Different forms of changed function were linked to four predictors, including: 1) Older age: decreased free T (FT; 3.11 pmol/liter/yr, $P<0.002$) and elevated LH, suggesting the reduced testicular function, 2) Obesity: lower total T (TT; 2.31 nmol/liter) and FT (17.61 pmol/liter) for body mass index (BMI; 24 to 29 kg/m2); lower TT (5.08 nmol/liter) and FT (52.71 pmol/liter) for BMI 29 kg/m2 or above ($P<0.002$-0.02, referent: BMI 24 kg/m2); 3) comorbidity: greater LH in older men but unchanged TT (0.81 nmol/liter, $P<0.02$) in younger men; 4. Smoking: higher SHBG (5.95 nmol/liter, $P<0.002$) and LH (0.76 U/liter, $P<0.02$) with increased TT (1.30 nmol/liter, $P<0.002$) but not FT, consistent with a resetting of T-LH-negative feedback due to raised SHBG.
Conclusions
Age-related testicular dysfunction is accompanied by complex multiple abnormalities in the hypothalamic-pituitary-testicular axis function in ageing men. Varied risk variables have different relationships with these changes. Some risk factors contribute to the T decrease independently of age, whereas others interact with it. These possibly modifiable risk variables point to potential preventive steps that men can take to preserve T as they age.

Background
Acromegaly is associated with increased morbidity and mortality if left untreated. The therapeutic options include surgery, medical treatment, and radiotherapy. Guidelines regarding treatment algorithms and follow-up vary considerably.
Aim
To evaluate consensus on the treatment and follow-up of acromegaly in the Scandinavian countries.
Methods
To map the landscape of acromegaly management in the Scandinavian countries, a Delphi process was used. An expert panel developed 37 statements on the treatment and follow-up of acromegaly. Dedicated endocrinologists ($n=35$) from the Scandinavian countries were invited to participate in three Delphi rounds and rate their extent of agreement with statements concerning management of acromegaly, using a Likert-type scale (1-7). Consensus was defined as $\geq$ 80% of panelists rating their agreement as 5–7 on the Likert-type scale.
Results
33 endocrinologists (94 %) answered the survey (55 % women; mean 19 years of experience). Consensus was achieved for 16 (43%) statements distributed as follows: *Primary treatment* 2/4 (50%), *preoperative treatment with Somatostatin analogues* 0/4 (0%), *second- and third-line treatment* 7/19 (36%), *treatment in relation to pregnancy* 5/7 (71%), *long-term follow-up after disease control* 2/4 (50%).
Conclusion
This work reflects the clinical perspective of expert endocrinologist from the Scandinavian countries. In >50 % of the statements, consensus was not reached, which may reflect the complexity of the disease and its management, and/or a shortage of evidence-based data.

The Role of the GH Receptor Polymorphism as Prognostic Factor of Vertebral Fractures in Acromegaly Patients Resistant to First Generation SSAs and Treated with GH Receptor Antagonist or Second-Generation Somatostatin Ligand

Flavia Costanza[1,2], Sabrina Chiloiro[1,2], Antonella Giampietro[1,2], Pierpaolo Mattogno[3], Infante Amato[1], Flavia Angelini[1], Liverana Lauretti[3], Alessandro Olivi[1], Alfredo Pontecorvi[1,2], Francesco Doglietto[3], Laura De Marinis[1,2] & Antonio Bianchi[1,2]
[1]Catholic University of Sacred Heart, Department of Translational Medicine and Surgery, Rome, Italy; [2]Pituitary Unit, Department of Endocrinology and Diabetology, Fondazione Policlinico Universitario A. Gemelli, Rome, Italy; [3]Fondazione Policlinico Universitario A. Gemelli, Department of Neurosurgery, Rome, Italy

Acromegaly is associated with skeletal fragility and an increased prevalence of vertebral fractures (VF). In recent years several authors have tried to investigate the markers that can predict the risk of bone fragility in this endocrine disorder. Two different isoforms of the GH receptor (GHR) have been described so far, which differ in the presence or absence of a transcript of exon 3 of the GHR gene. Both isoforms produce a functional receptor, but the exon 3-deleted isoforms (d3-GHR) have greater sensitivity to endogenous and recombinant GH than the full-length isoform (fl-GHR). We conducted a longitudinal, retrospective, observational, single-center study of first-generation SSA-resistant acromegaly patients, with the aim of investigating the role of GHR polymorphism as a prognostic factor of incidental VF (I-VF) in first-generation SSA-resistant acromegalic patients and treated with GH receptor antagonist (Pegvisomant) or second-generation somatostatin ligand (Pasireotide Lar). 72 patients with acromegaly were included. 28 patients carried d3-GHR isoform (38.9%) and 44 patients carried fl-GHR isoform (61.1%). At baseline, all patients were affected by active acromegaly; 46 patients were treated with Pegvisomant in combination with first generation SSA and 26 were treated with Pasireotide Lar. 18 patients (25%) carried P-VFs. At last follow-up, 58 patients achieved biochemical control of acromegaly (80.6%). 14 patients experienced the occurrence of I-VFs. From the group

treated with Pegvisomant in combination with first generation SSA, 32 patients carried fl-GHR polymorphism and 14 carried d3-GHR polymorphism. At baseline, 10 patients (21.7%) were I-VF carriers. At follow-up, 8 patients developed P-VF (17.4%). I-VF occurred more frequently in patients carrying fl-GHR isoform compared to d3-GHR ($P=0.04$). From the group treated with Pasireotide Lar, 12 patients carried fl-GHR isoform and 14 patients carried d3-GHR isoform. At baseline, 8 patients (30.8%) were I-VF carriers. At follow-up, 6 patients developed P-VF (23.1%). I-VF occurred more frequently in patients carrying d3-GHR isoform than fl-GHR ($P=0.01$) and in patients with P-VF as compared to patients without P-VF ($P=0.05$). In conclusion, the GH receptor polymorphism could assume greater relevance as a prognostic factor of VF in acromegaly patients. In the future, the knowledge of the GHR polymorphism may improve the therapeutic approach of acromegaly patients, tailored to the individual patient, in the context of personalized medicine.

Serial sampling of dried blood spots collected by a novel automated body-worn system, Fluispotter®

Jesper Krogh[1], Peter Plomgaard[2], Ruth Frikke-Schmidt[2,3], Sten Velschow[4], Jesper Johannesen[3,5], linda hilsted[2], Malene Schroeder[4] & Ulla Feldt-Rasmussen[1,3]
[1]Rigshospitalet, National University Hospital, Department of Endocrinology and Metabolism, Copenhagen, Denmark; [2]Rigshospitalet, National University Hospital, Department of Clinical Chemistry, Copenhagen, Denmark; [3]Faculty of Health and Cinical Sciences, Copenhagen University, Institute of Clinical Medicine, Denmark; [4]Fluisense ApS, Allerod, Denmark; [5]Herlev-Gentofte Hospital, Department of Paediatrics and Steno Centre Copenhagen, Denmark

Repeated blood sampling is required in certain clinical and research settings, which is currently performed by drawing blood from venous catheters requiring manual handling of each sample at time of collection. A novel body-worn device for repeated serial samples, Fluispotter®, with automated extraction, collection and storage of up to 20 venous dried blood spot samples (DBS) over the course of 20 h may overcome problems with current methods for serial sampling. The purpose of this study was to assess the performance and safety of Fluispotter for the first time in healthy subjects. Fluispotter consists of a cartridge with tubing, reservoir for flushing solution, pumps and filter-paper and a multi-lumen catheter placed in the brachial vein. The volumetric DBS technology used in the Fluispotter has previously been tested *ex vivo* for cortisol assessment by comparing cortisol concentrations from dried blood spots with cortisol plasma samples[1]. The interassay accuracy and precision were less than 10% across a range of different haematocrit values. The plasma cortisol concentration was predicted from cortisol concentration measurements extracted from the DBS using the following formula:

$$PC\_plasma = C\_(DBS)/((0.92+(-0.876 \times HCT)))$$

We recruited healthy subjects for testing in an in-hospital setting. Fluispotter was attached to 22 healthy subjects of which 9/22 (40.9 %) participants had all 20 samples taken successfully, which was lower than the expected 80% ($P=0.02$). The main reason for sample failure was clogging of blood flow which was observed in 11/22 (50 %) of the participants. No serious adverse events occurred, and the participants rated the pain from insertion and removal of catheter as very low. A cortisol profile showed nadir values at midnight and highest values at 5 a.m. In conclusion, although full sampling was not successful in all participants, the Fluispotter technology proved safe and highly acceptable to the participants. The blood clogging was expected to be solvable by simple technical amendments. Producing the expected cortisol profile without the requirement of staff during sample collection provides promising future applications for studying circadian variations of different compounds in the circulation.

Introduction
The good expression of somatostatin receptors in neuroendocrine tumor tissue enables effective treatment with peptide receptor radionuclide therapy (PRRT). To date, there is no clear consensus on the optimal PRRT arrangement due to the possibility of the use of different radiopharmaceutical regimens. In theory, the simultaneous use of two radionuclides (90Y and 177Lu) with different energy and radiation ranges should be more effective than monotherapy. The main objectives of DUONEN (a phase III study, EUDRACT No: 2020-006068-99) are: - development of a personalized (dosimetry-based) PRRT algorithm for patients with disseminated NETs -evaluation of the safety and effectiveness of personalized therapy with mixture of [177Lu]Lu- and [90Y] Y-DOTATATE compared to the use of [177Lu]Lu-DOTATATE in standard doses (7400MBq)
Methods
92 adult patients with advanced, unresectable well-differentiated (G1/G2) NETs, progressing on long-acting SSA are randomized into four arms: - A: treated with [177Lu]Lu -DOTATATE with constant radioactivity of 7400MBq per cycle - B: treated with a mixture of [177Lu]Lu-DOTATATE and [90Y]Y-DOTATATE, initially in a ratio of 3700:1850MBq/MBq, with constant [177Lu]Lu -DOTATATE dose in all cycles, [90Y]Y-DOTATATE dose is adjusted in each cycle based on bone marrow and kidney dosimetry to maintain the highest possible radiation dose in tumor tissue - C: treated with a mixture of [177Lu]Lu-DOTATATE and [90Y]Y-DOTATATE, initially in a ratio of 3700:1850 MBq/MBq, analogously to arm B, except that the dose of [90Y] Yu-DOTATATE is constant and the dose of [177Lu]Lu-DOTATATE will depend on the dosimetry results - D: treated with [177Lu] Lu -DOTATATE initially with a dose of 7400MBq and then with doses based on individual dosimetry results The treatment efficacy will be evaluated on morphological imaging (TK or MR) according to RECIST 1.1 criteria and compared between arms. The safety of individual PRRT schemes will be assessed by biochemical follow-up of the kidney and bone marrow.
Results
11 patients have already started PRRT (arm A-3, B-4, C-1, D-3 cases). Total reported cycles given 25, including 14 fixed doses (firsts doses or arm A). In 8 of 11 cycles provided for adjustment, the dose of radiopharmaceutical estimated on the basis of personalized dosimetry was increased in 6 and decreased in 2 cases.
Conclusion
Personalized renal and bone marrow dosimetry influences PRRT doses in subsequent treatment cycles, which is likely to affect the results and safety of therapy.
Acknowledgments
The study is funded by the Medical Research Agency (Project number 2019/ABM/01/00077-00).

Prevalence and related risk factors of simple renal cysts and nephrolithiasis in acromegaly

Hayri Bostan[1], Muhammed Kizilgul[1], Murat Calapkulu[1], Hatice Kozan Kalkisim[2], Fatma Betul Gulden Topcu[2], Umran Gul[1], Hakan Duger[3], Sema Hepsen[1], Bekir Ucan[1] & Erman Cakal[1]
[1]Ankara Etlik City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Etlik City Hospital, Internal Medicine, Ankara, Turkey; [3]Kilis State Hospital, Endocrinology and Metabolism, Kilis, Turkey

Background
The growth hormone (GH)/insulin-like growth factor-1 (IGF-1) axis has effects on renal growth and electrolyte regulation. However, data on adverse renal

comorbidities such as renal cysts and stones in acromegaly is scarce. The current study aimed to investigate the prevalence of radiologically detectable renal comorbidities and possible related factors in the acromegaly population.
Methods
A total of 125 patients with acromegaly (46.4 ± 11.6 years, 68 females/57 males) and 114 age-sex matched healthy subjects (45.3 ± 12.4 years, 59 females/55 males) were included in the study retrospectively. Abdominal/urinary system ultrasonography or abdominal computed tomography results at the time of diagnosis in patients with acromegaly and at any time in healthy controls were examined. Demographic data, clinical history, and laboratory data of the patients were also recorded.
Results
Renal cyst prevalence (28.8% vs. 8.8%, $P<0.001$) and the longitudinal and transverse lengths of kidneys ($P<0.05$) were significantly higher in patients with acromegaly compared to the control group. There was no significant difference between the two groups in terms of the number of renal cysts. The presence of acromegaly disease increased the risk of renal cyst formation 12.8 fold (95% confidence interval, 2.8-58.2, $P=0.01$). The frequency of nephrolithiasis in acromegaly patients was similar to the control group (15.2% vs. 7.9%, $P=0.08$). Patients with acromegaly with renal cysts ($n=36$) compared to the group without cysts ($n=89$) were older (53.9 ± 10.0 vs. 43.3 ± 10.8 years, $P<0.001$), had a higher male sex frequency (69.4% vs. 35.9%, $P=0.001$), had a longer pre-diagnosis symptom duration (5 (interquartile range, 4-10) vs. 4 (2-5) years, $P=0.005$), and had a higher active smoking frequency (54.3% vs. 33.8%, $P=0.04$) and incidence of hypertension (54.3% vs. 31.8%, $P=0.02$) and diabetes mellitus (47.2% vs. 23.6%, $P=0.01$) at the time of diagnosis. Multivariate logistic regression analysis showed that age was an independent risk factor associated with the presence of renal cysts in patients with acromegaly. There was no statistically significant difference between acromegaly patients with and without cysts in terms of basal GH, nadir GH levels during oral glucose tolerance test, IGF-1xupper limit normal levels, kidney lengths, presence of kidney stones, estimated glomerular filtration rates, and serum electrolyte levels.
Conclusions
The present study showed that acromegaly disease significantly increased the prevalence of renal cysts and kidney lengths compared to the age- and sex-matched healthy population, while the prevalence of nephrolithiasis was similar. Advanced age was found to be an independent risk factor for renal cyst formation in patients with acromegaly.

Phosphoproteomics analysis of aryl hydrocarbon receptor interacting protein (AIP) knockout cells reveals AIP-mediated kinase signalling cascades

Sayka Barry[1], Ashutosh Rai[1], Oliver Haworth[1], Vinothini Rajeeve[2], Pedro Cutillas[2] & Marta Korbonits[1]
[1]William Harvey Research Institute, London, United Kingdom; [2]Barts Cancer Institute, London, United Kingdom

Introduction
Aryl hydrocarbon receptor interacting protein (AIP) is a multifunctional co-chaperone protein: it behaves as a tumour suppressor in the pituitary, but may have other roles including oncogenic function in other tissues. Protein phosphorylation is an important posttranslational modification that regulates protein activity, which is crucial for understanding protein function. To understand the molecular pathways altered in AIP deficient cells, we have performed global phosphoproteomics analysis of Aip-knockout mouse embryonic fibroblasts (Aip-KO MEFs) cells.
Aim
The aim of this study was to discover altered protein phosphorylation-related signalling pathways in Aip-KO MEFs.
Method
Phosphoproteomics analysis was performed by mass spectrometry (MS). Lysates were collected in four replicates from WT and Aip-KO cells. Phosphopeptides were enriched using titanium dioxide and subsequently analysed by LC-MS/MS. Ingenuity pathway analysis (IPA) was used for pathway analysis.
Results
We have identified 352 significantly altered phosphopeptides (200 hyper- and 152-hypophosphorylated) in Aip-KO MEFs compared to wild type cells. Among the hyperphosphorylated peptides, 10 were kinases and five were phosphatases. IPA analysis revealed two significantly activated pathways. The "Endocannabinoid cancer inhibition pathway' (Camkk2, Map2k7, Prkab2, Smpd3, Tcf4 and Twist1) was not previously suggested to be involved with AIP. The "Epithelial adherens junction signalling' (Arhgef17, Ctnna1, Nectin-1, Prkab2, Tcf4, and Vcl) pathway we have previously identified in gene expression and protein data of AIPpos human and mouse pituitary tumours. Functional enrichment analysis showed adherens junction, tight junction and actin cytoskeleton are the top significantly enriched pathways. Protein-protein interaction networks also showed the tight junction and signalling by Rho GTPases. Multiple kinase-mediated signalling pathways are altered in Aip-KO MEFs. The exact mechanism for the differential phosphorylation for these kinases needs to be validated by functional assays and explored further.
Conclusions
This study revealed novel insights into AIP-mediated signalling events and can be used as a valuable resource for further understanding of its function in invasive pituitary tumour development. It appears that adherens junction and tight junction pathways are of the most enriched pathways de-regulated in Aip-KO MEFs, suggesting a critical role of AIP in these pathways. Therefore, new treatments targeting these pathways may have potential to the management of patients with aggressive *AIP*pos pituitary tumours.

Introduction
Phase II (LINC2, NCT01331239) and Phase III (LINC3, NCT02180217; LINC4, NCT02697734) studies showed that osilodrostat, a potent oral 11β-hydroxylase inhibitor, was an effective long-term treatment for Cushing's disease patients. In this LINC programme pooled analysis, we examined how dose uptitration and adjustments during long-term maintenance can provide rapid, sustained mean urinary free cortisol (mUFC) control, and minimise AEs.
Methods
Data from 229 patients enrolled in LINC2, LINC3 (both mUFC>1.5x the upper limit of normal [ULN]) and LINC4 (mUFC>1.3xULN) were pooled and analysed. Placebo treatment periods were excluded. In LINC2, patients started open-label osilodrostat 2 mg twice daily (bid), with dose increases every 2 weeks (W) if mUFC>ULN. In LINC3, patients started open-label osilodrostat 2 mg bid, with dose increases every 2W until W12 if mUFC>ULN, then every 4W thereafter. In LINC4, patients were randomised to osilodrostat 2 mg bid or placebo (W1–W12), then increased every 3W until W12 if mUFC>ULN and every 3W thereafter. Maximum dose was 30 mg bid in all studies (reduced from 50 mg bid in LINC2 core phase). Dose adjustments were permitted during the extensions based on efficacy/tolerability.
Results
Median (min–max) osilodrostat exposure was 100W (1–351). Median (min–max) dose was 6.8 mg/day (1–47); dose needed to achieve mUFC control varied widely. Median time to first mUFC control: all patients, 35 days (D; 95% confidence interval [CI]:34–41); by baseline mUFC severity: <2xULN, 28D (95% CI:17–34); 2–5xULN, 40D (95% CI:34–42); >5xULN, 52D (95% CI:41–56). Median time to first AE of special interest (AESI) was 12W (95% CI:10–15); AESIs occurred at different osilodrostat doses. Fewer hypocortisolism-related (baseline to W12, 23%; W12–48, 24%; W48–72, 8%; W72–≤ W351, 20%) and adrenal hormone precursor accumulation-related AEs (baseline to W12, 36%; W12–48, 37%; W48–72, 14%; W72–≤ W351, 18%) occurred during long-term maintenance than dose titration. AESIs were mostly manageable with dose interruption and/or additional therapy, with few patients discontinuing treatment (hypocortisolism-related [$n=8$]; adrenal hormone precursor accumulation-related [$n=3$]).

Conclusions
Osilodrostat provided sustained mUFC control in all studies; time to control was shorter with lower baseline mUFC values. Median daily osilodrostat dose was low but varied widely. Dose titration differed between studies, but AESIs were less frequent during long-term treatment than dose uptitration and were mostly manageable without stopping treatment. Personalised therapy during dose titration and lifelong monitoring are needed to optimise clinical outcomes.

Sleep Quality and Associated Factors in Patients with Non-functioning Pituitary Adenoma

Tugba Barlas[1], Mehmet Muhittin Yalcin[1], Doga Ecem Avci[2], Yigit Kaplan[2], Mujde Akturk[1], Fusun Toruner[1], Ayhan Karakoc[1] & Altinova Alev[1]
[1]Gazi University Faculty of Medicine, Endocrinology and Metabolism, Ankara, Turkey; [2]Gazi University Faculty of Medicine, Ankara, Turkey

Aim
Sleep disturbances are widespread and closely associated with pituitary diseases, even those under long-term therapeutic management. The aim of this study was to investigate sleep quality, depression, anxiety, and physical activity in patients with non-functioning pituitary adenoma (NFPA) and determine the factors that might be associated with decreased quality of sleep.
Method
Eighty-two patients with NFPAs and 82 age- and gender-matched control subjects were included. Information on the patients' clinical findings, laboratories and imagings, therapies for pituitary insufficiency were documented. Pittsburgh Sleep Quality Index (PSQI), Hospital Anxiety and Depression Scale (HADS) and International Physical Activity Questionnaire (IPAQ-SF) were used to evaluate sleep quality, depression, anxiety, and physical activity of participants.
Results
Eighty-six percent of the patients with NFPAs had macroadenoma and mean largest diameter was 22.0 mm. Intact pituitary function was present in 47.6% of patients with NFPAs. In the NFPA group, 57.3% of patients had decreased sleep quality, while 35.4% of patients in the control group ($P=0.005$). Anxiety and depression scores were higher and physical activity scores were lower in NFPAs than in the control group ($P<0.05$). Although there was no relationship between the presence of hydrocortisone replacement or total daily dosage and sleep quality in patients with secondary adrenal insufficiency ($P>0.05$), there was a strong positive correlation between PSQI and morning hydrocortisone replacement time ($r=0.834$, $P<0.001$). The presence of both transcranial surgery and diabetes insipidus was also found to be significantly higher in the group with decreased sleep quality ($P<0.05$). There was a negative correlation between PSQI and IGF-1 and free T4 levels in patients with NFPAs ($r=$-0.259, $P=0.01$) ($r=$-0.392, $P<0.01$). A multivariate logistic regression model revealed that depression score and free T4 level in the upper half of the normal limit were the most associated factors for sleep quality.
Conclusions
Our study indicated that patients with NFPAs had decreased sleep quality compared to age- and gender- matched controls. Presence of depression and a free T4 level in the upper half of the normal range were the most associated factors, along with presence of transcranial surgery, low IGF-1 levels, diabetes insipidus, and morning hydrocortisone replacement time.

Psychopathological characteristics in patients with arginine vasopressin deficiency (central diabetes insipidus) and primary polydipsia

Julia Beck[1], Cihan Atila[1], Julie Refardt[1], Erlic Zoran[2], Juliana Drummond[3], Beatriz Santana Soares[3], Felix Beuschlein[2], Bettina Winzeler[1] & Mirjam Christ-Crain[1]
[1]University Hospital Basel, Department of Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]University Hospital Zürich, Department of Endocrinology, Diabetology and Clinical Nutrition, Zürich, Switzerland; [3]Universidade Federal de Minas Gerais, Belo Horizonte, Departamento de Medicina Interna, Faculdade de Medicina, Brazil

Introduction
The differential diagnosis between arginine vasopressin deficiency (AVP-D), formally known as central diabetes insipidus, and primary polydipsia (PP) is challenging. In clinical routine, psychopathologic findings are often used as a hallmark for diagnosing PP; thus, it is often referred to as psychogenic polydipsia. Yet, psychopathologic characteristics are barely assessed in patients with AVP-D, and to date, no data exist comparing AVP-D and PP with regard to these features. Therefore, in this study, we aimed to compare levels of anxiety, depression, alexithymia, and overall mental health in patients with AVP-D and PP.
Methods
This study combined data from two diagnostic studies conducted at three tertiary medical centers. In total, 82 participants ($n=39$ with AVP-D, $n=28$ with PP, and $n=15$ healthy controls [HC]) underwent a psychological evaluation with standardized questionnaires at study inclusion. Anxiety levels were assessed using the State-Trait Anxiety Inventory, mood using the Beck's Depression Inventory, alexithymia using the Toronto Alexithymia Scale, and overall physical and mental health using the Short Form 36 Health Survey (SF-36). Higher STAI, BDI, and TAS scores indicate higher anxiety, depression, and alexithymia levels. Higher SF-36 scores indicate better health and less disability.
Results
Compared with HC, patients with AVP-D and PP showed increased levels of anxiety (HC 28 points [24, 31] vs. AVP-D 36 points [31, 45], $P<0.01$; vs. PP 38 points [33, 46], $P<0.01$), depression (HC one point [0, 2] vs. AVP-D 7 points [4, 14], $P<0.01$; vs. PP 7 points [3, 13], $P<0.01$), and alexithymia (HC 30 points [29, 37] vs. AVP-D 43 points [35, 54], $P<0.01$; vs. PP 46 points [37, 55], $P<0.01$). Levels of anxiety, depression, and alexithymia showed no difference between patients with AVP-D and PP ($P=0.58$, $P=0.90$, $P=0.50$). Compared with HC, patients with AVP-D and PP reported comparable reduced self-reported mental health scores (HC 84 [68, 88] vs. AVP-D 60 [52, 80], $P=0.05$; vs PP 60 [47, 74], $P<0.01$).
Conclusion
This is the first study demonstrating comparable increased levels of anxiety, depression, alexithymia, and overall reduced mental health in patients with AVP-D and PP. Based on these data, psychopathological findings should not be used as a hallmark to differentiate between both conditions.

Hyperosmolar Hyperglycaemic State (HHS) and severe decompensated heart failure as presenting features of ectopic ACTH Syndrome

David McDonnell[1], Leanne Cussen[1], Julie Martin-Grace[1], Paul Cotter[2], Liam Grogan[3] & Amar Agha[1]
[1]Beaumont Hospital, Endocrinology Department, Dublin, Ireland; [2]St. Lukes Hospital, Geriatric Medicine, Kilkenny, Ireland; [3]Beaumont Hospital, Oncology, Dublin, Ireland

Ectopic ACTH syndrome is a rare condition occurring in five to ten percent of ACTH dependent hypercortisolism. We present the case of a fifty eight year old gentleman who presented with severe hyperosmolar hyperglycaemic state (blood glucose fifty seven mmol/l) and acute decompensated heart failure associated with elevated liver enzymes. Liver ultrasound followed by computed tomography of thorax abdomen and pelvis showed a lung tumour with liver metastases. Clinical suspicion of Cushing's syndrome was confirmed by with an overnight dexamethasone suppression cortisol of three thousand nine hundred and forty two nmol/l. A twenty four hour urine free cortisol was markedly elevated at a hundred fold with an adrenocorticotropin hormone level of one thousand four hundred and forty six pg/ml (7.2-63.3). Liver biopsy confirmed small cell carcinoma. Following initial treatment of his hyperosmolar hyperglycaemic state and heart failure, he was commenced on four grams of metyrapone per day which normalised his cortisol day curve. His insulin therapy and diuretics were later stopped and he maintained euglycaemia without glucose lowering therapy. Following carboplatin/etoposide chemotherapy, his metyrapone dose was reduced to two grams/day due to hypocortislaemia and replacement Hydrocortisone was added. This is a case of very severe hypercortisolaemia secondary to ectopic ACTH syndrome presenting with life threatening complications. Prompt diagnosis and rapid cortisol control with high dose metyrapone resulted in marked clinical and biochemical improvement.

The diagnostic accuracy of dex-CRH test in differentiating between Cushing's disease and pseudo-Cushing syndrome. A single-center experience

Carlien De Herdt[1], Eveline Dirinck[1], Philipse Eva[1,2] & Christophe De Block[1]

[1]Antwerp University Hospital, Diabetology, Endocrinology, Metabolic Disorders, Edegem, Belgium; [2]HHZH Lier, Diabetology, Endocrinology, Lier, Belgium

Background
Distinguishing pseudo-Cushing syndrome (PCS) from mild forms of Cushing's disease (CD) is a challenge. The dexamethasone-Corticotropin Releasing Hormone test (dex-CRH) assumes that cortisol response to CRH is preserved in CD while suppressed in PCS after the low dose dexamethasone suppression test (LDDST).
Methods
Persons with a suspicion of CD based on mild clinical features and a positive first-line screening test were included. They underwent a dex-CRH test between 2010 and 2020. Adrenal causes of hypercortisolism and women using estrogens were excluded. Those with a positive dex-CRH underwent neurosurgery. Those considered as PCS needed to be followed for at least 2 years and not develop new Cushingoid features.
Results
Dex-CRH was performed in 36 cases (F: 24) with a median age of 50 years (IQR; 32-56). Thirteen cases were diagnosed with CD (F: 11), 22 with PCS (F: 13) and 1 had an indeterminate result. The following Cushingoid features were present in cases diagnosed with CD vs PCS: moon face (15 vs 14%), buffalo hump (38 vs 27%), striae (0 vs 9%), myopathy (64 vs 19%), hypertension (54 vs 45%), type 2 diabetes (23 vs 23%) and BMI $>$ 30 kg/m^2 (46 vs 77%). 7/13 CD cases had a biochemical mild form (UFC $<$2xULN). UFC was mildly elevated in 16/22 of the PCS group and clearly elevated ($\geq$ 2x ULN) in 4/22 cases. Using a cut-off value of 38 nmol/l, LDDST was positive in 12/13 cases with CD and in 0/22 with PCS and the ensuing CRH-stimulation was positive in respectively 13/13 vs 1/22 cases. Mean serum cortisol level after LDDST in the CD group was 226.5 nmol/l compared to 16.8 nmol/l in the PCS group. After dex-CRH test mean serum cortisol was 433.1 nmol/l compared to 18.8 nmol/l, respectively. Increasing the cut-off value to 87 nmol/l led to exclusion of al PCS cases but also misdiagnosis of 1 CD case.
Conclusions
The prevalence of various Cushingoid features between mild CD and PCS was quite similar except for myopathy being more prevalent in CD. The majority of cases with PCS were obese (77%). LDDST had a good diagnostic accuracy (sensitivity 92%, specificity 100%, PPV 100%, NPV 96%). Additional CRH stimulation improved the sensitivity (100%) but had a negative effect on the specificity (95%). In conclusion, Dex-CRH test with a cut-off value of 38 nmol/l is a good test to differentiate between mild forms of CD and PCS.

Objective
Hereditary pituitary adenomas (PAs) are rare and occur either isolated or as part of a syndrome. Familial isolated pituitary adenoma (FIPA) is the presence of only PA in at least two members of a family, where "Aryl hydrocarbon receptor interacting protein-*AIP*" gene mutations have been identified in 10-20% of cases. However, the cause of tumorigenesis in the majority is unknown. We aimed to identify novel genetic variants in a cohort of FIPA patients from Turkiye.
Materials and Methods
Twelve centers in various geographical regions of the country were included. FIPA cohort involving 20 index cases and 17 affected relatives were recruited. Whole exome sequencing was performed on 20 cases on Illumina NextSeq550 system. Bioinformatic analyses and variant prioritization at MAF$<$1% were performed, where variants for PA-related genes followed by novel candidate genes were filtered. Affected relatives were utilized in confirmation of candidate variants by Sanger sequencing.
Results
Our cohort consisted of 10 homogeneous (index cases: 4 prolactinomas/6 acromegaly) and 10 heterogeneous (index cases: 4 prolactinomas,3 Cushing's disease and 3 acromegaly) FIPAs. The gender distribution of indexes in each group is equal (5F/5M). The mean age at diagnosis of index cases was 38.44$\pm$13.25 years for acromegaly (n=9), 36.25$\pm$17.13 for prolactinoma (n=8), 44.67$\pm$2.31 for Cushing's disease (n=3). Eight out of 20 index cases of FIPA families were found to carry variations in PA-related genes, where a novel *AIP* variant (c.646-1G>C) was identified (Table 1). Confirmation and familial segregation are ongoing for variants in heterogeneous FIPAs.
Conclusion
Consistent with the literature, our preliminary results detected *AIP* mutation frequency as 15% in the FIPA cohort. Novel variants in our study highlight the genetic heterogeneity and phenotypic diversity of FIPA patients, which complicate the diagnosis.

Funding

Introduction
Endogenous hypercortisolism is associated with cardio-metabolic complications and promotes the deposition of lipids in different tissues, particularly in the liver. However, the prevalence of hepatic steatosis in patients with Cushing's syndrome (CS) has been little investigated so far and only one previous study reported a prevalence of 20% using computed tomography. The aim of the study is to evaluate the prevalence of hepatic steatosis and the organ-specific distribution of adipose tissue in patients affected by CS.
Methods
We performed a cross-sectional collection of clinical, biochemical and instrumental data (abdominal ultrasound, fibroscan, assessment of epicardial fat, supra-aortic trunks ultrasound and body composition through BIA) of patients diagnosed with CS and followed at our Endocrinology Unit.
Results
Forty-three CS patients were studied (M/F: 8/35; age 53 ± 13 years; 4: active disease, 29: disease remission, 6: disease control, 4: partial remission). The prevalence of hepatic steatosis was 49% (21/43 patients, of which 9 with moderate to severe degree), but only 1 patient showed fibroscan values consistent with significant hepatic fibrosis. The prevalence of carotid atherosclerosis was 58%, while an increase in epicardial fat was found in 37% of patients. CS patients with steatosis, when compared to those without steatosis, had a higher number of previous cardiovascular events (4 vs 0, $P=0.045$), a higher BMI (27.7 ± 5.4 vs 22.4 ± 3.3, $P<0.01$), a higher fat mass (34.8 ± 8.4 vs 24.7 ± 6.7, $P<0.01$), a higher prevalence of metabolic syndrome (57% vs 18%, $P<0.05$) and hyperuricemia (45% vs 9%, $P<0.05$). In a multivariate analysis model including age, sex, hyperuricemia and metabolic syndrome, the latter was associated with the development of hepatic steatosis (OR: 4.98, IC 1-25.65). Finally, the CS group with steatosis was compared to a group of 42 subjects with NAFLD, matched for age and sex. Compared to the latter, despite a similar prevalence of metabolic comorbidities, patients with CS showed a lower fat mass ($34.8 \pm 8.7\%$ vs $40.2 \pm 8.8\%$, $P<0.05$) and a higher prevalence of carotid atherosclerosis (62% vs 31%, $P<0.05$).
Conclusions
CS is characterized by a high prevalence of hepatic steatosis, carotid atherosclerosis and increase in epicardial fat. In these patients, metabolic syndrome is associated with the development of hepatic steatosis. At the same degree of steatosis, CS patients have a lower percentage of fat mass but an increased prevalence of carotid atherosclerosis compared to NAFLD patients, suggesting the pathogenetic role of hypercortisolism in the development of these complications.

Impact of Setmelanotide Treatment on Reducing Hyperphagia in Pediatric and Adult Patients With Hypothalamic Obesity

Christian L. Roth[1,2], Ashley H. Shoemaker[3], Michael Gottschalk[4], Jennifer Miller[5], Guojun Yuan[6], Sonali Malhotra[6,7,8], Cecilia Scimia[6] & M. Jennifer Abuzzahab[9]
[1]Seattle Children's Research Institute, Seattle, WA, United States; [2]University of Washington, Division of Endocrinology, Department of Pediatrics, Seattle, WA, United States; [3]Vanderbilt University Medical Center, Ian Burr Division of Endocrinology and Diabetes, Nashville, TN, United States; [4]University of California San Diego/Rady Children's Hospital, Pediatric Endocrinology, San Diego, CA, United States; [5]University of Florida College of Medicine, Pediatric Endocrinology, Department of Pediatrics, Gainesville, FL, United States; [6]Rhythm Pharmaceuticals, Inc., Boston, MA, United States; [7]Massachusetts General Hospital, Boston, MA, United States; [8]Harvard Medical School, Boston, MA, United States; [9]Children's Minnesota, Pediatric Endocrinology and Diabetes, St. Paul, MN, United States

Objective
To report hunger-related results from a Phase 2 trial of setmelanotide in patients with hypothalamic obesity (HO).
Methods
A Phase 2, open-label, 16-week trial of setmelanotide in patients aged ≥ 6 to ≤ 40 years with body mass index (BMI) $\geq$95th percentile (aged <18 years) or ≥ 35 kg/m^2 (aged ≥ 18 years) and HO caused by hypothalamic damage secondary to brain tumor, surgical resection, and/or chemotherapy was performed. The primary endpoint was the proportion of patients reaching $\geq 5\%$ BMI reduction from baseline at Week 16. Change from baseline in daily hunger scores was a secondary endpoint. A daily hunger questionnaire was completed before morning meal (ie, while fasted) and setmelanotide administration each morning. Patients aged ≥ 12 years rated their past 24-hour hunger on an 11-point numerical rating scale, where 0 = not hungry at all and 10 = hungriest possible, with 3 questions assessing maximal, average, and morning hunger; patients aged <12 years used a pictorial version of the scale. Daily hunger scores were averaged weekly and compared with baseline score, calculated as the average of the 7 days before setmelanotide initiation. Hunger analyses were stratified by age (<12 and ≥ 12 years).
Results
Eighteen (13 pediatric, 5 adult) patients were included in the study. At Week 16, most (16/18) patients met the primary endpoint (88.9% [90% confidence interval, 69.0%-98.0%]; $P<0.0001$), with a mean percent change in BMI of -14.9% in all patients adhering to treatment administration ($n=17$). In patients aged ≥ 12 years ($n=11$), the mean (standard deviation [SD]) change from baseline in maximal daily hunger score was -2.9 (2.3) (percent change, -45.0% [36.3%]), in average hunger score was -3.1 (2.0) (percent change, -56.7% [35.4%]), and in morning hunger score was -2.7 (1.9) (percent change, -65.3% [35.2%]). Baseline maximal hunger scores ranged from 5.8 to 7.5; decreases were seen independent of baseline score. In patients aged <12 years ($n=5$), the mean change from baseline in daily hunger score was -1.4 (-62.0%). Treatment-related adverse events occurred in 18 patients (100%); nausea ($n=11$; 61.1%), skin hyperpigmentation ($n=6$; 33.3%), vomiting ($n=6$; 33.3%), diarrhea ($n=4$; 22.2%), and COVID-19 ($n=4$; 22.2%) were most frequently reported.
Conclusions
Patients with HO had reductions in hunger scores across all domains. These findings support continued development of setmelanotide for treatment of HO; a Phase 3 trial will begin in early 2023.

Erythropoiesis in endogenous Cushing syndrome: sex-related and subtype-specific differences

Mario Detomas[1], Timo Deutschbein[2], Mariangela Tamburello[3], Irina Chifu[4], Otilia Kimpel[4], Silviu Sbiera[3], Matthias Kroiß[3,5], Martin Fassnacht[3] & Barbara Altieri[3]
[1]University Hospital, University of Würzburg, Würzburg, Germany, Department of Internal Medicine I, Division of Endocrinology and Diabetes, Würzburg, Germany; [2]University Hospital of Würzburg, Department of Internal Medicine I, Division of Endocrinology and Diabetes, Würzburg, Germany; [2]University Hospital of Würzburg, Department of Internal Medicine I, Division of Endocrinology and Diabetes, Würzburg, Germany; [2]University Hospital of Würzburg, Department of Internal Medicine I, Division of Endocrinology and Diabetes, Würzburg, Germany; [5]University Hospital Munich, Ludwig-Maximilians-Universität München, Department of Internal Medicine IV, München, Germany

Context
Endogenous Cushing syndrome (CS) is associated with hematological abnormalities. Nevertheless, conflicting data have been reported on erythropoiesis. Some studies reported an association between CS and anemia in men, whereas others described erythrocytosis in affected patients. Furthermore, it is unclear whether there are CS subtype-specific changes in red blood cells (RBC) parameters.
Objective
To investigate sex and subtype-specific changes in RBC in a large cohort of patients with CS at initial diagnosis and after curative surgery.
Design
Retrospective, monocentric study including 210 patients (females, $n=162$; males, $n=48$; median age 49 and 48, respectively) with ACTH-dependent (Cushing's disease (CD), $n=85$; ectopic CS (ECS), $n=31$) and ACTH-independent CS (cortisol-producing adrenocortical adenoma, $n=46$; adrenocortical carcinoma $n=48$)). These patients were matched 1:1 for sex and age with patients suffering from either hormonally inactive pituitary microadenomas ($n=117$) or adrenal incidentalomas ($n=93$). RBC parameters were evaluated at initial diagnosis and after surgical cure of CS (at 3 months, 12 months, and ≥ 24 months).
Results
Women with active CS had higher hematocrit (median 42.3 vs 40.4%), hemoglobin (14.1 vs 13.8g/dl), and mean corpuscular volume (MCV) (91.1 vs 87.8fl) than female controls (all $P<0.005$). Women with CD showed higher hematocrit (43.3 vs 36.1%), RBC count (4.8 vs 4.0n*106/µl), and hemoglobin (14.3 vs 12.2 g/dl) than those with ECS (all $P<0.0005$). The same differences

were found if women with ECS due to malignant tumors were excluded from the analysis. Men with active CS had lower hematocrit (42.9 vs 44.7%), RBC count (4.8 vs 5.1n*106/μl), and hemoglobin (14.2 vs 15.4g/dl), but higher MCV (90.8 vs 87.5fl) than controls (all $P<0.05$). 20 out of 48 men with CS (42%) had hemoglobin levels below the normal range. In men with CS, no subtype specific differences but a negative correlation between 24h-urinary free cortisol and hematocrit, RBC count, and hemoglobin ($r=$-0.426, $r=$-0.477, $r=$-0.347, $P<0.05$) were identified. Compared to baseline, hemoglobin decreased in both women (-8.3%) and men (-5.8%) three months after remission from CS.

Conclusion

CS is characterized by pronounced sexual and subtype-specific changes in erythropoiesis. Women s with CS showed higher hematocrit and hemoglobin levels compared to controls. In contrast, men with CS had lower hematocrit/hemoglobin levels, which further decreased in the first months after remission. Therefore, anemia should be considered as a potential complication of CS in males. In females with CS, differences in RBC parameters may allow for a first subtype differentiation between CD and ECS.

Introduction

A robust clinical programme of 14 trials demonstrated pasireotide as an effective treatment for patients with rare endocrine disorders, including acromegaly and Cushing's disease (CD). Patients with acromegaly or CD have significant morbidity, reduced quality of life and, if inadequately treated, higher mortality risk than the general population. This 8-year interim analysis evaluated long-term safety of pasireotide treatment in patients with acromegaly, CD or other endocrine disorders.

Methods

This ongoing, open-label, multicentre study allows continued treatment for patients who completed a previous pasireotide parent trial (NCT01794793). Patients who continued receiving clinical benefit, according to the parent study investigator, entered the rollover study and remained on pasireotide. Depending on the administration route in the parent study, patients received pasireotide long-acting release (LAR; $n=303$) or subcutaneous (sc; $n=38$) as monotherapy ($n=36$), or sc combined with cabergoline ($n=2$). The primary objective was to evaluate long-term safety, determined by frequency of adverse events (AEs)/serious adverse events (SAEs).

Results

Overall, 341 patients from 29 countries have entered the study from 14 parent studies: 228 patients had acromegaly, 64 had CD and 49 had other endocrine disorders, including melanoma, dumping syndrome and neuroendocrine tumours. Median (min−max) exposure to all pasireotide formulations from rollover baseline to data cut-off and across all indications was 45.3 months (0.9–100.8). Median (min−max) dose from rollover baseline was 45.4 mg/month (5.3–128.3) with pasireotide LAR and 1200 μg/day (300–1800) with pasireotide sc. Altogether, 89 (26.1%) patients discontinued treatment, most commonly because of consent withdrawal ($n=21$, 6.2%). The most common AEs during rollover ($\geq 10\%$ in all patients) were nasopharyngitis (acromegaly $n=13$, 5.7%; CD $n=14$, 21.9%; other diseases $n=14$, 28.6%), hyperglycaemia (acromegaly $n=29$, 12.7%; CD $n=2$, 3.1%; other diseases $n=7$, 14.3%), back pain (acromegaly $n=20$, 8.8%; CD $n=7$, 10.9%; other diseases $n=8$, 16.3%) and headache (acromegaly $n=21$, 9.2%; CD $n=6$, 9.4%; other diseases $n=7$, 14.3%). SAEs were reported in 87 (25.5%) patients, most commonly cholelithiasis and COVID-19 (both $n=9$, 2.6%). Overall, 18 (5.3%) patients discontinued treatment because of AEs. Incidence of new hyperglycaemia-related AEs during rollover was low. No new safety signals were identified.

Conclusions

Hyperglycaemia is an expected AE during pasireotide treatment, often occurring in the first 3 months of therapy. These data support pasireotide as a well-tolerated long-term treatment in patients with acromegaly, CD or other endocrine disorders and affirm that patients receive long-term benefit, with a low discontinuation rate over 8 years.

Association of Pituitary Adenoma (Pa)/Pituitary Neuroendocrine Tumor (Pit-Net) and Cerebral Aneurysm: risk factors, peculiar features and management

Federica Guaraldi[1], Matteo Zoli[1], Noah Nawabi[2], John L. Kilgallon[2], Davide Gori[3], Sofia Asioli[3], Diego Mazzatenta[1] & Tim Richard Smith[2]

[1]IRCCS Istituto delle Scienze Neurologiche di Bologna, Pituitary Unit, Bologna, Italy; [2]Brigham and Women's Hospital, Computational Neurosciences Outcomes Center, Department of Neurosurgery, Boston, United States; [3]Alma Mater Studiorum - Università di Bologna, Department of Biomedical and Neuromotor Sciences (DIBINEM), Bologna, Italy

Rationale and aim

The incidence of intracranial aneurysms (IA) appears increased in patients with PAs/PitNETs. Changes in hemodynamics and vascular structure secondary to mass effect, inflammation, and hormonal changes (primarily, GH hypersecretion) have been suggested as risk factors. Study aim was to define typical features, timing of occurrence and treatment, and identify risk factors in patients with PA/PitNET and IA.

Patients and methods

Data of 57 cases (20 males) of IA associated with PA/PitNET, identified by screening 5,146 patients with PA/PitNET and 25,104 with IA evaluated at two referral Centers from 1998 to 2022, were retrospectively reviewed.

Results

Mean age at diagnosis was 52.6 ± 12 (range 28-84) years for PA/PitNET, 57.4 ± 11.6 (30-83) for IA. Forty-one (77.4%; 18 males) had a macroadenoma, 32 (82%) with extrasellar extension, and 24 (61.5%) with cavernous sinus invasion. IA was diagnosed after PA/PitNET in 30 (52.6%) cases, simultaneously in 17 (29.9%), before in 10 (17.5%). 50 (87.7%) PAs/PitNETs were treated by transsphenoidal surgery, 6 (10.5%) by craniotomy. Based on histology, 29.6% were lactotroph, 11.1% corticotroph, 18.5 somatotroph, 14.8% somato-lactotroph, 14.8% gonadotroph, and 11.1% plurihormonal. Six patients (10.5%) presented multiple IAs. Mean IA size was 4.8 ±3.9 (range 1-26) mm. Typical localizations were internal carotid artery (47.4%), anterior carotid artery (19.3%), and middle cerebral artery (14%); 56.1% of IA originated in proximity of the sella turcica. Treatment consisted of endovascular embolization in 17 (29.8%) patients, surgery in 4 (7.1%), clipping in 1 (1.8%), multiple treatments in 3 (5.3); 31 (55.4%) were not treated. Regarding risk factors, 20 (35.1%) patients had familiarity of aneurysm, none of pituitary adenoma; 2 (3.5%) had connective disorders; 18 (32.1%) had previously undergone sellar surgery and 8 (14%) radiotherapy. 54/57 (94.7%) patients presented ≥1 cardiovascular risk factor (i.e., smoking 47.4%, hypertension 70.2%, dyslipidemia 36.8%, diabetes 28.1%, overweight/obesity 71.7%, stroke/infarction 24.6%, other cardiovascular diseases 12.8%), 46 (80.7%) ≥2 risk factors.

Conclusions

Our study supports the need of screening for AI in patients with invasive macroadenomas, especially with previously surgery/radiotherapy, cardiovascular risk factors and GH hypersecretion.

Fibroblast Activation Protein in Patients with Growth Hormone Deficiency and Acromegaly: Before and After Treatment

Amanda Baek[1,2], Mai C. Arlien-Søborg[1,2,3], Anne Kathrine Nissen Pedersen[2], Niels Jessen[3,4], Mette Bjerre[1,2] & Jens Otto Lunde Jørgensen[1,2,5]

[1], The Department of Endocrinology and Diabetes, Department of Clinical Medicine, Aarhus University, Aarhus, Denmark; [2]Medical Research Laboratory, Department of Clinical Medicine, Aarhus University, Aarhus,

Denmark; [3]SDCA-Steno Diabetes Center Aarhus, Department of Clinical Medicine, Aarhus University Hospital, Aarhus, Denmark; [4]The Research Laboratory for Biochemical Pathology, Department of Clinical Medicine, Aarhus University, Aarhus, Denmark; [5]The Department of Endocrinology and Diabetes, Aarhus University Hospital, Aarhus, Denmark

Background
It is well-known that growth hormone (GH) potently stimulates collagen turnover and it is associated with fibrosis in several tissues, but the mechanisms involved in GH-stimulated fibrosis are poorly elucidated. Fibroblast activation protein-α (FAPα) is an enzyme that can cleave collagens and is expressed almost only under pathological conditions such as fibrosis. FAPα also cleaves and inactivates fibroblast growth factor 21 (FGF21), which is a circulating hormone with pleiotropic metabolic effects. Despite their related involvements, data regarding the interaction between GH and FAPα are scarce.
Aim
To measure circulating FAPα, FGF21 components and biomarkers of collagen turnover in patients with adult-onset GH deficiency (GHD) and in patients with acromegaly before and after treatment, compared to a control group.
Methods
Serum samples obtained from 16 patients with adult-onset GHD at time of diagnosis and after GH treatment have been analyzed using immunoassays for FAPα concentration and activity, and total FGF21. Repeated serum samples obtained from 9 patients initially suspected for GHD but with a normal GH response to an insulin tolerance test serve as controls. This study is ongoing and biomarkers of collagen turnover are yet to be analyzed at time of abstract submission. Furthermore, we have obtained serum samples from 14 patients with acromegaly before and after treatment, which will be analyzed for the same parameters.
Results
Our preliminary data show that serum levels of FAPα (ng/ml) significantly increase in the GHD patients after GH treatment [135.6 (111.6-163.8) vs 168.5 (107.3-233.9), $P<0.05$], and FAPα activity (RFU/min) in serum likewise increase after GH treatment [719.0 (467.3-1104.2) vs 1277.8 (668.9-1609.4), $P<0.05$], [median (IQR)]. Total FGF21 remain unchanged after GH treatment. In the control group, FAPα concentration and activity as well as total FGF21 remain unchanged over a corresponding time period.
Conclusions
Circulating FAPα concentration and activity increase in response to GH treatment in patients with adult-onset GHD, whereas total FGF21 do not change in response to GH treatment. Further analyses in this study are ongoing, including comparable analyses in patients with acromegaly. It remains to be studied if the fibrotic and FAPα -stimulating effects of GH are causally linked.

Panhypopituitarism in an Adult Patient with William-Beuren Region Duplication Syndrome: A Rare Case Report

Derya Sema Yaman kalender[1], Roya Gasımlı[2], Aslı Subaşıoğlu[3], Mehmet Sercan Ertürk[1], Umit Çavdar[1], Güzide Gonca Örük[1] & Barış Önder Pamuk[1]
[1]Katip Celebi University School of Medicine, Atatürk Training and Research Hospital, Endcorinology and Metabolism, Izmir, Turkey; [2]Ege University Faculty of Medicine, Department of Medical Biology, Turkey; [3]Katip Celebi University School of Medicine, Department of Medical Genetics, Turkey

Background
William-Beuren region duplication syndrome (WBDS) is a rare multisystem disease caused by the gain on chromosome 7q and transmitted autosomal dominant, with approximately a population frequency of 1 in 13,000-20,000. The age of diagnosis is variable, but generally, it is diagnosed during childhood. It include endocrine (growth hormone deficiency) and non-endocrine (facial dysmorphology, cardiovascular problems, gastrointestinal and genitourinary problems, neurological problems, behavioral and psychiatric disorders) abnormalities.
Case
A 60-year-old female patient applied to our outpatient clinic with fatigue. She had a history of irregularly applying to another endocrinology clinic and using hydrocortisone and levothyroxine with the diagnosis of panhypopituitarism. We confirmed the diagnosis of panhypopituitarism with retrospective laboratory tests evaluation. She had primary amenorrhoea but never received hormone replacement. She had a hepaticojejunostomy due to Caroli's disease and was frequently diagnosed with cholangitis, which sometimes becomes a clinical manifestation of adrenal insufficiency. On physical examination, her height: was 145 cm, weight: was 42 kg, body mass index: was 19.9 kg/m^2, and she had no secondary sex characteristics. In addition, the patient's epiphyseal openings are still not closed. She had some characteristic facial features, including a round face, full cheeks, and thick lips. In retrospective examinations, it was seen that pituitary tissue was not seen, and the sella turcica was smaller than usual on the pituitary magnetic resonance imaging (MRI). The uterus and ovaries were absent on the pelvic computer tomography. She had also basal ganglion calcification on brain MRI, but had not hypercalcemia. Bisphosphonate treatment was started for her because of osteoporosis. A cardiac examination revealed intermittent ventricular extrasystole and moderate tricuspid regurgitation. In order to determine the genetic background of the patient, a molecular karyotyping test was performed with the microarray method on the Illumina iScan platform. Although the mutation causing the gain in the detected 7q11.23 region overlaps with WBDS, the common and different clinical reflections of our case and WBDS are compared in **Table.1**
Conclusions
GH deficiency, shown at a rate of 9% in the literature, was also present in our case. WBDS patient with panhypopituitarism was not found in the literature but was described in limited cases of WBS deletion syndrome. WBDS patients may present with variable clinics, but facial features may be suspicious for diagnosis. A complete endocrine evaluation aimed at detecting abnormalities of hypothalamus-pituitary-thyroid and adrenal axes and multisystem evaluation for other endocrinological abnormalities should be considered.

Diagnostic criteria for the hypothalamic syndrome in childhood

Hanneke van Santen[1,2], Jiska van Schaik[1,2], Ichelle van Roessel[1,2], Svenja Boekhoff[3], Julia Beckhaus[3] & Hermann Müller[3]
[1]Wilhelmina Kinderziekenhuis (WKZ), Pediatric Endocrinology, Utrecht, Netherlands; [2]Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands; [3]Klinikum Oldenburg gGmbH, Oldenburg, Germany

Objective
Hypothalamic syndrome (HS) in childhood is a rare condition. Its epidemiology is not well known because incidence and prevalence are related to very rare underlying diseases. In addition, different criteria for the syndrome are used across studies. Recognizing HS may be difficult, due to its rareness and variety of symptoms. Having diagnostic criteria for signs and symptoms of hypothalamic dysfunction may aid in early recognition and diagnosis, in the reporting and understanding of its etiology, in predicting its course and its management. We aimed to define diagnostic criteria for hypothalamic dysfunction and a score for the presence of HS in childhood.
Methods
Diagnostic criteria for hypothalamic dysfunction were developed and subdivided into hyperphagia, hypophagia, body mass index, behavioral problems, sleep disorders, temperature regulation disorders, pituitary dysfunction, Muller grading and presence/suspicion of a hypothalamic genetic syndrome. Subsequently, the scoring system was tested in a retrospective cohort of 120 patients at risk for hypothalamic dysfunction.
Results
A score for presence of HS was developed. Using this new hypothalamic score, in total 52.5% were scored as having HS. Of these patients, 76.7% were diagnosed with pituitary dysfunction, 32.5% with hyperphagia, 40% with sleep disorders and 14.2% with temperature dysregulation. For several criteria, clinical data was missing in more than 50% of cases.
Conclusions
The here proposed diagnostic criteria and score for presence of HS may be used for care purposes and will aid in early recognition. Also it will be useful for research or registration purposes.

Smartphone App on Follow-up of Adult Growth Hormone Deficiency (AGHD) Patients: Results From the Management of AGHD (MAGHD) Study

Alessio Bellelli[1,2], Caterina Golinelli[1,2], Maria Laura Monzani[3], Simone Pederzoli[3], Elisa Magnani[3], Elisa Beltrami[2], Marco Pacchioni[4], Mirko Orsini[4], Chiara Diazzi[1], Sara De Vincentis[1,2] & Vincenzo Rochira[1,2]
[1]Unit of Endocrinology, Azienda Ospedaliero-Universitaria of Modena, Department of Medical Specialties, Modena, Italy; [2]Unit of Endocrinology,

University of Modena and Reggio Emilia, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy; [3]Unit of Endocrinology, AUSL-IRCCS of Reggio Emilia, Reggio Emilia, Italy; [4]DataRiver S.r.l., Modena, Italy

Background
AGHD significantly impacts on metabolism, body composition and quality of life (QoL), including sexuality.
AIM
To investigate the impact of a smartphone App on AGHD monitoring, especially QoL and comorbidities as well as on both body composition and biochemical parameters.
Methodology
83 AGHD patients were enrolled in this prospective, open-label, monocentric study (MAGHD Study) of 24-month duration. Patients were evaluated (clinical, biochemical and multidimensional investigations) every 6 months, for a total of 5 visits (from V0, V1, V2, V3 e V4). Multidimensional evaluation included the following questionnaires: QoL-AGHDA, QLS-H, WEMWBS, IPAQ, PSQI e IIEF-15 e FSFI for QoL and sexual function. Body composition was evaluated at V0, V2 and V4 by DEXA. After the first year (Phase 1), patients were grouped according to the acceptance to use (Group 1) or not (Group 2) the smartphone App (MAGHD App) for answering questionnaires. Thus, during the second year (Phase 2), 58 patients provided questionnaires answers through MAGHD App (Group 1) and the remaining 25 patients continued with standard compilation of questionnaires only at visits every 6 months without using MAGHD App (Group 2).
Results
The use of the MAGHD App resulted in a higher number of completely filled questionnaires in Group 1 (15.68 ± 8.10) compared to Group 2 (10.33 ± 2.09) ($P < 0.001$). QoL-AGHDA ($P = 0.001$), QLS-H ($P = 0.030$), IPAQ ($P < 0.001$), IIEF-15 ($P = 0.005$) and FSFI ($P = 0.002$) scores were significantly better in Group 1 than Group 2. Compliance to r-hGH therapy increased in Group 1 comparing Phase 1 to Phase 2, but without statistical significance ($P > 0.05$). Comorbidities resulted increased in number in Group 2 compared to Group 1 ($P < 0,05$). No differences were found between Group 1 and 2 in biochemical and hormonal outcomes.
Conclusions
The use of an *ad hoc* designed smartphone App is well-accepted by patients and associated with a good adherence in its use, suggesting positive effects on QoL in AGHD patients. The integration of a smartphone App in the clinical practice is feasible and may help empowering patients with chronic diseases such as AGHD on daily self-monitoring of their disease trend, beyond helping physicians in tailoring the clinical management. This study belongs to the Pfizer Inc. "Independent Grant for Learning and Change, Dissemination & Implementation' (Grant ID 34515061).

Incidental pituitary macroadenoma: natural history and surgical results

Stefan Matei Constantinescu[1], Orsalia Alexopoulou[1], Thierry Duprez[2], Raluca Furnica[1], Edward Fomekong[3], Christian Raftopoulos[3] & Dominique Maiter[1]
[1]Cliniques universitaires Saint-Luc (UCLouvain), Department of Endocrinology and Nutrition, Bruxelles, Belgium; [2]Cliniques universitaires Saint-Luc (UCLouvain), Department of Radiology, Bruxelles, Belgium; [3]Cliniques universitaires Saint-Luc (UCLouvain), Department of Neurosurgery, Bruxelles, Belgium

Introduction
The Incidental diagnosis of non-functioning pituitary macroadenomas (NPFMA) is becoming more prevalent with the spread of modern imaging techniques. More clinical data about their natural history and surgical results are needed.
Methods
We retrospectively analyzed medical files of patients referred to our clinic for an incidental NFPMA between 2010 and 2019. In particular, we compared patients that experienced tumor growth or not during surveillance, and surgical results in patients who had deficits or not at surgery.
Results
We included 65 patients (mean age $\pm$ SD: 60 $\pm$ 14 years; mean maximal diameter: 20.0 $\pm$ 7.3 mm). 44% had pituitary hormone deficits (LH/FSH 41%, TSH 29%, ACTH 15%) and 12% had visual field deficits. 26 patients had early surgery and 13 had delayed surgery after initial surveillance. In the surveillance group ($n = 35$), the risk of tumor growth was estimated at 10%/year (median time of 57 months to reach 50%). Patients with hormonal deficit at diagnosis tended to experience earlier growth ($P = 0.082$). Overall surgery led to stable or improved endocrine function in 91% (31/34) of patients, with only 6% (2/34) post-operative permanent diabetes insipidus. Surgery was more effective in preserving intact endocrine function (10/12) than restoring altered endocrine function to normal (6/22, $P = 0.03$),
Conclusion
Incidental NFPMA are often responsible for unrecognized endocrine and visual deficits and require careful evaluation. If surveillance is chosen, the risk of growth is significant (10%/year) and seems to occur faster in patients already harboring an endocrine deficit. Early surgical removal before endocrine deficits occur might lead to better endocrine outcome.

Evaluation of Serum Omentin-1 Levels and Atherosclerotic Risk Factors in Patients with Prolactinoma

Zuleyha Can Erdi[1], Cigdem Ozkan[2], Mustafa Ozgur Ceylan[3], Hamza Eren Guzel[4], Gizem Ercan[5], Giray Bozkaya[5] & Zehra Hilal Adibelli[4]
[1]Health Sciences University Izmir Bozyaka Education And Research Hospital, Internal Medicine, Izmir, Turkey; [2]Health Sciences University Izmir Bozyaka Education And Research Hospital, Endocrinology and Metabolism, Izmir, Turkey; [3]Health Sciences University Izmir Bozyaka Education And Research Hospital, Cardiology, Izmir, Turkey; [4]Health Sciences University Izmir Bozyaka Education And Research Hospital, Radiology, Izmir, Turkey; [5]Health Sciences University Izmir Bozyaka Education And Research Hospital, Clinical Biochemistry, Izmir, Turkey

Background
Prolactinoma is the most common functioning pituitary adenoma. Subclinical atherosclerosis and cardiovascular risk in patients with prolactinoma were reported but have not been clarified yet.
Aim
Our study aims to compare prolactinoma patients with a control group in terms of lipid profile, body fat distribution, and subclinical atherosclerosis markers.
Methods
This single-center, prospective study included 32 patients diagnosed with prolactinoma and 32 control groups with similar clinical features. Patients newly diagnosed with prolactinoma were evaluated before and 6 months after treatment. Patient and control groups were compared according to their serum omentin-1 levels, lipid profile, body fat ratio, epicardial adipose tissue thickness (EATT), and carotid intima-media thickness (CIMT).
Results
25 of the patients were diagnosed with microprolactinoma, 7 with macroprolactinoma, 25 were female and 7 were male. Similar omentin-1 levels were found in prolactinoma and control groups ($P = 0.368$). A total of 20 patients, 15 female, and 5 male, were re-evaluated after the treatment. The mean omentin-1 levels of 20 patients evaluated six months after the treatment was not significantly different from the pre-treatment level ($P = 0.526$). The median EATT in the patient group which was higher than in the control group ($P = 0.021$) significantly regressed and was found similar to the control group six months after treatment ($P = 0.036$, $P = 0.248$; respectively). The median CIMT which was similar between patients and control groups ($P = 0.723$), was significantly regressed ($P = 0.040$) after treatment. In terms of median body fat rate, total cholesterol, low-density lipoprotein, high-density lipoprotein, and triglyceride levels were found to similar between patient and control groups ($P = 0.445$, $P = 0.079$, $P = 0.200$, $P = 0.056$, $P = 0.243$; respectively). In the control group, prolactin levels were negatively correlated with EATT, CIMT, BMI, waist-hip ratio, and age ($P = 0.025$, $P = 0.006$, $P = 0.029$, $P < 0.01$, $P = 0.021$; respectively).
Discussion
Increased EATT plays a role in the development of coronary and myocardial disease, as a result of inflammation and fibrosis. CIMT is commonly used in the follow-up of subclinical atherosclerosis. In our study, EATT was found significantly higher in untreated prolactinoma patients than in the control group while CIMT was found similar. After the treatment, EATT and CIMT values,

which are two subclinical atherosclerosis markers, decreased significantly. Our results show that hyperprolactinemia is associated with subclinical atherosclerosis. More comprehensive studies are needed to evaluate cardiovascular risk in prolactinoma patients.

Diabetes Mellitus Secondary to Cushing'S Disease or Acromegaly: a Single-Centre Experience

Roberta Scairati[1], Sara Di Meglio[1], Rosa Pirchio[1], Alice Vergura[1], Nicola Di Paola[1], Angelica Larocca[1], Guendalina Del Vecchio[1], Chiara Simeoli[1], Renata Simona Auriemma[1], Annamaria Colao[1,2] & Rosario Pivonello[1,2]
[1]Dipartimento di Medicina Clinica e Chirurgia, Università Federico II di Napoli, Naples, Italy; [2]UNESCO Chair for Health Education and Sustainable Development, Federico II University, Naples, Italy

Rationale
Type 2 diabetes mellitus (DM) is common in patients with Cushing's disease (CD) and Acromegaly (AC), and contributes to increased mortality. This study aimed at investigating the prevalence and characteristics of DM in CD and AC patients at diagnosis and after disease control (DC).
Patients and Methods
34 CD patients (8M,26F, 24 microadenomas(mA),6 macroadenomas (MMA) and 4 empty sella) and 35 AC patients (16M,19F, 7 mA,28 MMA) were included in the study. Anthropometric, biochemical and hormonal parameters, tumor size (TS), disease and DM duration were registered in the entire patient cohort.
Results
At diagnosis, among CD 22 patients had DM (64.6%), 10 IGT/IFG (29.4%) and 2 NGT (6%). In CD patients without DM, ACTH correlated with weight ($r=0.71$, $P=0.001$) and HOMA-IR ($r=0.72$; $P=0.02$); serum cortisol (SC) with total cholesterol (TC, $r=0.73$, $P=0.007$), and urinary free cortisol (UFC) with fasting glucose (FG, $r=0.81$, $P=0.009$) and HbA1c ($r=0.71$, $P=0.02$). In patients with CD and DM, age at onset correlated with HOMA-IR ($r=0.53$, $P=0.019$) and HbA1c ($r=0.49$, $P=0.03$). In the entire CD cohort, ACTH was the best predictor of insulin levels (FI, $P=0.004$). At diagnosis, among AC 16 patients had DM (45.7%), 17 IGT/IFG (48.5%) and 2 NGT (5.8%). In AC patients without DM, age at diagnosis correlated with TS ($r=-0.71$, $P<0.001$) and FG ($r=0.47$, $P=0.04$), and GH with TC ($r=0.73$, $P<0.001$). In the entire AC cohort, age at onset correlated with weight ($r=-0.37$, $P=0.02$), waist circumference (W, $r=-0.34$, $P=0.04$) and FI ($r=-0.37$, $P=0.04$), while GH with TC ($r=0.63$, $P<0.001$) and triglycerides (TG, $r=0.8$, $P<0.001$). 26 CD (76.4%) and 30 AC (85.7%) were re-evaluated at DC, and all had DM. At DC, age correlated with UFC in CD ($r=-0.42$; $P=0.03$); in AC, FG was significantly higher ($P=0.007$) and TG lower ($P=0.04$) in patients treated with somatostatin analogues (SRL) than in those treated with SRL + pegvisomant (PEG).
Conclusions
In CD patients, ACTH and SC influence glucose and lipid metabolism, while UFC affects mainly glucose metabolism, and ACTH is the best predictor of FI. In AC patients, GH impact on glucose metabolism adds to the detrimental effect of ageing. Despite achieving disease control, the metabolic damage was only partially reverted in CD, suggesting a mechanism of IR independent of hormonal correction; in AC, DC allows the most pronounced IR improvement, especially in PEG-treated patients.

