Melika Chihaoui
Rabta Hospital, Endocrinology, Tunis, Tunisia

Gender is a factor in clinical presentation, biological and morphological characteristics in certain types of pituitary adenomas. Concerning acromegaly, this influence is not well known. In our retrospective study of 32 patients, 12 women and 20 men, hospitalized in our department from 2002 to 2019, we have realized a comparative clinical, para-clinical, therapeutic and prognosis. The median age of women is 47 years, the same as that of men. The average duration of disease progression is similar in both sexes (2.8 years). Extremity hypertrophy affects 88% of women vs. 80% of men, dysmorphic syndrome: 100% vs 95%, arthralgias: 83% vs. 63%, sleep apnea: 85% vs. 60%, organomegaly: 75% vs. 56%, diabetes mellitus: 41% vs. 45%, hypertension: 58% vs. 40%, hypertrophy of the left ventricle: 54% vs. 42%. We found microadenomas in 10% of men, macroadenomas: 100% vs. 89%. Acromegaly was associated with hyperprolactinemia in 54% of woman vs 11% of men, and complicated by corticotroph insufficiency in 66% vs 87%, thyreotropic and gonadotropic insufficiency were slightly the same in both sexe. Complications are slightly similar in both sexes except

for microadenomas which seems to be less frequent in the woman group and hyperprolactinemia which is more frequent in this group.

Delayed diagnosis of acromegaly: a two-year journey

Asma Bitar De Zayas-Enriquez, Nemanja Stojanovic & Gideon Mlawa
Barking, Havering and Redbridge University Hospitals NHS Trust, UK

Aims
To present the case of a 69 year-old female patient who was diagnosed with acromegaly two years following the initial onset of facial and acral symptoms, having already developed colonic hyperplastic polyps, one of the complications associated with acromegaly, one year prior to diagnosis.
Material
Case report and literature review.
Method
Acromegaly was diagnosed based on clinical suspicion, raised IGF-1 level, absence of GH suppression following OGTT, brain MRI and histology.
Results
After recognition of phenotypical, particularly facial and acral, features of acromegaly, IGF-1 level was elevated at 624 nmol/l, OGTT failed to suppress GH nadir levels, and brain MRI showed a pituitary macroadenoma which was identified histologically as a mixed, sparsely granulated somatotroph and lactotroph adenoma.
Conclusion
The onset of acromegaly can be insidious in older patients leading to complications and delayed diagnosis. Early diagnosis of acromegaly and effective screening and monitoring for its complications decrease morbidity and mortality and improve overall prognostic outcomes and quality of life.

Acromegaly and discoid lupus: a case report

Samira Bichri, Nassim Essabah Haraj, Siham El Aziz & Asmaa Chadli
Department of Endocrinology and Metabolic Diseases University Hospital Center Ibn Rochd - Casablanca, Laboratory of Clinical Neurosciences and Mental Health Faculty of Medicine and Pharmacy – Hassan II University, Casablanca, Morocco

Introduction
Acromegaly is an acquired endocrine pathology associated with the overproduction secondary to hypersecretion of growth hormone, by a somatotropic pituitary adenoma in more than 90% of cases, the symptoms of which may concern various organs (eye, heart, colon, etc.). skin….). Occasionally, it can present itself in association with skin changes which in some cases are very rare. We report the observation of a patient followed for acromegaly and discoid lupus
Presentation of the case
his is a 43-year-old patient, followed for acromegaly since 2014, held in front of a facial dysmorphia and on a paraclinical level on an IGF-1 level at 337 ng/ml (80–271) × 1.49 normal and pituitary MRI: pituitary macroadenoma of 24 × 17 × 27 mm somatotropic on anathomopathological examination operated twice in 2014 then resumption of surgery in February 2017 by the transphenoid route, complicated by an anterior pituitary thyreotropic and gonadotropic insufficiency started on treatment substitute Levothyrox 75 µg/d; Trisequens, with surgical failure then put on somatostatin analogues. On skin and mucous membrane examination: presence of two atrophic lesions with irregular borders surmounted by scales on both cheeks suggesting discoid lupus. At skin biopsy: Appearance compatible with lupus. The anti native DNA and antinuclear antibodies are negative.
Conclusion
The association of discoid lupus and acromegaly is exceptional, one can observe during acromegaly hypertrichosis, multiple pendulum molluscums, diffuse melanoderma or acanthosis nigricans, frontal skin signs and scalp and therefore know these associated skin lesions. at acromegaly can facilitate its diagnosis.

Multiple endocrine neoplasia type 1: clinical features, diagnostics

Andrew Burak
Ternopil State Medical University, Department of Surgery №1, Ukraine

Background
In medical practice, there occurs an increasingly common pathology of various endocrine and not only these organs, which is known as multiple endocrine neoplasia – MEN syndrome, which, depending on the affected organs, is classified as MEN type 1, MEN type 2 and MEN type 3. Multiple endocrine neoplasia type 1 (MEN-1, Wermer syndrome) is a rare hereditary disease with an autosomal dominant type of inheritance characterised by high penetrance and the presence of hyperplasia and neoplasia in at least two different endocrine organs. The purpose of the study is to to investigate the features of diagnosis and treatment tactics of the MEN syndrome type 1 based on a clinical case.
Materials and methods
We examined Patient K. born in 1979. Diagnostics methods used in this case were: laboratory – determination of the level of prolactin, vasoactive intestinal peptide, calcitonin, vitamin D3 (25-OH) D, parathormone, calcium, aldosterone, chromatographic A; and instrumental – ultrasound, CT, PET/CT.
Results
The peculiarity of this case is that the disease started with persistently recurrent prolactinoma, which was characterised by the resistance not only to therapeutic but also to surgical treatment. Treatment with radiolabeled somatostatin analogues is a new promising treatment for patients with inoperable or metastatic neuroendocrine tumors.
Conclusions
The difficulty of diagnosis of patients with combined pathology is that by fixing on one disease, you can miss the beginning of the other diseases. In this particular case, by concentrating on a tumor of the pancreas, it was possible to omit the recurrence of prolactinoma.

Gonadotropic pituitary adenomas

Soumiya Berrabeh, Imane Assarrar, Ouafae Elmehraoui, Wahiba Abdellaoui, Siham Rouf & Hanane Latrech
Mohammed VI University Hospital, Department of Endocrinology-Diabetology-Nutrition, Oujda, Morocco

Introduction
Gonadotropin-secreting adenomas occupy nowadays the third or fourth place of all pituitary adenomas (12 to 17% of pituitary adenomas operated on), after prolactinomas, somatotropic adenomas and corticotropic adenomas. They can be either accompanied by hypersecretion of gonadotropins or their dosable subunits in plasma recognized only by immunocytochemistry. Gonadotropic adenomas are not uncommon. They are often misknown because they lack any particular clinical expression. Indeed, they are most often revealed at the macro adenoma stage by a tumor syndrome or signs of anterior pituitary insufficiency. The objective of our work is to describe the epidemiological, diagnostic and therapeutic aspects of gonadotropic adenomas.
Material and methods
This is a retrospective study that focused on the cases of pituitary adenomas, collected at the Endocrinology – Diabetology and Nutrition Department of Mohammed VI University Hospital in Oujda, over a period of 6 years and a half. The data were collected from medical records and the analysis was done by SPSS version 21 software.
Results
The gonadotropic adenoma represents 4% of all pituitary adenomas. The average age of our patients was 44.6 years, mostly present in women (sex ratio: 2/1). The reason of consultation was a pituitary tumor syndrome with a decrease in visual acuity in the majority of cases. The average body mass index was 28.2 ± 5.01 kg/m^2. All of our patients had a macro adenoma with signs of ophthalmologic and neurological impact. In our series, all the patients were symptomatic and showed at least one endocrine sign; the most common one being hypogonadism in 66.6% of cases and isolated amenorrhea in 33.3% of the cases. Regarding biological assessments, only one patient had a high level of FSH and LH gonadotropins with low estradiol and a high level of subunits, while the rest of the patients had hypogonadotropic hypogonadism. All our patients benefited from a partial removal of the macro adenoma using endoscopic transsphenoidal surgery, with simple post-operative care. A revision surgery was noted in one patient

and all our patients had a corticotropic and thyroid hormone substitution postoperatively.
Discussion/conclusion
Gonadotropic pituitary adenomas, now recognized with greater frequency with the progress of immunocytochemistry, have become an important chapter in pituitary pathology. A better analysis of the secretion of gonadotropins and their free subunits, with the help of stimulation tests if necessary, allows a significant number of these adenomas to be recognized.

Acromegaly in the elderly: about 3 cases
Ajili Rihab, Yosra Hasni, Gorchene Asma, Ben Abdelkarim Asma, Ghada Saad, Maha Kacem, Molka Chadli Chaieb, Amel Maaroufi & Koussay El Euch
Farhat Hached Sousse, Endocrinology, Sousse, Tunisia

Introduction
Somatotropic adenomas in the elderly are rare, and characterized by diagnostic delay and non-specific clinical signs. We report three cases of acromegaly discovered at a late age.
Observation
They are three women aged 66, 68 and 77 respectively. The circumstance of discovery of acromegaly was goiter in the first case (P1), poorly controlled diabetes in the second case (P2) and dysmorphic syndrome in the third case (P3). The level of IGF1 was respectively for P1 and P2, 1084 ng/ml and 1700 ng/ml. P1 had hyperprolactinemia with gonadotropic insufficiency. The pituitary axis was intact for P2 while P3 had panhypopituitarism. All the patients were diabetic and had joint involvement. P1 and P3 were hypertensive with left ventricular hypertrophy. It was a macroadenoma with invasion of the optic chiasm in all three cases. P1 presents with progressive acromegaly despite surgery twice with a preparation with somatostatin analogues. P2 was cured by the combination of surgery, radiotherapy and somatostatin analogues while P3 was lost to follow-up after surgery.
Discussion and conclusion
Acromegaly in the elderly is frequently associated with diabetes and hypertension. Surgery remains the treatment of choice. If it is contraindicated in the face of fragile conditions in the elderly, treatment with somatostatin analogues should be considered as a first-line treatment. The prognosis of acromegalic patients is inversely correlated with the patient's age.

Recurrence of hypercortisolism after long-term post-transsphenoidal surgery remission in a patient with Cushing disease
Anca Lorena Barbuceanu[1] & Constantin Cucu[1,2]
[1]'CI Parhon' National Institute of Endocrinology, Bucharest, Romania; [2]'Carol Davila' Univesity of Medicine and Pharmacy, Bucharest, Romania

Selective transsphenoidal resection of the pituitary adenoma is the initial treatment of choice for Cushing disease. Although the achievement of low cortisol levels following transsphenoidal surgery for Cushing disease is associated with surgical success, recurrence can still occur.
Case presentation
A 38 years old female patient, known with Cushing disease, secondary hypertension, type 2 diabetes and osteopenia, is admitted to our clinic in march 2019, after the second transsphenoidal surgery with symptoms suggesting a cortisol deficiency (nausea, vomiting, fatigue). The patient had her first transsphenoidal surgery in 2010, after which she also presented cortisol deficiency with the recovery of the hypothalamic–pituitary–adrenal axis after 1 year and maintenance of remission for several years.

	10.2010	01.2011	06.2011	09.2011	01.2017	07.2017	02.2019	03.2019
Cortisol 8^{00} (*n* 4.8–19.5 µg/dl)	33.77	0.78	2.70	6.25	10.54	12.09	17.5	0.37
ACTH 8^{00} (*n* 4–66 pg/ml)	68.42	–	11.22	18.68	36.35	49.95	39.83	8.3
Cortisol after DXM 2×2	17.56	–	–	–	2.78	2.6	4.39	–
Urinary free cortisol (n = 21–111 µg/24 h)	–	–	–	–	108.64	98.28	–	–
Imagistic exam (pituitary adenoma dimensions on CT or MRI)	0.8/0.69 cm	0.38/0.25 cm	–	–	0.7/0.4 cm	–	0.6/0.5 cm	0.37/0.27 cm
Secondary comorbidities					Newly diagnosed hypertension (maximal value 220/110 mmHg)		Newly diagnosed diabetes (HbA1c = 7.2%, a jeun glycemia = 138 mg/dl) and hypercholesterolemia	
		⇧ First TS Surgery					⇧ Second TS Surgery	

Clinical exam
BP = 140/80 mmHg, HR = 80 bpm, cushingoid facial features, axillary acanthosis nigricans, no headache, no visual field disturbance, central redistribution of obesity, reduction of muscle strength, no new stretch marks, old, whitish stretch marks with loss of substance on the lower abdomen, hyperpigmented areolas, regular menses.
Biochemical tests
secondary adrenocortical insufficiency, normal gonadotrophin levels, normal thyroid function
Treatment
Prednisone 5 mg per day was started and follow-up after 3 months was recommended
Conclusion and discussion
Patient diagnosed with Cushing disease 10 years ago, who seemed in remission after the first TS surgery, returned after 5 years with newly diagnosed hypertension, without any other clinical signs of Cushing and a non-suppressible cortisol value, but a normal urinary free cortisol. We recommended the patient to come for reassessment after 3 months, but she did not comply and returned after 2 years with newly diagnosed diabetes, Cushing phenotype and greater hypercortisolism**.** Even if the patient with Cushing disease seems to evolve favorably post-TS surgery, the long-term follow-up for the possibility of recurrence is needed.

The psychogenic polydipsia: clinical and biological profiles
Hadj Kacem Faten, Khouloud Boujelben, Dhoha Ben Salah, Frikha Hamdi, Charfi Nadia, Mnif Fatma, Mnif Mouna, Rekik Nabila, Elleuch Mouna & Abid Mohamed
Hedi Chaker Hospital, Sfax, Tunisia, Department of Endocrinology, Diabetology

Introduction
Psychogenic polydipsia (PPD), also known as self-induced water intoxication, is mostly seen in psychiatric populations. PPD can lead to life threatening complications and may even be lethal if not diagnosed and treated early. The aim of this study is to determine the clinical and biological features of PPD.
Patients and methods
A retrospective study including 11 patients consulting for polydipsia at the department of endocrinology at Hedi Chaker-hospital Sfax-Tunisia, between 2000 and 2020.
Results
Mean age was 39.6 years old, with no sex predilection (6 males and 5 females).
Family history of diabetes mellitus was observed in 6 patients. A history of psychiatric illness was found in 33.5% of patients. Average duration of symptoms was 2.6 years (range:5 months-5 years). Polydipsia was abruptly onset in 4 cases. The anamnesis revealed a pituitary tumor syndrome in 4 patients. On examination, none of our patients showed signs of dehydration. The natraemia varied between 136 and 141 mmol/l. No cases of hypokalemia, hypercalcemia, diabetes, or renal failure were found. The mean quantified diuresis was 5.8 l/24 h with a maximum of 9.5 l/24 h. The mean urine specific gravity was 1003. The mean urinary osmolality was 177.3 mOsmol/kg. All patients underwent an indirect water deprivation test (WDT) combined with the administration of desmopressin that concluded to PPD in all cases. Magnetic resonance imaging of the hypothalamic–pituitary

region was performed in 6 patients and showed microadenoma in 2 cases and partial empty sella in one patient.
Conclusion
PPD is common in patients with psychiatric personality and psychosis such as schizophrenia and psychotic depression. Though no specific treatment has been established for PPD, its management includes water restriction cognitive behavioral therapy.

Acromegaly and cardiovascular risk factors

Wiem Madhi, Nadia Khessairi, Yasmine Mouelhi, Wafa Grira, Meriem Yazidi & Melika Chihaoui
La Rabta Hospital, Endocrinology, Tunis, Tunisia

Introduction
Acromegaly is a rare chronic disorder caused by GH hypersecretion. It's associated with an elevated morbidity and mortality rate. Cardiovascular diseases' complications are the first cause of mortality in patients. In this study we conducted an assessement of cardivascular risk factors in patients with acromegaly.
Patients and methods
A retrospective evaluative study of 32 patients followed for acromegaly from 2002 to 2019 in the department of Endocrinology, University Hospital La Rabta.
Results
Patients were 63% male and 37% female, sex ratio was 1.7. The mean age was 47.9 ± 13.2, six (19%) female patients were older than 50 years and five (16%) male patients were older than 60. Nine patients (28%) were active smokers and 17 (54%) were obese. Diabetes was present in 14 patients (44%) and glucose intolerance in 6 (18%). Hypertension was diagnosed in 15 patients (47%). Ten (21%) patients had dyslipidemia in which 7 had hypercholesterolemia and 9 had hypertriglyceridemia. Two patients had no CV risk factors, four had only one factor, 11 patients (34%) had two factors and 15 (47%) had three or more CV risk factors.
Conclusion
Incidence of cardiovascular risk factors in patients with acromegaly is higher than general population. This is explained by the insulinoresistance caused by the excess of growth hormone. Thus to reduce cadiovacular morbidity and mortality, it is necessary to diagnose and treat the acromegaly and the associated cardiovascular risks as early as possible.

Gynecomastia: a descriptive analysis

Mouna Elleuch[1], Oumeyma Trimeche[1,2], Dhoha Ben Salah[1], Wajdi Safi[1], Fatma Mnif[1], Nabila Rekik Majdoub[1], Mouna Mnif[1], Nadia Charfi[1], Hadj Kacem Faten[1] & Abid Mohamed[1]
[1]Hedi Chaker Hospital, Sfax, Tunisia; [2]Khniss, Tunisia

Introduction
Gynecomastia is the most common breast condition in men. The aim of our study is to describe clinical and therapeutic characteristics of patients with gynecomastia.
Methods
A descriptive retrospective study was conducted in the department of endocrinology at the Hedi Chaker hospital, Sfax, Tunisia.
Results
We collected the data of 28 patients with an average age of 37 years (extreme: 6 and 76 years) when having gynecomastia. Most patients presented spontaneously at the endocrinology office (53.3%). The rest were referred by other specialists. Five patients had a personal history of diabetes (17.9%), 3 had psychiatric disorder (10.7%).2 had a history of sterility (7.1%).1 had a renal failure, 1 was treated for hyperthyroidism, 1 had a bladder cancer and 1 subject had a Klinefelter disease. Symptoms associated with gynecomastia were hypogonadism in 39.3%, pituitary tumor syndrome in 3.6% and weight loss in 3.6%. The mean BMI was 29.4 ± 4.4 kg/m^2. Overweight and obesity were objected in 14.3% and 25% of patients respectively. Gynecomastia was bilateral for 18 patients (64.3%) and unilateral for 10 patients (35.7%) (left in 28.6% and right in 7.1%). No one in our group presented nipple discharge and only 2 had a painful gynecomastia. Gonadal examination was performed in 19 patients, and it was normal in 78.9% of them. Ectopic testicles were noted in 21.1% of cases. Laboratory tests showed hypergonadotropic hypogonadism in 35.5% of cases, hypogonadotropic hypogonadism in 14.3% and elevated PRL in 21.7%. Breast ultrasonography was performed in 35.7% of cases. The etiology was identified in 25 patients. The most common cause was physiological gynecomastia in 32% of cases, followed by drug induced gynecomastia in 24% (the drugs mostly incriminated were spironolactone, anti-depressants, omeprazole, chemotherapy). Treatment was conducted in only 10.7% of cases. The follow up of 22 of these patients showed a reduction in the volume of gynecomastia in 33.6% of cases and its disappearance in 66.7%.
Conclusion
Whereas in almost all the cases, gynecomastia has benign causes, it shouldn't be ignored because it can hide life threatening diseases.

DOI: 10.1530/endoabs.73.EP175

The coexistence of triple A syndrome and congenital hypogonadotropic hypogonadism

Marwa Majdoub, Meriem Adel, Imen Rojbi, Chayma Besrour, Lakhoua Youssef, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Charles Nicolle Hospital, Tunis, Tunisia

Introduction
Triple-A syndrome (AS) is a rare autosomal recessive disorder, defined by the coexistence of primary adrenal insufficiency (PAI), alacrimia and achalasia cardia. The association to other endocrine has so far not been reported in the literature. Herein, we describe the coexistence of AS and congenital hypogonadotropic hypogonadism in two cases.
Case presentation 1
An 18-year-old patient, child of a consanguineous family, was admitted for short stature, delayed puberty and gynecomastia. He had a medical history of triple AS: alacrimia, PAI was revealed at the age of 5 by recurrent convulsive seizures secondary to hypoglycemia, achalasia cardia diagnosed one year later and treated by Heller myotomy. Examination showed obesity, a height of 142 cm; his stature age = 11 years while his bone age = 13 years. Tanner stage G1P1A1. Growth hormone (GH) secretion was normal after stimulation. The testosterone serum level was low (0.14 nmol/l), basal LH level = 0.18 mU/ml and basal FSH level = 1.6 mU/ml. The positive response to the GnRH test indicates a hypothalamic origin of the gonadotropin deficiency. Hypothalamic pituitary MRI was normal. The karyotype was normal. A homozygous splice-donor site mutation (IVS14 + 1G > A) was found in the AAAS gene.
Case presentation 2
A 5-years-old male with a medical history of alacrimia, first consulted at the age of 5 for dysphagia, regurgitations and growth delay. Esophageal manometry confirmed the diagnosis of achalasia. And the low levels of serum cortisol at 28 nmol/l confirmed the diagnosis of PAI. A replacement therapy with hydrocortisone was started, and the patient underwent a myotomy at the age of 6. The patient's younger sister was also being treated in the same pediatric hospital for AS. He was referred to our department at the age of 23 for acute adrenal insufficiency. Examination showed a stature delay (height = 141 cm) and a normal development of secondary sex characteristics. His bone age corresponded to that of 14 years. Further investigation revealed a GH deficiency (L-Dopa test), and a hypogonadotropic hypogonadism (testosterone = 1.26 ng/ml, FSH = 3.3 mU/ml and LH = 3.97 mU/ml) resulting in osteoporosis. Pituitary MRI showed no abnormalities. Mutation screening is not yet performed.
Conclusions
To our knowledge, the association of AS to Hypogonadotropic Hypogonadism was never reported outside of our department. In absence of achalasia and alacrimia, PAI and hypogonadotropic hypogonadism in a male would point towards X-linked adrenal hypoplasia congenita. Nevertheless, AS diagnosis in these two cases was evident.

EP177

Marfan syndrome: a case report

Mansour Fatiha[1], Fedala Saida[1] & Djamila Meskine[2]
[1]Bologhine Hospital, Endocrinology, Algiers, Algeria; [2]Medical university of Algiers, Endocrinology & Metabolism laboratory Algiers 1, EPH Bologhine, Algiers, Algeria

Introduction
Marfan syndrome is a rare autosomal dominant genetic disease resulting from a mutation in the gene encoding type 1 fibrillin (FBN1), which is a glycoprotein in the composition of elastic fibers in connective tissue. It mainly affects the cardiovascular, musculoskeletal and ocular systems.
Case presentation
We report the case of a 14-year-old girl, with no particular history, referred to an endocrinology consultation for exploration of gigantism. At the clinical examination we immediately note her tall size: 185 cm which corresponds to more 3DS compared to the normal and to more 4 S.D. compared to the target size. Ligament hyperlaxity was objectified (wrist and thumb sign) associated with skeletal deformities such as pectus carinatum, arachnodactyly, hallux valgus of both feet, clawed toes and dorsal scoliosis. The hormonal tests shows an IGF1 level at 428 ng/ml (normal for the age and the pubertal stage (S4, P4)), in front of the strong suspicion of Marfan Syndrome a cardiac MRI was done, objectified a dilation of the sinus segment of the thoracic aorta, with a CMD on the left.
Discussion
marfan syndrome is the most likely diagnosis in front of a height increase associated with a dysmorphic syndrome, according to the criteria of GHENT (revised 2010): in the case of no family history of Marfan syndrome, the association of dilation of the ascending aorta to a systemic score > 7 (which = 9 in our patient) confirms the diagnosis.
Conclusion
Marfan syndrome is a disease that affects the connective tissue of several systems, hence the need for long-term multidisciplinary management in order to treat or even better prevent complications, specially cardiovascular complications.

Precocious puberty: two siblings, two diagnosis

Maria João Ferreira[1,2], Rita Moita[2,3], Sofia Ferreira[2,3], Carla Costa[2,3], Rita Santos Silva[2,3] & Cíntia Castro-Correia[2,3]
[1]Department of Endocrinology, Diabetes and Metabolism of Centro Hospitalar Universitário de São João, E.P.E., Portugal; [2]Faculty of Medicine of University of Porto, Portugal; [3]Department of Medical Pediatrics of Centro Hospitalar Universitário de São João, E.P.E., Portugal

8-year-old girl is referred to a Pediatric Endocrinologist for the appearance of thelarche, first noted at 6.5 years. She had a relevant clinical history of a neonatal meningitis, requiring prolonged hospitalization and the need for ventriculoperitoneal shunt. On physical examination, she had breast development and dark, coarse pubic hair compatible with Tanner stage 3. She weighed 32.3 kg (percentile – Pc- 75–90), her height was 128 cm (Pc 50) and her annual growth rate was 11 cm (> Pc 87). Clinical work-up was performed. Among the analytical study, evidence of central precocious puberty (CPP) was shown by an increase in gonadotropins and estradiol (LH 2.78 mUI/ml, FSH 3.58 mUI/ml, estradiol 53.7 pg/ml). The remaining analytical study showed no further alterations, namely a normal 17-hydroxyprogesterone value (17-OHP). The wrist X-ray revealed an advance of 3.5 years in bone age. The gynecological ultrasound showed characteristics compatible with the pubertal stage. Cerebral MRI revealed: 'Clastic area sequelae in the frontal region, correlating with antecedents. No other relevant lesions with a sure pathological significance in the rest of the brain parenchyma.' She was diagnosed with CPP and treatment with triptorelin was started. Months later, the patient's brother, aged 7 years and 9 months, is referred to a Pediatric Endocrinologist because of precocious pubarche. He had Wolff-Parkinson-White syndrome and no usual medication. On physical examination, he showed pubic hair compatible with a Tanner stage 2 and a testicular volume of about 2 ml. He weighed 25.5 kg (Pc 50–75), his height was 131.5 cm (Pc 75–90) and his annual growth rate was 7.9 cm (> Pc97). Among his clinical work-up, his high 17-OHP stood out (12.92 ng/ml), whilst gonadotropins' and testosterone' values were adequate for his age. His wrist X-ray showed a 2 years advance in bone age. The patient was diagnosed with non-classical congenital adrenal hyperplasia (CAH), treatment with hydrocortisone was initiated and genetic study is being performed. In view of the brother's diagnosis, it was decided to perform the Synachten test on the girl. The final 17-OHP value was 3.95 ng/ml, excluding CAH. Although the sister was previously diagnosed with Central Precocious Puberty and the brother a Precocious Pubarche, it was hypothesized that the girl might have a Pseudo Precocious Puberty, taking into account the boy's diagnosis. The coexistence of two different disorders with impact in puberty in the same family is noteworthy. The timely recognition and treatment of the different pathologies allowed a good clinical outcome.

A difficult diagnosis: menstruation-related periodic hypersomnia

Natalia Raluca Mitru[1], Sorana Vasilescu[1], Anca Andrei[1], Diana Preda[1,2] & Alexandra Mirică[1,2]
[1]Emergency Hospital for Children Grigore Alexandrescu, Bucharest; [2]Carol Davila University of Medicine and Pharmacy, Bucharest

Introduction
Kleine-Levin syndrome, also called recurrent hypersomnia is a rare sleep disorder characterized by recurrent episodes of severe hypersomnia associated with cognitive and behavioral disturbances such as confusion, derealization, apathy, compulsive eating and hypersexuality. Menstrual-related hypersomnia is classified as a subtype of syndrome Levin-Kleine consisting of recurrent hypersomnia that is temporally linked with menses.
Case presentation
An unusual case of an 15-year-old girl with repeated episodes of hypersomnia, bradymenorrhea, behavioral disturbances similar to psychotic episodes including visual hallucinations (spiders) and anxiety. The sleep periods occurred in connection with ovulatory menstrual cycles and it was observed the absence of hallucinatory episodes during menstrual supression. Various pharmacological options have been proposed to reduce symptoms during the episodes, including anti-psychotics (haloperidol, risperidone), anti-depressants (sertraline, lorazepame), but with little amelioration on the patient's symptoms. Her physical examinations revealed no abnormalities and on mental status examination, she appeared to be very distressed due to her symptoms. Investigation of the menstrual cycle failed to document any striking hormonal abnormality. Serum levels of follicle stimulating hormone, luteinizing hormone, estradiol and progesterone were normal. The thyroid function tests showed Hashimoto's thyroiditis with normal thyroid hormone levels. Hormone evaluation also indicated minimal hyperprolactinemia secondary to psychiatric treatment. CSF levels of hypocretin-1, a hypothalamic peptide that has been shown to be deficient in narcolepsy was less < 30 pg/ml. A magnetic resonance imaging scan was performed and showed no cerebral abnormality. Nocturnal polysomnogram and multiple sleep latency testing were positive for narcolepsy and central sleep apnea.
Conclusion
Symptoms similarities between menstrual-related hypersomnia and other psychiatric disorders make effective diagnosis challenging. Consequently, additional clinical features and ineffective psychiatric treatment mandate further diagnoses. Sex hormones play a role in the menstrual cycle and frequently in the regulation of daily sleep-wake rhytm in women. The patient's treatment proposed was combined oral contraceptive treatment: chlormadinone acetate and ethinylestradiol. This case underlines the importance of multidisciplinary evaluation and treatment in unusual cases.

The clinical, biological and etiological aspects of hirsutism

Marwa Ben Jemaa, Nadia Khessairi, Sahar Abidi, Fatma Chaker, Wafa Grira & Melika Chihaoui
Rabta Hospital, Endocrinology, Tunis, Tunisia

Objective
To determine the clinical, biological and etiological aspects of hirsutism.
Material
A retrospective study from 2009 to 2017 included 51 patients explored and followed for hirsutism in the endocrinology department of the Rabta hospital.
Results
The mean age of hirsute patients was 29 years, their average age of menarche was 12 years old. Hirsutism appeared before puberty in 2%, during the puberty in 49% and after puberty for 49%, It appeared progressively in 97% and abruptly in 3% of the cases. The degree of hirsutism according to the Ferriman and Gallway score was minimal in 48%, moderate in 41% and finally severe in 11%. It was associated with cycle disorders in 52% of the cases. Signs of hyperandrogenism were found in 6.5% of our patient. 62% of them were obese and 30% were overweight. An arterial hypertension was

found in 18%, diabetes in 22%, glucose intolerance in 2% and dyslipidemia in 29% of the cases. Testosteronemia was increased in 31% of cases. The etiologic investigation showed polycystic ovary syndrome (PCOS) in 30 patients (59.2%) associated with obesity in 19 cases and eleven patients had metabolic syndrome. Idiopathic hirsutism was found in 13 patients (25%), congenital adrenal hyperplasia in 10% with only one case of ovarian tumor and two cases of cushing syndrome (1.6%).
Discussion
Hirsutism is a frequent endocrinopathy. It may be associated with a metabolic syndrome. A rigorous etiological investigation is required before the treatment. The total testosterone assay is recommended for this etiologic survey in first intention.

Polycystic ovarian syndrome and metabolic syndrome

Marwa Jemaa, Nadia Khessairi, Sabrina Ayari, Ibtissem Oueslati, Meriem Yazidi & Melika Chihaoui
Rabta Hospital, Endocrinology, Tunis, Tunisia

Patients with polycystic ovary syndrome (PCOS) have features of the metabolic syndrome, including insulin resistance, obesity, and dyslipidemia, suggesting an increased risk for cardiovascular disease.
Objective
To assess the prevalence of metabolic syndrome in patients with a polycystic ovarian sydrome (PCOS).
Material
We conducted a retrospective study including 51 patients with secondary hirsutism. The PCOS was retained in 28 patients after elimination of other causes (Rotterdam2003) and the definition of metabolic syndrome was based on the following criteria of IDF 2005.
Results
The mean age of patients was 28 years, hirsutism was mild in 49%, moderate in 42% and severe in 9% of the cases, it was associated with cycle disorders in 60% of cases. Mean testosteronemia level was 0.92 ng/ml. Diabetes was found in 21.6% of our patients, arterial hypertension in 17.6% of them, waist circumference was > 80 cm in 66.7%, triglycerid levels were > 1.5 g/l in 12%, HDLc < 0.5 g/l in 69% of the cases. The metabolic syndrome was retained in 40.6% of our patients according to the IDF criteria. A low-calorie diet and metformin were instituted in 24.5% of our patients. Cyproterone acetate was added in 61% of the cases. The evolution was marked by weight loss and improvement in their metabolic profile.
Conclusion
The prevalence of the metabolic syndrome in patients with a PCOS was high, hence the importance of screening and treatment in order to prevent cardiovascular diseases.

Anthropometric parameters vary slightly but sexual maturation rating and bone age delay and reproductive hormones reduce significantly in patients with delayed puberty

Maleeha Akram[1], Syed Shakeel Raza Rizvi[1], Shahid Ahmed[2], Osama Ishtiaq[3], Rauf Niazi[4], Afzaal Ahmed Naseem[1,5] & Mazhar Qayyum[1]
[1]Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Department of Zoology/Biology, Rawalpindi, Pakistan; [2]Military Hospital, Rawalpindi, Department of Endocrinology, Rawalpindi, Pakistan; [3]Shifa International Hospital, Islamabad, Department of Endocrinology, Islamabad, Pakistan; [4]Pakistan Institute of Medical Sciences (PIMS), Islamabad, Department of Medicine, Islamabad, Pakistan; [5]University of Lahore, Islamabad Campus, Islamabad, Institute of Diet and Nutritional Sciences, Islamabad, Pakistan

Puberty, a crucial biological process, ends up in sexual maturation, reproductive capability and adult body size. It is controlled by hypothalamo–pituitary–gonadal axis (HPG), where hypothalamus synthesizes and secretes gonadotropin releasing hormone, which stimulates the adenohypophysis to produce follicle stimulating hormone (FSH) and luteinizing hormone (LH). FSH causes formation of sperms and LH stimulates production of testosterone (T). Puberty needs an intact HPG axis and any interruption in this axis may result in short-term or long lasting dysfunction of reproductive axis. Delayed puberty in boys is typically described by the deficiency of masculinization and reduced volume of testes (< 4 ml) in combination with absent or low sperm count until 14 years of age. The current investigation determined anthropometric parameters (height, weight, BMI), bone age, sexual maturation rating (SMR) and plasma levels of FSH, LH and T through respective ELISA systems in 37 sporadic cases of male delayed puberty and 55 age matched controls of 14 to 23 years of age visiting Pakistan Institute of Medical Sciences, Islamabad, Shifa International Hospital, Islamabad and Military Hospital, Rawalpindi. SMR was assessed by measuring penile length, testicular volume, pubic hair and facial hair stage. Interpretation of results was carried out by employing Student's *t*-test and ANOVA. The results revealed that the height of delayed puberty patients was lower than controls between 14 and 23 years of age, whereas weight of delayed puberty patients was slightly higher as compared to controls. Most of delayed puberty patients were in over-weight category of BMI. Bone age of most of delayed puberty patients was also delayed than chronological age. SMR of delayed puberty patients indicated that all patients had significantly lower penile length, testicular volume, pubic hair stage and facial hair stage than controls. The hormonal analysis displayed significantly decreased plasma FSH, LH and T levels in patients with pubertal delay as compared to controls. In conclusion, our investigation demonstrates a slight difference in anthropometric parameters of controls and delayed puberty patients during later stages of puberty while sexual maturation rating and hormonal parameters were significantly decreased in delayed puberty patients as compared to controls throughout the pubertal period.

Interventions affecting blood pressure and anxiety in women with mild preeclampsia: a narrative review

Farzaneh Askari, Mehdi Pourasghar & Zhila Ganji
[1]Mazandaran University of Medical Sciences, Sari, Iran; [2]Department of Psychiatry, Psychiatric and Behavioral Sciences Research Center, Addiction Institute, Mazandaran University of Medical Sciences, Sari, Iran; [3]Department of Reproductive and Midwifery Health, Sexual and Reproductive Health Research Center, Mazandaran University of Medical Sciences, Sari, Iran

Introduction
Preeclampsia (PE) accounts for approximately 2–5% of pregnancies, leading to several maternal-fetal complications. The present study aimed to review types of interventions affecting blood pressure and anxiety in women suffering from mild PE.
Materials and methods
This study was a narrative review based on keywords determined by the MeSH terms. For this purpose, the databases of PubMed, Scopus, Google Scholar, Scientific Information Database (SID), and Magiran were searched using the keywords of 'preeclampsia, intervention, blood pressure, anxiety, EPH-gestosis, pregnancy toxemia, and toxemia of pregnancy' in Persian and English for relevant articles published from 1980 to 2020. The inclusion criteria were all randomized clinical trials (RCTs) associated with interventions affecting blood pressure and anxiety in cases with mild PE.
Results
a total number of 16 RCTs were reviewed in this study. After reviewing, 12 articles were recruited for developing this study and the non-relevant cases were excluded. Accordingly, interventions affecting blood pressure and anxiety in women with mild PE were classified into four groups: Group 1: psychological–educational interventions, Group 2: complementary medicine interventions, Group 3: pharmacological interventions, and Group 4: others.
Conclusion
Health care providers are suggested to reflect on these interventions and make use of this classification of interventions in accordance with patients' conditions when hospitalizing women with mild PE.
Keywords
Mild Preeclampsia, Intervention, Anxiety, Blood Pressure, Review

The SARS-CoV-2 infection and PCOS: what we know nowadays?

Anna Dabrowska[1,2] & Jaroslaw Dudka[1]
[1]Medical University of Lublin, Department of Toxicology, Lublin, Poland; [2]Endocrinology Outpatient Clinic, Lublin, Poland

Introduction
The novel COVID-19 has been rapidly expanding and causing many deaths all over the world, since December 2019. The health condition and the coexistence of other diseases may affect the severity of SARS-CoV-2 infection.
The state of the art
PCOS is a common endocrine and metabolic disorder, afflicting females of reproductive age, with an incidence up to 10%. It is a heterogeneous clinical syndrome, characterized by hyperandrogenism, menstrual irregularity and hyperinsulinaemia, in which both genetic and environmental factors are thought to play a role. Women with PCOS are considered to belong to an age and sex group which is at lower risk for severe COVID-19. However, the possible pathophysiological mechanisms regarding PCOS and more severe COVID-19 have been hypothesized. Insulin resistance and hyperinsulinaemia result in enhanced hyperandrogenism. Androgens may drive clinical results in COVID-19. First, sexual hormones affect the immune system and testosterone suppresses it. Second, SARS-CoV-2 gains entry to target cells via the angiotensin-converting enzyme 2 (ACE-2) receptor and male hormones are effective in the ACE-2 passageway and simplify SARS-CoV-2 entry into cells. Finally, the lung expression of TMPRSS2 (transmembrane protease, serine 2), a cellular co-receptor necessary for SARS-CoV-2 infection, is associated with an androgen-regulated gene. What is more, Renin-Angiotensin-System (RAS) overactivity has been described in type 2 diabetes and obesity, the conditions markedly frequent in PCOS, which are known to be the factors increasing the risk of severe COVID-19. Moreover, the overactivity of the RAS system has been also proven in PCOS. Thus PCOS may predispose these women to more severe SARS-CoV-2 infection. Vitamin D deficiency, identified as a global public health matter, may be another important factor, potentially involved in the increased risk of developing severe forms of COVID-19 in PCOS women. It has been reported that poor vitamin D status can affect a variety of diseases, including SARS-CoV-2 infection, because of its crucial role in the functioning of the immune system. Vitamin D is also a negative endocrine RAS modulator and inhibits renin expression and generation. Hypercytokinemia, presented in obesity as well as in PCOS, may be another risk factor for severe SARS-CoV-2 infection in PCOS women.
Conclusions
The complexity of PCOS, including the coexistence of many metabolic disorders as well as hormonal and cytokine disturbances, may increase the susceptibility of severe COVID-19 in PCOS women. Further studies are needed to clarify the link between severe COVID-19 and PCOS, to provide the optimal management.

Growth retardation: epidemiological, clinical and etiological aspects

Sawsen Essayeh, Bel Hadj Sliman Chayma, Bchir Najla, Kardi Asma, Zouaoui Chadia & Ouertani Haroun
Military Hospital of Tunis, Endocrinology-Nutrition, Tunis, Tunisia

Introduction
Growth retardation (GR) is a frequent complaint in pediatrics. A clear and rapid diagnostic process is essential in order to improve the prognosis for height. The aim of our study was to review the epidemiological, clinical and etiological aspects of GR and to assess the height gain particularly after treatment for Growth hormone (GH) deficiency.
Methodology
This is a retrospective study of 27 consulting patients for GR at the endocrinology department of the Military Hospital of Tunis between January 2000 and December 2019.
Results
Our population was predominately male (sex ratio = 2). The mean chronological age (CA) at the time of diagnosis was 13.8 ± 3.8 years. The mean linear growth retardation was −3.02 ± 0.73 standard derivation (S.D.). Fifteen patients (62%) had severe GR (≤−3S.D.). The mean bone age (BA) was 10.23 ± 2.49 years, with a mean delay (CA-BA) of 3.5 ± 2.06 years. Dysmorphia was found in 11% of cases. Delayed puberty was associated in 62% of cases. GH deficiency was found in 56% of cases; 71% had total GH deficiency and 29% had partial GH deficiency. They were treated with somatotropin. The height gain after treatment for GH deficiency was 20.62 ± 14.32 cm. The other causes were celiac disease (8%), constitutional GR (8%), genetic and malformative diseases (14%), 1 case of type 1 diabetes, 1 case of peripheral hypothyroidism and 1 case of GR secondary to a small size from birth.
Conclusion
Monitoring growth should be systematic and regular in all children. By an early diagnosis of GR, serious diseases can be detected and an appropriate treatment can be started at an early stage.