Characterisation of the clinical and biologic behaviour of acromegaly caused by pluri-hormonal tumours in a cohort of 75 patients

Mafalda Martins Ferreira, Ana Carreira, Luis Cardoso, Patrícia Oliveira, Miguel Melo & Isabel Paiva
Centro Hospitalar e Universitário de Coimbra, Portugal, Endocrinology, Diabetes and Metabolism, Coimbra, Portugal

Introduction
The clinical and biochemical spectrum of pituitary acromegaly is wide and variable. There are pure somatotroph tumors(ST), immunohistochemically positive only for GH, and pluri-hormonal(PL), also positive for other hormones, and they appear to have different presentations and responses to treatment.
Aims
To compare the clinical presentation, imaging characteristics and response to treatment of acromegalic patients according to the pituitary tumour histopathology.
Descriptive statistics
From the 75 patients, 66.7%($n=50$) were female with mean age at diagnosis of 48.8 ± 12.7 years. At diagnosis, 79.2%($n=57$) had acromegaloid phenotype, 60.9%($n=39$) presented with headaches and 39.3%($n=24$) suffered from visual impairment. Hypertension (39,2%), diabetes/pre-diabetes (35.1%) and obstructive sleep apnea (24.3%) were the most prevalent comorbidities. Regarding the biochemical profile, 88% patients ($n=66$) had functioning tumors: 77.3% ($n=51$) of these producing only GH, 19.7% ($n=13$) GH plus prolactin and 1 case produced GH plus ACTH. 33.3% patients($n=25$) had pituitary hormone deficiencies at diagnosis: hypogonadism being the most common (32.4%). In the MRI, 77.3%($n=58$) had a macroadenoma. Postoperative remission (nadir GH $<1\mu g/l$) occurred in 29.3%($n=22$) and 32% patients($n=24$) developed new pituitary insufficiencies, mainly adrenal insufficiency (16%). In the anatomopathological analysis, 64%($n=48$) were pure ST and 36% ($n=27$) were PL.
Results
There were no differences between ST and PL in terms of age (47.5 ± 12.2 vs. 48.9 ± 13.7 years), comorbidities, and pituitary hormone deficiencies at diagnosis or MRI-adenoma dimensions (19 ± 10.3 vs. 25.4 ± 14.4 mm, respectively). However, ST had greater GH levels at diagnosis than PL: 9.9(IQR 22.5) *vs.* 4.6(IQR 11.8) times above the upper limit of normal($P=0.043$). PL were more often non-functioning: 22.2%($n=6$) *vs.* 4.2%($n=2$): $P=0.045$. ST also had greater suprasellar extension(56.3%) than PL(33.3%): $P=0.009$. PL showed greater sphenoid sinus invasion: 25.9% vs. 6.3% ($P=0.03$). There was no statistically significant difference in cavernous sinus invasion between ST and PL. Sparsely granulated tumors(SG) tended to show greater compression of the optic chiasm ($P=0.05$) than densely granulated(DG). There were no statistically significant differences in immediate and long-term post-operative remission and relapse between ST and PT, and between DG and SG. However, DG had better response to medical treatment given after surgery: 61.5% had parcial/complete responses (defined as IGF-1 reduction $\geq$ 50%/normalization, respectively) *vs.* 41.7% in sparsely granulated tumors($P=0.03$).
Conclusions
In this cohort, PL had lower GH levels at diagnosis, more frequently were non-functioning and more frequently had sphenoid sinus invasion, but this was not reflected on the remission rates. Therefore, PL tumours appear to have different biologic behaviour than ST, but the clinical implications of these findings require further clarification.

Characterizing the expression of thyroid hormone transporter MCT8 for the treatment of Allan-Herndon-Dudley syndrome

Anna Molenaar[1,2,3,4], Sonja Schriever[1,2], Alberto Cebrian Serrano[2], Ekta Pathak[1,2], Gandhari Maity-Kumar[2,4], Lisa Ständer[2,4], Felix Englmaier[5], Timo Müller[2,4] & Paul Pfluger[1,2,3,4]
[1]Helmholtz Munich, Research Unit Neurobiology of Diabetes, OberschleiOberschleiheim, Germany; [2]Helmholtz Munich, Institute for Diabetes and Obesity, OberschleiOberschleiheim, Germany; [3]Technical University Munich, School of Medicine, Munich, Germany; [4]CRC/TR 296 - LOCOTACT, Germany; [5]Helmholtz Munich, Institute of Medicinal Chemistry, OberschleiOberschleiheim, Germany

Allan-Herndon-Dudley syndrome (AHDS) is a genetic disorder characterized by intellectual disability and movement disorders. AHDS patients have mutations in the monocarboxylate transporter 8 (MCT8) that impedes thyroid hormone (TH) transport to the brain during crucial phases of brain development. In mice, the resulting structural and functional pathologies of human AHDS patients can be mimicked by knocking out murine MCT8 and the Solute Carrier Organic Anion Transporter Family Member 1C1 (SLCO1C1). Murine models such as these will thus guide us in understanding the disease and in finding AHDS treatments. To investigate the expression pattern of MCT8 we employed antibody stainings and a novel MCT8-Cre line, backed by analysis of single cell RNA sequencing data. MCT8 immunofluorescence showed strong expression in the choroid plexus and in tanycytes, both in the adult brain as well as in the embryonic and early postnatal brain. At postnatal day P8, neuronal MCT8 expression was strong enough to be detected in the cortex and hippocampus. Next, to visualize MCT8-expressing cells using an antibody independent method, we generated a new MCT8-Cre knock-in mouse and crossed it with CAG-Sun1/sfGFP mice that express a GFP-marked nuclear lamina protein only after Cre-mediated stop-cassette-excision. Fluorescence microscopy of adult brains showed reporter expression in virtually all nuclei. This near ubiquitous fluorescence suggested very early embryonal

activation of MCT8 which happens after the blastocyst stage, since they show no fluorescence. Indeed, using publicly available single cell RNA sequencing data we saw that MCT8 expression starts at but not before E5.25, which coincides with implantation. To trace MCT8 expressing cells in later stages of the developing embryo, we currently investigate an alternative strategy based on a tamoxifen-inducible MCT8-CreERT2 line. Last, we wanted to explore potential treatment options against AHDS by attaching TH to peptides targeting the brain. As delivery peptide, we used a 13 amino acid derivative of leptin, a hormone secreted by fat tissue that acts as satiety signal in the hypothalamus. Leptin enters the brain via the leptin receptor (LepR), which like MCT8 is highly expressed in the choroid plexus and tanycytes. First, we compared the ability of leptin and the leptin derivative to bind and activate the LepR. However, while leptin showed strong activity, the leptin derivative was inactive, highlighting the need for peptides with better binding and uptake characteristics.

Management challenges of gestational pituitary adenoma

Hedi Chaker Hospital, Endocrinology, Sfaz, Tunisia

Pituitary apoplexy is a rare condition and gestational pituitary apoplexy (GPA) is even more exceptional. Clinical presentation of GPA is often non-specific overlapping with other conditions, making its diagnosis challenging. Additionally, therapeutic management is often limited since it depends on both the mother's and the fetus's prognosis. Herein we report of a woman who was diagnosed with GPA and we discuss the management of her case. A 34-year-old woman with no notable familial nor personal medical history, presented with severe headaches of sudden onset, paroxystic and holocranial associated with a blurred vision predominantly at the left eye. Her symptomatology appeared for the first time in the second trimester of her first pregnancy. Six weeks later, she consulted a neurologist. An MRI showed the presence of a pituitary macroadenoma of 21*16 mm, hyperintense T1 and hypointense T2, with hemorrhagic necrosis and abutting the optic chiasma. The patient was admitted therefore in our department of Endocrinology. Hormonal evaluation concluded to the presence of corticotropic and thyrotropic insufficiency. As hormonal changes occur in pregnancy, evaluation of secreting adenoma is mostly challenging. Nonetheless prolactin level was evaluated, demonstrating a high level of 965 ng/ml, surpassing 600 ng/ml which the maximum level of prolactin found in pregnant normal women. Thus, a substitutive treatment with levothyroxine and hydrocortisone was started. Since the patient's neuro-ophthalmologic status was stable, urgent surgery was not indicated. Bromocriptine was prescribed to our patient at progressive doses. The evolution under treatment was marked by the relief of her headaches and the improvement of her visual acuity. The delivery was successful and the baby as well as the mother were normal. GPA is an exceptional finding. Both hormonal evaluation of hypopituitarism and hypersecreting adenomas can be challenging. Therapeutic approach depends essentially on the patient's symptomatology and pregnancy term.

Sporadic neuroendocrine neoplasm: a survival analysis in a monocentric cohort

Alessia Liccardi, Roberto Minotta, Giuseppe Cannavale, Elio Benevento, Roberta Modica & Annamaria Colao
Federico II University of Naples, Department of Clinical Medicine and Surgery, Operative Unit of Endocrinology, Andrology and Diabetology, Napoli, Italy

Introduction
Neuroendocrine neoplasms (NEN) are heterogeneous tumors, usually sporadic and non-functioning, with a favorable long-term prognosis if localized. Metastases are common and survival outcomes of metastatic patients (pts) is worse than in localized disease.
Aim
To investigate survival outcomes in a monocentric cohort of sporadic NEN.
Materials and Methods
Clinical data of pts with histologically confirmed sporadic NEN, referred to the Endocrinology Unit of Federico II University of Naples from 2012 to 2023, were evaluated retrospectively. The Kaplan-Meier method and log-rank test were used for survival analysis and comparison between groups.
Results
We included 272 pts (137 females/135 males; 50.3%/49.7%) with sporadic NEN, mean age at diagnosis 55.3 years (11-89). Mean follow up was 46.19 months (m) (range 3-276). NEN were identified as incidentalomas in 64 pts (23.5%), due to symptoms in 139 (51.1%) and after surgery in 39 (14.3%); the majority were non-functioning (245; 90%). The most common primary site was pancreas (73, 26.8%), followed by lung (47, 17.3%), and stomach (41, 15.1%); liver was the main metastatic site (80, 29.4%). Grading was G1 in 125 patients (45.9%), G2 in 118 (43.4%) and G3 in 29 (10.7%). Metastatic disease was found in 125 pts (45.9%) and with significant prevalence in male ($P<0.03$). G1 prevalence was significantly higher in non-metastatic group (M-) (48.3% vs. 27.2%, p: 0.0005); G2-3 prevalences were significantly higher in metastatic group (M+) (respectively 46.4% vs. 32.6%, p: 0.024 and 18.4% vs. 4 %, p: 0.001). Surgery was performed in 134 of 272 pts (50.9%). Mean overall survival (OS) was 46.2 months (m) in M+ and 56.8 m in M-. Kaplan Meier analysis showed a better survival in M- than M+, with no difference between genders (female $P=0.001$ and male $P<0.001$). Moreover, a better OS was observed in pts who underwent surgery ($P=0.001$) and in this subgroup metastases did not show a significant impact on OS ($P<0.001$).
Conclusions
These data prove that surgery improves OS in metastatic NEN, regardless of the presence of metastases, maybe due to reduced tumor burden. Moreover, metastatic disease is mainly associated with male gender and G2-3 with liver as main metastatic site.

In the Phase III studies LINC 3 and LINC 4, osilodrostat was effective and well tolerated in patients of Asian and non-Asian origin with Cushing's disease

Shimatsu Akira[1], Beverly M.K. Biller[2], Maria Fleseriu[3], Rosario Pivonello[4], Eun Jig Lee[5], Leelawattana Rattana[6], Jung Hee Kim[7], Rama Walia[8], Yerong Yu[9], Zhihong Liao[10], Andrea Piacentini[11], Alberto Pedroncelli[12] & Peter Snyder[13]

Introduction
Osilodrostat (oral 11β-hydroxylase inhibitor) demonstrated rapid, sustained cortisol normalisation in Phase III studies (LINC 3, NCT02180217; LINC 4, NCT02697734) in patients with Cushing's disease (CD). Relative osilodrostat bioavailability is ~20% higher in Asian patients than other ethnicities; body weight is not a major determinant of this difference. This analysis of LINC 3 and LINC 4 evaluated osilodrostat efficacy and safety in Asian and non-Asian patients with CD.
Methods
Data were pooled from LINC 3 and LINC 4. LINC 3 comprised a 48-week (W) core phase, including an 8W randomised withdrawal for eligible patients. LINC 4 included an upfront 12W, double-blind, placebo-controlled period followed by 36W of open-label osilodrostat. Both studies had an optional extension. Outcomes were evaluated separately in Asian and non-Asian patients. Periods where patients received placebo were excluded.
Results
In total, 56/210 (27%) patients were of Asian origin, enrolled in China ($n=16$), South Korea ($n=14$), Japan ($n=9$), Thailand ($n=9$), India ($n=7$) and USA ($n=1$). Most non-Asian patients were Caucasian ($n=138/154$, 90%). Median (min−max) osilodrostat dose was 3.8 (1−25) and 7.3 mg/day (1−47) in Asian and non-Asian patients, respectively. Mean urinary free cortisol (mUFC) control was achieved at W48 and W72 in 64.3% and 68.1% of Asian and 68.2% and 75.8% of non-Asian patients, respectively. Improvements from baseline in most cardiovascular and metabolic-related parameters and physical manifestations of hypercortisolism were similar across groups during treatment. Osilodrostat was generally well tolerated. The most common investigator-reported adverse events (AEs) were: adrenal insufficiency

(44.6%), nausea (33.9%) and decreased appetite (26.8%) in Asian patients; nausea (45.5%), fatigue (40.9%) and headache (39.0%) in non-Asian patients. The most common serious AE in Asian and non-Asian patients was adrenal insufficiency (5.4% and 5.2%, respectively). Hypocortisolism-related AEs occurred in 58.9% of Asian and 40.3% of non-Asian patients, commonly reported by study investigators as adrenal insufficiency (44.6% and 22.1%). AEs related to pituitary tumour enlargement occurred in 21.4% of Asian and 9.1% of non-Asian patients. Arrhythmogenic potential and QT prolongation AEs were infrequent in all patients.
Conclusions
Osilodrostat demonstrated similar beneficial effects in Asian and non-Asian patients in mUFC control and improvements in cardiovascular and metabolic-related parameters and physical manifestations of hypercortisolism. The mean dose to achieve beneficial effects was lower in Asian than non-Asian patients. Osilodrostat was generally well tolerated in Asian and non-Asian patients; AEs related to hypocortisolism and pituitary enlargement were more frequent in Asian than non-Asian patients.

Transphenoidal surgery for sellar and suprasellar lesions: a prospective analysis of factors affecting inpatient length of stay

Mudassir Ali, Japhet Olaremi, Razan Ali Rashid & Yaasir Mamoojee
Royal Victoria Infirmary, Newcastle upon Tyne Hospitals NHS Foundation Trust, Department of Endocrinology, United Kingdom

Background
The recent Get It Right First Time (GIRT) report suggests short stay pathways should be aimed for in pituitary surgery in England, with 1–2 days being realistic. We prospectively audited the length of stay (LOS) for patients undergoing transsphenoidal surgery (TSS) for sellar and suprasellar lesions at the Royal Victoria infirmary hospital (RVI) over a 2-year period, from October 2019.
Methods
Data was prospectively collected for each patient: demographics, LOS, post-operative complications.
Results
78 patients underwent TSS during the audit period, with a mean LOS of 9.4 days. 31% of patients suffered a post-operative CSF leak and 45% experienced post-operative serum sodium imbalances. Patients with craniopharyngioma had a longer LOS compared to those with benign pituitary tumours (13.3 vs. 8.8 days). Rates of post-operative CSF leaks were higher in patients with Cushing's disease (50%) but post-operative sodium imbalances occurred most frequently in patients with craniopharyngioma (70%). The mean LOS, for two-thirds of patients with non-functioning pituitary adenomas or acromegaly with no post-operative complications, was 5 days. Older patients (aged >60 years) were more likely to have longer LOS at 12 days (vs. 6 days) and were more likely to suffer from post-operative CSF leak (38% vs. 18%) and electrolyte imbalances (38% vs. 21%). Patients on four or more regular medications, a marker of comorbidities, stayed 1.5 times longer in hospital than those on less regular medications. On average, post-operative sodium imbalances occurred 2 days after surgery and took 7 days to resolve.
Conclusions
LOS for patients undergoing TSA for sellar and suprasellar lesions is influenced by the etiology of the lesion, age of the patient, existing comorbidities and post-operative complications. Younger patients with non-functioning pituitary adenoma or acromegaly should be the more realistic cohort to aim for shorter LOS.

Evaluation of the Association of Primary Empty Sella Syndrome in Neurobehçet Syndrome

Taner Yilmaz[1], Medine Nur Kebapci[2], Cengiz Korkmaz[3], Timuçin Kaşifoğlu[3], Döndü Üsküdar Cansu[3] & Nazife Şule Yaşar Bilge[3]
[1]Eskisehir Osmangazi University Faculty of Medicine, Department of Internal Medicine, Eskisehir, Turkey; [2]Eskisehir Osmangazi University Faculty of Medicine, Department of Endocrinology and Metabolism Diseases, Eskisehir, Turkey; [3]Eskisehir Osmangazi University Faculty of Medicine, Department of Rheumatology Science, Eskisehir, Turkey

Central nervous system involvement is observed in 5-14% of Behçet's disease and this form is called neurobehçet syndrome (NBS). There are two main forms of CNS involvement in Neurobehçet syndrome, in which parenchymal involvement and vascular involvement are prominent. Cerebral venous thrombosis (CVT), the most prominent form of vascular involvement, has been reported in 8% in Behçet's disease and in approximately 18% in NBS. Although CVT is the most common cause of intracranial hypertension in Behçet's disease, it can also manifest as a form of idiopathic intracranial hypertension in the absence of cerebral venous thrombosis. In this study, it was thought that these patients are in the risk group for the development of empty sella due to the risk of developing intracranial hypertension, which is not uncommon in patients with neurobehçet syndrome. The files and electronic data of 732 patients with behçet's who were followed up in Eskişehir Osmangazi University Rheumatology Polyclinic between 2000-2021 were retrospectively scanned, and 74 patients with neurobehçet's diagnosis were recruited from these patients. Gender of the patients, age at diagnosis, time elapsed between the diagnosis of neurobehçet syndrome and the diagnosis of Behçet's disease, time spent as Behçet's disease, the form of neurological involvement, the initial symptom of neurological involvement, the localization of the vessels involved in vascular NBS patients, the presence of empty sella and cases with primary empty sella. The pituitary hormone profile was examined. Of the 74 patients included in the study, 31 (41.9%) were female and 43 (58.1%) were male. In our study, 32 (43.2%) patients with parenchymal neurobehçet syndrome and 42 (56.8%) patients with vascular neurobehçet syndrome were found among neurobehçet syndrome patients. Empty sella was detected in 19 (25.6%) of 74 patients in our study. Of the empty sella ($n=19$) cases, 13 (68.4%) were vascular and 6 (31.6%) were parenchymal patients. There was no statistically significant difference between these two groups in terms of the presence of empty sella. Hypopituitarism was detected in 2 of the cases accompanied by primary empty sella syndrome.

Keywords: neurobehçet, empty sella, intracranial hypertension, hypopituitarism

Non-functioning PitNETs: positive or differential diagnosis?

Iulia Florentina Burcea[1,2], Ramona Dobre[1,2], Valeria Nicoleta Nastase[3], Amalia Raluca Ceausu[3], Anca Maria Cimpean[3], Marius Raica[3] & Catalina Poiana[1,2]
[1]Carol Davila University of Medicine and Pharmacy, Bucure?ti, Romania; [2]C.I. Parhon National Institute of Endocrinology, Pituitary and Neuro-endocrine Disorders, Bucure?ti, Romania; [3]Victor Babeş University of Medicine and Pharmacy, Timi?oara, Romania

Introduction
Clinically non-functioning pituitary neuroendocrine tumours (NFPitNETs) include all anterior pituitary tumours that are not hormonally active. In histopathology (HP) and immunohistochemistry (IHC), most of NFPitNETs are gonadotroph (1). Immunolabeling is negative in only 10% of cases ('null-cell'). Occasionally, NFPitNETs are positive for GH, PRL, TSH or ACTH despite absent or only minimal secretion of these hormones *in vivo*, which are known as silent somatotroph, lactotroph, thyrotroph or corticotroph tumours.
Materials and methods
The study included 27 patients with NFPitNETs, with a male:female ratio of 19:8 and a median age at diagnosis of 51.8 years (($\pm$13,7). The HP-IHC features were correlated with the clinical, imaging and laboratory data. Tumour specimens were assessed for anterior pituitary hormones, pituitary-specific transcription factor 1 (PIT-1), T-box transcription factor (TPIT) and steroidogenic factor 1 (SF-1) transcription factors (TF), Ki-67 labelling index, vimentin and reticulin.
Results
All patients had macroadenomas (median 35.5 mm $\pm$11.9 DS), the symptoms being associated with the tumoral syndrome (70.3% had headache and optic chiasm disorder). The treatment was mostly surgical, with association of radiotherapy in 33.3% of cases. Of the 16 patients with pituitary deficiency, only 2 had remission of the deficit after surgery. Most NFPitNETs were acidophilic, with alveolar and papillary growth patterns in many cases. After the IHC evaluation of anterior pituitary hormones, the 27 NFPitNETs were reclassified, according to WHO 2022 criteria. Over half of them had positive expression of LH and/or FSH, being, in fact silent gonadotropinomas. 18.5% were hormone-negative, 11.1% expressed ACTH, 7.4% expressed GH and ACTH and 7.4% expressed GH. After IHC evaluation of pituitary TF, only 4 out of 5 tumours were, in fact, 'null-cell'. The expression of Ki-67 was $<3\%$ in all cases.
Conclusion
The clinical term 'non-functioning' is not a diagnosis, yet a description of a clinical scenario that has many differential diagnoses (2). More than 50% of clinically and biochemically NFPitNETs are silent gonadotropinomas, some of which have negative immunohistochemical expression of the hormones FSH and LH.

Grading of pituitary adenomas (PitNets): clinical and prognostic implications in a monocentric series

Giuseppe Giuffrida[1], Rosalinda Casablanca[2], Marta Ragonese[3], Salvatore Giovinazzo[3], Oana Ruxandra Cotta[2], Rosaria Certo[2], Ylenia Alessi[3], Marianna Scordo[2], Cristina Pizzimenti[4], Giovanni Tuccari[5], Filippo Flavio Angileri[4], Francesco Ferraù[2,3] & Salvatore Cannavò[2,3]
[1]Department of Human Pathology of Adulthood and Childhood, University of Messina, Messina, Italy; [2]Endocrine Unit, 'G. Martino' University Hospital, Messina; [3]Department of Human Pathology of Adulthood and Childhood, University of Messina; [4]Department of Biomedical and Dental Sciences and Morphofunctional Imaging, University of Messina; [5]Department of Human Pathology of Adulthood and Childhood, Section of Pathology, University of Messina

Rationale
Pituitary neuroendocrine tumors (PitNets) are aggressive in 20% of cases, with local invasion, relapse/scarce response to conventional treatment, in the absence of reliable predictive parameters. In 2018, Trouillas *et al*. proposed a 5-tier prognostic classification, not widely validated yet. In our study we evaluated the outcomes of a PitNets monocentric series in the context of this classification.
Materials & Methods
We retrospectively evaluated 88 patients (51 M, 50.5 ± 14.7 yrs) with functioning (FPA) or non-functioning pituitary macroadenomas (NFPA), referred to the Endocrine Unit of Messina University Hospital, and operated by the same neurosurgeon in the period 2015-2020. Of each patient we recorded demographic, clinical, radiological, biochemical data and visual field, both at diagnosis/last follow-up (median 3 ± 1.5 yrs), therapeutical history and pathological data. Once defined the PitNets grade according to Trouillas *et al*., we correlated it to clinico-pathological features at diagnosis, and to the outcomes (last follow-up).
Results
38.6% of patients were in the 1a grade, 7.9% in the 1b, 48.9% and 4.5% among 2a and 2b, respectively. Of 10 giant PitNets, 70% were 2a. At diagnosis, panhypopituitarism and visual field alterations were higher among 2a. GH-omas were significantly prevalent among 1a tumors, NFPA among 2a. 1a and 2a grade PitNets had a better response to single surgery ($P < 0.01$), while cyberknife stereotactic radiotherapy was needed in 2a and 2b tumors. Panhypopituitarism/visual field alterations were more frequent among 2a PitNets even after surgery. Ki-67 was positively associated to persistent disease in FPA, while radiological invasion was associated to remnant presence among NFPA.
Conclusions
Invasive and not-proliferating PitNets (2a) were more frequently associated to impaired pituitary function/visual field before and after surgery. Less proliferating tumors (1a and 2a) were more responsive to surgery. Ki-67 related to disease persistence in FPA, while adiuvant radiotherapy was more used among invasive tumors. Thus, among ± 1 cm PitNets, tumor invasion influences clinico-biochemical outcomes, while Ki-67 influences surgical outcomes.

Emergence of De-novo Steroid-Responsive Conditions Following Remission of Cushing's Syndrome: A Case Report and Scoping Review

Noémie Desgagnés[1], Laura Senior[1] & Kirstie Lithgow[2]
[1]Cumming School of Medicine U C, Department of Medicine, Calgary, Canada; [2]Cumming School of Medicine U C, Division of Endocrinology, Department of Medicine, Calgary, Canada

Background
Endogenous Cushing's syndrome is caused by chronically elevated glucocorticoid levels. The most common etiology is ACTH hypersecretion from a pituitary adenoma; other causes include hypersecretion of cortisol from an adrenal source or ectopic ACTH secretion. Following successful treatment, a period of adrenal insufficiency is expected due to chronic suppression of the HPA axis. Onset and exacerbation of steroid-responsive conditions have been reported following remission of Cushing's syndrome, leading to challenges in distinguishing a new condition vs. expected symptomatology following remission.
Objective
Describe a case of a 44-year-old man presenting with new-onset sarcoidosis diagnosed 12 months following surgical cure of Cushing's syndrome secondary to adrenal adenoma, and synthesize existing literature reporting on de-novo steroid-responsive conditions presenting after Cushing's syndrome remission.
Methods
A scoping review was conducted in September 2022 in Medline, Epub, Ovid, and PubMed. Case reports and case series detailing adult patients with biochemical and clinical remission of endogenous Cushing's syndrome presenting with new-onset steroid-responsive conditions were included.
Results
1641 articles were screened, 138 full-text studies were assessed for eligibility, and 45 studies were included and underwent data extraction and analysis, of which 83 cases were identified. Thyroid diseases (Graves, Hashimoto's thyroiditis, subacute thyroiditis) were the most commonly reported conditions (41/83; 49%), followed by sarcoidosis (14/83; 16.8%). Psoriasis, lymphocytic hypophysitis, idiopathic intracranial hypertension, multiple sclerosis, rheumatoid arthritis, lupus, and seronegative arthritis were reported in more than one case. All patients achieved clinical remission of Cushing's syndrome following surgical management via transsphenoidal resection or adrenalectomy with or without additional medical or radiotherapy, and one patient via medical management alone. The average duration between Cushing's remission and de novo condition's symptomatology was 11 months. 57% of patients were receiving corticosteroid therapy at the time of onset.
Conclusion
First presentations of several distinct steroid-responsive conditions have been reported as following remission of Cushing's syndrome. Of these, thyroid disorders and sarcoidosis were the most commonly reported and are well-characterised in the literature. Clinicians should have a low index of suspicion for the emergence of autoimmune and inflammatory conditions in the first year following surgery or initiation of treatment of Cushing's syndrome.

A Low Incidence of Transient Anti-Drug Antibodies Is Observed Upon Long-Term Exposure to Lonapegsomatropin in Children With Growth Hormone Deficiency

Per Holse Mygind[1], Allison Komirenko[2], Meng Mao[2], Aimee Shu[2] & Vibeke M. Breinholt[1]
[1]Ascendis Pharma A/S, Hellerup, Denmark; [2]Ascendis Pharma, Inc, Palo Alto, CA, United States

Objectives
Lonapegsomatropin (SKYTROFA; TransCon hGH), a prodrug of somatropin, is approved by the EMA and FDA for once-weekly treatment of pediatric growth hormone deficiency (GHD). Lonapegsomatropin uses TransCon® technology, which combines a parent drug transiently linked to an inert carrier to achieve sustained release. The characterization of anti-drug antibodies (ADAs) was assessed in 3 phase 3 trials of lonapegsomatropin in pediatric GHD.
Methods
Samples were collected at baseline and at 13-week intervals and analyzed for the presence of ADAs using validated immunoassays. Bridging ELISA, a bridging ECLIA, and an indirect ECLIA assay were set up to assess ADAs against human growth hormone (hGH), lonapegsomatropin (prodrug), and mPEG (carrier), respectively. A cell-based proliferation assay was used to assess the presence of neutralizing anti-hGH antibodies. Analysis of ADAs was performed on samples from 305 participants, with a mean duration of treatment of 3 years (157 weeks (data cutoff date: September 1, 2021)).
Results
No neutralizing antibodies were detected at any time point. At baseline, 1.3% of participants had positive results for anti-hGH antibodies. Treatment-emergent or treatment-boosted anti-hGH antibodies were detected in 5.2% and 0.3% of participants, respectively. Anti-mPEG antibodies at baseline were detected in 2.8% of participants, treatment-emergent anti-mPEG antibodies in 0.7% of participants, and no treatment-boosted anti-mPEG antibodies were detected. Anti-lonapegsomatropin antibodies were detected in 0.4% of participants at baseline, and 4.3% of participants were positive for treatment-emergent anti-lonapegsomatropin antibodies. All antibody titers were low (≤ 400). Antibodies were considered transient, and primarily appeared within 6 months of treatment initiation.
Conclusions
Lonapegsomatropin did not give rise to neutralizing antibodies, and no impact of binding ADAs on efficacy or safety was observed in any of the 305 participants with pediatric GHD. With an average of 3 years of trial participation, these data support the safety of long-term treatment with lonapegsomatropin.

Diabetes insipidus in children secondary to a germinoma diagnosed after 3 years of follow-up

Mouna Mezoued, Bessaid Khadidja & Malha Azzouz
Bologhine Hospital, Endocrinology, Alger, Algeria

Central diabetes insipidus (CDI) is rare in children and has a wide variety of causes. In children, the majority of central DI is acquired, but 30 to 50% is considered idiopathic. However, the natural history of isolated idiopathic central ID is unpredictable and germinoma should always be considered during the first 3 years of follow-up.

Case report

We report the observation of a 16 year old patient, in whom the diagnosis of idiopathic central diabetes insipidus was retained in front of a polyuro-polydipsic syndrome with hypotonic urines and a restriction test in favour of a complete deficit, without antehypophyseal involvement, the morphological exploration (hypothalamo-hypophyseal MRI) did not objectify any intrasellar process, nor thickening of the pituitary stalk with absence of visualization of the post pituitary. The etiological exploration came back without anomaly. The patient was regularly followed by hormonal and morphological evaluation every 6 months. During the follow-up, a corticotropic deficit appeared after 2 years and morphologically an intrasellar process 30×16×24 mm was found after 3 years of monitoring, in comparison with bHCG and apha protein not elevated. In this context the patient benefited from a surgical management, the anathomo-pathological study came back in favor of a dysgerminoma. The treatment was completed by chemotherapy and radiotherapy, the patient is currently in remission for 2 years.

Discussion

This observation reminds the necessity of strict surveillance of patients with a diagnosis of idiopathic retained central diabetes insipidus, This joins the cohort of D. Lorgi in 61 children with diabetes insipidus considered idiopathic at diagnosis and prospectively followed by regular imaging, 11 finally had a diagnosis of germinoma or histiocytiosis within 2.5 years.

Conclusion

Once a diagnosis of CID is made, an etiologic investigation is necessary to tailor management. Patients with CID of undetermined etiology (idiopathic CID) require long-term clinical, radiological and biological monitoring to detect a specific etiology in time.

Solitary pulmonary nodule developing ectopic Cushing's Syndrome over the years: Awakening of a Sleeping Giant

Hayri Bostan[1], Muhammed Kizilgul[1], Özgür Özçelik[1], Umran Gul[1], Tugba Taskin Turkmenoglu[2], Mustafa Ozbek[3] & Erman Cakal[1]
[1]Ankara Etlik City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Etlik City Hospital, Pathology, Ankara, Turkey; [3]University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey

Background

A rare cause of ectopic Cushing's Syndrome (ECS) is pulmonary neuroendocrine neoplasm (NEN) with a broad spectrum of clinical behavior. At the time of diagnosis, pulmonary NENs may present as occult tumors or well-defined round-to-oval lesions in close relationship to the bronchus. Herein, we describe a NEN that developed ECS three years later in a patient followed up for a solitary pulmonary nodule (SPN).

Case Presentation

A 56-year-old female patient with diabetes, hypertension, and obesity presented with complaints of excessive swelling in the hands, feet and legs for the last two months and fatigue in July 2022. Adrenocorticotropic hormone (ACTH)-dependent CS was detected in the patient whose physical examination suggested CS (moon face, buffalo hump, purple stria, and easy bruising) based on the following test results: ACTH= 149 pg/ml (reference range (RR):0-46), low-dose dexamethasone suppression test (DST)= 34.6 mg/dl, midnight salivary cortisol= 23.03 ng/ml (RR:0.7-2.2), and 24-hour urine cortisol= 1915 mg/day (RR:3-45). The presence of severe hypercortisolemia not suppressed by high-dose DST and deep hypokalemia (K^+ = 2.49 mmol/l (RR:3.5-5.1)) and the absence of any lesion on pituitary MRI suggested an ectopic focus. Subsequently, thin-slice thorax CT showed a 20 mm SPN in the middle lobe of the right lung. The retrospective evaluation revealed that the present SPN was first detected as 15 mm in June 2019. At that time, the nodule had low FDG uptake (SUVmax=2.7) in ^{18}FDG PET/CT, and a pulmonologist followed up the patient for about 2 years. During this period, the patient did not have any complaints suggesting CS. Moreover, serum cortisol level was suppressed after 1 mg DST which was examined as part of an obesity evaluation in 2019. With this clinical history, Gallium-68 PET/CT was performed but no uptake was detected. Since no extrathoracic focus was detected, a transthoracic fine-needle aspiration biopsy of the nodule was performed. Immunohistochemical studies demonstrated diffuse staining with chromogranin and ACTH and moderate staining with synaptophysin and CD56 in tumoral monomorphic epithelial cells. The absence of mitosis and necrosis in the samples suggested a typical bronchial carcinoid. During the evaluation, hypercortisolemia was controlled with metyrapone at a dose of 1250 mg/day. The multidisciplinary council made the surgical decision.

Conclusions

The present case demonstrates that a stable SPN followed without any clinical findings may actually be a NEN and may lead to ECS over time. Therefore, we believe that rare bronchial carcinoids should be kept in mind during SPN follow-up.

Isolated IgG4 Hypophysitis

Nwe Ni Aung & Nouman Butt
Portsmouth Hospitals University NHS Trust, Diabetes and Endocrinology Department, Portsmouth, United Kingdom

Hypophysitis is an inflammatory disorder of the pituitary gland and among them, IgG-4 hypophysitis is rare and presents in less than 5 % of cases.

Case

59 years old lady with a past medical history of asthma presented Rheumatology with? giant cell arthritis due to constant frontal headache, pain behind her eyes, and raised inflammatory markers (ESR 15, CRP 17) three weeks after COVID infection. After review, rheumatology team concluded unlikely giant cell arthritis and she was then seen by medical team who arranged MRV to exclude the central venous thrombosis due to raised BMI of 35 and recent COVID. MRV exclude thrombosis however there was a bulky pituitary gland. Subsequent MRI pituitary showed a 12 mm pituitary macroadenoma extending superiorly out of sella and contact the optic chiasm without compression or deviation. The visual field was normal. Hydrocortisone 10 mg in the morning, 5 mg in the afternoon, and 5 mg in the evening were started followed by Levothyroxine 50 mg a few weeks later. When reviewing in 2 months' time she complained of left-sided vision changes and repeated visual field showed left upper quadrantanopia. An urgent MRI showed a rapidly enlarging hemorrhagic pituitary macroadenoma with a 6 mm increase in size with increasing chiasmatic compression. Endoscopic endonasal resection of the pituitary gland was performed and she recovered well from the surgery. Histopathology of pituitary biopsy showed IgG-4 hypophysitis. Interestingly measured IgG-4 was normal – 0.57 g/l (Reference range 0.0 – 1.3). CT chest, Abdomen, and Pelvis were performed to look for systemic involvement of IgG-4 and she was referred to the rheumatology team. There were no systemic features suggestive of IgG-4 with a negative autoimmune screen and clear CT chest, abdomen, and pelvis apart from an incidental finding of an 11 cm right ovarian dermoid cyst causing hydronephrosis which has been referred to Gynaecology for further management.

Conclusion

Many cases of IgG4 hypophysitis present as a part of a multisystemic disease however it can be present as isolated primary hypophysitis. Although systemic involvement will be less common in the latter, close follow-up is required for early recognition and further management.

Results of pituitary profile blood test:

Test	Results	Reference range
T4	7.3 pmol/l	12 – 22
TSH	0.79 m IU/l	0.27- 4.20
LH	1.7 IU/l	
FSH	4.3 IU/l	
Prolactin	815 m IU/l	60-620
Cortisol	13 nmol/l	140-170
ACTH	14 ng/l	0-46
IGF-1	19.2 nmol/l	5.9-27.5

Rare causes of adrenal tumours and the possible role of adrenal arterial embolization - two case reports

Inês Manique[1], Luísa Cortez[1], Silvestre Abreu[2] & José Silva-Nunes[1]
[1]Centro Hospitalar Universitário de Lisboa Central, Endocrinology, Lisboa, Portugal; [2]Hospital do Funchal, Endocrinology, Funchal, Portugal

Introduction
Adrenal oncocytoma (AO) and ganglioneuroma (GN) are rare causes of adrenal masses, corresponding usually to nonfunctional and benign tumors. However, 20% of the AO shows some elements of malignancy and 10–20% of them affect adrenal hormone production. GNs account for 0.3%-2% of adrenal incidentalomas, with punctate calcifications in CT imaging being highly suggestive. However, preoperative differential diagnosis remains challenging. Adrenal arterial embolization may reduce tumor bulk and tumor vascularity; sometimes it is performed to suppress excess adrenal hormone production
Patient 1
A 57 years-old female with type 2 diabetes, dyslipidemia and hypertension presented with episodic flushing and right flank pain. Abdominal CT imaging showed a 12 cm enhancing right adrenal mass, wash-out >50%, 35 UH, diverting the right kidney and duodenoum. These findings suggested an atypical appearance. Physical exam revealed class I obesity (BMI 32,8 Kg/m2), high blood pressure (170/80 mmHg), facial and abdominal hirsutism. Blood tests revealed hypercortisolism (cortisol 5,31 mg/dl after 1 mg dexamethasone suppression test; ACTH 15,2 pg/ml) and hyperandrogenism (total testosterone 3,83 ng/ml (0,108-0,569), androstenedione >10,10 ng/ml (0,5-4,7), DHEA-SO4 >3000 mg/dl (29,7-182,2), 17 alpha progesterone 26,68 ng/ml (0,32-2,72). Renin, aldosterone and urinary metanephrines were unremarkable. The patient underwent selective right adrenal arterial embolization; 3 days later she was submitted to right adrenalectomy. Histopathology revealed an oncocytic neoplasm of uncertain malignant potential. After surgery a clinical and hormonal improvement was observed without any signs of disease persistence or recurrence
Patient 2
A 40 years-old male without relevant past medical history, presented an incidental finding in abdominal CT: a suspicious and heterogeneous 8,9 cm right adrenal lesion, with 31 UH and some punctiform calcifications, contacting but not invading right kidney and inferior vena cava. Physical exam revealed BMI 26 Kg/m2, normotensive and without stigmata. He had not any signs or clinical analysis suggesting hypercortisolism. Renin, aldosterone, urinary metanephrines and DHEA-S were normal. He underwent right adrenalectomy; histopathology revealed an adrenal ganglioneuroma (mature type). He had a good postoperative evolution.
Conclusions
In both, adrenalectomy was indicated given the large size and the imaging appearance of adrenal masses. In patient 1, hormonal production raised the suspicion for adrenal carcinoma secreting cortisol and androgens. Adrenalectomy is the gold standard for the treatment of adrenal GNs and AO. Histopathology is necessary to confirm these diagnoses, which usually have a benign prognosis. Adrenal embolization may have a role preoperatively.

Acromegaly and its ophthalmic, neurological and psychiatric complications

Andra Cristiana Istrate[1], Maria Christina Ungureanu[2], Letitia Leustean[2], Simona Juliette Mogos[2], Stefana Bilha[2], Alexandru Florescu[2] & Cristina Preda[1]
[1]Universitatea de Medicină şi Farmacie Grigore T. Popa' din Iaşi, Endocrinology, Iaşi, Romania; [2]Universitatea de Medicină şi Farmacie Grigore T. Popa' din Iaşi, Iaşi, Romania

Introduction
Acromegaly is a rare, complex condition that throughout its evolution affects the body on numerous levels, especially if inappropriately managed. Some of the complications it develops over time are ophthalmic, neurological and psychiatric.
Aim
The aim is to asses the impact of long-term acromegaly on the eye, nervous system and mental health of previously diagnosed patients.
Patients and method
90 patients' records (mean age 53.91 years) with previously diagnosed acromegaly, who have been assessed at least once in our tertiary referral centre (Department of Endocrinology, University Hospital 'Sfântul Spiridon', Iaşi) over a period of 7 years have been reviewed.
Results
Out of the 90 assessed patients (33 male - 36.66% and 57 female - 63.33%), 26 (28.88%) had opthalmic complications, 11 (12.22%) had neurological complications and 17 (18.88%) were diagnosed with psychiatric conditions in the context of the endocrine alterations caused by the disease. The diagnosed ophthalmic complications are as follows: partial optic atrophy in 7 patients (26.92%), total optic atrophy in 5 patients (19.23%), temporal hemianopsia in 2 patients (7.69%), quadrantanopia has been also found in 2 patients (7.69%), retinal angiosclerosis in 2 patients (7.69%), the presence of scotoma has been determined in 2 patients (7.69%), diabetic retinopathy in 2 patients (7.69%), hypertensive retinopathy grade 1 in 3 patients (11.53%), and grade 2 in 5 patients (19.23%), glaucoma in 1 patient (3.84%) and cataract in 2 patients (7.69%). Neurology-wise, a history of stroke has been reported in 4 patients (36.36%), facial palsy in 1 patient (9.09%), peripheral neuropathy has been diagnosed in 4 subjects (36.36%) and grand mal seizures in 2 individuals (18.18%). When it comes to psychiatric manifestations associated with endocrine diseases, anxiety was reported in 13 patients (76.47%), depression in 5 patients (29.41%) and delusional disorder in 1 subject (5.88%).
Conclusions
The present research has offered insight into the ophthalmic and neuropsychiatric complications frequently associated with the development of acromegaly, thus reiterating the need of an interdisciplinary approach to these patients, in order to insure correct diagnosis and treatment and an improved quality of life.

Key words
acromegaly, opthalmic complications, neuropsychiatric complications

Congenital, isolated, and lifetime growth hormone deficiency provides superior cognitive performance in senescence

Vanderlan O. Batista[1], Michael Kellner[2], Roberto Salvatori[3], Walter Oliveira[1], André Faro[1], Lucas B. Santos[1], Enaldo V. Melo[1], Alécia A. Oliveira-Santos[1], Carla R. P. Oliveira[1], Viviane Almeida[1], Cynthia S. Barros-Oliveira[1], Elenilde G. Santos[1], Nathalie O. Santana[1], Keila R. Villar-Gouy[1], Angela Leal[1], Rivia S. Amorim[1] & Manuel H. Aguiar-Oliveira[1]
[1]Universidade Federal de Sergipe, Aracaju, Brazil; [2]University Hospital Hamburg-Eppendorf, Hamburg, Germany; [3]The Johns Hopkins University School of Medicine Baltimore, Department of Medicine, Maryland, United States

Mice with isolated GH deficiency (IGHD) due to GHRH receptor mutations live longer than their normal siblings with an extended healthspan, i.e., the period of life free from disabilities. Human IGHD individuals due to a mutation in the GHRH receptor gene from Itabaianinha, Brazil, has a normal lifespan with an extended healthspan (1). Our hypothesis is that their aging is accompanied by a delayed cognitive decline. Accordingly, we used the Literacy Independent Cognitive Assessment (LICA) in 15 IGHD individuals over 50 years of age and 15 controls matched by age, sex, years of education, and percentage of illiteracy. All individuals were negative for HIV and syphilis serology, and exhibited normal serum levels of folate, vitamin B12 and TSH. IGHD subjects had a higher total LICA score than the control group, without reaching statistical significance. However, they showed better attention ($P=0.013$) and executive function ($P=0.034$). MANCOVA revealed that group had a significant effect on attention (partial eta squared of 0.216, power of 0.749, $P=0.011$), and on the executive function (partial eta squared of 0.154, power of 0.570, $P=0.035$), translating into superior cognitive performance in the IGHD group. In conclusion, untreated lifetime IGHD is associated with superior cognitive performance in senescence.

Adrenocortical, somatotropic and antidiuretic response to nasal glucagon in healthy subjects

Emanuele Varaldo[1], Fabio Bioletto[1], Daniela Cuboni[1], Nunzia Prencipe[1], Chiara Bona[1], Marco Barale[2], Ezio Ghigo[1], Silvia Grottoli[1], Alessandro Maria Berton[1] & Valentina Gasco[1]
[1]University of Turin, Division of Endocrinology, Diabetes and Metabolism, Turin, Italy; [2]University of Turin, Oncological Endocrinology Unit, Turin, Italy

Rationale
In the diagnosis of hypopituitarism, the glucagon stimulation test allows for the simultaneous and safe evaluation of the somatotropic and corticotropic axes; recent data have highlighted a stimulating action also on the neurohypophyseal secretion of arginine-vasopressin. This procedure involves the intramuscular or subcutaneous administration of 1-1.5 mg of glucagon based on the patient's weight (respectively less or more than 90 kg). Nowadays no data are available regarding the new intranasal formulation (Baqsimi®, 3 mg single-dose nasal powder). This considered, the primary outcome of this pilot proof-of-concept study was to evaluate the anterior and posterior pituitary response in healthy subjects, in terms of changes in ACTH and cortisol, GH and copeptin levels, after administration of 3 mg of glucagon nasal powder or placebo.
Design and methods
For this non-randomized cross-over study, we recruited 10 healthy subjects (50% women) aged $\geq$ 18 years and with a BMI between 18.5 and 25 kg/m^2. Exclusion criteria were any current ongoing treatment, pregnancy and breastfeeding. All participants underwent to 2 different days of testing, when glucagon or placebo were administered intranasally in a random order. At baseline (immediately before taking glucagon or placebo), every 15' up to +90', and then every 30' up to +180' a blood sample was taken for ACTH, cortisol, GH, copeptin, glucose, insulin, sodium, potassium, plasma osmolarity. At baseline and the end of the test urinary osmolarity was evaluated as well.
Results
After administration of both placebo and glucagon ACTH and cortisol values progressively decreased over time ($P<0.001$) but in the drug group the reduction in cortisol was blunted up to +90' ($P<0.05$). GH values decreased after placebo administration ($P<0.001$) while after glucagon there was a non-significant trend towards its increase ($P=0.096$) with the difference between the two groups evident starting from +120' onwards ($P<0.005$). The placebo administration led to a reduction of copeptin ($P=0.008$), while its stability was observed after glucagon administration. Six subjects developed hypokalemia (potassium <3.5 mmol/l) post-glucagon. The potassium nadir at 45' was significantly correlated with the immediate post-glycemic rise insulin peak (Spearman's rho -0.719; $P=0.019$). No significant differences were observed regarding the other analytes tested.
Conclusions
Nasal administration of glucagon, unlike the intramuscular or subcutaneous injection, does not constitute an effective stimulus for anterior and posterior pituitary secretion, at least at the dose typically used for severe hypoglycemia. Hypokalemia secondary to hyperinsulinemic rebound appears to be a frequent complication of acute glucagon administration.

Chordomas of the parasellar region: description of 4 cases of a rare disease

Ines Cosme, Ema Nobre & Maria João Bugalho
Centro Hospitalar Universitário Lisboa Norte, Endocrinology, Lisbon, Portugal

Background
Chordomas are rare, invasive and slow growing bone tumours with different locations. Parasellar chordomas are even more rare and the initial manifestations include visual and/or neurological symptoms. In addition, endocrine dysfunction may be present. We describe 4 cases of parasellar chordomas.
Clinical cases
1) Female, 55-years-old, reported headache associated with restriction of left eye movement for the past 3 months. Brain magnetic resonance imaging (MRI) revealed a solid destructive lesion in the left cavernous sinus hypointense on T1 and hyperintense on T2. The patient underwent a left frontotemporal craniotomy with subtotal tumour resection followed by conventional fractionated radiotherapy (RT). Surgical histology identified a conventional chordoma. Due to tumour recurrence, the patient was submitted to proton beam therapy. Over the 4-year follow-up period no endocrine dysfunction was documented. 2) Female, 49-years-old, complained of diplopia, right eyelid ptosis and restriction of right eye abduction. A brain MRI showed a lesion adjacent to the right cavernous sinus. A right pterional craniotomy was performed and its histology revealed a chondroid chordoma. Six years later, a centimetric tumour residuum in posterior fossa cisterns was identified and proton beam therapy was performed. Endocrine dysfunction was not identified during the entire follow-up. 3) Female, 42-years-old, reported facial paralysis and hypoesthesia for several months. A cerebral MRI identified a clival lesion hypointense in T1 and hyperintense in T2. A transsphenoidal surgery was performed and the surgical histology identified a conventional chordoma. Due to a tumoral residuum, this patient was also submitted to proton beam therapy. Her endocrine evaluation did not identify any deficit, during the 3 years follow-up period. 4) Male, 45-years-old, reported headaches, diplopia and left sixth nerve palsy was observed. The brain MRI showed a clivus lesion that was submitted to transsphenoidal surgery and radiosurgery. It was identified a conventional chordoma. Two years later, he started with third, fourth and fifth nerves paralysis and a left spheno-cavernous and orbital apex recurrence was identified on MRI. A near-total tumoral resection was done. After that, he initiated polyuria, polydipsia and severe tiredness. His endocrine evaluation revealed insipidus diabetes, central hypothyroidism and central hypocortisolism.
Conclusions
We describe 4 cases of rare tumours with a follow-up ranging from 3 to 6 years. Despite the proximity of sella turcica, pituitary deficits were rare and were associated with tumour growth and aggressive behaviour. Nevertheless, follow up of pituitary function is recommended.

Prevalence and associated factors related to combined hypopituitarism in patients with congenital Growth Hormone deficiency

Faten Haj Kacem Akid, Wafa Belabed, Abdel Mouhaymen Missaoui, Wajdi Safi, Dhoha Ben Salah, Fatma Mnif, Nabila Mejdoub, Mouna Mnif & Mohamed Abid
Hedi Chaker University Hospital, Department of Endocrinology and Diabetology, Sfax, Tunisia

Background and aim
Congenital Growth hormone deficiency (CGHD) may result from genetic or congenital disorders of pituitary development. It could be isolated or combined with other types of hypopituitarism. This study aims to evaluate the prevalence of combined hypopituitarism and its associated factors in patients with CGHD.
Patients and Methods
We conducted a retrospective study (1991-2019) at the Endocrinology department of Hedi Chaker University Hospital, Sfax, Tunisia. We involved 87 patients diagnosed with CGHD, whose clinical, biochemical, and imaging peculiarities were collected from medical charts.
Results
The mean age at diagnosis was 14 years (1-33 years), with a male predominance (59%). Seventy-five percent of cases were referred for short stature. We noted a delayed diagnosis in 65% of cases. The median height was 131 cm (67 - 169 cm). Severe growth delay was noticed in 38.6% of cases. The bone age was delayed in all cases comparing to chronological age. The average delay was of 48 months (6-152 months). Patients with isolated CGHD represented 20% compared to those with combined hypopituitarism (80%). Gonadotropic insufficiency was most often associated with GHD in 64%, followed by corticotropic and thyrotropic insufficiency in 48% and 38%, respectively. The prolactin axis was involved in 18%. The most characteristic profile of combined hypopituitarism implicated two or three axes in 25.9 % of each, four axes in 17.6 %, and all five pituitary axes in 10.6%. Associated factors related to the number of defective pituitary axes are displayed in table 1. Family occurance of hypothyouism is more frequent in patients featured as combined hypotuirism.
Discussion
Our work features a high prevalence of combined hypopituitarism in patients with CGHD of 80% vs 10% in the literature. These disparities could be partially explained by the pediatric age and the relatively short follow-up duration (<5 years) in the published studies. Otto *et al*. have shown the development of a second hormonal deficit in patients with isolated CGHD occurs on average 5.4 years after the initial diagnosis. In patients with CGHD, we recommend a regular evaluation of the remaining pituitary function to detect and treat delayed and subclinical forms of combined hypopituitarism.

Table 1:

Hypopituitarism	Isolated CGHD	2 axes	3 axes	4 axes	5 axes	P value
Consanguinity	46%	50%	68%	75%	100%	**0.001**
Familial cases	0%	15%	23%	40%	57%	**0.001**
Severe growth retardation	68%	66%	72%	86%	100%	**0.025**
Micopenis	0%	13%	18%	26%	33%	**0.001**

Successful management of severe hypoglycemia by octreotide LAR in an insulinoma patient

Erhan Hocaoglu, Ensar Aydemir, Coskun Ates, Filiz Mercan Saridas, Muge Yasar, Ozen Oz Gul, Soner Cander, Canan Ersoy & Erdinc Erturk
Uludag University Medical School, Endocrinology and Metabolism, Bursa, Turkey

Introduction
Surgical removal of the tumor is the primary treatment modality for insulinomas. However, in some patients, surgery is not possible. Octreotide, a somatostatin analogue, is known to suppress insulin secretion. However, there are little data on the use of octreotide in the treatment of insulinoma. Here, we present an insulinoma patient with severe clinical findings and successful control of hypoglycemia after long-acting octreotide.
Case
A 71-year-old male patient with hypertension was admitted to our clinic with long-standing hypoglycemia. He had frequent (1-2 times a day) neuroglycopenia symptoms, especially during fasting. He described that he detected glucose values below 40 mg/dl almost every day. Laboratory tests were as follows: fasting plasma glucose 23 mg/dl, insulin 34 mU/l, c-peptide 5 mg/l. Hospitalization was planned for further examination. At the 120th minute of the prolonged fasting test, capillary blood sugar was 39 mg/dl, plasma glucose was 33 mg/dl, insulin was 13.3 mU/l, c-peptide level was 3.1, and cortisol level was 14.5 mg/dl. Continuation of the test was not considered necessary, and 1 mg of glucagon was administered. Plasma glucose increased to 91 mg/dl at the 30th minute after glucagon. The patient, who was diagnosed with endogenous hyperinsulinism, was found to have negative insulin antibodies. Abdominal tomography revealed a 13x10 mm hypervascular lesion in the tail of the pancreas. The patient was diagnosed with insulinoma, and the operation was planned. He had episodes of severe hypoglycemia, and dextrose infusion was started. The patient was screened for multiple endocrine neoplasia, and no such finding was found. The importance of the operation was explained, however, the patient did not accept the surgical procedure. Under these circumstances, octreotide treatment was given at a dose of 3x50 mg for five days. Hypoglycemia did not recur, and dextrose infusion was interrupted. Monthly administration of octreotide LAR was planned, considering patient compliance. The patient who received octreotide LAR 10 mg and did not have hypoglycemia in the follow-up was discharged with the recommendation of frequent self-monitoring of blood glucose. His blood glucose monitoring at home ranged from 82 to 145 mg/dl. No hypoglycemia or complication was detected in the patient's subsequent outpatient follow-ups.
Conclusions
In patients with insulinoma who are unsuitable for surgery, long-acting octreotide formulation may be an effective therapy, even at low doses.

RANKL signalling in female reproduction: a novel role of RANKL outside the skeleton?

Lív Bech Árting[1], Ireen Kooij[1], Nadia Krarup Knudsen[1], Christine Hjorth Andreassen[1,2,2], Li Juel Mortensen[1], Anders Juul[1,3,4] & Martin Blomberg Jensen[1,5]
[1]Rigshospitalet, Department of Growth and Reproduction, Copenhagen, Denmark; [2]Copenhagen University Hospital – Rigshospitalet, International Centre for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen OE, Denmark; [3]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; [4]Rigshospitalet, International Centre for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen, Denmark; [5]Harvard University, Division of Bone and Mineral Research, Boston, United States

Background and Purpose
Infertility affects 15% of couples globally, and only few treatment options are available. Gonadotropins are classic and potent regulators of ovarian and female reproductive function, but novel endocrine crosstalk appears to exist between gonads and the skeleton that may influence female fertility. One of the new players include the RANKL signalling system, which consists of the receptor activator of nuclear factor κβ ligand (RANKL), the receptor RANK, and the decoy receptor osteoprotegerin (OPG). Recent studies suggest that the RANKL system is expressed in testis and is a novel regulator of germ cell proliferation and maturation. However, little is known about the role of the RANKL system in female gonads and whether it affects reproductive function, which is explored in the present study.
Methods
QPCR, immunohistochemistry and *in situ* hybridisation were performed to investigate the expression pattern of the RANKL system in mouse and human female reproductive organs. To explore the role of RANKL in ovaries, we utilised the Cre-loxP system to generate a granulosa cell-specific *Rankl* knockdown mouse model. The phenotype of the reproductive system was evaluated on sexually mature female mice. To extrapolate the data into the human setting RANKL and OPG were measured in serum and follicular fluid and associated with live birth rate after assisted reproductive techniques.
Results
The present study indicates that RANKL, RANK, and OPG are expressed in the female gonads. We validated that the *Amh* promotor can be exploited to achieve selective Cre recombinase activity in granulosa cells in female gonads. Pilot data indicate a higher pregnancy and birth rate in mice when RANKL is genetically suppressed in granulosa cells. In humans, we found that follicular fluid levels of RANKL and OPG are linked with number of stimulated follicles and live birth rate in women undergoing assisted reproductive techniques.
Conclusion
These preliminary findings suggest a role of RANKL in ovarian physiology and future investigations may untangle the exact role of RANKL for female reproductive function.

Chronic Unpredictable Stress (CUS) Induced Abnormal Sperm Morphology Associated with Male Reproductive Hormones and Phoenixin Expression in Male Rats

Zahra Isnaini Mohamed[1,2], Ammu K Radhakrishnan[1], Syafiq Asnawi Zainal Abidin[1] & Faizul Jaafar[1]
[1]Monash University Malaysia, Subang Jaya, Malaysia; [2]Monash University Malaysia, Jeffrey Cheah School of Medicine and Health Science, Subang Jaya, Malaysia

Introduction
Chronic stress caused by prolonged emotional pressure may cause to multiple physiological problems including reproductive dysfunction. There is no doubt that infertility can cause chronic stress. However, the effect of chronic stress-induced reproductive dysfunction is still debatable. Thus, this study aims to demonstrate CUS effect on reproductive system.
Methodology
Sprague Dawley (SD) rats ($n=16$) were divided into two groups: i) non-stress control group ii) CUS-induced group. The CUS consists of different stressors that were induced for 28 days, and each group was subjected to behavioural tests. To identify the effect of CUS at the hypothalamic level, gene expression study was done to determine the expression of stress and reproductive neuropeptides. As hypothalamic neuropeptides responsible to regulate hormone circulation, ELISA test was done to measure the plasma stress and reproductive hormones concentration. To identify the effect of CUS on the peripheral level, histopathologic evaluation of the rats' testis was done with H& E staining. The seminal fluid was analysed for sperm count and morphological changes.
Results
The stress model was confirmed by the sucrose-preference and force-swimming test. Hypothalamically, the expression of *corticotropin-releasing hormones* (*CRH*) in CUS-induced rats increased significantly compared to control group ($P<0.05$). The upregulated CRH was supported by the elevation of plasma cortisol in CUS-induced rats ($P<0.05$). The effect of CUS also downregulated *phoenixin* (*PNX*) expression in the hypothalamus of CUS-induced rats by 0.5 fold lower than the control group ($P<0.05$). However, *kisspeptin*, *spexin* (*SPX*) and *gonadotropin-inhibitory hormone* (*GnIH*) showed no difference between the two groups. The primary regulator of reproductive system, *gonadotropin-stimulating hormone* (*GnRH*) expressed significantly higher than control ($P<0.05$). Despite the increased expression of *GnRH*, plasma LH and testosterone concentration were significantly low ($P<0.05$) in CUS-induced rats compared to control group. The effect of CUS demonstrated anomalous testis morphology of CUS-induced rats consisting of abnormal architecture with visible interstitial spaces between seminiferous tubules and the absence of spermatogenesis. The reproductive deficit of CUS-induced rats was further demonstrated with an increase of 20% in abnormal sperm count compared to only 3% in control group ($P<0.0001$).
Conclusions
Our CUS model of chronic stress demonstrated a correlation with reproductive function where chronic stress caused low concentration of reproductive hormones, high abnormal sperm count and abnormal testis morphology. These findings interestingly suggest the correlation with low phoenixin expression as reproductive system regulator.

Ketoacidosis in Type 1 Diabetics: Epidemiological and Clinico-Biological Profile: About 423 Patients

Sofia Ouhessaine[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]Ibn Rochd University Hospital of Casablanca, Morocco Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy-University Hassan II, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Department, Casablanca, Morocco

Introduction
Diabetic ketoacidosis (DKA) is a serious metabolic complication of diabetes with an annual incidence between 4.6 and 8 episodes per 1000 diabetic patients, it is responsible for a considerable socio-economic impact, however its mortality remains low.
Objectives
The objective of the study is to clarify the epidemiological and clinico-biological profile of type 1 diabetic patients hospitalized and followed for diabetic ketoacidosis.
Materials and Methods
Retrospective descriptive study about 423 type 1 diabetic patients hospitalized in the department of endocrinology and metabolic diseases followed for diabetic ketoacidosis between 2012 and 2022.
Results
The average seniority of diabetes was 6.7 years, inaugural ketoacidosis was recorded in 89 cases. All the patients had stayed in intensive care for an average of 2.1 days. The mean HbA1c was 10.9 $\pm$ 0.8%. The most common decompensation factors were infection in 50.6%, discontinuation of insulin therapy in 24.8% and a combined cause in 24.6%. Our patients were not aware of the vital necessity of insulin in 43.9% of the cases.
Conclusions
Despite recent progress in the management of type 1 diabetes, ketoacidosis is still common in some young patients, in chronic imbalance, new to therapeutic education. Good education and personalized support are essential to prevent and reduce the incidence of this severe metabolic complication and thus limit its socio-economic cost.

Iodine deficiency in pregnancy reflected by ioduria and mother-child pairs thyroid status

Dorota Filipowicz[1], Aniceta Ada Mikulska-Sauermann[2], Marta Karaźniewicz-Łada[2], Ewelina Szczepanek-Parulska[1], Franciszek Główka[2] & Marek Ruchała[1]
[1]Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Medicine, Poznań, Poland; [2]Poznan University of Medical Sciences, Department of Physical Pharmacy and Pharmacokinetics, Poznań, Poland

Background
Iodine deficiency disorders are a global health problem partially eliminated by salt iodization national programmes. In Poland, this micronutrient shortage diminished over the last two decades, however in some particularly vulnerable groups like pregnant and breastfeeding women additional supplementation of iodine is beneficial for both mother and newborn. The programme's effectiveness should be regularly evaluated. The matter of concern remains the optimal recommendation of additional iodine intake in hypothyroid women.
Objectives
The study aimed to evaluate the adherence of pregnant females to recommendations and iodine intake impact on thyroid parameters of both – mothers and their newborns.
Methods
Healthy and euthyroid levothyroxine-treated women in 3rd trimester of a pregnancy before delivery ($n=91$) and their newborns ($n=101$) were recruited to the study. The questionnaire concerning iodine supplementation was performed. Thyroid hormones analyses (TSH, ft3, ft4, a-TPO, a-Tg) measured by ECLIA were performed in mothers and cord blood of newborns, with additional assessment of screening thyrotropin (TSHs) from heel prick at the 3rd-4th day of life. Ioduria was assessed by maternal urinary iodine concentration (UIC), corrected by urine creatinine (ELISA) as UIC/crea ratio from a single urine sample by HPLC-UV method. This research was funded by National Science Centre in Poland (2019/33/N/NZ5/02303) as PRELUDIUM-17 grant.
Results
Supplementation of iodine was declared by 68% of women. The recruited cohort of females had median UIC (IQR) 106 (69 - 156) µg/l and UIC/crea ratio was 104 (62 - 221) µg/g, revealing iodine deficiency (according to WHO criteria UIC or UIC/crea <150). Additionally, almost 20% had UIC/crea as low as <50 µg/g. No significant difference in median UIC (IQR) was observed in patients supplemented (105 µg/l, 69-170) and non-supplemented iodine (99 µg/l, 84-130; $P=0.55$). Optimal UIC/crea was reflected by the lowest TSH ($P=0.02$) and a-TPO ($P=0.02$) in mothers. TSHs above 5 mIU/l was seen in 6% of newborns.
Conclusions
The presented group of pregnant women was iodine deficient in terms of ioduria and TSHs due to WHO/UNICEF criteria. Almost one-third of women did not follow the recommendation to supplement I during pregnancy. Nevertheless, in women who declared I intake, the supplementation seemed ineffective. A sufficient iodine supply may improve the thyroid parameters of mother and newborn.

Congenital Adrenal Hyperplasia – When does Gender Identity Begin?

Sofia Lopes, Mafalda Ferreira, Bárbara Araújo, Luísa Ruas, Sandra Paiva, Patrícia Oliveira & Isabel Paiva
Coimbra Hospital and Universitary Centre, Endocrinology, Diabetes and Metabolism, Coimbra, Portugal

Introduction
Congenital adrenal hyperplasia (CAH) is a genetic condition which impairs enzymatic steroidogenesis of the adrenal cortex, leading to excessive androgen production. CAH phenotype is heterogeneous. In the mildest forms, it can present with hirsutism, acne and menstrual irregularities. Problems related to gender identification arise in about 5% of people with CAH with a 46,XX karyotype.
Objective
We present the case of a young female-to-male (FtM) transgender, who was diagnosed with non-classical CAH during medical evaluation prior to the initiating of hormone therapy.
Clinical Case
We present the case of a 23 year old youth, who was born from a twin pregnancy, with female gender assigned at birth. Since early, this child identified with the opposite sex – he would mostly play with boys and dressed up to look like one of them. Their parents report that as soon as 4 years of age, he would already tell he was a boy. Menarche occurred at teh age of 15, with irregular menstrual cycles and dysmenorrhea. He reports hirsutism since adolescence. At 17 years of age, he sought medical evaluation, as he was determined to go through a sexual reassignment process. The initial biochemichal evaluation showed an increase in basal plasma 17-hydroxyprogesterone (17-OHP) (9.75 ng/ml), increased 17-OHP in the cosyntropin stimulation test (0 min: 9.48 ng/ml, 60 min: 20.31 ng/ml) and normal dehydroepiandrosterone (199 mg/dl (35-430)). There results suggested the diagnosis of non-classical CAH. The karyotype revealed a 46, XX pattern. When he as 19 years old, he was started on hormone therapy with testosterone and underwent bilateral mastectomy. He is currently awaiting the remaining gender-affirming surgical procedures – he intends to undergo phalloplasty, hysterectomy and adnexectomy.
Conclusions
Non-classical CAH may be associated with atypical sexual development and, occasionally, with changes in gender identity, as in the presente case. Sexual development seems to be influenced by the exposure to androgens, which occurs since intrauterine life. This argument is supported by the masculinizing effects of androgen exposure in children with 46,XX karyotype, which may determine their behaviours, sexual orientation and gender identity. This issue becomes particularly relevant given the preference for early feminization in clinical practice in these individuals. Indeed, there is no evidence that this early gender definition approach is associated with better quality of life and sexual function. The approach to transgender individuals should be multidisciplinary and concomitant anomalies of sexual development, such as CAH, must be investigated.