Testicular regression syndrome, a case study

Bessaid Khadidja
El Djazair, Algeria

Introduction
XY testicular agenesis is a very rare disease. The phenotype of persons suffering is variable depending when the gonadic regression in utero occurs.
Observation
We have reported a 26 years old patient case, without particular history, monitored for puberty delay from the age of 17 years. The clinical examination reveals a very tall patient: 1m92, with macroskelia, a penis of normal size, a classified P2 pubic pilosity, absence of axillary pilosity as well as at the level of face, no gynecomastia nor spontaneous or induced galactorrhea. Absence of palpable gonads in intrabotal or inguinal position. Morphological exploration did not visualize testes in normal or ectopic position with a hypoplastic prostate. The hormonal assessment found a hypogonadism, hypergonadotropic, negative HCG test. The karyotype is normal: 46 XY eliminating a Klinefelter syndrome. The exploratory laparotomy did not find a gonad in the abdominopelvic position.
Discussion
The TRS is a rare etiology, of unknown cause, it is an elimination diagnosis, at the end of a negative etiological investigation without objectifying morphological or hormonal stigma of gonad within our patient, we completed a TRS in the absence of Mullerian structure and the normality of the external genitalia. The patient received hormone replacement therapy with a good clinical course without improving the fertility prognosis.
TRS: testicular regression syndrome.

Gynecomastia – what is behind the curtain?

Georgiana Cristina Taujan, Mihaela Rosu, Felicia Baleanu, Olga Ana Kosmopoulou, Ioanna Blerta Papadopoulou & Laura Iconaru
CHU Brugmann, Endocrinology, Bruxelles, Belgium

Introduction
Although addressability for breast pathology is much lower in men than in women, the underlying causes of the initial complaints are often much more spectacular. Gynecomastia is one of the principal reasons for addressing the endocrinologist and next to the important psychosocial impact, sometimes it seems to be only the tip of the iceberg, revealing important underlying medical conditions.
Case reports
We present the cases of two male patients who addressed our clinic for gynecomastia. The first case is of a male patient, aged 40, who addressed our service for a painful right breast nodule, appeared 2 weeks prior to the presentation. The patient reported having two other similar episodes in Maroc, 7 years ago and 1 year ago, considered to be infectious mastitis and treated by antibiotics. Only regular blood tests were performed during the previous episodes, with no hormonal profile and no imaging or histopathological studies. The physical evaluation at the current presentation revealed a painful nodule in the upper external quadrant of the right breast. Laboratory evaluation revealed important hyperprolactinemia and hypogonadotropic hypogonadism, with normal liver, renal and thyroid tests. The ultrasound revealed bilateral gynecomastia, with no tumoral process. The testicular ultrasound was normal. The pituitary MRI revealed a microadenoma measuring 6.3/5/6 mm. The patient was initiated on dopamine-agonist therapy and the prolactin level returned to normal within 2 months. The second case is of a male patient, aged 65, who was hospitalized for atypical chest pain. The physical examination revealed bilateral gynecomastia, reported by the patient as being present from his early 20s. After complete cardiac evaluation, he was addressed to us. The laboratory evaluation revealed hypergonadotropic hypogonadism. The ultrasound revealed bilateral gynecomastia with an ACR4 area of 11.5/9.5/10 mm in the left breast, with no pathological

adenopathy. The percutaneous biopsy performed showed discrete fibrocystic dysplasia. The testicular ultrasound found small, hypervascularised testes with microcalcifications. The karyotype performed showed a Klinefelter syndrome mosaicism 46, XX/47, XXY. The osteodensitometry revealed femoral osteopenia. The patient was initiated on testosterone substitutive therapy and vitamin D and calcium supplementation.
Conclusion
Although in more than 50% of cases gynecomastia is idiopathic, complete clinical, biochemical and imaging assessment is required in order to exclude rare or life-threatening conditions. Initiation of adequate treatment, when needed, will have a high impact on patient satisfaction and on the outcome, preventing possible serious complication, as those associated with hypogonadism, neoplasia, liver or renal diseases.

ANCA vasculitis: a rare and serious complication of Benzylthiouracil

Raida Ben Salah[1], Hadj Kacem Faten[2], Chabchoub Imen[1], Faten Frikha[1], Mohamed Abid[2] & Zouhir Bahloul[1]
[1]Hedi Chaker Hospital, internal medicine, SFAX, Tunisia; [2]Hedi Chaker Hospital, Endocrinology, Sfax, Tunisia

Introduction
Vasculitis with antineutrophilic cytoplasmic antibodies (ANCA) has been reported in patients treated with anti-thyroid drugs, especially Propylthiouracil and exceptionally with benzylthiouracil (BTU). We present here a case of ANCA-anti-MPO-associated vasculitis related to BTU.
Case presentation
A 46 old women was treated with BTU during 18 months for Basedow's disease. She showed abruptly an alteration of the general state with fever, hepatosplenomegaly, cytopenia with microcytic anemia at 6.8 g/dl and leucolymphopenia at 2500, proteinuria between 0.4 and 0.8 g/24 h with normal kidney function and biological inflammatory syndrome. A chest-abdominal-pelvic CT showed hepatosplenomegaly with splenic infarction. The p- ANCA assay was positive with anti-myeloperoxidase specificity. The benzylthiouracil was discontinued. The patient was treated with bolus of solumedrol relayed by corticosteroids at a dose of 1 mg/kg per day with disappearance of bicytopenia and regression of hepatosplenomegaly. She reconsults few weeks later for respiratory failure, with crackling rattles in pulmonary auscultation, anemia at 5.4 g/dl and images of alveolar condensation to chest radiography. The diagnosis of intra-alveolar hemorrhage was retained. She was treated with solumedrol bolus. One month later, she developed a high-abundance hemoptysis with hemodynamic failure and death.
Conclusion
Because of the gravity of this complication, clinical monitoring is recommended in patients taking benzylthiouracil. If vasculitis develops, the anti-thyroid drug should be discontinued and corticosteroid treatment, with immunosuppressors in some cases, is initiated. Prognosis is less severe than primary ANCA vasculitis, and death due to anti-thyroid therapy-induced AAV as our case is exceptional, related generally to severe alveolar hemorrhage.

Papillary carcinoma arising in retrosternal ectopic thyroid tissue. A case report

Lamya Echchad, Sohaib Khamal Doghri, Kaoutar Rifai, Hind Iraqi & Mohamed El Hassan Gharbi
University Hospital Ibn Sina, Endocrinology and Metabolic Diseases Department, Morocco

Introduction
Ectopic thyroid tissue is a rare clinical entity, with a prevalence of 1: 300 000 in the general population. The ectopic tissue may be located anywhere from the base of the tongue to the diaphragm, the most frequent sites being lingual, thyroglossal, laryngotracheal, and lateral cervical regions. It may also occur in less frequent sites such as the esophagus, mediastinum, heart, adrenal glands, and pancreas. The mediastinum is the most frequent location after the neck. Malignant transformation of ectopic thyroid is uncommon; but even rarer is the development of papillary carcinoma in it. We report the case of papillary carcinoma arising in retrosternal ectopic thyroid tissue in association with an oncocytic variant of papillary carcinoma arising from the thyroid gland.
Case
A 50 years old female patient was presented to the medical consultation with 6 months history of neck swelling. Her medical and family histories were non-specific. The physical examination found a slight anterior cervical painless swelling. The neck ultrasonography was performed revealed 2 nodules of 4×9 mm and 4×3 mm classified Tirads 5. Besides, a nodule of 4 cm in size was identified in the superior mediastinum on the right. The USG-guided fine needle aspiration cytology performed on the retrosternal mass was reported to be in favor of ectopic thyroid tissue with malignant nature. Thyroid functional tests, calcitonin, and thyroid antibodies were within normal limits. A total thyroidectomy was scheduled for the patient. During the surgical exploration, the retrosternal ectopic thyroid mass of 4 cm was identified and removed. The histopathological examination was in favor of a retrosternal ectopic papillary thyroid carcinoma and a multifocal oncocytic variant of papillary carcinoma arising from the thyroid gland. The patient then underwent radioiodine ablation therapy (100 mCi) and was put on Levothyroxine suppression therapy.
Discussion and conclusion
Ectopic thyroid tissue results from abnormal embryologic development and migration of the thyroid gland. True malignant transformation in ectopic thyroid tissue is extremely rare and is always diagnosed after surgical excision of the lesion by pathology examinations. There are well-documented cases of ectopic thyroid cancer while primary tumoral lesion occurs in the orthotopic thyroid as described in our case. However, it is not always possible to detect the presence of these anomalies, during the preoperative examinations of the patients who will undergo thyroid surgeries; therefore, one must be careful about these types of anomalies in the perioperative examinations.

EP190

A case of primary hyperparathyroidism associated with papillary thyroid carcinoma

Ines Bayar, Soumaya Tahri, Bilel Ben Amor, Hanene Sayadi, Héla Marmouch & Inès Khochteli
University Hospital of Monastir, Endocrinology and Internal Medicine, Monastir, Tunisia

Introduction
The association between parathyroid and thyroid diseases is not uncommon; however concurrent presence of parathyroid adenoma and thyroid cancer is rare (1). As a natural consequence, preoperative imaging studies for diagnosis and localization of parathyroid adenomas may result with the detection of thyroid incidentalomas and most of these thyroid nodules should be evaluated by fine-needle aspiration biopsy before parathyroid surgery (1). We have recently encountered a case of papillary thyroid carcinoma (PTC) associated with primary hyperparathyroidism (PHPT).
Methods
We describe the clinical findings, thyroid and parathyroid function tests, and imaging data of a patient presenting with hypercalcemia and thyroid nodule.
Results
A 56-year-old female with chronic epigastric pain, was referred to our department after discovery of hypercalcemia. In the routine laboratory tests, we noticed to a serum calcium of 11.1 mg/dl [8.2–10.2]. Further evaluation, confirmed a low serum phosphorus and a high serum parathyroid hormone (126 pg/ml), low vitamin D while renal functions tests, and thyroid test levels was within normal range. Patients had not history of treatment with calcium or vitamin D supplements. Cervical ultrasound showed 4 parathyroid glands increased in size and a 3.5 cm thyroid nodule in the lower right pole classified EU-TIRADS 5. 99 Tc-sestamibi scanning revealed features of parathyroid adenoma adjoining the lower pole of right thyroid lobe. A conducted aspiration biopsy of thyroid nodule was indicative of PTC. The patient was referred to the otorhinolaryngology department for surgery.
Conclusion
Concomitant PTC and PHPT are rare. The underlying mechanisms are not yet established and may be coincidental. Goitrogenic and carcinogenic factors have been implicated in the pathogenesis with no conclusive evidence. Shared embryological origin, genes and transcription factors, high parathyroid hormone (PTH), low vitamin D and hypercalcemia could result in high levels of angiogenic growth factors (2).

Place of surgery in Basedow's disease 'About 100 cases'

Samira Belkacem
Endocrinology, Pierre Marie Curie Center of Medecine, Algiers, Algeria

Introduction
Graves' disease is an autoimmune thyroid disease manifested by hyperthyroidism, homogeneous goiter and sometimes ophthalmopathy. The frequency of the disease is less than 1% with a female predominance of 5–10/1 male. Its treatment is difficult because of the evolving vagaries of this disease. We report the results of surgery for Graves' disease through a retrospective study.
Material and methods
100 files of patients operated on for Graves' disease (MB) either as first-line after preparation for medical treatment (average duration of less than 6 months) in 9 or after failure of medical treatment in 91%.
Results
Average age: between (20–60 years)
Female predominance
Reason for consultation: goiter + signs of hyperthyroidism): 79%
Basedowian ophthalmopathy 69%.
Palpation of the neck: goiter type 2: 74 (firm, elastic, vascular in 70%)
The thyroid hormone balance: TSHus slowed down in all cases (avg: 0.12 U/ml) associated with an increase in peripheral hormones FT3 and/or FT4.
The autoimmunity assessment
Anti TPO Ab: 13% positive, Anti TSHus receptor TSI 20% positive, TG Ab 3% positive
Surgery results
65% of patients (P) underwent a total thyroidectomy.
35% (P): subtotal thyroidectomy
Histology
82% of patients: Typical basal disease
17% (P) Graves' disease associated with cell variants
• Oncocytic metaplasia
• Functional hyperplasia
1% (P) papillary microcarcinoma + MB.
Conclusion
The management of Graves' disease requires a precise diagnosis as well as an appropriate treatment. Follow-up depends on the speed of the response and the occurrence of recurrence. The medical treatment for Graves' disease takes a long time. It imposes physical and economic constraints with a high rate of relapses. If remission does not occur radical treatment is indicated by radioiodine or surgery.

DOI: 10.1530/endoabs.73.EP191

DeQuervain's subacute thyroiditis

Hadj Kacem Faten[1], Molka Ben Bnina[2], Kouloud Boujelben[1], Mouna Elleuch[1], Dhouha Ben Salah[1], Nadia Charfi[1], Nabila Rekik[1], Mouna Mnif[1], Fatma Mnif[1], Mohamed Abid[1]
[1]Hedi Chaker Hospital, Endocrinology and Diabetology, Tunisia; [2]Farhat Hached Hospital, Endocrinology and Diabetology, Tunisia

Introduction
DeQuervain's subacute thyroiditis (DST) is a rare pathology, defined by the involvement of the thyroid gland by an inflammatory process probably of viral origin, not suppurative and not autoimmune. In this context, we report 4 cases of TSD followed up in the endocrinology department over a period of 23 years, to highlight diagnostic and therapeutic particularities.
Results
The average age was 38.5 years with extremes ranging from 31 to 46 years. The sex ratio was equal to 0.33. A family history of goiter existed in one patient. The reason for consultation was anterior cervicalgia occurring as a result of influenza-like illness with a biological inflammatory syndrome in all patients. A goiter was found in all 4 patients, compressive and painful in three of them. One patient had hypothyroidism, the other 3 had hyperthyroidism. The anti-thyroperoxydase antibodies were positive in 2 patients. The scintigraphy was white in all 4 patients. Beta-blockers were considered in 2 patients, associated with corticosteroids in the first and non-steroidal anti-inflammatory drugs (NSAIDs) in the second patient. Therapeutic abstention was indicated for the third case. L-thyroxine was prescribed in patient with deep hypothyroidism. The evolution was favorable with return to euthyroidia in 3 patients but the fourth was lost sight of.
Conclusion
DST is an easy-to-diagnose pathology, usually of favourable evolution. The use of NSAIDs or corticosteroids may be necessary. Cases of definitive hypothyroidia are possible.

DOI: 10.1530/endoabs.73.EP192

EP193

Depression among patients with autoimmune thyroiditis

Sergio Roman Gimeno[1], Rosana Urdaniz Borque[1], Elena Pérez Galende[1], Borja Sanz Martín[1], Jose Jorge Ortez Toro[2]
[1]Hospital Clinico Universitario Lozano Blesa, Endocrinology and Nutrition, Zaragoza, Spain; [2]Hospital Reina Sofía, Endocrinology and Nutrition, Tudela, Spain

Introduction
Today, it is well recognized that disturbances in thyroid function may significantly affect mental status including emotion and cognition. Several studies have demonstrated the existence of a relationship between depression and hypothyroidism, although there is still no clear explanation of the pathophysiology that causes this association.
Objectives
To assess whether there is a higher prevalence of depression among patients with hypothyroidism and whether it is correlated with laboratory parameters such as TSH, free T4 or the levels of anti-peroxidase (TPO) and anti-thyroglobulin antibodies.
Methods
We collected the medical and psychiatric history and laboratory tests of 200 patients with autoimmune hypothyroidism treated in our hospital (Hospital Clínico Lozano Blesa, in Zaragoza; Spain). Student's T test was used for statistical analysis.
Results
A high prevalence of depression was observed among patients with autoimmune hypothyroidism (46.5%), in addition, higher mean values of anti-TPO antibodies have been obtained in patients with depression (552.87 IU/ml versus 337.12 IU/ml, $P = 0.015$), as well as anti-thyroglobulin antibodies (371.52 IU/ml vs. 135.27 IU/ml, $P = 0.034$) and TSH (20.55 mU/l vs. 9.31 mU/l $P = 0.012$). There were no differences between the FT4 values of both groups.
Discussion and conclusion
There is a significant prevalence of depressive symptoms among hypothyroid patients, being present in almost half of the individuals studied, as well as higher levels of TSH and anti-TPO and antithyroglobulin antibodies in subjects diagnosed with depression, all of that according to the published data in previous studies. Therefore, it could be interesting to quantify thyroid hormones in those patients who present with symptoms of depression, especially those who are more refractory to antidepressant treatment. However, the mechanisms underlying the interaction between thyroid function and depression remain to be clarified and a causal relationship between the two cannot be established yet, so more studies are needed to clarify the specific reason for this association. Moreover, further studies are required to determine if thyroid-related genes can influence well-being in subjects that are not on thyroid hormone replacement and if thyroid hormones may be beneficial in these subjects if they are not responding to standard antidepressant therapies.

Problems in the diagnosis of thyroid orbitopathy

Natalya Volkova, Irina Dzherieva, Ilya Davidenko, Lilia Ganenko, Igor Reshetnikov, Yulya Sorokina, Alexander Zibarev, Yuliya Degtyareva, Gulnara Gizatulina, Nikita Koshkin
Rostov State Medical University, Rostov, Russian Federation

Thyroid orbitopathy (TO) is an autoimmune inflammatory disease of retroocular tissues. Mostly, TO is associated with Graves' hyperthyroidism. The development of TO is accompanied by pathological changes in the soft tissues of the orbit with damage to the optic nerve and cornea, the accessory apparatus of the eye. Despite the presence of specific symptoms, the diagnosis of TO causes problems for doctors. A 61-year-old man complained of discomfort in the eyes, double vision, lacrimation, dryness and redness of the eyes, swelling under the eyes, palpitations, which first appeared in June 2020. At first, the patient did not go to the doctor, but decided to do an MRI of the orbit, which revealed a thickening of the lower and internal oblique muscles of the eye, more pronounced on the left, bilateral exophthalmos, edema of the lower eyelid on the left, expansion of the sheathing spaces of the optic nerves. The patient consulted an ophthalmologist after a sharp decrease in visual acuity in the right eye (diagnosis: embolism of the central retinal artery of the right eye, treatment without a pronounced positive effect, subclinical thyrotoxicosis was additionally revealed). The patient was referred to an endocrinologist, who diagnosed obesity, prescribed a diet and examination (results: TSH-0.02 mIU/ml, T4-15.76 pmol/l, T3-8.59 pmol/l). In September 2020, an ophthalmologist diagnosed the patient with reactive edema of unknown etiology in both eyes. In parallel, the patient is monitored by an endocrinologist and undergoes another additional examination: ultrasound of the thyroid gland (an increase in the volume of the thyroid gland with diffuse changes, an increase in the cervical lymph nodes), an increased titer of antibodies to TSH receptors (16.05 IU/l) was detected. However, the diagnosis was not changed, no treatment was prescribed. On physical examination: HR-98 beats per minute, the presence of spontaneous retrobulbar pain, redness and edema of the eyelids, conjunctival injection, redness and edema of the lunate fold, lacrimal meatus, chemosis. The patient was diagnosed with Grave`s disease, which was complicated by TO in both eyes, active stage, CAS 6 points. Thyroidectomy was recommended for the patient, Tyrosol 30 mg per day was prescribed, pulse therapy with Prednisolone was performed. Thus, we can say that thyroid orbitopathy is a multidisciplinary problem that requires closer interaction of ophthalmologists and endocrinologists, which will lead to early diagnosis and timely prescribed treatment, which, in turn, will improve the prognosis and quality of life of patients.

Prevalence of double vision (diplopia) and strabismus in patient with Graves' orbitopathy

Georgios Boutzios, Eleni Koukoulioti, Athina Karampela, Sofia Chatzi, Ilias Giovannopoulos, Sofia Kouvelioti, Athanasios Tzioufas
Medical School, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece

Introduction
Graves' disease (GD) is an autoimmune thyroiditis frequently associated with development of Graves' orbitopathy (GO). Diplopia (double vision) is a major determinant of work disability in patients with GO. The aim of our study was to assess the prevalence of diplopia and strabismus in patients with GO.
Methods
This is a single-center observational study in an outpatient clinic of autoimmune endocrinopathies at a Tertiary, General, University Hospital. Patients with GO and increased levels of thyroid-stimulating immunoglobulin (*TSI > 1.75 IU/l)* were included in the study. Clinical activity score (CAS), diplopia and strabismus were evaluated by a single ophthalmologist according to the European Consensus Report. Laboratory tests for TSH, T3, FT4, TSI, TgAbs, TPOAbs, complete blood count, liver enzymes and thyroid sonography were performed in all patients.
Results
A total of 36 patients (72.2% females) with a mean age of 54 ± 11.8 years were analyzed. The median TSI levels were 9.1 IU/l (IQR 22.3), and the mean CAS score was 3.24 ± 1.4. 19.4% (7/36) of the patients had undergone total thyroidectomy, 11.1% (4/36) had thyroid cancer, 47.2% (17/36) had other autoimmunities, and 65.6% (21/32) had smoking history. Diplopia was present in 38.9% (14/36) and strabismus in 5.6% (2/36) of the patients. Diplopia was not significantly associated with gender, TSI levels, thyroidectomy, thyroid cancer, and the presence of other autoimmunities (P = NS), but patients with diplopia were older than those without (60.8 ± 11.3 vs 49.7 ± 10.1, P = 0.004).
Conclusion
The prevalence of diplopia was 38.9% in the studied group of patients with GO, whereas strabismus was much less frequent (5.6%). Diplopia was associated with older age in patients with GO.