Women with preeclampsia show altered cortico- and sex steroid profiles

Olivia Trummer[1], Christina Stern[2], Sharmaine Reintar[1,3], Veronika Tandl[1], Karoline Mayer-Pickel[2], Mila Cervar-Zivkovic[2], Martin Fassnacht[4], Max Kurlbaum[4], Berthold Huppertz[5], Herbert Fluhr[2] & Barbara Obermayer-Pietsch[1]
[1]Medical University of Graz, Department of Internal Medicine, Graz, Austria; [2]Medical University of Graz, Department of Obstetrics and

Gynecology, Graz, Austria; [3]CBmed, Center for Biomarker Research in Medicine, Graz, Austria; [4]University Hospital Würzburg, Department of Internal Medicine I, Würzburg, Germany; [5]Medical University of Graz, Gottfried Schatz Research Center, Division of Cell Biology, Histology and Embryology, Graz, Austria

Background
Preeclampsia (PE) is a complex condition of pregnancy, associated with substantial perinatal morbidity and mortality, affecting 2% to 8% of pregnancies worldwide. Its hallmarks are high blood pressure (hypertension) and endothelial dysfunction, leading to potential end-organ injury. Affected organ systems include liver, blood, kidneys, brain and placenta. In the present study, we investigated steroid hormones such as progestagens, estrogens, androgens, and glucocorticoids during pregnancy in order to describe maternal and fetal development. Aim of the present study was to compare steroid hormonal profiles throughout pregnancy between pregnant women, who develop preeclampsia and normotensive pregnant women.
Methods
Serum levels of 15 steroids were measured in 14 pregnant women with preeclampsia and 36 normotensive pregnant women by isotope-dilution liquid chromatography tandem mass spectrometry (ID-LC-MS/MS) at 8 different time points throughout pregnancy (12, 20, 24, 28, 32, 36 weeks of gestational age) as well as at delivery and 24h postpartum.
Results
Pregnant women with PE showed significantly higher mean levels of dehydroepiandrosterone (DHEA; $P \leq 0.001$), dehydroepiandrosterone sulfate (DHEAS; $P \leq 0.001$), testosterone ($P \leq 0.001$) as well as androstenedione ($P \leq 0.001$) and significantly lower mean levels of the cortisol/cortison ratio ($P = 0.001$), 11-deoxycortisol ($P = 0.001$), dihydrotestosterone ($P \leq 0.001$) and estradiol ($P = 0.024$ throughout pregnancy compared to healthy controls.
Conclusion
PE status significantly altered serum steroid levels compared to normotensive pregnant women throughout pregnancy. A comparison of substrate-product ratios between women with PE and normotensive pregnant women may serve to derive new indices and candidate genes for steroid-metabolizing enzymes that should be further investigated as potential biomarkers for the prediction of PE.

Machine learning algorithm for predicting polycystic ovary syndrome based on voice samples

Ewa Stogowska[1], Jacek Jamiołkowski[2], Marcin Kondraciuk[2], Michał Kucharski[3], Paweł Paszcza[3], Bartosz Ziółko[3], Karol Kamiński[2] & Irina Kowalska[1]
[1]Medical University of Bialystok, Department of Internal Medicine and Metabolic Diseases, Bialystok, Poland; [2]Medical University of Bialystok, Department of Population Medicine and Lifestyle Diseases Prevention, Bialystok, Poland; [3]Techmo, Kraków, Poland

Introduction
Several investigations proved the presence of receptors for androgens, estrogens and progesterone in vocal folds. The most common endocrine disorder causing alterations in the aforementioned hormones concentrations is polycystic ovary syndrome (PCOS), which, according to several studies, can cause voice changes, especially deepening of its timbre. Over last few years, vocal changes accompanying many different disorders have been a subject of research with the use of machine learning (ML) - an algorithm-centered branch of artificial intelligence.
Aim
The aim of this work was the voice analysis in PCOS and its subgroup - PCOS with laboratory hyperandrogenism (PCOS-HA). The analysis of voice samples comprised evaluation of chosen acoustic features in terms of their ability to predict selected groups, as well as training the classifiers evaluating the probability of a given voice sample's owner belonging to PCOS or PCOS-HA.
Materials and Methods
The first study group comprised 39 patients with PCOS, while control group included 56 healthy women. The PCOS-HA subgroup comprised 17 patients and 49 healthy women as a control group. All participants underwent anthropometric measurements, oral glucose tolerance test, hormonal profile assessment and transvaginal ovarian ultrasonography. All participants provided voice recordings, further submitted for analysis by ml.
Results
The acoustic analysis revealed the differences between study groups and their healthy counterparts in terms of several dozen of acoustic features. Two of them were associated with PCOS independently of age, free androgen index and fasting glucose concentration. The classifier evaluating the probability that the voice analysis of the recorded woman indicates her belongingness to the PCOS group was distinguished by the balanced accuracy equal to 74.4%, the sensitivity of 57.1%, the specificity of 91.7%, the precision of 80% and the area under the curve (AUC) of 0.810. Five acoustic features were associated with PCOS-HA independently of age, BMI and fasting glucose concentration. The classifier evaluating the probability that the recorded woman belongs to the PCOS-HA group was distinguished by the balanced accuracy equal to 85%, the sensitivity of 100%, the specificity of 70%, the precision of 57.1% and the AUC of 0.950.
Conclusions
PCOS and PCOS-HA influence vocal changes. The classifiers predicting the probability of PCOS, based on the voice analysis, do not fulfil the criteria of a useful screening test in case of no additional information about the recorded patient. The classifier predicting the probability of PCOS-HA, based on voice analysis, fulfils the criteria of a useful screening test.

Hyperandrogenism-related metabolic changes in drug-naive transmen compared to cisgender women: A case-controlled study

Pnar Erel[1], Onur Elbasan[2], Neşe Yorguner[3], Eren Imre[4] & Özlem Üstay[5]
[4]Koç University, Internal Medicine, İstanbul, Turkey; [2]Sinop Ataturk State Hospital, Endocrinology and Metabolism, Sinop, Turkey; [3]Marmara University School of Medicine, Psychiatry, İstanbul, Turkey; [4]Basaksehir Cam and Sakura City Hospital, Endocrinology and Metabolism, İstanbul, Turkey; [5]Marmara University School of Medicine, Endocrinology and Metabolism, İstanbul, Turkey

Introduction
The etiology of gender dysphoria is still unclear. Although prior studies have shown trans men have higher androgen levels than cisgender women, they all concluded unselected populations. Our purpose to perform this study is to evaluate transmen's hormone profile and metabolic status to compare cisgender women in a more selected population. This is the first case-controlled study to compare anthropometric, metabolic, and endocrinological parameters of drug-naïve transmen with those of cisgender women.
Methods
We designed this study as a single-center observational cohort study. We included 70 drug-naive transmen, and the control group comprised 34 healthy cisgender women. We measured and compared hormone profiles and metabolic parameters in the two groups.
Results
Of the 70 transmen individuals, 16 (22.85%) met Rotterdam criteria and were diagnosed with polycystic ovary syndrome (PCOS), 4 individuals in the control

Table 1 Comparison of the parameters after patients with polycystic ovary syndrome excluded

	Transmen($n=54$)	Ciswomen($n=30$)	p
Age(Years)	25.09±5.02	26.86±3.81	0.044
BMI	22.88±3.48	23.71±5.39	0.863

HOMA-β	180.52±85.80	159.39±99.88	0.124
AUC(Glucose)	203.61±39.68	197.59±51.47	0.571
AUC(Insulin)	94.75±47.75	87.14±86.54	**0.032**

LDL:Low Density Lipoprotein, HDL:High Density Lipoprotein, IGF-1:Insulin Like Growth Factor, SHBG: Sex Hormone Binding Globuline, FAI:Free Androgen Index, DHEAS:Dihidroepiandrosetenedione Sulfate, HsCRP:High Sensitive-C Reactive Protein, HOMA-IR:Homeostatic Model Assessment for Insulin Resistance, AUC:Area Under the Curve

group met the criteria (11.7%). Although we matched body mass index in the groups, total testosterone, free androgen index, androstenedione, 17-hydroxy-progesterone, muscle strength, triglyceride, and homeostatic model assessment of insulin resistance levels were significantly higher in the trans men than in the cisgender women ($P<0.05$). Even after were excluded PCOS patients, hyperandrogenemia was apparent in the transmen.
Conclusions
Our study showed that transmen have clearly higher androgen levels, which may have been the reason for metabolic changes compared to cisgender women. But the main reason for hyperandrogenism in drug-naïve transmen is still not known, and more comprehensive studies are needed.

Are there Differences Between Androgens When Studying Androgenisation in the Transgender Patient?

Carlos Latorre Mesa[1], Guillermo Velasco de Cos[2], Aurelia Villar Bonet[3], Ana Moyano Martinez[2], Gabriela Alexandra Zapata Maldonado[3], Maialen Ormazabal Monterrubio[2], Bernardo Alio Lavín Gómez[2] & María Teresa García-Unzueta[1,2]
[1]Universidad de Cantabria - Facultad de Medicina, Santander, Spain; [2]Hospital Universitario Marqués de Valdecilla, Clinical Biochemistry, Santander, Spain; [3]Hospital Universitario Marqués de Valdecilla, Endocrinology and Nutrition, Santander, Spain

Introduction
In gender affirming therapy of the transgender male, increasing doses of testosterone are administered and as the androgen dose increases, various biochemical parameters such as haematocrit, creatinine and PSA increase. It is not known whether any parameters have advantages in monitoring this androgenisation. Our study evaluates the correlation between the increase in androstanediol glucuronide, testosterone, free testosterone and free androgen index (FAI) with the aforementioned biochemical parameters in a cohort of 20 trans men who started gender affirming therapy.
Material and Methods
Samples were obtained from 20 transgender men at the initiation of testosterone cypionate therapy and after each 3-monthly dose increment of 25 mgrs, up to a maximum of 250 mgsr during one year of treatment. Testosterone, free testosterone, DHEAS, on the Snibe Maglumi platform, PSA and creatinine on the Siemens atellica autoanalyser and haematocrit on the Beckman Coulter DXH900 analyser were analysed. The 3α androstanediol glucuronide (3αAG) was analysed by ELISA (DRG). Correlations were performed with Sperman's test between the different parameters using SPSS 25.0 statistical software.
Results
For haematocrit all androgens analysed were significantly correlated, however there are differences in the Rho (ρ) between each pair. FAI has the best correlation:ρFAI= 0.568/$P<0.001$. The correlation coefficients of the other androgens were:ρtestosterone= 0.556,ρfTestosterone= 0.545,ρ3αAG = 0.535,ρDHEAS= 0.532 with a $P<0.001$ for all of them. Serum creatinine levels correlate only with androstenedioneρandrostenedione=0.373/$P=0.002$, and DHEASρDHEAS=0.297/$P=0.010$. This correlation decreases in oophorectomised patients. For PSA, as for haematocrit, all androgens were significant. The best correlation was for testosteroneρTestosterone= 0.347/$P=0.003$ followed by free testosterone:ρfTestosterone= 0.274/$P=0.021$. The other androgens showed no significant correlation, although FAI ($P=0.088$) and androstenedione ($P=0.078$) showed a clear trend towards a significant correlation.
Conclusions
The different androgens have different correlation coefficients depending on the marker used. FAI obtained the best result with haematocrit, making it the parameter of choice when assessing the relationship between a given dose and its increase. Significance was obtained for creatinine with androstenedione and DHEAS and for PSA with testosterone and free testosterone. The different androgens are associated with different biochemical parameters and should therefore be assessed individually when evaluating androgenisation in these subjects.

Turner syndrome (TS) is a rare condition with a high frequency of aortic dilatation (AD) and a risk of aortic dissection. Our objective was to evaluate the characteristics of the aorta in patients with TS.
Methods
Analyses of aortic walls were obtained during prophylactic aortic replacement. Histological description and measurement of a standardized media degenerative score (MDC) were performed. Cytogenetic analysis quantified the level of monosomy X in blood karyotype, buccal smear and aortic media by FISH technique.
Results
Eleven patients aged 39 years (median; IQR: 29.5-46.5) with a mean aortic index of 29 mm/m^2 (IQR: 26.7-30.1) were enrolled. Ten had a bicuspid aortic valve (BAV). Blood karyotypes showed 45,X; 45,X/46,XX and an abnormal X chromosome in 7/11, 1/11, and 3/11 cases, respectively. Degenerative elements were present in all aortas, with an MDC score=9.0 (IQR: 7-10.5). Aortic monosomy was correlated with that of the blood karyotype ($P=0.003$). However, one patient with 5% of 45,X mosaicism in blood cells had a 70% X monosomy in her aortic media. To our knowledge, this is the first systematic histological analysis showing early degenerative aortic characteristics in young women with ST. Our study shows that a low level of monosomy 45,X in the blood is not necessarily reassuring regarding a potential risk of aortic dilatation and therefore dissection.

Vitamin D and IVF/ICSI outcome: Are we measuring the right metabolites?

Ireen Kooij[1], Stine Gry Kristensen[2], Ursula Bentin-Ley[3], Mette Lorenzen[1], Hans Krog[4], Anders Juul[1,4,5], Rune Holt[1] & Martin Blomberg Jensen[1,6]
[1]Rigshospitalet, Department of Growth and Reproduction, Copenhagen, Denmark; [2]Rigshospitalet, Laboratory of Reproductive Biology, Copenhagen, Denmark; [3]TFP Danfert Fertility, Copenhagen, Denmark; [4]Rigshospitalet, International Centre for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen, Denmark; [5]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; [6]Harvard University, Division of Bone and Mineral Research, Boston, United States

Background
Numerous studies have suggested that optimal vitamin D status increases treatment success of women undergoing assisted reproductive treatments. However, conflicting data exist, and the relationship remains controversial, prompting the need for more comprehensive studies investigating all the metabolites of vitamin D in women undergoing IVF/ICSI treatment.
Objective
To investigate the relationship between follicular fluid levels of the three main vitamin D metabolites 25OHD$_3$, 24,25(OH)$_2$D$_3$ and 1,25(OH)$_2$D$_3$ and IVF/ICSI treatment outcome.
Study design
Follicular fluid and serum samples from 116 women undergoing IVF/ICSI treatment were analyzed. Expression of the vitamin D regulating enzymes (CYP2R1, CYP27B1, CYP24A1) and the vitamin D receptor (VDR) was investigated in human ovaries.

Results
The vitamin D regulating enzymes CYP2R1, CYP27B1, CYP24A1 and VDR were expressed in the human ovary, enabling the follicles to activate, inactivate and respond to vitamin D metabolites. Moreover, all three investigated vitamin D metabolites $25OHD_3$, $24,25(OH)_2D_3$ and $1,25(OH)_2D_3$ were present in follicular fluid and in serum. 25OHD levels were similar in serum and follicular fluid, while levels of $24,25(OH)_2D_3$ were higher and $1,25(OH)_2D_3$ lower in follicular fluid than in serum. Upon stratifying women according to live birth outcome, women achieving a live birth had significantly higher follicular fluid levels of the $24,25(OH)_2D_3$ metabolite (17.4 $\pm$ 8.5 vs 13.5 $\pm$ 6.3 nmol/l, $P=0.015$) and a higher $24,25(OH)_2D_3/25OHD_3$ ratio (0.25 $\pm$ 0.07 vs 0.21 $\pm$ 0.07, $P=0.029$) compared to women with an unsuccessful cycle. Also, when grouping women in intervals according to their follicular fluid $24,25(OH)_2D_3/25OHD_3$ ratio the live birth rate significantly increased across increasing ratio intervals (15%, 20% and 50% for the <0.2, 0.2-0.3 and >0.3 group, respectively, $P=0.019$).
Conclusions
This study reveals that a higher follicular fluid $24,25(OH)_2D_3$ level and $24,25(OH)_2D_3/25OHD_3$ ratio is associated with increased live birth rate in women undergoing IVF/ICSI treatment.

[1]Centro Hospitalar e Universitário de Coimbra, Endocrinology, Diabetes and Metabolism, Coimbra, Portugal; [2]CNC-Center for Neuroscience and Cell Biology, Portugal; [3]Centro Hospitalar e Universitário de Coimbra, Reproductive Medicine Unit, Gynecology, Obstetrics, Reproduction and Neonatology Department, Coimbra, Portugal; [4]CICS-UBI-Health Sciences Research Centre, University of Beira Interior, Covilhã, Portugal

Introduction
Polycystic ovary syndrome (PCOS) is one of the most common causes of anovulatory infertility. Polymorphisms in genes related to follicular recruitment and development, such as the follicle-stimulating hormone receptor (FSHR) and the oestrogen receptor 1 (ESR1) genes, and their impact on biochemical phenotype and response to controlled ovarian stimulation in women with PCOS have been studied in different populations, with inconsistent results.
Aims
To evaluate the influence of FSHR rs6166, p.Asn680Ser (c.2039A>G) and of ESR1 rs2234693 (Pvull c.453-397 T>>>C) polymorphisms on biochemical phenotype and response to controlled ovarian stimulation in women with PCOS and infertility.
Materials and methods
Retrospective observational study of women with a diagnosis of PCOS (by Rotterdam criteria) and infertility, who underwent *in vitro* fertilization (IVF). A short GnRH antagonist protocol was used for controlled ovarian stimulation. Genotyping of the FSHR rs6166 and of the ESR1 rs2234693 polymorphisms was performed and hormone levels and IVF results were compared between different genotypes.
Results
80 women with PCOS and infertility were evaluated, with median age of 33.1 $\pm$ 3.6 years and mean body mass index of 26.8 $\pm$ 5.4 kg/m^2. The genotype distribution of FSHR rs6166 polymorphism was 32.5% AA, 48.8% AS and 18.8% SS, and of ESR1 rs2234693 polymorphism was 21.5% CC, 46.8% CT and 31.3% TT. Women with the SS variant of the FSHR rs6166 polymorphism had higher FSH levels on the third day of the menstrual cycle (9.6 $\pm$ 9.8 vs 6.52 $\pm$ 1.6 [AA] and 5.5 $\pm$ 1.6 [AS] UI/ml, $P=0.006$), with no differences in other baseline hormonal parameters (LH, oestradiol, progesterone, testosterone and anti-mullerian hormone) or in antral follicle count between genotypes. Additionally, women with the SS variant of the FSHR polymorphism required higher cumulative doses of FSH for controlled ovarian stimulation (1860.5 $\pm$ 627.8 vs 1498.1 $\pm$ 359.3 [AA] and 1425.4 $\pm$ 474.8 [SA] UI, $P=0.046$), but showed no difference in response (follicle count on the day of ovulation induction, number of oocytes and number of blastocysts obtained). Women with different ESR1 genotypes showed no differences on baseline hormonal parameters or response to controlled ovarian stimulation.
Conclusions
The SS variant of the FSHR rs6166 polymorphism was associated with higher baseline FSH levels and higher cumulative doses of FSH in controlled ovarian stimulation, which may suggest a lower sensitivity to FSH. Thus, controlled ovarian stimulation with higher doses of FSH may be more appropriate in women with this genotype. The ESR1 rs2234693 polymorphism was not associated with differences in biochemical phenotype or response to ovarian stimulation.

Sublingual estradiol only, offers no apparent advantage over combined oral estradiol and cyproterone acetate, for Gender Affirming Hormone Therapy (GAHT) of treatment-naïve transwomen: Results of a prospective pilot study

Guy Gindis[1,2], Iris Yaish[1], Yona Greenman[1,2], Yaffa Moshe[1], Mira Arbiv[1], Asaf Buch[1,2], Yael Sofer[1,2], Gabi Shefer[1] & Karen Tordjman[1,2]
[1]Tel Aviv Sourasky Medical Center, Institute of Endocrinology, Metabolism, and Hypertension, Tel Aviv, Israel; [2]Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv-Yafo, Israel

Background
The standard approach for Gender-Affirming Hormone Therapy (GAHT) of transgender women (TW) in Israel is oral estradiol (OE) combined with the potent anti-androgen cyproterone acetate (CA). Recently, many of our non-binary patients have requested sublingual estradiol (SLE) without CA, under the unproven belief it preserves erectile function, and does not induce depression. Preliminary data in a few subjects, who self-practiced this approach, suggested it also maintained higher testosterone levels.
Hypothesis
By not suppressing testosterone (T) as profoundly, SLE should be less detrimental to sexual function, and might be superior to OE for improving dysphoria.
Study design
A 6 months controlled, unblinded and non-randomized, prospective study of treatment-naïve TW seeking GAHT.
Patients and Methods
22 healthy, treatment-naive TW. The SLE arm consisted of 0.5 mg of estradiol 4 times a day, while the OE consisted of oral 2 mg estradiol together with 10 mg CA once daily. Subjects underwent exhaustive chemical, hematologic and hormonal laboratory assessments, and body composition analysis at baseline and after 6 months. Furthermore, they completed validated dysphoria, sexual desire and function questionnaires.
Results
At baseline, the only difference between the groups was age. Subjects who chose SLE, were older 26.3 $\pm$ 5.8, vs. 20.1 $\pm$ 2.3 yr for OE ($P=0.006$). Baseline testosterone 19.5 $\pm$ 6.8 nmol/l; estradiol 113.3 $\pm$ 32.7 pmol/l; LH 4.3 $\pm$ 1.4 IU/l; FSH 4.5 $\pm$ 3.4 IU/l; and prolactin 226 $\pm$ 150 mIU/l were identical between the groups. By paired comparisons, GAHT generated significant, and expected changes at 6 months in both groups: creatinine, hemoglobin, hematocrit, total and LDL cholesterol, testosterone, gonadotropins all decreased, while estradiol and prolactin rose. BMI remained unchanged, but there was a significant increase in fat mass, and a decrease in lean body mass in both groups. At 6 months, the only differences between the treatment groups were higher estradiol, and LH in the SLE group: 204.6 $\pm$ 63.3 vs. 109.7 $\pm$ 53 pmol/l, $P=0.02$; and 3.5 $\pm$ 1.2 vs. 1.6 $\pm$ 1.3 IU/l, $P=0.007$, respectively. Median estradiol, 90 minutes after 0.5 mg SLE was 1721 [IQR 1000-2432] pmol/l. Remarkably, dysphoria did not improve in either group during the study period. Sexual desire and function decreased significantly with both treatments, and were not spared by the SLE protocol.
Conclusions
GAHT of TW with SLE over 6 months, offers no clear advantage over the standard OE approach that includes CA, neither in hormonal, biochemical and body composition variables, while it generates recurring supraphysiological estradiol concentrations throughout the day, the safety of which, particularly with respect to thrombogenicity, remains to be determined.

Misdiagnosis of 46, XY DSD in a childhood Bone Marrow Transplantation survivor

Sheena Thayyil, Rama Hamed, Tahir Omer & Jennifer Prouten
Northampton General Hospital NHS Trust UK, Diabetes and Endocrinology, Northampton, United Kingdom

Introduction
Endocrine late effects can manifest in hemopoietic stem cell transplantation survivors who were exposed to myelosuppressive conditioning treatment. These include dysfunction of the hypothalamic/pituitary, thyroid, and gonads leading to

premature ovarian insufficiency and primary amenorrhoea. In addition, metabolic dysregulation and increased risk of diabetes have been observed in these patients. The investigation for primary amenorrhoea in this condition can rarely be complicated by an abnormal karyotype of 46XY in females who received HSCT from male donors leading to a misdiagnosis of disorder of sex development (DSD). To the best of our knowledge, only a handful of cases of misdiagnosed 46, XY DSD following bone marrow transplantation have been reported worldwide.
Case history
A 17-year-old female was referred to our endocrine clinic for the management of primary amenorrhoea as she was newly relocated to the UK. She was diagnosed with Beta Thalassemia Intermedia at age of 2 and had allogeneic hemopoietic stem cell transplantation from her brother at age of 2.5 with complete recovery. She had chemotherapy including Cyclophosphamide and Busulfan for myelosuppression in preparation for HSCT. Later, she consulted an endocrinologist abroad at the age of 16 due to delayed puberty. Her blood test showed a picture of hypergonadotrophic hypogonadism. Further investigations revealed a hypoplastic uterus. Genetic studies performed on a peripheral blood lymphocyte showed karyotype of 46XY which led to the suspicion of DSD. This usually necessitates surgical removal of gonads due to the risk of gonadoblastoma. However, as the clinical manifestations were not entirely consistent with the diagnosis given the presence of gonads and some secondary sexual characteristics, the diagnosis was revisited. A repeat chromosomal analysis on skin fibroblasts was arranged this time and demonstrated a karyotype of 46XX. This led to a diagnosis of premature ovarian insufficiency likely due to childhood chemotherapy. She was started on conjugate oestrogen and achieved pubertal changes in line with Tanner stage III. The oestrogen dose was incrementally built up, and her sexual development improved to Tanner stage IV. Her repeat ultrasound pelvis in Dec 2022 showed a small left ovary and an unidentified right ovary with a normal uterus.
Conclusion
Chromosomal analysis could be misleading following gender mismatched bone marrow transplant. This can lead that the patient to undergo unnecessary and potentially life changing invasive procedures. Pre- and post-treatment chromosomal analysis is essential in such cases.

Human muscle fibers in previous users of anabolic steroids display persistent increased myonuclei number years after cessation

Jon Rasmussen[1], Jakob Nielsen[2], Mikkel Frandsen[1], Yeliz Bulut[1], Niels Brandt-Jacobsen[1], Per Aagaard[2] & Caroline Kistorp[1]
[1]Copenhagen University Hospital - Rigshospitalet, Department of Medical Endocrinology, Copenhagen, Denmark; [2]University of Southern Denmark, Department of Sports Science and Clinical Biomechanics, Odense, Denmark

Background and Objective
Information on the long-term effects of anabolic androgenic steroids (AAS) use on the myocellular properties of human skeletal muscle is scarce, despite being the primary target of AAS. Animal studies suggest persistence of upregulated myonuclei numbers following AAS discontinuation. Few human studies have investigated the effects of AAS on human skeletal muscle cell morphology and exclusively focused on current AAS users. No data exist elucidating the long-term effect on human skeletal myofiber properties in previous AAS users. The objective of this study was to investigate the effects of AAS use on myofiber morphology and myonuclei content in current and former AAS users.
Methods
Community-based cross-sectional study including men involved in recreational strength training. Biopsies were obtained from the quadriceps muscle (*vastus lateralis*). Immunofluorescence analysis was performed to quantify myofiber size (CSA) and myonuclei numbers. AAS usage was evaluated using standardized questionnaires.
Results
We included a total of 25 participants: 8 current and 7 previous AAS users and 10 controls with no prior AAS use. Mean (SD) age was 31 (7) years and did not differ between groups. Median (25^{th}-75^{th} percentiles) accumulated duration of AAS intake was 174 (101 – 206) and 140 (24 – 260) weeks in current and former AAS users, respectively ($P=0.482$). Mean (95% CI) elapsed duration since AAS cessation was 4.0 (1.2; 12.7) years among former AAS users. Type II muscle fibers in former AAS users displayed smaller myonuclear domains than controls ($P=0.013$), corresponding to a higher myonuclei-cytoplasma ratio. Further, the ratio of perimeter per myonuclei in type II fibers tended to be lower in former users than controls ($P=0.060$). Type I fibers in current AAS users exhibited increased amounts of satellite cells per myofiber ($P=0.031$) and more myonuclei per myofiber ($P=0.043$) compared with controls.
Conclusions
AAS use is associated with increases in satellite cell and myonuclei content. Elevated myonuclei content was observed in type II fibers obtained from previous AAS users with a mean of 4 years after AAS cessation. Thus, AAS usage may lead to superior re-training ability ('muscle memory') years after AAS cessation. The findings enhance our understanding of the long-term effects of supraphysiological AAS intake on human skeletal muscle mass.

Fear of Hypoglycemia in Parents of Young Type 1 Diabetic Patients and Impact on Glycemic Control

Sofia Ouhessaine, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Ibn Rochd University Hospital of Casablanca, Morocco Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy-University Hassan II, Endocrinology, Diabetology, Nutrition and Metabolic Diseases, Casablanca, Morocco

Introduction
Hypoglycemia is the most frequent iatrogenic acute complication in type 1 diabetics, it is a potentially serious complication, which can lead to coma. Many advances in new generation insulins, self-monitoring methods and therapeutic education have reduced the incidence of this complication. Nevertheless, hypoglycemia still generates great fear and anxiety in parents of young type 1 diabetic patients, which can be accompanied by several therapeutic errors.
Objectives
To describe the fear of hypoglycemia in parents of young T1D patients as well as the resulting therapeutic errors and the impact on glycemic control.
Materials and Methods
Cross-sectional descriptive study carried out in the endocrinology and metabolic diseases department, including the parents of young T1D patients aged between 15 and 20, hospitalized in the departments or received in transition consultation during the year 2022. Our study excluded severe hypoglycaemia.
Results
Our study included 92 parents of young T1D patients aged on average 17.1 years, the mother was the most involved in the management of diabetes in 75%, and the father in 25%. It was noted a fear of hypoglycemia in all parents but mainly nocturnal in 89%. In cases of mild to moderate hypoglycemia, 90% of parents advised a double consumption of the carbohydrates necessary for resugar, a snack was taken in 45%, the next insulin dose was generally reduced in 50% of cases, not taken in 5%, the average HBA1C was 9.4%.
Conclusions
Hypoglycemia is a frequent complication, a source of anxiety for patients and their families requiring targeted education of patients but also of parents and siblings. Education should be a flexible process, adapted to the specific and changing needs of young people and their families, as they go through the different stages of their lives.

Gene expression differences between small and large follicles

Lara Baschieri[1,2], Danilo Cimadomo[3], Federica Davolio[1], Samantha Sperduti[1], Elisa Mascolo[1], Elia Paradiso[1], Clara Lazzaretti[1], Carmela Perri[1], Neena Roy[1], Federica Innocenti[3], Laura Albricci[3], Laura Rienzi[3,4], Alberto Vaiarelli[3], Filippo Maria Ubaldi[3], Manuela Simoni[1,5,6] & Livio Casarini[1,5]
[1]Unit of Endocrinology-University of Modena and Reggio Emilia, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy; [2]International Ph.D. School in Clinical and Experimental Medicine (CEM), University of Modena and Reggio Emilia, Modena, Italy; [3]Clinica Valle Giulia, GeneraLife IVF, Rome, Italy; [4]University of Urbino 'Carlo Bo', Department of Biomolecular Sciences, Urbino, Italy; [5]Center for Genomic Research-University of Modena and Reggio Emilia, Modena, Italy; [6]Azienda Ospedaliero-Universitaria di Modena-Baggiovara Hospital, Department of Medical Specialties, Modena, Italy

In assisted reproduction, poor ovarian response to controlled ovarian stimulation (COS) leads to poor oocyte yield and depends on the genetic background. We compared the expression of key-genes, coding proteins regulating follicular development, between small (<10 mm) and large ovarian follicles (>16 mm), assuming the size as a hallmark of follicle maturation and oocyte fate. Twenty-

two patients undergoing COS were enrolled in a fertility clinics. Granulosa cells and follicular fluids (FFs) were grouped according to size of ovarian follicles (small follicles, 'SFs', diameter <10 mm, $n=22$; large follicles, diameter, 'LFs', >16 mm, $n=22$) and collection in the antral or luteal stage. Gene expression was analyzed by digital droplet PCR, while testosterone (T) and estradiol (E_2) levels were measured by homogeneous time-resolved fluorescence. Results were matched with clinical data by principal component analysis (PCA). Ethics Committee approval was obtained, and statistical analysis was performed using Mann-Whitney's U-test ($P<0.05$; means$\pm$SEM). *FSHR* and *GPER* gene expression was higher in SFs than LFs, supporting their role in promoting follicular dominance via activation of proliferative signals ($P<0.05$; *FSHR*-LFs: $1x10^{-3}\pm0.1x10^{-3}$ fold/housekeeping gene expression; *FSHR*-SFs: $4.6x10^{-3}\pm1.1x10^{-3}$; *GPER*-LFs: $2.8x10^{-3}\pm0.3x10^{-3}$; *GPER*-SFs: $7.8x10^{-3}\pm1.7x10^{-3}$). *FSHR/GPER* gene expression ratio resulted to be lower in LFs than SFs, indicating the potential to counteract apoptotic signals linked to FSHR overexpression ($P<0.0001$; *FSHR/GPER*-SFs: 1.065 ± 0.3 fold/housekeeping gene expression ratio; *FSHR/GPER*-LFs: 0.37 ± 0.052). Marked *CCND2* and *AMHR2* expression were found in SFs as well, indicating cell proliferation ($P<0.05$; *CCND2*-LFs: $0.1\pm8x10^{-3}$ fold/housekeeping gene expression; *CCND2*-SFs: $0.15\pm18x10^{-3}$; *AMHRII*-LFs: $5x10^{-3}\pm0.8x10^{-3}$; *AMHRII*-SFs: $8x10^{-3}\pm1.3x10^{-3}$). No different *CYP19A1*, *LHCGR*, *XIAP* and *TP53* gene expression was found between SFs and LFs ($P\geq0.05$). In FFs, higher T levels were detected in LFs *vs* SFs ($P<0.05$; SFs: $1.7x10^{-9}\pm1.3x10^{-10}$ hormone level/total protein amount; LFs: $2.2x10^{-9}\pm2x10^{-10}$) while not significantly different E_2 levels were detected ($P\geq0.05$). *In vitro* data were matched with follicular diameter by PCA, revealing that LFs are a sub-cluster of SFs data, suggesting higher gene expression variability in SFs vs LFs. Heatmap hierarchical clustering revealed inverse relationship between *AMHR2* and *CYP19A1* expression levels. *CYP19A1*, *FSHR* and *CCND2* were downregulated in LFs while upregulated in SFs, oppositely to what observed for *LHCGR* and *GPER*. *XIAP* and *TP53* have similar expression levels in SFs and LFs. The present study confirms different expression of follicle maturation genetic markers.

In vitro effect of visfatin on progesterone and prostaglandins' secretion by the porcine corpus luteum. Involvement of insulin receptor and different kinases' signalling pathways

Ewa Mlyczyńska[1,2], Ewa Zobidna[3], Edyta Rytelewska[4], Natalia Respekta[1,2], Kamil Dobrzyń[5], Marta Kieżun[4], Grzegorz Kopij[4], Nina Smolińska[4], Tadeusz Kamiński[4] & Agnieszka Rak[1]
[1]Jagiellonian University, Institute of Zoology and Biomedical Research, Laboratory of Physiology and Toxicology of Reproduction, Krakow, Poland; [2]Jagiellonian University, Doctoral School of Exact and Natural Sciences, Krakow, Poland; [3]University of Warmia and Mazury, Faculty of Biology and Biotechnology, Department of Biochemistry, Olsztyn, Poland; [4]University of Warmia and Mazury, Faculty of Biology and Biotechnology, Department of Animal Anatomy and Physiology, Olsztyn, Poland; [5]University of Warmia and Mazury, Faculty of Biology and Biotechnology, Department of Zoology, Olsztyn, Poland

Visfatin is one of adipokines that particularly regulates metabolic homeostasis. Literature data of the last decade indicate also that visfatin participates in the regulation of ovarian follicles' steroid synthesis and oocyte maturation in women, mice, hens, and cows. However, there is still a gap in knowledge about the effect of this adipokine on the corpus luteum (CL) functions. Our previous study documented visfatin mRNA and protein expression in the porcine CL. Therefore, the aim of the present study was to determine the impact of visfatin on endocrine functions of the porcine CL during the estrous cycle. Corpora lutea were collected from gilts on days 2–3, 10–12, 14–16 of the estrous cycle and luteal cells were treated with visfatin (1, 10, 100 ng/ml) alone or together with visfatin blocker FK866 (10 μM). Then, we analyzed the secretion of progesterone (P_4), prostaglandin E_2 (PGE_2) and $F_{2\alpha}$ ($PGF_{2\alpha}$) as well as protein expression of steroidogenic enzymes (StAR, CYP11A1, 3βHSD) and prostaglandins' receptors (PTGER1, PTGFR). Moreover, we investigated the impact of visfatin (10 ng/ml) on activation of MAPK, AMPK, and AKT kinases as well as the involvement of these kinases and insulin receptor (INSR) in visfatin action. Statistical analysis was performed using one-way ANOVA and Tukey's post-hoc test. The results of the study demonstrated that visfatin decreased P_4secretion by luteal cells from days 2-3 and 14-16, while increased on days 10-12 of the cycle. These results were confirmed by visfatin stimulatory effect on protein levels of StAR, CYP11A1 and 3βHSD on days 10-12. We noted that visfatin enhanced PGE_2 secretion by the cells from days 2-3 and 10-12, while decreased PGF_{2a} release on days 14-16 of the cycle. These changes were also accompanied by increased luteal PTGER1 protein expression on days 10-12 and decreased PTGFR on days 14-16 of the cycle. Treatment with the visfatin blocker, FK866, suppressed the observed visfatin effect on steroids' and prostaglandins' secretion. Interestingly, visfatin in time-dependent manner stimulated MAPK, AKT and AMPK pathways. Moreover, MAPK, AKT, AMPK and INSR were involved in visfatin effect on P_4, while MAPK and INSR on prostaglandins' secretion. The obtained results indicate that visfatin affects luteal endocrine functions, depending on the phase of the estrous cycle, and could be the new regulator of the porcine ovary.

Prognostic Value of Hormonal Examination in Adolescent Girls with Polycystic Ovarian Syndrome

Nigar Kamilova
Azerbaijan Medical University, Department of Obstetrics and Gynecology, Baku, Azerbaijan

Relevance
PCOS is a multifactorial heterogeneous disease associated with endocrine, reproductive, and metabolic manifestations. The relevance of the PCOS problem is determined by its high prevalence worldwide among women of childbearing age (5 - 20%). It is worth noting that the main reproductive signs of PCOS appear in late prepubertal and pubertal periods.
The aim is to carry out a comparative analysis of hormonal indicators in PCOS
Materials and Methods
A total of 120 adolescent girls aged 14-18 years, diagnosed with polycystic ovarian syndrome, were included in the study. Hormone balance was determined using a «PW 300 M Chemistry Analizator» (USA). The results obtained were statistically processed by determining the mean mathematical limit (m), standard deviation, mean error of mathematical limit (m). The results were considered statistically significant at $P<0.05$. Statistical studies were performed using Microsoft Excel and Statistica 10.0 software.
Results of discussion
The most typical manifestations of PCOS that appeared from the age of menarche were: menstrual cycle (86%), mostly by the type of oligomenorrhea (52%); hirsutism (81.2%). Hormonal analysis revealed a wide variability in FSH in adolescent girls from 3.4 to 64.3 IU/l, and from 2.8 to 7.2 IU/l in the control group, which is associated primarily with insufficient hormonal function of the ovaries. The analysis of the LH content revealed rather high LH values in the blood serum of adolescent girls ($13.3+1.6$ IU/l). The LH/FSH ratio was $2.3+0.4$ (normal-. Thus, changes in the gonadotropin indices are already a precursor of functional disorders of the hypothalamic-pituitary system of menstrual function regulation. In patients with polycystic ovary syndrome individual values of testosterone ranged from 1.8-3.9 (mean $3.1+1.2$ nmol/l). The serum AMH content in LPS patients ranged from 2.4 ng/ml to 18.0 ng/ml and averaged 7.6 ± 0.8 ng/ml, which was significantly ($P<0.001$) higher than its content in healthy women (2.5 ± 1.3 ng/ml). The volume of each ovary ranged from 11.3 to 16.0 cm3 and was larger than that in women without PCOS. The mean number of antral follicles in the ovary was 8.8 ± 1.0 (11 to 12), which was also greater than in women without PCOS.
Conclusions
In PCOS, there is an imbalance between the amount of androgens, antimullerian hormone (AMH), LH and FSH, which results in the failure to select the 'dominant' follicle despite relatively rapid and early follicle growth.

45X/46XY Mosaicism in a Male as a Rare Cause of Absence of Sexual Interest

Nuriye Hale Erbatur[1], Mina Gülfem Kaya[2], Serife Mehlika Kuskonmaz[3] & Cavit Çulha[3]
[1]Health Sciences University Sultan Abdulhamid Han Training and Research Hospital, Endocrinology and Metabolism, İstanbul, Turkey; [2]Lokman Hekim University, Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara Training and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey

Introduction
The incidence rate of 45X / 46XY karyotype and variants has been reported as 1 / 15,000 live births and is rare. The phenotypic spectrum of patients with 45X / 46XY varies widely from women with Turner syndrome to normal androgenized men. In adult male infertility studies, 45X / 46XY karyotype cases diagnosed as a result of genetic screening have been reported. However, there are case reports showing that, despite their normal appearance, these patients may have dysgenetic testes that can result in decreased testicular function, delayed puberty, and infertility. In this article, we will describe a rare, apparently normal 45X / 46 XY male case.
Case Presentation
A 33-year-old male patient consulted the endocrinology department for primary infertility. He suffered from erectile dysfunction. He had been married for one year but had never had an intercourse with his partner. He reported a normal pubarche at the age of 14 with normal development of facial hair however, in time, had lost interest for the opposite sex and had no sexual partner at all. Physical examination was unremarkable and axillary and pubic hair development were consistent with Tanner Stage V. Stretched penile length was 11 cm. Scrotal ultrasonography showed bilateral small testes: (right testicular volume:12x17x28mm and the left testicular volume: 115x23x25mm) Bilateral epididymis were normal in size and sonographically homogenous. Penile ultrasonography suggested findings of venous insufficiency. Laboratory analysis revealed hypergonadotropic hypogonadism. Complete blood count, liver and kidney function tests, and thyroid function tests were normal in the examinations. FSH was 33.1 mIU / mL, LH was 17.44 mIU / mL and T. testosterone 277.4. Azoospermia was detected in semen analysis. Karyotype analysis showed, 46XY (13) 45, X (17) mosaicism.
Conclusion
45, X / 46, XY mosaicism can occur with a wide variety of phenotypes and patients without gender growth retardation can be easily ignored. It can affect hormonal balance, gonadal development, growth, and fertility. Chromosomal abnormalities should be considered in patients with absence of sexual desire and erectile dysfunction and hypergonadotropic hypogonadism, including phenotypically normal males.

Mitochondrial uncoupling proteins (UCPs) regulate mitochondrial function in mouse Leydig Cells: a possible role on steroidogenesis?

Bárbara Guerra-Carvalho[1,2,3,4,5], Beatriz C. Matos[1,5], David F. Carrageta[1,2,5], Raquel L. Bernardino[1,2], Pedro F. Oliveira[3] & Marco G. Alves[1,2,5]
[1]Clinical and Experimental Endocrinology, UMIB - Unit for Multidisciplinary Research in Biomedicine, ICBAS - School of Medicine and Biomedical Sciences, University of Porto, Porto, Portugal; [2]Laboratory for Integrative and Translational Research in Population Health (ITR), University of Porto, Porto, Portugal; [3]LAQV-REQUIMTE and Department of Chemistry, University of Aveiro, Aveiro, Portugal; [4]Department of Pathology, Faculty of Medicine, University of Porto, Porto, Portugal; [5]Laboratory of Physiology, Department of Imuno-Physiology & Pharmacology, ICBAS - School of Medicine and Biomedical Sciences, University of Porto, Porto, Portugal

Introduction
Mitochondrial uncoupling proteins (UCPs) are transmembrane channels present in the inner mitochondrial membrane whose function is the transport of protons and small substrates between the intermembrane space and the mitochondrial matrix. UCPs are key regulators of cellular metabolism, including mitochondrial function, oxidative phosphorylation, and reactive oxygen species (ROS) production. UCPs' dysfunction has been associated with the onset of metabolic diseases, such as obesity and diabetes mellitus. In men, metabolic diseases are closely linked to hypogonadism and lower testosterone production in Leydig cells, however, the molecular mechanisms are still poorly understood. The dysfunction of UCPs could play a role in the crosstalk between metabolic diseases and hypogonadism but their expression and function in Leydig cells is still unknown.
Aim of the study
The aim of this study was to identify the expression of UCP1, UCP2, and UCP3 in mouse Leydig Cells (mLCs). Additionally, the influence of UCPs on the mitochondrial function was assessed, through its inhibition by genipin, a selective UCP inhibitor.
Materials and methods
Culture of mouse Leydig cells (BLTK1 cell line) were established ($n = 10$). Total RNA was extracted and *Ucp1*, *Ucp2*, and *Ucp3* mRNA expression were assessed by RT-PCR. UCP1-3 protein expression was determined by Western Blot and immunofluorescence. To assess UCPs function, mLCs were treated with genipin (0.5, 5, 50 and 100 μM). After 24 h treatment, cellular proliferation and viability were evaluated. Mitochondrial function was accessed by Seahorse XF Cell Mito Stress assay kit.
Results
We were able to identify both the mRNA and protein expression of UCP1-3 in mLCs. The inhibition of UCPs decreased cellular proliferation and viability of mLCs. Additionally, the mitochondrial function was severely affected by UCPs' inhibition.
Conclusion
In this work, we were able to identify for the first time, to the best of our knowledge, the expression of UCP1-3 in mLCs. Our data highlight that UCPs are modulators of mLCs mitochondrial function, suggesting a potential regulatory role of UCPs on steroidogenesis. Taken together, the discovery of UCPs in Leydig cells opens the path for future studies focusing on the molecular mechanisms responsible for the metabolic diseases-induced male hypogonadism.

Objective
Transgender individuals endure gender dysphoria and incongruence between physical appearance and gender identity. We aimed to investigate effects of gender affirming treatments on sex hormone levels, mental well being and body image quality of life in these individuals.
Material and Method
This is a descriptive cross sectional study. Transgender individuals who were transitioned from pediatric to adult care (n: 12) and who were formerly followed up in endocrinology department for at least six months (n:25) were included. Groups consisted of female to male (FTM, n: 19) and male to female (MTF, n:18) transgender individuals. Treatments were classified as gender-affirming hormone therapy [GAHT: GnRH analog (GnRHa) and/or cross sex hormone treatment (CHT)] and gender affirming surgery (GAS). Participants were invited to complete Patient Health Questionnaire (PHQ-9) and Body Image Quality of Life Inventory (BIQLI). Sex hormone levels, onset of virilization or feminization symptoms, patient outcome questionnaire scores were compared.
Results
Demographic and clinical characteristics are demostrated in Table-1. PHQ-9 scores were correlated with age ($P=0,03$, r:-0,56), BIQLI score ($P=0,006$, r:-0,674), onset of treatment benefit ($P=0,03$, r: 0,58) and BIQLI scores were correlated with age ($P=0,02$, r:0,57) and presence of GAS ($P=0,006$, r:0,67) among transmale individuals. In Transfemale individuals BIQLI scores were correlated with age ($P=0,008$, r:0,601), PHQ scores ($P=0,002$, r:-0,936), testosterone levels on 6th and 12th months ($P=0,02$, r:-0,93 and $P=0,02$, r:-0,93, respectively).
Conclusion
Apart from GAHT, age and presence of GAS are prominent factors effecting body image quality of life and PHQ-9 scores in transgender individuals.

Progesterone Limits the Increase in p53 caused by Dexamethasone Treatment in the Labyrinth Zone of Rat Placenta

Mariam Alqaryyan, Maryam Alawathi & Maie Albader
Kuwait University, Faculty of Medicine, Physiology, Kuwait

Introduction and objectives
Placental apoptosis plays important roles in both normal physiological and abnormal pathological placental development. Fetal growth is highly dependent on the placenta, thus any disruption in placental formation may lead to intrauterine growth restriction (IUGR). The rat placenta consists of a basal zone (BZ) and labyrinth zone (LZ). The BZ is the major site of placental hormone production and it goes under physiological apoptosis at the end of term. While the LZ is the major site for nutrient/waste exchange which is essential till the end of term. Dexamethasone (DEX) is a synthetic glucocorticoid that stimulates placental apoptosis and inhibits feto-placental growth which leads to IUGR. Research on rats indicated that DEX-induced IUGR is associated with placental apoptosis. In the LZ of IUGR placentas the activity of p53 a tumor suppressor protein that initiate apoptosis is increased. Progesterone (P), on the other hand, has been shown to inhibit placental apoptosis. Furthermore, research conducted on human and rat placentas showed that low maternal progesterone level during pregnancy is associated with low fetal and placental weights and development of IUGR. We hypothesize that P will reverse the apoptotic effects of DEX-induced IUGR
Methods
Pregnant Sprague-Dawley rats received daily intra-peritoneal injections of either saline (C group), DEX (0.2 mg/kg; DEX group), P (5 mg/Kg/day: P group) or mixture of DEX + P (0.2 mg/kg + 5 mg/Kg/day: DEX+P group) starting from 15 days of gestation (dg) to 21 dg. Gene and protein expressions of p53 in the BZ and LZ were investigated by RT-PCR and Western blotting in all groups.
Results
In BZ, DEX decreases the p53 mRNA and protein expression while P treatment increases it and returned it normal levels ($P<0.05$). p53 mRNA expression decreased also in DEX group compared to that in P ($P<0.05$). In P group, p53 protein expression was lower compared than in C and DEX+P ($P<0.05$). In the LZ, DEX increases the p53 mRNA and protein expression while P treatment decreases it but not to normal levels ($P<0.05$). p53 mRNA and protein expression was higher in P group compared to C ($P<0.05$). Also in P group p53 mRNA expression was higher than that in DEX+P, while the p53 protein expression was lower than that in DEX group ($P<0.05$).
Conclusions
In the LZ, P reduces the high level of p53 caused by DEX which could be associated with reduction in apoptosis.

Occurrence of vertebral fractures, hypovitaminosis D, and osteoporosis among postmenopausal women living in rural areas

Subhash Kumar[1], Shaibal Guha[2] & Md. Ekram[3]
[1]Diabetes and Obesity Care Center, Medicine, Patna, India; [2]Positive Health Centre, Internal Medicine, Patna, India; [3]Madhubani Medical College & Hospital, Orthopaedics, Keshopur, India

Background
The likelihood of developing a fragility fracture rises with age. Osteoarthritis, osteoporosis, and hypovitaminosis D are all extremely common diseases, with 50% of women and 20% of men experiencing a fragility fracture at some point in their lives.
Objectives
First, compare the occurrence of osteoporosis, fragility fractures, and risk factors such as low vitamin D levels, low bone mineral density, and the presence of other illnesses that predispose to their occurrence in two groups of postmenopausal women living in different populations centers (rural vs. urban); second, observe the impact of low socioeconomic status, or poverty.
Material and Methods
Study participants included 260 postmenopausal women, 115 (31.6%) of who resided in rural areas and 145 (68.2%) in urban areas. In addition to other biochemical measurements, 25-hydroxyvitamin D and parathyroid hormone were identified among the information on risk factors for osteoporosis. Along with lateral X-rays of the dorsal and lumbar spine, bone densitometry was done on the proximal femur and the lumbar spine. The statistical analysis was performed utilizing SPSS® (Statistical Package for the Social Sciences) version 18.0 of the statistical program. The means were compared using the Student's t test or the Wilcoxon test, and the percentages were compared using the Chi-squared test (in the case of non-normality).
Results
Compared to women who resided in urban areas, rural women were older, shorter, heavier, and had a higher body mass index. There was a higher frequency of poverty, as well as higher levels of obesity, arterial hypertension, diabetes mellitus, and densitometric osteoporosis, among women from rural areas. The rural women exhibited greater rates of vertebral fractures and hypovitaminosis D, as well as poorer values for bone mineral density in the lumbar spine. Poverty, obesity, vertebral fractures, BMD in the lumbar spine, and levels of 25-hydroxyvitamin D were the factors that were independently linked to residing in rural areas.
Conclusions
According to this study, postmenopausal women who reside in rural areas are more likely to be poor, have lower vitamin D levels, have lower lumbar spine BMD, and have a greater incidence of osteoporosis and vertebral fractures. These women's increased rates of obesity, arterial hypertension, and diabetes mellitus may all be contributing causes to their socioeconomic status as poor.

Masculinizing Hormone Therapy: What Happens to Estradiol and To Total, Free and Biovailable Testosterone?

Miguel Saraiva, Lia Ferreira & Isabel Palma
Centro Hospitalar Universitário do Porto, Endocrinology, Diabetes and Metabolism, Universidade do Porto, Portugal

Introduction
Masculinizing Gender-Affirming Hormone Therapy (GAHT) generally aims to induce testosterone levels equivalent to those of cisgender men and to reduce estradiol levels. There are no studies about bioavailable testosterone in this population.
Aims
To determine the variation of the serum levels of sexual hormones in transmasculine people under GAHT and study the correlations between them and with BMI.

Table 1 (Abstract P194)

Months	M0	M6	M12	M24	M36	M60
N	78	15	6	13	11	12
Total testosterone (ng/ml)	0.34 (0.23-0.49)	4.26 (2.65-6.90)	4.78 (1.59-12.47)	4.53 (4.07-6.33)	4.93 (4.22-6.12)	4.20 (2.99-6.29)
Free testosterone (pg/ml)	1.66 (1.04-2.42)	12.22 (7.91-15.33)	10.55 (4.76-17.17)	10.71 (7.76-14.27)	9.84 (8.54-13.12)	7.95 (6.58-11.46)
Bioavailable testosterone (ng/ml)	0.10 (0.07-0.17)	2.84 (1.77-4.43)	2.51 (1.10-2.98)	2.80 (2.21-4.76)	2.76 (2.28-3.51)	2.65 (1.85-5.02)
Estradiol (pg/ml)	62.45 (34.08-132.00)	38.85 (29.08-60.08)	30.10 (25.48-43.08)	41.40 (29.00-65.80)	34.90 (24.90-74.00)	22.70 (18.50-55.25)

Methods
Longitudinal retrospective study which included adult transmasculine patients currently under follow up at our center. Data collected at 0, 6, 12, 24, 36 and 60 months of GAHT were analyzed.
Results
A total of 91 patients were included (85 trans men and 5 non-binary people). At the first visit at our center their median age was 24(20-28) years and their median BMI was 24.1(21.5-29.1) Kg/m^2. The median serum concentration of sexual hormones during follow-up was: Comparing with M0, at every visit there was a significant increase ($P<0.001$) in the serum level of testosterone – total, free and bioavailable. The reduction in the estradiol serum level only reached statistical significance at M60 ($P=0.005$). However, if the patients that underwent oophorectomy are excluded from the analysis, this reduction also becomes not significant at M60 ($P=0.125$). No correlation was found between the serum levels of estradiol or testosterones and BMI. Total testosterone serum levels showed a strong positive correlation with those of free and bioavailable testosterone (0.854 and 0.954, $P<0.001$). Only total testosterone serum levels reached statistical significance when testing the correlation with estradiol serum levels (-0.215, $P=0.010$).
Conclusions
Masculinizing GAHT alone does not seem to be enough to significantly reduce estradiol serum levels, but oophorectomy seems to make a difference. Total testosterone correlates properly with free and bioavailable testosterone, which may imply that measuring the latter may be futile in most situations. Similarly to other studies, no correlations with BMI were found.

School Failure in Type 1 Diabetic in Transition Period

Sofia Ouhessaine, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Ibn Rochd University Hospital of Casablanca, Morocco Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy-University Hassan II, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Department, Casablanca, Morocco

Introduction
Adolescence represents the passage from childhood to adulthood, this transition is characterized by physical and psychological transformations as well as many social challenges. The presence of chronic disease such as diabetes makes this a major challenge.
Purpose
Describe the impact of diabetes on the school career of adolescents during the transition period.
Methods
Descriptive study involving 79 young people aged 15 to 20 years cared for in hospitalization or in transition diabetology consultation.
Results
The average age is 16.2 years, divided into 38% young men and 62% young girls. The duration of diabetes evolution is 7.93 $\pm$ 4.02 years. Late pediatric transition was noted in 5% of patients. Glycemic control is poor (average HBA1c = 11.19 $\pm$ 2.12%). Diabetic retinopathy is present in 7.5%. We note that 29% have left school voluntarily, 59% say they have academic difficulties, only 12% say they are fulfilled and plan to go to higher education. The main causes reported are; the stigmatization of the entourage and denigration of the person in 35%, 28% are ashamed to inject themselves in a public environment, 12% incriminate the number of hospitalizations, 29% mark the frequency of hypoglycaemia at school, and alone 7% blame the decline in visual acuity.
Conclusion
Adolescent diabetes is a major challenge for the attending physician, the patient and his family, requiring close monitoring, psychological care and education of those around him

Metabolic syndrome in Turner syndrome

Faten Haj Kacem Akid, Oumeyma Trimeche, Mouna Mnif, Abdel Mouhaymen Missaoui, Dhoha Ben Salah, Mouna Elleuch, Mnif Fatma, Nadia Charfi, Nabila Rekik Majdoub & Mohamed Abid
Hedi Chaker Hospital, Endocrinology, Sfax, Tunisia

Introduction
Turner syndrome (TS) is a feminine chromosomic disease, defined as the partial or total loss of the X chromosome. Classic phenotype includes growth and pubertal retardation as well as a characteristic dysmorphic syndrome. Other accompanying comorbidities are frequently associated with TS such as metabolic diseases: overweight, diabetes, hypertension (HTA) and dyslipidemia. Through this report we aim to determine the frequency of metabolic diseases associated with TS and to identify the karyotypes mostly associated with these conditions.
Methods
We carried out research that took place in the Endocrinology department of Hedi Chaker Hospital, between 1990 and 2021. We enrolled in our study patients with TS. Overweight is defined by a BMI between 25 and 29,9 kg per m^2, while obesity corresponds to a BMI above 30 kg per m^2.
Results
Our cohort enclosed 45 patients. The mean age of diagnosis was 16 years. The vast majority were diagnosed between 10 and 20 years (44.2%). Three were diagnosed after 40 years. A wide range of chromosomic abnormalities were noted in our series, dominated by 45, X karyotype (49%). The other karyotype findings were: mosaicism without structural abnormalities of X chromosome (31%) and mosaicism with structural variants of X (20%). Most of our study population had a normal BMI (55.6%). Only one patient was obese (2.2%) whereas eight had overweight (17.8%). The frequency of diabetes and prediabetes was 9.7% and 25.8%, respectively. At a mean age of 24.8 $\pm$ 10.5 years, nine patients were diagnosed with hyperlipidemia (29%): type IIa in three cases and type IV in five cases while a mixed hyperlipidemia was found in one case. As for hypertension, it was found in 13.3 % of our study population. Concerning the genotype-phenotype correlation, we noted a higher BMI in patients with structural abnormalities of X: 21.02 kg/m^2 vs 20. 37 kg/m^2 and 20.24 kg/m^2 in 45, X and mosaicism without structural abnormalities, respectively ($P=0{,}908$). However, these differences were non-significant. Otherwise, there was no specific karyotype associated with metabolic conditions ($P=0{,}660$).
Conclusion
Metabolic disorders are frequent in TS and thus an annual screening of these diseases is mandatory. Patients with structural abnormalities seem to be more prone to develop overweight. However, larger studies are needed to confirm these findings.

DOI: 10.1530/endoabs.90.P196

P197

Polycystic ovary syndrome phenotype and therapeutic outcomes

Mouna Elleuch, Hamdi Frikha, Dhoha Ben Salah, Molka Triki, Younes Ayadi, Fatma Mnif, Mouna Mnif, Nabila Rekik Majdoub, Nadia Charfi, Faten Haj Kacem Akid & Mohamed Abid
Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction
Polycystic ovary syndrome (PCOS) is a common endocrinopathy affecting women of reproductive age. PCOS has two phenotypes, obese and lean, the latter being a much less common presentation of the syndrome.
Aim
Compare PCOS outcomes in patients with obese PCOS and patients with lean PCOS.
Methods
A retrospective, single-center, descriptive and comparative study including patients with PCOS followed at the endocrinology department of Hedi Chaker University Hospital of Sfax, Tunisia. G1 included patients with obese PCOS and G2 included patients with lean PCOS.

Results
We included 50 female patients, of which 28 had obese PCOS. G1 patients had significantly higher BMI, waist circumference, weight and systolic blood pressure. Menstrual cycles disturbances was equally reported in the two groups while hirsutism was more common in G1 (96,7% vs 72.1%; $P=0.019$). Fertility issues were more frequent in obese PCOS patients (71.1% vs 45.2%; $P=0.036$). Response to therapeutic measures was more favorable among G2 patients as they had a more significant reduction in Ferryman and Gallway score ($P=0.01$). However, weight loss and normalization of menstrual cycles were comparable between the two groups ($P=0.7$ and $P=0.22$ respectively).
Discussion & Conclusion
PCOS phenotype seems to dictate some aspects of the therapeutic outcomes. Insulin resistance, low grade inflammation, adherence to treatment and psychosocial factors may be some of the main underlying explanations. Mackens *et al*. demonstrated that cumulative birth rates were lower after ovarian stimulation in obese PCOS patients. In a recent prospective study; Sachdeva *et al*. reported higher resistance to Clomiphene among obese PCOS patients. A phenotype-based, personalized approach needs be adopted in PCOS management.

The Effect of Menopausal Status On Anthropometric Measurements and Nutritional Status
Yonca Sevim & Selenay Kutukluler Dogan
Bahcesehir University, Nutrition and Dietetics, Istanbul, Turkey

Menopause defines the period in which women's menstrual periods cease permanently, significant hormonal changes begin, and fertility is lost. In addition to the fact that menopause causes body weight gain, it has been found that body weight gain can negatively affect the menopausal process. In this study, the relationship between food consumption and body composition changes that may be caused by the menopause period and menopausal symptoms was investigated. In the study, 66 menopausal women without any chronic disease were evaluated through sociodemographicform, anthropometric measurements, menopausal symptoms evaluation scale (MRS), and 3-day food consumption record. Participants were evaluated as two groups, MRS <15 (n:16) and MRS>15 (n:50). The mean age of the participants evaluated in the study was 51.7 ± 4.6 years. It was found that the mean menopause age was 48 ± 3, the mean time spent at menopause was 3 ± 2 years, and the mean body weight gain during the menopause period was 6 ± 4 kg. The mean MRS total score was 22 ± 10, the somatic complaints factor mean score was 8 ± 4, the psychological complaints factor mean was 8 ± 5, and the urogenital complaints factor mean was 5 ± 3. It was found that the averages of body mass index (kg/m2), waist circumference (cm), hip circumference (cm), and neck circumference (cm) of the women with MRS>15 were significantly higher than the averages of the woman with MRS <15 ($P<0.05$). Dietary intake of total fat, saturated fatty acids, unsaturated fatty acids, and eicosapentaenoic acid were positively correlated with somatic complaints in menopausal women ($P<0.01$), the amount of protein consumption ($P<0.01$), and animal protein ratio ($P<0.05$) in menopausal women was significantly and negatively correlated with somatic symptoms, and the amount of energy intake (both total intake and kcal intake per body weight) was positively correlated with somatic complaints ($P<0.01$). As a result of the research, it was thought that somatic and psychological complaints would decrease with a healthy and balanced diet in menopausal women.

Estetrol: estrogenic activity and coregulator profiling
Celine Gerard[1], Guillaume Chatel[1], Maud Jost[1] & Jean-Michel Foidart[2]
[1]Mithra Pharmaceuticals, Liege, Belgium; [2]University of Liège, Liège, Belgium

Estetrol (E4) is a natural estrogen produced by the human fetal liver during pregnancy. E4 is the estrogenic component of a new combined oral contraceptive and is also in development for its use as menopausal hormone therapy. E4 displays a selective binding to human estrogen receptors (ER). In humans, after oral administration, E4 undergoes phase 2 metabolism leading to the formation of the two major metabolites E4-3-glucuronide and E4-16-glucuronide. The objectives of this study were (*a*) to compare the estrogenic activity of E4 to estradiol (E2) and ethinylestradiol (EE) induced via both ERα and ERβ; (*b*) to determine the estrogenic activity of E4 metabolites and (*c*) to characterize the ER coregulator recruitment profile induced by E4. In order to determine the estrogenic activity of E4 and its metabolites, a luciferase reporter assay (ER-CALUX bioassay) was conducted. Briefly, human osteoblastic U2-OS cells stably expressing ERα or ERβ, as well as an estrogen-responsive luciferase reporter gene, were exposed to increasing concentrations of E4 or metabolites for 24 h. Reference estrogens E2 and EE were also included as comparators. The coregulator recruitment assay was performed with the MARCoNI technology, and the binding pattern of ERα to 154 coregulator-derived peptides was analyzed. E4 displayed estrogenic activity in both ERα and ERβ assays. However, the potency of E4 was lower than that of E2 or EE. In addition, the potency of the metabolites was several hundred-fold lower than the potency of the parent molecule E4. The EC_{50} value and relative transactivating potency of E4 and the metabolites with E2 and E4 as a benchmark, respectively, are presented below:
In conclusion, E4 induces transcriptional activity via both ERα and ERβ, although with a lower potency than E2 and EE. E4 induces the recruitment of the same profile of coregulators to ER as E2, suggesting that E4 and E2 induce transactivation via the same molecular mechanisms. Glucuronidation of E4 leads to the formation of metabolites with negligible estrogenic activity.

	EC_{50} (M) [Relative potency]	
	ERα	ERβ
E4	6.2×10^{-10} [0.0037]	1.2×10^{-8} [0.0044]
E2	2.3×10^{-12} [1]	5.3×10^{-11} [1]
EE	8.7×10^{-13} [2.6]	2.5×10^{-10} [0.21]

	EC_{50} (M) [Relative potency]	
	ERα	ERβ
E4-16-Gluc	1.7×10^{-6} [0.0017]	9.0×10^{-6} [0.0024]
E4-3-Gluc	1.1×10^{-5} [0.00026]	*
E4	2.9×10^{-9} [1]	2.2×10^{-8} [1]

*No full curve obtained
Overall, E4 and E2 induced a similar coregulator recruitment profile.

Effect of Overweight On the Course of Early Menopause in Women
Ziyoda Umarkhodjaeva, Irodakhon Inoyatkhodjaeva & Mukhlisa Vahabova
The Republican Specialized Scientific and Practical Medical Center of Endocrinology, Endocrinology, Uzbekistan

Purpose
To study the role of varying degrees of overweight in the course of menopause.
Materials and methods of the study
The study involved 278 women in the menopausal period aged 40 to 46 years, of which the main group (MG) consisted of 218 women with overweight and obesity of varying degrees. The control group (CG) included 60 women with normal body weight and a waist
Results of the study
As a result of the studies, we found that overweight (BMI - 25.0-29.9 kg/m2) was observed in 62 women (28.4%) out of 218 examined in the main group; in other cases, obesity of various severity (BMI - 30.0-41.2 kg/m2). 72.0% of overweight women noted an increase in BMI after 36 years, i.e. at the beginning of the late reproductive period, while women with obesity of varying severity after 40 years. In the CG, 33% of women from the CG noted weight gain after 36 years, although these indicators did not go beyond the normal range. Circumference of 80 cm. Women with overweight and obesity had a high comorbidity, so 36% of women from the MG had arterial hypertension, 22% had coronary heart disease, 10% had chronic venous insufficiency, and 10% of women noted arrhythmias. I would especially like to highlight the frequency of gastrointestinal diseases in women with OH, of which 42% is cholelithiasis, 62.4% is chronic gastritis, 18.3% is chronic colitis, 6% is peptic ulcer and 28.4% is chronic pancreatitis. The frequency of occurrence of gynecological pathology also depended on BMI, so in women with overweight in 58.4% of cases, uterine fibroids, adenomyosis, etc. were noted, while in the CG this percentage was 13.8%. The range of clinical symptoms in women with overweight, obesity and normal body weight differs, the former and the latter are dominated by headaches (in 95.0%), irritability (in 72.5%), sleep disturbance (in 67.5%), muscle and joint pain (in 62.5%), sexual dysfunction (in 52.5%). The climacteric syndrome in obese patients is more

severe and often manifests with climacteric symptoms such as palpitations and tachycardia, excitability, dizziness, muscle and joint pain, hot flashes, and sexual dysfunction.
Conclusion
Thus, menopause is associated with an increased prevalence of overweight. Increased central fat deposition, reduced peripheral fat deposition, and ectopic fat accumulation contribute to cardiometabolic abnormalities, resulting in an increased prevalence of metabolic syndrome after menopause.