'Colloid leak'-An Phenomenon in thyroid surgery

Sabaretnam Mayilvaganan[1], Ramakanth Bhargav Panchangam[2] & Sarrah Idrees[1]
[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; [2]Endocare Hospital, Vijayawada, India

Background
Thyroidectomy is the common most common endocrine surgical procedure varies from Scalpel to Robotic transoral thyroidectomy. Colloid nodules are common and easily operable without any difficulty. We report a phenomenon where in the surgery becomes difficult and lead to complications if not thought with this phenomenon – colloid leak.
Material and method
The endocrine surgeon (Associate Professor) has been involved in training of over 25 superspeciality endocrine trainers over a period of nine years in a tertiary referral high volume center. He has participated in 700 Thyroidectomies of which 250 thyroidectomies for colloid goiter. We have observed this phenomenon in 5 patients over 5 years in a tertiary referral centre in north India
Result
5 male patients (46.7 ± 12.1 years) had this colloid leak. Mean BMI was (22.4 ± 2.9). FNAC was colloid in all patients. 3 had colloid leak in all planes. 2 had only per thyroidal leak. All patients had Recurrent Laryngeal nerve identified. In 1 patient only 1 parathyroid gland could be identified. Mean duration of surgery was 120 ± 12 min. Mean blood less was 10 ml ± 2.5 ml. Mean duration of stay after surgery was 48. ± 12 h. No permanent complication was observed. All patients operated within 2 weeks of FNAC. All HPT was colloid. Immunohistochemistry revealed IgG4 stained plasma cell aggregates in the line of colloid leak.
Discussion
This phenomenon was observed in muscular males in the colloid goiters where in there is leak of colloid after FNAC and this colloid elicited an inflammatory response in the surrounding tissues as evidenced by IgG4 positive immunohistochemistry staining for plasma cells. This phenomenon was more pronounced 5 to 7 days after FNAC. The planes were stuck and mobilization of gland was difficult in one patient a small cuff of muscle had to be removed. This fact of colloid leak causing chronic inflammation may be a harbinger of chronic changes and may a role in tumorogenesis
Conclusion
Astute Endocrine Surgeon should be aware of this colloid leak phenomenon and when found the dissection should be very careful to present complications during thyroidectomy.

Transient thyrotoxicosis after laryngeal carcinoma surgery

Sofia Maria Lider Burciulescu[1], Mariana Costache Outas[2], Irina Bunea[1] & Monica Livia Gheorghiu[3,4]
[1]C.I. Parhon National Institute of Endocrinology, Bucureşti, Romania; [2]Coltea Clinical Hospital, ORL, Bucharest, Romania; [3]National Institute of Endocrinology CI Parhon, Thyroid 1, Bucharest, Romania; [4]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucureşti, Romania

Introduction
Thyrotoxicosis debuted early after thyroid lobectomy is described in approximately 54% of cases. It has also been described in a few case reports after non thyroid neck surgeries or in invasive laryngeal cancer after total laryngectomy and debulking hemithyroidectomy.

Case presentation
Patient aged 53 years old, known with laryngeal carcinoma of 37/28/40 mm located at piriform sinus, linked by the left vocal chords, with posterior invasion of cricoid cartilage, and with lysis of the left lamina of the thyroid cartilage. He is referred for surgical cure. One months before surgery the patient had normal TSH and FT4. The day after laryngectomy and debulking left thyroid lobectomy, the patient developed tachycardia (113 bpm), without other symptoms for hyperthyroidism, associated with normal TSH: 0.95 uUI/ml and increased FT4. Day 3 after surgery, TSH was undetectable with a highly increased FT4: 87 pmol/l (4 times x ULN). He received Metoprolol 100 mg/zi and no antithyroid medication. Six days post-surgery, the FT4 levels decreased to almost half 48 pmol/l (2× ULN). At day 12 after surgery, under 100 mg Metoprolol/day, the patient still had tachycardia, with no other signs of hyperthyroidism, the right thyroid lobe was not palpable, while biologically he had only a subclinical thyrotoxicosis TSH: 0.016 uUI/ml, FT4: 18.5 pmol/l (*n*: 9–19), TPOAb: 14.4 UI/ml (*n* < 5.6).
Discussion
Thyrotoxicosis debuted early after thyroid lobectomy alone or in the context of other neck surgery (eg for invasive laryngeal cancer) needs correct diagnosis and differentiation from Graves' disease. It is transient, probably due to cell destruction produced by intrasurgical manipulation of the thyroid gland, therefore requires only symptomatic, but not antithyroid drug treatment. A clue for the diagnosis is the rapid decrease of FT4 and the lack of TRAb antibodies.
Conclusion
Clinicians should be aware of the potential for a transient episode of thyrotoxicosis early after thyroid lobectomy + /– associated with other non-thyroid neck surgeries.

Frequency and diagnostic value of Thyroid Autoantibodies

Dinora Urinbaeva, Mohina Salimova, Jasurbek Islomov, Said Ismailov & Zulaykho Shamansurova
Tashkent Pediatric Medical Institute, Endocrinology, Tashkent, Uzbekistan

Introduction
Thyroid autoantibodies can detected in many disorders not only at the Hosimoto autoimmune thyroiditis. Their level and frequency may vary depending on many factors both thyroidal and nonthyroidal. Anti thyroid peroxidase autoantibodies (ATPO) is one of the well known among them. We analysed frequencies of higher level of ATPO among people with different types of thyroid diseases.
Material and methods
In 94 people blood serum ATPO, TSH, T3, T4 levels were measured in the laboratory unit of the Republican Specialized Scientific Practical Medical Centre of Endocrinology and Vitamed clinic in Tashkent. Data were collected, analysed and compared by age, gender, thyroid state and diseases.
Results
High level of antiperoxidase autoantibodies were detected in 46% of observed persons, where the mean age were 42.5 ± 3.8 years old. As noted in many studies woman composed the most part of observed persons with higher ATPO level and male patients consist about 17% among them. Thyroid state were assessed by TSH, T3, T4 level. Euthyroid goiter detected in 46% of people with high ATPO, 18% of them thyrotoxicosis, 18% with hypothyroidism, and 13% cases were thyroid cancer and 22% in healthy pregnant woman.
Conclusion
ATPO is a frequent laboratory findings reflected thyroid function. Higher level of antiperoxidase autoantibodies mostly detected in middle aged people predominantly in woman, 46% cases of high ATPO were combined with euthyreosis state, 18% with hyperthyroidism, 18% of hypothyroidism, 13% cases were with cancer.

Unmasked Graves' disease following tamoxifen withdrawal

Kawthar El ArbI, Wajdi Safi, Khouloud Boujelben, Mohamed Abdellahi Mohamed Ahmed, Sidina Mohamed Elmoctar, Nabila Mejdoub, Mouna Mnif, Hadj Kacem Faten & Abid Mohamed
Hedi Chaker Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction
The synthetic anti-oestrogen tamoxifen is the endocrine treatment modality most commonly used for therapy of hormone sensitive breastcancer. The influence of tamoxifen on thyroid function has not been fully elucidated.
Observation
A 46-year-old female patient who presented a Graves' disease diagnosed 10 years ago. She had a moderate vascular goiter and no ocular signs. She presented firstly a severe hyperthyroidism: an elevated FT4 = 82.5 pmol/l (NR = 11–21) and a suppressed TSH = 0.001 UI/l (NR = 04–4). Thyrotropin receptor antibodies (anti-rTSH) were strongly positive at 23.6 IU/l (NR < 2). The patient was treated with Benzylthiouracil for 3 years followed by voluntary interruption of treatment. The patient was later lost to follow-up. Four years later, she had a suspicious nodule in her left breast. The diagnosis of Invasive ductal carcinoma was confirmed. Tumor extension was negative. The procedure was a tumorectomy and lymph node dissection followed by adjuvant radiochemotherapy. The patient then received an antiestrogen for 5 years. The senological evolution was favourable. During these years, she was in clinical euthyroidism despite stopping all antithyroid treatment. When she stopped taking tamoxifen, she again presented a biologically confirmed severe hyperthyroidism (FT4 = 83 pmol/l, TSH = 0.001). Anti-rTSH antibodies were overtly positive (> 40). A radical treatment was indicated for our patient.
Conclusion
In conclusion, our case suggests that tamoxifen may influence thyroid hormone levels by mechanisms related to its known effect on thyroxine-binding globulin.

Graves'disease and breast cancer: Is there a link

Kawthar El Arbi, Wajdi Safi, Hadj Kacem Faten, Sidina Mohamed Elmoctar, Mohamed Abdellahi Mohamed Ahmed, Dhoha Ben Salah, Nabila Mejdoub, Mouna Mnif & Abid Mohamed
Hedi Chaker Hospital, Department of Endocrinology, Sfax, Tunisia

Intoduction
The link between hyperthyroidism and breast cancer has been the subject of much controversy and literature in the past. It poses a daily clinical problem of information and senological follow-up of thyroid patients. We report our patient's case.
Observation
A 46-year-old female patient who presented a Graves' disease diagnosed 10 years ago. She had a moderate vascular goiter and no ocular signs. She presented firstly a severe hyperthyroidism: an elevated FT4 = 82.5 pmol/l (NR = 11–21) and a suppressed TSH = 0.001 UI/l (NR = 04–4). Thyrotropin receptor antibodies (anti-rTSH) were strongly positive at 23.6 IU/l (NR < 2). The patient was treated with Benzylthiouracil for 3 years followed by voluntary interruption of treatment. The patient was later lost to follow-up. Four years later, she had a suspicious nodule in her left breast. The diagnosis of Invasive ductal carcinoma was confirmed. Tumor extension was negative. The procedure was a tumorectomy and lymph node dissection followed by adjuvant radiochemotherapy. The patient then received an antiestrogen for 5 years. The senological evolution was favourable.
Conclusion
Women with hyperthyroidism may be at increased risk of breast cancer. This suggests that in the case of hyperthyroidism, special attention may also need to be paid to breast cancer screening.

Encapsulated follicular tumours of uncertain biological behaviour – clinicopathological and molecular analysis

Jindrich Lukas[1,2], Alzbeta Vorackova[1], Barbora Hintnausova[3], Vlasta Sykorova[4], Martin Syrucek[5] & Jaroslava Duskova[6]
[1]Na Homolce Hospital, Department of Otolaryngology-Head and Neck Surgery, Praha 5, Czech Republic; [2]Faculty of Medicine in Pilsen, Charles University in Prague, Ear, Nose, and Throat Department, Pilsen, Czech Republic; [3]Na Homolce Hospital, Department of Endocrinology, Praha 5, Czech Republic; [4]Institute of Endocrinology, Department of Molecular Endocrinology, Praha 1, Czech Republic; [5]Na Homolce Hospital, Department of Pathology, Praha 5, Czech Republic; [6]Charles University, Institute of Pathology, 1st Faculty of Medicine, Praha, Czech Republic

Background
The latest WHO classification of tumours of endocrine organs defines new units of borderline thyroid tumours (BTT) of uncertain biological behaviour. The aim of our study was to evaluate ultrasonographic, cytological features, mutation profile and surgery treatment in patients with these rare tumours.
Methods
The analysis of 8 out of 487 operated patients, who underwent thyroid surgery between June 2016 and June 2020. The definitive diagnosis was made postoperatively by extensive histopathological examination. Molecular genetic analysis of genes associated with thyroid oncology (BRAF, HRAS, KRAS, NRAS, TERT, TP53, fused genes) was performed from one FNAB and 7 formalin-fixed paraffin-embedded (FFPE) samples.
Results
BTT were found in a total of 8 patients (1, 6%), with a predominance of men (6 men/2 women) in contrary to other operated patients. Preoperative cytological samples were classified in the Bethesda system as non-diagnostic (Bethesda I), benign (Bethesda II) and atypia/follicular lesions of undetermined significance (Bethesda III) in one, four and three cases, respectively. Hemithyroidectomy was performed in four cases and total thyroidectomy in four patients. The definitive histological diagnosis revealed non-invasive encapsulated follicular neoplasm with papillary-like nuclear features (NIFTP) in three patients, follicular tumour of uncertain malignant potential (FT-UMP) in three patients, well differentiated tumour of uncertain malignant potential (WDT-UMP) in one patient and hyalinizing trabecular tumour (HTT) in one case. The patients with NIFTP had mutations in HRAS - in one patient also in combination with pathogenic variant in TP53 gene and mutation in NRAS gene in two patient was detected and in HTT patient PAX8/GLIS3 fusion gene was detected from the surgically removed tissue. In remaining four cases, no somatic pathogenic mutations or fusion genes were found.
Conclusion
The surgical treatment of borderline thyroid tumours (BTT) is necessarily individual. It is influenced by preoperative clinical, ultrasonographic, cytological and molecular genetic findings, as well as the presence of other comorbidities.
Key words
borderline thyroid tumour, thyroid FNAB, molecular testing of thyroid tumours, thyroid surgery.

Selpercatinib as an alternative therapy to Lenvatinib for metastatic medullary thyroid cancer. A case report.

Cristina Contreras Pascual, Cristina Montalban Mendez, Antonio Moreno Tirado, Maria Zhao Montero Benítez, Paloma González Lázaro, Julia Silva-Fernández, Florentino Del Val Zaballos, Francisco Javier Gómez Alfonso, Amparo Lomas Meneses & Inés Gómez García
La Mancha Centro Hospital Centre, Endocrinology Department, Alcázar de San Juan, Spain

Selpercatinib is a receptor tyrosine kinase RET inhibitor for the treatment of cancers such as RET-mutant medullary thyroid cancer, demonstrating partial response and low incidence of serious adverse events. Vandetanib, a tyrosine kinase inhibitor, has shown promising results with an increase in progression-free survival and prolonged lifetime, but it causes adverse events such as hypertension, diarrhea, rash, or long QT interval. Most of them are can be even disabling for the patient, leading to discontinuation of the medication, but do not necessarily suppose a severe health risk. In this report, we describe a case of an advanced medullary thyroid carcinoma who could not stand Vandetanib therapy and who needed a change of its therapy. A 47 years-old woman asked the Digestive System Unit complaining of chronic diarrhea that worsened the last week. They performed a complete study including a blood test, abdominal ultrasound, gastroscopy, and colonoscopy. The last of them revealed an 8–10 cm polypus near to the ileocecal valve with a malignancy appearance that could not be resected by endoscopy. After that a whole-body CT scan was performed as a tumor extension study, identifying a right thyroid lobe enlargement (73 × 50 × 45 mm) with endothoracic extension that caused tracheal displacement to the left. It also evidenced several cervical, mediastinal and hilar lymphadenopathies, suggestive of metastatic spread. Eco-guided fine-needle aspiration of the right thyroid lobe suggested a medullary thyroid carcinoma (Category V of Bethesda). Endocrinology Unit performed a blood test and a 24-hour urinary fractionated metanephrines determination to rule out primary hyperparathyroidism and pheochromocytoma respectively, that were negative. One month later, a subtotal thyroidectomy and a wide lymphadenectomy was performed. Because of the incomplete resection and the tracheal compression, the colonic polypus resection needed to be delayed. A (18)F-FDG PET/TC revealed two bone metastatic lesions (T4bN1bM1). The patient started Vandetanib 300 mg diary, but six months later she suffered severe hypomagnesemia (0.5 mg/dl) that needed intravenous replacement. Also, she developed a rash and long QT interval. The hypomagnesemia persisted despite a Vandetanib dose reduction and oral magnesium replacement, because of that we decided to change ITK therapy to Selpercatinib (after positive determination of RET mutation). Three months later, she has no adverse events with the new RET inhibitor therapy. Could Selpercatinib be a better therapeutic option than Vandetanib for our patients in the next future? further studies will be necessary to answer this question.

A rare brain metastases of papillary thyroid cancer

Ioannis Svilias, Jan Cap & Filip Gabalec
Charles University Hospital and Faculty of Medicine in Hradec Králové, 4th Dep. of Internal Medicine - Hematology and Endocrinology, Hradec Králové, Czech Republic

Introduction
Papillary thyroid cancer (PTC) has generally good prognosis irrespective of lymph node metastases. The rate of survival in patients with distant metastases is variable, depending upon the site of metastases and radioiodine accumulation status. The median survival of patients with brain metastases is approximately one year.
Case
We present a 66 years old woman with a tumour triplicity (PTC, breast cancer and ovarian cancer). She underwent total thyroidectomy (T1bmN1bM0, stage IV A) in 2013. Radioiodine was administered twice with a cumulative dose of 7.4 GBq (300 mCi) 131-I. The other tumours were in remission. Since May 2018 there was a slight increase of thyroglobulin (0.52 µg/l). In December 2018 the thyroglobulin level was 2.24 µg/l and the ultrasound of the neck was negative. She was treated with radioiodine (100 mCi) with a negative post-radioiodine whole-body scan. During next follow-up there was further increase of thyroglobulin level (6.53 µg/l). CT scan of the whole body provided a negative result. After two months she was examined for malaise, vertigo and left hemiparesis. Brain MRI showed a solitary tumour of the frontal lobe 25 × 26 × 26 mm. The thyroglobulin level was 12.56 µg/l at that time. Extirpation of the tumour confirmed metastases of PTC. Follow-up MRI of the brain was without any residual tumour. She was treated with radioiodine (150 mCi) after administration of recombinant human TSH. The patient, two years after operation, has a stable level of thyroglobulin (0.94 µg/l), with negative brain MRI and whole-body FDG-PET scan.
Conclusion
Brain metastases of papillary thyroid cancer are very rare. Surprisingly our patient had only mild increases of thyroglobulin level, that did not allow us, in the beginning, to suspect possible brain metastases. We diagnosed the metastases only after the patient started to have neurological symptoms. There are no guidelines for the treatment of brain metastases from the thyroid cancer. Surgical resection is probably associated with prolonged survival but till now there is no evidence of survival benefit from radioiodine therapy.

Management of papillary thyroid microcarcinomas

Mohamed Masmoudi, Mehdi Hasnaoui, Thabet Wadii, Hammemi Rim & Mighri Khalifa
Tahar Sfar Hospital Mahdia, ENT Department, Mahdia, Tunisia

Objective
The study's purpose is to describe the therapeutic management of papillary thyroid microcarcinoma.
Material and methods
This is a retrospective study including 55 cases of papillary thyroid microcarcinoma treated at our department, from 2000 to 2020.
Results
Our study included 8 men and 47 women. The mean age was 48.64 years with extreme ages from 24 to 73 years old. Three patients had hypothyroidism,

one patient had hyperthyroidism and two had a history of loboisthmectomy for benign nodules. No personal history of cervical irradiation or thyroid cancer in the family have been noted. The average consultation delay was 14 months. The circumstances of discovery were: lateral cervical lymph node metastases in 5 cases, incidentally discovered by histological examination of the thyroidectomy specimens in 51 cases and ultrasound-guided fine-needle aspiration in 4 cases. The surgical procedure towards the gland was total thyroidectomy in 47 cases, loboisthmectomy in 6 cases and lobectomy in 2 cases (totalization). Central lymph node dissection was performed in 42 cases and 5 patients had lateral lymph node dissection. The postoperative course was complicated by: lymphorrea in 1 case, hematoma in 1 case, transient hypocalcaemia in 5 cases, transient recurrent laryngeal nerve paralysis in 3 cases. The mean size of microcarcinomas was 5 mm [1 mm–10 mm]. Microcarcinoma was multifocal in 16 cases, non-encapsulated in 28 cases and with extra thyroid extension in 12 cases. Fifteen patients had central lymph node metastasis and lateral lymph node involvement was noted in 5 cases. None of the patients had distant metastasis. Radioactive iodine has been indicated in 42 cases with a dose ranging from 100 mCi to 400 mCi. Thyroid hormone suppression was indicated in all cases. After a mean follow up of 3 years and 6 months, 2 patients presented a recurrence. Five patients were lost to follow-up.
Conclusion
The incidence of papillary thyroid microcarcinoma is increasing. Its therapeutic management, which must be multidisciplinary, is still a controversial subject. It remains an entity with a good.