Dopamine Agonist-Resistant Prolactinoma: Case report and literature review

Teona Nutsubidze[1], Tekle Bakhtadze[1], Tamta Sharadze[2], Medea Zhgenti[2], Rezo Jamburia[1] & Shota Janjgava[2]
[1]National Institute of Endocrinology, Endocrinology, T'bilisi, Georgia; [2]National institute of Endocrinology, Endocrinology, T'bilisi, Georgia

The therapy of hyperprolactinemia with dopamine agonists (DAs) is highly effective in the majority of cases (1). However, some patients fail to achieve normal prolactin levels and develop drug resistance towards prescribed medicine. This case study describes a medical history of The Georgian National Institute of Endocrinology patient, with a drug-resistant hyperprolactinemia and inability to conceive. The patient's MRI scan result has not indicated incidence of prolactinoma.
The Case Study
A 27-year-old female visited ambulatory clinic with severe headache and amenorrhea. The patient asked to reassess previously prescribed treatment protocol. According to her medical history, she has been diagnosed with hyperprolactinemia and nodular goiter, since she was 14 years old. The patient has been prescribed the dopamine agonist cabergoline (CAB, 0.25 mg, to be taken twice a week). The prolactin levels remain high despite dose escalation. A pituitary MRI with contrast was performed twice: at aged 20 and aged 26. Both scans have not indicated any abnormal lesions. The patient has denied taking any other medicine or recreational drugs.
First ambulatory visit
Prescribed medicine CAB 1.75 mg twice a week (3,5 mg per week). Levothyroxine 25 mg daily. Blood test Showed increased prolactin level - 56,94 ng/ml. (normal range: nonpregnant females: 2 to 29 ng/ml) (2) The blood test was conducted to check hyperprolactinemia level due to non-reactive isoforms. The fraction of polyethylene glycol (PEG)-precipitated (complexed) prolactin was <40 % of total prolactin, therefore the specimen was considered negative for macroprolactin. The further evaluations of pituitary hormones didn't reveal deviation from the norm. Bromocriptine (2,5 mg) 1/2 pill was added to the patient's existing prescription.
Second ambulatory visit (after six months)
The prolactin level has increased up to 61,10. ng/ml. Updated prescription: Quinagolide 150 mg daily. CAB and Bromocriptine were discontinued due to low efficacy.
Third ambulatory visit
(after three months): regular menses has been restored. On the third regular menstrual cycle, a successful ovulation has been confirmed by appearance and disappearance of a dominant follicle on transvaginal ultrasound (TVUS), performed every third day and by blood test: mid-luteal phase progesterone -12 ng/ml.(3) The prolactin decreased by - 30 ng/ml (1.8–20).
Conclusion
We concluded that partial resistance can be managed by drug shifts, leading to hormonal control of initially resistant patients. As a result the restoration of a normal gonadal axis can be achieved.

The effect of thyroid function and estrogen levels on Body Mass Index in women of reproductive age

Assel Issabayeva, Aigul Durmanova, Gul'nur Slyamova & Ulpan Ibraikhanova
Corporate Fund 'University Medical Center', Department of Internal Medicine, Astana, Kazakhstan

Background
Obesity in women of reproductive age has a number of negative metabolic consequences, including dyslipidemia, type 2 diabetes, cardiovascular diseases, certain types of cancer. It is associated with increased ovulatory dysfunction, complications during pregnancy, endometriosis and endocrine abnormalities, including thyroid dysfunction.
Aim
To study the prevalence of BMI and its correlation with thyroid disorders, female sex hormones and presence of endometrial hyperplasia.
Materials and methods
A single-center, retrospective, observational study included 250 women aged between 18-45 years. The anthropometric measurements, laboratory and outcomes data were compared.
Results
Additional statistical analysis included correlation matrix between several numeric variables (Table 1). Investigation the presence of association between seven numeric variables revealed six statistically significant correlations. Specifically, values of BMI negatively correlated with estradiol ($r=$-0.14) and T4 levels ($r=$-0.18). Also, a statistically significant positive correlation was detected between BMI and TSH variables ($r=0.21$). The strongest correlation was observed between LH and FSH levels ($r=0.77$). Elevation in values of LH corresponds to an increase in FSH levels. Estradiol levels possessed a low positive correlation with LH levels ($r=0.16$). The TSH is negatively related to T4 variable ($r=$-0.17). Lastly, the association between T4 and T3 levels entailed a moderate positive correlation ($r=0.6$). Moreover, 132 (84.08%) women with BMI >30 and 86 (95.56%) women with BMI <30.
Conclusion
Obesity in women is one of the prevalent global public health problem that crucial in all stages of women's life. Weight gain in women of reproductive age leads to a low estradiol level and, as a result, to ovulatory dysfunction, thus underweight women have an increased risk of experiencing early menopause. We suggest that the relationship between obesity, low estradiol, thyroid disorders are bidirectional. All values are three common conditions and there is an intriguing relationship between these entities, of course, further investigation is warranted in this field.

Predictive factors of infertility among patients with polycystic ovary syndrome

Mouna Elleuch, Hamdi Frikha, Molka Triki, Dhoha Ben Salah, Trigui Souleima, Nadia Charfi, Mouna Mnif, Fatma Mnif, Nabila Rekik Majdoub, Faten Haj Kacem Akid & Mohamed Abid
Hedi Chaker University Hospital, Department of Endocrinology

Introduction
Polycystic ovary syndrome (PCOS) is occurring in approximately one in seven women. Infertility is a major issue in PCOS. Recognizing patients with higher risk of infertility is still a matter of debate.

Table 1 Correlation of BMI level with clinical/biochemical variables.

	BMI	Estradiol	LH	FSH	TSH	T4	T3
BMI	1.0000						
Estradiol	-0.1383*	1.0000					
LH	0.0047	0.1640*	1.0000				
FSH	0.0331	-0.1180	0.7730*	1.0000			
TSH	0.2053*	0.0365	-0.0725	-0.0545	1.0000		
T4	-0.1847*	-0.0024	-0.0461	-0.0626	-0.1716*	1.0000	
T3	0.0454	-0.0421	-0.0155	-0.0129	-0.0742	0.5987*	1.0000

BMI, body mass index; LH, luteinizing hormone; FSF, follicle-stimulating hormone; TSH, thyroid stimulating hormone; T4, free thyroxine
*$P<0.05$

Aim
Study the predictive factors of female infertility in patients with PCOS
Methods
A retrospective, single-center, comparative and analytical study including patients with PCOS followed at the endocrinology department of Hedi Chaker University Hospital of Sfax, Tunisia. G1 included PCOS patients with inability to conceive and G2 included fertile PCOS patients.
Results
We compared two groups. Of whom 30 had fertility issues (G1). And 20 fertile patients. Age was comparable between the two groups. Using univariate analysis, G1 patients had higher frequency of menstrual disturbances (87.2% vs 63.6% $P=0.04$) and obesity rates (66% vs 40.7%; $P=0.035$). Other comorbidities, PCOS features, metabolic and hormonal parameters did not significantly differ between the two groups. Using multivariate analysis, PCOS phenotypes ($P=0.04$; OR = 1.2 ;CI [1.01-1.4]), menstrual disturbances ($P=0.01$, OR = 2.1, CI[1.2-2.4]) and BMI ($P=0.045$; OR = 1.12; CI[1.1-1.4]) were significantly associated with poor fertility outcomes.
Discussion & Conclusion
PCOS is one of the most common infertility causes due to its strong association with hyperandrogenism and dysovulation. In a large, multicenter study Rausch *et al*. found that BMI, hirsutism score and duration of attempting conception were the main predictors of fertility outcomes. Rafique *et al*. were able to construct an infertility risk score for patients with PCOS that featured age, BMI, oligo/anovulation, androgen excess and ovary volume on transvaginal sonography as the major conception failure determinants. In conclusion, every PCOS patient should be assessed and counseled regarding fertility derangements using a personalized approach.

Searching For The Testicles: A Medical Mystery?

Sabina Maria Dumitrache[1], Raluca Stan[2], Iustina Grosu[1], Ana Zubaci[3], Marina Iliescu[3], Mihaela Tarna[3], Alexandra Mirica[4], Luminita Nicoleta Cima[1] & Luminita Cima[1]
[1]Spitalul Universitar de Urgen? Elias, Endocrinology, Bucure?ti, Romania; [2]Spitalul Universitar de Urgen? Elias; [3]Spitalul Universitar de Urgen? Elias, Bucure?ti, Romania; [4]Spitalul Clinic de Urgen? pentru Copii Grigore Alexandrescu, Endocrinology, Bucure?ti, Romania

Introduction
Cryptorchidism is unilateral or bilateral absence of the testes from the scrotum. One of the differential diagnosis is congenital bilateral anorchia. Vanishing testes syndrome is associated with low serum AMH concentrations and an absent or subnormal response to stimulation with hCG. We report the case of a 22-year-old boy diagnosted with bilateral cryptorchidism and hypergonadotropic hypogonadism at the age of 17 years old. At the time of diagnosis the scrotum was empty and we could notice the failure of secondary sexual development (no pubic and axillary hair was present). The laboratory tests showed a low total testosterone = 0.11ng/ml, low free testosterone with elevated FSH = 37.30mUI/ml and LH = 14.2mUI/ml and beta-hCG. Altough congenital bilateral anorchia is quite rare, it must be distinguished from bilateral cryptorchidism. The most commonly used test is measurment of AMH, in our case: AMH < 0.010 ng/ml. The laboratory tests showed discordant values of Inhibin B: low/normal. To evaluate the testicular function, beta-hCG stimulation test was performed and the result was negative. Also, the pacient unterwent a spermiogram revealing aspermia. The patient performed multiple imaging investigations (repeated ultrasound scans, abdominal and pelvis MRI, abdominal and pelvis CT) that couldn't identify the gonads. The imaging investigations were completed with chromosomal analysys which disclosed a 46XY karyotype (Klinefelter syndrome being thus excluded). Together with the urologist, we decided to monitorize beta-hCG values and undergo an exploratory laparoscopy when the value will be five times upper high. The pacient started treatment with transdermic testosterone that was replaced after 1 year with intramuscular testosterone
Conclusions
Altough vanishing testes syndrome is extremly rare, it must be differentiated from bilateral cryptorchidism, a much more common disorder that can be complicated by testicular germ cell neoplasm if not healed in early childhood. At the same time, it must be emphasized the importance of self-examination and complete physical exam of the genital development from an early age.

HAIR-AN syndrome: about a case

Debbah Wissam, Mouna Mezoued, Bessaid Khadidja & Malha Azzouz
Bologhine Hospital, Endocrinology, Alger, Algeria

Introduction
HAIR-AN syndrome is a rare condition, which can affect up to 5% of women with hirsutism. It is formed by the initials of the following clinical entities: HyperAndrogenism (hyperandrogenism), Insulino-Resistance (insulin resistance) and Acanthosis Nigricans. It is therefore a clinical triad that is considered as a severe subtype of PCOS, characterized by insulin resistance that appears early, constant and major. We present the case of a patient with Hair-an syndrome.
Observation
This is a 19-year-old adolescent girl presenting a primary amenorrhea with a progressive hirsutism at 13 years old. This hirsutism as scored 36 in ferriman and gallwey associated with acne as well as Acanthosis nigricans, without abnormal pubertal development. Hormonal assessment showed severe hyperandrogenism with a testosterone level of 3.32 ng/ml and an SDHEA level of around 525 µg/dl (N) as well as a delta 4 androstenedione (2.41 ng/ml) and 17OHP (1.44 ng/ml) within the standards. E2 at 203 pmol/l, FSH: 4.36 ui/l, LH: 6.8 ui/l are normal. Biologically: hyperinsulinism at 97.51 µ IU/ml was objectified, as well as diabetes discovered during an OGTT. Morphologically: The pelvic ultrasound shows pubescent-looking female OGI with a large dystrophic ovary 2-10 g, without tumor process, as well as an abdomino-pelvic CT scan that returned without abnormality. Given the above features, the diagnosis of hyperandrogenism-insulin resistance-acanthosis nigricans syndrome (hairan syndrome) is made.
Conclusion
HAIR-AN syndrome is an extreme form of PCOS. It is necessary to know how to evoke it in front of a clinical picture of severe hirsutism in the presence of acanthosis nigrigans.

Do we know how to supplement selenium in pregnancy to provide a proper micronutrient status for mother-newborn pairs?

Dorota Filipowicz[1], Ewelina Szczepanek-Parulska[1], Lutz Schomburg[2] & Marek Ruchała[1]
[1]Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Medicine, Poznań, Poland; [2]Charité - Universitätsmedizin Berlin, Institute for Experimental Endocrinology, Berlin, Germany

Background
Selenium (Se) sufficiency is beneficial for thyroid metabolism and pregnancy course due to its antioxidant and anti-inflammatory properties. As a part of selenoenzymes, it ameliorates autoimmune thyroid disease (AITD) progression in mothers and provides proper neurogenesis in fetuses. Despite lacking or conflicting recommendations for its supplementation in pregnancy, Se is used in a clinical setting, as a common constituent of multivitamin pregnancy diet supplements.
Objectives
The aim of the study was to evaluate Se supply and real-life supplementation effectiveness in pregnancy, based on Se biomarkers assessment in mothers and their newborns.
Methods
115 mother-child pairs were recruited at term delivery from obstetric department in one Polish centre. By the medical interview Se supplementation during pregnancy was assessed. The blood was collected before childbirth in mothers and during the third phase of delivery from the newborns' cord blood. Se status was assessed by measuring serum Se with Total Reflection X-ray Fluorescence analysis (on TXRF spectrometer S4 T-STAR) and selenoprotein P (SELENOP) with colorimetric enzyme immunoassay (selenOtest) concentrations and glutathione peroxidase 3 (GPX3) activity with a coupled enzymatic assay with t-butyl hydroperoxide as a substrate. This research was funded by National Science Centre in Poland (2019/33/N/NZ5/02303) as PRELUDIUM-17 grant.
Results
Se intake was declared by 30% of women, using multi-micronutrient supplements, with a mean Se dosage ($\pm$ SD) of 42 $\pm$ 14 µg/day. The whole group was deficient in Se in 89% (Se < 70 µg/l) and SELENOP in 77%. Median serum Se (54 vs. 58 µg/l), SELENOP (2.2 vs. 2.3 mg/l), or GPX3 (199 vs. 208.5 U/l) concentrations were slightly but not significantly higher in the supplemented than non-supplemented group. However, in the subgroups of low (< 55 µg/day) and moderate ($\geq$ 55 µg/day) daily Se dosage, median SELENOP was significantly higher in the latter group (1.84 vs. 3.17 mg/l, $P=0.006$).

Additionally, positive correlations of Se ($r=0.4$, $P<0.001$) within mother-newborn pairs and SELENOP ($r=0.78$, $P<0.001$; $r=0.72$, $P<0.001$), GPX3 ($r=0.78$, $P<0.001$; $r=0.53$, $P<0.001$) with Se between mothers and newborns adequately was observed.

Conclusions

Se supplementation from pregnancy multivitamin formulas was ineffective in the presented cohort. The mothers' Se supply reflects Se bioavailability for newborns. Considering diversity in geographical Se stores, differences in diet and individual Se level, no common guidelines can be applied worldwide, thus, there is a need of local Se status verification and adjusted recommendations.

Protein kinase B (Akt) blockade inhibits LH/hCG-mediated 17,20-lyase, but not 17α-hydroxylase activity of CYP17a1 in mouse Leydig cell steroidogenesis

Elia Paradiso[1], Clara Lazzaretti[1], Samantha Sperduti[1,2], Beatrice Melli[3], Carmela Perri[1], Sara D'Alessandro[1,3], Lara Baschieri[1,3], Elisa Mascolo[1], Neena Roy[1], Manuela Simoni[1,2,4] & Livio Casarini[1,2]

[1]Unit of Endocrinology-University of Modena and Reggio Emilia, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy; [2]University of Modena and Reggio Emilia, Center for Genomic Research, Modena, Italy; [3]University of Modena and Reggio Emilia, International Ph.D. School in Clinical and Experimental Medicine (CEM), Modena, Italy; [4]Azienda Ospedaliero-Universitaria di Modena, Department of Medical Specialties, Baggiovara Hospital, Modena, Italy

Androgens are sex steroid hormones fundamental for human reproduction. In males, they are produced upon luteinizing hormone (LH) action through its specific receptor (LHCGR) expressed in Leydig cells, supporting spermatogenesis. The human chorionic gonadotropin (hCG), acting on the same receptor but not expressed in men, is administered to improve testosterone synthesis in specific pathological contexts, such as hypogonadotropic hypogonadism and cryptorchidism. *In vitro* studies demonstrated that LHCGR mediates hormone-specific signaling patterns. In particular, LH mediates survival events in human ovarian cells, specifically induced via protein kinase B (AKT) phosphorylation, while hCG is relatively weak in inducing the same effect. We investigated the role of protein kinase B (Akt) in the modulation of Δ4 steroidogenic enzymes' activity, in the mouse Leydig tumor cell line (mLTC1). Cells were treated for 0-24 h with the 3-times 50% effective concentration of LH and hCG, in the presence and in the absence of the specific Akt inhibitor 3CAI. Cell signaling analysis was performed by bioluminescence resonance energy transfer (BRET) and Western blotting, while the expression of key target genes was investigated by real-time PCR. The synthesis of progesterone, 17α-hydroxy (OH)-progesterone and testosterone was measured by immunoassay. Control experiments for cell viability and caspase 3 activation were performed as well. We found that both hormones activated cAMP and downstream effectors, such as extracellularly-regulated kinase 1/2 (Erk1/2) and cAMP response element-binding protein (Creb), as well as Akt, and the transcription of *Stard1*, *Hsd3b2*, *Cyp17a1* and *Hsd17b3* genes, boosting the Δ4 steroidogenic pathway. Interestingly, Akt blockade decreased selectively *Cyp17a1* expression levels, inhibiting its 17,20-lyase, but not the 17-hydroxylase activity (Kruskal Wallis test and Dunn's post-test; $P<0.05$; $n=9$). This effect is consistent with lower Cyp17a1 affinity to 17α-OH-progesterone than progesterone. As a result, cell treatment with 3CAI resulted in 17α-OH-progesterone accumulation at 16-24 h and decreased testosterone levels after 24 h (two-way ANOVA and Bonferroni post-test; $P<0.05$, $n=16$). In conclusion, in the mouse Leydig cell line mLCT1, we found substantial Akt dependence of the 17,20-lyase activity and testosterone synthesis. Our results indicate that different intracellular pathways modulate selectively the dual activity of Cyp17a1.

Gender Affirming Hormonal Treatment (GAHT) and Demographics of Slovenian Transgender Adults

Katarina Mlekus Kozamernik[1,2] & Tina Krokter Kogoj[1,2]

[1]University Medical Center Ljubljana, Endocrinology, Ljubljana, Slovenia; [2]Faculty of Medicine, Ljubljana, Slovenia

Introduction

The number of individuals seeking gender-affirming hormonal treatment (GAHT), as well as the ratio between transgender men and transgender women, has increased over the past two decades. The type of GAHT varies significantly among different countries due to differences in availability and reimbursement policies. We aimed to analyze the kinds of GAHT and demographic characteristics of transgender adults at our endocrine clinic, the only center caring for transgender adults in Slovenia.

Methods

A retrospective analysis of the baseline demographic characteristics and GAHT type of transgender adults at our endocrine clinic from 2016 to 2022 was performed.

Results

From January 2016 until December 2022, 141 transgender adults (66 transgender women and 75 transgender men) were examined at our clinic. Transgender men were significantly younger at their first visit, with average age of 24.11 (6.51) vs. 31.35 (10.34) years for transgender women; $P<0.01$. The baseline BMI did not differ significantly between the two groups: for transgender men, BMI was 23.96 (5.61) kg/m^2 vs. transgender women 23.25 (4.24) kg/m^2. Transgender men use transdermal testosterone in 25% and depo testosterone undecanoate in 52%. We have lost follow-up for 10%, and 13% haven't started with testosterone therapy yet. Transgender women use anti-androgen treatment in 53% (25% have already had gender-affirming surgery, 10% haven't started with treatment yet, we have lost follow-up for 8%, and 6% refuse to use antiandrogen therapy). Half (54%) use cyproterone acetate, 42% spironolactone, and only one uses GnRH agonist. As for estrogen therapy, 56% of transgender women use peroral estradiol, 31% transdermal estradiol, and 13% intramuscular estradiol valerate.

Conclusion

Our analysis shows a slight predominance of transgender men receiving GAHT in Slovenia. They are significantly younger than transgender women when they first seek GAHT. At baseline, transgender men do not differ in BMI from transgender women. More than half of transgender men use intramuscular depo testosterone. About the same number of transgender women use cyproterone acetate and spironolactone as antiandrogen therapy. Over half of transgender women use peroral estradiol, and about a third use transdermal estradiol. So far, only a minority use intramuscular estradiol valerate.

Auto-immune diseases in Turner syndrome

Faten Haj Kacem Akid, Oumeyma Trimeche, Mouna Mnif, Rihab Khochtali, Dhoha Ben Salah, Mouna Elleuch, Mnif Fatma, Nadia Charfi, Nabila Rekik Majdoub & Mohamed Abid

Hedi Chaker Hospital, Endocrinology, Sfax, Tunisia

Introduction

Turner syndrome (TS) is a genetic disease, attributable to the total or partial loss of an X chromosome. The classic phenotype encompasses short stature, hypergonadotropic hypogonadism and dysmorphic features. It's also associated with other conditions such as autoimmune (AI) diseases.

Aim

Herein we aim to determine the frequency of AI diseases in TS and to identify the genetic variants of TS mostly associated with this latter condition.

Methods

We conducted a retrospective descriptive study. We collected the medical records of patients who had a turner syndrome and consulted our Endocrinology department at the Hedi Chaker University Hospital in Sfax, Tunisia, between 1990 and 2021. We included patients who had the cytogenetic confirmation of TS.

Results

The total number of our patients was 45. The mean age of diagnosis was 16 years with extremities varying from 3 months to 44 years. The majority of our patients were diagnosed between the age of 14 and 20 years (44. 2%). The most frequent karyotype among the patients with TS was X monosomy (49%). Mosaic forms without structural abnormalities of the X chromosome were found in 31 % whereas mosaic karyotype with structural abnormalities represented only 20 %. A total of 11 patients had auto immune diseases (24.4%), predominantly represented by disorders of thyroid gland (72.2 %). In fact, seven patients had hypothyroidism while only one had hyperthyroidism related to Graves' disease. The other AI diseases identified in our cohort were: alopecia areata, rheumatoid arthritis, Behcet disease and psoriasis, found in one case each. AI diseases were mostly seen in patients with monosomy of X: 22.4% vs 17.4% in mosaic forms ($P=0,72$). Particularly, it was the mosaic variants with structural abnormalities of the X chromosome who were prone to develop AI conditions when comparing it with those without structural variants of the X chromosome: 20% vs 15.4%.

Conclusion

Patients with TS are prone to develop AI conditions as demonstrated by our study and thus a systematic clinical as well as biological screening oh these conditions should be conducted at least on an annual basis.

DOI: 10.1530/endoabs.90.P445

Delineating molecular mechanisms involved in hypo- and hyper-prolactinemia affecting male fertility

Sanketa Raut, Kushaan Khambata & Nafisa Balasinor
ICMR-National Institute for Research in Reproductive and Child Health, Neuroendocrinology, Mumbai, India; ICMR-National Institute for Research in Reproductive and Child Health, Gamete Immunobiology, Mumbai, India

The endocrine system is crucial in spermatogenesis and any hormonal alterations may affect fertility. Prolactin (Prl) plays a role in male reproduction, as evidenced by presence of prolactin receptors on various testicular cells. However, the exact mechanism and physiological role of testicular prolactin receptor during spermatogenesis remains elusive. Clinical conditions such as hyper- and hypo-prolactinemia are known to have deleterious effects on male reproduction. The aim of this study is to delineate the mechanisms by which hyper- and hypo-Prl affects male fertility. *In vivo* male rat model for hyper- and hypo-Prl was established using dopamine receptor antagonist (Fluphenazine) and agonist (Bromocriptine), respectively. Treatment with fluphenazine (hyper-Prl) and bromocriptine (hypo-Prl) for 60 days results in a significant decrease in fertility as compared to control male rats. This subfertility was due to an increase in pre- and post-implantation loss and a concomitant decrease in litter size when mated with control female rats. There was also a significant increase in the time taken for copulation after fluphenazine treatment. A significant reduction in sperm counts was observed in both the treatments. Sperm motility was found to be reduced significantly in hyper-Prl. Hormonal analysis revealed that LH, FSH, testosterone, and estrogen are significantly decreased in hyper-Prl group. In hypo-Prl group, LH and FSH were significantly increased, whereas testosterone and estrogen remained unaffected. Further, analysis of differential germ cell population by flow cytometry revealed that hyper-Prl group showed significant reduction in elongated and elongating spermatids and a concomitant increase in round spermatids indicating an arrest in differentiation of round to elongated spermatids. Additionally, these findings were confirmed by expression of cell-type specific markers by qPCR. To further delineate the molecular mechanisms underlying hyper-Prl v/s hypo-Prl, transcriptome analysis to study testicular gene expression was carried out. Differentially expressed genes obtained were subjected to gene ontology, pathway analysis, and enrichment map analysis. In conclusion, the results of this study demonstrate that altered levels of prolactin can have deleterious effects on different aspects of male fertility. It also suggests that the detrimental effects of hyper-Prl are more profound than hypo-Prl. Hyperprolactinemia could be one of the factors of idiopathic male infertility and routine screening of prolactin levels in infertile males should be recommended.

Influence of ovulation, anovulation and progestin on Phoenixin-20 and Nesfatin-1 in patients with polycystic ovary syndrome (PCOS)

Julia Schommer[1], Susanne Weber[2], Olga Sydorivska[1], Lisa Emmer[1], Peter Luppa[2] & Vanadin Seifert-Klauss[1]
[1]Klinikum rechts der Isar der Technischen Universität München, Department of Gynecology and Obstetrics, München, Germany; [2]Klinikum rechts der Isar der Technischen Universität München, Institute of clinical chemistry and pathobiochemistry, München, Germany

Polycystic Ovary Syndrome (PCOS) is the most common endocrinological dysfunction among women of reproductive age, often featuring hyperandrogenemia and anovulation. Reciprocal effects exist between elevated LH, androgens, anovulation and other features, increasing the hormonal disbalance, while the origins of PCOS are still not fully clear. The neuropeptides Phoenixin-20 (PNX20) and Nesfatin1 (NES1) are being co-expressed and thought to play opposing roles in the hypothalamic–pituitary–gonadal axis. PNX20 seems to regulate pituitary LH secretion and to be elevated in PCOS. NES1 is involved in metabolism and inflammation. This study characterized changes of PNX20 and NES1 within cycles of PCOS patients with anovulation, ovulation and progestin administration.

Methods

Women of reproductive age with PCOS, diagnosed according to the Rotterdam Criteria were included in this observational study after informed consent. All women had a clinical indication for a progestin test, conducted with 10 mg dydrogesterone daily for 14 days in the second half of the first menstrual cycle. For observational purposes 5 blood samples were taken from each participant, on day 3 - 7 of the menstrual cycle and 14 - 19 days later, spanning two and a half consecutive menstrual cycles – one under dydrogesterone and 1.5 cycles thereafter. Follicle stimulating hormone (FSH), luteinizing hormone (LH), estradiol, progesterone, testosterone, dehydroepiandrosterone-sulfate (DHEAS), prolactin, and sexual hormone binding globulin (SHBG) were measured.

Results

40 complete cycles in 26 patients were analyzed. 20 cycles were anovulatory, 20 ovulatory-marked by a progesterone increase over 5.8 ng/ml. A linear association was found between PNX20 and LH levels and significant ($P<0.05$) differences in anovulatory cycles were noted between follicular phase (mean PNX20 = 1.89 ng/ml ± 1.16 ng/ml) and the second half of the cycle (mean PNX20 = 2.90 ng/ml ± 1.52 ng/ml). Pearson's coefficient between progesterone and PNX20 was -0.551 ($P<0.05$). In the follicular and luteal phase of ovulatory cycles, the difference was not significant. By contrast, NES1 levels only differed significantly between phases of ovulatory cycles (mean follicular NES1 = 1.83 ng/ml ± 1.20 ng/ml, mean luteal NES1= 2.16 ng/ml ± 1.22 ng/ml). Exogenous progestin administration at the dose administered had no significant influence on PNX20 or NES1 levels. We conclude that endogenous progesterone and/or ovulation itself may be important modulators of PNX20 and NES1. This opens different explanation models as to why PNX20 is elevated amongst PCOS patients.

Persistent effects of anabolic, androgenic steroids on muscle mass and strengths years after cessation?

Niels Høeg Brandt-Jacobsen, Jeppe Fredberg, Jon Rasmussen, Yeliz Bulut & Caroline Kistorp
Rigshospitalet, Department of Medical Endocrinology, København, Denmark

Objective

The use of anabolic, androgenic steroids (AAS) to increase muscle mass and strength has become widespread among younger men engaged in recreational strength training. Although, repercussions exist for elite athletes with a ban of two to four years, the long-term effects on muscle mass following cessation are currently unknown. The present study aims to investigate previous users' ability to retain lean mass and strength after long-term AAS cessation.

Design and methods

A cross-sectional study of men involved in strength training, including current and previous users of AAS, and recreational athletes with no prior use of AAS (controls). Lean body mass was assessed by dual-energy X-ray absorptiometry (DXA). Strength was assessed by one repetition max (1RM) bench press and leg press performed under controlled laboratory settings. Standardized questionnaires were used to assess AAS use, and blood was drawn, measuring serum total and free testosterone using liquid chromatography mass spectrometry.

Results

We included 40 participants (14 current, 11 previous, and 15 controls with no AAS use). The mean (SD) age was 31.3 (6.8) years, with no differences between groups (0.920). The median (IQR) length of AAS use was 149.5 (104-208) vs. 48 (24-186) weeks for current and previous users ($P=0.049$). Median (IQR) time since cessation was 5.0 (1-14) years among previous users. As expected, free testosterone levels were increased in current AAS users ($P=0.017$), while no difference was observed among previous users ($P=0.332$) and controls (median (IQR): 1.7 (0.5-3.1) vs. 0.4 (0.4-0.5) vs 0.6 (0.5-0.7) nmol/l). Interestingly, lean mass of the upper extremities was higher in both current ($P=0.010$) and previous users ($P=0.021$) compared with controls (12.4 vs. 12.3 vs. 10.8 kg). In contrast, no difference in lean mass was observed for the lower extremities ($P=0.200$). Strength performance in 1RM leg press was significantly higher in current users ($P=0.015$), while a benefit was suggested in previous users ($P=0.068$) as compared with controls (367 vs. 279 vs. 235 kg). Accordingly, current, and previous users showed a tendency towards outperforming controls in 1RM bench press with (133 vs. 136 vs. 111 kg)($P<0.010$).

Conclusion

Previous users showed compartmentally increased lean body mass and a tendency towards greater strength even 5 years after discontinuation of AAS when compared with controls, mirroring findings among current users. The suggested ability to retain an increase in lean mass following AAS use may translate to retaining an advantage in competitive settings.

Maternal cortisol levels in 3rd trimester and early language development, a study of 1,093 mother-child pairs from Odense Child Cohort

Hanne Mumm[1], Anja Fenger Dreyer[1,2], Dorthe Bleses[3], Dorte Glintborg[1,2], Tina Kold Jensen[4,5,6], Henriette Boye[4,6], Fabio Trecca[3] & Marianne Andersen[1,2]

[1]Odense University Hospital, Department of Endocrinology, Odense, Denmark; [2]University of Southern Denmark, Department of Clinical Research, Faculty of Health Sciences, Odense, Denmark; [3]Aarhus University, TrygFonden's Centre for Child Research and School of Communication and Culture, Aarhus V, Denmark; [4]Odense University Hospital, Odense Child Cohort, Hans Christian Andersen Hospital for Children, Odense C, Denmark; [5]University of Southern Denmark, Department of Clinical Pharmacology, Pharmacy and Environmental Medicine, Odense, Denmark; [6]University of Southern Denmark, OPEN Patient data Explorative Network (OPEN), Odense, Denmark

Background
Language development during early childhood is considered an important marker of fetal neurodevelopment. Prenatal cortisol exposure plays a critical role in maturation of the fetal brain; however, the effect on offspring language development needs further investigation. This study aimed to evaluate the association between maternal 3rd trimester cortisol and early longitudinal offspring language development and to test whether there was sex differences in the association.
Design
Prospective observational study.
Setting
Odense Child Cohort.
Patients
The study cohort included 1,093 mother-child dyads (570 boys and 523 girls).
Intervention
Fasting morning serum (s-) cortisol was collected from 3rd trimester (gestational week 26-28) pregnant women and measured by liquid chromatography–tandem mass spectrometry.
Main Outcome Measures
Offspring receptive and productive vocabulary assessments by MacArthur-Bates Communicative Development Inventories parent reports were completed every third month from child age 12 to 37 months.
Results
Levels of cortisol were higher in women carrying a girl (858 $\pm$ 214 nmol/l) than in women carrying a boy (820 $\pm$ 222 nmol/l). Higher 3rd trimester maternal cortisol levels showed a positive association with development of productive vocabulary in boys at age 12-21 months ($OR = 1.23$, $SE = 0.07$, $P = .005$) and age 22-37 months ($OR = 1.09$, $SE = 0.06$, $P = .967$). Higher maternal cortisol levels in 3rd trimester were positively associated with receptive vocabulary in girls at 12-21 months-of-age ($OR = 1.16$, $SE = 0.05$, $P = .002$).
Conclusions
Maternal 3rd trimester s-cortisol levels were positively associated with early language development in children age 12-37 months.
Funding
Salary of presenting author Anja Fenger Dreyer is funded by the Novo Nordisk Foundation as part of a collaborative grant entitled 'DOUBLE EDGE – Characterization and mitigation of adverse effects of glucocorticoid treatment' (NNF20OC0063280).

Cardiovascular Events and Gender-Affirming Hormone Therapy, 10 Years of Follow-Up

Karla Mariaca Riveros[1], Veronica Martinez[2], Maria Claro[1], Clara Solá[1], Gloria Aranda[2], Felicia Alexandra Hanzu[1], Emilio Ortega[1], Aida Orois[1], Esther Gomez[2], Teresa Godas[2], Manel Mateu Salat[1], Irene Halperin[1] & Mireia Mora[1]
[1]Hospital Clínic de Barcelona, Endocrinology and Nutrition, Barcelona, Spain; [2]Hospital Clínic de Barcelona, Barcelona, Spain

Objectives
Most transgender persons (0.3-0.5% of total population) are under gender-affirming hormone therapy (GAHT). Several studies have reported an increased morbimortality due to cardiovascular events (CVE), infectious disease and suicide. However, these studies were made on small populations and short follow up. We evaluated the changes on anthropometric variables, risk factors for cardiovascular diseases (CVD) and CVE at 5 and 10 years of follow up in a transgender population followed in a Gender Identity Unit in Catalonia.
Methods
Retrospective longitudinal study including transgender people visited at the Hospital Clinic of Barcelona between 2006 and 2010. Anthropometric variables, analytical parameters, clinical data on hypertension, diabetes, dyslipidemia, thrombotic events (deep venous thrombosis (DVP) and pulmonary embolism), cerebrovascular events (stroke or transient vascular accident) and ischemic heart disease (heart attack, stable and unstable angina) were collected at baseline, 5 and 10 years together with the GAHT schedule. The events were compared with the Spanish ciswomen and cismen population age adjusted.
Results
248 transgender people were included, 60.9% transwomen (32.6$\pm$10.0y) and 39.1% transmen (28.8$\pm$8.4y). At 5- and 10- years follow-up body mass index, total cholesterol and LDL levels increased in both transmen and transwomen as well as triglycerides in transmen; $P<0.01$. Hypertension increased in transwomen and transmen at 10 years ($P<0.01$ and $P=0.02$, respectively). During follow-up, two DVTs, two ischemic events, and two strokes were reported in transwomen, with an incidence rate of 0.33 %-year (ciswomen, age range 27-60: 0.22%-year; cismen, age range 27-60: 0.36 %-year); one DVT was reported in transmen, an incidence rate of 0.10%- year (cismen, age range 27-35: 0.07 %-year; ciswomen, age range 27-35: 0.05%-year). Obesity was associated to cyproterone acetate in transwoman; and hypertension and dyslipidemia were associated to testosterone treatment. No person died.
Conclusion
These data suggest that there is a small increased risk of CVE in transwomen in comparison to ciswomen and no difference with cismen. In transmen, small increased risk of CVE in comparison to ciswomen was observed. However, no association was found with the regimen of GATH and low number of events and small population should be considered. Toxic habits are highly prevalent in our population (42% of transwomen and 60 % transmen in comparison with 16.4% of ciswomen and 23.3% of cismen in Spanish population). Recommendation of healthy lifestyle habits should be made. There are no previous data regarding CVE at 10 years of follow up in Spanish trans population.

Dysfunction of Estrogen Signaling as a Novel Molecular Signature of PolyCystic Ovary Syndrome

Clémentine Marie[1], Alice Pierre[1], Anne Mayeur[2], Frank Giton[3], Michaël Grynberg[2], Joëlle Cohen-Tannoudji[1], Celine Guigon[1] & Stéphanie Chauvin[1]
[1]Unité BFA UMR 8251, CNRS-Université Paris Cité, ERL Inserm U1133, Physiologie de l'Axe Gonadotrope, PARIS, France; [2]Hôpital Antoine Béclère, Service de Médecine de la Reproduction et Préservation de la Fertilité, Clamart, France; [3]Inserm IMRB U955,, Plateforme Spectrométrie de Masse, Créteil, France

Estradiol (E2) plays an essential role in woman fertility. E2, locally produced by granulosa cells (GCs) of ovarian antral follicles, controls follicular development and selection, and triggers the gonadotropin surge that leads to ovulation. Dysovulation arising from the arrest of antral follicle growth and maturation occurs in up to 10 % of reproductive-aged women suffering polycystic ovary syndrome (PCOS). Although the diagnostic criteria for PCOS are clearly established, the molecular etiology of this syndrome is still under debate. Given the high importance of E2 in follicular growth and selection, our study aimed at identifying the possible disturbances of E2 signaling, predominantly mediated by estrogen receptors ERα and ERβ, that could impact GCs steroidogenic function and participate in PCOS. For this purpose, we performed primary cultures of GCs from follicles of 30 patients undergoing *in vitro* fertilization either for male factor infertility (control) or for PCOS. First, we analyzed by RT-qPCR the expression level of the two transcription factors ERα and ERβ in GCs, and demonstrated that they exhibited the same level of expression in control and PCOS patients. Strikingly, E2 treatment significantly regulated the expression of genes involved in various biological processes (*steroid biosynthesis: Cyp19a1 and Cyp11A1; cell survival: Bcl-2*) in primary cultures of control GCs, whereas in PCOS cells, E2 was ineffective despite the presence of ERα and ERβ. Then, we characterized the steroidogenic activity of GCs from control and PCOS, by measuring steroid hormone concentrations in both cells and follicular fluids (FF) using GC/MS. Our analyses demonstrated that E2, pregnenolone (P5) and progesterone (P4) concentrations were significantly lower (by 27 %, 41 % and 45 % respectively) in PCOS FF when compared to control. They also revealed that contrary to P5, the reduction of concentrations of E2 and P4 in FF did not correlate with a decrease in their intracellular biosynthesis. Indeed, intracellular concentrations of E2 and P4 were similar in both groups, whereas that of P5 was significantly reduced (by 59 %) in PCOS, probably through the down-regulation of *Cyp11A1* expression that we observed. Altogether, our study provides a novel signature of PCOS by revealing an impairment in E2 signaling that may contribute to follicular growth

dysregulations. In addition, our results suggest the existence of a selective steroid degradation in FF of PCOS patients that may explain lower levels of anti-inflammatory steroids P4 and P5, and enhance the local ovarian inflammation contributing to unsuccessful oocyte maturation.

The relationship between steroidogenesis and healthy eating index in polycystic ovary syndrome

Tülay Omma[1], Yucel Cigdem[2], Murat Kızılgün[3,4], Seyma Osmanlıoglu Coskun[5], Fatmanur Humeyra Zengin[6] & Cavit Culha[7]
[1]Ankara Training and Research Hospital, Endocrinology and Metabolic Diseases, Ankara, Turkey; [2]University of Health Sciences, Gulhane Training and Research Hospital, Biochemistry, Ankara, Turkey; [3]Biochemistry, Ankara, Turkey; [4]University of Health Sciences, Gulhane Training and Research Hospital, Biochemistry, Ankara, Turkey; [5]Ankara Medipol University, Faculty of Medicine, Obstetrics and Gynecology, Ankara, Turkey; [6]Kastamonu University, Institute of Health Sciences, Nutrition and Dietetics, Kastamonu, Turkey; [7]University of Health Sciences, Ankara Training and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey

Aim
We aimed to examine the relationship between the healthy eating index (HEI) and steroidogenesis in polycystic ovary syndrome (PCOS) patients and healthy controls.
Materials and Methods
In addition to demographic records and routine biochemical tests, HEI was calculated from three-day nutritional records in the Bebis program. Adrenal steroidogenesis panel was measured by LCMS.
Results
The study included 50 women with PCOS and 42 healthy controls. The groups were matched in terms of age and BMI. Waist circumference and hip circumference were significantly higher in the patient group. Although there was no difference in terms of fasting blood glucose and hba1c, HOMA IR was statistically significantly higher in favor of the patient group. However, there was no difference between the groups in terms of HEI. In the steroidogenesis hormone panel, only total testosterone, dheas and 17OHP and 11 deoxycorticosterone were statistically different in favor of the PCOS group. There was a positive relationship between HEI and 11 deoxycortisol in the PCOS group, while a negative relationship was found in the control group. On the other hand, while there was a negative relationship between HEI and pregnenolone in the PCOS group, no relationship was found in the control group. The rest showed no correlation with HEI scores in either group.
Conclusions
Although PCOS patients have similar weight and nutrition patterns to healthy controls, they may have metabolic dysfunction. A healthy eating pattern may be likely to shift the axis of andogenesis to the side of the cortisol axis. Nutrition can play a major role in the management of these patients.

In between isolated premature thelarche and central precocious puberty: when DHEAS makes the difference

Giulia Rodari[1], Valentina Collini[2], Federico Giacchetti[1], Eriselda Profka[1], Maura Arosio[1,2], Giovanna Mantovani[1,2] & Claudia Giavoli[1,2]
[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milano, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milano, Italy

Background
Precocious puberty (PP) in girls is most frequently an idiopathic gonadotropin-releasing hormone (GnRH)-dependent PP, being thelarche the typical first sign. It is well established that increased dehydroepiandrosterone sulphate (DHEAS) levels are associated with premature adrenarche and may characterize PP too. However, its relationship with signs of hypothalamic-pituitary-gonadal (HPG) axis activation and oestrogen exposure is still to be elucidated.
Aims
Assessing the association between DHEAS levels and other parameters of HPG activation in girls with precocious thelarche.
Methods
At this aim, 60 girls (median chronological age-CA 7.8 years, range IQ 7.0-8.3) referring to our Endocrine Clinic for suspected PP were consecutively enrolled. In all patients the following data were collected: basal and stimulated (GnRH test at 2.5 mg/kg) LH and FSH levels, basal ACTH, cortisol, DHEAS, androstenedione, testosterone, 17-α hydroxyprogesterone, 17-βoestradiol levels, pelvic ultrasound (US) and hand and wrist X-ray for bone age (BA) assessment.
Results
Median DHEAS values were 506 mg/l (range IQ 265-872), 0.77 SDS (range IQ -0.72-2.15), being >2 SDS in 19/60 patients. In all patients, other adrenal function tests were in the normal range. Out of 60 girls, 27 showed a pre-pubertal response to GnRH test (LH <5 mIU/l). Higher DHEAS levels were found in this group vs girls with pubertal LH peak (2.07 SDS, range IQ 0.09-2.76 SDS vs -0.07 SDS, range IQ -0.87-1.28 SDS, $P=0.004$). At logistic regression DHEAS SDS was negatively associated with LH response to GnRH test ($P=0.006$). Similarly, at multiple regression, DHEAS values were negatively associated with LH peak ($P=0.04$) and oestradiol levels ($P=0.04$). Patients with elevated DHEAS concentrations showed higher levels of testosterone ($P=0.04$) and androstenedione ($P=0.02$). No other differences were found between the two groups regarding clinical presentation, pelvic US and BA.
Conclusion
In the presence of signs of HPG axis activation and oestrogen exposure, pubertal GnRH test response confirms PP. Our data suggest that elevated DHEAS concentrations, in the absence of HPG axis activation, may drive estrogenization signs. Indeed, an oestrogen receptor concentration-dependent transactivity action of DHEAS has already been described in *in vitro* studies. Moreover, this condition can be different from a mere normal variant of PP thus requiring an appropriate follow-up and eventual therapeutic approach. Further studies are needed to support our findings and to insight into their impact in patients' management.

Effect of selective oestrogen receptor modulators/aromatase inhibitors on semen parameters in men with secondary hypogonadism; systematic review and meta-analysis

Nipun Lakshitha de Silva[1], Harsha Dissanayake[2], Camila Suarez[3], R. E. Wickramarachchi[1], Ranjith Ramasamy[3], Waljit Dhillo[4], Suks Minhas[5], Giovanni Corona[6] & Channa Jayasena[4]
[1]Faculty of Medicine, General sir John Kotelawala Defence University, Clinical Sciences, Colombo, Sri Lanka; [2]Faculty of Medicine, University of Colombo, Clinical Medicine, Colombo, Sri Lanka; [3]Desai Sethi Urology Institute, Miller School of Medicine, University of Miami, Miami, United States; [4]Faculty of Medicine, Imperial College, Department of Metabolism, Digestion and Reproduction, London, United Kingdom; [5]Imperial College NHS Healthcare, Urology, London, United Kingdom; [6]Azienda USL, Maggiore-Bellaria Hospital, Endocrinology Unit, Medical Department, Bologna, Italy

Introduction
Selective oestrogen receptor modulators (SERMs) and aromatase inhibitors (AIs) potentially increase endogenous gonadotrophin and testosterone secretion in men. They are used off-label in men with hypogonadism and/or infertility. There is a lack of guidance on using these agents in men with secondary hypogonadism, though these agents are widely used in these people as a cheaper alternative to gonadotrophins.
Methods
Systematic search was conducted in PubMed, MEDLINE, Cochrane library and ClinicalTrials.gov for randomised controlled trials (RCTs) and non-randomised studies of intervention (NRSI) reporting SERM and/or AI effects on semen parameters or fertility in men with secondary hypogonadism (PROSPERO-CRD42022306535). Study selection and data extraction were performed by two reviewers independently. The risk of bias (ROB) was assessed using ROB-2 and ROBINS-I tools. Results of RCTs were summarised using vote counting while summarising effect estimates where available. NRSI meta-analysis was conducted using the random-effect model. Certainty of evidence was assessed using GRADE.
Results
Five NRSIs ($n=105$) of SERMs showed an increase in sperm concentration [pooled mean difference 6.64 million/ml; 95% CI 1.54, 11.74] and three NRSIs ($n=3$) of SERMs showed an increase in total motile sperm count [pooled mean difference 10.52; 95% CI 1.46-19.59], with very low certainty of evidence due to critical ROB. All participants had infertility, however, the aetiology of hypogonadism was not specified in four studies and the mean BMI of participants in those studies was >30 kg/m^2. All three RCTs ($n=275$) comparing SERMs to testosterone gel showed the benefit of SERMs on sperm concentration. Four RCTs ($n=591$) comparing SERMs to placebo showed a heterogeneous effect on

sperm concentration. Three RCTs included men with overweight/obesity, whereas participants in the other studies also had a mean BMI >28 kg/m^2. Results were of very low/low certainty of evidence due to the high ROB. Limited pregnancy or live birth data were available. No AI data on sperm parameters or fertility compared placebo or testosterone were found. Single cases of fatal stroke and venous thromboembolism were associated with SERMs and AIs, respectively; however, no causality could be established.
Conclusions
Current studies are of limited size and quality but suggest that SERMs may improve semen quality in men having low testosterone with low/normal gonadotrophins, particularly when associated with obesity. Well-designed, randomised studies recruiting men with a clear diagnosis of secondary hypogonadism are needed to determine whether SERMs improve spermatogenesis and live-birth rates in couples affected by secondary hypogonadism.

Decreased Quality of Life in Previous Users of Anabolic Androgenic Steroids Years After Cessation

Yeliz Bulut, Niels Brandt-Jacobsen, Caroline Kistorp & Jon J. Rasmussen
Rigshospitalet, Copenhagen University Hospital, Department Of Endocrinology, Copenhagen, Denmark

Background and Aim
Use of anabolic androgenic steroids (AAS) has moved from elite sports to the broader population. Studies suggest that AAS cessation is often associated with immediate various AAS withdrawal and hypogonadal symptoms. Quality of life using a standardized questionnaire has never been assessed in AAS users. The Short-Form 36 (SF-36) questionnaire is a highly validated and used instrument for assessment of quality of life. The questionnaire consists of a total eight subcategories divided into four physical health categories and four mental health categories. The objective of this study was to assess quality of life in current and previous illicit AAS users compared with healthy control participants who had never used AAS.
Methods
Community-based cross-sectional study including men involved in recreational strength training. SF-36 questionnaire was completed, history of AAS use was obtained using a standardized questionnaire and blood was drawn for measurement of serum total testosterone using liquid chromatography mass spectrometry.
Results
We included 89 current and 61 former AAS users and 30 healthy age-matched never users, as controls. The mean (SD) age of all participants was 34 (8) years. Accumulated duration of AAS use, was 163 (127;208) weeks among current users and 104 (78;138) weeks among former users, (P= 0.019). Duration since AAS cessation, was 50 (33;68) months and 45 (74%) former AAS users discontinued AAS use more than one year prior to inclusion. Previous AAS users displayed impaired quality of life on all eight SF-36 subcategories compared with the never users (P<0.001). Ongoing AAS users perceived their general health as impaired and displayed decreased social functioning compared with healthy controls (P<0.05), while quality of life did not differ between the two groups with respect to the other six categories. Mean (SD) serum testosterone was lower in previous AAS users 14 (6) nmol/l compared with healthy controls 19 (5) nmol/l (P=0,0002). In age-adjusted analyses of covariance, among former AAS users and non-AAS users, lower serum total testosterone levels were associated with impaired quality of life in all SF-36 subcategories, except bodily pain (P<0.05). The SF-36 score were not associated with accumulated duration of AAS use among current and former AAS users.
Conclusions
Previous AAS users exhibited impaired quality of life on all physical and mental health parameters years after AAS discontinuation, which may be related to lower serum testosterone levels in this group compared with non-users.

Nurse-Led Care for Transgender and Gender Diverse Individuals: A Cross-Sectional Study of International Context and Practice

Debra Greenspan[1], Bradley P. White[2], Eli G. Bobrowich[3], Paul Carruthers[4], Dallas Ducar[5], Camilla Ernstsson[6], Sophia Barrett[5] & Andrew Dwyer[2]
[1]Vanderbilt University School of Medicine, Endocrine / Transgender Health, Nashville, United States; [2]Connell School of Nursing, Boston, United States; [3]Massachusetts General Hospital, Transgender Health Program, Boston, United States; [4]Leeds Teahing Hospitals, NHS Trust, Northern Adolescent Gender Identity Centre, Leeds, United Kingdom; [5]Transhealth Northampton, Florence, United States; [6]Norrlands University Hospital of Umea, Umea, Sweden

Introduction
Gender minorities, including transgender and gender diverse (TGD) individuals face health disparities and significant barriers in accessing healthcare. Lack of access to providers knowledgeable in TGD health needs is the single greatest barrier to care. Existing literature on TGD care has almost exclusively focused on physicians and there is scant literature on the role of nurses. We aimed to describe exemplars of nurse-led TGD care internationally to better understand the structure, process, and outcomes of nurse-led TGD care as well as recommended best practices nurse-led TGD care.
Methods
This descriptive cross-sectional study used a convenience sample of nurse-led TGD clinics drawn from international endocrine nursing organizations. Identified clinics completed an online survey based on the Donabedian Model of quality care (structure, process, outcome). 'Structure' included a description of health system, guidelines used by the clinic, team composition/organization, and contextual medico-legal issues. Process assessed nursing roles/activities and perceived promoters/barriers to TGD care. Outcomes were assessed by identifying metrics employed by the clinics. Two independent investigators reviewed survey responses and collated descriptive findings in tables, used thematic analysis to identify salient features and themes, and validated the synthesis with respondents.
Results
Five established TGD clinics were identified from the United States (n=3), United Kingdom, and Sweden. Clinics were government funded (n=2), based within academic medical centers (n=2), and a free-standing community practice. Respondents included both registered nurses and advance practice nurses (nurse practitioners/nurse prescribers) who provide pediatric (n=2), adult (n=1), and care across the lifespan (n=2). Common 'structure' elements included: creating a welcoming environment, interprofessional team, and use of clinical guidelines. The 'process' of care was characterized by: commitment to a gender-affirming philosophy and person-centered care, emphasis on collaborative care/team communication, and dedicated time for case management. Few outcomes were measured (primarily client census). All clinics noted the importance of access to care, training clinicians/staff, and structured data collection methods as promoters of high-quality TGD care.
Discussion
Findings suggest nurses play an important role in increasing access to gender-affirming and person-centered care. Nursing care emphasizes interprofessional collaboration, health promotion, empowerment, and patient advocacy. We identify promoters and best practices based on expert opinion - yet more work is needed to establish evidence-based practices and nurse-sensitive outcome measures for TGD care.

Evaluation of Oxidative Stress Parameters and Serum Fetuin-A Levels in Patients with Polycystic Over Syndrome

Bedriye Gizem Tekin[1], Esma Gülsun Arslan Cellat[2], Suzan Tabur[2] & Seyithan Taysı[3]
[1]Gaziantep 25 December State Hospital, Internal Medicine, Gaziantep, Turkey; [2]Gaziantep University Faculty of Medicine, Endocrinology and Metabolism, Gaziantep, Turkey; [3]Gaziantep University Faculty of Medicine, Medical Biochemistry, Gaziantep, Turkey

Introduction
Polycystic ovary syndrome (PCOS) is characterized by hyperandrogenism, oligo-anovulation and/or polycystic ovary. Hypotheses such as genetic and environmental causes, disruption of the hypothalamo-pituitary-gonadal axis, insulin resistance, hyperinsulinemia and increased oxidative stress have been proposed to explain the etiopathogenesis of PCOS. In our study, we aimed to evaluate oxidative stress parameters and serum fetuin-A levels and to investigate their role in PCOS.
Materials and Methods
32 PCOS patients aged 18-40 years and 25 women without any known systemic disease were included in the study. After their systemic examination, body weights and heights were measured. In the first 3 days of their menstruation, following 8-10 h of fasting, a morning blood sample is taken and hormone profile

(FSH, LH, estradiol, progesterone, testosterone, DHEA-S, 17-hydroxyprogesterone, TSH, fT4), lipid profile (total cholesterol, HDL, LDL, TG), fasting glucose, HbA1c, insulin, liver and kidney function tests were studied. To investigate the role of oxidative stress in PCOS, the levels of oxidant substances Malondialdehyde (MDA), 4-hydroxynonenal (4HNE), peroxynitrite and Nuclear factor erythroid 2 (NRF2), which is considered as an indicator of the antioxidant system, were measured. Serum Fetuin-A levels were measured.
Results
It was shown that there was no statistically significant difference between the groups in terms of mean age, height, weight and body mass index. Insulin, fasting glucose, HbA1c levels and HOMA-IR values were found to be significantly higher in the PCOS group ($P=0.001$, $P=0.001$, $P=0.001$, $P=0.034$, respectively). Fetuin-A level did not differ significantly in both groups ($P=0.342$). Total cholesterol, HDL and triglyceride levels were found to be significantly higher in the PCOS group ($P=0.001$, $P=0.004$, $P=0.001$, respectively). MDA and 4HNE levels were found to be significantly higher in the PCOS group ($P=0.001$, $P=0.001$, respectively). Peroxynitrite levels were higher in all patients in the PCOS group, but there was no statistically significant difference between the groups ($P=0.546$). NRF2 levels was found to be significantly lower in the PCOS group ($P=0.018$).
Conclusion
In our study, PCOS was found to be associated with insulin resistance and dyslipidemia. This may pose a risk factor for metabolic complications and cardiovascular diseases. The fact that there was no significant difference between the groups in terms of fetuin-A levels indicates that additional studies are needed on the relationship between fetuin-A and insulin resistance. The fact that oxidative stress markers are high and antioxidant metabolites are low in PCOS patients may contribute to the determination of new strategies in the follow-up and treatment of long-term metabolic complications of this syndrome.

Association between androgen levels and SPISE index in patients with polycystic ovarian syndrome

Lena Radic[1], Sanja Ognjanovic[1], Bojana Popovic[1], Dusan Ilic[1], Jelica Bjekic Macut[2], Milica Opalic[1], Valentina Elezovic Kovacevic[1], Olivera Stanojlovic[3], Dragan Hrncic[3], Danijela Vojnovic Milutinovic[4] & Djuro P. Macut[1]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Department for Endocrine Tumors and Hereditary Cancer Syndromes, Belgrade, Serbia; [2]Clinical Hospital Centre Bezanijska Kosa, Belgrade, Serbia; [3]Institute of Physiology, Faculty of Medicine, Belgrade, Serbia; [4]IBISS, University of Belgrade, Belgrade, Serbia

Introduction
Polycystic ovarian syndrome (PCOS) is characterized by hyperandrogenism, chronic oligo-/anovulation and polycystic ovarian morphology. Hyperandrogenism is a key diagnostic feature of PCOS and according to ESHRE/ASRM criteria it can be clinical and/or biochemical. SPISE index (single-point insulin sensitivity estimator index) is a new indicator of insulin sensitivity and a predictor of abnormal glucose metabolism. The aim of the research was to analyse association between SPISE index and androgenic disorders which are highly prevalent in PCOS.
Subjects and methods
We analysed 145 female patients with PCOS diagnosed using ESHRE/ASRM criteria and with exclusion of relevant diseases. Patients were divided according to age into two groups, $\leq$ 30 years (PCOS A, n: 74, age: 23.3 ± 3.1 years, body mass index (BMI): 23.1 ± 4.4 kg/m^2) and >30 years old (PCOS B, n: 71, age: 35.6 ± 4.9 years, BMI: 25.3 ± 6.3 kg/m^2). We measured serum levels of total cholesterol, LDL and HDL cholesterol, triglycerides, total testosterone, SHBG, DHEA-S, androstenedione and 17OH-progesterone, while values of free androgen index (FAI) and SPISE index were calculated using appropriate formulas. Statistical analysis was performed using the SPSS software.
Results
The two groups did not differ in BMI (23.3 ± 4.4 vs. 25.3 ± 6.3 kg/m^2, $P=0.126$), waist circumference (77.0 ± 12.9 vs. 82.0 ± 15.2 cm, $P=0.071$) and total testosterone levels (2.0 ± 1.0 vs. 1.9 ± 0.9 nmol/l, $P=0.332$). SPISE index was lower in PCOS B group (PCOS A:PCOS B: 8.7 ± 2.6 vs.7.6 ± 2.6, $P=0.022$). There was a statistically significant higher value of SHBG in B group (PCOS A:PCOS B: 44.0 ± 30.7 vs. 48.2 ± 17.1 nmol/l, $P=0.037$), but there was no difference in FAI ($P=0.291$). The SPISE index positively correlated with SHBG levels in both groups of patients (PCOS A: $P=0.006$, PCOS B: $P=0.001$), but negatively correlated with FAI in B group ($P=0.018$).
Conclusion
Hyperandrogenism in patients with PCOS is associated with poor metabolic outcome. Our analysis showed worsening of the SPISE index with age of our subjects, and its association with indicators of hyperandrogenism could predict metabolic events during the life of patients with PCOS.

Improved self-reported confidence levels to manage transitional endocrine cases following Simulation via Instant Messaging – Birmingham Advance (SIMBA) training

Tamzin Ogiliev[1], Pavithra Sakthivel[2], Mirna Elghobashy[2], Anoushka Devi Bucktowar[2], Abby Radcliffe[2], Maiar Elhariry[2], Anisah Ali[2], Sangamithra Ravi[2], Carina Synn Cuen Pan[2], Sung Yat Ng[2], Celia Akpeki[3], Dengyi Zhou[4], SIMBA and CoMICs Team[5] & Punith Kempegowda[5,6]
[1]University of Plymouth, Faculty of Health, Plymouth, United Kingdom; [2]University of Birmingham, College of Medical and Dental Sciences, Birmingham, United Kingdom; [3]Whittington Health NHS Trust, London, United Kingdom; [4]Imperial College London, Department of Metabolism, Digestion and Reproduction, Faculty of Medicine, London, United Kingdom; [5]University of Birmingham, Institute of Metabolism and Systems Research, College of Medical and Dental Sciences, Birmingham, United Kingdom; [6]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom

Introduction
Simulation via Instant Messaging – Birmingham Advance (SIMBA) is an online real-time simulation-based learning model which has proven to improve participants' confidence in managing simulated cases in various conditions. Transitional endocrinology is a unique set of conditions which not only needs clinical skills but also requires excellent team working and communication skills. The aim of the study was to assess the effectiveness of the SIMBA model in improving self-perceived clinician confidence in the management of transitional endocrinology cases.
Methods
The session was conducted on 4 November 2022 as a hybrid option where participants joined the session either in person or virtually. Four transitional endocrinology scenarios, focussing on Turner's syndrome, congenital adrenal hyperplasia, type 1 diabetes mellitus and type 2 diabetes mellitus, were simulated using participant-moderator interaction via Whatsapp. These scenarios were based on real-life cases, anonymised to maintain confidentiality. After conducting the simulated cases the content was discussed on Zoom by three expert chairs, each a specialist in various subspecialities of transitional endocrinology. During this discussion, participants interacted with chairs and fellow participants via chat option. Participants completed pre- and post-SIMBA surveys designed to evaluate self-perceived improvement in confidence and ACGME Core Competencies, and perceptions surrounding SIMBA. Responses were quantitatively analysed using the Wilcoxon Signed Rank test and answers to open ended questions were qualitatively assessed using a thematic analysis.
Results
20 participants completed both pre- and post- SIMBA surveys. Participant self-perceived confidence in the management of simulated topics increased following the session (pre- vs post-SIMBA survey: 31.3% to 91.3%, $P<.0001$). There was also an increase in confidence to manage non-simulated conditions which were included in the discussion (14.0% to 66.0%; $P<.0001$). However, the change was greater with simulated cases (simulated vs non-simulated: 60% vs 52%). Most participants reported an improvement in Core Competencies defined by Accredited Council of Graduate Medical Education (patient care, 95%; knowledge on patient management, 95%; practice-based learning, 90%; systems-based practice, 85%; professionalism, 80%). 95% rated the quality of SIMBA session as excellent or good. 85% of participants strongly agreed or agreed that the topics simulated were applicable to their practice and 90% would attend SIMBA sessions in the future.
Conclusion
SIMBA is an effective tool for improving clinician confidence in the management of transitional endocrine topics. Focus for future studies will be implementing SIMBA for larger groups of clinicians to determine the wider effectiveness of simulation-based learning for transitional endocrinology.

Prevalence of body dysmorphism in PCOS women

John Flood[1] & Fatima Alili[2]
[1]Royal College of Surgeons in Ireland - Bahrain, Medicine, Manama, Bahrain; [2]Royal College of Surgeons in Ireland - Bahrain, Medicine, Al Sayh, Bahrain

Polycystic ovary syndrome (PCOS) is the most common reproductive problem in women of childbearing age attending an endocrine clinic with a reported prevalence of between 4-8 %. The classical symptoms result from excess ovarian androgen production and chronic anovulation. Ovarian ultrasound shows more than 10 follicles, 2-10mm in diameter. A common presentation in the clinic can be menstrual dysfunction but the most characteristic feature of the syndrome is the hirsutism which varies in severity and site. Hair growth on the face and chin can be quite extensive as can excessive hair loss on the head and frontal balding and acne all due to androgen excess. Obesity has also been reported in about half of PCOS patients. It is characterised by an increase in waist- to-hip ratio or android appearance as opposed to truncal obesity with an incidence of 7.5% of type 2 diabetes. It is well established that PCOS women suffer from impaired emotional well being and have a marked reduction in the quality of their life, as well as anxiety and depression. The role of physical appearance, obesity, and hirsutism have been well established as contributing to this reduced quality of life in studies done in USA but not to the same extent in the Middle East. The purpose of our study is to review the impact of PCOS on a cohort of young women attending an endocrine clinic in a tertiary referral teaching hospital in the Kingdom of Bahrain. We enrolled 40 PCOS women in a cross-sectional survey between the ages of 19 and 40 years to determine the severity and prevalence of body dysmorphism in our PCOS patients. We used a questioner of 30 questions which enquired about BMI, hair distribution, acne, menstrual cycle, and patients' perception of their bodies. Based on WHO classification of weight, 20% were of normal weight, 12.5 % overweight and 45% were obese. 66.6% had male pattern hair growth with 91.6 % having male pattern balding. 87.5% mentioned that their weight/body shape influenced in a negative way the way they saw themselves. Nevertheless 58.3 % felt that they were attractive. Finally, 90 % expressed the desire to lose weight, although they felt that minor weight gain did not influence how they saw themselves. In conclusion, the evidence in this study to date is that the main problem that influenced their perception of their body was their weight and not hirsutism.