Using TI-RADS classification increased accuracy of Thyroid cancer diagnosis

Mohina Salimova, Said Ismailov & Zulaykho Shamansurova
Tashkent Pediatric Medical Institute, Endocrinology, Tashkent, Uzbekistan

Introduction
Problems with thyroid cancer and its diagnosis are one of the current issues in modern endocrinology. Ultrasound examination detects thyroid nodules in 19-67%of the population, whereas the new classification of thyroid ultrasound examination proposed by the American Association of Thyroidologists – the use of TI-RADS in the diagnosis of thyroid cancer increases the diagnostic accuracy of this test by 91–95%. The aim of our study was to assess the importance of laboratory-instrumental, cytological examination methods and TI-RADS classification in the early diagnosis of patients with thyroid cancer.
Material and methods
In 34 patients with operative treatment at Republican Specialized Scientific Practical Medical Centre Endocrinology and Vitamed Clinic with a diagnosis of thyroid cancer and 10 healthy subjects observed. The blood serum level of TSH, T4, calcitonin, Anti-TPO, Anti-TG, CEA titers were determined. Results of laryngoscopy, scintigraphy, as well as fine-needle aspiration biopsy (FNAB), express histology compared. Thyroid ultrasound examination performed according to the traditional and newly proposed TI-RADS classifications.
Results
Thyroid cancer diagnosed in 6.5 times more often in women than in men. The mean age of observed patients were 43 ± 1.2 years. 50%of patients were found to be obese and 13%were found to have a hereditary predisposition to thyroid cancer. The amount of TSH in the blood were in 13.3% ($P < 0.05$) higher than in healthy subjects. The results of blood biochemistry were not significantly differ from healthy subjects. Whereas diagnosis of thyroid cancer by traditional ultrasound examination were 23%of patients, by before surgery FNAB in 64%, while diagnosis accuracy increased by 80%with TI-RADS classification. Thyroid cancer confirmed by histology after surgery in 100%by using of TI-RADS classification, whereas in 80%in those observed by traditional ultrasound.
Conclusion
The incidence of thyroid cancer was higher in women than in men and affected middle-aged (mean 43-year-olds) patients. Thyroid cancer diagnosis confirmed in 23%cases by conventional ultrasound examination, in 64%by FNABs, and 80%by ultrasound using TI-RADS classification. After surgery histology confirmed diagnosis in 80%by traditional ultrasound and in 100%by using TI-RADS classification and prevented unnecessary thyroidectomy.

The impact of clinicopathological characteristics of differentiated thyroid cancer on free-disease survival

Hana Charfi, Hamza Fatma, Gherissi Wiem, Jardak Issam, Maaloul Mohamed, Kallel Faouzi, Amouri Wissam, Charfeddine Salma, Chtourou Khalil & Guermazi Fadhel
Hbib Bourguiba Hospital, Nuclear Medicine, Tunisia

Introduction
Differentiated thyroid cancer (DTC) is a rare disease (1%), and usually has good prognosis if well treated. However, the percentage of mortality due to this cancer is about 0.5%. Moreover, 5 to 27%of patients treated for DTC suffer from regional recurrence. Therefore, many research tried to identify predective factors for the survival, relapse and progression of this cancer.
Purpose
The aim of our study was to identify the histopathologic characteristics considered as bad prognosis signs.
Methods
This is a descriptive retrospective study for patients who had DTC and were treated either in the nuclear medicine departement or the ear, nose and throat (ENT) departement in Hbib Bourguiba hospital, Sfax, Tunisia.
Results
A total of 115 consecutive cases of DTC were reported. The median age at diagnosis was 40 years (13-83 years). Sex ratio was 5.38 (97/18). The cases included classical papillary thyroid cancer (PTC) in 88.7% and follicular thyroid cancer (FTC) in 11.3%. Total thyroidectomy was performed on all our patients : central and/or lateral neck dissection in 95.7%of patients, and radioactive iodine ablation in all the cases. Additional therapies were administered to 10 patients. A 10-year period follow-up, showed that 78.4%of patients had excellent response. Disease-free survival (DFS) was described in 81.1% of PTC and 58.3%of FTC, but differences were not statistically significant ($P = 0.075$). Unique tumor had better prognosis than multiple tumors : 84.9% versus 68.6%. A more than 4 cm tumor size had statistically more risk of relapse with $P = 0.006$. Patients with intact tumor capsule had 87.4%of DFS versus 67%in case of tumor capsule invasion ($P = 0.039$). In small tumors limited to the thyroid, the pourcentage of DFS was 83.3%versus 31.1%in tumors with extrathyroidal invasion. Tumor necrosis was significantly associated with bad prognosis with DFS pourcentage of 42% ($P = 0.013$). Finally, we noted that patients with more than 5 nod lymph involvement had a very bad prognosis ($P < 0.0001$). However, the affected lymph node territory had no statistically significant difference ($P = 0.112$).
Conclusion
Differentiated thyroid cancers account for 0.5–1% of all cancers and are usually of good prognosis. It depends on a number of factors. Some of these factors are of controversial therapeutic importance. As a result, several prognostic evaluation systems have been developed (EORTC, AMES). But not all of these factors are unanimously accepted and no international scores have been adopted.

Patients with differentiated thyroid cancer treated with low iodine dose: clinical results

Enrique Redondo, Sara León Utrero, María Del Carmen Andreo-Lopez, Mª del Carmen Serrano Laguna, Maria Hayon Ponce & Maria Dolores Aviles Perez
San Cecilio University Hospital, Endocrinology and Nutrition

Introduction and objectives
Thyroid cancer treatment tends to be individualized based on risk stratification and increasingly less aggressive for low-risk tumors, as recent studies have shown that low doses of I-131 are just as effective than higher doses with excellent remission rates. The objective of our study was to evaluate the response after 1 year of treatment with 30 mCi of I-131 in patients with differentiated thyroid cancer.
Material and methods
Retrospective observational study. 13 patients were included with a mean age of 49.8 ± 10.4 years (61%women). All of them underwent total thyroidectomy followed by a 30 mCi dose of I-131. To evaluate the response at one year, TSH and thyroglobulin levels, cervical ultrasound and total body scan were performed. At each visit, dynamic risk staging was performed, classifying them into: excellent response, incomplete biochemical and/or structural response, and indeterminate response. Statistical analysis was performed using the SPSS program (SPSS, inc, v 15.0)

Results
The pathological study showed 76.9%papillary thyroid carcinoma, 58.3%high risk variants (38%classic variant, 15.4%follicular pattern, 15.4%minimally invasive encapsulation, 7.7%tall cells, 7.7%columnar cells, 7.7%oncocytic features). 92%of the patients were classified as low risk or stage I, according to the TNM system. The mean MACIS value was 4.79 ± 0.87. Mean TSH at follow-up 0.84 ± 1.59 µIU/ml. 69.2%presented an excellent response, 23.1%an indeterminate response, and 7.7%an incomplete structural response.
Conclusions
In our experience, patients appropriately selected to receive low doses of iodine have a good response and tolerance to treatment. Dynamic risk staging is an effective follow-up tool, allowing individualization of the therapeutic strategy to reduce the risk of recurrence.

Lymph node metastasis in thyroid papillary microcarcinoma

Mohamed Masmoudi, Thabet Wadii, Zitouni Chaima, Ben Arfi Taissir, Mehdi Hasnaoui & Mighri Khalifa
Tahar Sfar Hospital mahdia, ENT Department, Mahdia, Tunisia

Introduction
Thyroid papillary carcinoma is the most common type of thyroid cancer. Thyroid papillary microcarcinoma is a subtype of papillary carcinoma that includes tumors with 10 mm or less diameter. As a result of diagnostic methods improvement, prevalence of this tumor is increasing. In this study, we reviewed lymph node metastasis characteristics among patients with papillary microcarcinoma.
Methods
A retrospective study about 55 patients operated for a papillary microcarcinoma, at our institution, from 2000 to 2020.
Results
The average age of our patients was 48 years. The sex-ratio (H/F) was 0.17. The circumstances of the discovery were a metastatic cervical adenopathy in 5 cases, incidental on histological examination in 45 cases, on an echoguided fine needle aspiration in 5 cases. We performed a total thyroidectomy without lymph node dissection in 3 cases. A total thyroidectomy with central lymph node dissection was done in 39 cases, lateral and central lymph node dissection were performed in 5 cases. It was a two-stage thyroidectomy in 15 cases. Lobo-isthmectomy was performed in 6 cases, and a lobectomy (totalization) in 2 cases. Lymph node metastasis was diagnosed on the anatomopathological examination in 15 cases: 10 of them presented central lymph nodes metastasis, 5 of them presented central and lateral lymph nodes metastasis. Among those patients, the mean papillary microcarcinoma size was 8 mm. It was multifocal in 1 case, non-encapsulated in 8 cases, infiltrating perithyroid tissue in 10 cases. All patients, having lymph node metastasis, had radioactive iodine. No cases of recurrence or distant metastasis have been reported.
Conclusion
Papillary microcarcinoma has a benign behavior with excellent prognosis in most cases however lymph nodes metastases are frequent and seem to be correlated with tumor size, capsule, and multifocality.

Differentiated thyroid carcinoma with metastatic presentation

Lucia Almeida, Marta Almeida Ferreira, Ana Sousa, Helena Alves, Diogo Ramalho, Sara Correia & Maria João Oliveira
Centro Hospitalar de Vila Nova de Gaia/Espinho, Endocrinologia, Vila Nova de Gaia/Espinho, Portugal

Introduction
Follicular thyroid carcinoma (FTC) has metastasis in 10-15%; papillary thyroid carcinoma (PTC) rarely metastasizes. Bone metastasis are rare and can cause pain, fractures and spinal cord compression.
Case-1
72 year-old male referred to the hospital with lower back pain. Imaging examination revealed lytic lumbar lesions. Thoracic-abdominal-pelvic-CT showed trachea compression by a multinodular right thyroid lobe. Thyroid-US revealed a 35 mm nodule in that lobe – FNAC: Bethesda IV. Biopsy of one lytic lesion showed thyroid carcinoma metastasis. Total thyroidectomy was performed – histology: PTC. Therapy with ^{131}I took place; post-treatment ^{131}I-scintigraphy revealed low back hyperfixation. During follow-up, he maintained signs of bone metastases, confirmed by FDG-PET-CT. Heunderwent radiotherapy and further ^{131}I treatment. The disease progressed with bone and pulmonar lesions and eventually he lost his mobility. He declined TKI treatment and died 4 years after diagnosis.
Case-2
59-year-old female referred to the hospital, in 2011, with inferior limb pain. Pelvic-CT revealed lesions around the left iliac bone: biopsy revealed FTC metastasis. A thyroid-US showed a 32 mm left lobe nodule – FNAC: Bethesda V. She underwent total thyroidectomy (histology: FTC) and ^{131}I; post-treatment ^{131}I-scintigraphy showed hyperfixation of ileum, sacrum and scapula. Before any further treatment, she died with generalized bone metastatic disease.
Case-3
76-year-old female (prior history of right hemithyroidectomy in 2014, for benign nodular goiter) sent to neurosurgery in 2018, with occipital headache. Brain-MRI showed lytic lesions of the occipital bone: biopsy revealed FTC metastasis. Thyroid-US showed 2 nodules on the remaining thyroid (18 mm; 7 mm) – FNAC: Bethesda IV. Totalization of thyroidectomy was performed – histology: NIFTP. She underwent ^{131}I therapy. Post-treatment ^{131}I-scintigraphy revealed hyperfixation of the thyroid bed, occipital bone (confirmed by brain-MRI), right ribs and lung. After another ^{131}I therapy, scintigraphy showed persistent disease. Radiotherapy is on demand.
Case-4
In 2015, a 82 year-old female was admitted to the hospital with thoracic pain. Thoracic-CT showed a 38 mm pulmonary nodule and sternum lytic lesion (histology compatible with FTC metastasis). Thyroid–US revealed a 22 mm left lobe nodule – FNAC: Bethesda VI. Total thyroidectomy took place in 2016 – histology: FTC. ^{131}I therapy was proposed. Post-treatment ^{131}I-scintigraphy revealed hyperfixation of the thyroid bed, sternum and lungs, confirmed by thoracic-CT. The patient underwent a second ^{131}I therapy, but the disease progressed. She refused further treatment and died 1 year later.
Conclusion
These cases show rare presentations of differentiated thyroid carcinoma. We must pay attention to osteartícular complains, especially in the presence of thyroid nodules or previous thyroid surgery.

Epithelioid hemangioendothelioma with thyroid involvement – case report

Sara Franco, Catarina Cardoso, Rafaela Correia, Mafalda Sequeira, Magno Dinis Sousa, Filipa C. Bastos, Pedro Sequeira, Ana Raquel Miranda, Francisca Abecassis, Ana Gonçalves Ferreira, David Barbosa, Henrique Vara Luiz & Jorge da Cunha Oliveira
Hospital Garcia de Orta, Almada, Portugal

Epithelioid hemangioendotheliomas (EHE) are rare vascular tumors that are typically low to intermediate grade, but they can also have an aggressive behaviour. Mortality rate is dependent on the tumor location. It is frequently a solitary lesion located in the superficial or deep soft tissues, but they can be found in liver, lungs (normally multifocal), pleura, bones, lymph nodes and rarely in the thyroid gland. We describe a case of metastatic EHE with involvement of the thyroid gland, liver and lungs (probably primary tumor) and aggressive behaviour. A 73-year-old woman was admitted to our hospital due to progressive tiredness, pleuritic pain and episodic cough. Thorax CT scan showed diffuse lung nodularity and micronodularity suggestive of metastatic disease. SARS COV2 infection was excluded. An abdominopelvic CT showed multiple hepatic lesions suggestive of metastases. She underwent lung and liver biopsy both suggestive of EHE (cells with little atypia, round nucleus and rare mitosis, vascular lumens with hemosiderin pigment, CD34+, CD31+). She was also submitted to ultrasound-guided thyroid fine needle aspiration cytology due to a hypoecogenic macronodule, detected on thorax CT, located on the right lobe and isthmus of the thyroid gland, that exceeded the limits of the ultrasonographic image. Thyroid cytology showed moderate cell atypia, CD34+, with features similar to the other biopsy results. She was discharged and referred to Portuguese Oncology Institute. Few days after discharge, she presented at the ER with liquid and solid dysphagia and dyspnea. Neck CT showed a substernal goiter with the right lobe measuring 50 × 65 × 95 mm and mass effect on the larynx, trachea and esophagus, causing an important reduction of laryngeal air column. After a multidisciplinary approach it was decided to perform surgical tracheostomy. During this procedure a biopsy

of the cervical mass was performed and showed a malignant epitheliod neoplasm, without vascular differentiation but also areas with features of EHE, co-expression of CK AE1/3 and CD34, expression INI1. Few days later the patient presented with acute respiratory insufficiency and died. Although rare, EHE can have several locations and mimic many other malignant and non-malignant diseases. Involvement of the thyroid gland is very uncommon. Clinicians should be aware of this diagnosis and include it in the differential diagnosis of a cervical mass. Surgery is the usually the treatment of choice in case of primary EHE of the thyroid gland. Our case of metastatic disease had a very bad prognostic and showed an aggressive course.

Therapeutic and evolutive aspects of cardiothyreosis in adult population of southern tunisia

Mouna Elleuch, Sawssan Ben teber, Dhoha Ben Salah, Hadj Kacem Faten, Nadia Charfi, Nabila Mejdoub, Mouna Mnif, Fatma Mnif & Mohamed Abid
University Hospital Hedi Chaker, Endocrinology, Sfax, Tunisia

Introduction
Cardiothyreosis is associated with higher morbidity and mortality than other forms of hyperthyroidism. The aim of our study was to identify its therapeutic and evolutive aspects in an adult population of southern Tunisia.
Methods
Retrospective study including all cases of cardiothyreosis followed in our department during a period of 20 years.
Results
100 cases of cardiothyreosis were collected. To treat the hyperthyroidism, the association of antithyroid drugs and radioactive iodine was used in 52%of patients. Thyroidectomy was performed in 9%of cases. For the cardiothyreosis, 90%of patients went under ß-blockers. All patients with congestive heart failure (CHF) were treated with diuretics. Patients with atrial fibrillation have received anticoagulants. The most used molecule was acenocoumarol (86%). The evolution of cardiothyreosis was favorable in 64.4%of cases while 9%of patients died. In our study, the association of atrial fibrillation and CHF in the same patient, and the elevation of the end-systolic and end-diastolic diameters of the left ventricular were significantly associated with higher risk of mortality ($P < 0.05$).
Conclusion
While its diagnosis is often easy, the management of cardiothyreosis remains difficult. The prognosis of this disease may be ameliorated by an early and efficient treatment.

Ectopic thyroid tissue: about 2 cases

Chtioui Sara, Bammou Sanaa, Rafi Sanaa, El Mghari Ghizlane & El Ansari Nawal
Mohammed VI University Hospital Center, Endocrinology, Diabetology and Metabolic Diseases Department, Marrakech, Morocco

Introduction
Accessory thyroid is defined as the presence of thyroid tissue in locations other than the normal anterior neck region between the second and fourth tracheal cartilages. It is a congenital disease caused by the abnormal migration of thyroid tissue in the embryonic stage. Lingual thyroid is the most common form of ectopic thyroid, extra lingual thyroid tissue is commonly located in the anterior cervical area, along the path of the thyroglossal duct.
Case report
Through a review of 2 different cases, the etiopathogenetic, clinical-diagnostic, and therapeutic aspects of ectopic thyroid tissue are here in discussed to highlight the main presentations of this polymorphous disease. The first case involved an ectopic thyroid gland in the submandibular region with no normally positioned thyroid in a male child of 9 years old with congenital hypothyroidism without mental retardation. The child was put on thyroid hormone treatment and the thyroid hormone level was restored. The second case involved a 40-year-old woman, presenting 3 months after total thyroidectomy, two right lateral cervical masses with moderate signs of compression and without signs of inflammation or thyroid dysfunction. The Cervical tomodensitometry revealed the presence of three tissue formations above the hyoid bone 7.6 × 7 mm, pre hyoid 16 × 12 mm and para hyoid 40 × 31.5 mm compatible with accessory thyroid with empty thyroid lodge.
Conclusion
The ectopic thyroid is classified under the category of congenital hypothyroidism, and it is one of the top causes of thyroid dysgenesis. The first case illustrate the importance of newborn screening and identification of congenital hypothyroidism which is the commonest treatable cause of mental retardation.

Coexistence of Hodgkin lymphoma and papillary thyroid carcinoma: 3 years follow up of a case report.

Yusuf Bozkus, Ozlem Iyidir, Feride Pınar Altay & Neslihan Başçıl Tütüncü
Başkent University Ankara Hospital, Endocrinology and Metabolism, Ankara, Turkey

Introduction
Thyroid cancers account for about 2.9%of all cancers. Although it is reported that the risk of developing PTC as the second primary cancer increases after treatment of Hodgkin lymphoma (HL), concomitant PTC and HL are quite rare and to the best of our knowledge we found only three cases in the literature. This case report presents the treatment management and three-year course of a male patient with simultaneous diagnosis of PTC and HL.
Case
A 26-year-old male presented with a complaint of neck swelling. On physical examination, 3 cm mobile, painless, stiff lymphadenopathy (LAP) was detected in the right cervical region. He did not have fever, night sweats or weight loss. The ultrasonography revealed 6 mm, hypoechoic nodule with irregular boundries and microcalcifications and several hypoechoic LAPs with asymmetric cortical thickness. FNAB was applied to the 6 mm nodule in the right thyroid lobe. Since FNAB reported as suspicious cytomorphological findings for malignancy, patient went on total thyroidectomy and lymph node dissection. Pathology revealed three foci of PTC with sizes of 7 mm, 0.5 mm and 0.75 mm in the right lobe. The first focus was 7 mm in size, with minimal extrathyroidal extension and adjacent to the surgical border posteriorly and no lymphovascular invasion. According to the ATA guidelines, the case was intermediate risk. Nodular lymphocyte predominant Hodgkin lymphoma was detected in the lymph nodes, removed from the right cervical region. On postoperative 1st month, ^{18}F-FDG whole body positron emission tomography (PET) revealed pathological involvements in the right jugulodigastric and right cervical chain. The patient was diagnosed with low-risk, stage IA lymphocyte predominant Hodgkin lymphoma. In the second postoperative month, conventional radiotherapy (RT) was applied to the neck region. Radioactive iodine was given at the postoperative 5th month. Whole body scan showed an activity in thyroid bed. The patient was then followed up with TSH suppression. Whole body scan with recombinant human TSH, 1.5 years after RAI treatment was normal. The patient, who is currently at the 36th month of his follow-up, is in remission for lymphoma and PTC.
Discussion
Cases with simultaneous diagnosis of PTC with HL are very rare. In these cases it is important to decide which cancer to treat first. It is thought that therapeutical time interval does not affect mortality and morbidity in the treatment of differentiated thyroid cancer. Therefore, as we did in our case, we recommend giving priority to lymphoma treatment.

EP214

Disorders of carbohydrate metabolism in hyperthyroidism in children and adolescent

Shakhlo Muratova & Anvar Alimov
Republic specialist scientific-practice medical Centre of endocrinology named after academician Ya. Kh. Turakulov, Thyroidology, Tashkent, Uzbekistan

Relevance
Excess thyroid hormone as a result of thyroid hyperstimulation affects all types of metabolism, including carbohydrate metabolism

Purpose
To assess the incidence of carbohydrate metabolism disorders in children and adolescents with hyperthyroidism.
Materials and methods
Hormonal analysis of thyroid status (TSH, free and total T3, free and total T4, TSHRAb, TPOAb), and biochemical studies (glycemia, glycated haemoglobin, total cholesterol, urea, creatinine, hepatic transaminases) in 79 children and adolescents who received inpatient and outpatient treatment at the RSSPMC after Ya. Kh. Turakulovin the period from 2007 to 2020.
Results
In the period from 2007 to 2020, we examined 73 children with hyperthyroidism in the active phase at the age of 2–18 years, the control group consisted of 21 children of the same age without endocrine pathology, living in the Republic of Uzbekistan. The mean serum level of sugar, creatinine, ALT, AST in the group with hyperthyroidism was significantly higher than in the control group, the mean values of urea did not have a significant difference, the mean total cholesterol level in the group with hyperthyroidism was significantly lower than in the control group (Table 1). Among children and adolescents with hyperthyroidism, 6.85%(5) were simultaneously diagnosed with type 1 diabetes mellitus. In 11%(8) adolescents, fasting hyperglycemia and impaired glucose tolerance were revealed.

Table 1. Indicators of glycemia and some biochemical tests in the study groups

	Sugar	Total cholesterol	Urea	Creatinine	ALT	AST
Hyperthyroidism	6.0 ± 0.4	2.7 ± 0.1	4.75 ± 0.1	65.7 ± 2.6	33.4 ± 1.9	34.3 ± 1.8
The control	4.2 ± 0.3	4.2 ± 0.2	4.3 ± 0.4	57.9 ± 2.4	13.0 ± 1.4	16.6 ± 2.5
p	0.0004	0.0003	0.27	0.04	0.001	0.002

In 56 children and adolescents with hyperthyroidism, we analyzed the correlation between glycemic and other biochemical tests and thyroid status. A weak negative correlation between TSH and creatinine ($r = 0.3$, $P < 0.05$) and a direct correlation with fT4 ($r = 0.3$, $P < 0.05$), a high correlation of fT3 and glycemia ($r = 0.8$, $P < 0.05$) and weak with AST ($r = 0.3$, $P < 0.01$), as well as the level of fT4 with glycemia ($r = 0.4$, $P < 0.05$), ALT ($r = 0.4$, $P < 0.01$), AST ($r = 0.4$, $P < 0.01$) and creatinine ($r = 0.3$, $P < 0.05$). A weak direct correlation between TSHRAb and AST level was revealed ($r = 0.4$, $P < 0.05$).
Conclusions
This study shows the presence of carbohydrate metabolism disorders in hyperthyroidism in children and adolescents, demonstrated by diabetes mellitus (6.85%), fasting hyperglycemia and impaired tolerance to glucose (11%). A direct correlation was found between thyroid hormones and blood sugar.

DOI: 10.1530/endoabs.73.EP214

EP215

A neck mass revealing thyroid hemiagenesis in an adolescent girl with euthyroidism.

Ibtissem Oueslati, Asma Kardi, Meriem Yazidi, Amani Terzi, Fatma Chaker & Melika Chaker
La Rabta Hospital, University of Tunis El Manar, Faculty of Medicine, Endocrinology, Tunis, Tunisia

Introduction
Thyroid hemiagenesis is defined as the absence of one lobe of the thyroid gland. It represents a rare congenital abnormality with a prevalence of 0.05 to 0.2%. The left lobe is more commonly affected than the right lobe. Thyroid hemiagenesis is incidentally found during a routine thyroid screen. Herein, we report a thyroid hemiagenesis revealed by a compensatory hypertrophy of the contralateral thyroid lobe in an adolescent girl with euthyroidism.
Observation
A 16-year-old girl was referred to our department for an anterior right neck mass. Her past medical history was unremarkable. On physical examination, she had a large right thyroid lobe with a complete absence of the left lobe. On biological investigations, she had a TSH level of 1.07 mIU/l (nr: 0.35–4.95) and a FT4 level of 1.09 ng/dl (nr: 0.70–1.50). Cervical ultrasound showed a complete absence of the left lobe of the thyroid and a large heterogeneous right lobe with hypervascularity. Scintigraphy confirmed the hemiagenesis of the left lobe of the thyroid gland and showed a diffuse enlargement of the right lobe with a high and uniform accumulation of the tracer. No ectopic thyroid tissue was noted. Anti-thyroperoxydase antibodies and anti-TSH receptor antibodies were negative. The patient remained euthyroid over the course of follow-up.
Conclusion
Thyroid hemiagenesis is commonly asymptomatic and thyroid function is usually normal. However, patient may present a goiter resulting from the development of a compensatory hypertrophy of the contralateral lobe as in our case.

DOI: 10.1530/endoabs.73.EP215

EP216

A case of Hashimoto's thyroiditis following Graves'disease

Ibtissem Oueslati, Asma Kardi, Meriem Yazidi, Amani Terzi, Fatma Chaker & Melika Chihaoui
La Rabta Hospital, University of Tunis El Manar, Faculty of Medicine, Endocrinology, Tunis, Tunisia

Introduction
Graves' disease is typically characterized by the presence of circulating autoantibodies that stimulate the TSH receptor, inducing hyperthyroidism and goiter. Hashimoto's thyroiditis is an autoimmune disease leading to thyroid tissue destruction by cell and antibody-mediated immune processes. The development of Hashimoto's thyroiditis following Graves' disease is rarely reported. Its pathogenesis is not confirmed. Herein, we report a case of Hashimoto's thyroiditis following Graves'disease treated with radioactive iodine.
Observation
A 40-year-old woman was referred to our department for thyrotoxicosis. She presented with a weight loss, palpitations, excessive sweating, tremor, and nervousness. On physical examination, she had a regular pulse of 112 beats/mn, a diffusely enlarged thyroid gland, and a tremor in both hands. Laboratory tests revealed overt hyperthyroidism with free thyroxine (FT4) level of 6 ng/ml (normal range: 0.7-1.48) and thyroid stimulating hormone (TSH) level of 0.001 µIU/ml (normal range: 0.35-4.94). Thyroid scintigraphy showed an enlarged gland with diffusely increased tracer uptake, confirming the diagnosis of Graves's disease. The patient was treated with propranolol and thiamazole. Two months later, she received a radioactive iodine therapy. Three years and 9 months later, the patient had a TSH level of 8.787 µIU/ml with a very high level of thyroperoxydase antibodies (2208 IU/ml; nr: < 35 IU/ml) consisting with the diagnosis of Hashimoto's thyroiditis. She was treated with levothyroxine.
Discussion and conclusion
In the early stage of Hashimoto' thyroiditis, a mild and transitory hyperthyroidism may occur as a result of thyroid cells destruction and the releasing of thyroid hormones into circulation. In our patient, based on the severity of hyperthyroidism and the scintigraphic feature, we concluded that the etiology of the initial thyrotoxicosis was Graves' disease. The occurrence of hypothyroidism could be secondary to radioiodine therapy. However, the very high level of thyroperoxydase antibodies is consisting with the diagnosis of Hashimoto' thyroiditis. In 10 to 15%of Graves' disease, Hashimoto's thyroiditis may occur after remission. The precise mechanisms are not known.

Thyroid dysfunction associated with immune checkpoint inhibitors therapy

Natalya Mazurina[1], Anastasiya Glibka[1], Ekaterina Troshina[1], Konstantine Laktionov[2], Galina Kharkevich[2], Kseniya Sarantseva[2] & Svetlana Kruteleva[2]
[1]Endocrinology Research Center, Moscow, Russia, therapeutic endocrinology, Moscow, Russian Federation; [2]N.N. Blokhin National Medical Research Center of Oncology, chemotherapy department, Moscow, Russian Federation

Introduction
Prospective and retrospective trials report the incidence of endocrine adverse events provoked by immune checkpoint inhibitors (ICI) up to 30%. PD-1/PDL inhibitors have a higher incidence of thyroid dysfunction: hypothyroidism 5%-14%, transient hyperthyroidism – 3%-5%.
The aim of the study was to assess thyroid function in PD-1/PDL treated patients.
Materials and methods
69 patients were included in the study: 27 melanoma patients and 42 non-small cell lung cancer patients. 46 patients were treated with nivolumab,

10 – with pembrolizumab, 9 – with atezolizumab and 4 – consistently with nivolumab and pembrolizumab or atezolizumab. TSH, free T4 and freeT3 were assessed before ICI therapy (visit 0) and every time before the next administration of the drug. The minimum period of observation was 3 months, so we report results obtained at this point in the study.
Results
Before starting ICI 6 patients had TSH and thyroid hormones levels beyond the limits of the reference range: subclinical hyperthyroidism – 2 cases, subclinical hypothyroidism – 1 case, overt hyperthyroidism – 2 cases, overt hypothyroidism – 1 case. In 5 cases we found low T3 (euthyroid sick syndrome). After 3 months of therapy 9 new cases of low T3, 2 cases of persistent hyperthyroidism, 2 cases of subclinical hyperthyroidism and 2 cases of destructive thyroiditis with two phases were revealed.
Conclusions
ICI therapy induced thyroid dysfunction in 21.7%of patients during 3 month after it's initiation, however endocrine related adverse events were not considered as an indication for discontinuation of treatment.

A rare case of Graves' disease development from Hashimoto thyroiditis

Jelena Vainikonyte Kristapone[1], Ernesta Samuiloviene[1] & Gintaras Kuprionis[2]
[1]Siauliai Outpatient Clinic, Siauliai, Lithuania; [2]The Hospital of Lithuanian University of Health Sciences Kauno klinikos, Radiology Department, Kaunas, Lithuania

The conversion of Hashimoto thyroiditis (HT) to hypothyroidism is frequently observed in daily clinical practice, but the development of Grave's disease (GD) after long-standing hypothyroidism is rare and intriguing. A 70-year-old woman visited an endocrinologist, complaining of increased heart rate, anxiety, and a feeling of discomfort in the neck. Past medical history revealed HT with hypothyroidism. Laboratory tests showed significantly increased thyroid-stimulating hormone (TSH) and positive anti-thyroid peroxidase antibodies. Replacement therapy with levothyroxine 100 µg daily was initiated and implemented for approximately ten years. During the annual follow-up, thyroid hormones were found to be in the normal range. The recent physical examination revealed a firm and slightly enlarged thyroid. TSH suppression was detected, the peripheral thyroid hormone concentration and thyroid-stimulating hormone receptor antibodies (TRAB) were seen to have increased. Neck ultrasound showed slight thyroid hypoechogenicity and non-homogeneity due to multiple hypoechogenic zones. Sonographically, the thyroid lesions were indicative of chronic thyroiditis. Overactive thyroid was suspected. Therefore, levothyroxine was gradually withdrawn. Six months later, hyperthyroidism was seen to have persisted and, ultimately, required anti-thyroid treatment. This case demonstrates a rare case of HT converting to GD. We suggest that the possibility of conversion from hypothyroidism to hyperthyroidism should be considered even if there is long-standing hypothyroidism. We propose measuring TRAB in suspected cases. Further studies are needed to confirm this proposal.

The influence of age-related androgen deficiency on risk factors for cardiovascular diseases in men with hypothyriodism

Taras Krytskyy
TNMU, Ukraine

The long-term androgen deficiency (AD) in men with hypothyroidism is an important problem due to the fact that it leads to concomitant cardiac pathology, which remains the leading cause of mortality in the world. The presence of different points of view on the problem of AD and its effect on the risk factors for cardiovascular disease in patients with hypothyroidismattracts attention. The aim of the study is to assess the clinical signs of age-related androgen deficiency and their association with cardiovascular risk factors in men with hypothyroidism. 84 patients were examined, 38 of them - with hypothyroidism and age-related androgen deficiency, 46 patients with hypothyroidism and normal testosterone levels. The control group was formed of 20 men without hypothyroidism. The lipid and carbohydrate metabolism status, the presence and type of obesity, the level of depression, daily blood pressure monitoring were determined. AD was verified by decrease the total testosterone concentration in serum (< 12 nmol/l). The level of total testosterone and sex hormone binding globulin in serum were determined by radioimmunoassay analysis. The decrease of testosterone level in men with hypothyroidism is accompanied by an increase in the frequency of abdominal obesity, triglycerides and glucoseescape, and is associated with subclinical depression. In men with hypothyroidism and AD, the average blood pressure in the daytime significantly exceeds the similar rates in patients with hypothyroidism and normal levels of testosterone. AD was verified by decrease the total testosterone concentration in serum (< 12 nmol/l). The level of total testosterone and sex hormone binding globulin in serum were determined by radioimmunoassay analysis. The presence of androgen deficiency negatively affects the risk factors of cardiovascular disease in men with hypothyroidism.

Thyrotoxic periodic paralysis presenting in an adult male from Cambodia: a case report

Faïza Bensmaine[1], Barrande Gaelle[1], Desaint Paul[2], Jardin Alexis[2], Plantefeve Gaetan[2] & Guillausseau Pierre Jean[3]
[1]Victor Dupouy Hospital, Department of Diabetology, Endocrinology and Nutrition, Argenteuil, France; [2]Victor Dupouy Hospital, Intensive Care Unit, Argenteuil, France; [3]Lariboisière University Hospital, Department of Internal Medicine, Paris, France

Introduction
Thyrotoxic periodic paralysis (TPP) is a rare complication of hyperthyroidism characterized by the sudden onset of hypokalemia and muscle paralysis. This rare but possible clinical presentation of thyrotoxicosis is significantly more predominant in males of asian descent. The mechanisms of hypokalemia are incompletely understood. The prevailing theories include increased Na-K ATPase pump activity and mutations in genes encoding Kir channels in skeletal muscle. Common factors triggering attacks of periodic paralysis include the consumption of carbohydrate-rich foods, strenuous physical activity, high salt/sodium intake, stresses (surgical, infectious, psychological), trauma, and drugs.
Case presentation
We describe a case of a 52 years-old asian-french male who presented to the emergency department with complaints of acute onset of bilateral lower extremity weakness. He also endorsed a history of weight loss, palpitations, heat intolerance and tremors. Physical examination revealed a slightly enlarged thyroid gland. No exophtalmus or skin changes were present. Laboratory assessment showed severe hypokalemia with serum potassium level 1.5 mmol/l, low serum Thyroid Stimulating Hormone (TSH) (< 0.01 mUI/l) and increased both serum free triiodothyronine (27.3 pmol/l) and free thyroxine (63 pmol/l). TSH receptor antibodies were identified (4.2 IU/l). Hence, the patient was diagnosed as having thyrotoxic periodic hypokalemic paralysis associated with Graves' thyrotoxicosis. Treatment with antithyroid drugs and potassium supplements reversed the symptoms and the episodes of acute muscular weakness did not reappear.
Take-away lesson
TPP is a rare and reversible cause of paralysis. Thus, in cases of acute muscle paralysis, it is important to consider thyrotoxicosis as one of the possible causes, and take measures accordingly. Correction of hypokalemia improves acute presentation, but the patient will remain at risk for paralysis until euthyroid state is achieved.

NIvolumab induced grade 3 hypothyroidism – case series

Muhammet Cuneyt Bilginer, Yasemin Emur Gunay, Damla Tufekci, Ahmet Suat Demir, Hulya Coskun, Irfan Nuhoglu, Ozge Ucuncu & Mustafa Kocak
Karadeniz Technical University Medical Faculty, Department of Endocrinology and Diabetes, Trabzon, Turkey

Introduction
Immunological side effects related with use of immune checkpoint inhibitors (ICIs) are named as immune-related adverse events (irAEs). irAEs include clinical pictures such as autoimmune thyroiditis, hypophysitis, primary adrenal insufficiency and autoimmune diabetes mellitus. Nivolumab is an

anti-PD-1 (anti-programmed cell death-1) monoclonal antibody approved for the treatment of malignant melanoma, advanced non-small cell lung cancer and advanced renal cell carcinoma. In the literature, Nivolumab was reported for causing thyroid dysfunction in some patients treated for cancer. The incidence of Nivolumab-induced grade 3 hypothyroidism is reported as 0.12%. Here, we present two cases of overt hypothyroidism after nivolumab treatment.
Case-1
A 49-year-old male patient with a diagnosis of metastatic malignant melanoma has a treatment history for 9 cycles of nivolumab. The patient has no known thyroid disease and no history of thyroidectomy or longitudinal radiotherapy. TSH (Thyroid stimulating hormone) and FT4 levels were checked 3 months before Nivolumab therapy and were measured as 1.43 mIU/l (normal range) and 1.21 ng/dl (normal range), respectively. Overt hypothyroidism was detected in the workup performed due to the headache complaint of patient 2.5 months after the last nivolumab treatment. Result of biochemical workup was as follows: TSH>47.9 mIU/l (high), FT4:0.27 ng/dl (low), FT3: 2.71 ng/dl (low), anti-TPO(Anti-thyroid peroxidase): 0.6 IU/ml (negative), anti-TG (Anti-thyroglobulin):1651 IU/ml (positive). Performed neck ultrasound was compatible with chronic thyroiditis. Patient started receiving levothyroxine treatment and was followed up.
Case-2
A 65-year-old female patient with a diagnosis of metastatic breast cancer received 11 cycles of nivolumab treatment, and the last cure was 1 month ago. The patient has no known thyroid disease and no history of thyroid surgery or longitudinal radiotherapy. TSH measured 2 years ago was.6 mIU/l and patient was euthyroid. Overt hypothyroidism was detected in the patient's workup: (TSH> 47.9 mIU/l (high) FT4: 0.2 ng/dl (low) FT3: 1.07 ng/l (low) anti-TPO: 0.5 IU/ml (negative), anti-TG: 680 IU/ml (positive)). Patient was started on levothyroxine treatment.
Conclusion
Although there was no known history of thyroid disease; anti-TPO was negative and anti-thyroglobulin was positive at high titer and overt hypothyroidism was identified in both patients who received Nivolumab. Since there are no thyroid autoantibody tests before the treatment, it is not known whether the anti-thyroglobulin positivity alone is due to the treatment. Performing thyroid autoantibody and thyroid ultrasound before treatment would guide the follow-up of patient's thyroid function tests.

Difficulties in differential diagnosis of thyrotoxicosis: case report

Natalya Volkova, Irina Dzherieva, Ilya Davidenko, Yuliya Degtyareva, Lilia Ganenko, Alexander Zibarev, Igor Reshetnikov, Yulya Sorokina & Anastasia Chernova
Rostov State Medical University, Department of Internal Diseases #3, Rostov-on-Don, Russian Federation

Thyrotoxicosis (T) develops as a result of persistent excess of thyroid hormones (TH). There are two groups of diseases that are fundamentally different in pathogenesis. The first group includes those in which the production of TH increases. Diseases of the second group are accompanied by T caused by destruction of the thyroid gland tissue. Therapeutic approaches for different types of T are different, therefore, a careful differential diagnosis of T is necessary, even if at first glance the diagnosis seems obvious. A 35-year-old patient presents with complaints of weakness, weight loss (11 kg in 1.5 months), tremors, palpitations, which first appeared about a month ago. On examination: BMI = 24 kg/m^2, HR = 100 bpm, BP = 115/80 mmHg, the thyroid gland is no larger than the distal phalanx of the subject's thumb. Laboratory examination: TSH < 0.0083 mU/l, free T4 = 28.29 pmol/l (9.0-19.05). Ultrasound of the thyroid gland: signs of diffuse changes in tissue, the total volume = 16.8 ml^3. For differential diagnosis of T, antibodies to TSH receptors were determined, the titer of which turned out to be slightly increased 1.43 IU/l (< 1). A diagnosis of Graves' disease (GD) was made, and treatment was prescribed (Tyrozol 30 mg, Bisoprolol 2.5 mg per day). After 3 weeks, the patient noted an improvement in well-being, but weakness, tremor, an increase in free T4 (23.33 pmol/l) and total T3 (3.26 nmol/l at a rate of 0.98–2.33) remained. The lack of achievement of the target values of TH levels was regarded as inadequacy of the received dose of Tyrozol, in connection with which it was decided to increase the dose to 40 mg per day. After 2 weeks: free T4-27.26 pmol/l and total T3-3.84 nmol/l. The lack of positive dynamics called into question the diagnosis of GD. With a more thorough collection of anamnesis, it was found that 1.5 years ago, the patient took amiodarone for 6 months. In this connection, to establish the cause of T, scintigraphy was performed: a weak accumulation of a radiopharmaceutical with diffuse uneven distribution. Thus, amiodarone-induced T type 2 was verified. Treatment was corrected: Tyrosol withdrawal and Prednisolone administration, 40 mg/day with positive dynamics from treatment. It is important to carefully collect the patient's history and follow the algorithms for differential diagnosis. Errors in diagnosis lead to improperly prescribed treatment, an increase in the duration of symptoms, which affects not only the patient's quality of life, but also reduces the level of his trust in medical workers.