Introduction
High androgen levels and infertility in reproductive women, beyond the most common cause of polycystic ovary syndrome (PCOS), is often a challenge diagnosis. Ovarian steroid cell tumor is considered a rare subtype of hormone-secreting ovarian tumor, accounting for about 0.1% of all ovarian tumors.
Aim
To report a case of extremely high testosterone levels in a woman with secondary amenorrhea but without signs of virilization, and describe diagnostic assessment of testosterone levels.
Methods
Assessing true testosterone levels by three different manufacture methods Centaur (Siemens), Cobas (Roche manufacture), Architect (Abbott manufacture), respectively and extraction procedure with diethyl ether prior to immunoassay.
Case Presentation
A 27 years old woman was followed for a presumed ovarian dermoid cyst and PCOS. Two years later hormonal treatment was stopped in intention for conceive, but menstruation did not resume. Evaluation revealed extremely high testosterone level of 22.1nmol/l, (reference value $<$2.1 nmol/l) measured by Centaur analyzer (Siemens manufacture) without signs of virilization. Levels of SHBG, FSH and LH were within the normal range. The sample was processed by two alternative methods, Cobas (Roche manufacture) and Architect (Abbott manufacture), showing similar results for testosterone: 19.5 and 23.0 nmol/l, respectively. The same values of total testosterone were found after heterophile and nonspecific antibodies blocking test. At this point, extraction procedure with diethyl ether was performed prior to immunoassay, then testosterone was measured on Cobas/Roche analyzer. A level of 5.6 nmol/l total testosterone was found after the extraction procedure. An abdominal contrast computed tomography scan (CT) confirmed a 30 mm X 36 mm round solid mass in the left ovary, not characteristic of a dermoid cyst. The ovarian mass was resected. Histological diagnosis reveled an ovarian steroid-cell tumor (SCT) not otherwise specified (NOS). Twenty-four h after the surgery total testosterone level returned to normal range, 0.6 nmol/l. A month after surgery the patient resumed menstruation.
Conclusions
1. Our case demonstrates that in some instances, the produced testosterone by the tumor can have a selective influence on peripheral tissues causing only menstrual irregularity without virilization. Since these tumors have malignant potential, differential diagnosis of ovarian mass with high levels of testosterone is essential even without signs of virilization. 2. Elimination of the interferences by extraction with diethyl ether demonstrated that the cause of pitfall in total testosterone level was hydro soluble fragments of the steroid hormone pathway which react with testosterone antibodies in the direct assay.

Remission of ovarian hyperandrogenism in two post-menopausal women treated with GnRH analogue

Paola Dionese[1], Laura Rotolo[1], Claudio Bongiorno[1], Carolina Cecchetti[1], Michela Starace[2], Francesca Bruni[2], Uberto Pagotto[1], Alessandra Gambineri[1] & Carla Pelusi[1]
[1]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum, University of Bologna, Division of Endocrinology and Diabetes Prevention and Care; [2]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum, University of Bologna, Dermatology Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Italy

Background and aim
Ovarian hyperandrogenism is a known cause of post-menopausal hirsutism and virilisation, more frequently of a benign nature (e.g. ovarian hyperthecosis, Leydig cell hyperplasia). Bilateral salpingo-oophorectomy delivers both definitive diagnostic and therapeutic results. However, after excluding the presence of a suspicious ovarian mass, the use of GnRH analogues (GnRH-a) offers a valuable therapeutic alternative with cases reporting a sustained response in time, besides suggesting an ovarian origin of the hyperandrogenism by their suppressive action on gonadotropins.
Cases presentation
Two post-menopausal women (aged 73 and 74 years) presenting with progressive hirsutism and alopecia were referred to our unit for further evaluation. They both showed high testosterone (T) levels (1.71 and 0.80 ng/ml, respectively), not adequately suppressed after low-dose dexamethasone suppression test (48-h 2 mg/d) and dosable oestradiol (E2) levels. All other steroidal hormones were in the normal range. The second patient underwent videodermatoscopy, showing an increase of hair diameter variability $>$20%, some empty follicles, peripilar depressions and some small short regrowing hair. No ovarian or adrenal findings suspicious for malignancy were found at the abdominal CT scan and pelvic US. The pituitary MRI scan was within the normal range. We started both patients on a 3-month treatment with GnRH-a (triptorelin 3.75 mg im injection every 28 days) to confirm the presumed ovarian origin of T overproduction and to achieve both clinical and biochemical regression of their hyperandrogenic condition.
Results
We re-evaluated both patients one month after the first GnRH-a injection, three months after the last injection and then every 4-6 months, up to 2.5 years after the treatment initiation for the first patient. Both patients showed suppression of gonadotropins and E2 levels and reduction in T levels to within the normal range

one month after the first injection (<0.1 and 0.46 ng/ml, respectively). Gonadotropin levels then progressively rose up to a post-menopausal range after finishing the treatment, while E2 levels remained suppressed and T levels remained within a normal range (0.19 and 0.54 ng/ml, respectively). Both patients reported clinical improvement for both hirsutism and alopecia. Videodermatoscopy re-evaluation confirmed a marked trichoscopical improvement.
Conclusions
GnRH-a is a valid choice for the treatment of post-menopausal hyperandrogenism of presumed benign ovarian origin, as an alternative to surgery. It has shown a sustained clinical and biochemical response up to 6 months in both patients and up to 2.5 years for one patient.

Benificial Effects of Antioxidant Combination in Dimining Oxidative Stress Status and Improves Semen Parameters in Infertile Men: One Blind Placebo Controlled Trial

Vegim Zhaku[1] & Sheqibe Beadini[2]
[1]University of Tetova, Physiology, Struga, Macedonia; [2]University of Tetova, Biochemistry, Tetovo, Macedonia

Male infertility every year is becoming one of the main problems of the health system, which requires serious steps in coping this health and socioeconomic burden. Oxidative stress is emphasized as the main factor of idiopathic etiology resulting with the inability to conceive because of poor semen quality. Antioxidants have shown their beneficial effects in various studies conducted, resulting both in improving semen quality and higher chance of natural conception. Thus, the aim of this study is to verify the impact and effectiveness of the antioxidant formula both in oxidative stress status and semen parameters. A total of 211 infertile men were enrolled in the study after passing the inclusive criteria, 50 of them were used only for comparison while 161 were divided in two groups: interventional ($n=80$) and the placebo group ($n=81$). Standard semen analysis along with biochemical analysis of malondialdehyde (MDA), caspase-3 (cas-3) and total antioxidant capacity (TAC) levels were analyzed in two points: T_0 (before the antioxidant/placebo therapy) and T_6 (six months after antioxidant/placebo therapy). Mean ± SD and Wilcoxon signed ranks was used to asses changes in two points. After six months the interventional showed significant improvements in terms of sperm concentration ($P=0{,}00006$), motility ($P<0{,}001$) and morphology ($P<0{,}001$), while changes in the placebo group where not statistically significant ($P=0{,}713$, $P=0{,}428$ and $P=0{,}606$, respectively). In the group treated with antioxidants we had a reduction in MDA, Cas-3 levels (6,01 ± 0,83 to 3,25 ± 0,68 and 3,82 ± 0,53; $P<0{,}001$ respectively) and increase in TAC levels (45,53 ± 9,15 to 74,88 ± 12,63; $P<0{,}001$). While in the placebo group the mean MDA, Cas-3 and TAC levels had no statistically significant changes (6,49 ± 1,40 to 6,51 ± 1,45; $P=0{,}65$), (4,11 ± 0,68 to 4,12 ± 0,77; $P=0{,}89$) and (45,41 ± 7,78 to 44,67 ± 8,44; $P=0{,}37$), respectively. Looking at the cost-benefit aspect and rationale behind antioxidant therapy in infertile men, we strongly suggest their use before any other procedure.

Visfatin expression and regulation by E2, P4, hCG and insulin in human placental cells

Monika Dawid[1,2], Patrycja Kurowska[1], Piotr Pawlicki[3], Małgorzata Kotula-Balak[4], Tomasz Milewicz[5] & Agnieszka Rak[1]
[1]Institute of Zoology and Biomedical Research, Jagiellonian University, Laboratory of Physiology and Toxicology of Reproduction, Cracow, Poland; [2]Doctoral School of Exact and Natural Sciences, Jagiellonian University, Cracow, Poland; [3]Center of Experimental and Innovative Medicine, University of Agriculture, Cracow, Poland; [4]University Centre of Veterinary Medicine JU-UA, University of Agriculture, Department of Animal Anatomy and Preclinical Sciences, Cracow, Poland; [5]Jagiellonian University Collegium Medicum, Department of Endocrynological Gynecology, Cracow, Poland

Introduction
Visfatin belongs to adipokines, i.e. hormones produced mainly by adipose tissue; its expression and role have been described in many organs, where it regulates energy metabolism, insulin resistance and inflammatory reactions. Moreover, the level of visfatin changes during pregnancy and in obese women and those with obesity related pregnancy pathologies: preeclampsia (PE), gestational diabetes (GDM) or intrauterine growth restriction (IUGR) its level increases. There is no data about the role of adipokine in placenta so the aim of this study was to: 1) determine the expression and immunolocalization of visfatin in the trophoblast cell lines JEG-3 and BeWo, as well as in the maternal and fetal parts of placentas from normal and PE, GDM and IUGR complicated pregnancies; 2) examine the effect of: estradiol (E_2), progesterone (P_4), human chorionic gonadotropin (hCG) and insulin (INS) on visfatin level in JEG-3.
Materials and Methods
To study the mRNA (real time PCR), protein (Western blot) expression and immunolocalization (immuno -cytochemistry, -histochemistry) of visfatin, JEG-3/BeWo were cultured in time-dependent manner, while fragments of terminal placentas were collected after delivery. Furthermore, the effect of: E_2 (1, 10, 100 nM), P_4 (1, 10, 100 nM), hCG (0.1, 1, 10 ng/ml), INS (10, 50, 100 ng/ml) on visfatin protein expression (Western blot) and concentration (ELISA) was examined. Next, the involvement of signaling pathways of extracellular signal-regulated kinase (ERK 1/2), transcription factor NF kappa B (NF-κB) and receptors (PR, GPR30, ER, LHCGR, INSR) in visfatin regulation was analyzed. Statistical analysis was performed in Graph Pad Prism 7, using one-way ANOVA and Tukey's test ($n=5$, $P<0.05$).
Results
We demonstrated the mRNA and protein expression of visfatin in JEG-3/BeWo cells and in normal/pathological placentas. Our studies showed the immunolocalization of visfatin in cytoplasm of both cell lines, syncytiotrophoblasts of placenta fetal part and capillary epithelium of maternal part while in the pathologies additionally in decidual cells. Moreover, we explored a stimulatory effect of all tested hormones on visfatin level in JEG-3 with the involvement of specific signaling pathways.
Conclusion
Differences in the localization of visfatin in the maternal part of normal and pathological placentas, suggested that adipokine may be a potential marker for pregnancy disorders diagnosis. In addition, variable level of visfatin during individual trimesters may be the result of pregnancy hormones, which stimulate its level in the human placenta cells.

Sexual dimorphism in the LH responses to kisspeptin and senktide administration in prepubertal mice

Luigi Maione[1,2], Lydie Naulé[2], Chloe Yang Ling Li[2], Melissa Magnuson[2], Jacques Young[1], Rona Stephanie Carroll[2] & Ursula Kaiser[2]
[1]Paris Saclay University, Endocrinology and Reproductive Diseases, Le Kremlin-Bicêtre, France; [2]Harvard Medical School, Brigham and Women's Hospital, Dpt. of Endocrinology, Diabetes and Hypertension, Boston, United States

Introduction
The hypothalamic-pituitary-gonadal (HPG) axis is regulated by pulsatile GnRH secretion and its action on the anterior pituitary, leading to the synthesis and secretion of LH and FSH. KNDy neurons, expressing kisspeptin, neurokinin B and dynorphin A, are the GnRH/lH pulse generator and are key regulators of puberty and fertility. The HPG axis is active during prenatal and early postnatal life in humans and rodents, but then remains quiescent until puberty in both species. The response of gonadotropes to exogenous upstream GnRH signals such as kisspeptin and neurokinin during prepubertal development in mice is unknown.
Aim
To conduct a systematic assessment of LH responsiveness to exogenous kisspeptin and to the neurokinin-3 receptor agonist senktide at regular intervals postnatally and across pubertal maturation in mice.
Materials and Methods
Male and female J129Sv mice were treated with intraperitoneal injections of kisspeptin-10 (0.0023 nmol/g), senktide (0.023 nmol/g) or vehicle every 3 days from postnatal day (PND) 10 until completion of puberty. Serum LH was measured by an ultra-sensitive ELISA at baseline and 15 minutes after injection.
Results
Prepubertal mice responded in an age-dependent and sexually dimorphic manner to kisspeptin and senktide. LH levels increased following kisspeptin stimulation in both sexes, but responses were higher in females than in males from PND10 to PND16. The highest response was observed at PND10, with a pattern of decreasing response with advancing age. Senktide induced a robust increase in serum LH in females from PND10 to PND16, with a decrease in response with age, similar to that observed after kisspeptin treatment. In contrast, in males there was no increase in serum LH in response to senktide at any age. No difference in

the onset of puberty or body weight was observed across treatment groups.
Conclusions
The assessment of serum LH levels following IP administration of kisspeptin and senktide in prepubertal male and female mice demonstrated distinct age and sexually dimorphic patterns of LH responses to GnRH upstream signals, with greater responses at early postnatal ages and in females than in males. These findings provide new evidence for sexual dimorphism of the HPG axis in mice early in postnatal life, prior to the onset of puberty, and raise the possibility of additional restraining factors on HPG axis activity in early life.

Hyperprolactinemia in Turner syndrome

Faten Haj Kacem Akid, Oumeyma Trimeche, Mouna Mnif, Frikha Hamdi, Dhoha Ben Salah, Mouna Elleuch, Mnif Fatma, Nadia Charfi, Nabila Rekik Majdoub & Mohamed Abid
Hedi Chaker Hospital, Endocrinology, Sfax, Tunisia

Introduction
Hyperprolactinemia is a relatively frequent finding. A wide range of conditions can be responsible of this biochemical abnormality. Herein we report a rather rare etiology of hyperprolactinemia which is Turner syndrome (TS).
Methods
Aiming to determine the frequency of hyperprolactinemia in patients with TS, we enrolled a retrospective descriptive study in the department of Endocrinology at the Hedi Chaker Hospital. We included patients who have the cytogenetic confirmation of Turner syndrome and who consulted our department between 1990 and 2021. As for hyperprolactinemia, it is defined as a prolactin level above 25 ng/ml.
Results
The total number of patients in our study was 45. Their mean age of diagnosis was 16 years. Most of them were diagnosed after the age of 10 years (88.9 %). Karyotype analysis revealed the presence of X monosomy in 49 % of cases, mosaicism without structural alterations of X in 31 % and mosaicism with structural variants of the X chromosome in 20 % of cases. Dosage of prolactin was performed in 29 patients with primary amenorrhea. The median prolactin level was 11.7 ng/ml [Q1, Q3: 8.8-16.6 ng/ml]. Four patients had hyperprolactinemia which corresponds to a frequency of 13.8 %. The mean age of these patients was 17.5 years, with extremities ranging from 15 to 21 years. Cytogenetic findings were variable among these patients as one had 45, X, the second had 45, X/46, XX, the third had an Y chromosome and the karyotype of the fourth girl was 46, XX/46, X i(Xq). This latter patient had a positive SRY. As for the mean prolactin level, it was 49.05 ng/ml. The maximum was 60.8 ng/ml. Regarding the etiology of this biochemical abnormality, we excluded hepatic dysfunction, renal insufficiency and hypothyroidism. Drug-induced hyperprolactinemia was also dismissed. A pituitary MRI was performed in two cases and it was normal. The evolution of hyperprolactinemia was marked by its spontaneous regression in two cases: after one year in the first case and after four years in the second. Conversely, the two other patients had persistent hyperprolactinemia.
Conclusion
Hyperprolactinemia is not an exceptional finding in TS. However, gaps remain in our understanding of the pathophysiological mechanisms underlying this abnormality. Therefore, more research is warranted.

A rare co-occurence of Turner syndrome and acromegaly complicated by the presence of a solid pseudopapillary neoplasm of pancreas-a case report

Karolina Cylke-Falkowska[1], Maria Stelmachowska-Banaś[2], Andrzej Cichocki[3], Grzegorz Zieliński[4] & Wojciech Zgliczyński[5]
[1]Bielański Hospital, I Department of Internal Medicine, Warsaw, Poland; [2]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland; [3]Curie National Research Institute of Oncology, Department of Surgery, Oncological Clinic; [4]Military Institute of Medicine, Department of Neurosurgery; [5]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland

Background
Turner syndrome (TS) is the most common chromosome deficiency in women, with an incidence of 1 in 2 000 female newborns. Acromegaly is a rare disease, which occurs with a frequency of 1:140 000–250 000 of the population. To our knowledge only several cases of TS and acromegaly coexistance have been reported up to date.
Case presentation
A 43-year-old woman with TS was referred to our Department with an accidentally discovered pituitary macroadenoma (3.5×3.4×2.6 cm). The patient presented a typical picture of acromegaly and has been chronically taking hormone replacement therapy due to hypogonadism in the course of TS. In our Department hormonal tests revealed hyperprolactinemia (PRL = 46.8ng/ml) and active acromegaly (IGF-1 = 962 ng/ml; GH = 74.4 μg/l). In the dermatological and pathomorphological consultations multiple skin neurofibromas were described. A well-defined unenhanced lesion 70x58x77 mm in size, with thick wall, fluid level and a heterogeneous content was described in the abdominal MRI. The endoscopic ultrasound-guided fine needle aspiration did not succeed. Somatostatin receptor scintigraphy revealed an abnormal radiolabel uptake of the pituitary tumor and did not show any other lesions with pathological radiotracer accumulation. While awaiting for pituitary surgery the patient was administered lanreotide autogel 120 mg every 4 weeks s.c. for acromegaly, bromocriptine 2,5 mg/day due to the coexistance of hyperprolactinemia. After 5 months of preoperative medical treatment transsphenoidal pituitary adenoma resection was performed. A pathological report revealed a mixed somatotroph and lactotroph PitNET with GH, α-subunit and PRL positive immunostaining and Ki-67 labeling index 1%. Due to the persistent active acromegaly (IGF-1 = 442 ng/ml; GH = 3 μg/l) after the operation the treatment with lanreotide autogel was restarted which resulted in complete biochemical acromegaly control after 6 months. After surgical, gastroenterological consultations, the patient was qualified for pancreatic tumor resection and the pathology report revealed solid pseudopappilary neoplasm of the pancreas (SPNP): Vim (+++), cyclin D1 (+), PGR (++/+++), CD10 (+++).
Conclusions
To date, the coexistence of TS and acromegaly is considered a rare coincidence. Despite the presence of multiple skin neurofibromas in our patient, the diagnosis of neurofibromatosis type 1 was excluded. SPNP which is a very rare tumor of the pancreas is usually described in females under the age of 30 years, however the effect of estrogens and progesterone on SPNP remains still uncertain. In order to expand the knowledge it is necessary to collect similar cases to assess the effect of GH excess in TS.

Follicle stimulating hormone (FSH) is produced by the anterior pituitary gland and it is a key hormone in the reproductive system. FSH is a heterodimeric glycoprotein composed with two extensively glycosylated protein sobunits (α and β) N-glycosylated in two positions (Asn^{52} and Asn^{78} in the FSHα subunit and Asn^{7} and Asn^{24} in the FSHβ subunit) giving rise to numerous isoforms of FSH. Glycosylation has been shown to impact on the *in vivo* activity of FSH by influencing its clearance and its ability to bind and activate receptors. Different FSH glycoforms are used for assisted reproduction. The aim of this study *in vitro* is to compare the intracellular signaling pattern mediated by two differently glycosylated, recombinant FSH. Gonal-f® (Merck KGaA) is produced using a modified chinese hamster ovary (CHO) cell line while Rekovelle® (Ferring Pharmaceuticals) is produced by the human fetal retinal PER.C6® cell line. Transfected HEK293 cells overexpressing the FSH receptor (FSHR) were treated by increasing FSH doses (0.0-1.0 μM range). The intracellular cAMP and Ca^{2+} increase, IP1 production, FSHR homomers formation and the evaluation of transcriptional activity of genes dependent on cAMP and pERK1/2 activation, using both CRE- and NFAT-luciferase reporter assay, were evaluated by energy transfer-based methods. Results were compared by two-way ANOVA and Bonferroni post-test ($P<0.05$). The two differently glycosylated rFSH impact differently on FSHR homomer formation ($n=4$). No statistically significant difference was evaluated regarding the intracellular accumulation of cAMP ($n=6$). However, Gonal-F® is more effective than Rekovelle®. Gonal-f® was less potent but more effective than Rekovelle® in activating the CRE-controlled reporter gene ($n=5$). Furthermore, Rekovelle® induced a biphasic response, at low concentrations it is

more potent than Gonal-f® while at high concentrations it seems to inhibit the activation of the reporter gene controlled by CRE. In order to understand the contribution of 'non-classical' FSH-dependent pathways, not necessarily dependent on cAMP, on cell functions the CRE-controlled reporter gene activation was evaluated in the presence or absence of Dynasore or specific PKA, PLC, AKT, MEK-ERK1/2 inhibitors ($n=6$). The two differently glycosylated rFSH induce a different signal pattern given by the activation of CRE-controlled reporter gene in the presence of inhibitors except in the presence of AKT inhibitor. Rekovelle® is more potent to induce intracellular Ca^{2+} release ($n=6$) than Gonal-F® but no different IP1 production and NFAT-controlled reporter gene activation were detected ($n=4$). Recombinant FSH used in clinical practice may impact differently intracellular signaling cascades *in vitro*.

Gestational thyrotoxicosis due to molar pregnancy complicated by pre-eclampsia

Kalyan Mansukhbhai Shekhda[1], Vladislav Zlatkin[2], Saroj Kumar Sahoo[1], Quazi Tamjidul Islam[1], Ammara Naeem[1], Munachiso Nwokolo[1], Ahmed Yousseif[1], Efthimia Karra[1], Dipesh Patel[1], Bernard Khoo[1] & Eleni Armeni[1,3]
[1]Royal Free Hospital, Department of Endocrinology, London, United Kingdom; [2]University College London, London, United Kingdom; [3]Aretaieio Hospital, University of Athens, 2nd Department of Obstetrics and Gynaecology, Greece

Introduction
Gestational trophoblastic disease (GTD) is a group of disorders arising from abnormal proliferation of placental trophoblasts. Hydatiform mole (molar pregnancy) is a premalignant condition which is further devided in to partial and complete mole. Incidence of molar pregnancy is estimated to be 1 in 1000 pregnancies. Hyperthyroidism is one of the rare complications of molar pregnancy which, if not detected and treated, can lead to adverse consequences. We describe the case of a 42-year old lady, who presented to the hospital at a gestational age of 10 weeks.
Case History
Her symptoms at presentation included vaginal spotting and palpitations of 5 days onset. The background included hypertension following her last pregnancy, on treatment with labetalol 200 mg, pre-eclampsia, two previous spontaneous miscarriages, four spontaneous vaginal deliveries. At the time of assessment, pulse rate was 95/min, and the blood pressure 185/118 mmHg up to 199/123mmHg. The electrocardiogram showed sinus rythm. An ultrasound scan showed large multi-cystic/haemorragic lesion measuring 82 x 110 x 66mm within the endometrium in keeping with a complete molar pregnancy. The blood tests showed: thyroid stimulating hormone (TSH) of <0.01 munit/l (Range: 0.3-4.2nunit/l), Free thyroxine of >100pmol/l (Range: 12-22pmol/l), Free T3 of 28.6pmol/l (Range: 3.1-6.8pmol/l), b-chorionic gonadotrophin (b-HCG) levels 553,445units/l, alanine aminotransferase 47units/l, aspartate aminotransferase 41units/l. The urine was positive (++) for protein. Burch-Wartofsky score was 20, making thyroid strom less likely. Given the clinical picture of mild thyrotoxicosis she was started on carbimazole 60 mg daily, and continued on Labetalol 200 mg three times per day. She underwent surgical removal of molar pregnancy with uneventful post-operative course. One week later she was weaned off carbimazole. Histology confirmed the diagnosis of molar pregnancy, and her thyroid function test (TSH: <0.01munit/l, FT4: 11.7pmol/l) with bHCG levels (573 units/l) normalised two weeks later. Following discharge, the results of the thyroid receptor antibodies (<0.4 units/l) were made available, and confirmed the diagnosis.
Discussion
The clinical and biochemical picture of this patient were compatible with GTD, on the background of molar pregnancy. The sinus tachycardia was likely related with the early onset of pre-eclampsia. Careful clinical assessment is required to ensure the clinical signs are correctly interpreted prior to the surgery, as thyroid storm can easily be triggered in the context of an incorrect diagnosis. Surgical removal of mole is the definitive treatment in these cases. HCG and thyroid function test should be monitored afterwards to ensure gestational trophoblastic neoplasia doesn't develop.

Unveiling follicular fluid oxidative stress biomarkers at polycystic ovary syndrome

Mafalda V. Moreira[1,2,3,4], Emídio Vale Fernandes[1,2,5], Raquel Bernardino[1,2], Marco Alves[1,2,3] & Mariana P Monteiro[1,2]
[1]Unit for Multidisciplinary Research in Biomedicine, School of Medicine and Biomedical Sciences (ICBAS), University of Porto, Endocrine and Metabolic Research, Porto, Portugal; [2]Laboratory for Integrative and Translational Research in Population Health (ITR), University of Porto, Porto, Portugal; [3]School of Medicine and Biomedical Sciences (ICBAS), University of Porto, Laboratory of Physiology, Department of Imuno-Physiology and Pharmacology, Porto, Portugal; [4]i3S-Institute for Research and Innovation in Health, University of Porto, Porto, Portugal; [5]Centre for Medically Assisted Procreation / Public Gamete Bank, Centro Materno-Infantil do Norte Dr. Albino Aroso (CMIN), Centro Hospitalar Universitário do Porto (CHUPorto), Porto, Portugal

Polycystic ovary syndrome (PCOS) is one of the most prevalent endocrine disorder of women at reproductive-age and accounts for 80% of the causes of anovulatory infertility. Despite the widely characterized reproductive, endocrine, and metabolic abnormalities, the mechanisms underlying PCOS remain unclear. Thus, it is essential to identify novel biomarkers that will allow to disclosure novel pathways involved PCOS pathophysiology, which could then be used to improve PCOS management and treatment. Although oxidative stress has been suggested to play a central role in PCOS associated reproductive dysfunction, the potential use of follicular fluid (FF) oxidative stress-related molecular profiling as reproductive function biomarker in women with PCOS, has not been widely explored. Herein, we investigated and compared the levels of lipid peroxidation (LPO) and total antioxidant capacity (TAC) FF of women with and without PCOS undergoing *in vitro* fertilization (IVF), in addition, the association between those oxidative stress markers and IVF outcomes was examined. A total of 84 women were enrolled in this study, 30 women with PCOS and 54 women ovulatory controls. FF was obtained from mature follicles at the time of oocyte retrieval. Oxidative stress was examined by measuring TAC levels by ferric reducing antioxidant power (FRAP) and by assessing LPO through quantification of malondialdehyde levels at the FF. Our results showed that TAC levels were lower in the FF of women with PCOS when compared to the non-PCOS group (1.704 ± 0.275 vs 2.903 ± 0.43; $P<0.0001$). There were no significant differences in LPO levels, although these levels tended to be higher in PCOS group compared with the non-PCOS group (19.23 ± 1.68 vs 16.66 ± 1.34). No correlation was found between LPO or TAC levels and the number of oocytes retrieved and fertilized, cleavage and fertilization rate. Unravelling FF profile of women with PCOS may help the recognition of potential biomarkers that disturb normal female function leading to infertility problems. Overall, our preliminary findings suggest that oxidative stress is involved in the pathophysiology of PCOS and, therefore oxidative stress parameters may be crucial to understand the mechanisms underlying the manifestations of this syndrome.

Establishing LOQ for estradiol, LH, FSH and testosterone on Roche Cobas e801

Sanja Goreta, Ivana Zec, Adriana Bokulić[1] & Domagoj Marijančević
Sestre Milosrdnice University Hospital Center, Department of Clinical Chemistry, Zagreb, Croatia

Introduction
The limit of quantification (LOQ) is defined as the lowest analyte concentration that can be reproducibly measured with defined imprecision expressed as CV (coefficient of variation). Low concentrations of hormones estradiol, LH, FSH and testosterone are essential in diagnosis and monitoring of various endocrine disorders. Automated immunoassays have well known advantages, but still limited in achieving necessary analytical sensitivity. The major concern is to produce low values with low imprecision. Our aim was to determine the lowest concentration of the listed hormones with CV $<20\%$.
Aterials and Method
According to LOD (limit of detection) and LOQ declared by the manufacturer we selected similar estradiol, LH, FSH and testosterone concentrations. Serum pools were prepared from patients residual samples. Final pool concentrations were: (i) estradiol 88,9 pmol/l, 50,7 pmol/l and 27,4 pmol/l; (ii) LH and FSH 0,3 IU/l; (iii) testosterone 0,5 nmol/l and 0,17 nmol/l. Pools were analyzed over five days in triplicates on Roche Cobas e801 and CV was calculated. Inter-assay variation (bias) was eliminated by analyzing all specimens in a single batch using a single instrument, one analyst, one set of calibrators with the same lot of reagents.
Results
The determined CV for estradiol at 88,9 pmol/l, 50,7 pmol/l and 27,4 pmol/l was 6,0%, 9,3% and 19%, respectively. The remaining pools obtained CVs as follows: 4% for LH at 0,3 IU/l; 2,3% for FSH at 0,3 IU/l; 4,9% and 7,8% for testosterone at

0,5 nmol/l and 0,17 nmol/l.
Conclusion
All selected estradiol, LH, FSH and testosterone concentrations met the defined criteria of CV <20%. Therefore, they represent the reliably measured low concentrations on analytical system Roche Cobas e801 and could be defined as LOQ.

Normosmic idiopathic hypogonadotropic hypogonadism: A case report
Nahudan Akmador & Jerome Barrera
Zamboanga Doctors' Hospital, Inc., Internal Medicine, Zamboanga, Philippines
Background
Idiopathic hypogonadotropic hypogonadism (IHH) is manifested as absent or incomplete puberty and biochemically low levels of sex hormones, with low or inappropriately normal gonadotropin hormones. In the absence of structural or functional lesions of the hypothalamic or pituitary gland, the hypogonadism is referred as idiopathic hypogonadotropic hypogonadism (IHH). IHH is a genetically heterogeneous disorder which can be caused by pathogenic variants affecting proteins involved in the pulsatile gonadotropin-releasing hormone release, action, or both.
Case Presentation
A 16-year-old male who presented to the endocrinology clinic with complaints of micropenis and absent secondary sex characteristics. Work up showed an unremarkable cranial MRI, low testosterone, LH, normal FSH, with normal Karyotyping.
Conclusions
Idiopathic hypogonadotropic hypogonadism (IHH) is a rare genetic disease with a complex and still have more to discover about its pathogenesis. The requirements for the diagnosis include low testosterone, low or normal serum luteinizing hormone (LH) and follicle-stimulating hormone (FSH) concentrations, and a normal appearance of the hypothalamus and pituitary region on magnetic resonance imaging (MRI). A prompt recognition of a clinical hypogonadotrophic hypogonadism is pivotal especially in a peripubertal age to initiate early sex hormone replacement as the failure of secondary sex characteristics could have a derogatory impact on individual's personal and social life.
Keywords
Hypogonadism, Idiopathic hypogonadotropic hypogonadism (IHH)

Change in lipid profile and glucose levels after 12 months of testosterone therapy in transgender men
Laura Montanez Fernandez & Ane Bayona Cebada
Hospital Ramón y Cajal, Endocrinology, Madrid, Spain

Introduction
Approximately 0.5% of the world population experiences gender dysphoria, a discrepancy between one's biological sex and gender identity. Transgender men (TM), individuals who were assigned female at birth but who identify as men, can benefit from therapy with testosterone (T) to address gender dysphoria. Although unfavourable changes in lipid profiles have been previously reported, most studies did not show an adverse impact of testosterone treatment on fasting glucose levels.
Methodology
We performed a retrospective analysis to compare lipid profile - total cholesterol (TC), low density lipoprotein (LDL), high density lipoprotein (HDL) and triglycerides (TG) levels-, fasting plasma glucose (FPG) levels and weight, from baseline to 12 months after the initiation T therapy. We included a cohort of 60 TM who attended our clinic from January to December 2021. After assuring normal distribution of the variables using Kolmogórov-Smirnov test, we performed a Paired samples t-test to compare pre- and post-treatment parameters. Results were presented as total number (percentage) for qualitative variables and as mean ± standard deviation for quantitative variables. Statistical analysis was conducted using SPSS software v.23.
Results
The mean age of our cohort was 20.6 ± 5.3 years and 16 of them (26.7%) were smokers. Regarding T therapy, 15 of TM (25%) were using transdermal testosterone, 32 (53.3%) testosterone undecanoate and 13 (21.7%) testosterone cypionate. Lipid profile, FPG and weight, baseline and 12 months after the initiation of testosterone therapy were compared (Table 1). A significant increase in LDL levels (mean difference +6.050, $P = 0.008$) and a significant decrease in HDL levels (mean difference -8.050, $P < 0.001$) were observed. These changes did not correlate with testosterone levels or treatment modality.
Conclusion
As observed in other publications, this study shows a significant impairment in LDL and HDL levels 12 months after the initiation of testosterone treatment. Unlike, no worsening in FPG levels or weight gain were observed. We should take these results into consideration to address cardiovascular risk and promote positive changes in lifestyle to TM who start testosterone therapy.

Measurements	Baseline	After 12 months of T	*P* values
TC(mg/dl)	169.7 ± 25.0	167.4 ± 28.8	$P = 0.342$
LDL(mg/dl)	96.9 ± 22.9	102.9 ± 27.0	$\mathbf{P = 0.008}$
HDL(mg/dl)	56.3 ± 11.6	48.3 ± 9.3	$\mathbf{P < 0.001}$
TG(mg/dl)	73.7 ± 30.5	78.5 ± 31.2	$P = 0.261$
FPG (mg/dl)	87.2 ±8.0	84.4 ± 10.5	$P = 0.060$
Weight (Kg)	66.2 ± 14.6	66.8 ± 12.6	$P = 0.525$

Significant hyponatremia as a manifestation of severe pre eclampsia
Shyam Seshadri[1], Salman Kidwai[2] & Marwa Shousha[2]
[1]The Queen Elizabeth Hospital King's Lynn NHS Foundation Trust, Diabetes and Endocrinology, King's Lynn, United Kingdom; [2]Queen Elizabeth Hospital, Obstetrics and Gynaecology, Kings Lynn, United Kingdom

A 32-year-old primigravida woman, low risk pregnancy, BMI 20, presented at 29 weeks of gestation with headache and mildly raised blood pressure and normal laboratory tests. The patient had no signifcant medical history and the pregnancy to date had been uneventful. Physical examination showed blood pressure (BP) of 145/93 mm Hg. (Baseline, 100/70 mm Hg). Laboratory tests showed a baseline sodium of 134 mmol/l, with the rest of the biochemistry normal. She had been commenced on Labetalol. At 29+4 weeks, the patient was admitted with headache, feeling unwell, leg and hand oedema and raised blood pressure. Physical examination showed BP of 168/105mm Hg with significant pedal oedema and proteinuria +4. Other physical findings were unchanged. Laboratory investigations showed serum sodium level of 122 mmol/l), with normal kidney and liver function test results. A urine osmolality was elevated at 433 mmol/kg while her urine sodium measured at 22 mmol/l and her urine potassium at 33 mmol/l. A short synacthen test was normal including normal thyroid biochemistry. The patient was admitted for observation including blood pressure monitoring. Liver function test results and serum uric acid level were normal. A growth scan of the foetus showed normal growth. Subsequent BP readings were under control while her urine protein creatinine ratio was 100 mg/mmol. During her hospital stay, her serum sodium level continued to decline. Although she was put on fluid restriction, her hyponatremia continued to worsen, with development of generalised oedema and imaging picking up sub pulmonary pleural effusion and mild pericardial effusion. Volume overload signs included engorged neck veins, presacral oedema were evident. Laboratory signs of severe preeclampsia as elevated liver enzymes (ALT 248), thrombocytopenia (platelets at 77) was also seen. In addition, her urine protein creatinine ratio had further increased to 416 mg/mmol. Essentially, she had developed severe hyponatremia in the setting of preeclampsia. Decision for delivery was made at 30 weeks by elective CS and planned admission to intensive care unit after multidisciplinary team discussion including obstetrician, Endocrinologist, neonatologist, cardiologist and anaesthetist. She was delivered by caesarean section, which was uneventful. Magnesium sulphate was given before delivery for neuroprotection and continued 24 hrs post-partum to reduce the risk of seizures. Serum sodium levels improved after 48 hrs post-delivery and returned to normal values on day 5 post-partum as well as the oedema. This presentation highlights the importance of hyponatremia as a prognostic factor guiding management of severe pre-eclampsia.

Not what it seems: an exuberant case of hirsutism in polycystic ovary syndrome
Mariana de Griné Severino[1], Marta Vaz Lopes[1], Carolina Peixe[1], José Vicente Rocha[1], Ema Lacerda Nobre[1,2] & Maria Joao Bugalho[1,2]

[1]Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Serviço de Endocrinologia, Lisboa, Portugal; [2]Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal

Introduction
Hirsutism is the presence of terminal hair growth in females with a male distribution pattern. It affects 5-15% of women, being an important sign of androgen excess. The main causes of hirsutism are polycystic ovary syndrome (PCOS) and idiopathic hyperandrogenism. Other significant but less frequent causes of hirsutism include nonclassic congenital adrenal hyperplasia (NCAH), androgen-secreting tumors, and Cushing's syndrome.
Case report
A 24 year old obese female patient was referred to the Endocrine Department due to marked hirsutism, which began at the age of 15 and worsened from 18 years onwards. She had no other complaints. Menarche occurred at 13 years old. Even though her menstrual cycles were initially regular, she was in amenorrhea for the past 5 years. She had no history of pregnancy and had never taken oral contraceptives. She was medicated with sertraline for depression and topiramate for chronic headaches. There was no known family history of hirsutism. On physical examination, the patient had a BMI of 36.8 kg/m2, acanthosis nigricans, a Ferriman-Gallwey score of 31 and a marked androgenic pattern alopecia. Blood pressure was normal and there were no purple striae, proximal myopathy or other signs of virilization such as acne or voice changes. The blood tests showed normal thyroid function, prolactin and gonadotropin levels, an estradiol of 46.3 pg/ml (NR 12-398), total testosterone 61.9 ng/dl (NR 5-48), free testosterone 3.40 ng/dl (NR <4.2), SDHEA 347 µg/dl (NR 98-340), delta-4-androstenedione 5.13 ng/ml (NR 0.3-3.7) and a basal 17OH-P 1.30 ng/ml (NR <2), which excluded NCAH. The dexamethasone 1 mg suppression test also excluded Cushing's syndrome, with a cortisol of 0.6 µg/dl. A CT scan of the abdomen showed no changes of the adrenal glands. Pelvic ultrasound showed increased volume of both adnexa (14 and 13cc), globous, with sonolucent formations of both central and peripheral location, features suggestive of micropolycystic ovaries. The diagnosis of PCOS was assumed, and the patient was medicated with daily drospirenone, ethinyl estradiol and ciproterone acetate 10 mg (for 15 days of the menstrual cycle), with no perceived improvement. Mechanical terminal hair removal was encouraged.
Conclusions
Androgen levels correlate poorly with hirsutism severity in PCOS, given that clinical manifestations are dependent on the individual's pilosebaceus unit response to androgens. Therefore, individuals can present with very exuberant hirsutism, suggesting more serious underlying disease, despite modest androgen levels, as in the case of our patient.

Galanin-Like Peptide and its' Correlation With Androgen Levels in Patients with Polycystic Ovary Syndrome

Yilmaz Hamiyet & Muhammed Mustafa Demirpence
Tepecik Research and Training Hospital, Endocrinology, Izmir, Turkey

Introduction
We aimed to investigate serum galanin-like peptide levels and its'correlation with hormonal and metabolic parameters in patients with polycystic ovary syndrome (PCOS)
Material and Methods
The study included 48 women (age range, 18-44 years) with a diagnosis of PCOS and control group that included 40 healthy females (age range, 18-46 years). Body mass index (BMI), waist circumference, Ferriman-Gallwey score, was evaluated and plasma glucose, lipid profile (total cholesterol, HDL cholesterol, LDL cholesterol and triglycerides), estradiol, progesterone, total testosterone, prolactine, insulin, DHEA-S, FSH, LH, free T3, free T4, TSH, anti-TPO, 25(OH)D, fibrinogen, d-dimer, CRP and GALP levels were measured in all study subjects.
Results
Waist circumference ($P=$ 0,044) and Ferriman-Gallwey score ($P=$ 0,002) were significantly higher in patients with PCOS compared to control group. Among the metabolic and hormonal parameters studies, only total testosterone was significantly higher in patients with PCOS ($P=$ 0,002). Also, serum 25(OH)D level was significantly lower in PCOS group ($P=$ 0,001). CRP, fibrinogen and D-dimer levels were all similar between the two groups. Serum GALP level was significantly higher in PCOS patients ($P=$0,001). GALP was negatively correlated with 25(OH)D ($r=$-0.401, $P=$ 0.002) and positively correlated with total testosterone values ($r=$ 0.265, $P=$ 0.024)) Multiple regression analysis revealed that both total testosterone and 25(OH)D significantly contributed to GALP levels.
Conclusions
Our study is the first study in the literature that evaluated serum GALP levels in patients with PCOS. Increased GALP levels in PCOS and its' association with total testosterone levels, might show that GALP may act as an intermediary in increased GnRH mediated LH release that is one of the underlying pathogenetic mechanism of PCOS.

Hidden Cause of Decreased Fertility Rate During Grave's Disease

Tinatin Kutchukidze[1] & Tea Khurodze[2]
[1]David Tvildiani Medical Univeristy, Tbilisi, Georgia; [2]David Tvildiani Medical University, Endocrinology and Metabolism, Tbilisi, Georgia

Introduction
Thyroid autoimmune disorders interfere with the physiology of reproduction, cause premature ovarian aging, and mimic the early stage of menopause. Recently, no specific research was made to measure Grave's disease and infertility rates in young patients.
Case Report
Due to an inability to conceive for two years, a 24-year-old Caucasian female was referred to the clinic with typical symptoms and complaints of Grave's disease. She has a family history of Grave's disease and Diabetes mellitus. Ultrasound confirmed the presence of a highly vascularized non-homogeneous hyperplastic thyroid gland. A thyroid scan with Tc99m revealed generalized increased uptake. Laboratory investigations showed a decrease in TSH-<0.005mIU/ml (n.0.4mIU/ml - 4.0mIU/ml), elevated FT4-31.8 pmol/l (n.8.0pmol/l-22.0pmol/l), FT3- 9.69pmol/l (n3.4 pmol/l-6.76pmol/l) and positive Anti-TG -190.05 AU/ml (n>150), Anti-TPO - 75.7 IU/ml (n>75) Anti-TSHR-27.3 IU/l (n>1,5). Prolactin and gonadal hormones were within normal limits AMH - 1.8 ng/ml(n1.52ng/ml-9.95ng/ml), Fsh-6mIU/ml(n3.9mIU/ml-12.4mIU/ml). The patient was started on Methimazole and Beta-blocker. While decreasing the Methimazole dosage for further discontinuation, disease recurrence developed, and a total thyroidectomy was performed. Post-operatively, the patient was maintained on Levothyroxine. After 6 months of follow-up due to irregular Levothyroxine intake, the patient reached a hypothyroid status, during which, the patient had 2 consecutive spontaneous pregnancies, from which, one ended with spontaneous miscarriage in the early weeks of pregnancy and another, ectopic pregnancy treated with right salpingectomy. HSG confirmed weak left fallopian tube patency. After several months of keeping TSH below 2.5 mIU/ml, IVF treatment was scheduled. The results of the infertility workup showed a decrease in ovarian reserve AMH - 0.163ng/ml (n1.52ng/ml-9.95ng/ml), Fsh-16.23 mIU/ml(n3.9mIU/ml-12.4mIU/ml), due to it, modified natural cycle IVF was performed. She received 2 oocytes and 2 embryos. One high-grade blastocyst was transferred in a fresh cycle that ended with pregnancy and delivery. The child was born without a genetic disorder but with natal teeth.
Conclusion
This is a rare case of infertility with diminished ovarian reserve due to Grave's disease. A pregnancy was reached by proper correction of thyroid hormonal parameters and modified natural cycle IVF. It indicates a possible need for close monitoring of the functional ovarian reserve in patients planning pregnancy even in the young age group.

A case of prolactin increase with cyproterone acetate: sublingual use of estradiol in transgender woman

Hüseyin Cihan & Banu Sarer Yurekli
Ege University Faculty of Medicine, Endocrinology, Izmir, Turkey

Introduction
Transgender women and gender diverse individuals with functioning testicles who are eligible for estrogen-based hormone therapy need to use antiandrogens in addition to estrogen to achieve adequate desired physical changes and suppress testosterone to cisgender women levels. Sublingually administered estradiol can achieve higher serum estradiol levels than traditionally administered oral estradiol, but may require multidaily dosing (1). We present a case of transgender woman who uses estrogen sublingually and cyproterone acetate as antiandrogen.

Case
Twenty-four years old transgender woman has been using estradiol in dose of 1 mg four times a day sublingually for 6 months. She has been started on cyproterone acetate 12.5 mg/day as antiandrogen. She has no chronic disease in her past medical history. During her fourth month follow-up visit, the laboratory values as FSH:1.93 U/l, LH: 5.4 U/l, estradiol 131 pg/ml, testosterone <12 ng/dl, prolactin level was 141.2 mg/l. When the prolactin level was measured in other day, it confirmed the high prolactin levels. She has no galactorrhea. There was no gender affirming surgery in her medical history. She has no complaint of headache or visual problems which could accompany with pituitary adenoma. Cyproterone acetate was stopped and after 6 week of period in which sublingual estradiol was the only gender affirming hormonal therapy, prolactin level turned back to normal levels as 15.7 mg/l. She continued to have sublingual estradiol as gender affirming hormonal therapy. Appropriate testosterone suppression was provided with estrogen only therapy.
Conclusion
Hyperprolactinemia can be seen in transgender women receiving gender affirming hormonal therapy. Cyproterone acetate could be a cause for high prolactin levels. Not only cyproterone acetate but also there are cases in the literature that shows prolactin increase with sprinolactone use as antiandrogen. It has been shown that normalization of prolactin levels occurs when cyproterone acetate is ceased. However, antiandrogens is generally needed to provide suppression of testosterone levels in transgender women. In our case, cyproterone acetate caused increase in serum prolactin levels although it has been given in low doses. We would like to draw attention to the fact that sublingual use of estradiol could provide better serum estradiol levels and testosterone suppression compared to oral use of estradiol.

Newly diagnosed diabetes in Turner syndrome: what is the role of incretins?

Carolina Cecchetti[1], Paola Dionese[1], Elisabetta Belardinelli[1], Laura Rotolo[1], Beatrice Solmi:[1], Flaminia Fanelli[2], Uberto Pagotto[1] & Alessandra Gambineri[1]
[1]Via Giuseppe Massarenti, 9, Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Italy; [2]Via Giuseppe Massarenti, 9, Center for Applied Biomedical Research, Department Of Medical and Surgical Sciences, Alma Mater Studiorum - Bologna University, Bologna, Italy

Introduction
Diabetes mellitus (DM) develops early in Turner syndrome (TS) and appears not related to common risk factors. The precise mechanism of its development is still a matter of debate: a defective insulin response seems to be involved, but the role of incretins is still undefined.
Objective
To evaluate the implication of incretin release in the early stages of DM development in TS.
Materials and Methods
153 Turner patients with normal glucose tolerance (NGT) state at baseline were prospectively evaluated for DM development until 2020 (75 gr OGTT every two years). Samples were collected at 0, 30, 60, 90 and 120 min: glucose and insulin dosage was immediately performed, while incretins were dosed at study end on samples stored at -80°. 10 TS with newly diagnosed DM (120 min glucose ≥ 200 mg/dl) and 10 NGT TS (0 min glucose <100 mg/dl and 120 min glucose <140 mg/dl) were finally evaluated. 19 females comparable for age, BMI and waist circumference were used as controls, 6 with a new diagnosis of type 2 DM and 13 with NGT. An autoimmune cause of DM was excluded by dosing specific autoantibodies. EMD Millipore Corporation© kits were used to measure incretins, through enzyme linked immunosorbent assay (ELISA).
Results
Within controls, insulin to glucose ratio (INS/GLUC) was significantly higher in DM compared to NGT at OGTT 0 ($P=0.003$), 90 ($P=0.052$) and 120 min ($P<0,001$). Differently, within TS, INS/GLUC ratio was comparable between DM and NGT, except a borderline significant decrease at times 60 ($P=0.062$) and 90 min ($P=0.064$) in DM; INS/GLUC total area under the curve was also tendentially decreased ($P=0.081$) in DM vs NGT. GLP-1 levels were similar in TS NGT and DM patients at any time during OGTT, while baseline GLP-1 was significantly higher in DM vs NGT controls (57.5pmol/l$\pm$19.0 vs 34.2 $\pm$ 7.80; $P=0.05$) and higher with a borderline significance at 30 and 60 min ($P=0.072$; $P=0.058$). Regarding GIP, DM controls had higher levels than NGT controls only at 30 min (100.9pmol/l$\pm$35.0 vs 68.8$\pm$30.9, $P=$ 0.046), but there was no such distinction in TS.
Conclusions
In TS, DM has a specific pathogenesis, with insulin secretion deficiency present since the earliest stages. This study suggests that incretins are one of the mechanisms potentially involved in the pathogenetic process, probably through an insufficient release. Further studies on larger cohorts will be needed to provide stronger results and guide clinical practice.

A systematic review of gonadotropin and GnRH therapy for the induction or completion of puberty in males with hypogonadotropic hypogonadism

Emma Alexander[1], Duaa Faruqi[2], Robert Farquhar[2], Ayesha Unadkat[2], Kyla Ng Yin[1], Vasilis Kokotsis[1] & Sasha Howard[1]
[1]Centre for Endocrinology, William Harvey Research Institute, Barts and the London School of Medicine and Dentistry, London, United Kingdom; [2]Barts and The London School of Medicine and Dentistry, Queen Mary University of London, Charterhouse Square Campus, London, United Kingdom

Background and aims
Hypogonadotropic hypogonadism is characterised by inadequate secretion of gonadotropins (luteinising hormone (LH) and follicle-stimulating hormone (FSH)) leading to absent, partial or arrested puberty. In males, classical treatment with testosterone promotes virilisation but does not facilitate testicular growth or spermatogenesis. Conversely, treatment with gonadotropins or gonadotropin-releasing hormone (GnRH) stimulates Sertoli and Leydig cells directly, leading to increased testicular volumes, appropriate serum testosterone concentrations and spermatogenesis. To quantify treatment practices and efficacy, we aimed to systematically review all studies investigating gonadotropin and GnRH therapies for the induction or completion of puberty in males with hypogonadotropic hypogonadism.
Methods
A systematic review of Medline, EMBASE, Global Health, and PsychInfo databases was conducted in December 2022, with RoB 2.0/ROBINS-I/NHLBI scoring for quality appraisal. Protocol registered on PROSPERO (CRD42022381713). Eligibility criteria: studies since 1990 of patients with hypogonadotropic hypogonadism treated with gonadotropins/GnRH for 6+ months assessing pubertal outcomes, including testicular volumes, penile length, LH/FSH, testosterone, inhibin B, anti-Müllerian hormone (AMH), spermatogenesis and fertility.
Results
After screening 3,917 abstracts, 102 studies met inclusion criteria (78 pre-post observational studies, 18 comparative non-randomised studies, 6 randomised controlled trials), including 4,945 patients from 24 countries. Median NIHLBI score for observational studies was 9/12 (interquartile range (IQR) 8-10) and 41.6% of comparative studies had serious risk of bias in at least one domain. The average age of participants was <25 years in 47.1% ($n=48$) of studies. The most frequently described gonadotropin was hCG ($n=96$, 94.2% of studies), followed by FSH ($n=36$, 35.3%) and hMG ($n=36$, 35.3%). 22.5% ($n=23$) of studies described use of GnRH. Median reported duration of treatment/follow-up was 17 months (IQR 10-24 months). 73 studies described change in testicular volume, and 51 of 55 statistical analyses (92.7%) reported a significant increase in size post-treatment. Among other outcomes, 12 studies (11.8%) assessed penile length, 27 (26.4%) LH, 35 (34.3%) FSH, 73 (71.6%) testosterone, 14 (13.7%) inhibin B, 7 (6.9%) AMH, 67 (65.7%) spermatogenesis and 31 (30.4%) fertility. 37 (36.2%) of studies characterised adverse effects, most frequently local reactions, changes to biochemical parameters, acne and gynaecomastia.
Conclusions
There is a growing body of evidence regarding the use of gonadotropins or GnRH for attainment of pubertal outcomes in patients with hypogonadotropic hypogonadism and outcomes are promising. However, there remains substantial heterogeneity in terms of treatment choice, dose, duration, and outcomes assessed, and in particular, randomised studies are needed to increase the quality of evidence for this important patient group.

Interleukin-22/Interleukin-22 binding protein axis and oral contraceptive use in polycystic ovary syndrome

Seren Aksun[1], Ece Ersal[1], Oytun Portakal[2] & Bulent Yildiz[3]
[1]Hacettepe University School of Medicine, Department of Internal Medicine, Ankara, Turkey; [2]Hacettepe University School of Medicine, Department of Biochemistry, Ankara, Turkey; [3]Hacettepe University School of Medicine, Division of Endocrinology and Metabolism, Ankara, Turkey

Background and Aim
Polycystic ovary syndrome (PCOS) is associated with compositional and functional alterations in gut microbiota. The cytokine interleukin-22 (IL-22) is produced by both innate and adaptive immune cells and closely linked to gut immunity. IL-22 is tightly controlled by its binding protein (IL-22BP), which serves as an antagonist of IL-22 signaling. Preliminary animal studies and limited human data in Asian populations suggest lower circulating levels of IL-22 in PCOS. In this study, we aimed to assess whether IL-22/IL-22BP axis is altered in PCOS at baseline and in response to short-term oral contraception.
Methods
We have evaluated circulating concentrations of IL-22 and IL-22BP in serum samples of 63 PCOS patients and 39 age- and BMI-matched healthy controls who were enrolled for PCOS follow-up studies previously. Blood samples were taken in the early follicular phase of a cycle and stored at -80 ^{0}C. Serum IL-22 and IL-22BP levels were measured by ELISA at baseline in both women with PCOS and controls, and after 3 months of OC use in PCOS group. IL-22/IL-22BP ratio was calculated in order to have a better reflection of IL-22 biological activity.
Results
At baseline, serum IL-22, IL-22BP concentrations and IL22/IL-22BP ratio were similar between women with PCOS and healthy controls. Three months of OC use along with general lifestyle advice resulted in a significant increase in IL-22/IL-22BP ratio in the PCOS group. (62.4 [IQR:14.7-172.7] at baseline vs 73.8 [IQR:15.1-264.3] after OC use respectively $P=0.011$).
Conclusions
Results of the current study show that women with PCOS have similar circulating concentrations of IL-22 and IL-22BP with healthy women and that short term oral contraception is associated with an increase in IL-22/IL-22BP ratio suggesting higher biological activity of the IL-22 system with OC use in PCOS.

Phenotypic and genotypic variation in pubertal presentation among patients with self-limited delayed puberty and hypogonadotrophic hypogonadism

Yuri Aung[1], Vasilis Kokotsis[2] & Sasha Howard[2]
[1]Royal London Hospital, London, United Kingdom; [2]William Harvey Research Institute, Queen Mary University of London, London, UK, Centre for Endocrinology, London, United Kingdom

Introduction
Delayed puberty (DP), affecting over 2% of adolescents, is defined as pubertal onset at 2-2.5 SDs later than the general population. Two common underlying aetiologies are self-limited DP (SLDP) and congenital hypogonadotrophic hypogonadism (HH). However, these can be difficult to discern between on first presentation of a patient to endocrinology services. This study sought to elucidate phenotypic and genotypic differences between the two diagnoses in order to optimise patient treatment and pubertal progression.
Methods
This was a retrospective study of a UK DP cohort managed from 2015-2022, identified through the NIHR clinical research network. Patients were diagnosed with SLDP if they had attained Tanner stage G4/B4 by age 18 years. Alternatively, they were diagnosed with HH if they had not commenced (complete, cHH) or had arrested puberty (partial, pHH) prior to age 18 years. Phenotypic data pertaining to auxology, Tanner staging, biochemistry, bone age and hormonal treatment were analysed. Genetic scores for likelihood of HH were assigned from 1-5 after whole-exome sequencing and identification of predicted pathogenic variants in genes associated with either SLDP or HH (1=known SLDP variant, 2=likely SLDP variant, 3=no or overlap variant, 4=likely HH variant, 5=known HH variant). Statistical analysis was completed using IBM SPSS and R.
Results
78 patients were included in this study. 52 (66.7%) patients had SLDP and 26 (33.3%) patients had HH, comprising 17 (65.4%) pHH and 9 (34.6%) cHH patients. Probands were predominantly male (90.4%). Male SLDP patients presented with significantly lower height and weight SD than HH patients ($P=0.004$, $P=0.021$). HH patients had lower testicular volumes, particularly cHH patients ($P=0.019$). 23.1% of SLDP and 2.9% of HH patients had a family history of DP ($P=0.709$). 17.3% of SLDP compared to 34.6% of HH patients had classical symptoms of HH (e.g. micropenis, cryptorchidism, anosmia, renal or limb anomalies, $P=0.807$). Mean first recorded LH and inhibin B were also lower in HH patients, particularly in cHH patients ($P=0.005$, $P=0.002$). Mean genetic score of SLDP patients was lower at 3.00 ± 0.55 as compared to 3.47 ± 0.70 in HH patients ($P=0.008$). There were no significant differences identified in FSH, testosterone, AMH or bone age delay.
Discussion
This study identifies key phenotypic markers that help distinguish between SLDP and HH on first presentation, and that could be incorporated with genetic scoring to improve diagnostic accuracy. Further research into such an integrated framework or scoring system would be useful in aiding clinician decision-making and treatment optimisation.

Correlation between both serum and seminal fluid vitamin D levels and vitamin D receptor CDX polymorphism in male infertility

Suzana Vladoiu[1], Anca Botezatu[2], Andrei Muresan[3], Adrian Albulescu[2], Oana-Monica Popa[1], Fudulu Alina[2], Ples Adriana[2], Cristina Stancu[1], Iancu Iulia Virginia[2], Corin Badiu[4,5] & Dinu Draganescu Daniela[1]
[1]National Institute of Endocrinology, Molecular, Cellular and Structural Research Laboratory, Bucharest, Romania; [2]'Stefan S. Nicolau' Institute of Virology, Department of Molecular Virology; [3]National Institute of Endocrinology, Molecular, Cellular and Structural Research Laboratory; [4]'C. Davila' University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania; [5]National Institute of Endocrinology, Thyroid Related Disorders, Bucharest, Romania

Vitamin D (VD) now considered a steroid hormone, has been correlated with male reproductive disorders. The activity of VD is mediated through its receptor (VDR), distributed in various tissues including reproductive tissues. VDR polymorphism located in the promoter region of the gene, rs17883968 (Cdx2) G → A associated with transcriptional activity. The aim of this study was to assess both seminal and serum VD levels in a group of infertile patients ($n=87$, median: 34 years, range 20–55 years) vs control ($n=24$, median: 33 years, range 20–45 years) to establish the relation with Cdx2 VDR polymorphism. Subjects presenting known causes of infertility were excluded from the study. The patients were divided in three groups according to sperm count analysis: oligoasthenospermia, oligoterato-asthenospermia and azoospermia group. In this purpose, freshly collected blood was drawn from the subjects. Seminal fluid was harvested after 3–5 days of sexual abstinence. 25(OH) Vit. D serum and seminal levels were assayed using the electrochemiluminescence method according to the manufacturer's recommendations (Roche Diagnostics, Basel, Switzerland) with the RocheCobas E601 autoanalyzer. CDX polymorphism was evaluated through specific VDR gene PCR followed by digestion with the restriction enzyme Bpu10I (New England Biolabs). The VD serum levels was found to be low in the subjects infertile compared to the control group, and the analysis of the three groups of infertile vs. control shows differences Statistically significant for oligoasthenospermia ($P=0.0109$), oligoteratoasthenospermia ($P=0.0420$). No notable differences were observed in the seminal fluid. However, the VD levels were higher in seminal fluid than serum in all groups and a strong statistical significance was observed, suggesting the ability of reproductive tract to synthesize VD locally. VD levels were found to be significantly decreased in subjects with CDX- AA genotype especially in azoospermia ($P=0.0028$) and oligoasthenoteratospermia ($P=0.0198$). This study demonstrates a direct and positive relationship between serum VD level and overall semen quality. The results provide new insights into the involvement of the Cdx-2 polymorphism and VD deficiency in male infertility, providing genetic evidence for the role of the VDR in the development of male infertility. Taking into account the results, we highlight the important role of genetic changes at the VDR level associated with VD deficiency in male infertility.

The fertility status of patients with Cushing's disease under treatment

Fatma Nur Korkmaz, Asena Gökçay Canpolat, Özgür Demir & Demet Çorapçıoğlu
Ankara University, Faculty of Medicine, Department of Internal Medicine, Endocrinology and Metabolism, Ankara, Turkey

Introduction
The main goal of treatment in Cushing's disease (CD) is to induce remission as well as to restore reproductive function. We aimed to evaluate the reproductive status of the female patients with CD encountered in sexually active patients after surgical with/without medical treatments.
Method
The retrospective data was obtained from the medical records of the 72 female patients diagnosed with CD at hospital registration system. The patients were contacted on 8/2022 by phone and were asked about their CD and reproductive histories. Two patients having a history of TAH-BSO, 15 individuals who could not be reached by phone, and three dead patients were excluded from the study.
Results
Six of the patients were single at the time of the research, so no further inquiries regarding fertility status were made. At the time of the diagnosis, 39 of the females were premenopausal. Thirty premenopausal patients were followed in remission. In terms of the number of pregnancies before CD diagnosis, 33 sexually active individuals had 72 pregnancy and 60 live births. Before CD diagnosis, two patients had attempted *in vitro* fertilization (IVF) once, and one patient had attempted IVF twice. Four IVF attempts resulted in three pregnancies and one live birth. Twenty four patients had no pregnancy loss, six patients had one pregnancy loss, and three patients had two pregnancy losses. During the post-treatment period, hypogonadism was detected in 12 of 33 premenopausal individuals following CD treatment. Six of the 33 patients were using contraception. Eleven patients wanted to get pregnant. Twenty seven contraceptive-free patients had a history of ten pregnancies, seven live births, and two pregnancy losses. Two patients experienced miscarriage once. Two (7%), one (%3.7), and one (3.7%) couples underwent IVF once, four and five times, respectively. The number of pregnancies and live births during the remission period of CD were reduced, while the frequency of miscarriage was the same.
Conclusion
While current therapies achieve remission in the majority of the patients, they do not contribute to the formation of adequate reproductive functions despite the improved infertility treatment procedures. Endocrinologists' and pituitary surgeons' incorrect assumption of the low possibility of achieving pregnancy rates even if remission is achieved, should be corrected, and refer patients with CD at the correct time without delay for assisted reproductive procedures if necessary.

Endocrine and Non-Endocrine Causes of Fatigue in Adults With Turner Syndrome: Cohort Study and Review of the Literature

Anna Rosenberg[1], Veerle D.A. Dingemans[1], Anja Roubos[2], Sanne Luijks[3], Arianne B. Dessens[4], Ramon Dykgraaf[3], Jolien W. Roos-Hesselink[5], Elisabeth van Rossum[1], Aart Jan van der Lely[1] & Laura De Graaff[1]
[1]Internal Medicine, division of Endocrinology, Erasmus MC, University Medical Center, Rotterdam, Netherlands; [2]Center of Excellence for Neuropsychiatry, Vincent van Gogh, Venray, Netherlands; [3]Obstetrics and Gynecology, Erasmus MC, University Medical Center, Rotterdam, Netherlands; [4]Department of Child and Adolescent Psychiatry and Psychology, Erasmus MC, University Medical Center, Rotterdam, Netherlands; [5]Department of Cardiology, Erasmus MC, University Medical Center, Rotterdam, Netherlands

Background
Turner syndrome (TS) is a rare genetic developmental disorder characterized by gonadal dysfunction, short stature and heart defects, among others. Women with TS often suffer from severe fatigue, for which they are typically referred to endocrinologists. The diagnostic work-up is generally time-consuming and invasive, but it rarely solves the problem. To prevent the personal and financial burden of unnecessary diagnostic procedures, it is crucial to understand fatigue in TS. Therefore, in this study, we explored the association between fatigue and endocrine and non-endocrine comorbidities in a – for rare disorders – large group of TS women.
Design
Cross-sectional study.
Methods
170 genetically confirmed TS women who attended the TS reference center underwent a systematic health screening, including a structured interview, complete physical examination, biochemical measurements, perceived stress and fatigue questionnaires and additional tests when indicated.
Results
Median age was 32.6 years (IQR 23.9 – 41.4 years) and median BMI was 25.4 kg/m^2 (IQR 22.6 – 28.5 kg/m^2). One in three TS women experienced severe fatigue. Liver enzyme disturbances and body mass index were significantly associated with higher fatigue scores, while childhood growth hormone treatment was associated with lower fatigue scores. Perceived stress was highly correlated with fatigue ($\rho = 0.71$; $P<0.001$).
Conclusions
There was no association between fatigue and most endocrine and non-endocrine disorders, which implies that fatigue is only partly explained by somatic disorders. The high correlation between perceived stress and fatigue suggests that TS-specific neuropsychological processes may play an important role in the etiology of fatigue in TS women. We provide a practical algorithm for the endocrine, non-endocrine and psychological approach to fatigue in TS women.

Introduction
Atrazine is one of the most widely used pesticides worldwide and a common contaminant in human drinking water. Atrazine is also a potent endocrine disruptor capable of causing a variety of negative health outcomes, including decreased testosterone production and infertility. Although harmful effects of atrazine on male reproductive health have been reported, little is known about its molecular mechanisms. Within the seminiferous tubules, Sertoli cells are responsible for ensuring a suitable environment for spermatogenesis, providing mechanical and nutritional support to germ cells. However, the cytotoxic and metabolic effects of atrazine on Sertoli cells remain unknown.
Aim of this study
In this work, we aimed to elucidate the effects of the endocrine disruptor atrazine on the nutritional support of spermatogenesis by studying its effect on the metabolic profile and mitochondrial function of Sertoli cells.
Materials and methods
Mouse Sertoli cells (TM4 cell line, $n=10$) were exposed to biologically relevant concentrations of atrazine (in µg/l: 0.3, 3, 30, 300 and 3000). After 24 h, cytotoxicity was accessed. The mitochondrial activity and total ROS production were accessed by JC-1 dye and CM-H_2DCFDA probe, respectively. FRAP assay was used to measure the antioxidant potential of culture media. Lactate dehydrogenase (LDH) protein levels were analyzed by Western Blot and the glycolytic function was evaluated by Seahorse XF Glycolysis Stress Test Kit.
Results
Despite no cytotoxicity was observed, our results show a decreased metabolic activity when cells were exposed to 300 µg/l and 3000 µg/l of atrazine for 24 h. Additionally, a dose-dependent decrease in the expression of LDH was observed after exposure. Although the mitochondrial function of Sertoli cells was not affected by atrazine, we observed a tendency for increased endogenous ROS production in the highest atrazine concentrations (300 µg/l and 3000 µg/l) associated with a decreasing trend in the antioxidant potential of the culture media in the same concentrations, suggesting a pro-oxidant status.
Conclusions
Our data suggest that atrazine interferes with the glycolytic metabolism of mouse Sertoli cells, by reducing oxidoreductase activity and LDH expression. Since lactate is the preferred energetic source for developing germ cells, the nutritional support of spermatogenesis may be compromised. In addition, our results suggest that atrazine may induce a prooxidant status, leading to increased ROS production and oxidative stress. Overall, the endocrine disruptor atrazine induces a pro-oxidant state and modulates Sertoli cells metabolic support of spermatogenesis which can compromise it and lead to male infertility.