Prominent multinodular goiter in a patient with Williams-Beuren Syndrome

Maria del Pino Perez-Garcia[1], Esther Hernandez-Felipe[2], Paula Gonzalez-Diaz[3], Alba Lucia Tocino-Hernandez[3], Esperanza Perdomo-Herrera[4], Agnieszka Kuzior[5], Paula Maria Fernandez-Trujillo-Comenge[6], Alba Hernandez-Lazaro[6], Ricardo de Leon-Durango[6] & Francisco Javier Martinez-Martin[7]
[1]Facultad de Ciencias de la Salud, Universidad de Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain; [2]Centro de Salud Guanarteme, Las Palmas de Gran Canaria, Spain; [3]Centro de Salud de Arucas, Arucas, Spain; [4]Centro de Salud de Escaleritas, Las Palmas de Gran Canaria, Spain; [5]Hospitales San Roque Meloneras, Endocrinology & Nutrition, San Bartolome de Tirajana, Spain; [6]Hospital Universitario de Gran Canaria Dr. Negrín, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [7]Hospital Universitario de Gran Canaria Dr. Negrín, Outpatient Hypertension Clinic, Las Palmas de Gran Canaria, Spain

Objective
Presentation of multinodular goiter as an unusual feature in a patient with Williams-Beuren Syndrome.
Methods
Review of the patient's clinical records and of the relevant literature.
Introduction
The Williams-Beuren Syndrome is a multisystem disorder caused by a microdeletion of 1.5–1.8 megabase pairs on chromosome 7q11-123, with loss of 26–28 genes centered around ELN, which codifies elastin. The partial loss of elastin is the cause of cardiovascular abnormalities, particularly supravalvular aortic stenosis and other arterial stenoses. Most patients are hypertensive, and prone to stroke and sudden death. The phenotype of Williams-Beuren patients includes growth failure with adult short stature, a characteristic facial appearance, and mental retardation with a friendly, sociable character. The endocrine manifestations include precocious puberty, partial GH deficiency, hypercalcemia, osteopenia/osteoporosis, glucose intolerance or type 2 diabetes mellitus. Up to Cof Williams-Beuren patients develop subclinical or overt hypothyroidism, often not requiring treatment; in some cases the hypothyroidism is congenital with associated thyroid hypoplasia. Antithyroid antibodies are usually negative. Goiter is, however, not included in the usual descriptions of the syndrome.
Case description
A 45 year old male patient had been diagnosed with Williams-Beuren syndrome, and had the characteristic facies (short nose with upturned tip, small chin) and mild mental retardation. A cardiology workup had shown hypertension, systolic murmur, supravalvular aortic stenosis and mild mitral regurgitation, with preserved ventricular function; normal sinus rhythm with isolated ventricular extrasystoles. He was on treatment with delapril, manidipine, atenolol and hydrochlorothiazide. He had complained of an indolent cervical lump in the last year, without symptoms of thyroid dysfunction or local compression and was referred to our Endocrinology Clinic. Physical examination showed: Height 161 cm, Weight 75 kg, BMI 28.9 kg/m^2, diffusely enlarged thyroid gland, non-painful, without adherence, increased consistency, palpable nodules or adenopathies. Lab tests showed: Blood glucose 129 mg/dl, HbA_{1C} 6.2%, LDL-cholesterol 117 mg/dl; TSH 1.89 µU/ml, negative antithyroid antibodies. Cervical ultrasonography showed an enlarged thyroid gland with 6.5 cm (left lobe) and 6.2 cm (right lobe) craniocaudal diameter, and multiple subcentimeter colloid cysts, not susceptible of FNAC. Thyroid scintigraphy showed diffuse hyperplasia. The additional diagnoses were micronodular euthyroid goiter, overweight, type 2 diabetes mellitus and dyslipidemia.
Conclusions
Although mild hypothyroidism is common in patients with Williams-Beuren syndrome, goiter is not usually described. Its presence in our patient might be coincidental, but cervical ultrasonography for goiter screening may be considered.

Acute myocaditis : a rare complication in the Graves disease

Rihab Laamouri, Ghachem Aycha, Imen Rojbi, Chayma Besrour, Youssef Lakhoua, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Charles Nicolle Hospital, Endocrinology Department, Tunisia

Introduction
Graves' disease is an autoimmune disorder that has multiple cardiac repercussions including arrhythmias and heart failure. Acute myocarditis is a rarely described complication. In this context, we report a case illustrating this association.
Case presentation
A 23-year-old man has been followed for Graves' disease that had been suspected by weight loss, tachycardia and bilateral and asymetric proptosis. The diagnosis had been confirmed with an fT4 at 27 pmol/l (1.42 times the normal), TSH at 0.04 IU/l (*n*:0.35-4), anti-TSH receptor antibodies positive at 40 IU/l and on thyroid ultrasound a hypervascular and enlarged thyroid gland. The patient was treated with carbimazole 30 mg per day and propranolol 60 mg per day. One year later, he was seen for oppressive chest pain, with an ECG showing an inferolateral elevated ST segment and an anteroseptal ST segment depression. The troponin level was 21.627 ng/l. Acute coronary syndrome has been suspected. The patient was put on dual antiaggregant and anticoagulation. He had a coronarography showing normal coronary arteries. Transthoracic ultrasound showed hypokinesia of the mid and basal segments of the anterolateral and inferior walls with an ejection fraction at 50%. A myocardial magnetic resonance imaging was then practiced and showed an aspect of myocarditis. Since the patient was apyretic, did not present arthromyalgia and there was no biological inflammatory syndrome, the viral origin was eliminated. The diagnosis of autoimmune myocarditis was then retained. Therapeutically, he was kept on a beta blocker and received radioiodine therapy twice. The evolution was marked by post radioiodine hypothyroidism which was then substituted with L-thyroxin and by the absence of recurrence of chest pain.
Conclusion
Acute myocarditis is an unusual affection in Graves' disease. The mechanism is different from of the cardiothyreosis which is linked to a direct effect of thyroid hormones on the heart. An autoimmune mechanism has been implicated in this entity which can be confirmed histologically by the presence of anti TSH receptor antibodies in cardiomyocytes. Hence the importance of careful cardiac exploration in Graves' disease.

Pancytopenia in Grave's disease: due to ATD or other autoimmune disease ?

Chayma Besrour, Imen Rojbi, Rihab Laamouri, Youssef Lakhoua, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Hospital Charles Nicolle, Endocrinology-Diabetology, Tunis, Tunisia

Introduction
Grave's disease is an autoimmune disease characterized by hyperthyroidism. It is in some cases associated to more autoimmune organs dysfunction. The antithyroid drugs are the first line treatement, and sometimes they are responsible for severe adverse effects.
Observation
We report the case of a 34 year-old man, treated for his grave's disease with thiamazol for two years. Two weeks after interrupting his treatment of his own volition, then reintroducing it, he consulted for asthenia, fever at 40°C and a poor state of health, the blood count revealed a severe pancytopenia with agranulocytosis (Hemoglobin 4.5 g/dl, WBC 760/µl, Neutrophils 320/µl, Platelets 23 000/µl). In front of this emergency, the antibiotherapy was started, and the thiamazol was immediately interrupted, but there was no noticeable amelioration in the blood count, so we suspected the presence of another factor such as the pernicious anemia, and a low level of vitamine B12 was indeed found (46 pg/ml). The anti intrinsic factor was positive at 80 RU/ml, and the gastric tissue biopsy showed a non active chronic gastritis with severe atrophia and moderate intestinal metaplasia confirming the diagnosis of the Biermer disease. The procedure to follow was to treat the patient with intra-muscular injection of vitamine B12 and his condition as well as his blood count improved within two weeks (Hemoglobin 9.6 g/dl, WBC 2330/µl, Neutrophils 1150/µl, Plateles 151 000/µl). As for his Grave's disease, he received a radioactive iodine therapy. The severe pancytopenia was in this case due to two factors ; the allergic reaction to the antithyroid drug and the insidious presence of Biermer's disease. This association of these two diseases is called autoimmune polyendocrine syndrome type 3B which is a group of rare diseases.
Conclusion
Pancytopenia with agranulocytosis is a rare adverse effect of the antithyroid drugs. Blood count must be evaluated before and after initiation. Moreover, the autoimmune thyroid disease may be associated to other autoimmune disorders, hence the importance of screening for other autoimmune diseases in front of new symptoms.

Assessment of clinical burden and practice patterns in patients with chronic hypoparathyroidism in the United States (US): A claims data analysis using a surgery-based approach

Dolly Sharma[1], Kathleen L Deering[1], Patrick Loustau[2], Michael D. Culler[2], Soraya Allas[3], Blandine Weiss[2], Deborah Michelle Mitchell[4], Danette Astolfi[5] & Michael Mannstadt[4]
[1]EPI-Q Inc, Oak Brooks, IL, United States; [2]AMOLYT PHARMA, Cambridge, MA, United States; [3]AMOLYT PHARMA, Ecully, France; [4]Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, United States; [5]Hypoparathyroid Association

Objectives
There is a paucity of real-world studies on the clinical burden and practice patterns associated with chronic hypoparathyroidism (cHP). This study assesses the comorbidities, treatment and lab testing patterns in cHP patients identified using surgery-based criteria.
Methods
This was a retrospective study conducted using a large (130 million individuals) US claims database (HealthVerity Closed Payer Claim Medical and Pharmacy database (Private Source 20) from Oct 2014 to Dec 2019. The patients were eligible if they had a procedure claim of either parathyroidectomy, complete or partial thyroidectomy, or neck dissection, followed by a HP diagnosis claim (6–15 months apart), with a subsequent second HP diagnosis claim at any time point. Patients also had to be continuously enrolled for 15 months before the index date (the date of the first qualifying HP diagnosis claim) and □6 months after. Patients were followed one year before the surgery and up to two years after the index date. Demographics, comorbidities, lab tests and treatment patterns were analyzed.
Results
1406 patients met the eligibility criteria and 1184 patients had complete data for 1-year follow-up. The mean age was 52.1 ± 16.4 (S.D.) years, and 83.2%were females. The mean time between surgery and qualifying HP diagnosis claim was 8.7 ± 2.3 (S.D.) months, and 115 patients (8.2%) had a HP diagnosis prior to surgery. During the 1-year follow-up, the most common comorbidities were cancer (54.2%, of which 49%were thyroid cancers), hypertension (49.7%), hypocalcemia (47.1%), chronic pulmonary disease (21.9%), diabetes (21.7%), cardiac arrhythmias (18.4%), CKD stage 3-5 (11.3%), osteoporosis (9.8%), and neuropsychiatric disorders, including anxiety (23.9%), depressive disorders (21.8%), and sleep-wake disorders (20.9%). Lab tests ordered during the 1-year follow-up included serum calcium (93.2%), eGFR/creatinine (86.2%), 25-Hydroxy Vitamin D (66.5%), intact PTH (63.0%), serum magnesium (40.9%), serum phosphorous (38.4%), bone mineral density (9.8%), and 24 h-urine calcium (8.4%). During the same period, 66.9%of patients had a prescription claim for thyroid replacement therapy, 51.6%for calcitriol, 13.3%for ergocalciferol, and 5.5%for PTH.
Conclusion
This large cohort of cHP patients, identified using surgery-based criteria, was recently diagnosed and had a substantial comorbidity burden that was aligned with the lab testing patterns. Already at this early stage of cHP, kidney function appears to be a key concern, and may be important when considering therapeutic intervention. These data are consistent with our findings from a larger cHP population identified in the same database using a diagnosis-based approach.

EP227

Limitations for the use of ultrasound ablation of thyroid nodules

Yuriy Aleksandrov[1,1] & Yury Patrunov[2]
[1]Yaroslavl State Medical University, Surgery, Yaroslavl, Russian Federation; [2]Yaroslavl State Medical University, Ultrasound, Yaroslavl, Russian Federation

High-intensity focused ultrasound ablation (HIFU) was used in the treatment of thyroid nodules using the device "Echopulse" (Theraclion, France). The therapeutic sensor is represented by a piezoelectric lens with a diameter of 12 cm, with a variable radiation frequency from 0.8 to 1.6 MHz. The treatment was carried out automatically after preliminary planning. The impact zone (ablation focus) was marked automatically on the device screen. The limitations for using HIFU were evaluated. It was found that the localization of the thyroid node is important. Optimal is the presence of a layer of healthy thyroid tissue between the treatment area and the adjacent structures and organs of the neck. The most favorable is the central location of the node and the size of 15–25 mm in diameter. Of the local constraints, the following are marked. There are limitations in performing HIFU in people with short, thick necks and partially retrosternal nodules (cervical-mediastinal goiter) due to the complex and time-consuming positioning of the lens. HIFU application in the event that the thyroid node contour is located close to the trachea, carotid artery and esophagus is difficult, the HIFU program will automatically exclude this area from the ablation zone. With HIFU, the distance to the carotid artery should be more than 4.5 mm (especially if the carotid artery is behind the focal point), and the distance to the trachea should be more than 5 mm (if the trachea is behind the focal point, then more than 10 mm). There are also restrictions for HIFU subcapsular nodes: the depth of the leading edge of the node should not be less than 5.0 mm, the depth of the trailing edge of the node should not be more than 26.7 mm. When selecting patients, the volume of the liquid component was taken into account, HIFU is ineffective in cystic nodules, since the ultrasound energy is not focused in the liquid. A contraindication is the detection of calcifications of various sizes. Macrocalcinosis interferes with the effect of HIFU. There are also limitations in identifying large hyperechoic areas with reduced vascularization (signs of a pronounced fibrous component). Common contraindications for performing HIFU that are not related to thyroid pathology are: Mental instability of the patient. Pacemakers and pacemakers are installed. Recurrent neural abnormalities on the opposite side of the HIFU exposure side. The presence of scars and pigmented nevi in the area of placement of the therapeutic lens.

EP228

Case report of a female patient with primary hyperparathyreoidism and acute pancreatitis

Martina Jambrović, Maja Mikolaj Kirić & Andreja Marić
County Hospital Čakovec, Internal Medicine, Department of Endocrinology and Diabetology, Čakovec, Croatia

A 65-year-old patient was hospitalized three times over a two-year period for severe acute pancreatitis. After the first hospitalization, cholecystectomy was performed. During the second hospitalization she was treated in the ICU because of the development of necrotizing emphysematous pancreatitis with the development of sepsis. During the third hospitalization the patient presents clinically with general weakness, agitation, visual hallucinations, disorientation and damaged cognitive-mnemonic functions. While being treated, elevated blood calcium levels were detected (Ca 3.35 mmol/l), and additional laboratory tests were performed (PTH 9.55 pmol/l, total Ca 2.80 mmol/l, vitamin D 8.53 mmol/l, anorganic phosphate 0.98 mmol/l). Ultrasound examination of the neck reveals a solid-cystic formation behind the left lobe of the thyroid gland. Cytological finding of the puncture formation indicates hyperplasia of the thyroid gland, and scintigraphy with Tc-99m MIBI indicates pathological accumulation of radiopharmaceuticals in the left thyroid lobe and hyper functional parathyroid gland tissue behind the left thyroid lobe. Initially she was treated with pamidronate, followed by a left thyroid lobectomy and parathyroidectomy of the left parathyroid glands. Pathohistological diagnosis indicates a parathyroid adenoma. Postoperative calcium values were normal (Ca 2.27 mmol/l) with marginally elevated TSH (TSH 5.12 mIU/l, fT4 14.03 pmol/l). Low-dose levothyroxine substitution was prescribed. Three years after the development of pancreatitis and thyroid lobectomy with parathyroidectomy, the patient was hospitalized for a new verified type 2 diabetes (FPG 19.0 mmol/l, HbA1c 13.7%) without developed micro and macrovascular complications of the disease. Insulin therapy was started, according to basal- bolus protocol (insulin aspart with human insulin) and glycaemic control was achieved.

Conclusion

Hypercalcemia was an etiopathogenetic basis for recurrent acute pancreatitis.

Key words

hypercalcemia, acute pancreatitis, primary hyperparathyroidism

Prifictive factors of malignancy in thyroid nodules: About 304 cases

Bellakhdar Mouna[1], Amal Kdissa[1], Ghammam Monia[1], Ben Abdelkrim Asma[2], Meherzi Abir[1], Kermani Wassim[1], El Euch Koussay[2] & Abdelkefi Mohamed[1]
[1]CHU Farhat Hached, ENT Department, Sousse, Tunisia; [2]CHU Farhat Hached, Endocrinology Department, Sousse, Tunisia

Background

The thyroid nodule is a common presentation. Its prevalence is estimated to be 5%. Surgical treatment could not be systematic. It requires structured diagnostic approach to ascertain the risk of malignancy and determine appropriate management.

Aim

To evaluate potential role of epidemiological, clinical and para clinical criteria as preoperative indcators of malignancy in thyroid nodules.

Methods

This is a retrospective analytical study of 304 cases of patients who undergone surgery for thyroid nodule in ENT Departement of Farhat Hached Hospital from 2012 to 2019.

Results

The median age at diagnosis was 44, 73 years. It is more common in women with sex-ratio (M/F) is 0.1. Cancer risk is 36%in men versus 25.1%in women. The mean delay of consultation was 12 months(extrêmes de 1 à 276 moths). Family history of thyroid disorders were present in 10.2%of cases. Personal history of goiter was found 12 patients (3.9%). de compressive symtomps were detected in 22.7%of cases. Cervical lymph nodes were présentes in 36 patients (11.8%of cases). Hard consistency was found in 44 patients (14.5%). Le nodule was fixed in 38 patients (12.5%). Margins were irregular in 23 patients (7.6%). Several US features have been found to be indicative of malignant potential. Microcalcifications(33.6%, p), irregular limits(46 Patient, 15.1%), or microlobulated margins(28 patients (9.2%), hypoechogenicity (95 pateinst, 31.3), taller-than-wide shape(70 patents, 23%), and increased intranodular vascularity(118 patients, 39%) were found to be independent risk factors for malignancy. Scintigraphy with technétium99 was performed in 15.9%of cases and FNA in 16%of cases. An analatycal study was concucted in order to determnates pedictive factors of malignancy:family history of thyroid disorder, personal history of thyroitidis, goiter, hard consistency ($P < 0.001$), fixity ($P < 0.001$), irregular limits ($P = 0.002$, cervical lymph nodes($P < 0.001$), and flush syndrome ($P = 0.007$), hypoecgogenecity ($P < 0.001$), blurred margins($P < 0.001$), taller-than-wide shape ($P = 0.002$), microcalcifications ($P < 0.001$),, intranodular vascularisation ($P = 0.003$) and the score EUTIRADS V ($P < 0.001$).

Conclusion

The risk stratification based on clinical features and US findings is useful to determinate the convenient management of thyroid nodules.

Exceptional thyroid cancer: a challenging diagnosis

Mouna Bellakhdher[1], lobna Chouchane[1], Monia Ghammem[1], Sarra Mestiri[2], Yosra Hasni[3], Abir Meherzi[1], Wassim Kermani[1], Moncef Mokni[2], Koussay El Ach[3] & Mohamed Zbdelkafi[1]
[1]ENT and Neck Surgery Department Farhat Hached Hospital, Susa, Tunisia; [2]Pathology department, Farhat Hached University Hospital, Susa, Tunisia; [3]Endocrinology department Farhat Hached hospital, Susa, Tunisia

Introduction

Thyroid carcinoma is the most common type of endocrine malignancy and the cancer with the largest annual increase in incidence in recent decades. They are classified as primary or metastatic. The most common thyroid cancer subtypes include papillary, follicular, medullary, and anaplastic. We aim to present 11 cases of exceptional thyroid malignancies managed in our department.

Materiel and methods

A retrospective study of 11 cases of exceptional thyroid cancer was performed in ENT and neck surgery department Farhat Hached hospital Sousse Tunisia.

Results

Our study included: six cases of lymphomas, a case of insular carcinoma, two cases of thyroid metastasis of lung cancer, a case of neuroendocrine thyroid carcinoma and two sarcomas. On cervical examination, a multinodular thyroid gland was noted in the 6 cases of lymphomas. Cervical lymph node involvement was present in 6 cases associated with laryngeal nerve

palsy in 3 cases. Ultrasound demonstrated a multinodular thyroid gland in all cases associated with microcalcifications in one case. CT scan showed lung metastasis in two cases (angiosarcoma and mantle cell lymphoma). A gastroscopy confirmed the stomach localization in a mantle cell lymphoma. A total thyroidectomy was performed in 4 cases. A bilateral lateral lymph nodes dissection was performed in 2 cases. an emergency tracheotomy was performed for 4 patients who presented with dyspnea. Chemotherapy was administrated in 5 cases. The evolution was fatal in 6 cases.
Conclusion
An accurate diagnosis is important despite the immense difficulties. The management remains challenging. The ideal treatment modality should be determined considering the presence or absence of metastases, the patient's general condition, and the presence or absence of local symptoms.

Background
Epidemiological studies revealed up to 5-6 undiagnosed cases of type 2 diabetes mellitus (DM2) per 1 registered patient. The late diagnosis of DM2 presents a medical and socio-economic problem.
The aim of the study to identify the most cost-effective, easy-to-use method for regular screening for DM2 in primary care settings in the Republic of Uzbekistan.
Materials and methods
4 diabetes screening scenarios differing in the inclusion criteria (age 45 vs age 45 plus arterial hypertension plus obesity), and screening methods (testing for glycemia and/or HbA1c) were studied in urban and rural primary care polyclinics among 2430 people.
Results
In primary health care real clinical practice, the most cost-effective and easy-to-follow strategy for active screening for DM2 is testing for random glycemia using a certified glucometer, in any resident aged 45 or older visiting his/her GP for any reason. If test results are intermediate, the person is called again the next day for fasting glycemia testing to confirm the diagnosis. If the test results are normal, the person is given recommendations of healthy lifestyle and re-testing in 1 year. If the test result corresponds to DM, the person is referred to a local endocrinologist.