Comparison of omentin (intelectin-1) expression and regulation in ovarian follicle cells from normal weight Large White and obese Meishan pigs

Karolina Pich[1,2], Natalia Respekta[1,2], Patrycja Kurowska[1], Christelle Rame[3], Joëlle Dupont[3], Kamil Dobrzyń[4], Nina Smolińska[4] & Agnieszka Rak[1]
[1]Institute of Zoology and Biomedical Research, Jagiellonian University in Krakow, Laboratory of Physiology and Toxicology of Reproduction, Krakow, Poland; [2]Doctoral School of Exact and Natural Sciences, Jagiellonian University, Krakow, Poland; [3]INRAE, UMR85, Unité Physiologie de la Reproduction et des Comportements, Nouzilly, France; [4]Faculty of Biology and Biotechnology, University of Warmia and Mazury in Olsztyn, Department of Animal Anatomy and Physiology, Olsztyn-Kortowo, Poland

Introduction
Omentin, also known as intelectin-1 (ITLN1), is a novel adipokine produced predominantly by visceral adipose tissue, which improves insulin sensitivity. Decreased levels of ITLN1 have been reported in the serum of obese and polycystic ovary syndrome patients, as well as in the serum and adipose tissue of obese Meishan (MS) compared to normal weight Large White (LW) pigs. However, the role of ITLN1 in female reproduction at different metabolic status is still unknown.
Aims and methods
This study aimed to 1) examine the mRNA (real-time PCR) and protein (Western blot) expression and immunolocalization (immunofluorescence) of ITLN1 in the ovarian follicles as well as its concentration in follicular fluid (FF, ELISA) at different days of estrous cycle (days 2-3, 10-12 and 14-16 of estrous) in LW and MS pigs; 2) determine the *in vitro* effect of gonadotropin (LH, FSH) and steroids (P_4, T, and E_2) on ITLN1 expression in ovarian follicular cells and its secretion to the culture medium in LW and MS pigs; 3) the involvement of extracellular signal-regulated kinase (ERK1/2) and phosphatidylinositol 3'-kinase (PI3K) signalling pathways in the regulation of ITLN1 expression in LW pigs. Statistical analysis was performed using a one-way analysis of variance and Tukey's test ($P<0.05$).
Results
We showed elevated ITLN1 expression in the ovarian follicles as well as its concentration in FF of LW compared to MS pigs; interestingly, in both breeds of pig, the level of ITLN1 increased with the progression of the estrous cycle. Immunofluorescence showed ITLN1 presence in granulosa, theca, cumulus cells, and oocytes. Both gonadotropins and steroids increased the level of ITLN1 in the ovarian follicle cells as well as in culture medium from LW pigs through kinases ERK1/2 and PI3K, while in MS pigs we observed only the stimulatory effect of LH and T on ITLN1 levels.
Conclusions
For the first time we demonstrated dependent on metabolism condition and the estrous cycle phase ITLN1 expression in the porcine ovarian follicles as well as its regulation by gonadotropins and steroid hormones through ERK1/2 and PI3K signaling pathways. Future studies will be necessary to understand the role of ITLN1 on ovarian function like steroid synthesis of animals with different metabolic states.

Early markers of metabolic disorders, such as leucin and isoleucine level and lipid accumulation product, should be considered as the potential additional criterium in PCOS classification

Katarzyna Paczkowska[1], Dominik Rachoń[2], Andrzej Berg[3], Jacek Rybka[4], Katarzyna Kapczyńska[4], Marek Bolanowski[1] & Jacek Daroszewski[1]
[1]Wroclaw Medical University, Department of Endocrinology, Diabetes and Isotope Therapy, Wroclaw, Poland; [2]Medical University of Gdansk, Department of Clinical and Experimental Endocrinology, Gdańsk, Poland; [3]Medical University of Gdansk, Department of Pharmaceutical Chemistry, Gdańsk, Poland; [4]Polish Academy of Sciences, Laboratory of Medical Microbiology, Hirszfeld Institute of Immunology and Experimental Therapy, Wrocław, Poland

Background
Polycystic ovary syndrome (PCOS) is a common endocrine disorder that affects reproductive age women and predispose to the development of metabolic disturbances. However, Rotterdam criteria, commonly used to diagnose and classify this disorder, do not include metabolic markers. Recent research has shown that several metabolic factors may play a role in PCOS pathogenesis. Branched-chain amino acids (BCAA) are the group of essential amino acids including leucine, isoleucine and valine and studies have shown that PCOS women have higher levels of BCAA compared to healthy individuals. LAP (lipid accumulation product) is an index combining waist circumference and triglycerides concentration that was found to be helpful in recognizing insulin resistance and predicting liver steatosis.
Methods
A group of 326 women: 209 diagnosed with PCOS and 117 healthy individuals, was included in the study. Multiple parameters were assessed, including anthropometrical, biochemical and hormonal ones; HOMA-IR and LAP were calculated using known formulas. The gas–liquid chromatography combined with tandem mass spectrometry was used to investigate BCAA level. PCOS women were grouped using Rotterdam criteria into four main phenotypes, which included: A-46, B-92, C-43 and D-28 individuals. Additionally, from the PCOS group, 46 women diagnosed with obesity were separated for further analysis. Subsequently, obese PCOS patients were classified as Metabolically Healthy (MHO) and Metabolically Unhealthy Obesity (MUO); these subgroups consisted of 27 and 19 age-matched individuals, respectively.
Results
Statistical analysis of metabolic parameters showed significant differences in BMI, HOMA-IR and total cholesterol level between PCOS phenotypes; however, fasting glucose, HDL, triglycerides, valine, leucine and isoleucine concentrations, as well as LAP do not differ in these subgroups. Comparison of MHO and MUO PCOS women, revealed that LAP, leucine and isoleucine concentrations were significantly higher among MUO subgroup: 101.98 ± 34.74 vs 55.80 ± 24.33 ($P<0.001$); 153.26 ± 22.26 vs 137.25 ± 25.76 nmol/ml ($P=0.04$) and 92.92 ± 16.09 vs 82.60 ± 18.70 nmol/ml ($P=0.02$), respectively. No significant differences in BMI, fasting glucose and HOMA-IR between MHO and MUO were found: 35.0 ± 4.8 vs 36.1 ± 4.6 kg/m2 ($P=0.59$); 88.0 ± 6.0 vs 87.73 ± 6.28 mg/dl ($P=0.67$); 3.36 ± 1.70 vs 4.17 ± 1.77 ($P=0.1$), respectively.
Conclusions
PCOS phenotypes distinguished with Rotterdam criteria represent the differences between patients according to ovulatory and androgen excess symptoms. However, to better identify patients at risk of metabolic disorders, a new classification is needed. Leucine and isoleucine concentrations, as well as lipid accumulation product, should be taken into consideration as metabolic factors that might be included in PCOS classification since they are helpful in differentiation of 'metabolic health'.

Effects of testosterone therapy on erythrocytosis and prostate adverse events in obese males with functional hypogonadism and type 2 diabetes

Kristina Groti Antonic
University Medical Center Ljubljana, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia

Aims
Testosterone therapy (TTh) has been postulated to increase the risk of prostate adverse events (PAEs) and erythrocytosis, risk further exacerbated in high-risk obese patients with type 2 diabetes (T2D) and functional hypogonadism (FH). We investigated safety aspects of TTh in obese males with FH and T2D by observing the incidence of PAEs and erythrocytosis and determining when statistically significant difference from the baseline manifests in hematocrit (Hct) and prostate-specific antigen (PSA) levels.
Materials and Methods
Fifty-five obese men with FH and T2D participated in a two-part, prospective observational clinical study (first year: double-blind, randomized, placebo-controlled trial employing testosterone undecanoate; second year: open-label follow-up with all participants receiving TTh). Outcomes were assessments of Hct and PSA levels at the baseline, and 3, 6 and 12 months into each of two years of the study.
Results
No adverse cardiovascular events or PAEs were observed. Hct first increased at statistically significant level from the baseline after 3 months of TTh in group T and after 6 months of TTh in group P. Individual Hct values for all participants remained below 0.52 throughout 2-year course of the study. PSA increased from the baseline in both groups within 3-6 months of trial start regardless of intervention applied (placebo or TTh). 52 patients never exceeded PSA level of 4.0 μg/l nor experienced year-on-year PSA increase $>$ 1.4 μg/l. No subject ever reached supraphysiological concentration of total testosterone.
Conclusions
Our results show that TTh may be safe in obese males with FH and T2D.

The Role of Testosterone Treatment in Patients with Type 2 Diabetes Mellitus: Results from A Meta-Analysis Study

Walter Vena[1], Linda Vignozzi[2], Mario Maggi[2], Alessaandra Sforza[3], Alessandro Pizzocaro[4] & Giovanni Corona[2,3]
[1]Cliniche Gavazzeni Humanitas, Diabetology & Endocrinology Unit, Bergamo, Italy; [2]University of Florence, Andrology, Women's Endocrinology and Gender Incongruence Unit, 'Mario Serio', Florence, Italy; [3]Maggiore Bellaria Hospital, Endocrinology Unit, Medical Department, Bologna, Italy; [4]Humanitas Research Hospital, Endocrinology, Diabetology and Andrology Unit, Rozzano, MI, Italy

Introduction
type 2 diabetes mellitus (T2DM) and hypogonadism are common conditions afflicting the aging male, often present together. The specific role of testosterone (T) replacement therapy (TRT) on glycometabolic profile and body composition, particularly in patients with T2DM, is still the object of an intense debate. The aim of the present study is to meta-analyze the role of TRT in T2DM considering all placebo and non-placebo-controlled randomized clinical trials (RCTs).
Methods
an extensive Medline, Embase and Cochrane search was performed. We did not employ search software but hand-searched bibliographies of retrieved papers for additional references. All RCTs studies investigating the impact of TRT on glycometabolic outcomes without any restriction were included.
Results
overall, 12 studies were available including 684 patients with a mean follow-up of 38.4 weeks. These trials differ in basal TT levels and type of T preparation used. In addition, only 10 were placebo controlled Patients with impaired fasting glucose were characterized by a 3 nmol/l lower level of total testosterone when compared to controls. Similarly, impaired fasting glucose was associated with a 1.8-fold increased risk of hypogonadism, when compared to subjects with normal glucose levels. Secondary hypogonadism was two times higher in subjects with impaired fasting glucose when compared to rates observed in the general population. Testosterone replacement therapy was able to improve body composition, insulin resistance, and glucose profile both in impaired fasting glucose and type 2 diabetes mellitus whereas its role on body weight, lipid profile, and sexual function was less evident.
Conclusions
The overall data analysis indicates that TRT favorably affects glycemic control in diabetic subjects reducing fasting glycaemia, HbA1c and HOMA index and decreasing triglyceride levels and fat mass. All these differences were confirmed when only placebo-controlled studies were evaluated, with the exception for HbA1c decrease, where only a trend towards a decrease was apparent. Conversely no effects on TRT on erectile function was observed.

The impact of pharmacological treatments on oxidative stress, inflammatory parameters and semen characteristics

Virginia Zamponi, Rossella Mazzilli, Soraya Olana, Flaminia Russo, Camilla Mancini, Antongiulio Faggiano & Gerardo Salerno
Department of Clinical and Molecular Medicine, Sapienza University of Rome, Rome, Italy

Introduction
Although the pathogenic mechanism is not completely understood, pharmacological treatments could negatively affect seminal parameters. The analysis of inflammatory (i.e. cytokines) and oxidative stress parameters represent a new tools to investigate the causes of idiopathic male infertility. The aim of this study was to evaluate the impact of medications on oxidative stress, inflammatory parameters and semen characteristics in male with idiopathic infertility.
Materials and Methods
In this observational, case-control, clinical study 50 men with idiopathic infertility, referring to the Endocrinology-Andrology Unit of Sant'Andrea Hospital – 'Sapienza' University of Rome, from October 2017 to June 2018 were enrolled. Of them, 38 subjects (study group) were on pharmacological treatment from at least three months and 12 subjects were enrolled as a control. The study group were clustered according to the medications (Group A: antihypertensive, n.10; Group B: thyroxine, n.6; Group C: chronic anti-inflammatory, n.13; Group D: miscellaneous, n.6; Group E: lipid-lowering agents, n.4). Semen analysis were performed according to WHO 2010 guideline. Interleukins (IL)-10, IL-1beta, IL-4 as anti-inflammatory cytokines, IL-6, TNF-alpha as pro-inflammatory, and IL-1alpha, as a marker of testicular function, were determined using a solid phase sandwich immunoassay. The d-ROM test was assessed through a colorimetric determination of reactive oxygen metabolites and measured by a spectrophotometer. Beta-2-Microglobulin and Cystatin-C, were measured with an immunoturbidimetric analyzer.
Results
No difference between study and control group for age and macroscopic and microscopic semen characteristics were found. The same result was obtained after clustering and comparing the study group according to the drug categories. IL-1 alpha and IL-10 were significantly lower in the study group compared to control. After clustering the study group, IL-10 was significantly lower in groups A, B, C and D compared to control group. Furthermore, a direct correlation between IL-1alpha, IL-10 and TNF-alpha and leukocytes was found. Conversely, a statistically significant inverse correlation between IL-4 and sperm concentration, and between beta-2 Microglobulin and total sperm number were highlighted.
Conclusions
This study represents a first attempt to understand how drugs belonging to different categories could affect the properties of semen. Although the sample size was not large, the data suggests a correlation between the use of medications and inflammation. This could clarify the pathogenic mechanism of action for several pharmacological classes on male infertility, which is not completely known. Further studies on larger populations are needed to investigate the possible role of the various drug categories on male fertility.

Resistin as A New Regulator of Luteolysis: *in Vitro* Effect of Resistin on Proliferation, Apoptosis, and Autophagy in Porcine Luteal Cells

Patrycja Kurowska[1], Kinga Gaździk[1], Agata Jasińska[1], Ewa Mlyczyńska[1,2], Dominika Wachowska[1,2] & Agnieszka Rak[1]
[1]Institute of Zoology and Biomedical Research, Jagiellonian University, Laboratory of Physiology and Toxicology of Reproduction, Krakow, Poland; [2]Doctoral School of Exact and Natural Sciences, Jagiellonian University, Krakow, Poland

To maintain proper fertility the balance between formation and luteolysis of corpus luteum (CL) are necessary and strictly controlled events in female reproduction. Degeneration of CL is correlated with apoptosis and autophagy as well as connected with decreased progesterone (P4) level. Resistin is a new key player in the regulation of luteal cells function; our previously study showed that resistin have negative effect on P4 synthesis. Thus the aim of the present study was to investigate the effect of resistin on proliferation, apoptosis, and autophagy of porcine luteal cells and involvement of mitogen-activated kinase (MAP3/1), protein kinase B (AKT), and signal transducer and activator of transcription 3 (STAT3) in these processes. Porcine luteal cells at the middle luteal phase were incubated with resistin (0.1-10 ng/ml) for 24 h to 72 h and cells proliferation was assessed by alamarBlue or MTT assay. Then, the time-dependent (24 h to 72 h) effect of resistin (1 ng/ml) on the transcript and protein level of proliferation: proliferating cells nuclear antigen (PCNA), apoptosis: caspase 3, BCL2-like protein 4 (BAX), B-cell lymphoma (BCL2), and autophagy: beclin1, microtubule-associated protein 1A/1B-light chain 3 (LC3), lysosomal-associated membrane protein 1 (LAMP1) markers were measured by real-time PCR and Western blot, respectively. We noted that resistin stimulated luteal cell proliferation with no effect on caspase 3, increased BAX/BCL2 ratio and enhanced the initiation of autophagy, which promotes the maintenance of luteal function rather than its luteolysis. Besides, using pharmacological blockers of MAP3/1 (PD98059), AKT (LY294002), and STAT3 (AG490) we observed that the effect of resistin was downregulated to the control level in proliferation and by activation MAP3/1 and STAT3 in autophagy. Summarizing, our results indicated that resistin is a new regulator of female reproduction by direct effect on CL regression, formation and maintenance of luteal cell function. It may be a future therapeutic target in luteal cells deficiency treatment leading to enhanced numbers of healthy pregnancies. However, *in vivo* experiments are necessary to confirm this hypothesis.

Polygenic Score for Dizygotic Twinning in Mothers of Spontaneously and Artificially Conceived Twins and Singletons

Nikki Hubers[1,2,3], Christian Page[4], Hamdi Mbarek[1,2,5], Nils Lambalk[2], Lannie Ligthart[1], René Pool[1,3], Jouke Jan Hottenga[1], Jenny van Dongen[1,2,3],

Siri Håberg[4], Erik Ehli[6], Jennifer Harris[4], Gonneke Willemsen[1,2,3] & Dorret Boomsma[1,2,3]
[1]Vrije Universiteit Amsterdam, Biological Psychology, Amsterdam, Netherlands; [2]Amsterdam Reproduction and Development, Netherlands; [3]Amsterdam Public Health, Netherlands; [4]Norwegian Institute of Public Health, The Centre for Fertility and Health, Norway; [5]Qatar Genome Program, Development and Innovation, Qatar; [6]Avera Institute for Human Genetics, Sioux Falls, United States

Spontaneous dizygotic (DZ) twinning results from a double ovulation and runs in families indicating a genetic component. Endocrinology studies in mothers of DZ twins observed higher levels of follicle stimulation hormone (FSH) and *FSHB* was, together with *SMAD3*, one the first loci identified as genome wide significant in genome-wide association studies (GWAS) of having DZ twins. Several additional loci were recently found that indicate genes involved with female endocrinology and fertility such as *FSHR*, and *GNRH1*. A polygenic score (PGS) for spontaneous DZ twinning, which summarises an individual's genetic risk, explained ~1.5% of the phenotypic variance when comparing mothers of spontaneously conceived DZ twins to controls. Here we compare the PGS in mothers of spontaneously conceived DZ twins with other twin mothers in the Netherlands twin register (NTR) and in the Norwegian Mother, Father and Child Cohort Study (MoBa). In the NTR, we contrast the PGSs and several demographic and lifestyle traits in four groups ($n=34.895$): those who conceived DZ or monozygotic (MZ) twins spontaneously, and those who conceived DZ or MZ twins through artificial reproductive techniques (ART) with logistic regression. Mothers of spontaneously conceived DZ twins differed in maternal age, body composition, parity and smoking behavior compared to the other groups. The PGSs ($n=4.498$), both corrected and uncorrected for these demographic and lifestyle traits, were higher in mothers of spontaneously conceived DZ twins compared to all other twin mothers, whereas the PGSs of the other three groups did not differ. We are currently conducting the PGS analyses in mothers of twins and singletons from MoBa ($n=$approximately 95.000 mothers). Our study shows that mothers of spontaneously conceived DZ twins are genetically different, and also differ in demographics and lifestyle traits compared to the other groups of twin mothers. Further endocrine, metabolomics and gene expression studies are required to help elucidate underlying processes.

Sex hormones as independent predictors of severe COVID-19 in patients with SARS-CoV-2 infection

Cristina Quinzaños Ruiz[1], Gabriela Alexandra Zapata Maldonado[1,2,2,3], María Teresa García-Unzueta[1], Luis Vázquez[1], Bernardo Alio Lavín Gómez[1] & David Ruiz Ochoa[1]
[1,2]Hospital Universitario Marques de Valdecilla, Endocrinology and Nutrition Department, Santander, Spain; [3]Hospital Universitario Marqués de Valdecilla, Endocrinology and Nutrition Department, Santander, Spain

Introduction
The SARS-CoV 2 pandemic has resulted in millions of deaths worldwide. It has been suggested that sex steroids may be involved in the prognosis of the disease.
Material and methods
Male patients diagnosed with SARS-CoV-2 infection admitted to the Marqués de Valdecilla University Hospital (Spain). Testosterone, androstenedione, estradiol, DHEA and DHEAS were determined in the first 24 h of admission and severe COVID was defined as mortality or ICU admission. For each biomarker, area under curve (AUC) and its 95% CI were estimated by using ROC curves. Levels of biomarkers were ordinal categorized in tertiles (T1, T2 and T3), and as association measure odds ratios (OR) with their 95% CI adjusted for age, BMI, smoking, renal disease and diagnosis of diabetes.
Results
Data were obtained from 98 patients: mean age 63.65 ± 15.53y; 54/98 showed severe covid (55.1%). Predictive accuracy of biomarkers was: AUC total testosterone 0.72; 95% CI (0.61–0.82); AUC androstenedione 0.59; 95% CI (0.47-0.71); AUC estradiol 0.70; 95% CI (0.60-0.80); AUC DHEA 0.75; 95% CI (0.65–0.85); AUC DHEAS 0.66; (0.55–0.78). With regard to the risk of severe COVID for the patients at the lower tertil (T1) in comparison with the higher tertile (T3), except for estradiol in which the lower tertile was the reference, the associations were: OR (total testosterone) = 3.90 (1.38-11.04); OR (androstenedione) = 2.20 (0.77-6.30); OR (estradiol) = 4.62 (1.60-13.35); OR (DHEA) = 6.17 (1.97-19.35) and OR (DHEAs) = 3.90 (1.38-11.04). The results were not affected after adjusting for age, BMI, smoking, renal disease and diagnosis of diabetes.
Conclusion
Our results suggest that sexual steroids are independent predictors of severe COVID-19 (mortality or ICU admission) in patients with SARS-CoV-2 infection. The predictive ability discriminated by the AUC of the ROC curve is higher for testosterone and DHEA.

Influence of Obesity on Medically Assisted Reproduction Techniques

Cátia Araújo[1], Carla Baptista[1], Isabel Paiva[1], Paulo Cortesão[2] & Mafalda Martins Ferreira[1]
[1]Centro Hospitalar Universitário de Coimbra, Serviço de Endocrinologia, Diabetes e Metabolismo, Coimbra, Portugal; [2]Centro Hospitalar Universitário de Coimbra, Serviço de Reprodução Humana, Coimbra, Portugal

Introduction
Evidence has suggested a relationship between female obesity and the outcomes of medically assisted reproduction techniques (MRT); however, the evidence regarding male obesity is still scarce and discordant.
Aim
Evaluate the influence of female and male obesity on the results of MRT.
Materials and methods
Retrospective analysis of 2159 couples, with and without obesity, submitted to the first treatment of medically assisted reproduction. Considering each individual of the couple, four groups were defined according to sex and body mass index (BMI) (non-obese group with BMI <30 kg/m^2 and obese group with BMI ≥ 30 kg/m^2).
Results
Among female individuals, 235 were obese (10.9%). Median age was similar between groups with and without obesity (35 years (31-37) vs 34 years (31-37), $P=0.541$). Ovarian stimulation was mostly performed with a short cycle with an antagonist in both groups (75.1% vs 68.6%, $P=0.674$) and *in vitro* fertilization was the most frequent technique in both groups (60.9% vs 66.9%, $P=0.086$). The obese group had a lower number of mature oocytes (4 (2-7) vs 5 (2-8), $P=0.015$) and of fertilized oocytes (2 (0-4) vs 2 (0-5), $P=0.026$). The fresh embryo transfer rate was similar between groups (50.2% vs 54.8%, $P=0.119$), as well as the probability of pregnancy (31.4% vs 38.3%, $P=0.103$). Among male individuals, 336 were obese (15.6%) and median age was similar between groups (36 years (33-39) vs 35 years (32-39), $P=0.357$). No differences were observed in the several parameters evaluated on the semen analysis or in the results of MRT, namely in the number of embryos obtained, transfer rate or pregnancy.
Conclusions
In this population, female obesity influenced the number of mature and fertilized oocytes. We believe that the lack of statistically significant difference in the rate of freshly transferred embryos between the female groups is related to the lack of fresh transfer in several patients due to the risk of Ovarian Hyperstimulation Syndrome. The analysis of frozen embryo transfer data would have been important for a better characterization of the embryo transfer rate in these groups. In this study, there does not seem to be a relationship between male obesity and sperm analysis parameters or the success of MRT.

Bilateral ovarian mass due to primary hypothyroidism - a case report

Vimal M V[1], Nikitha K[2] & Ajitha P N[3]
[1]Aster MIMS, Endocrinology, Kozhikode, India; [2]Aster MIMS, Internal Medicine, Kozhikode, India; [3]Aster MIMS, Gynecology, Kozhikode, India

Introduction
The triad of primary hypothyroidism, precocious puberty and delayed bone age in children with cystic ovarian enlargement constitutes the syndrome of van wyk grumbach. Commonly reported as a rare complication of hypothyroidism in children, there are only a few case reports in adult population. Herewith, we are reporting the case of a 22-year-old hypothyroid lady, who presented with bilateral ovarian cysts. Considering hypothyroidism, a high risk for surgery, thyroxine dose was optimised; to see that the cysts started shrinking in size and eventually disappeared.
Case
22-year-old lady, with no known comorbidities, presented with complaints of lower abdominal pain for 1 week. On examination, there was a mass felt in the left iliac region, reaching up-to the umbilicus. It was non-tender and non-ballotable

with cystic consistency. USG Abdomen showed bulky uterus with multiseptated cystic lesions in the adnexa, with no significant vascularity or solid components. It was succeeded with an MRI abdomen, which confirmed the same. There was age lobulated septate thin-walled cystic lesion in the right ovary measuring 13.5 x 8.1 x 6.9 cm, and a lesion in the left ovary measuring 7.3 x 6.4 x 6.5 cm, with probable haemorrhagic content. CA-125 was also found to be elevated. Though non-specific, with multicystic ovarian lesions and elevated CA-125 in a young lady, the possibility of an ovarian neoplasm was thought of and she was planned for laparoscopic ovarian cystectomy. On pre-operative evaluation, TSH was found to be significantly elevated – 65.42 mcIU/ml. Endocrinology consultation was sought and she was started on Thyroxine supplementation. Surgery was postponed in view of peri-operative morbidity, and she was discharged. She was followed-up and thyroxine dose was optimised in subsequent visits. Repeat imaging showed complete resolution of mass after 6 months.

Conclusion

Multiple ovarian cysts in a young lady can be indicative of an infection or malignancy, but at times can be due to benign systemic conditions like hypothyroidism. Prompt treatment of hypothyroidism made the ovarian cysts to disappear, which otherwise would have resulted in a major futile surgery.

Impact of chromium picolinate on testicular steroidogenesis

Rúben Moreira[1,2], Silvia Moreira[1,3,4], Marco Alves[5], Pedro Oliveira[1,2] & Maria de Lourdes Pereira[3,4]
[1]University of Aveiro, Department of Chemistry, Aveiro, Portugal; [2]University of Aveiro, LAQV-REQUIMTE, Aveiro, Portugal; [3]University of Aveiro, Department of Medical Sciences, Aveiro, Portugal; [4]University of Aveiro, CICECO-Aveiro Institute of Materials, Aveiro, Portugal; [5]Abel Salazar Biomedical Sciences Institute - University of Porto, UMIB - Unit for Multidisciplinary Research in Biomedicine, Porto, Portugal

Low testosterone levels are one of the causes of male infertility since testosterone is a crucial hormone for the regular functioning of the male reproductive tract. Testosterone is produced by Leydig cells (LC) in a process called testicular steroidogenesis, and if these cells are injured in any way, then the steroid production may be compromised. Endocrine Disrupting Chemicals (EDCs) are a group of substances that disturbs hormonal signaling. Their chemical nature and mode of action are diverse and chromium, a heavy metal, has been classified among EDCs. Trivalent chromium (Cr(III)) is one form of chromium controversially considered an essential metal. Chromium (III) picolinate (CrPic3) is a Cr(III) organic salt that is used as a nutritional supplement due to its antidiabetic properties, among others, despite the controversies surrounding the safety of Cr(III). The main effect identified in LC was the inhibition of enzymes involved in steroidogenesis, while in other somatic cells, CrPic3 appears to induce mutagenesis and apoptosis. The production of testosterone seems to be affected by this supplement, however we found conflicting results on this subject. In this work we aimed to evaluate whether CrPic3 displays cytotoxic effects in the murine LC line BLTK1, to understand if it could affect this population of cells and the production of testosterone. The cytotoxicity assays preformed with 5 different concentrations of CrPic3 (0.1, 1, 10 and 100 μM) showed that this supplement does not significantly affect the proliferation, viability of cell membrane integrity of these cells. These results suggest that CrPic3 the LC themselves are not harmed by the supplement, however our ongoing work is now focused on understanding if testosterone production is compromised.

Periodic Assessment of Biochemical-Hematological Changes in A Series of Transgender Men After 1 Year of Gender Affirming Therapy

Guillermo Velasco de Cos[1], Carlos Latorre Mesa[2], María Teresa García-Unzueta[1], Luis Vázquez[3], Maialen Ormazabal Monterrubio[1], Armando Guerra Ruiz[1], Ana Moyano Martinez[4], Gabriela Alexandra Zapata Maldonado[3] & Aurelia Villar Bonet[3]
[1]Hospital Universitario Marqués de Valdecilla, Clinical Biochemistry, Santander, Spain; [2]Universidad de Cantabria - Facultad de Medicina, Santander, Spain; [3]Hospital Universitario Marqués de Valdecilla, Endocrinology and Nutrition, Santander, Spain; [4]Hospital Clínico Universitario de Salamanca, Clinical Biochemistry, Salamanca, Spain

Introduction

During gender affirming therapy in transgender men (TXM), androgens are administered at escalating doses. As therapy progresses, changes in various analytical parameters occur that may be of potential use in establishing a personalised androgen dosage and avoiding deleterious effects of the medication. The aim of our study was to study the evolution of different parameters throughout the course of gender affirming therapy.

Material and methods

The study was conducted in a cohort of 20 TXM. Treatment was initiated with 25 mg/month of IM testosterone cypionate. Every three months the dose was increased by 25, 50 and 150 mg/month until the maximum dose of 250 mg/month is reached after a year. Samples at 3, 6, 9 and 12 months were analysed by spectrophotometric and automated immunoassay techniques on Snibe Maglumi and Siemens Atellica platforms. Friedman's test and Wilcoxon pairwise comparisons were performed in SPSS25.0.

Results

The most significant results are summarised in the following tables: No significant differences were found for lipid profile, HbA1c, bilirubin, urea, cortisol, insulin, androstenedione, gonadotrophins and oestradiol. While LH, oestradiol and HDL tended to decrease and triglycerides, cholesterol and urea tended to increase, given the sample size, this was not significant. However, we did obtain significance for haematocrit, haemoglobin, FAI, creatinine and both free and total testosterone.

Conclusions

Several of the parameters analysed change as gender affirmation therapy progresses. Haematocrit is the earliest change. The first significant changes occur after 6 months of treatment. It would be of interest to study a cut-off point for each parameter to allow dose adjustment according to the changes found. The study should be completed when a larger number of subjects in our study who are currently in evolution complete one year of therapy.

Table 2 (Abstract P733) Friedman results and pairwise comparison with Wilcoxon test for hormonal parameters:

	Testosterone	Free testosterone	FAI	DHEAS
Significance Friedman test	$P<0.001$	$P<0.001$	$P<0.001$	$P=0.024$
First time at which differences are found with basal	$t_{0\text{-}6}$: $P=0.003$	$t_{0\text{-}6}$: $P=0.003$	$t_{0\text{-}6}$: $P=0.004$	$t_{0\text{-}3}$: *$P=0.033$

* Taking into account the Bonferroni adjustment it would not be significant for any time.

* Non significant with Bonferroni adjustment ($P>0.01$), although a clear trend can be observed.

Introduction
Maternal thyroid function is put under stress during pregnancy. Thyroid disorder is very common among expectant mothers. 10% of pregnancies have subclinical hypothyroidism. Anemia, low birth weight, and neonatal mental retardation are among side effects of hypothyroidism during pregnancy.
Objective
The primary and main objective is to evaluate the results for pregnant women with abnormal thyroid profiles, both for the mother and the fetus. This study is important because it provides evidence of the link between hypothyroidism and harmful consequences on both mother and fetus.
Method
At Patna Medical College, this retrospective observational study was conducted. Informed consent was obtained from the 190 prenatal women participating in this study, who were in their third trimester and had singletons. Regardless of their age, parity, place of residence, or social level, women were chosen. All pre-existing medical conditions, multiple pregnancies, thyroid disorders known to exist, and multiple pregnancies were prohibited. Routine hematological parameters and T3, T4, and TSH estimates were done. Patients with abnormal thyroid profiles were then evaluated for issues that could affect the mother or the fetus. The primary study variables included menstruation pattern, recurrent abortion, history of infertility, family history of thyroid disease, hemoglobin level, and fetal outcome. SPSS software was used to analyze the data for statistical correlation.
Results
Subclinical hypothyroidism, overt hypothyroidism, and subclinical hyperthyroidism occur in 5.5, 3.4, and 1.4% of individuals, respectively, according to the prevalence of thyroid disorders, which is 10%. Anemia was seen in 26.2% of women with subclinical and overt hypothyroidism, and it was substantially correlated with hypothyroidism ($P=0.007$). In terms of foetal outcome, hypothyroidism was statistically linked with LBW 31.5% ($P=0.002$), NICU admission 42.0% ($P=0.001$), and low APGAR Score (21.0%, $P=0.041$). Mothers with hypothyroidism had a 4.6, 6.2, 0.13, and 3.63 times higher risk of anemia, low birth weight, NICU hospitalizations, and a low APGAR score than women who are euthyroid.
Conclusions
In the third trimester of pregnancy, subclinical hypothyroidism is present in 5.5% of women. Significant correlations exist between hypothyroidism and anaemia, pre-eclampsia, high caesarean rates, and infant morbidities.

Biological variation data of anti-Müllerian hormone and androstenedione among women of reproductive age

Domagoj Marijančević, Adriana Bokulić, Ivana Zec & Sanja Goreta
Sestre Milosrdnice University Hospital Center, Department of Clinical Chemistry, Laboratory of Endocrinology, Zagreb, Croatia

Introduction
Biological variation (BV) data describe the variability of clinically important measurands around homeostatic set points within subjects (CVI) and between subjects (CVG). The availability of well characterized data enables the interpretation of laboratory results in clinical settings and can also be used to define analytical performance specifications. The aim of this study was to deliver BV estimates for anti-Müllerian hormone (AMH) and androstenedione among women of reproductive age.
Materials and Method
In total, 40 healthy women of reproductive age (19–42 years) were bled for three consecutive menstrual cycles, on the 2nd or 3rd day of the cycle. Sera were stored at -80°C before analysis. Analyses for each patient were performed in duplicate within a single run on the Roche Cobas analyser e801 (Roche Diagnostics GmbH, Mannheim, Germany) by electrochemiluminescence immunoassay. The BV estimates with 95% CIs were obtained by CV-ANOVA, after analysis of variance homogeneity and outliers.
Results
The CVI and CVG for AMH were 15.3% and 67.7%, respectively. Analytical variation (CVA) was calculated as 4.6%. The CVI and CVG for androstenedione were 17.9% and 41.2%, respectively. CVA was calculated as 2.1%.
Conclusion
In cycling women, the variability in AMH should be considered by clinicians, especially if a result is close to a clinical cutoff. The serum AMH CVI obtained by this study specifies more stringent analytical performance specifications than previously identified. The added value of this research is the availability of updated BV data, in the case of androstenedione that were not previously published.

The Impact of Covid-19 Lockdown on Pubertal Onset in A Second Level Center

Giovanni Goggi[1], Mirella Moro[1], Alessandro Chilà[2], Letizia Fatti[1], Biagio Cangiano[1,2], SIlvia Federici[1,2], Elena Galazzi[1], Erika Carbone[3], Davide Soranna[3], Valeria Vezzoli[3], Luca Persani[1,2] & Marco Bonomi[1,2]
[1]Italian Auxological Institute San Luca Hospital, Milano, Italy; [2]University of Milan, Milano, Italy; [3]Istituto Auxologico Italiano, Cusano Milanino, Italy

Background
As of December 2019, the COVID-19 pandemic has spread rapidly, therefore Governments from all over the world promoted a strategy of social confinement through a general lockdown in order to contain it. During the months following its introduction, many studies reported a significant increase in the incidence of idiopathic central precocious puberty (CPP) throughout several countries, especially in girls.
Purpose
The aim of our study was to compare the incidence of idiopathic CPP before and after the onset of COVID-19 lockdown (which started on March 9th 2020 in Italy) among the medical records of patients who were referred to our highly specialized Endocrinological Center from 2014 to July 2021; we also aimed to identify any potential differences in either anamnestic, clinical, biochemical or radiological characteristics between patients in whom CPP occurred before and after the beginning of lockdown.
Methods
We retrospectively analyzed the characteristics of 51 patients with idiopathic central precocious puberty: 32 with pre-lockdown CPP onset and 19 with post-lockdown CPP onset. Firstly, we compared the incidence of the disease between the two time periods. Secondly, we collected information from patients' medical history, physical examination, baseline and dynamic hormonal assessment, bone age, and pelvic ultrasound around the time of diagnosis and compared such information between the two groups.
Results
We registered an almost threefold increase in CPP incidence in the 2020-2021 period compared to the previous six years. We also found that post-lockdown patients had a trend for lower delta LH percentage value (P 0.0633) and for an earlier diagnosis in terms of both chronological age at diagnosis (P 0.0628) and days between the onset of first pubertal signs and diagnosis (P 0.0762) compared to pre-lockdown patients. Furthermore, post-lockdown patients also had lower delta-4-androstenedione levels (P 0.0244) and mothers with an older age at menarche (P 0.0078).
Conclusions
Our study confirmed a significant increase in the incidence of CPP in the post-lockdown period. Moreover, taking into account both the positive correlation that exists between maternal age at menarche and the timing of pubertal onset of children, and the fact that the mothers of post-Covid patients had menarche significantly later than those of pre-Covid patients, our results suggest that the influence of genetics in determining the timing of pubertal onset of Post-Covid patients has been scaled back in favor of a stronger environmental influence (the lockdown itself).

Insulin-like growth factors: possible players regarding male fertility

Nair Agualusa[1,2], David F. Carrageta[2], Sara C. Pereira[2], Alberto Barros[3,4,5], Luís Crisóstomo[2,6], Marco G. Alves[2] & Pedro F. Oliveira[7]
[1]University of Aveiro, Department of Chemistry, Aveiro, Portugal; [2]Institute of Biomedical Sciences Abel Salazar (ICBAS) - School of Medicine and Biomedical Sciences, University of Porto, UMIB - Unit for Multidisciplinary Research in Biomedicine, Porto, Portugal; [3]Centre for Reproductive Genetics Professor Alberto Barros, Porto, Portugal; [4]Faculty of Medicine, University of Porto, Department of Genetics, Porto, Portugal; [5]i3S – Instituto de Investigação e Inovação em Saúde, Porto, Portugal; [6]Institute of Biomedicine, University of Turku, Turku, Finland; [7]University of Aveiro, QOPNA & LAQV, Department of Chemistry, Aveiro, Portugal

Infertility affects about 15% of couples, and, among these, 50% are related to the male factor. Male infertility can be caused by intrinsic factors, and these may either directly or indirectly affect gamete and testicular development as a consequence of endocrinopathies. In that sense, research regarding the involvement of endocrine hormones, particularly of nutritional status-linked hormones, in the male reproductive system has increased over the years. In fact, the rise on the incidence of metabolic diseases is positively associated with a decrease in fertility rates, suggesting that nutritional status-linked hormones may play a role in the crosstalk between both conditions. Among the nutritional status-linked hormones, little is known concerning the role of insulin-like growth factors for several facets of testicular development, spermatogenesis, and steroidogenesis. IGF-1 was found to be expressed in multiple testicular cells and some germ cells, being the Sertoli cells their main source in the seminiferous tubules. *IGF-2* mRNA has been found in human spermatozoa and is believed that IGF-2 is possibly produced by other cells of the male reproductive system, such as germ cells. However, the roles of both IGF-1 and IGF-2 for the male reproductive health and fertility outcomes remain poorly understood. Hence, the main goal of this work was to understand the contribution of IGF-1 and IGF-2 on male fertility. For that purpose, we identified and quantified the expression of *IGF-1* and *IGF-2* mRNA in spermatozoa samples of men ($n=111$) that underwent medically assisted reproduction (ART) treatments, through RT-PCR and RT-qPCR, respectively. We were able to identify for the first time, to the best of our knowledge, the expression of *IGF-1* mRNA in human spermatozoa. In addition, we also positively identified the expression of *IGF-2* mRNA in human spermatozoa. Further studies will disclosure the potential association between *IGF-1* and *IGF-2* mRNA expression and ART outcomes. The discovery of the expression of both IGF-1 and IGF-2 in human spermatozoa also opens the path for future studies concerning the role of nutritional status-linked hormones for male fertility and ART outcomes.

46, XX male (SRY positive): recalling a clinical case

Guilherme V. de Assunção & Rui Morais Carvalho
Centro Hospitalar e Universitário do Porto, Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal

Introduction
XX male syndrome is a disorder of sex development associated with a 46, XX karyotype and is characterized by such features as: small testes, hypergonadotropic hypogonadism, male external genitalia, gynecomastia and azoospermia. The estimated prevalence is 1/20.000 males. Gender role and gender identity are reported as male. Identification and subsequent treatment is necessary to avoid the manifestations of testosterone deficiency.
Clinical Case
23 year old male presented to our medical appointment manly due to a history of erectile dysfunction but also presented with loss of libido, bilateral gynecomastia, infertility and showed signs and symptoms of clinical depression. He had no relevant family history. In the physical examination the patient had a weight of 70 Kg, normal development of secondary sexual characteristics and presented with a bilateral testicular atrophy with a volume of 6ml/testis. Blood analysis showed: LH 11.04 mUI/ml [Reference range (RR) 1.3-12.9], FS 30.81 mUI/ml (RR 0.9-15); Free testosterone 1.56 ng/ml (RR 2.7-10,7) and total testosterone 7,6 pg/ml (RR 2.7-10.7). There were no findings on the brain MRI. There were no other alterations in the US besides the atrophy. The karyotype test revealed the following: 46,XX. ish ins(X,Y)(p2;q11.2)(SRY+). The patient promptly started on testosterone with meaningful improvement of is libido, erectile dysfunction and return of LSH, FH and testosterone to levels within range. The bone densitometry reported an osteopenia and the spermiogram revealed an azoospermia. Medically assisted reproduction was initiated but the patient renounced it after a while. Until this day, the patient hasn't had any relevant clinical problem since the beginning of the treatment with testosterone.
Discussion
We present a clinical case of a male with an XX male syndrome positive for SRY gene. This is due to a Y to X translocation during meiosis and SRY is the main driver to testes formation. Our patient presents with an array of classical signs and symptoms and although it is reported that infertility is mainly the first recognisable problem, for our patient, erectile dysfunction was the main cause for seeking medical attention. Obstructive azoospermia was ruled out after performing US.
Conclusions
In these patients we should performed an adequate screening to set the better treatment depending on the phenotypic characteristics and be vigilante for any morbidity related to testosterone deficiency. The follow up by a multidisciplinary approach is ideal, especially if the patients seeks fertility options.

Experiences and expectation of young women with PCOS and their mothers: A Qualitative study in India

Tejal Lathia[1], Chitra Selvan[2], Shweta Chawak[3], Niveditha Akula[4] & Mahati Chittem[5]
[1]Apollo Hospitals, Navi Mumbai; [2]Ramaiah Medical College, Ramaiah University of Applied Sciences, Bengaluru, India; [3]Jindal School of Psychology & Counselling, Health & Medical Psychology, Haryana, India; [4]Indian Institute of Technology Hyderabad, Hyderabad, India; [5]Indian Institute of Technology Hyderabad, Department of Liberal Arts, Hyderabad, India

Women diagnosed with polycystic ovarian syndrome (PCOS) experience several physiological (weight gain, hirsutism, acne) and psychological challenges (emotional distress, anxiety, shame). This is particularly apparent in India where PCOS intersects with gender and patriarchal notions of womanhood (interfering with one's marital prospects, compromising one's ability to procreate). A young woman's first source of support, therefore, is usually their mother. In India, a mother plays a pivotal role in managing and responding to one's outer, social world. However, little is known about the communication and coping efforts among Indian young women and their mothers with regard to the former's diagnosis and lived experiences of PCOS.
Objectives
This study aimed to understand the experiences of coping with PCOS-related challenges and communication between young women diagnosed with PCOS and their mothers in India
Methods
Semi-structured interviews were conducted with 12 mother-daughter pairs (total $n=24$; mean age of daughters = 22.4 years and mean age of mothers = 49.5 years). The individual, telephonic, audio-recorded interviews explored each respondent's experiences of managing PCOS-related symptoms, responses of their wider social network, concerns regarding the PCOS, and how they were communicating with their counterpart (i.e., mother or daughter). All interviews were all conducted in English and transcribed verbatim. The interviews were analysed using thematic analysis.
Results
Three themes were identified: (1) emotional turmoil and the emotional impact of having PCOS: how mothers and daughters felt about the PCOS-related symptoms and social reception of PCOS, (2) coming to terms with and adapting to the condition: mothers' and daughters' individual and collaborative responses to PCOS management, and (3) need for (empathic) communication between the mothers and daughters.
Discussion and conclusion
These findings indicated that both women with PCOS and their mothers experienced immense emotional turmoil, with the former describing feelings of shame and the latter feelings of worry. Mothers played a crucial role in aiding their daughters in lifestyle management, although mothers preferred attempting at multiple alternate remedies while daughters wanted to adhere to the physician prescribed management choices. The dyads reported a need for effective empathic communication between one another, particularly about lifestyle management. These findings highlight the need for (1) physicians to include mothers in PCOS-related discussions in their daily practice, (2) communication skills interventions for mothers and daughters, and (3) community outreach so as to improve sensitivity and awareness to the psychological aspects of having PCOS in India.

Improving detection of rare overgrowth syndromes among patients referred to the endocrinology ward for treatment of acromegaly

Trui van Essen, Anna Rosenberg, Wouter W de Herder, Aart Jan van der Lely & Laura De Graaff
Erasmus MC, Internal Medicine, Endocrinology, Rotterdam, Netherlands

Background
A common request at an endocrine outpatient clinic is to rule out acromegaly in a patient with acromegaloid features. It is important to do so, since the excessive excretion of growth hormone can result in various serious comorbidities. But when growth hormone-IGF-1 axis abnormalities are excluded, the physician faces

a diagnostic dilemma. Here we provide a systematic approach to these patients.
Methods
We present a case series of patients visiting our outpatient clinic for 'acromegaly', from presentation to diagnosis. We describe the diagnostic challenges and illustrate the added value of multidisciplinary treatment, initiated once patients were diagnosed with overgrowth syndromes. Additionally, we conducted a systematic review of the literature on overgrowth syndromes.
Results
The patients presented with acromegaloid characteristics without growth hormone/IGF-1 axis abnormalities. Endocrine and genetic work-up ruled out acromegaly and revealed mutations in *CHD8*. Neuropsychological assessment revealed a mild intellectual disability in one of the patients, which had remained unnoticed for years due to relatively strong verbal performance. To initiate ID support, the patient was referred to the physician for intellectual disabilities. Based on our own expertise in combination with the existing literature, we made an algorithm to improve diagnostics and management of adults with overgrowth syndromes. Due to their physical and neuropsychological problems associated with some overgrowth syndromes, multidisciplinary care is often necessary.
Conclusions
When a patient presents with acromegalic features in the presence of normal IGF-1, the diagnosis of overgrowth syndromes should be considered as underlying condition. As overgrowth syndromes may be associated with neurodevelopmental delay, we recommend to screen for mild ID and refer patient for multidisciplinary management to prevent the complications of undiagnosed ID.

Functional hypogonadism and prevalence of decreased total testosterone level in type 2 diabetic male patients

Kristina Groti Antonic[1]
[1]University Medical Center Ljubljana, Department of endocrinology, diabetes and metabolic diseases, Ljubljana, Slovenia

Functional hypogonadism and prevalence of decreased total testosterone level in type 2 diabetic male patients
Background
Approximately 50 % of older males with obesity and type 2 diabetes, exhibit low total testosterone levels, many also signs of hypogonadism. Functional hypogonadism negatively affects glycemic control, exacerbates early cardiovascular complications, causes lower bone mineral density, erectile dysfunction, reduces lean body mass, and accelerates the accumulation of visceral fat. We aimed to determine the prevalence of decreased total testosterone level type 2 diabetic males in Slovenia.
Research design and methods
We presents the results of cross-sectional study in male patients with type 2 diabetes and obesity, with goal to assess prevalence of decreased total testosterone level. Participants were inquired to answer the The Aging Males' Symptom (AMS) scale questionnaire. Functional hypogonadism was diagnosed as a biochemical deficiency of circulating testosterone levels (total testosterone below 11 nmol/l and free testosterone below 220 pmol/l) on at least two separate morning measurements after an overnight fast.
Results
165 patients were included in this cross-sectional study. 87 patients exhibited decreased total testosterone level (below 11 nmol/l) while 78 had normal level of total testosterone.
Conclusion
Prevalence of decreased level of total testosterone among obese male patients with type 2 diabetes was found to be 52.7 %. Symptoms of androgen deficiency should be corroborated with testosterone level to establish a multidisciplinary approach for management of hypogonadism.

Correlation of different types of headaches, their severity with BMI and hyperandrogenism in PCOS patients

Salome Kaldani[1], Mariam Alavidze[1,2], Lana Oren[1], Shamaila Basheer[1,2] & Vazha Vacharadze[3]
[1]Tbilisi State Medical University, T'bilisi, Georgia; [2]Tbilisi State Medical University, T'bilisi, Georgia; [3]National Institute of Endocrinology, Endocrinology, T'bilisi, Georgia

Background
Polycystic ovary syndrome (PCOS) is a highly prevalent disorder affecting 4%-20% of reproductive-aged women worldwide. Those affected by PCOS have a variety of clinical findings, which can affect their quality of life. Evidence suggests that polycystic ovarian syndrome and migraines are linked. However, the relationship between polycystic ovary syndrome and other types of headaches and their severity has not been studied.
Objectives
The purpose of this study was to look into the prevalence and severity of different types of headaches in individuals diagnosed with PCOS, as well as how this could be influenced by BMI, hyperandrogenism, menstrual dysfunction, and other risk factors of PCOS.
Methods
A cross-sectional study was conducted on 473 females with the diagnosis of PCOS who were surveyed using an anonymous questionnaire that included questions about their age, medications, PCOS clinical symptoms, and menstrual cycle. Chi square test and odds ratio were preferred analysis methods for this study.
Results
466 (98.5%) of the 473 respondents experiencing headaches. Those with BMIs more than 30 had a higher incidence of headaches (Chi square $=9.613$; df$=9$; $P=0.3827$) and Females above the age of 25 have a greater number of different forms of headaches, (Chi square $=3.284$; df$=3$; $P=0.3499$), this was not shown to be statistically significant. The Chi square test for headache intensity in girls with PCOS with various BMI (underweight, normal, overweight, and obese) revealed that headaches were severe in females with BMI more than 30. (Chi square $=14.60$; df$=6$; $P=0.0236$) and headache intensity increased with BMI, especially during menstruation. Chi square $=22.62$; df$=6$; $P=0.0009$). OCPs do not influence the incidence of any kind of headache in females with PCOS. Metformin use was mildly associated with tension headaches (O $r=1.12$, $P=0.6107$, 95%CI-0.7489, 1.676) and cluster headaches (OR$=1.366$, $P=0.1155$, 95% CI-0.9282, 2.01). Oral contraceptive use was not associated with migraines in PCOS patients. (OR$=0.932$, $P=0.762$, 95% CI$=$ 0.6276, 1.384)
Conclusion
The results of the study reveal that tension and migraine headaches are the most prevalent types of headaches among PCOS patients. During menstruation, the pain rises in intensity. This brings up new opportunities for the development of preventative and management strategies for PCOS patients with frequent headaches, which effectively contribute to an increased quality of life.

Sertoli-leydig cell tumours

Fatima Azad[1], Nwe-Ni Aung[2] & Najaf Haider[1]
[1]Portsmouth Hospitals NHS Trust, Endocrinology, Portsmouth, United Kingdom; [2]Portsmouth Hospitals University NHS Trust, Endocrinology, Portsmouth, United Kingdom

Introduction
Sertoli-leydig cell tumours are neoplasms of ovarian sex cord stromal cells and account for 0.5-2% of ovarian tumours with reported incidence <0.5 % of all ovarian tumours. These tumours usually manifest in women at younger age (in 75 % patients average age of onset <30). Majority of these tumours produce hormones and up to 80% of ovarian Sertoli-Leydig cell tumours can manifest with signs of virilization.
Case report
18 year old female who presented to endocrine outpatients with secondary amenorrhoea of 6 months and raised androgens on biochemical testing. Further history revealed she had noticed change in voice for 6 months, increase in facial hair growth, reduction in breast size and enlargement of clitoris. Biochemical testing yielded high testosterone level of 8, raised FAI of 12.8, normal prolactin, HSE2 138, LH 19.4 and FSH 2.9. She had never used contraception and was not on any regular medication. Repeat hormone profile was booked from clinic along with U/S pelvis,17OH PG and DHEAS. On repeat testing testosterone levels had risen to 12.6 from 8, with FAI of 28.6, 17OH progesterone of 16.1 (0.5-4.4) and raised DHEAS of 11.1 (1.8-10). Right ovary showed multi septated ovarian cyst. Due to raised DHEAS and 17 OHPG adrenal MRI was requested and case was discussed with gynaecology. MRI adrenal was unremarkable. Patient attended A n E department with abdominal pain, repeat ultrasound and MRI pelvis was arranged which showed progressively enlarging multi cystic right ovary with increased complexity and moderate volume of pelvic fluid/ascites. She underwent laparotomy and tumour excised along with associated fallopian tube, histology examination of the mass confirmed tumour to be Sertoli-Leydig cell tumour. She is doing well at 6 months follow up with return of menstruation.
Discussion
Sertoli Leydig cell tumours are rare tumours of ovarian stromal sex cord origin. Due to low incidence of these tumours, their presentation to endocrine clinic is a rarer

occurrence. Majority of ovarian sex cord stromal tumours are hormonally active and some can present without typical symptoms of abdominal pain, it is important to recognise this early and consider this as part of differential diagnosis in females with signs of virilization. Early recognition and appropriate referral ensures optimal outcome

Parental Experience of the Announcement of the Diagnosis of Diabetes in Adolescents

Sofia Ouhessaine[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]Ibn Rochd University Hospital of Casablanca, Morocco Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy-University Hassan II, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Department, Casabanca, Morocco

Introduction
The discovery of a chronic pathology in a child upsets the pre-existing family balance and generates emotional reactions in the family. With the incidence of type 1 diabetes doubling over the past 30 years, many families find themselves faced with this emblematic situation.
Objectives
To describe the parental experience of being diagnosed with type 1 diabetes in adolescents.
Materials and Methods
Retrospective descriptive study, carried out at the Endocrinology and Metabolic Diseases Department of Casablanca, during the year 2022, including 45 parents of adolescent type 1 diabetics followed in transition consultation, questioned about the experience of the announcement diabetes.
Results
The circumstances of the diagnosis were an inaugural ketosis in 43 cases, and only 2 cases of diabetic ketoacidosis, our patients were aged between 15 and 19 years. The testimony of the parents was collected on average 6 months after the diagnosis. The announcement was made to both parents in 32 cases and the mother alone in 8 cases. Fear of the future was reported in 34 parents, and shock in 30 parents, thus representing the most frequently cited affects, followed by anxiety in 24 parents, and guilt in 5 parents, including 2 diabetic parents. All the parents interviewed said they wanted an information and education program dedicated to parents.
Conclusions
The trauma caused by the announcement of diabetes, a chronic disease requiring a change in the lifestyle of the whole family justifies bringing the 2 parents together from the initial interview to inform them about diabetes and allay some of their fears as well as to educate them on acute complications at first and degenerative later.

Models of care for polycystic ovary syndrome: A systematic review

Meri Davitadze[1], Eka Melson[2], Aya Mousa[3], PCOS SEva working group[4], Helena Teede[3], Jacky Boivin[5], Mala Thondan[6], Chau Thien Tay[3] & Punith Kempegowda[4,7]
[1]Clinic NeoLab, Tbilisi, Georgia; [2]University of Leicester, Leicester, United Kingdom; [3]Monash University, Monash Centre for Health Research and Implementation, Melbourne, Australia; [4]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom; [5]Cardiff University, School of Psychology, Cardiff, United Kingdom; [6]Harp Family Medical Centre, Melbourne, Australia; [7]University Hospitals Birmingham NHS Foundation Trust, Queen Elizabeth Hospital, Birmingham, United Kingdom

Introduction
Polycystic ovary syndrome (PCOS) is associated with broad reproductive, metabolic and psychological complications, as well as significant heterogeneity in presentation between and within individuals across the lifespan. Therefore, there is a need for a multidisciplinary approach. A model of care (MoC) is conceptualised as an overarching provision of care that is codesigned with end-users and aligns with evidence-based practice and defined standards. The international PCOS guideline from 2018 recommends to ensure best practices while providing care for women and individuals with PCOS. Exploration of existing MoCs for PCOS can help identify and share learnings from current practice.
Aim
To perform a systematic review to identify available PCOS MoCs and describe their characteristics and alignment with the international PCOS guideline.
Methods
This systematic review was prospectively registered on PROSPERO CRD42022346539. OVID MEDLINE, All EBM, PsycInfo, EMBASE, and CINAHL were searched from inception until 11 July 2022. Any English study with a detailed description of a PCOS MoC was included. Abstracts, study protocols, and clinical trial registrations were excluded. Data extracted included the service name and detailed descriptions of the model, specialities involved, services provided in alignment with the PCOS guideline and evaluations. Data were synthesised narratively.
Results
Of 3670 articles, five articles describing four MoCs were included in our systematic review—two from Australia, three from the US, and none from developing countries. All MoCs described a multidisciplinary approach ranging from 4-8 specialties including a health nurse, dietitian, endocrinologist, gynaecologist, psychologist, dermatologist, etc. Two MoCs—Monash Health state-wide integrated PCOS service and the Multidisciplinary clinic for PCOS at Children's Hospital Colorado—described all aspects of PCOS care aligning with the international guideline. These include providing education on long-term risks, lifestyle interventions, screening and management of emotional well-being, cardiometabolic diseases, and dermatological and reproductive elements of PCOS. Two MoCs were evaluated via focused-group discussions, semi-structured interviews, and surveys to understand patients' and healthcare professionals' satisfaction, with generally positive findings. Only one MoC explored the impact of their service on patients' health outcomes and showed improvement in BMI and weight.
Conclusion
There is limited literature describing PCOS MoCs in routine practice. Future research should explore the various PCOS MoCs globally, particularly from low- and middle-income countries, and their alignment with international guidelines as well as focusing on patient satisfaction and needs. This may facilitate the exchange of best practices between institutions and support the development of a best-practice framework in PCOS care.

Falsely elevated estradiol levels in a young female with iatrogenic menopause

Daniela Dias[1], Tânia Matos[1], Mário Fontes-Sousa[2], Catarina Silvestre[1], Filipa Serra[1] & Inês Sapinho[1]
[1]Hospital CUF Descobertas, Endocrinology, Lisbon, Portugal; [2]Hospital CUF Tejo, Endocirnology, Lisbon, Portugal

False elevation of estradiol(E2) due to immunoassay interference is a rare but important phenomenon reported in the literature. It is most commonly related to cross-reactivity(CR) from drugs sharing structural similarity with E2, namely fulvestrant and exemestane. These laboratory interferences(LI) can lead to unnecessary investigation/inappropriate treatments. Therefore, in such instances, a more selective and sensitive method is required. We present the case of a young female with high E2 levels inconsistent with her clinical iatrogenic menopause. A 34 years-old female with a history of breast cancer(BC) was examined for estradiol(E2) concentration. Her past medical history was remarkable for BC diagnosed at age 31. She underwent a right simple mastectomy with sentinel node biopsy. Pathology revealed an invasive BC, that was estrogen and progesterone receptor positive-pT4N0M0. Oocyte cryopreservation was performed. The patient was treated with chemotherapy(doxorubicin, cyclophosphamide, paclitaxel), followed by locoregional radiotherapy. Given her high-risk lifetime BC occurrence as well as the fact that her BC was strongly estrogen receptor positive, she initiated ovarian suppression with goserelin plus exemestane. The determination of serum E2 concentration, being a part of the patient's therapeutic monitoring, was requested. E2 levels were persistently elevated(90-100pg/ml) over a year, measured by the chemiluminescent immunoassay method, that rendered exemestante therapy ineffective. The patient had a complete clinical response to treatment, according to clinical symptoms, radiologic findings and normal levels of tumor biomarker. One year after starting hormone therapy(HT), since she maintained elevated levels of E2, a bilateral salpingo-oophorectomy was performed, no pathological changes were found. Three months after surgery she was referred to our Endocrinology Department for further investigation due to persisting elevated E2 levels (83-87). She was in amenorrhea since chemotherapy, reporting vasomotor symptoms since that time. Her clinical status was inconsistent with elevated E2 values.

A suspicion of LI was raised. To rule out the suspected exemestane CR with 17β-estradiol levels were subsequently obtained and tested with a more sensitive and specific method(access sensitive estradiol-assay-competitive binding immunoenzymatic assay-Beckman Coulter), which showed the patient's serum estradiol levels were undetectable. This confirmed that an exogenous compound, most likely exemestane, caused the CR with the immunoassay resulting in falsely increased serum E2. Clinicians should keep in mind that LI must be considered in the presence of increased estradiol levels that are contradictory to the clinical picture, in a patient under anti-HT, and therefore should be confirmed using alternative assays.

Post-Menopausal Hyperandrogenism Secondary to an Ovarian Cause – When Surgery is not An Option

Carolina Antunes[1], Leonor Guia Lopes[1], Paula Calvo[1], Francisco Sousa Santos[1], Verónica São Pedro[2] & João Sequeira Duarte[1]
[1]Hospital Egas Moniz, Lisboa, Portugal; [2]Hospital de São Francisco Xavier, Lisboa, Portugal

Introduction
Hyperandrogenism is a relatively common medical condition, however severe post-menopausal hyperandrogenism should raise suspicion of a malignant etiology and prompt clinical evaluation. Furthermore, androgen excess has also been associated with severely decreased quality of life. As such, identification of its cause and adequate treatment should not be delayed.
Case Report
We report a case of a 66-year-old woman, who had a 5-year history of worsening hirsutism - particularly on the face, neck, chest, back, and abdomen (Ferriman-Gallwey score = 15) – without signs of virilization. She had been taking prednisolone 5 mg for the last 7 years due to hemolytic anemia. She also had a prior medical history of diabetes, hypercholesterolemia and hysterectomy with right oophorectomy. On examination she had central obesity, with a BMI of 38 Kg/m2, facial plethora and buffalo-hump, and male pattern hair loss. Laboratory tests showed a total testosterone of 253 ng/dl (2.9-40.8), delta-4-androstenedione 1.7 ng/ml (0.3-3.3), dehydroepiandrosterone sulfate 16.3 (9.4-246), follicular stimulating hormone (FSH) 48.1 IU/l, luteinizing hormone (LH) 30.1 IU/l and a serum estradiol 45.0 pg/ml. A CT scan of the abdomen did not show adrenal lesions. Transvaginal pelvic ultrasound did not identify the left ovary, hence a pelvic MRI was performed which showed a solid mass with 18mm in the left ovary. A GnRH stimulation test was performed - one month following the administration of triptorelin (3 mg) total testosterone levels decreased to 25 ng/dl, LH to 0.87 IU/l and FSH to 6.03 IU/l. Given the previous surgical history and medical comorbidities with a significantly increased operatory risk, the surgical team decided against surgery and the patient was initiated on oral anti-androgenic medication - cyproterone 50 mg daily. Two months after starting therapy there was a remarkable clinical improvement, with significant regression of alopecia and decrease of the terminal hair on the chest, back and abdomen. A biochemical response was also achieved, with total testosterone levels decreasing to 33 ng/dl. No side effects were reported.
Conclusions
A detailed clinical history, physical examination and directed laboratory and imaging exams are essential to identify the cause of post-menopausal hyperandrogenism. Treatment should be promptly started, ideally aimed at the primary cause. However, especially in case of benign etiologies and/or unacceptable surgical risk, anti-androgenic medications can be an alternative. This case illustrates that when surgery is not feasible, hyperandrogenism control is still achievable using anti-androgenic therapy.

Small for gestationnal age and short stature: What is the growth prognosis?

Nada El Yamani, Salma Derbel, Siham Rouf & Hanane Latrech
Mohammed VI Hospital, Medical School, Mohamed the First University, Department of Endocrinology, Oujda, Morocco

Introduction
The term « Small for gestationnel age » (SGA) defines newborn infants whose birth weight and/or crown-heel length is less than 10th percentile for gestational age, or at least 2 standard deviation below the mean for the infant's gestational age. It is considerd as a common aetiology of short stature. The aim of our study is to describe the prevalence of SGA in short stature, and thee growth prognosis in this population.
Material and methods
We conducted a retrospective study on 14 patients presenting with short stature and SGA admitted in the Endocrinology-Diabetology-Nutrition department of Mohammed-VI University Hospital Center of Oujda, in the eastern of Morocco. The results were collected and processed using the SPSS software V21.
Results
The prevalence of patients defined as SGA among patients presenting with short stature was 7%. The mean age of patients at diagnosis was 8 years ± 4, and the sex ratio M/F was 1,8. The mean birth weight of patients was 2,2 ±0,4 kg. No obstetric history was found in any patient's mother, and a neonatal suffering history was found in 25% of patients. The mean height at diagnosis was 120 cm ±18 cm, and the mean weight was 22 kg ±7. The mean standard deviation (SD) score for height was -4 SD ±0,8, and the mean standard deviation score for weight was -2,8 ±0,7SD. The median difference between bone age and chronological age was 16 months (ranging from 10 to 49 months). A Glucagon-Propranolol test was performed in 75% of patients. One patient had a partial growth hormone deficiency, in whom a Silver syndrome was suspected. Growth hormone (GH) therapy was assessed in 78,5% of patients. It was not used in 21,5% of patients for lack of means. After one year of treatment, the mean height of patients was 131 cm ±21 cm, with a gain of 11 cm, and the mean standard deviation (SD) score for height was -3,6SD ±1SD.
Discussion and conclusion
An increased risk for short stature is discribed in infants born small for gestationnal age. Growth hormone therapy is indicated in children born small for gestationnal age with failure to catch up to the normal height percentiles. The growth promoting effect of continuous GH treatment was noticed in our case series.

Thyroid Pyramidal Lobe Detection by Ultrasound in 1275 Consecutive Patients

Emin Mammadov
Regina Maria Private Healthcare Network, Bucharest, Romania

Background
The thyroid pyramidal lobe (TPL) represents a normal anatomical variation of the thyroid gland. Intraoperative TPL identification is of paramount significance, taking into account that the remnant TPL leads to higher thyroglobulin, could contain thyroid carcinoma foci and lead to recurrence.
Methods
We conducted a prospective single-center, single-operator study to identify TPL in 1275 consecutive patients undergoing thyroid ultrasound for any indication. We extended the standard technique to actively search for TPL. The findings reported were presence and site of the TPL, presence of incidentally discovered nodules in TPL and thyroglossal duct cysts (TGDC). We excluded patients who underwent thyroid surgery or radioiodine therapy.
Results
Of the 1275 consecutive patients (1011 female), TPL was identified in 584 (45.8%), 12 (0.9%) had TGDC, 2 had hemiagenesis of the left thyroid lobe, 1 had thyroid agenesis with ectopic thyroid tissue. 227 patients (38.9%) presented with left-sided TPL, 220 (37.7%) with right-sided, 111 (19%) with median line and 26 (4.5%) with bilateral TPL. In 27 patients (4.6%), we identified incidental asymptomatic nodular lesions or possibly pseudonodular lesions (in some cases probably structural heterogeneity due to autoimmune thyroid disease) within TPL.
Conclusions
We suggest to routinely screen for thyroglossal duct remnants (TPL or TGDC) during thyroid ultrasound. This may reduce the rate of postoperative remnant TPL, obtain lower postoperative thyroglobulin levels and potentially lead to less frequent radioiodine therapy indication. Incidental discovery of thyroid nodules within TPL could also play important role in patient management. The investigation is not time-consuming (average time <10 seconds) and could be considered a cost-effective strategy.

Thymic Hyperplasia and Graves's Disease: A Non-Incidental Association

Begoña Pla Peris, Pablo Abellán Galiana, Sara Franch Salvador, Margarita González Boillos, Javier Maravall & Agustín Ángel Merchante Alfaro

Hospital General Universitario de Castellón, Endocrinology and Nutrition, Castellón, Spain

Introduction
Grave's disease (GD) is an autoimmune disease characterized by the development of thyroid-stimulating hormone (TSH) receptor antibodies that have a stimulating effect on the thyroid gland. There is a rare but non-incidental and well-documented association between GD and thymic hyperplasia (TH). Nonetheless, this association is often underdiagnosed in routine clinical practice and the mechanisms behind this association have yet to be thoroughly elucidated. Thymic regression with the resolution of hyperthyroidism is characteristic. We describe one case of TH in a patient with Grave's disease.
Case Presentation
We present the case of a 40-year-old male with no personal or family history of interest, referred for primary hyperthyroidism. A chest computed tomography (CT) scan had been performed in Primary Care in the setting of constitutional symptoms, and revealed a 3 cm anterosuperior mediastinal mass consistent with TH. No signs or symptoms of myasthenia gravis were noted. A positron emission tomography CT scan was performed in order to exclude a thymoma, revealing no metabolic activity increase. He presented with diffuse goiter, hand tremor and increased heart rate. Laboratory findings showed TSH <0.01 mIU/l [0.380-5.330] with T4L 4.2 ng/dl [0.54-1.24]and positive anti-TSH receptor antibodies (TRAB)(40 U/l, reference range <1.75). Thyroid ultrasound showed an enlarged thyroid with increased vascularity. Based on these findings, the patient was diagnosed with GD and coexisting TH. Since TH is an uncommon but known manifestation of GD, no further investigations of the thymic mass were done and medical treatment of GD was started with a titration regimen of methimazole and propranolol. A conservative and observational approach was taken to monitor TH. Twelve months later and after maintaining a euthyroid state with negative TRAB, a repeat CT scan was performed and revealed total regression of the mass seen on the previous CT.
Conclusion
Mediastinal tumours located in the anterosuperior mediastinal compartment are usually malignant, the detection of an anterior mediastinal mass usually leading to biopsy or even surgical removal. Nonetheless, in Grave's disease the diagnostic approach is different. Resolution of hyperthyroidism together with back to normal anti-TSH receptor antibodies is associated with regression of thymic hyperplasia. Several hypotheses have been proposed to explain the mechanisms behind the association of GD and TH, including an immunology-based pathogenesis and a direct thymic trophic effect from excess thyroid hormones. Benign evolution as evidenced by regression of thymic hyperplasia after resolution of hyperthyroidism in all cases described in the literature, supports a conservative approach.

Novel Thyroid Hormone Receptor-β Agonist TG68: a polypharmacological approach for the treatment of obesity-associated diseases

Caterina Ricardi, Beatrice Polini, Cristina Dettori, Federica Saponaro & Grazia Chiellini
University of Pisa, Pathology, Pisa, Italy

Obesity is a multifactorial disease in which environmental conditions and genetic factors play an important pathogenic role [1]. Interestingly, some of these obesogenic environmental and genetic conditions are shared with neurodegenerative diseases (NDD). The common biological mechanisms involved in obesity and NDD are insulin resistance, pro-inflammatory cytokines, and oxidative damage, in turn leading to cognitive dysfunction or cell death. In this aspect, a poly-pharmacological drug approach which targets multiple pathological pathways at the same time, should provide the best way to treat such complex networked diseases. Activation of thyroid hormone receptor β (THRβ) has shown beneficial effects on metabolic and neurologic alterations, without cardiotoxicity. Therefore, selective TRβ-agonists might represent promising multitarget agents for the treatment of interlinked diseases such as obesity and NDD. Recent investigations, allowed the selection of the novel thyromimetic TG68 as a very powerful lipid lowering, transthyretin (TTR) protein stabilizer, and antiamyloid agent [2,3]. With the aim to expand our knowledge on the multitarget potential of this novel TH analog, we investigated the effects on lipid metabolism, neuroinflammation and behavior produced by chronic administration of TG68 in high fat diet (HFD) obese and insulin resistant mice, a well established model of obesity/neuroinflammation neurotoxicity. Even though still at a preliminary level, the results of our study provided evidence that in HFD mice (24 CD-1 male mice exposed to HFD C1090-60 for 10 weeks), treatment with TG68 (10 mg/kg/day; 7days; in drinking water) significantly ($P=0.02$) reduced anxiety, as detected by performing stretch-attend posture (SAP) tests, while inducing a 20% body weight loss and a significant ($P<0.05$) decrease in blood lipid levels, including cholesterol and triglicerides. A significant ($P<0.01$) anti-inflammatory activity in LPS/THFa stimulated human microglial cells (HMC3) was also observed after treatment with 10 μM TG68, providing support to the ability of this novel THRβ-selective thyromimetic to efficiently modulate multiple pathological pathways involved in complex networked diseases, such as obesity and NDD.

The TNAPP web-based algorithm improves thyroid nodule management in clinical practice. A retrospective validation study

Giuseppe Lisco[1], Giuseppina Renzulli[2], Andrea Frasoldati[3], Rinaldo Guglielmi[4], Vito Angelo Giagulli[1], Edoardo Guastamacchia[1], Jeffrey R Garber[5], Vincenzo Triggiani[1] & Enrico Papini[4]
[1]University of Bari 'Aldo Moro', Interdisciplinary Department of Medicine - Section of Internal Medicine, Geriatrics, Endocrinology and Rare Diseases, School of Medicine, Bari, Italy; [2]University of Bari 'Aldo Moro', Department of Emergency and Organ Transplantation, Section of Pathological Anatomy, University of Bari 'Aldo Moro', Bari, Italy, Bari, Italy; [3]Endocrinology and Metabolism Department, Arcispedale Santa Maria Nuova IRCCS-ASL, Reggio Emilia, Italy, Reggio Emilia, Italy; [4]Endocrinology and Metabolism Department, Regina Apostolorum Hospital, Albano Laziale – Rome, Italy, Albano Laziale (Rome), Italy; [5]Endocrine Division, Harvard Vanguard Medical Associates Harvard Medical School, Boston, MA, United States, Boston, United States

The detection of thyroid nodules has been increasing over time, resulting in an extensive use of fine-needle aspiration (FNA) and cytology. Tailored methods are required to improve the management of thyroid nodules, including algorithms and web-based tools. To assess the performance of the Thyroid Nodule App (TNAPP), a web-based, interactive algorithmic tool, in improving the management of thyroid nodules, we carried out a preliminary analysis on a cohort of outpatients. One hundred twelve consecutive individuals with 188 thyroid nodules who underwent FNA from January to December 2016 and thyroid surgery were retrospectively evaluated. Neck ultrasound images were collected from a registry and re-examined to extract data to run TNAPP. Each nodule was evaluated for ultrasonographic risk and suitability for FNA. The sensitivity, specificity, positive and negative predictive values, and overall accuracy of TNAPP were calculated and compared to the diagnostic performance of two algorithms by the American Association of Clinical Endocrinology/American College of Endocrinology/Associazione Medici Endocrinologi (AACE/ACE/AME), and the American College of Radiology Thyroid Imaging Reporting and Data System (ACR TI-RADS). TNAPP performed better in terms of sensitivity (>80%) and negative predictive value (68%) with an overall accuracy of 50.5%, which was similar to that found with the AACE/ACE/AME algorithm. TNAPP displayed a slightly better performance than AACE/ACE/AME and ACR TI-RADS algorithms in selectively discriminating unnecessary FNA for nodules with benign cytology (Bethesda class II: TNAPP 32% vs. AACE/ACE/AME 31% vs. ACR TI-RADS 29%). The TNAPP reduced the number of missed diagnoses of thyroid nodules with suspicious and highly suspicious cytology (Bethesda classes V + VI: TNAPP 18% vs. AACE/ACE/AME 26% vs. ACR TI-RADS 20.5%). A total of 14 nodules that would not have been aspirated were malignant, 13 of which were microcarcinomas (92.8%). TNAPP's use of size >20 mm as an independent determinant for considering or recommending FNA reduced its specificity. The rate of malignant nodules missed because of inaccurate characterization at baseline by TNAPP was lower compared to the other two algorithms and the tumors were microcarcinomas, suggesting the risk of missing diagnoses would have been favorable in terms of overall patients' prognosis. Overall, the TNAPP algorithm is a reliable, easy-to-learn tool that can be readily employed to improve the selection of thyroid nodules requiring cytological characterization. Additional studies are needed to confirm and guide the development of future iterations that incorporate different risk stratification systems and targets for diagnosing malignancy while reducing unnecessary FNA procedures.

The role of 18F-DOPA-PET/CT in medullary thyroid cancer patients with biochemical incomplete response

Carla Gambale[1], Alessio Faranda[1], Antonio Matrone[1], Alessandro Prete[1], Sandra Brogioni[1], Valeria Bottici[1], Laura Agate[1], Duccio Volterrani[2] & Rossella Elisei[1]
[1]Unit of Endocrinology, Department of Clinical and Experimental Medicine, Pisa University Hospital, Pisa, Italy; [2]Nuclear Medicine Unit, Pisa University Hospital, Pisa, Italy

Background
PET/CT scan with ^{18}F-fluoro-dihydroxyphenylalanine (^{18}F–DOPA) is an emerging useful tool in medullary thyroid cancer (MTC) patients with high calcitonin (CTN) values. The aim of this study is to evaluate the potential usefulness of ^{18}F-DOPA-PET/CT in MTC patients with biochemical incomplete response (BiR) (detectable CTN values and negative/indeterminate findings at CT scan with i.v. contrast).
Materials and Methods
Fifty-three MTC patients with BiR performed ^{18}F-DOPA-PET/CT scan between May 2021 and December 2022 after having performed CT scan with i.v. contrast.
Results
Most of patients were females (60.4%). The median age at the diagnosis was 47 years. Sixteen (30.2%) patients were positive for RET germline mutation. At the time of ^{18}F-DOPA-PET/CT [median 37 months (IQR: 102-196.5) from diagnosis], the median serum CTN value was 399 (165-1135) pg/ml. ^{18}F-DOPA-PET/CT was negative in 15 (28.3%) cases, while an uptake of the radiotracer was detected in 38 (71.7%). Conversely, CT scan was negative in 21 (39.6%) while in the remaining 32 (60.4%) patients, indeterminate findings were highlighted. When comparing the two imaging methods, both were negative in 11 (20.8%) cases. In the remaining 10 (18.9%) cases of negative CT scan; ^{18}F-DOPA-PET/CT showed pathologic uptake mainly in neck. However, in 2 patients the uptake was in liver. Among 32 patients with indeterminate findings at CT scan, 28 showed an uptake at ^{18}F-DOPA-PET/CT while 4 did not. When we analyzed the concordance between the two methods (uptake of ^{18}F-DOPA in the same sites of indeterminate lesions described at CT scan), 9 patients showed a concordance while 4 patients a discordance (uptake of ^{18}F-DOPA in other sites than those described at CT scan). The other 15 patients showed a partial concordance, most of whom (9/15 – 60%) had more indeterminate lesions at CT scan than ^{18}F-DOPA uptake.
Conclusions
In most of the cases of MTC patients with BiR and negative or indeterminate findings at CT scan; ^{18}F-DOPA-PET/CT scan showed radiotracer-enhancing lesions. Therefore, in this setting; ^{18}F-DOPA-PET/CT can be useful to clarify and define as metastases those lesions with indeterminate features at CT scan. However, although these findings are relevant and useful to better follow-up the disease, the clinical management rarely has been changed.

Improving the surgical indication of the Indeterminate TIR3B nodules: a prediction model based on clinical, ultrasound and cytological features

Clotilde Sparano[1], Matteo Puccioni[1], Virginia Adornato[1], Elena Zago[1], Mario Maggi[1] & Luisa Petrone[2]
[1]University of Florence, Department of Experimental and Clinical Biomedical Sciences 'Mario Serio', Florence, Italy; [2]Careggi Hospital, Endocrinology Unit, Florence, Italy

Introduction
Indeterminate cytology still puzzles clinicians, due to its wide range of oncological risks. The new Italian cytological classification introduced in 2014 by SIAPEC-IAP split this category into TIR3A and TIR3B, according to a different cancer risk of $<10\%$ and $<30\%$, respectively. Consequently, TIR3B nodules still have a surgical indication, even if more than half of cases will not result in thyroid cancer. The present study aims to analyse a consecutive series of TIR3B nodules referred to surgery, to identify potential features able to improve the surgical indication.
Methods
A consecutive series of thyroid nodules referred to the Endocrine Unit of Careggi Hospital from 1st May 2014 to 31st December 2021 has been considered to build a prediction algorithm. The main clinical, US and cytological features have been collected, with particular regard to the secondary cytological features such as cell configurations, presence of colloid, aggregates, anisonucleosis, nuclear atypia and Hurtle cells. According to Akaike Information Criterion (AIC), a stepwise logistic regression has been performed to find the best prediction algorithm, using the histological outcome as the dependent variable. Thereafter, this algorithm has been verified in a smaller confirmatory sample of consecutive TIR3B diagnosed and referred to surgery from 1st January 2022 to 31st June 2022.
Results
Of 502 TIR3B nodules referred to surgery, 451 cases were included in the exploratory analysis. The observed rate of positive histology was higher than expected, with 161 cases (36%) of thyroid cancer ($P=0.010$). Considering the final outcome, a stepwise logistic regression showed that the presence of colloid (OR = 0.18, CI95%:0.04-0.88, $P=0.034$), age>55 years (OR = 0.49, CI95%:0.31-0.77, $P=0.002$) and a nodule size >18 mm (OR = 0.354, CI95%:0.22-0.56, $P<0.0001$) were favourable prognostic factors, at odds with the presence of chronic autoimmune thyroiditis (OR = 1.7, CI95%:1.05-2.9, $P=0.032$), Hurtle Cells (OR = 4.2, CI95%:1.35-14.1, $P=0.020$), hypoechoic nodules (OR = 2.79, CI95%:1.62-4.81, $P=0.0002$), aggregate cells disposition (OR = 4.55, CI95%:1.57-13.2, $P=0.005$), and anisonucleosis (OR = 5.15, CI95%:1.6-166.1, $P=0.0049$). A unified prediction algorithm was built according to the multivariate results. A score >14.5 showed a sensitivity of 60.1% and a specificity of 76.8% in predicting the unfavourable outcome (AUC = 0.748, 95CI:0.699-0.797, $P<0.0001$), which corresponded to an OR = 4.98 (95CI:3.24-7.65, $P<0.0001$). When applying the same algorithm on a confirmatory sample of 58 TIR3B cytology, a threshold of 14.5 points showed a positive and a negative predictive value of 53% and 80%, respectively.
Conclusions
A new predictive algorithm which considers the main clinical, US and cytological features can significantly improve the oncological stratification of TIR3B cytology.

Iodine supply and thyroid status of women with gestational diabetes mellitus and their impact on birth outcomes

Hana Vitkova[1,2], Jan Kratky[1,2], Tomas Brutvan[1,3], Jan Jiskra[1,2], Katerina Anderlova[1,3], Veronika Radimerska[1,4], Radovan Bilek[5], Drahomira Springer[1,4], Felix Votava[6,7] & Eliska Potlukova[8]
[1]First Faculty of Medicine Charles University, Prague, Czech Republic; [2]General University Hospital in Prague, Third Department of Medicine, Czech Republic; [3]General University Hospital in Prague, Department of Obstetrics and Gynaecology, Czech Republic; [4]General University Hospital in Prague, Institute of Clinical Biochemistry and Laboratory Medicine, Czech Republic; [5]Institute of Endocrinology, Czech Republic; [6,3]rd Faculty of Medicine Charles University, Czech Republic; [7]University Hospital Královské Vinohrady, Department of Children and Adolescents, Czech Republic; [8]Universitätsspital Basel, Basel, Switzerland

Introduction
Urinary iodine concentration (UIC) and neonatal thyroid stimulating hormone (neoTSH) concentrations can reflect changes in iodine status and serve as a sensitive marker of iodine intake in pregnancy. As gestational diabetes mellitus (GDM) requires some diet modification, the study aimed to map the situation of iodine intake in women with GDM compared to healthy pregnant women and explore a relationship to thyroid function.
Methods
In the two groups consisting of 195 pregnant women with GDM and 88 healthy pregnant women, we assessed UIC using spectrophotometry after alkalisation and demineralisation and serum concentrations of TSH, free thyroxine (FT4) and autoantibodies against thyroid peroxidase (TPOAb) and thyroglobulin (TgAb) were detected by chemiluminescent immunoassay. Neonatal TSH was determined in the newborns of women with GDM by immunofluorescence from a dry drop of blood on a screening card.
Results
The median of UIC was significantly lower in women with GDM than in the control group (89.50 mg/l vs 150.05 mg/l; $P<0,001$). The optimal iodine supply was found only in nine women with GDM (4.62%) and 33 healthy pregnant women (37.5%) ($P<0.001$). Most pregnant women with GDM (88.72%) and half of the controls (50.00%) had iodine deficiency ($P<0.001$). Neither TSH serum concentrations nor the prevalence of TSH >4 IU/l were different in both groups. However, the women with GDM had a significantly higher prevalence of isolated hypothyroxinemia compared to controls (12.31 % vs 3.41 %, $P=0.032$). Also, the prevalence of neonatal TSH >5 IU/l was 5.22% in newborns of women with GDM and signalled iodine deficiency. The positive association between FT4 and HbA1c in women with GDM was found in the regression model. Hypothyroxinemia <11.5 pmol/l was also associated with a higher risk of preterm birth in the same group.

Conclusion
UIC was lower in women with GDM than in control and corresponded with the iodine deficiency. Most pregnant women with GDM (88.72%) and half of the controls (50.00%) had iodine deficiency. In addition, the women with GDM had a significantly higher prevalence of isolated hypothyroxinemia compared to controls (12.31 % vs 3.41 %, $P=0.032$). Also, the prevalence of neonatal TSH $>$ 5 IU/l was 5.22% in newborns of women with GDM and signalled iodine deficiency.

Patients with Covid-19 induced atypical thyroiditis have thyroid-resident memory T-cells specific for SARS-CoV-2

Ilaria Muller[1,2], Ylenia Silvestri[3], Francesca Clemente[3], Sara Maioli[1], Elena Carelli[3], Giorgia Moschetti[3], Alejandro Espadas[2], Tullia De Feo[2], Giovanna Mantovani[1,2], Maura Arosio[1,2], Mauro Bombaci[3], Elisa Pesce[3], Renata Grifantini[3], Sergio Abrignani[1,3], Mario Salvi[2] & Jens Geginat[1]
[1]University of Milan, Milano, Italy; [2]Policlinico of Milan, Milano, Italy

Background
The severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) pandemic disease (Covid-19) is associated with the onset of thyroid dysfunction via multiple mechanisms. Patients hospitalised for severe Covid-19 disease may develop painless atypical thyroiditis coexisting with non-thyroidal illness syndrome, which determines transient thyrotoxicosis with quick restoration of euthyroidism during the following weeks. However signs of thyroiditis at ultrasound and scintigraphy scans may persist up to one year. The SARS-CoV-2 immune responses play a key role in inducing secondary thyroid dysfunction, but little is known about anti-viral immune responses in the thyroid gland.
Methods
We analysed T-cell responses in 7 patients with severe Covid-19 disease developing atypical thyroiditis (COV-A-SAT). Paired blood and ultrasound-guided thyroid fine-needle aspiration (US-FNA) samples were obtained after 4 and 8 months following SARS-CoV-2 infection. Extracted lymphocytes were immunophenotyped by flow cytometry and stimulated with SARS-CoV-2 peptides. HLA-matched MHC I and II dextramers specific for SARS-CoV-2 peptides were also used to identify SARS-CoV-2-specific T-cells. The presence of intra-thyroid SARS-CoV-2 RNA on thyroid US-FNA samples was tested by real-time reverse transcriptase polymerase chain reaction 4 months post-infection.
Results
No intra-thyroid SARS-CoV-2 RNA was found 4 months post-infection. Despite the apparent viral clearing, COV-A-SAT patients still showed increased systemic T-cell activation as well as cytotoxic and Th1 effector cells, which returned to normal levels 8 months post-infection. Moreover, anti-SARS-COV2-specific CD4+ and CD8+ T-cell responses were readily detectable in peripheral blood 4 months post-infection, but were hardly detectable after 8 months. Unbiased bioinformatic analysis of T-cells in the thyroid gland and in peripheral blood unveiled unique T-cell clusters, in particular CD103+CD69+ tissue-resident memory cells (TRM) in the thyroid, and identified CXCR3+T-cells as their putative precursors in the blood. Importantly, SARS-COV2-specific T-cells were enriched in the thyroid gland, and acquired a TRM phenotype in particular 8 months post-infection.
Conclusions
These findings suggest that atypical thyroiditis developed by patients with severe Covid-19 is characterised by a prolonged, yet largely transient, systemic anti-viral effector T-cell response that results in the generation of long-lived tissue-resident memory cells in the thyroid. This local immune response may in part explain the persistence of signs of thyroiditis at thyroid ultrasound and scintigraphy scans up to one year following infection, despite the presence of normal thyroid function. Long-term clinical consequences are unknown.

Depression among hyperthyroid patients and the impact of Graves' orbitopathy

Bojan Marković[1], Mirjana Stojkovic[1,2], Tamara Janić[1], Sanja Klet[1], Biljana Nedeljkovic Beleslin[1,2], Jasmina Ciric[1,2] & Milos Zarkovic[1,2]
[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, University Clinical Center of Serbia, Thyroidology, Belgrade, Serbia; [2]Faculty of Medicine University of Belgrade, Belgrade, Serbia

Background
Thyroid hormones have regulatory effect on serotonin and noradrenaline and thyroid dysfunction is closely linked to some mental disorders. Besides depression and anxiety, and increased risk for suicide is demonstrated in patients with Graves' disease (GD).
The aim
of our research was to determine the symptomatology of depression in patients with hyperthyroidism and Graves' orbitopathy (GO) and compare it with hyperthyroid patients without GO. We also studied the influence of GO as an additional stressful long-lasting disease, known to have a great impact on quality of life due to disfiguring and eye function reduction.
Material and method
The study group included 36 patients (10 males and 26 females; age range 33-72 years) with GO, and 20 patients (3 males and 17 females; age range 21-75 years) without GO. For the assessment of depressive symptoms, we used the 9-item Patient Health Questionnaire (PHQ-9) for all patients and a disease-specific GO-QOL questionnaire for 30 patients with GO. The total scores for both GO-QOL scales (visual functioning and appearance score) were 0-100%, the higher values, the better quality of life. The results do not represent a definitive diagnosis of depression. All subjects were euthyroid on thioamides. Patients with GO had active moderately severe disease.
Results
In the group with GO, 5.6% had minimal symptoms of depression, 44.4% mild, and 50% had moderate-to-severe symptoms of depression. In the group without GO, 35% of patients had no symptoms, 35% had minimal symptoms, 25% had mild, and 5% moderate symptoms of depression. The frequency of depressive symptoms was significantly higher in patients with GO than in the control group ($P=<0.001$). The majority of the patients (38.8%) had difficulty concentrating when doing things like reading newspapers or watching television. In the GO-QOL questionnaire, minimal changes in the visual functioning were found in 30% of GO patients, while 33.3% had moderate, and 36.6% severe changes in visual functioning. The appearance score showed that 43.3 % of patients thought to have minimal, 46.6 % moderate, and 10 % severe changes in appearance.
Conclusions
Hyperthyroidism may have a significant impact on the development of depressive symptoms (low mood and difficulty enjoying things, loss of appetite, disturbed sleep, etc.). Furthermore, our results indicate that patients with GO are at greater risk of experiencing depressive symptoms. Thus, psychotherapy should be included in the treatment of hyperthyroid patients, particularly in those with Graves' orbitopathy.

Nonfunctioning thyroid nodules in graves' disease – do they harbor a higher risk of malignancy?

Maria Salomé Serranito, Nelson Cunha, Alexandra Abegão Matias, Teresa Sabino, Diana Martins, Ana Palha, Lurdes Matos & José Silva-Nunes
Hospital Curry Cabral - Centro Hospitalar Universitário de Lisboa Central, Lisbon, Portugal

Introduction
The prevalence of palpable thyroid nodules in Graves' disease (GD) is approximately 15%. Cytopathologic interpretation in GD is challenging due to frequent cytomorphologic changes, namely after radioactive iodine (RAI) therapy. Some of the few published studies regarding fine-needle aspiration (FNA) in patients with GD, suggest an increased risk of malignancy of thyroid nodules arising in GD patients. However, the results are inconsistent, and there is no consensus.
Objective
To characterize FNA results of thyroid nodules in GD patients and analyze if there is a higher rate of malignancy.
Methods
We conducted a retrospective review that included all patients who underwent FNA between 01/09/2021 and 01/09/2022 at our center. Statistical analysis was done using SPSS Statistics v.29.0. A P-value <0.05 was considered statistically significant.
Results
We analyzed 1281 FNA results from 1015 patients with an average age of 61.76±12.12 years. There were 852 women (83.9%) and 163 men (16.1%). FNA results were nondiagnostic (ND) in 480 cases (37.5%), benign in 660 (51.5%), follicular lesion of undetermined significance (FLUS) in 102 (8.0%), follicular neoplasm (FN) in 13 (1.0%), suspicious for malignancy (SM) in 9 (0.7%) and malignant in 17 (1.3%). Thirteen patients included (1.3%) had GD and their cytopathological results were: ND in 7 (41.2%), benign in 7 (41.2%), FLUS in 2

(11.8%) and malignant in 1 (5.9%). None of the nodules in patients with GD was diagnosed as SM or FN. The patient with a malignant result underwent total thyroidectomy, and histological examination revealed papillary carcinoma. One of the patients with FLUS underwent total thyroidectomy, and histological examination was benign. One of the patients with GD had FNA done after RAI, and the result was ND. We found no significant difference between FNA results in patients with or without GD ($P=0.393$). In a subanalysis of patients with only benign or malignant cytological diagnosis, there was no significant difference in the rate of malignancy between patients with or without GD (12,5 *vs*. 2,4%, $P=0,19$).
Conclusion
In this study, there was no significant difference in the malignancy rate of thyroid nodules in patients with or without GD. These findings are inconsistent with some published studies suggesting that GD is associated with a higher risk of thyroid cancer. However, this study is limited by the small number of GD patients with thyroid nodules requiring FNA. This reinforces the need for robust studies to clarify the risk of thyroid malignancy in GD.

UPLC-Q-TOF/MS-based metabolomics explored the metabolic mechanisms of thyroid cancer in different background

Danyang Sun[1], Xue Li[2], Xuan Wang[2], Yanhui Ji[2], Zhaowei Meng[2] & Wei Zheng[2]
[1]Tianjin Medical University General Hospital Airport Site, Nuclear Medicine, Tianjin, China; [2]Tianjin Medical University General Hospital, Nuclear Medicine, Tianjin, China

Thyroid papillary carcinoma (PTC) is the most common endocrine tumor, Hashimoto's thyroiditis (HT) is considered to be closely related to PTC pathogenesis, but their relationship still needs verification and exploration. *Aim of the study*. To analyze the differences and similarities of the metabolic mechanism of thyroid papillary carcinoma in normal and HT background, and to explore the relationship between HT and PTC. The Ultra performance liquid chromatography-quadrupole-time of flight-mass spectrometry (UPLC-Q-TOF/MS) technology was used to analyze 61 PTC patient tissues (31 HT background and 30 normal tissue (NC) background). Potential biomarkers were screened from principal component analysis (PCA) to orthogonal partial least square (OPLS) discriminant analysis and further evaluated by ROC analysis. The HMDB was searched to identify potential differential metabolites and the final metabolic pathway analysis was performed by MetaboAnalyst 5.0. The HT and NC group had common metabolic pathways, such as taurine and hypo-taurine metabolism, arginine biosynthesis, alanine, aspartate and glutamate metabolism, arginine and proline metabolism and D-glutamine and D-glutamate metabolism. Furthermore, arginine, glutamic acid, cysteine, citric acid, malic acid, uracil and taurine showed statistical significance in PTC diagnosis (the area under the curve values of HT group and NC group were 0.867 and 0.973 respectively). The HT group had specific metabolic pathways, including aminoacyl-tRNA biosynthesis, glycine, serine and threonine metabolism. The metabolic profiles of the NC and HT groups had important similarities and differences in thyroid cancer. The correlation of PTC with HT may be related to aminoacyl-tRNA biosynthesis, serine and threonine metabolism.

Autoimmune thyroid disease: a risk factor for thyroid cancer?

Maria Salomé Serranito, Nelson Cunha, Alexandra Abegão Matias, Teresa Sabino, Adelaide Milheiro & José Silva-Nunes
Hospital Curry Cabral - Centro Hospitalar Universitário de Lisboa Central, Lisbon, Portugal

Introduction
Some studies suggest a possible link between autoimmune thyroid disease (AITD) and thyroid cancer (TC). However, existing data is inconsistent, and no consensus exists regarding this question.
Objective
The aim of this study was to analyze the association between TC and AITD, namely Hashimoto's thyroiditis (HT) and Graves' disease (GD).
Methods
We conducted a retrospective and observational study of all patients who underwent thyroid surgery (lobectomy or total thyroidectomy) between January 2020 and September 2022 at our center. Patients were diagnosed with AITD if they had at least one positive thyroid antibody (TPOAb, TgAb and/or TRABs) or if they had lymphocytic thyroiditis on histology. Statistical analysis was done using SPSS Statistics v.29.0. A P-value <0.05 was considered as statistically significant.
Results
We analyzed a total of 695 patients. 145 patients were excluded due to lack of data regarding the diagnosis of AITD. The 12 patients diagnosed with Non-invasive Follicular Thyroid Neoplasm with Papillary-like Nuclear Features (NIFTP) were also excluded. The average age at the time of surgery of the 538 patients included was 55.8 $\pm$ 15.1 years. There were 456 women (84.8%) and 82 men (15.2%). Most patients did not have AITD (61.0% *vs*. 39.0%) and had a benign histology (66.9% *vs*. 33.1%). We identified 171 patients (31.8%) with HT and 39 patients (7.2%) with GD. We found no statistically significant difference between the prevalence of TC in patients with or without AITD (33.8% *vs*. 32.6%; $P=0.393$). Also, no statistically significant difference was found in terms of occurrence of TC in a subanalysis of subjects with HT *vs*. subjects without AITD (38.6% *vs*. 32.6%; $P=0.18$). In the subgroup of patients with GD, there was a significantly lower percentage of malignancy than in patients without AITD (12.8% *vs*. 32.6%; $P=0.01$).
Conclusion
In this study, there was no positive correlation between the presence of AITD and the occurrence of malignant disease, contrary to what is suggested in some studies published in the literature. On the other hand, the malignancy rate was significantly lower in patients with GD compared to patients without thyroid AITD; this association may be due to the fact that, in most cases, the surgical indication in patients with GD is the treatment of hyperthyroidism and not the presence of a suspicious nodule. This reinforces the need for robust studies to clarify the possible role of thyroid autoimmunity in thyroid carcinogenesis.

Sonographic pattern and risk factors and malignancy in indeterminate thyroid nodules

Maria Riestra[1,2], Marta Dieguez Felechosa[1,2], Carmen Gandara Gutiérrez[1], Pablo Gonzalvo Rodríguez[3], Diana Rodriguez Villar[3], Lorena Mendez López[3], Raquel Fernandez Morais[4], Mario Sánchez Canteli[4] & Nuria Valdés Gallego[1,2]
[1]Hospital Universitario de Cabueñes, Endocrinology and Nutrition, Gijon, Spain; [2]Instituto Investigación Sanitaria Principado de Asturias, Oviedo, Spain; [3]Hospital Universitario de Cabueñes, Pathological Anatomy, Gijon, Spain; [4]Hospital Universitario de Cabueñes, Otorhinolaryngology, Gijon, Spain

Introduction
Fine-needle biopsy with cytologic evaluation remains the diagnostic test of choice to distinguish benign from malignant thyroid nodules, but fails to classify thyroid nodules in 15% to 30% of cases (indeterminate thyroid nodules-ITN). 'Rule out' molecular testing improves the diagnostic accuracy, with high sensitivity and negative predictive value, ranging from 86 to 96%. However, these tests are not widely available, and notably increase costs.
Objective
To determine if sonographic patterns of the nodule and risk factors of thyroid cancer are as useful as molecular testing.
Methods
We evaluate sonographic patterns and clinical characteristics of ITN with histologic diagnosis. We define EUTIRADS 2 and 3 as low risk (LR), EUTIRADS 4 as moderate risk (MR) and EUTIRADS 5 as high risk (HR). Sociodemographic variables and thyroid cancer risk factors (cervical radiotherapy, familiar history or PET-positive) were collected, and we calculate sensitivity (S), specificity (E), positive predictive value (PPV) and negative predictive value (NPV) for globally low risk patients (sonographic and clinical). Statistical study was carried out using SPSS v21
Results
From 2017 to 2021, 112 ITN with histologic diagnosis were included, 80.2% women, mean age 55.03 $\pm$15.5. 11.7% has at least one thyroid cancer risk factors. 29.7% had LR sonographic pattern, 40.5% MR and 29.7% HR. Nodule mean size was 30.2 mm $\pm$ 18 The overall malignancy rate was 24.4%. For LR ultrasound and no risk factors (28.5% of all patients) overall S, E, PPV and NPV were 97.1, 40.8, 43.03 and 96.8 respectively.

Conclusions
Sonographic patterns and thyroid cancer risk factors has as high NPV as a 'rule out' molecular test, and it should be a first step prior to consider it use.

Graves ophthalmopathy in HIV patient: a case report

Aristia Seremet, Stela Vudu & Lorina Vudu
Nicolae Testemiţanu State University of Medicine and Pharmacy, Chişinău, Moldova

Background
Graves disease is a resurgent autoimmune condition that is known to occur during treatment and immune reconstitution in HIV, and it is one of the commonly diagnosed endocrinopathies in these patients. Graves orbitopathy, on the other hand, is a situation that occurs less frequently. We report the clinical features and manifestations of thyroid-associated orbitopathy in a case of an HIV patient with Graves disease.
Case Presentation
A 48-year-old woman presented with spontaneous retrobulbar pain, exophthalmos, periodic diplopia, palpebral edema, and conjunctival hyperemia. The symptoms reported appeared and advanced during the previous 12 months. Anamnesis revealed that she was diagnosed with Graves disease 3 years ago and is on antithyroid medication and beta-blockers with moderate success in achieving euthyroidism. The patient is also receiving antiretroviral treatment for the last 5 years, as she was diagnosed with HIV 10 years ago. The patient is a chronic tobacco user, for about 30 years. On admission, the patient had freeT4 - 35,3 pmol/l, freeT3 - 12,0 pmol/l, and antithyroid medication was adjusted to obtain euthyroidism. On the clinical examination, we appreciated a CAS score of 5 points and a moderate to severe case of ophthalmopathy, confirmed on MRI by hypertrophic orbital muscles. At the moment, the patient was aviremic and with a CD4 cell count of 665. The patient was started on pulse therapy with 750 mg of methylprednisolone, continued for 6 weeks, and 500 mg the following 6 weeks. No serious side effects were reported during treatment with steroids. Exophthalmos was the only remaining symptom after treatment, CAS score was reduced to 1 point.
Conclusions
Graves orbitopathy in HIV patients is uncommon and is not well-described in the literature. Many challenges may appear in these patients, especially regarding pharmacological interactions of antiretroviral, antithyroid and steroid drugs. Still, in our particular case, first-line treatment with steroids was efficient in reducing ophthalmopathy symptoms.

C-reactive protein level in patients with autoimmune hypothyroidism before and after levothyroxine treatment

Stela Vudu, Aristia Seremet & Lorina Vudu
'Nicolae Testemitanu' State University of Medicine and Pharmacy, Endocrinology, Chisinau, Moldova

Hypothyroidism is one of the most common endocrine disorders. The long-time debatable question is whether patients with subclinical hypothyroidism (SH) should be treated with levothyroxine. Data are contradictory and treatment decision depends on several factors: TSH level, anti-TPO level, age, presence of symptoms etc. Hypothyroidism is associated with cardiovascular disease. Even a minor increase in C-reactive protein (CRP) is considered a cardiovascular risk, therefore evidence of beneficial effect of levothyroxine treatment on CRP could be an argument in favour of therapy. The aim of the study was to assess the level of high sensitivity CRP (hs-CRP) in patients with overt and subclinical hypothyroidism and to evaluate the (potential) effect of levothyroxine treatment on hs-CRP. Parametric data were tested by one way ANOVA and non-parametric data – by Kruskal Wallis test. Effect of treatment was assessed by paired t-test or Wilcoxon signed Rank test. Analysis of frequencies was performed with the use of Pearson Chi-Square tests using Bonferroni-correction for multiple comparisons. $P<0.05$ was considered significant. 37 patients (17 with overt hypothyroidism, OH and 20 with SH) and 37 healthy controls were included in the study. TSH, fT4, total cholesterol (TC), HDL-C, LDL-C, creatinine, creatin kinase (CK) were determined in all participants. hs-CRP was measured at baseline visit, then after 2 and 4 months of levothyroxine therapy. hs-CRP was significantly increased in OH ($P<0.001$) and SH ($P=0.001$) at baseline as compared to controls. hs-CRP significantly decreased in SH (2.2 ± 1.6 mg/l at baseline visit, 1.4 ± 1.1 mg/l after 2 months of treatment, $P=0.017$) and tended to decrease in OH (2.3 ± 1.6 mg/l at baseline visit, 1.6 ± 1.1 mg/l after 4 months of treatment, $P=0.067$*). Mean hs-CRP in the control group was 0.9 ± 0.4 mg/l. Only 17.6 % of patients with OH and 30 % of those with SH had a hs-CR $P<1$ mg/l at baseline visit, as compared to control group, where 71.1 % of persons were at low cardiovascular risk. After 4 months of treatment 41.2 % and 40 % of patients with OH and SH respectively decreased their hs-CR $P<1$ mg/l. Levothyroxine treatment did not change the rest of biochemical biomarkers in patients with SH. Body mass index (BMI) was highest (29.1 ± 3.7 kg/m^2) in the subgroup of patients with hs-CR $P>3$ mg/l and lowest (23.8 ± 4 kg/m^2) in the subgroup of patients with hs-CR $P<1$ mg/l ($P=0.03$), which highlights the role of body weight in inflammation.

Effects of Growth Hormone Therapy on Thyroid Function in Adults with and Without Concomitant Central Hypothyroidism in Growth Hormone-Deficient Patients

Anand Shankar[1] & Amit Kumar Das[2]
[1]Shankar Diabetes Care Centre, Diabetes, Patna, India; [2]Shree Hospital & Maternity, Medicine, Muzaffarpur, India

Introduction
Numerous thyroid function disturbances have been linked to the administration of growth hormone (GH) to GH-deficient patients. There have been reports of anything from increased energy expenditure and improved peripheral thyroxine (T4) to triiodothyronine (T3) conversion to decreased thyrotropin (TSH) sensitivity to thyrotropin-releasing hormone (TRH) stimulation and induction of hypothyroidism.
Objective
GH has an impact on thyroid structure and function. Although goitre is common in acromegalic patients, it can be challenging to evaluate the consequences of GH deficiency (GHD) because hypopituitarism persons with GH deficiency frequently simultaneously have a partial or total deficit of TSH.
Method
Comparing subjects heterozygous for the same mutation (10 men and 9 women; HET group) and subjects homozygous for the wild-type allele [6 men and 10 women; control (CO) group] to subjects with the homozygous mutation in the GHRH receptor gene (GHRHR), the thyroid morphology and serum levels of thyroid hormones in adult members of a large kindred with untreated isolated GHD was compared. The statistical program SPSS/PC 8.0 was used to conduct the statistical analysis. For qualitative variables, values for continuous variables are given as the mean+sd. For the purpose of comparing the three groups, ANOVA was used. The correlation between TV and its determinants was calculated using the Spearman correlation. Statistics were judged significant at $P<0.04$.
Result
Thyroid volume (TV) in GHD participants was lower than in HET and CO subjects. Between the GHD and CO groups' TVs and those of the HET group, it was in the middle. When TV was adjusted for body surface area, the difference between the GHD and HET groups vanished but TV remained less in the GHD and HET groups than in the CO group. When compared to the CO group and HET and CO groups, the GHD group's serum T3 levels were lower and its free T4 levels were greater.
Conclusions
It is possible that GH plays a permissive role in the growth of the thyroid gland because people with severe untreated GHD caused by a homozygous GHRHR mutation and heterozygous carriers of the same mutation have smaller TV than healthy individuals. Additionally, blood total T3 and free T4 levels in GHD participants were lower, suggesting that the deiodinase system may not be functioning as well.

Prediction and Classification models for Hashimoto's thyroiditis risk using clinical and paraclinical data

Ana-Silvia Corlan[1], Babuc Diogen[2,3], Costi Flavia[4] & Onchis Darian[5]
[1]University of Medicine and Pharmacy Timisoara, Endocrinology, Timisoara, Romania; [2]West University of Timisoara, Informatics, Timisoara, Romania; [3]West University of Timisoara, Computer Science, Timi?oara, Romania; [4]West University of Timisoara, Informatics, Timisoara, Romania; [5]West University Of Timisoara, Machine Learning, Timisoara, Romania

Background
Hashimoto's thyroiditis (HT) is the most common autoimmune disorder and, also, the leading cause of hypothyroidism in iodine-sufficient areas. In recent years, a concept emerged, that thyroid autoimmunity could be associated with low-grade chronic inflammation, which may result in future cardiovascular comorbidities, independent of thyroid function. It is therefore essential to diagnose Hashimoto's thyroiditis as early as possible and to test for thyroid function.
Methods
We recruited 129 participants, including 104 diagnosed HT patients and 25 non-HT controls. Secondly, we collected 12 factors and analyzed their significant differences between controls and HT patients; the clinical factors analyzed were age, family history of autoimmune thyroid disease, personal history of: breast cancer, surgically induced menopause, diabetes mellitus type 2, polycystic ovary syndrome. The paraclinical parameters evaluated were: anemia, hemoglobin, hematocrite values, hypertriglyceridemia, hypercholesterolemia, hyperuricemia, fasting hyperglycemia, abnormal liver function tests. We evaluated the following models: Decision Tree, K-Nearest Neighbor, Extreme Gradient Boost, and Support Vector Machine for classification and regression, as well as neural networks: Artificial Neural Network and Deep Neural Network.
Results
The best model for binary classification was K-Nearest Neighbor, with an accuracy of 85%, sensitivity of 78% and specificity of almost 100%. Concerning regression analysis, we obtained a Pearson coefficient of 97% and an R-squared value of 94% for the Deep Neural Network. Statistical indicators, designed for the regression part confirmed a family history of autoimmune disease, personal history of breast cancer, surgically induced menopause, anemia, hypertriglyceridemia, hyperuricemia, fasting hyperglycemia, and increased alanine aminotransferase values as significant risk factors for Hashimoto's thyroiditis.
Conclusions
The proposed models of machine learning, combined with multiple factors, are efficient for HT diagnosis. These findings suggest screening for autoimmune thyroid disease in metabolic syndrome patients, in breast cancer patients and in women with surgically induced menopause.

The Association of Iodothyronine Deiodinase Gene Polymorphisms and Hashimoto's Thyroiditis: Does Free T3 Play a Role?
Cem Armağan Turan[1], Onur Elbasan[2], Tugce Apaydin[3], Büşra Gözaydınoğlu[4], Can Ilgin[5], Hande Akalan[6], Duygu Yaşar Şirin[6], Rıfat Bircan[6] & Hülya Ilıksu Gözü[3]
[1]Marmara University Pendik Research And Education Hospital, Internal Medicine, Istanbul, Turkey; [2]Sinop Ataturk State Hospital, Endocrinology and Metabolism, Sinop, Turkey; [3]Marmara University Pendik Research And Education Hospital, Endocrinology and Metabolism, Istanbul, Turkey; [4]Marmara University School of Medicine, Istanbul, Turkey; [5]Ministery of Health, Şırnak Province Health Directory, Şırnak, Turkey; [6]Tekirdağ Namık Kemal University, Molecular Biology and Genetics, Tekirdağ, Turkey

Introduction
Hashimoto's thyroiditis (HT) is caused by a variety of genes, cytokines, receptors, and environmental factors. A series of enzymes known as type 1 and type 2 deiodinases (D1, D2) are in charge of converting thyroxine (T4) into triiodothyronine (T3). It is believed that the low free T3 (fT3) levels caused by D2 polymorphism may result in thyroid autoimmunity through the induction of inflammation. However, iodothyronine deiodinase (DIO) gene polymorphism and HT in conjunction with fT3 levels have not been thoroughly investigated. In this study, we aimed to examine the relationship between HT and DIO polymorphisms (D1 rs11206244, D2 rs225014, and D2 rs12885300) as well as the effect of DIO gene polymorphisms on fT3 and autoantibody levels (anti-thyroid peroxidase, anti-thyroglobulin, thyroid receptor antibody).
Methods
Participants aged 18-65 years are included in this cross-sectional study. Among 183 participants, 87 is diagnosed with HT, and 96 are healthy subjects. We measured autoantibody levels and thyroid ultrasonography to determine the diagnosis of HT. Peripheral blood samples were collected from all participants for genetic analysis and to measure thyroid function tests. All participant's genomes were analyzed for DIO polymorphisms by PCR-RFLP method. We included only euthyroid HT patients with or without levothyroxine treatment for the evaluation of DIO gene polymorphisms on fT3 levels.
Results
HT patients were found to have D2 rs225014 'TC' and 'CC' alleles more frequently ($P = 0.025$) than in healthy controls. Free T3 levels were shown significantly lower in euthyroid HT patients compared to healthy subjects ($P = 0.007$). In addition, HT patients with D2 rs225014 'TC and CC' alleles were found to have significantly decreased fT3 levels ($P = 0.005$) compared to the healthy subjects. No association was found in the D1 rs11206244, D2 rs12885300 polymorphisms, HT and fT3 levels. None of the DIO gene polymorphisms was associated with the autoantibody levels.
Conclusions
We demonstrated that the D2 rs225014 'TC' and 'CC' alleles were associated with HT. HT patients with D2 rs225014 polymorphism 'TC and CC' alleles exhibited lower fT3 levels compared to the healthy subjects. Our findings support D2 rs225014 polymorphism is linked to HT and that fT3 may function as a potential mediating factor in this connection.

PAX8-PPARγ rearrangement, galectin-3 immunoreactivity and risk of deep vein thrombosis (DVT) in patients with metastatic follicular thyroid cancer (FTC)
Darko Katalinic, Ivan Aleric, Dragan Primorac & Aleksandar Vcev
Faculty of Dental Medicine and Health and Faculty of Medicine, J. J. Strossmayer University of Osijek, Osijek, Croatia

Introduction
Follicular thyroid cancer (FTC) account for approximately 15% of all thyroid malignancies, with about 65 % being conventional and 35 % Huürthle cell type. Recently a *PAX8-PPARγ* gene fusion was detected in a significant portion of FTCs, some with a chromosomal translocation t(2;3)(q13;p25). The t(2;3) rearrangement leads to an in-frame fusion of the *PAX8* gene, which encodes a transcription factor, with the peroxisome proliferator-activated receptor (PPAR) γ gene. They are able to promote neoplastic cell proliferation and possible hypercoagulability. The number of studies on deep vein thrombosis (DVT) coexist with FTC is limited and medical data are contradictory.
Aim
The aim of the study was to perform genomic analysis of the *PAX8-PPARγ* rearrangement in patients with metastatic FTC and to determine the prevalence and risk factors associated with DVT taking into consideration the status of *PAX8-PPARγ*. We have also analyzed the association between *PAX8-PPARγ* rearrangement and its correlation with galectin-3 immunoreactivity.
Material and Methods
The study included 57 patients who underwent a total thyroidectomy for FTC, aged 38-61 years. The *PAX8-PPARγ* status was detected using Real-time polymerase chain reaction. Diagnosis of the FTC was confirmed with histopathological examination. Diagnostic strategies were evaluated for DVT.
Results and Conclusion
Among 57 patients, only 3 patients (5.3 %) had *PAX8-PPARγ* rearrangement. The FTCs with *PAX8-PPARγ* typically showed immunoreactivity for galectin-3 and tended to present at a younger patient age. In our study, we could not confirm the connection between *PAX8-PPARγ* rearrangement and the occurrence of DVT in patients with metastatic FTC.

Clinical Characteristics of Differentiated Thyroid Carcinoma with Obesity and Glucose Metabolism
Xuan Wang[1], Wei Zheng[1], Xue Li[1], Danyang Sun[2] & Yanhui Ji[1]
[1]Tianjin Medical University General Hospital, Department of Nuclear Medicine, Tianjin, China; [2]Tianjin Medical University General Airport Hospital, Department of Nuclear Medicine, Tianjin, China

Objective
To explore the association between body mass index (BMI) and plasma glucose level with pathological features and clinical outcomes of differentiated thyroid cancer (DTC).
Methods
Clinical data of 1264 consecutive DTC patients treated with total thyroidectomy and enrolled at the time of the first ^{131}I treatment from April 2016 to July 2020. The clinicopathological findings were compared in the groups were categorized according to BMI and glycemic disorders. Independent samples t-test, Mann-Whitney U test and χ^2test were employed to compare the correlation between

BMI and plasma glucose level with pathological features and response evaluation of DTC. Logistic regression analysis was used to analyze the independent risk factors for the aggressiveness of DTC.
Results
The analysis according to BMI evidenced overweight and obesity were more frequent in males ($P=0.000$) while patients in the overweight group were older and had higher TNM stage ($P=0.000$, 0.004). The proportion of patients with bilateral tumors was higher in the overweight and obese group ($P=0.001$). However, there was no significant correlation between BMI and lymph node metastasis, TNM stage, T stage, N stage, M stage and response evaluation ($P>$ 0.05). Diabetes group are older than the other groups, and the proportion of men and bilateral tumors were found to be significantly higher ($P=0.000$, 0.000, 0.045). Compared with the normal blood glucose group, the BMI index of patients with prediabetes and diabetes is higher, and the BMI index of patients with prediabetes is the highest ($P=0.000$). The T stage and TNM stage were higher in the diabetes group ($P=0.032$, 0.000). However, there was no significant correlation between glycemic status and lymph node metastasis, N stage, M stage and response evaluation ($P>$ 0.05).
Conclusions
DTC patients with high BMI and diabetes may have more aggressive incidence. But BMI and glycemic status has no correlation with the response evaluation of DTC patients.

A retrospective study on the immunocitochemistry profile of benign thyroid nodules unresponsive to thermal ablation

Stella Bernardi[1], Silvia Taccogna[2], Martina D'Angelo[2], Fabiola Giudici[3], Giovanni Mauri[4], Bruno Raggiunti[5], doris tina[5], Fabrizio Zanconati[1], Enrico Papini[6] & Roberto Negro[7]
[1]University of Trieste, Department of Medical Surgical and Health Sciences, Trieste, Italy; [2]Regina Apostolorum, Pathology Unit, Albano Laziale, Italy; [3]Gustave Roussy, Bureau Biostatistique et Epidémiologie, Villejuif, France; [4]European Institute of Oncology, Italy; [5]ASL - Distretto di Atri, Atri, Italy; [6]Regina Apostolorum, Endocrinology Department, Italy; [7]Ospedale 'Vito Fazzi', Endocrinology Unit, Lecce, Italy

Objective
Thermal ablations (TA) are gaining ground as alternative options to conventional therapies for symptomatic benign thyroid nodules. Little is known on the impact of nodule biology on the outcomes of TA. The aim of our study was evaluating the baseline immunocytochemistry profile of thyroid nodules that are poorly responsive to TA, in order to identify potential predictors of treatment response.
Methods
we retrospectively selected by propensity score matching two groups of patients with benign thyroid nodules treated with TA, namely CASE (patients who did not respond to TA and were later surgically treated) and CNT (patient who responded to TA). The fine-needle aspiration cytology (FNAC) slides obtained before TA were stained for Galectin-3, HBME-1, CK-19, and Ki67.
Results
In both groups, patients were predominantly females in their mid 40s, their nodules measured 17 mL (range 10-55) and were mostly solid (that is with a solid component $>$ 90%) and non-functioning. Treatment modality was most often laser ablation (87-92% of cases). There were no differences in terms of energy delivered. Benign nodules of the CASE group ($n=24$), did not express CK-19 while expressed more frequently Ki-67 as compared to the CNT group ($n=26$). CK-19 appeared to be the most sensitive marker (high NPV), whereas Ki-67 was the most specific (high PPV) for retreatment and regrowth. When we combined CK-19 and Ki-67, the AUC was of 0.69 (0.57-0.81) for retreatment, and it had a sensitivity, specificity, PPV and NPV of 32%, 91%, 78%, and 58%.
Conclusions
CK-19 expression was predictive of no regrowth/retreatment. If confirmed, this finding could provide a rapid and inexpensive information about the potential outcome of TA on benign thyroid nodules. As CK-19 is more frequently expressed in adenomatous hyperplasia, it could be speculated that these nodules, rather than follicular adenomas, are better candidates for TA.

Radioactive Iodine Treatment in Hyperthyroidism is Associated with Increased Body Weight

Ali Al Jumaah[1,2], Shailesh Gohil[1,2], Miles J Levy[1,2] & Narendra Reddy[1,2]
[1]University of Leicester, Leicester, United Kingdom; [2]University Hospitals of Leicester NHS Trust, Endocrinology Department, Leicester, United Kingdom

Introduction
Definitive treatment of hyperthyroidism with Radioactive Iodine (RAI) ablation therapy has been associated with weight gain from RAI induced hypothyroidism. Literature on weight data of post-RAI patients following normalisation of thyroid function is equivocal.
Objective
We undertook a retrospective study to evaluate the effect of RAI on weight in Hyperthyroid patients in University Hospitals of Leicester NHS Trust (UHL).
Methods
Retrospective electronic records review on 'Clinical Workstation' database was undertaken to identify RAI-treated patients. We limited the electronic search to adults (>16 years old) who received at least one session of RAI for hyperthyroidism at UHL from 2003 to 2022. We only included patients with measured weight in the euthyroid state before and after RAI. We excluded patients with thyroid carcinoma due to direct effect of cancer on weight regardless of thyroid function. Euthyroid state was defined as normal thyroid function test and/or absence of clinical features of hyper/hypothyroidism at the time of body weight measurement.
Results
Of the 575 patients undertaken RAI treatment, $n=$ 51 patients were included to analyse as they fulfilled the criteria; a) had pre- and post-RAI weight data within 4-weeks of clinical encounter, and b) TSH normal. Majority were females (Female:Male = 42:9). Mean age = 57 years. Aetiology was Graves' disease in 20, Non-autoimmune in 31 patients. Mean duration of follow up was 52 months. All 51 patients were rendered euthyroid on anti-thyroid medications (ATDs) prior to definitive treatment with RAI. Mean weight gain was 4.02 kg (5.3%) following RAI treatment. Autoimmune hyperthyroidism patients gained 3.05 kg (4.2%) compared to 4.65 kg (6%) in the non-autoimmune group. Males appear to have gained more weight than females following RAI, 7.56 kg (8.2%) and 3.26 kg (4.5%), respectively.
Discussion
RAI appears to cause weight gain across gender and age groups. However, weight documentation during clinical encounters has been inconsistent. This study did not account for confounders like lifestyle, co-morbidities and medications that potentially impacted body weight and finally, it's unclear if there's an element of weight overcorrection prior to TSH normalisation from hypo/hyperthyroidism. We took findings of this study to set up a prospective cohort study looking for RAI impact on body weight across aetiologies, interventions (ATDs, surgery and RAI) and comorbidities.
Learning points
1. RAI treatment appears to cause weight gain across gender and age categories.
2. Patient information leaflet warning of potential weight gain side effect ahead of RAI treatment may influence treatment choice and help adopt preventative dietary and life-style measures.

The role of thyroid autoimmunity in assisted reproduction outcome-not yet solved puzzle

Sanja Medenica[1], Eliana Garalejic[2], Dzihan Abazovic[3], Zoran Bukumiric[4], Biljana Arsic[5] & Milos Zarkovic[6]
[1]Department of Endocrinology, Internal Medicine Clinic, Clinical Center of Montenegro, School of Medicine, University of Montenegro, Podgorica, Montenegro; [2]*In Vitro* Fertilisation Department, Clinic for Gynecology and Obstetrics 'Narodni front', School of Medicine, University of Belgrade, Belgrade, Serbia; [3]Emergency Medicine Center of Montenegro, Podgorica, Montenegro; [4]Institute for Medical Statistics and Informatics, Faculty of Medicine, University of Belgrade, Serbia; [5]*In Vitro* Fertilisation Department, Clinic for Gynecology and Obstetrics 'Narodni front', Belgrade, Serbia; [6]Department of Thyroid Gland Disease, Clinic of Endocrinology, Diabetes and Metabolic Diseases, University Clinical Center of Serbia, School of Medicine, University of Belgrade, Belgrade, Serbia

Background
hyroid autoantibodies cross blood-follicle barrier in titer dependent manner and may change oocyte microenvironment with adverse effects on implantation or

post-implantation period. Thyroid autoimmunity (TAI) interfers with pregnancy course and newborn anthropometry in pregnancy achieved by assisted reproduction (ART).
Objective
To light upon pregnancy course outcomes and newborn anthropometric characteristics regarding TAI in ART programme.
Methods
The course of clinical pregnancy achieved in 24 women undergoing ART was observed and pregnancy and newborn outcomes compared in two groups divided by the presence of TAI.
Results
In the study population, 33.3% were TAI positive and 66.7% TAI negative women. The special interest was adressed on anti-thyroglobulin antibodies with the important difference in serum, as expected, but in follicular fluid, $P<0.001$. Number of retrieved oocyte, number of embryos, *top quality* and embryo transferred were not significantly different between the groups, but higher percentage of good quality oocytes in TAI negative group were noticed (70.9% vs 81.5%, $P=0.053$), without affecting fertilization and implantation rates. Live birth rate was 96.0%, with preterm birth 16.7% and term birth rate 70.8%. Groups were no different comparing the rate of twin pregnancy, early, late miscarriage and preterm birth. Maternal complications, gestational diabetes mellitus or pregnancy induced hypertension, were present in 23.8% with no difference between the groups. In TAI positive group newborns had higher birth weight ($P=0.001$) and lenght ($P=0.008$). No congenital malformations in newborns were noted.
Conclusions
The study pointed out no adverse effects of TAI on ART achieved pregnancy outcomes, regardless the higher percentage of good quality oocytes in the women without TAI, but TAI could affect newborn anthropometry.

Severe malnutrition associated with amyloid goiter: A case report

Carlos Jareño Martínez[1], Ariadna Prats Custal[1], Cristina Franco Borras[1], Laia Martinez Guasch[1,2], Theodora Michalopoulou Alevras[1,2], Silvia Näf Cortés[1,2], Manel Castellote Caixal[2,3], Alejandro Samitier Pastor[2,4], Antoni Raventós Estellé[2,5] & Ana Megía Colet[1,2]
[1]Joan XXIII University Hospital, Endocrinology and Nutrition Department, Tarragona, Spain; [2]Rovira i Virgili University, Tarragona, Spain; [3]Joan XXIII University Hospital, General Surgery Department, Tarragona, Spain; [4]Joan XXIII University Hospital, Radiology Department, Tarragona, Spain; [5]Joan XXIII University Hospital, Pathology Department, Tarragona, Spain

Background
Amyloidosis is defined as the accumulation of amorphous, proteinaceous material in different parts of the body. It can be primary or secondary, having decreased the incidence of this last one due to the current therapeutic landscape of infectious and autoimmune diseases. This material can be deposited in the thyroid gland resulting in an enlargement known as Amyloid goiter. Although amyloid infiltration in thyroid is common, the occurrence of clinically enlarged thyroid owing to amyloid deposition, leading to goiter, is an extremely rare phenomenon.
Case Presentation
A 72-year-old woman with chronic pyelonephritis and hearth failure with preserved ejection fraction due to hypertrophic cardiomyopathy was referred to our outpatient clinic presenting severe malnutrition related to an enlarged thyroid gland with compressive symptoms (dysphagia). Thyroid function test results were in the normal range and serum thyroid autoantibodies were undetectable. Cervical ultrasound showed a diffusely swollen thyroid and fine-needle aspiration (FNA) cytology showed a pattern consistent with lymphocytic thyroiditis. Neck CT-scan again showed symmetrically enlarged thyroid lobes up to 107 mm at his largest diameter with retropharyngeal extension, surrounding trachea and esophagus. Abdomen CT-scan revealed a substantial dilation of calyces with lithiasis, a marked parenchymal atrophy with significant perirenal fat thickening, perirenal effusion and retroperitoneal adenopathies in his right kidney. Prior to surgery, the patient needed parenteral nutritional support. After preoperative work-up, total thyroidectomy was performed without complications. The histopathological study revealed the presence of amorphous protein aggregates that was stained with Congo-Red dye and the immunohistochemistry study was positive for Amyloid A and P proteins. The patient was later diagnosed with secondary amyloidosis due to xanthogranulomatous pyelonephritis.
Conclusion
Amyloid goiter is an extremely rare entity. Secondary amyloidosis must be considered in the differential diagnosis of thyroid enlargement, specially those with rapid onset, and particularly in patients with a history of chronic infections or inflammatory disorders predisposing to amyloid deposition. FNA biopsy should be performed to exclude malignancy and thyroidectomy is necessary for definitive diagnosis.

Exogenous Testosterone May Have A Effect on Thyroid Volume İn Trans-Men

Eren Imre[1], Seckin Akcay[2], Ceyda Dincer Yazan[2], Onur Elbasan[2], Neşe Yorguner[3] & Ozlem Ustay[2]
[1]Marmara University School of Medicine, Endocrinology and Metabolism, Istanbul, Turkey; [2]Marmara University School of Medicine, Endocrinology and Metabolism, İstanbul, Turkey; [3]Marmara University School of Medicine, Department of Psychiatry, İstanbul, Turkey

Purpose
Thyroid autoimmune diseases occur more frequently in women than men. A previous study reveals that exogenous testosterone may have a protective effect on thyroid autoimmunity in men with Hashimoto's thyroiditis. But no study has determined whether sex hormones produce any effect on thyroid antibody titreş in women. The primary study aim was to assess whether exogenous testosterone affects thyroid autoimmunity in trans-men with increasing testosterone levels.
Methods
We designed this study as a single-center prospective study. We included 60 drug-naive trans men, and the control group comprised 26 healthy cisgender women. We measured and compared hormone profiles and metabolic parameters in the two groups initially and after six months under exogenous testosterone. Each participants underwent a preliminary ultrasonography and it was investigated whether there was any abnormality such as a nodule or parenchymal heterogeneity. The thyroid gland was scanned in three dimensions. Depth, width (in transverse plane), and length (in longitudinal plane) of each lobe were measured. Volume of each lobe was calculated using the formula, volume (mL) = π/6 x width x depth x length (15). Total volume was determined as the sum of the volumes of the lobes except for the isthmus.
Results
In patient group, there was no significant difference according to TSH levels (P 0.308) and fT4 levels (P =0.650) before and after treatment. But total testesterone levels and thyroid volume (7.62 $\pm$ 2.57 mL and 8.37 $\pm$ 2.74 mL; before and after treatment, respectively) were significantly higher after treatment ($P<0.001$ and $P=0.042$, respectively). The existence of thyroid nodule didn't significantly change before and after the treatment ($P=0.791$)
Conclusion
This study is the first one to have shown that exogenous testosterone may have a effect on thyroid volume in trans men but doesn't cause an increase in thyroid nodul formation. Testesteron's effect on thyroid needs to be followed for a longer period to determine accurately.

Differences between Unilateral and Bilateral Graves' Orbitopathy. An observational study

Georgios Boutzios, Sofia Chatzi, Areti Mina, Maria Fanouraki, Ilias Giovannopoulos, Athina Karampela, Andreas Goules & Athanasios Tzioufas
National and Kapodistrian University of Athens, Department of Pathophysiology, Medical School, Athens, Greece

Introduction
Graves' Orbitopathy (GO), the most common extrathyroidal manifestation of Graves' disease (GD), usually presents bilateral disease. However, a minority of patients present with unilateral disease, the prevalence of which is between 4,5% and 14%. The aim of our study is to evaluate the specific demographic and clinical characteristics and potential differences between bilateral and unilateral GO, and the association with disease activity and severity.
Materials and Methods
We conducted an observational study in the outpatient clinic of autoimmune endocrinopathies of the Department of Pathophysiology at Laikon University Hospital. Patients with GD and GO were included in the study. Demographic and clinical characteristics were recorded. We evaluated disease activity with CAS and severity based on EUGOGO consensus. All patients were assessed for TSI levels, TgAbs, TPOAbs and proptosis with Hertel exophthalmometer. Data collected were compared between the two groups of bilateral and unilateral GO.

Results
A total of 102 patients were analyzed. Of whom, 19,6 % presented with unilateral GO. In the bilateral GO patient group mean age was 52.9 ± 13.2 years and 75.6% of them were females. Regarding disease severity, mild, moderate and severe disease accounted for 22.5%, 58.8% and 18.8%, respectively and 64,6% had active disease. The median TSI levels was 9.670 IU/l and the majority of them were negative for TgAbs. Median proptosis for the right eye was 21mm and 20mm for the left. 58% presented with diplopia and 18,3% with strabism. In the unilateral GO patient group the mean age was 56,1 ± 10,7 years and 60% of them were females. Regarding disease severity 40% presented with mild, 35% with moderate and 25% with severe disease. Active disease accounted for 50% of patients. Median TSI levels was 6,55 IU/l and median proptosis was measured 19mm for the right eye and 18,5mm for the left. Diplopia was present in 60% and strabism in 30 %.
Conclusion
In our study, in bilateral GO group the majority of patients presented with moderate disease whereas in unilateral GO group with mild disease. Mean TSI levels and median proptosis were higher in the bilateral GO group. Active disease presented more frequently in bilateral than in unilateral GO group.

Efficacy and Safety of Ultrasound-Guided Percutaneous Polidocanol Sclerotherapy Vs Percutaneous Ethanol Injection in Benign Cystic Thyroid Nodules: Preliminary Results

Hossam Ghazi[1], Sherihan Gouda[1], Mayada Saleh[1] & Dina Harb[2]
[1]Mansoura University, Internal Medicine Department, Mansoura, Egypt; [2]Mansoura, Diagnostic Radiology, Mansoura, Egypt

Introduction
Percutaneous Ethanol Injection (PEI) is well known treatment for benign cystic thyroid nodules; however, local pain is common side effect.
Objective
To compare between efficacy and safety of Percutaneous Polidocanol Sclerotherapy (PPS) vs PEI.
Patients and methods
We included 60 patients -with mean age 32 years- have benign thyroid nodules (9 of them were males). They were divided into 2 groups; *group 1* with 30 patients ablated by PEI as a control group & *group 2* with 30 patients ablated by PPS. The mean initial volume of nodules was estimated, and volume reduction rate (VRR) after 1 month & 3 months were compared. Moreover, compressive & cosmetic score were compared before and 3 months after ablation in addition to adverse events.
Results
The mean initial volume was 23.23 ± 6 ml in group 1 vs 24.57 ± 5 ml in group 2 (*P* value: 0.38). No statistically significant difference between 2 groups regarding VRR after 3 months (*P* value: 0.9). Local pain is statistically significantly higher among group 1 (*P* value: <0.001). Hoarseness of voice was found to be higher among group 1 (5 patients vs 1 patient). Fever after procedure was higher in group 2 (7 patients vs 1 patient)
Conclusions
PPS have similar efficacy to PEI in ablating benign cystic thyroid nodules with minimal side effects.