Evaluation of awareness about requirement of anti-obesity pharmacotheraphy before weight loss surgery in a tertiary outpatient Endocrine Clinic in Turkey

Zuleyha Can Erdi[1], Cigdem Ozkan[2], Ahmet Mucteba Ozturk[3] & Koray Bas[3]
[1]Health Sciences University Izmir Bozyaka Education and Research Hospital, Internal Medicine, Izmir, Turkey; [2]Health Sciences University Izmir Bozyaka Education And Research Hospital, Endocrinology and Metabolism, Izmir, Turkey; [3]Health Sciences University Izmir Bozyaka Education And Research Hospital, General Surgery, Izmir, Turkey

Background
Obesity is an increasing public health problem all around the world. It plays role in the pathogenesis of many diseases, especially diabetes, hypertension, hyperlipidemia, cardiovascular diseases and cancer. The prevalence of weight-loss surgery is increasing as a result of developments of surgical techniques. In parallel with these developments, more patients admit for weight-loss surgery. Pharmacotherapy is one of the most important component of interventions before surgery. In this paper we aimed to evaluate patients' awareness towards receiving pharmacotherapy before admission to surgery.
Method
Patients who had been referred from general surgery department to our clinic for endocrinological evaluation were included to our study. 47 patients were evaluated.
Results
21%(*n*: 10) of the patients were male and 79%(*n*: 37) were female. 17%of the patients (*n*: 8) had type-2 diabetes. Mean body mass index (BMI) was found to 44.1 kg/m^2. 80%(*n*: 38) of the patients had not received any pharmacological treatment before and directly preferred surgery as an anti-obesity treatment modality. None of these patients were aware of the importance and requirement of pharmacotherapy before surgery. Liraglutide was started in 4%(*n*: 2) patients, exenatide 17%(*n*: 8) diabetic patients and orlistat in 19%(*n*: 9) patients, respectively. Lifestyle changes were recommended to 60%(*n*: 28) patients and evaluation for pharmacotherapy planned for the next visit.
Discussion
Pharmacotherapy and behavioral modification are major interventions before weight loss surgery. Incompatibility with pharmocotherapy and behavioral modification is one of the contraindications for bariatric surgery. Besides, pharmacotherapy increases the success of weight loss surgery. To conclude, increasing awareness among patients to apply for pharmocotherapy and behavioral modification before surgical procedures may help us to achieve meaningful weight loss in long term.

Reduction in medication of multidrug hypersensitive patient by bariatric surgery

Sevgul Faki[1], Buğra Durmu[1], Serdar Deniz[1], Hüsniye Başer[2], Erdinç Çetinkaya[3], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Çakir[2]
[1]Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Yildirim Beyazit University, Faculty of Medicine, Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara City Hospital, Department Of surgery, Ankara, Turkey

Introduction
Type 2 diabetes and hyperlipidemia are primarily managed with lifestyle modifications, self-monitoring of blood glucose, and medication. Patients who are obese and cannot achieve normal blood glucose levels despite diet, exercise, and multiple medications may be considered for bariatric surgery. Many diabetic patients with very high triglyceride levels are at high risk for ASCVD and therefore after triglyceride levels are controlled the patient should be evaluated for cardiovascular disease risk. Bariatric surgery is more effective at inducing weight loss than either diet or medications. Baratric surgrey is alsow associated more robust decrease in serum triglyceride levels and increase in HDL-C levels. Here we describe a bariatric surgery results of obese multidrug hypersensitive patient with a high level of serum triglyceride.
Case
44 years old woman, had Type-2 Diabetes Mellitus and hyperlipidemia for at least 3 years. She had no medication due to multidrug hypersensitive. Her BMI was 39.9, fasting glucose, serum triglyceride, VLDL, HDL, HbA1C are: 166 mg/dl, 2166 mg/dl, 433 mg/dl, 32 mg/dl, 60 mmol/mol respectively. İn addition to Initial treatment of very low-fat diet, we immediately started medication to reduce triglyceride levels into a safe range to prevent triglyceride-induced pancreatitis. After 10 day of receiving fenofibrate and dapagloflozin she had an generalized acute urticaria need hospitalization and first treated with antihistamine drugs. Here serum triglyceride level was 1906 that force us to continue medication tratment with antihistamine drug. After 4 mounth of treatment and weight loss (10 kg) we didn't reach therapy goals of hyperlipidemıa. The patient had a bariatric surgrey after mutidisplanary consensur. After surgrey she stoped medication and her serum triglyceride measure was 240 mg/dl.
Conclusion
We report a case of generalized urticaria probable or very probable induced by fenofibrate underwent bariatric surgery. Approximately 60-70%of patients with obesity are dyslipidemic. The Roux-en-Y gastric bypass and laparoscopic sleeve gastrectomy have been shown to improve A1C, reduce weight, and reduce the number of medications patients need for diabetes management. Comorbidities such as hyperlipidemia and hypertension also

may improve. A reduction in medication of hypersensitive patients can be considered an additional benefit of bariatric surgery.

Short-term carbohydrate and lipid restriction impact on obese gerbil

Zineb Bellahreche, Nesrine Semiane, aicha mallek & yasmina dahmani
University of Science and Technology Houari Boumediene, Laboratory of Biology and Physiology of Organisms, Algiers, Algeria

The control of obesity and the regulation of its components are strongly linked to nutrition. Thus, low calorie diets restricted in carbohydrates and lipids are becoming increasingly suitable for combating the complications of obesity. In the present work, we propose to report the short-term repercussions of dietary carbohydrate and lipid restriction on the weight parameters of the obese gerbil. Our experiment was undertaken on a species of gerbil (Gerbillus tarabuli) and lasted 5 months. Gerbil is a wild animal from the Algerian desert. In captivity, this rodent subjected to a high carbohydrate high fat diet, develops metabolic disorders which are characterized by visceral obesity. The obese animals were subjected to carbohydrate and lipid restriction for 8 weeks. Gerbils submitted to carbohydrate and lipid restriction diet show a significant decrease in body masse (approximately 10%), in subcutaneous and epididymal adipose tissues weight (approximately 50%) compared to obese animals. However, no significant difference was recorded for mesenteric adipose tissue weight for the two groups. In conclusion, our results demonstrate that short-term carbohydrate and lipid restriction diet decreases body weight and reduces adiposity in obese gerbils.

Double diabetes mellitus: a case report

lamya Echchad, Sohaib Khamal Doghri, Khaoula Gorgi, Kaoutar Rifai, Hind Iraqi & Mohamed El Hassan Gharbi
University Hospital Ibn Sina, Endocrinology and Metabolic Diseases Department, Morocco

Introduction
Type 1 diabetes mellitus (T1DM) is an autoimmune disease in which pancreatic Cells are destroyed, generating an incapacity to maintain appropriate insulin and glucose concentration. On the other hand, type 2 diabetes mellitus (T2DM) is associated with varying degrees of insulin resistance (IR) and relative insulin deficiency. The association of T1DM and the clinical features of T2DM as obesity, hypertension, dyslipidemia, or metabolic syndrome (MS) is called “double-diabetes” and has been associated with an increased rate of chronic complications and cardiovascular diseases in patients with T1DM.
Case
A 46 years old female patient had had diabetes mellitus for 8 years, under premixed insulin (1.2 U/kg) and 2 g of metformin due to her glycemic imbalance (Hba1c: 14%) with a history of a few episodes of diabetic ketoacidosis (DKA), hypertension, weight gain under insulin, adult-onset diabetes in maternal grandfather, mother, brother, and sister. She was considered T2DM due to her clinical presentation that included a BMI of 30 kg/m^2, a waist circumference of 97 cm, acanthosis nigricans around her neck, and significant family history of diabetes. During her last hospitalization for glycemic imbalance, the biological assessment revealed positive antibodies to glutamic acid decarboxylase (GAD) over 2000 U/ml. The patient was diagnosed with T1DM and put under insulin in a basal/bolus regimen associated with 2 g of metformin to counter insulin resistance.
Discussion and conclusion
Double-diabetes (DD) was a term coined to describe individuals with type 1 diabetes showing clinical features compatible with type 2 diabetes. It has been variably used in literature, to describe both individuals with obesity and other insulin resistance (IR) characteristics. The mechanisms involved in the development of IR in patients with T1D remain unknown. Some studies have proposed that obesity due to a non-healthy lifestyle and over-insulinization in addition to the genetic background are its main cause. Meanwhile, others have reported that IR is present in patients with T1D even in the absence of obesity. Definition of a strict intermediate subtype between both types of diabetes is difficult, therefore this grey zone between them behaves more like a continuum according to current evidence.

EP236

Carney complex: a case report

lamya Echchad, Sohaib Khamal Doghri, Kaoutar Rifai, Hind Iraqi & Mohamed El Hassan Gharbi
[1]University Hospital Ibn Sina, Endocrinology and Metabolic Diseases Department, Morocco

Introduction
Carney complex (CNC) is an extremely rare genetic syndrome of pigmented skin lesions, endocrine hyper-function and myxoma. Given its diverse clinical manifestations, CNC is often misdiagnosed. Recognition of some special clinical manifestations and imaging features may help with the diagnosis. We report the case of CNC with endocrine and cutaneous tumors.
Case
A 50 years old female patient followed for acromegaly for 10 years, had undergone transsphenoidal surgery. She has a history of thyroidectomy for goiter, operated twice for melanotic schwannoma of the neck and multiple lipomas. There was no similar case in her family. The diagnosis of CNC was retained. Screening of PRKAR1A is ongoing.
Discussion and conclusion
Carney complex (CNC) is a very rare disease which is often misdiagnosed because of its diverse clinical characteristics. It was first described in 1985 by J Aidan Carney, and its main clinical features are spotty pigmentation, endocrine overactivity, and myxoma. The regulatory subunit (R1A) of the protein kinase A(PRKAR1A) gene is implicated in its causation. The PRKAR1A mutations causing CNC have been identified in 70%of the total cases reported worldwide. The exact prevalence of Carney complex is unknown. Around 750 cases from many ethnicities have been reported worldwide since 1985. The prevalence can be underestimated because the diagnosis is challenging, and the awareness of this rare and complex disorder is insufficient among the medical community.

EP237

An elderly woman with vitiligo and memory deficits

Muhammad Shoaib Zaidi
King Saud University, University Diabetes Center, Riyadh, Saudi Arabia

Introduction
Pernicious anemia is an autoimmune cause of Vitamin B12 deficiency, that can occur as part of polyglandular adenopathy Type 3. According to one prospective serial study, it’s incidence was 2.3%in people ≥ 60 years of age, being more common in women than men. A case of polyglandular syndrome, most likely PGA-3, is being described. She had Type 1 diabetes, Hashimoto’s thyroiditis, vitiligo & pernicious anemia.
Clinical case
63 years old post-menopausal lady with Type 1 DM>15 years, Primary Hypothyroidism, Dyslipidemia, Vitiligo & Minimal NPDR. She was worked up previously for evolving cognitive defects e.g. short term memory lapses & was found to have Vit. B12 deficiency(B12-69 pmol/l, S. folate NA). Was treated e Inj. B12 replacement and got somewhat improved. Family Hx insignificant. Systemic review: NAD(No GI symptoms, candidiasis). Drug Hx: Metformin 1 gBD, Novorapid(10-10-6 units), Lantus, 16 units PM, Levothyroxine100 µg/d, Aspirin, 81 mg/d, Inj. Methyl Cobalamin-1 mg/monthly, Ferrous-folic-once daily, Refresh eye drops. Exam: Vitally stable e no postural instability. Wt 62.6(62 kgs in 2017), BMI-27.85 kg/m^2 Vitiligo+ mouth, hands & feet. No hyperpigmentation. Otherwise General and Systemic exams unremarkable. Labs: HbA1c 9.8%(was 8.5%before), CBC-Hb%11.8 g/l, MCV 82.2 fl, ACR 7.68 mg/gm, Lipids(T. Cholesterol-5.91 mmols/l, LDL-3.41 mmols/l, TGs 0.95 mmols/l, HDL 2.07 mmols/l), Corrected Ca++ 2.43 mmols/l. TFTs(TSH 3.7 mIU/l, FT4 19.1 pmol/l). Rest WNL. Other Investigations: CT scan brain-normal, Short Synecthen Test negative(ACTH 4.8 pmol/l), Anti-gastric parietal cell & Anti-Intrinsic factor Antibodies strongly positive(Anti-parietal ;47.4 units-normal: 020), Anti-Intrinsic factor Abs-69.2 units-normal0-1.1 units). ECG & CXR-unremarkable. Anti-Islet cell Abs-Negative, Anti-GAD-65 Abs Highly Positive-5504.1 U/ml(0.0-5.0), S. Gastrin-30 pg/ml(0115). Anti-thyroid Abs: Anti TPO-1761 units(0-100), Anti TG-278.34 units (< 0.6

units-negative). Elective surveillance upper GI endoscopy: unremarkable apart from the finding of a 3 mms, whitish nodule in the gastric antrum. Gastric histopathology: (4 specimens). Specimen from the gastric nodule revealed mild to moderate inactive gastritis, gastric atrophy & intestinal metaplasia. Antral Bx-positive for H. pylori like organisms. Otherwise biopsies from incisura & body of stomach showed mild to moderate inactive gastritis. Gastroenterology follow-up was still awaited.
Conclusions
–Vitamin B12 deficiency should always be ruled out in people, esp. the elderly, having cognitive disturbances.
–In the presence of other autoimmune disorders like Type1 diabetes, vitiligo etc, Vitamin B12 deficiency is most likely due to pernicious anemia, which can be proven by checking anti-gastric parietal & anti-intrinsic factor antibodies.

Prostate cancer metastasis to cervical node chain-an unusual clinic

Gulsum Karahmetli[1], Kubra Solmaz[2], Fatma Dilek Kahramanca[2], Fatma Neslihan Cuhacı Seyrek[1], Onder kayıgil[3], Cevdet Aydın[1], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakır[1]
[1]Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Ankara, Turkey, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Bilkent City Hospital, Ankara, Turkey, Department of Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Ankara, Turkey, Department of Urology, Ankara, Turkey

Introduction
While cervical lymph nodes are the region where head and neck malignancies frequently metastasize, prostate carcinoma rarely metastasizes to this area. Here, we will present a case with papillary thyroid microcarcinoma whose pathological lymph node cytology in the cervical region was found to be prostate carcinoma metastasis.
Case
Since thyroid fine needle aspiration cytology (FNAC) results were non-diagnostic 3 times, an 64-year old male patient underwent bilateral total thyroidectomy. His pathological examination was compatible with papillary microcarcinoma, and was given 100 mci radioactive iodine (RAI) treatment. While post-ablation whole body scan (WBS) revealed the activity involvement compatible with residual tissue in the right lobe region, the diagnostic WBS was found to be normal (TSH, Tg and Anti Tg values are shown in Table 1). In PET-CT, pathological increased activity uptake was detected in the bilateral level IV lymph node area. Neck ultrasonography showed a lymph node with pathological appearance and 8.5 × 8.7 × 11 mm in size at left level IV. Cytological examination of this lymph node was compatible with carcinoma metastasis. Also, another pathological looking lymph node on the left level IV with 7.7 × 9.4 × 10.8 mm in size was found to be compatible with malignant cytology, carcinoma metastasis (Table 1). An immunohistochemical study of the prostate and thyroid origin (PSA, TTF1) has been conducted in cytology, but a definitive clue for the origin of the tumor has not been obtained. Thereupon, the FNAC was repeated from the level IV lymph node (8.5 × 8.7 × 11 mm) of the patient and non-diagnostic cytology was found, afterall the cell block was applied. Finally, left level IV lymph node cytology was reported to be compatible with prostate adenocarcinoma metastasis.

Table-1

	TSH(ıu/ml)	Tg (ng/ml)	Anti-Tg (u/ml)	Tg washout
Post-ablation WBS	73	27.3	19	
Diagnostic WBS	41.4	25.5	18	
Left level IV (8.5 × 8.7 × 11 mm)		4		0.89
Left level IV (7.7 × 9.4 × 10.8 mm)		4		0.3

TSH; thyroid stimulating hormone, Tg; thyroglobulin, Anti-Tg; anti- thyroglobulin, WBS; whole body scan, RAI; radioactive iodine

Conclusion
Metastatic prostate adenocarcinoma (PAC) to cervical lymph nodes is rare. If the history is unknown, cases may be misdiagnosed as metastases from cervical neoplasms. Findings showing metastatic PAC to the cervical lymph nodes in FNAC are; the involvement of left-sided cervical lymph nodes and cellular smears consisting of flat layers with granular cytoplasm and uniform polygonal cells arranged in the acini, fuzzy cell borders, and round-oval nuclei with prominent nucleoli.

A rare cause of levothyroxine malabsorption: İleostomy

Leyla Akdoğan[1], Konul Ahmadova[1], Muhammed Sacikara[2], Abbas Ali Tam[1], Didem Ozdemir[1], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Ankara Yildirim Beyazit University Faculty of Medicine, Ankara Bilkent City Hospital, Ankara, Turkey, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Bilkent City Hospital, Ankara, Turkey, Department of Endocrinology and Metabolism, Ankara, Turkey

Introduction
It is recommended to determine levothyroxine (LT4) dose individually in patients with hypothyroidism. However, higher doses of LT4 therapy are required to achieve target TSH levels in significant number of patients. Oral LT4 absorption occurs in the small intestine, especially in the jejunum and proximal ileum, while a small amount is absorbed in duodenum. Causes of LT4 malabsorption include helicobacter pylori infection, chronic atrophic gastritis, celiac disease, lactose intolerance, pancreatic insufficiency, cirrhosis, nephrotic syndrome, gastrointestinal malabsorptive surgical procedures, short bowel syndrome, drug and diet-related interactions. Here, we present a case of ileostomy with multiple small intestine resection, which is a rare cause of LT4 malabsorption.
Case
A 59-year-old male patient was consulted to our endocrinology clinic due to high TSH levels before ileostomy closure from the gastrosurgery clinic. The patient underwent total thyroidectomy in 2009 due to medical recurrence Graves disease and had postoperative hypothyroidism, he was euthyroid with levothyroxine treatment of 175 µg/day. With the diagnosis of rectal cancer in January 2020, the patient underwent a low anterior resection and colostomy. Pathology reported as moderately differentiated adenocarcinoma, followed by chemotherapy and radiotherapy. In October and November 2020, segmental small bowel resection due to radiation ileitis, ileus was performed. Ileostomy was performed in November 2020 for the patient whose colostomy did not work for a long time. Despite medical treatment, ileostomy was planned to be closed after 8 weeks due to the daily discharge of 14 times from ileostomy. It was consulted preoperatively in January 2021 due to TSH:66 mU/l. The oral levothyroxine dose was gradually increased from 150 µg/day to 350 µg/day due to increase in TSH to 80 mU/l, despite appropriate replacement of levothyroxine. When his TSH level was 37 mU/l, free T4 and T3 were normal with 350 µg/day oral levothyroxine, ileostomy was closed in February 2021. The patient's free T4 and T3 values started to increase in 3 days after ileostomy closure, and levothyroxine dose was gradually decreased. The patient has been followed euthyroid with levothyroxine döşe of 150 µg/day.
Conclusion
Intestinal absorption problems may cause high-dose LT4 therapy. The decrease of the intestinal absorption surface and the shortening of the intestinal transit time can be considered among malabsorption mechanisms. Further research should be conducted in the presence of increased serum TSH levels despite high dose LT4 therapy.

DOI: 10.1530/endoabs.73.EP239

EP240

Assesment of serum TSH concentrations in hypothyroid elderly patients (aged 75 and above) under levothyroxine treatment

Mustafa Ubay[1] & Cigdem Ozkan[2]
[1]Health Sciences University Izmir Bozyaka Education and Research Hospital, Internal Medicine, Izmir, Turkey; [2]Health Sciences University Izmir Bozyaka Education And Research Hospital, Endocrinology and Metabolism, Izmir, Turkey

Background
Hypothyroidism is a common disorder in elderly. Management of elderly population requires special attention since both undertreatment and overtreatment leads to increased mortality and morbidity. Normal ranges of TSH differs as patients get older and it is recommended as 4-6 mIU/l in patients older than 70–80 years. In this study we aimed to evaluate the TSH concentrations of elderly patients (75 years of age and older) who are under levothyroxine treatment

Method
We retrospectively evaluated elderly patients, aged 75 years and older, who applied to endocrinology clinic for hypothyroidism between March 2018 and November 2020. TSH values of patients who were under levothyroxine treatment were analysed
Results
57 hypothyroid patients who were under levothyroxine treatment were included in the study. 8 patients were male (14%), 49 (86%), were female. The mean age of patients' was found as 79.0. Only 4 (7%) of 57 patients TSH concentration was between 4-6 (mIU/l) ; 23 (40.4%) patients TSH concentration was below 4 mIU/l and even 9 patients' TSH concentration (15.8%) was below 0.5 (mIU/l). 21 (36.8%) patients' TSH concentration was above 6 (mIU/l).
Discussion
Our study showed that few patients stay in the recommended range during their treatment process for hypothyroidism. Elderly patients are more prone to adverse effects related to cardiovascular system with both undertreatment and overtreatment. Furthermore, overtreatment may lead to osteoporosis and fractures. Therefore, careful titration of levothyroxine treatment and monitoring of TSH values are especially important in elderly patients.