Impact of SARS-COV-2 infection on the endocrine system: a case series

Calin Cristiana[1,2], Iulia Florentina Burcea[1,2], Ramona Dobre[1,2], Roxana Dumitriu[1,2], Raluca Trifanescu[1,2] & Catalina Poiana[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Pituitary and Neuroendocrine Disorders Department, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology Department, Bucharest, Romania

Introduction
There is evidence that SARS-COV-2 infection can result in development of endocrine disturbances. Expression of the angiotensin-converting enzyme 2, which is postulated to be at the center of the pathogenesis of COVID-19, has been reported in various endocrine tissues.
Case Series
We retrospectively analyzed 12 patients with recent history of SARS-COV-2 infection: 5 cases with subacute thyroiditis (SAT), 2 cases with Graves' disease, 2 cases with adrenal insufficiency, 2 cases with secondary amenorrhea and 1 case with male hypogonadism. Out of 5 patients with SAT, 3 were females and 2 males (34-57 years). SAT developed after a median of 12.8 weeks following COVID-19 infection resolution. The main presenting symptoms were neck pain and palpitations. Thyroid function tests showed overt hyperthyroidism in all patients. Treatment was initiated (4 patients with prednisone, 1 patient with ibuprofen) and within 6 weeks, all patients were asymptomatic, with normalization of inflammatory markers, 3 out of 5 were euthyroid, whereas 2 were hypothyroid. Two female patients were diagnosed with Graves' disease right after COVID-19 infection (age 31 respectively, 39). Thyroid function tests showed transient hyperthyroidism in the first patient and overt hyperthyroidism in the second patient, with positive thyroid stimulating hormone receptor antibody (TRAb, 3.18 UI/l, respectively >40 UI/l, range 0-1.75). Only the first patient associated Graves' ophthalmopathy. The second patient had persistent atrial fibrillation and a 4-weeks follow-up showed normal thyroid function under treatment with methimazole. A 20-year-old male presented with chronic fatigue, nausea and vomiting 4 months following COVID-19 infection. He was diagnosed with primary adrenal insufficiency based on elevated ACTH level (1250 pg/ml, range 3-66), low cortisol level (2 µg/dl, range 4.82-19.5) and presence of 21-hydroxilase antibodies. Another 31-year-old female patient presented with orthostatic hypotension 14 months following COVID-19 infection. Laboratory tests revealed elevated ACTH level (195 pg/ml) and suboptimal stimulation after intramuscular 250-µg cosyntropin test. COVID-19 might have contributed to clinically relevant disease progression. Two female patients were diagnosed with secondary amenorrhea after COVID-19 infection (age 28, respectively 35) with good response to progesterone treatment. One male patient was diagnosed with transient hypergonadotrophic hypogonadism following COVID-19 infection. A 2-weeks follow-up showed normalization of serum FSH, LH and testosterone.
Conclusion
The endocrine system is vulnerable to perturbation from SARS-CoV2 infection, therefore among other symptoms and late complications, hormonal parameters should be monitored in these patients. Long-term effects of COVID-19 on the endocrine system remains to be investigated.

Lower expression of miR-21 is related to multifocal lesions of papillary thyroid carcinoma

Aistė Kondrotienė[1], Albertas Daukša[2], Diana Pamedytyte[3], Mintautė Kazlauskienė[1], Aurelija Žvirblienė[3], Dalia Daukšienė[1], Vaida Simanavičienė[3], Raimonda Klimaitė[1], Valdas Šarauskas[4], Rasa Verkauskienė[1] & Birutė Žilaitienė[1]
[1]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Institute of Digestive Research, Medical Academy, Faculty of Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Institute of Biotechnology, Life Sciences Center, Vilnius University, Vilnius, Lithuania; [4]Department of Pathology, Lithuanian University of Health Sciences, Kaunas, Lithuania

Introduction
Multifocality empirically is often treated as a risk factor for aggressive course of papillary thyroid carcinoma (PTC), encouraging aggressive treatments. However, inconsistency and even contradiction in a literature is present concerning the role of tumor multifocality in clinical outcomes of PTC. Therefore, the prognostic value of multifocality of PTC remains controversial, creating a difficulty in the current clinical management.
Methods.
We analyzed miR-146b, miR-21, miR-221, miR-21, and miR-181b in formalin fixed paraffin embedded PTC tissue samples of 312 individuals and evaluated their expression relationship with multifocality of a tumor.
Results.
Multifocality was observed in 68 (21,7%) of the PTC patients. Patients with multifocal lesions had significantly lower expression of miR-21 than those with unifocal ($n=224$) lesions ($P<0.011$) in our study. MiR-146b, -221, -222, 181b expression did not statistically significantly differ between these groups.
Conclusions
Our results suggest that lower expression of miR-21 is related to multifocal lesions. Data from numerous other studies confirm that miR-21 is usually overexpressed in PTC associated with aggressive clinicopathological features. So, our findings of lower miR-21 expression let us to hypothesize, that multifocality might not be a risk factor of poor PTC prognosis.

Role Of liothyronine + Levothyroxine combination therapy in 70 overweight/obese patients with TSH between 2.5-5 unable to loose weight

Vishal Gupta[1] & Vaishali Teli[2]
[1]Dr. Vishal Gupta's Advantage: Diabetes, Thyroid & Endocrine Center, Endocrinology, Mumbai, India; [2]Dr. Vishal Gupta's Advantage: Diabetes, Thyroid & Endocrine Center, Mumbai, India

Aim
To asses the role of Liothyronine (T3) + Levothyroxine combination (T4) therapy in 70 overweight/obese patients with Thyrotropin Stimulating Hormone (TSH mIU/ml) between 2.5-5 who were unable to lose weight.
Methods
Between Jan' 20 - Jan' 21, 70 overweight/obese patients with TSH 2.5 -5 performed on ± 2 occasions ± 4 weeks apart were retrospectively analyzed. 24% {17/70} had TSH 2.5-2.99, 37% {26/70} had TSH 3-3.99 & 39% {27/70} had TSH 4.0-4.99. Twenty% {14/70} were anti-topoisomerase antibody (TPOAb) +ve of which 5.71% had TSH 2.5-2.99, 5.71% had TSH 3-3.99 & 8.57% had TSH 4-4.99. Eighty% {56/70} were TPOAb -ve. They were referred by a nutritionist for inability to lose weight despite being on > 3 months weight loosing regimen (<1000Kcal/day). Protocol: Patients were initiated T3 25 mg/day along with varying doses of T4 to help optimize the TSH (lower limit of normal reference range) & followed 2-3 mths for 6 mths for clinical/cardiac parameters: weight (W-kg), body mass index (BMI-kg/m^2), systolic BP (SBP-mm of Hg), diastolic BP (DBP-mm of Hg), TSH, Lipid profile mg/dl (TC, LDL-C, TG, HDL) & Hs-CRP mg/l. Continuous variables were analyzed using paired & unpaired t-test expressed as mean ± standard error. For interaction between drug class, ANOVA was used & p value <0.05 was considered significant (S).
Results
Baseline (B) characteristics: Avg. age 39.89±11.215yrs, Female/Male ratio 62/8 (88.6%/11.4%), avg. BMI 29.0409±7.29339, SBP 119.79±15.752, DBP 80.37±12.040, TSH 3.824707±0.9896442, TC 184.3203±39.52749, LCL-C 116.6784±38.96588, hs-CRP 4.5114±5.59016. Differences between B to 6 months: S reduction in W (1.7500±0.4796, p-0.001), BMI (0.80243±0.21892, p-0.000), TSH (2.2562429±0.2213319, p-0.000), TC (17.85610±4.93128, p-0.001), LDL-C (17.09672±5.06238, p-0.001) were seen, with no changes in SBP, DBP, TG, HDL, hs-CRP.
Conclusion
T3/T4 combination therapy is effective in initiating weight loss and improving lipid profile in patients with TSH between 2.5-5, without any adverse effect on SBP/DBP. Symptomatic patients with TSH between 2.5-5 can be initiated T3/T4 combination therapy as it leads to both weight loss and improvements in TC & LDL which might have beneficial long term cardiovascular effects.

Clinical and Biochemical Comparative Evaluation of Thyroid Hormone Replacement in Patients with Hypothyroidism Due to Autoimmune Thyroiditis and Total Thyroidectomy

Zeynep Akgül Kızılçay, İlkay ÇAKIR, Alev Kural & Meral Mert
Sağlık Bilimleri Üniversitesi Bakırköy Dr. Sadi Konuk Eğitim ve Araştırma Hastanesi, Turkey

Aim
Hypothyroidism is a common chronical disease worldwide, leading to a lifelong metabolic slowdown that can have a significant negative impact on the quality of life, both physiologically and psychologically. Despite achieving euthyroidism with replacement, there is evidence that symptoms persist. In this study, we aim to examine the effectiveness of thyroid hormone replacement and the effect of autoimmunity from a clinical-biochemical point of view by evaluating the euthyroidic patients both due to autoimmune thyroiditis or total thyroidectomy comparatively.
Material and Method
The study is a prospective cross-sectional study consisting of a total of 60 patients and 30 healthy control individuals. Of 60 patients, there are 30 cases diagnosed with autoimmune thyroiditis and 30 patients with total thyroidectomy who applied to the internal medicine and endocrinology outpatient clinics of our hospital. The data was collected and maintained with a patient information form, which includes the sociodemographic characteristics, vital signs and clinical characteristics of the participants, the Billewicz Score in which hypothyroid-specific symptoms and signs are questioned, and the international SF-36 Quality of Life Scale in which the status of the quality of life is questioned. In addition, biochemical and hormonal profiles were measured and recorded.
Results
Weekly LT4 dosage was found to be higher in thyroidectomy-induced hypothyroidism group, serum fT4 levels were also statistically significantly higher in this group, whereas it was revealed that there was no difference in serum fT3 levels. There was a negative correlation between LT4 dose and SF 36 mental health and social functionality sub-parameters. Serum cholesterol levels were higher in the autoimmune thyroiditis group, and blood pressure levels were higher in the thyroidectomized group. There was no significant difference between the two patient groups in terms of Billewicz sub-parameters and total score classifications of hypothyroid patients. Similarly, physical function, physical role disability, emotional role difficulty, energy/vitality, mental health and general health perception, which belong to the SF-36 life quality scale sub-parameters, were considerably lower than the control group.
Conclusions
According to the data obtained from the study, while autoimmunity do not have an additional contribution to clinical, biochemical deterioration and quality of life. Patients with hypothyroidism should be evaluated periodically in terms of symptoms and quality of life, even though they become euthyroid.

Analysis of types of thyroid surgery before and after COVID19 pandemics

Humoyunxon Abdurakhmanov[1], Said Ismailov[1], Matluba Rahmonberdieva[1] & Zulaykho Shamansurova[1,2]
[1]Tashkent Pediatric Medical Institute, Endocrinology with Pediatric Endocrinology, Tashkent, Uzbekistan; [2]Institute Biophysics and Biochemistry at the National University of Uzbekistan, Metabolomics, Tashkent, Uzbekistan

Introduction
Thyroid surgery usually performed in 20% when traditional drug therapy was not effective, or development severe complications, or high risk/presence of cancer. New infection COVID19 affected whole body and probably thyroid results changes in clinical future and treatment. The aim of our study were investigate if frequency and type of thyroid surgery affected by COVID19 pandemics.
Material and methods
We analysed and compared data from one medical centre about thyroid surgery frequency and type before and after COVID19. Data of patients who were admitted for thyroid surgery in Vitamed Medical hospital in Tashkent from 2019 and 2022 were collected and analysed year by year.
Results
Patients chart of 525 people whose were admitted for thyroid surgery during 2019-2022 years were analysed. 86% woman and 14% men among them with average age 45.5±2.5 years old. Most part (60%) of all thyroid surgery were done for nodular goiters and 20% were done for thyroid cancer. Interestingly, before COVID19 pandemics nodular goiters were frequent causes and consisted 71% of all thyroid surgery. After COVID19 pandemics nodular goiters still frequent cases among all thyroid surgery but its pattern had decreased and consisted 57%. We found that surgery by thyroid cancer were increased after pandemics. If thyroid cancer were represented 14% of thyroid surgery cases before pandemics after pandemics the portion gradually increased to 20%. Moreover, gender distribution also were changed with increasing number of males after pandemics. It had shown mostly in thyroid cancer group, where male/female ratio was 1:13 in 2019 and become 1:3 after COVID19 pandemics.
Conclusions
Types of thyroid surgery were varied after COVID19 pandemics with gradually increasing number of thyroid cancer and also increasing number of male patients.

May Concomitant Thyroid Autoimmunity be Associated with Better Prognosis in Thyroid Papillary Carcinoma?

Dilan Çelik Eliş[1], İlkay Çakir[2], Ahmet Cem Dural[3] & Meral Mert[2]
[1]Sağlık Bilimleri Üniversitesi Bakırköy Dr. Sadi Konuk Eğitim ve Araştırma Hastanesi, İnternal Medicine, İstanbul, Turkey; [2]Sağlık Bilimleri Üniversitesi Bakırköy Dr. Sadi Konuk Eğitim ve Araştırma Hastanesi, Endocrinology, İstanbul, Turkey; [3]Dr. Sadi Konuk Devlet Hastanesi, General Surgery, İstanbul, Turkey

Aim
The association between thyroid autoimmunity and thyroid cancer has long been suggested, in addition whether and how the concurrent thyroid autoimmunity with Papillary Thyroid Carcinoma (PTC) affects clinicopathological features and prognosis is a matter of debate. In the present study, we aimed to evaluate the laboratory data, cancer characteristics and prognosis of PTC patients with and without thyroid autoimmunity.
Materials and Methods
Data of 2276 patients who underwent total thyroidectomy in our hospital from 2012 to 2022 was analysed. Total 202 patients diagnosed as PTC whose full data could be accessed were included in the study. The demographic, clinical and pathological features were recorded. Thyroid autoimmunity is defined as presence of antibodies against Thyroglobulin (Tg), thyroid peroxidase (TPO), and/or TSH receptor (TR).
Results
Mean age of patients was 46.67 ± 12.8/year, Majority of patients were female ($n = 165$, 81%). Autoimmunity was positive in 73 patients (36 %). Hundred seven patients (53%) were papillary microcarcinoma. Disease age in the majority of patients was between 1-5 years ($n = 161$, 79.7%). There was a statistically significant difference ($P < 0.001$) in postoperative Thyroglobuline measurements when autooimmune positive patients were compared with autoimmunity negative patients (5.522 ± 26.916 IU/MI and 16,489 ± 52.26 IU/MI respectively). The patients with pre-op Anti-Tg value > 115 IU/MI were excluded, and postoperative thyroglobuline levels remained lower in antiTPO and/or TRAb positive cases (mean post-op TG was 18.12 ± 55.9 in anti-TPO and TRAb negative group, the mean post-op TG level was 4.39 ± 11.05 in Anti-TPO and/or TRAb positive group) ($P < 0.001$).
Conclusions
Since the post-op Tg level is significantly low in autoimmunity positive patients, independent of pre-op anti-Tg elevation, it can be suggested that the prognosis of PTC may be better in individuals with autoimmunity with high anti-TPO antibody titers. However, larger and prospective studies are needed to clarify the relationship between PTC and autoimmunity

2D-SWE PLUS in the assessment of thyroid malignancy

Andreea Borlea & Stoian Dana
University of Medicine and Pharmacy Victor Babes Timisoara, Internal Medicine II, Timisoara, Romania

Our study assesses the diagnostic performance of 2D shear-wave elastography plane-wave ultrasound (2D-SWE PLUS) in detecting thyroid cancer. Using conventional ultrasound (2B-mode) and 2D-SWE PLUS with SuperSonic Mach30 equipment, 270 thyroid nodules were assessed (Supersonic Imagine, France). In every instance, the outcomes and the pathology reports were compared. 69 (or 25.5%) of the 270 nodules were malignant. 2D-SWE PLUS parameters demonstrated great diagnostic accuracy. The best parameter for the 2D-SWE PLUS was the mean elasticity index (AUROC 0.912); with a cut-off value of 30 kPa, it accurately predicted thyroid cancer with a sensitivity of 83% and a specificity of 98%.

Fatal bleeding and thrombosis in a patient with autoimmune primary hypothyroidism

Houcem Elomma Mrabet, Malak Belkhiri, Boubaker Fadia, Yesmine Elloumi, Zantour Baha, Alaya Wafa & Sfar Mohamed Habib
University Hospital Tahar Sfar, Department of Endocrinology, Mahdia, Tunisia

Introduction
Thyroid diseases have been known to cause haemostatic changes, either tendency to bleeding or thrombosis. We report a case of a patient with primary hypothyroidism presenting with spontaneous bleeding and jugular thrombosis.
Case report
An 85-year old patient with no medical history was admitted to the endocrinology department with primary auto-immune hypothyroidism. Hypothyroidism was suspected because of severe loss of weight and appetite, constipation and an extreme fatigue and lethargy. Initial TSH levels were>180 µUI/ml, FT4 was at 0pmol/l and morning serum cortisol was at 81ng/ml. Thyroid Peroxydase antibodies were at 643.2 UI/ml (Normal range <9UI/ml). Upon admission, patient was lethargic, had macroglossia and normal blood pressure. No bruising or spontaneous bleeding were noted or reported by the patient. The patient was started on 20 mg of hydrocortisone, and L-thyroxin was progressively initiated at the dosage of 12.5µg daily. Further work-up found megaloblastic anemia at 6,9g/dl along with moderately low level of Platelets at 111 000/µl. Prothrombin time (PT) was normal. On the sixth day of in-hospital stay, the patient presented a mild traumatic bruising on the right arm. Platelets count was normal (170 000/µl) and PT was normal again. CT scan showed an abdominal and pleural effusion, thrombosis of the left jugular vein and an aneurysm on the right iliac artery with partial thrombosis. The patient was started on low dose aspirin. However, the bruising extended to the right shoulder and thorax thus aspirin was discontinued after 2 days. The patient quickly developed unexplained neurological distress, hypoxemia and was started on large spectrum antibiotic. However, death occurred on the 21st day after admission.
Discussion
The association of bleeding state and thrombosis in our patient is remarkable. Overt hypothyroidism usually leads to tendency de bleeding due to a hypocoaguable state. This can be related to a decreased platelets count, an alteration of their aggregation and agglutination, and decreased levels of von Willebrand factor antigen and several multiple coagulation factors. Subclinical hypothyroidism, autoimmune thyroid disorders and hyperthyroidism are on the other hand associated to increased levels of fibrinogen thus a tendency to hypercoaguablity. These disorders are usually corrected after hormonal therapy. However in our case, spontaneous bleeding manifested and extended after initiation of L-Thyroxin. The use of aspirin was short in duration and could not explain its extension. No other cause for these haemostatic disorders was identified in our case. Prospective studies of thromboembolic states in auto-immune hypothyroidism are warranted.

Investigations on fibroblast growth factor 21 and lipid parameters in patients with Hashimoto thyroiditis

Sára Bak-Csiha[1], David Hutkai[2], Hajnalka Lőrincz[3], Mariann Harangi[3], Miklos Bodor[1,4], Mónika Katkó[1], Endre Nagy[5], György Paragh[3] & Berta Eszter[5]
[4]University of Debrecen, Department of Endocrinology, Debrecen, Hungary; [2]University of Debrecen, Department of Nephrology, Debrecen, Hungary; [3]University of Debrecen, Department of Metabolism, Debrecen, Hungary; [4]University of Debrecen, Department of Clinical Basics, Debrecen, Hungary; [5]University of Debrecen, Department of Endocrinology, Debrecen, Hungary

Background
Fibroblast growth factor 21 (FGF21) is a hormonal regulator of lipid and glucose metabolism exerting protection against atherosclerosis by multiple actions on the blood vessels, liver, and adipose tissues. Enhanced FGF21 production in diabetes and obesity reduces the level of LDL-C and triglycerides by suppression of hepatic SREBP-2. Hypothyroidism has also been shown to have unfavorable effects on atherogenesis and dyslipidemia. To date, the association of lipid parameters and FGF21 levels in autoimmune thyroiditis has not been studied.
Subjects and methods
We enrolled one hundred and ten patients with autoimmune thyroiditis (9 males, 101 females, mean age 49 ± 17 years, median BMI 25.6 (23.7-31.4) kg/m2) with various thyroid hormone status from hypo- to hyperthyroidism. Serum FGF21 concentrations were determined with enzyme-linked immunosorbent assay (ELISA). Thyroid hormone levels, anti-thyroperoxidase concentration and lipid parameters were measured by routine laboratory methods.
Results
Median serum FGF21 level was 81.4 (34.9-151.9) pg/ml, LDL-C was 3.2 (2.6-4.0) mmol/l, HDL-C was 1.6 (1.3-1.8), triglyceride was 1.3 (0.9-2.0) mmol/l, TSH was 2.8 (1.3-4.7) mU/l, while mean total cholesterol level was 5.3 ± 1.1 mmol/l. Mean fT3 and fT4 were 4.58 ± 0.71 and 17.8 ± 3.7 pmol/l, respectively. Significant positive correlations were found between age, BMI, total cholesterol, triglyceride, LDL-C, ApoB100, nonHDL cholesterol and FGF21 levels, while there was a significant negative correlation between fT3 and FGF21 levels. According to multiple regression analyses fT3 level is not a significant predictor of FGF21 or lipid levels.
Conclusions
The significant correlations between FGF21 and lipid parameters indicate the link between FGF21 regulating pathway and lipid metabolism in patients with autoimmune thyroiditis, regardless of thyroid function.

Thyroid manifestations in two different genetic syndromes

Muhammad Shoaib Zaidi
King Saud University Medical City, University Diabetes Center, Riyadh, Saudi Arabia

Introduction
The sensitivity of tissues to thyroid hormones can be impaired rarely, either due to the genetic anomalies of the thyroid hormone metabolism and transport. Consequently, the relative triiodothyronine(T3), thyroxine(T4), and reverseT3(rT3) levels get disturbed and different clinical manifestations ensue. Two recently admitted cases are briefly described.
First Case
A 32 yrs old Saudi housewife, had been admitted to our hospital on 05.01.2023, with 2 days history of lower limb pain and weakness. The patient had a past history(2015) of metastatic Papillary thyroid carcinoma(status post total thyroidectomy + radiotherapy with iatrogenic hypoparathyroidism). In 2017, she was diagnosed to have Myelin Oligodendrocyte Glycoprotein Antibody disease(MOGAD)[history of radicular lower-limb pain, paresthesiae, pseudoseizures, urinary urgency and incontinence, pain and temperature deficits in left upper & both lower limbs & positive MOG antibodies (1:40) (EEG, NCV, EMG, CT & MRI normal). It was followed by recurrent, bilateral granulomatous, Panuveitis (since 2019). The patient also had fibroadenoma left breast dyslipidemia and left sensorineural deafness(after radiation, followed by cochlear implantation). She was on regular daily oral Thyroxine150ug, Prednisolone, Mycophenolate, along with low dose Calcium & Vitamin D. Hemodynamically stable. BMI 26.53 kg/m^2 S. Ca + +1.98mmol/l(2.1-2.55), Mg + +0.88mol/l(0.7-1.10), Phosphorus 1.61 mmol/l(0.81-1.45), ALP 53U/l(35-104), PTH 1.36pmol/l(1.6-6.9), Vit. D 27.6nmol/l, TFTs[TSH 130mIU/l(0.25-5), FT4 6.43pmol/l(12-22)], Thyroglobulin 0.04ng/l(3.5-77). Rest of the labs-normal The patient got improved after the correction of hypocalcemia. Oral calcium & Vitamin D doses were optimized. Thyroxine was increased to 175ug/d.
Second Case
The second patient(admitted on 21.12.2022), was a 17yrs old, single, Saudi male(recently transferred under adult care), having Lipopolysaccharide responsive beige-like anchor protein gene mutation(LRBA),[with chronic diarrhea, malabsorption, electrolyte imbalance, iron deficiency anemia, chronic gall-bladder sludging & failure to thrive]. He also had multiple drug allergies. The patient was on regular total parenteral nutrition for 10 yrs, but there was some disruption before the admission. He had a past history of frequent ICU admissions due to TPN line sepsis (MSSA bacteremia in April,2022), electrolyte derangements (had cardiac arrest 2yrs ago). He was taking oral thyroxine, calcium, Vitamin D & iron supplement. Vitally stable. Weight 13.2 kgs. Stunted growth, but mentally like an adult. CBC[Hb%9.1g/l[13-18], MCV 63.6fl, TLC 18.17 x10^9/l (78%neutrophils)(4-11), PLTs 656x 10^9/l(14-450)], LFTs mildly deranged, Blood gases(pH 7.17, PCO2 26mmHg, HCO3-18mmol/l, Corrected Ca + +1.76 mmol/l (2.1-2.55), Phosphorus (0.65mmol/l(0.85-1.6), ALP 226U/l(55-149), Mg + +0.46mmol/l(0.7-1.1), Vit. D 40.5nmol/l ($\leq$ 25-severe deficiency), S. Proteins 53.10g/l(64-83), Albumin 33.2g/l(32-54), TFTs[TSH 8.18mIU/l(0.25-5), FT4 9.26pmol/l(12-22)], Random Glucose 4.1mmol/l(3.9-5.8). The patient's deficient electrolytes got corrected back to normal with replacement, I/V fluids and resumption of his TPN. Afterwards he was discharged home.
Conclusion
Thyroid involvement, although rare, but has been reported in MOGAD & LRBA gene defect.

Amiodarone-Induced Thyroid Disorders Not Uncommon

Alaina Khan[1,2], Miriam Lowe[1,2], Maisha Hayat[1,2], Sanjali Ahuja[1,2], Robert English[1,2], Kedir Hamid[2], Muhammad Saleem[2], Bashir Mahamud[2], Ayan Mohamed[2], Kirtanya Ramachandran[2], Mohammed Mohammed[2] & Gideon Mlawa[2]
[1]Barts and The London School of Medicine and Dentistry, Queen Mary University of London, Charterhouse Square Campus, United Kingdom, United Kingdom; [2]Queen's Hospital, United Kingdom

Introduction
Amiodarone is a highly effective drug, used for the treatment of arrhythmias. However, it can cause either hypothyroidism or thyrotoxicosis. It leads to alterations in thyroid gland function or thyroid hormone metabolism, due to its high iodine content. Amiodarone-induced hypothyroidism is common in countries with high iodine dietary intake, and Amiodarone-induced thyrotoxicosis is more prevalent in regions with low iodine dietary intake. A large amount of iodide released during the metabolism of Amiodarone causes the so-called Wolff-Chaikoff effect, in which there is a blockage of thyroidal iodide uptake and thyroid hormone biosynthesis. Here we report two cases of Amiodarone-induced thyrotoxicosis and one case of Amiodarone-induced hypothyroidism.
Cases
1) A 65-year-old male patient with a background of long-standing atrial fibrillation was on treatment with Amiodarone. He was subsequently diagnosed with dilated cardiomyopathy resulting in cardiac failure. A year later, the patient presented with thyrotoxicosis (likely secondary to Amiodarone) blood test showed FT4 20pmol/l, TSH $<$0.01 mIU/l. He was treated with carbimazole, and Amiodarone was discontinued. 2) A 72-year-old man presented to the hospital with palpitations, tremors, and dizziness. He was found to be thyrotoxic: T4$>$100pmol/l, TSH $<$0.01 mIU/l. His background includes atrial fibrillation, chronic obstructive pulmonary disease, Type 2 diabetes, hypertension, and high cholesterol. He was taking Amiodarone to manage atrial fibrillation. Amiodarone was then discontinued. 3) An 80-year-old man developed hypothyroidism after being started on Amiodarone. He was known to have ischemic heart disease, atrial fibrillation, and episodes of ventricular tachycardia. Amiodarone was continued as his implantable cardioverter-defibrillator was removed, and he was commenced on thyroxine.
Discussion
Amiodarone is used in some patients to treat arrhythmias. Amiodarone is no longer given as a first-line treatment due to the serious side effects caused by long-term therapy. Common side effects include QT prolongation leading to arrhythmias (Torsades de Pointes), hepatic dysfunction, and thyroid disorders. Amiodarone-induced thyrotoxicosis (AIT) is divided into type 1 and type 2. AIT type 1 occurs in patients with underlying unmasked thyroid disease such as Graves' disease or toxic nodule. Type 2 AIT is due to destructive thyroiditis. Amiodarone-induced hypothyroidism is likely due to the inhibition of thyroid hormone synthesis and is more common in patients with underlying subclinical hypothyroidism.
Conclusion
Patients commencing Amiodarone therapy should have their baseline thyroid function tests checked and then reviewed every six months for early detection of thyroid dysfunction thus avoiding severe episodes of both hypo- and hyperthyroidism.

Graves' Disease and Muscle Paresis

Miglė Francaitė-Daugėlienė
Hormodernus - Endocrinology Center, Endocinology, Kaunas, Lithuania

Background
Graves' disease is medical condintion requiring early diagnosis and urgent management, which can be challenging due to diverse clinical presentations. The presence of muscle paresis is rare.
Case Presentation
We report a 38-year-old female who presented with muscle paresis, urine and fecal incontinence, because of thyrotoxicosis due to Graves' disease. Clinical manifestation: general weakness, body tremor, tachycardia, palpitations, leg muscle weakness, urinary and fecal incontinence, sweating, weight loss, diarrhea.
Illness history
symptoms of the disease manifestated during the COVID-19 pandemic (March the 2020). As the complaints became more prominent, the patient turned to local hospital Emergency department, thyrotoxicosis was diagnosed (TSH - 0.0 mU/l), treatment with thiamazole 5 mg 3 times/day was prescribed (after a few weeks to reduce to 2 tablets). The patient's well-being improved, but after reducing to 2 tablets, the mentioned complaints reappeared. In June 2020, patient applied to outpatient department to endocrinologist, due to whole body tremor, leg muscle paresis (walking like having cerebral palsy), expressed tachycardia (HR 140 bpm), urinary and fecal incontinence. Patient was reffered and hospitalized to LHSU, Department of Endocrinology.
Investigations
Table No 1.
Ultrasound
Graves' disease.
Thyroid scintigraphy
The total concentration of technetium in the thyroid gland is up to 47.4% (the norm is up to 2.0%). Image of a hyperfunctioning thyroid gland.
Treatment
Thiamazole 40 mg/d, Propranolol 40 mgx3, Prednisolone treatment was given. After euthyroid was reached, total thyroidectomy was performed (Feb 2021) and Levothyroxine 100 mg x1 p/os was prescribed. Patient was referred to an endocrinologist consultation after 1.5 months. Patient had a good clinical recovery

following the treatment of thyrotoxicosis and postoperative hypothyrosis: the symptoms of Graves' disease, muscle paresis, urinary and fecal incontinence regressed. Women became pregnant and delivered healthy newborn in December 2022.

Conclusions

Muscle paresis with urinary and fecal incontinence can be a rare manifestation of Graves' disease, and should be considered in the differential diagnosis when other clinical features of thyrotoxicosis are present.

Table No. 1. Investigations

Result (normal range)	At diagnosis	1 week	3 months	After surgery
Glucose (4,1-5,9 mmol/l)	5,78			
Potassium (3,5-5,1 mmol/l)	3,47	3.67		4.32

Large rapidly developing goiter and Acute Leukemia

Nassim Ben Hadj Slama, Ghada Saad, Gorchene Asma, Hamza Elfekih, Maha Kacem & Chadli Molka
University Hospital of Farhat Hached Sousse, Endocrinology, Sousse, Tunisia

Introduction

Many thyroid conditions are associated with the development of a rapidly progressing goiter and should evoke several diagnoses, some of which may be of poor prognosis.

Case-presentation

A 47-year-old female patient with no previous pathological history presented with a large goiter associated with a deteriorated general condition that had been evolving for 3 weeks On examination, she presented with a fever at 39°C, multiple cervical adenopathies of hard and painful consistency, pallor, gingival enlargement, and a painless large goiter of hard consistency, associated with compressive signs: dysphagia and dysphonia. Her biological tests showed: hyperleukocytosis at 77390/mm^3 with 49% blasts, anemia at 7.3 g/dl, and thrombocytopenia at 33000/mm^3. TSH was elevated to 65 mIU/l, FT4 was low at 7.02 pmol/l, LDH was high at 560 IU/ml. Anti-thyroperoxidase and anti-thyroglobulin antibodies were positive at 468 and 566 mIU/ml respectively. The bone marrow aspiration revealed a marrow infiltrated by 59% blasts in favor of acute myeloblastic leukemia type 5 (AML). The karyotype was without abnormality. Immunophenotyping was in favor of Aml. A cervical ultrasound revealed an enlarged thyroid with heterogeneous pseudonodular hypoechoic echostructure associated with multiple cervical adenopathies. Fine needle aspirates (FNA) from the thyroid revealed the presence of benign epithelial cells in both lobes without signs of malignancy. The patient was put on Levothyroxine replacement therapy and treated with Cytarabine and anthracycline chemotherapy. The evolution was marked by a complete remission of her AML and an incomplete regression of her goiter with an improvement of compressive signs.

Discussion

The rapid development of a large goiter in the context of an deteriorated general condition should first evoke: anaplastic cancer, primary thyroid lymphoma, Riedel's Thyroiditis or a secondary thyroid tumor localization. FNA is the key examination in this situation. Our case illustrates the association of AML and Hashimoto's Thyroiditis revealed by a large goiter of rapid evolution. Hashimoto's thyroiditis is associated with a higher risk of developing certain cancers, including leukemia. Various hypotheses have been put forward regarding the underlying pathophysiological mechanisms, including chronic inflammation and its role in oncogenesis. Further studies will be necessary to better elucidate the mechanisms involved.

Hidden central hypothyroidism in an elderly patient following radioiodine therapy

Ghachem Aycha[1,2], Hamza Elfekih[1], Ben Bnina Molka[1,2], Ghada Saad[1,2], Houd Kenza[1,2], Yosra Hasni[1,2] & Molka Chadli Chaieb[1,2]
[1]Faculty of Medicine Ibn El Jazzar, University of Sousse, Sousse, Tunisia; [2]Farhat-Hached University Hospital, Sousse, Tunisia, Endocrinology-Diabetology Department, Sousse, Tunisia

Introduction

Thyrotropin deficiency is a rare etiology of hypothyroidism. The diagnosis can be easily confirmed in case of low FT4 level associated with normal or low TSH value. In patients with peripheral hypothyroidism treated by levothyroxine, this biochemical profile become difficult to find. Herein, we describe the case of a patient with peripheral hypothyroidism due to radioiodine therapy in whom the diagnosis of central hypothyroidism was made.

Observation

An 80-year-old patient, type 2 diabetic, followed initially, 15 years ago, for Graves' disease treated by radioiodine then he received levothyroxine for peripheral hypothyroidism. The replacement dose has been decreased gradually from 150µg q.d. to 75µg q.d. before the patient withdrew his treatment 4 months ago. The patient was admitted in our department for intense asthenia and hypoglycemia. He didn't take any medication recently. His renal and hepatic functions were normal. His TSH level was normal for his age at 5 µUI/l although the history of radioiodine therapy. Endocrinological assessment confirmed central hypothyroidism with low FT4 at 7 pmol/l (12-22 pmol/l), corticotropin deficiency with peak cortisol level after Synacthene test at 185 nmol/l and hypogonadotropic hypogonadism with a testosterone level at 0.22 ng/ml. His prolactin level was low at 68 IU/l. Pituitary MRI showed anterior pituitary hypoplasia and pituitary stalk thickening of 4 mm. hydrocortisone replacement therapy was prescribed at the dose of 15 mg q.d. in addition to levothyroxine at the dose of 75 µg q.d.

Conclusion

Decreased levothyroxine requirements in a patient with peripheral hypothyroidism, the persistence or the presence of nonspecific symptoms although normal TSH level should guide clinicians to the diagnosis of thyrotropin deficiency, most frequently associated with other pituitary hormone deficiency.

Noise Level, Salivary Cortisol Levels and Surgical Team Stress During Thyroidectomy in An Endocrine Surgery Operating Room

Sarrah Idrees, Sabaretnam Mayilvaganan, Ramakanth Bhargav Panchangam, Gyan Chan, Anjali Mishra & Gaurav Agarwal
Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

Introduction

Noise in the operating room is an ongoing problem and impacts the outcome of surgery. Noise as stressor can produce a startle reaction and activate fight or flight response of the autonomic and endocrine system. The psychobiology of the stress as assessed by salivary cortisol level is a sensitive measure of allostatic load. In this study, we correlated salivary cortisol levels of the surgical team with noise measurement and also whether the noise in OR subjectively affected the operating team.

Materials & amp; Methods

Prospective observational study conducted in OR of a tertiary referral centre. We recorded the noise or from shifting in to shifting out using digital sound level meter. The operating team – Operating Surgeon (S), Anaesthetist (A), Scrub Nurse (N) and Floor Nurse (F) all gave a salivary sample for measurement of cortisol at the end of the procedure. We had measured baseline salivary cortisol for Surgeons. Questionnaire for assessment of distraction was filled in by the S, A and N at the end of the procedure. Salivary cortisol levels were analysed using SLV-4635(formerly SLV-2930) DRG Instruments GmbH German using ELISA. Statistical analysis was performed using SPSS 22.0.

Results

Total of 37 procedures with 148 Salivary Cortisol samples and 111 responses from S, A and N were analysed. All Patients with benign FNAC were operated (64.9% - Colloid).

Mean TSH levels were 3.5 ± 6.7. Majority had STN (25/37 67.6%). 18 patients (48.6%) underwent open Hemithyroidectomy 10 patients TT and & amp; 8 patients Endoscopic HT and 1 Pt had sistrunk's procedure. The Mean Cortisol levels of S, N, A and F and mean noise levels are provided in the table1. There was significant Correlation between mean noise levels and S& #39;s levels. ($P < 0.05$).

Conclusion

Noise levels were high in the OR during initial phase and closure phase of thyroidectomy. 'S'' was more affected by noise especially during critical phases of Surgery such as RLN dissection. Serum cortisol level were high for S when compared to N, A and F. No studies in Literature regarding noise correlation and Surgeons stress. Noise is distracting and the effect of long term effect on the surgical team needs to be studied.

Individual experiences and patients' lives: Place of the narrative approach in the therapeutic education plan for thyroid cancer patients

Abdel Mouhaymen Missaoui[1], Fatma Hamza[2], Siddiqa Soomauroo[1], Khawla Ben Ahmed[2], Wafa Belabed[1] & Mohamed Abid[1]
[1]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Habib Bourguiba University Hospital, Department of Nuclear Medicine, Sfax, Tunisia

Objective

To describe the experience of patients with differentiated thyroid carcinoma (DTC) since their diagnosis.

Patients and Methods

Cross-sectional study including 25 patients with DTC who integrated the therapeutic education program (TPE) on DTC at the Nuclear Medicine Center, Sfax, Tunisia. Each participant recounted his or her experience during collective meetings (narrative approach).

Results

Our group was composed of 19 women and 6 men, with an average age of 45.5 ± 15.2 years. The diagnosis was made within the last 3 months in 52%. A thyroid nodule (32%) or adenopathy (32%) were the first warning signs. The diagnosis was announced by the ENT specialist (64%), the treating physician (20%) or the endocrinologist (16%). This experience was satisfactory for 72%. The doctor's communication about the cancerous nature of the CDT was 'vague' for 12%. Also, 16% would have preferred to receive more explicit information. While 68% claimed to have received a clear explanation about the surgical step, 16% would have liked to know more about its objectives. The rest of the treatment protocol (iratherapy, hormone replacement therapy) was fairly well detailed for 80% of the patients. Prior education on the signs of L-thyroxine deficiency/overdose was requested by 40% of participants.

Discussion

The diagnosis of CDT causes an alteration in the patient's identity, which will henceforth be organised around the tale of the disease and the demands of the medical world. The narrative therapy sessions integrated into the ETP programmes would allow access to the patient's subjective experience and lead him/her to reappropriate his/her experience in order to better adhere to the planned therapeutic protocol.

Papillary Thyroid Carcinoma with Abdominal Desmoid-Type Fibromatosis – A Case Report

Klodiana Poshi[1], Adela Haxhiraj[2], Marjeta Kermaj[1], Violeta Hoxha[1], Dorina Ylli[2], Florian Toti[1], Tea Shehu[1], Ardita Muja[3], Adishah Çerma[1], Ina Zotaj[3] & Agron Ylli[1,4]
[1]UHC Mother Teresa Tirana, Endocrinology, Tirana, Albania; [2]Salus Hospital, Endocrinology, Tirana, Albania; [2]University of Medicine Tirane, Endocrinology, Tirana, Albania; [3]Endocrinology, Tirana, Albania; [4]Tirana Medical University, Tirana, Albania

Introduction

Papillary Thyroid Carcinoma is the most frequent malignant tumour of the thyroid gland. It usually progresses slowly and is rarely metastatic. On the other side, fibromatosis are usually benign tumours with infrequent malignant appearances, which affect musculoaponeurotic structures. The aetiology remains unclear, although various possible factors are linked to it such as trauma, genetic predisposition, β-catenin heterozygous mutation, hormone disbalance etc. Even though it benign status, fibramatosis are locally aggressive and can be associated with carcinomas of different kind such as the thyroid. Very few cases are reported in the literature of papillary thyroid cancer with mesenchymal tumours. We present the case of a patient with papillary thyroid cancer in concomitant with a desmoid-type fibromatosis abdominal tumour.

Case Report

The patient, a female of 31 years, came to the Department of Endocrinology after receiving the result of a biopsy. She had undergone total thyroidectomy on February 2020 for a diagnosis of multinodular goitre. The biopsy confirmed papillary thyroid cancer (classical variant) of 2 cm diameter, with capsular and vascular invasion. She was started hormone replacement therapy shortly after the surgery. Upon the arrival of the biopsy, she was planned for radioactive iodine therapy. She received 100 mCi. The patient had a prior surgery, on July 2019. She had an abdominal mass removed. The biopsy of it, supported by immunohistochemistry analysis later, resulted in abdominal desmoids-type fibromatosis. She had no family known history for neither of the diseases. The patient did not receive, apart from surgery, any other therapy for the abdominal tumour. At the time no genetics tests were performed. She is currently under examinations and regular follow-ups with no signs of recurrence.

Conclusions

The presence of both mesenchymal and papillary thyroid malignancy is a rare but present finding. Usually the thyroid is the first to be diagnosed, followed by the mesenchymal tumour, but it depends on the location and aggressive nature of the tumours. Considering the multiple possible factors in fibromatosis, it is important to further explore them in order to choose the better way of treatment and follow up.

Introduction

Atypical parathyroid tumour (APT) is a rare cause of primary hyperparathyroidism (PHPT) with a frequency of 1.2-1.3%. APT is a lesion with suspicious clinical and histological features of malignancy which does not completely respect the World Health Organization (WHO) criteria for diagnosis of Parathyroid Carcinoma (PC). There is a well-known association with PHT and medullary thyroid carcinoma for multiple endocrine neoplasia. However, concurrence of thyroid papillary carcinoma and PHPT is rarely defined in the literature. Here we report a case of multifocal thyroid papillary carcinoma accompanying severe hypercalcemia caused by APT.

Case Report

43-year-old female patient was admitted to hospital with the complaint of weakness. Laboratory analyses revealed high serum calcium (14.45 mg/dl) and parathyroid hormone (PTH) (1651 ng/dl) with suppressed phosphorus (2.45 mg/dl). 24 hour urinary calcium excretion was 121 mg/day. The diagnosis was symptomatic PHPT. Bone densitometry showed osteopenia and ultrasonography(USG) was negative for renal calculus. Neck USG revealed a well-circumscribed, 43x27x33 mm, hypoechoic nodular lesion with cystic component close to the left lobe inferior pole, with intense vascularization in the inner structure. Technetium-99m-sestamibi parathyroid imaging showed parathyroid adenoma in the same localization. Also, a 9x8.5x6 mm hypoechoic solid nodule at the right thyroid lobe, containing punctate echogenic foci(ACR-TIRADS-V) and multiple nodules with the size of 5x5 mm (ACR-TIRADS II) and 7x6 mm (ACR-TIRADS IV) were shown by neck USG. Fine needle aspiration biopsy(FNAB) was resulted as Bethesda I for the right thyroid nodule twice. Serum calcitonin level was negative. Parathyroidectomy for symptomatic PHPT and thyroidectomy with frozen examination were planned as surgical procedure. Left lower parathyroid gland was excised. Since frozen examination was suspicious for papillary carcinoma, the patient underwent total thyroidectomy and central neck lymph node dissection. Pathology revealed APT, parathyroid cyst and multifocal classic type papillary microcarcinoma with lymph node metastasis. Serum

calcium, phosphorus and PTH levels returned to normal levels as was 8.6 mg/dl 3.94 mg/dl and 46ng/dl, respectively. The patient was discharged at first day postoperatively without any postoperative complication.
Discussion
Although rarely seen, APT may be the cause of severe hypercalcemia in patients with PHPT especially in those with high PTH and large tumour size. Patients with APT should be strictly followed up as outcome is not known exactly. Thyroid nodules in those undergoing parathyroid surgery should also be evaluated carefully for medullary and non-medullary thyroid carcinoma.

Dwarfism of the Laron type with normal high affinity serum growth hormone-binding protein

Abhishek Chandra[1] & Vijay Kumar Singh[2]
[1]Kurji Holy Family Hospital, Patna, India; [2]sri Krishna Medical College, Muzaffarpur, India

Introduction
An autosomal recessive illness called the syndrome of familial GH-resistant short stature is characterized by a phenotype that is similar to that of isolated GH deficiency, but with normal or excessive GH production and decreased IGF-I synthesis. When these individuals are treated with GH, neither growth nor a rise in blood somatomedin/IGF-I activity—the mediator of GH's growth-promoting effects—are stimulated. This suggests that the cause of the growth failure is end organ resistance.
Objective
A high-affinity GH-binding protein found in normal serum appears to be identical to the extracellular domain of the GH receptor. In the serum of people with Laron-type dwarfism, it is typically lacking. The goal of this study is to determine the status of a family with Laron-type dwarfism's serum GH binding protein.
Method
An open case study was conducted in a family in which four sisters, who ranged in age from four to sixteen, had the Laron-type dwarfism phenotype. Five unrelated girls with dwarfism of the Laron type and those without endocrine abnormalities served as the control samples. By showing elevated blood OH levels and low serum IGF-I levels on an immunoassay, along with a drop in serum IGF-I levels followed by an increase following GH treatment, Laron-type dwarfism was conclusively proven. Gel chromatography on Sephacryi S-100HR gel electrophoresis following covalent cross-linking to lZ5i-GH, Scatchard analysis of ligand binding, and polyacrylamide gel electrophoresis were used to characterise serum GHbinding proteins.
Results
The GH-binding protein activity in the serum of all family members was similar in affinity. In the same way that normal persons do, calculate the amounts and apparent affinity for OH. The unrelated youngster who had Laron type dwarfism and prior findings of blood OH-binding protein levels in this disorder contrasted this with the very low serum GH binding protein activity in that child.
Conclusions
Since normal cell responsiveness to GH is not required for the production of normal levels of serum GH-BP, it follows that serum GH-BP levels shouldn't be regarded as a quantitative indicator of GH receptor activity or GH bioactivity. When blood GH-binding protein levels are normal, the affected patients may have a unique metabolic abnormality that causes OH resistance and diminished IGF-l synthesis.

Role of Ayurveda based novel 'Thyroid detoxification program' in the management of hypothyroid patients

Dr Vikrant Patil[1], Dr. Sushama Patil[2], Bhavana Menkudale[2] & Ninad Naik[2]
[1]TATC -The Ayurvedic Thyroid Clinic, R& D, Pune, India; [2]TATC -The Ayurvedic Thyroid Clinic, Pune, India

Background
The aim of study was to determine the effectiveness of Thyroid detoxification program therapy in patients of hypothyroidism, attending TATC clinic in Maharashtra. According to the clinical survey from various studies on thyroid disease, it has been estimated that about 32% of people suffer from thyroid diseases in India out of which 10.7 % of people have hypothyroidism. According to health experts, even though hypothyroidism is easy to detect and inexpensive to treat, many patients remain undetected and untreated, thereby impairing their work performance and economic productivity. Common symptoms of hypothyroidism, fatigue, weight gain, constipation, dry skin, hoarseness and anemia (usually normochromic and normocytic but occasionally macrocytic). Levothyroxine, synthetic T4 hormone has always been considered as the mainstay of treatment in hypothyroidism. However even after normalization of TSH and T4 levels after LT4 treatment, many patients have persistent complaints. Thus there is an emerging need of an alternative therapy aiming at managing thyroid imbalance along with improvement in clinical symptoms.
Methods
This was a retrospective study conducted from June 21 to April 22, wherein we identified the data of 32 female patients suffering from hypothyroidism who had attended the outpatient departments of TATC clinics across Maharashtra. The data of patients, who had been administered with min of 2 detox procedures and oral Ayurvedic medication over a span of 16 weeks, considered for the study.
Results
Medical records of 32 patients were analyzed. At the end of the therapy, there was reduction in symptoms of hypothyroidism like palpitations, mood swings, fatigue, dry skin, joint pain, muscle crampsstiffness, indigestion, depression, anxiety. The alleviation of symptoms started in average one month from the commencement of treatment and patients were asymptomatic at the end of 16 weeks. There was reduction in standard of care thyroxine hormone for 100% subjects in four months. Average baseline levels of TSH in patients was found to be 9.49 uIU/ml. After two months of treatment, it was found that the TSH levels reduced significantly to 5.77 uIU/ml. The average duration required by the patients to reduce the dose was four months. Slight increase in TSH levels observed in further visits but it was not significant. Thus it indicates that intended therapy not only has a potential effect in maintaining normal thyroid hormone levels but it also treats root cause of thyroid imbalance which is evident by the reduced dose of medication and improved quality of life of patients.

Interplay between thyroid, amiodarone and heart - case presentation

Mirna Hrabar & Ana Matijaca
University Hospital Dubrava, Department of Endocrinology, Diabetes and Metabolic Diseases, Zagreb, Croatia

Background
Amiodarone is a commonly used antiarrhythmic drug, but because of its abundance with iodine and a direct toxic effect on the thyroid, it can have side effects like hypo- and hyperthyroidism. There are two types of amiodarone-induced thyrotoxicosis (AIT). We present a case which demonstrates the importance of timely diagnosis and appropriate treatment of amiodarone-induced thyrotoxicosis in patients with serious cardiac comorbidities.
Case presentation
A 74-year-old male with a history of a thyroid checkup in 2019 after accidental finding on CT, when neck ultrasound (US) and scintigraphy were performed (ultrasound showed a multinodular goiter; scintigraphy showed several warm nodules), hypertension, paroxysmal atrial fibrillation, implanted mechanical aortic valve because of aortic regurgitation, left ventricular hypertrophy, and reduced ejection fraction, was referred to our clinic because of hyperthyroidism. Four months prior to this visit amiodarone was discontinued by his cardiologist after five years of use. At the time of amiodarone discontinuation the patient had a thyroid stimulating hormone (TSH) level below the lower reference limit and no hypermetabolic symptoms. No thyrostatic treatment was initiated nor was he referred to an endocrinologist. The patient developed symptoms of hyperthyroidism two months later; TSH was suppressed. His primary care physician started him on 10 mg of thiamazole daily. After two more months, the patient's state worsened. He was referred to an otorhinolaryngologist who advised the patient to visit our clinic. US was repeated, confirming the presence of multinodular goiter, no signs of gland destruction were present, and vascularisation was neither increased nor absent. At that point urgent restoration of stable clinical state was necessary because the patient had cardiac decompensation and overt hyperthyroidism with suppressed TSH and high free thyroxine (FT4) level, as well as prolonged prothrombin time due to coumarin use. After cardiac recompensation, normalization of the coagulogram, and reduction of the FT4 level under full thiamazole dose (which stayed slightly above the upper reference limit), thyroidectomy was performed. Significant clinical and laboratory improvement followed.
Conclusions
AIT has been associated with increased morbidity and mortality, especially in older patients with impaired left ventricular function. The importance of regular monitoring of thyroid status in amiodarone users and rapid recovery and stable maintenance of euthyroidism when necessary, should be emphasized to both endocrinologists and non-endocrinologists.

Endocrine adverse events associated with immune checkpoint inhibitors - A case series

Andreea Anne-Marie Stefan[1], Burcea Iulia-Florentina[1,2], Dumitriu Roxana Ioana[1,2], Dobre Ramona[1,2], Baculescu Nicoleta[1,2], Baciu Ionela[1,2], ?erban Radian[1,2], Căpă?înă Cristina[1,2], Raluca Trifanescu[1,2] & Catalina Poiana[1,2]
[1]CI Parhon National Institute of Endocrinology, Pituitary and Neuroendocrine Disorders, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background
Immune checkpoint inhibitors (ICIs) are a novel group of drugs, used for treatment of various types of malignancies. The receptors cytotoxic T-lymphocyte antigen-4 (CTLA-4) and programmed cell death protein-1 (PD-1) or its ligand (PDL-1) are targeted by those inhibitors. They are associated with immune-related adverse events (irAEs). Endocrinopathies are the most frequent irAEs with a prevalence of approximately 10%.
Case study
We retrospectively described a series of patients with endocrine complications caused by ICIs. Out of 24 patients treated with single or combination therapies, 18 patients developed endocrinopathies. The median age at diagnosis was 59 years and onset of endocrine dysfunction occurred within a median of 12 weeks of first ICIs exposure. Our case reports uncover a broad spectrum of ICI-induced endocrinopathies: 13 patients with thyroid dysfunction, 6 patients with hypopituitarism and one with primary adrenal deficiency. Polyglandular endocrine complications were described in two patients. Clinical presentation varied from asymptomatic patients to life-threatening symptoms. Thyroid disease ranged from subacute thyroiditis to subclinical hypothyroidism or hyperthyroidism, overt thyrotoxicosis and even myxedema. The most frequent ICIs used were PD-1 and PDL-1 inhibitors. Three patients had previous tyrosine-kinase inhibitor (Sunitib)-induced hypothyroidism and four patients had already autoimmune thyroiditis. We encountered six patients with hypophysitis, from which four presented isolated deficiencies (2 with secondary adrenal deficiency and 2 with secondary hypogonadism) and two had multiple deficiencies (one with panhypopituitarism and one with secondary hypothyroidism and adrenal deficiency). Five patients were treated with anti PD-1 or PDL-1 monoclonal antibodies (mAb) and only one with anti CTLA-4 mAb (Ipilimumab).
Conclusions
The most frequent ICIs induced endocrinopathy is thyroid dysfunction, followed by hypophysitis. Primary adrenal insufficiency, although a rare complication, was also reported. In most of our cases, they were irreversible and required hormone replacement. Anti-PD-1 and anti-PDL-1 mAb were frequently associated with thyroid disease. Several studies indicate that CTLA-4 inhibitor is most related to hypophysitis (1), but in our series, we had a single patient in treatment with Ipilimumab, being the one with panhypopituitarism. Therefore, physicians should be aware of ICIs induced-endocrine irAEs in order to properly address, diagnose and treat them at onset and follow-up.

Two-year case series of a thyroid consultation at a hospital unit

Maria Helena F. Silva[1], Rita Serejo Portugal[1], André Matos Gonçalves[1], Volodymyr Nagirnyak[1], Baltazar Gabriel Oliveira[1], Carlos Marques[2], Joana Cabeleira[1], Ana Rita Sanches[1], Sónia Cunha Martins[1] & Margarida Sousa Carvalho[1]
[1]Centro Hospitalar do Médio Tejo - Unidade de Torres Novas, Medicina Interna, Torres Novas, Portugal; [2]IPO de Lisboa, Endocrinologia, Lisboa, Portugal

This paper aims to describe the followed population in the consultation, through a retrospective study in a hospital unit. This retrospective study was carried out during February 2020 to February 2022, and analyses the clinical processes of the patients that were followed in this consultation, and later analysing the data using Microsoft Excel® Over these two years, 395 patients were observed. These patients age average 61 years old, ranging from 17 to 93 years of age. Most patients (83.80%) are female. The most prevalent pathology was thyroid nodule (20.60%), followed by multinodular goiter (20.20%), multinodular thyroid (19.20%), hypothyroidism (14.00%), hyperthyroidism (9.80%), autoimmune thyroiditis (6.40%). The least frequently observed pathologies were thyroid neoplasia (0.40%), myxedema (0.60%), goiter (1.80%), Hashimoto's thyroiditis (2.00%), substernal goiter (2.40%) and Graves' disease (2.60%). 51.14% of the patients underwent aspiration puncture of the nodule. In the majority (87.62%) this nodule was Bethesda category I/II. During the analyzed period, 27.34% of the patients were discharged, 2.03% were referred to the endocrinology consultation at the central reference hospital and 2.03% to the surgery consultation. Thyroid pathology is a multifactorial disease, that mainly affects women and elderly people. There are many diseases that affect the thyroid. These diseases afflictions range from functional deficits to autoimmune pathologies. The most prevalent is the presence of nodules, in patients with or without goiter. This particular result goes against what was observed in our previous statistical work. Despite this, and since biopsies were carried out in most patients, it is important to note that in this specific sample, only two patients were identified with neoplasia.

Non-secreting pheochromocytoma or adrenal metastasis of medullary thyroid cancer? When the differential diagnosis is difficult

Amira Bouchenna & Ould Kablia Samia
Hopital Central de l'Armée Alger, Endocrinology, Alger, Algeria

Introduction
Medullary thyroid cancer (MTC) accounts for 5-10% of thyroid cancers.25% of cases may be hereditary related to multiple endocrine neoplasia type 2 A (MEN2A) and associated with pheochromocytoma. Metastases from CMT are preferentially lymph node chains. However, other localizations are possible such as adrenal metastases which remain exceptional.
Observation
We report the case of a 35-year-old patient with CMT for which he underwent thyroidectomy and lymph node dissection classified as PT2N0Mx. A search for an associated pheochromocytoma and primary hyperparathyroidism in the context of MEN2A, metoxylate assay and a phosphocalcic assessment were normal. A thoracic-abdominal-pelvic CT scan showed a right adrenal nodule measuring 18x25 mm with a spontaneous density of 31 HU, an absolute washout of 25% and a relative washout of 16% in favour of malignancy. No other secondary locations were found. In order to assess the secretory or non-secretory nature of the nodule, the biological tests for hypersecretion of glucocorticoids, catecholamines and mineralocorticoids were normal. A MIBG scan was performed, showing a right adrenal neuroectodermal process. The patient underwent surgery and the pathological study came back in favour of a non-secreting pheochromocytoma.
Discussion
Two diagnostic hypotheses presented themselves:
- Non-functional pheochromocytoma which can be observed in 14-55% of cases. Although in the case of MEN2A, the pheochromocytoma is most often bilateral.
- The second is a metastasis of medullary thyroid carcinoma, which remains exceptional.

Fear of recurrence of differentiated thyroid cancer in patients in remission

Abdel Mouhaymen MissaouI[1], Fatma Hamza[2], Siddiqa Soomauroo[1], Khawla Ben Ahmed[2], Wafa Belabed[1] & Mohamed Abid[1]
[1]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Habib Bourguiba University Hospital, Department of Nuclear Medicine, Sfax, Tunisia

Objective
to evaluate the fear of recurrence of differentiated thyroid cancer (DTC) in patients in complete remission.
Patients and Methods
Cross-sectional study of 41 patients in complete remission after treatment of DTC, followed up at the Nuclear Medicine Centre of Sfax, Tunisia. The evaluation was based on the administration of a shortened version of the Fear of Cancer Recurrence Inventory (FCRI-SF) to all patients (maximum score 36 points)

Results
The mean age of the patients interviewed was 45.4 ± 13.4 years with a predominance of females (92.7%). The majority had papillary carcinoma (87.8%), more rarely vesicular carcinoma (12.2%). Initial metastases were reported in 9.8% of cases. Thus, 21.9% of carcinomas were classified as high risk. The mean cumulative ablative dose of iodine-131 was 265.9 ± 197 mCi. The mean disease-free survival was 5.1 ± 3.9 years. The FCRI score was 10.9 ± 8 points with extremes ranging from 0 to 26 points. A significant fear of recurrence was noted in 10.8% of the patients surveyed. Concerns about DTC relapse were ' unclear ' for 18.9%. The majority of patients were no longer worried about the relapse (70.3%). Factors associated with a significant fear of recurrence were vesicular type (OR = 0.16; $P = 0.028$) and histological evidence of angioinvasion (OR = 0.12; $P = 0.022$).
Discussion
The fear of recurrence in DTC is significantly lower than that observed in other cancers (breast = 60%, colorectal = 38%). A collaborative therapeutic approach including the patient and his relatives helps to reassure patients about the good prognosis of DTC.

P258

Widely invasive follicular thyroid carcinoma. A case report

Cristina Contreras Pascual[1], Paloma González Lázaro[2], Maria Zhao Montero Benítez[2], Pedro Jimenez Torrecilla[2] & Karol Almendra Alvarado Rosas[3]
[1]Hospital Santa Bárbara, Endocrinology, Soria, Spain; [2]Hospital La Mancha Centro, Endocrinology, Alcázar de San Juan, Spain; [1]Hospital Santa Bárbara, Endocrinology, Soria, Spain

Follicular thyroid carcinoma (FTC) is the second most common type of thyroid cancer, making up about 10 to up to 15% of all thyroid cancers. It is called a 'well differentiated' thyroid carcinoma, like papillary thyroid cancer, but it is typically more aggressive than this. We report the case of a 75-year-old man with personal history of Type 1 Diabetes since he was 25 years old, with severe nonproliferative diabetic retinopathy (blindness) and multinodular goiter. In 2020, a hypoechoic thyroid nodule of 45 mm with intranodular hypervascularity (TIRADS 4) was detected, but the patient refused to perform a fine-needle aspiration biopsy because of COVID-19 pandemic. He didn't come to Endocrinology appointments until 2022, when we performed a new thyroid ultrasound. The TIRADS-4 thyroid nodule had grown up 7 mm and another nodules had appeared. In addition, the patient reported compressive symptoms, so we offered him a total thyroidectomy, but he refused. Several months later, the patient reported 10 kg weight loss and dysphagia, so he accepted thyroidectomy and we ordered a computed tomography (TC) and a general surgeon consult. TC shown a severe tracheal compression and the patient developed in a few days dyspnea and hoarseness. He was admitted to the hospital and a bronchoscopy was performed, revealing tracheal compression by extraluminal mass on the left lobe of the thyroid. Tracheal lumen was narrowed by 40%, so he was admitted to the intensive care unit (ICU) and, some days after that, a total thyroidectomy was performed. The microscopic examination of the surgical piece established the diagnosis of a widely invasive FTC (angioinvasion, extrathyroidal extension and lymph node metastasis) T4aN1Mx (stage IV AJCC 8th edition). During hospitalization the patient received nasogastric tube feeding. It was difficult for him to express his desires and to communicate with others because of his blindness and the tracheostomy, but due to the speech therapist work he returned to talk some weeks later. Two months after surgery, serum thyroglobulin level was 6,5 ng/ml and antithyroglobulin antibodies were negative. At this time our patient is waiting to radioactive iodine therapy. Most FTCs are slow growing and are associated with a very favorable prognosis. Despite of that, we must pay attention to a very rapid growth of a thyroid nodule because it should raise the suspicion of thyroid carcinoma, especially in patients affected by multiple chronic diseases.

Male with Graves Disease and Primary Thyroid Cancer in the Thyroglossal Cyst

Sergio Logwin, Daisy Ruiz Diaz, Violeta Jimenez, Elvio Bueno & Fabiola Romero
Hospital de Clínicas, Endocrinology, Asuncion, Paraguay

Introduction
The malignancy of the thyroglossal duct cyst is infrequent, 0.7 to 1% of the thyroglossal duct cysts, predominantly in women and euthyroid subjects, some associated with Hashimoto's Thyroiditis.
Clinical case
Male, 42 years old, with a 5-year history of a large anterior cervical tumor, diagnosed with Graves' disease and thyroid orbitopathy. Cervical ultrasound reports right submandibular region mixed tumor mass 36 x30. mm with nonspecific lateral cervical lymph nodes and multiple mixed oval images, well-defined borders, less than 13 mm in diameter. The ophthalmological evaluation reports moderate quiescent orbitopathy. He received treatment with high doses of methimazole and lithium carbonate for severe hyperthyroidism with difficult stabilization. Sistrunk surgery and total thyroidectomy was performed. Histology reports papillary thyroid carcinoma on a thyroglossal duct cyst, 1, 5 cm, without evidence of thyroid neoplasia.
Discussion
In the literature reviewed, no association was reported with primary papillary thyroid carcinoma in a thyroglossal cyst and Graves' disease. Due to the low frequency of papillary thyroid carcinoma in the thyroglossal duct, a single algorithm has not been reached for its treatment and follow-up, it must be approached by a multidisciplinary team based on the current guidelines for differentiated thyroid cancer, which coincide that Sitrunk surgery and total thyroidectomy is the most appropriate initial treatment.

Mouse model of Graves' ophthalmopathy induced by the immunization with TSHR A and IGF-1Rα subunit gene

Wei Zheng[1], Ruixin Wu[1,2], Ning Li[1], Xuan Wang[3], Shen Wang[1] & Jian Tan[1]
[1]Tianjin Medical University General Hospital, Nuclear Medicine, Tianjin, China; [2]Shanghai Tenth People's Hospital, Shanghai, China; [1]Tianjin Medical University General Hospital, Nuclear Medicine, Tianjin, China

Background
The study aimed to establish a mouse model of Graves' disease (GD) with Graves' ophthalmopathy (GO; GD + GO) that can represent the clinical disease characteristics.
Methods
A eukaryotic expression plasmid of insulin-like growth factor 1 receptor (IGF-1R) α subunit (pcDNA3.1/IGF-1Rα) and a thyrotropin receptor (TSHR) A subunit plasmid (pcDNA3.1/TSHR-289) were injected in female BALB/c mice to induce a GD + GO model. Grouping was performed according to the frequency of injection (2- to 4-week intervals) and type of injected plasmids: T: pcDNA3.1/TSHR-289(+), I:pcDNA3.1/IGF-1Rα(+), or co-injection T + I: pcDNA3.1/TSHR-289(+) and pcDNA3.1/IGF-1Rα(+). Serum TSH, T4, TSAb, body weight, and blood glucose levels were evaluated. Thyroid $^{99m}TcO_4^-$ imaging and retrobulbar magnetic resonance imaging (MRI) were performed, and bilateral eye muscle volumes were measured. Immunohistochemistry and hematoxylin-eosin (HE) staining of relevant tissues were performed.
Results
A total of 60% of mice (3/5, one mouse died) in the pcDNA3.1/TSHR-289(+) group developed GD + GO. In the pcDNA3.1/TSHR-289(+) and pcDNA3.1/IGF-1Rα (+) groups, 83.3% of mice (5/6) developed GD + GO. Mice in the pcDNA3.1/IGF-1Rα (+) group did not develop GD. Compared with the control group, serum T4, TSAb, and TSBAb of the mice in the GD + GO model groups were increased to varying degrees ($P < 0.05$), and serum TSH and body weight were significantly lower compared to the control group ($P < 0.05$). The blood glucose of the mice in each group had no significant difference. The thyroid uptake capacity of $^{99m}TcO_4^-$ and the volume of eye muscle of mice in the GD + GO group were significantly higher compared to the control group ($P < 0.05$). The thyroid, retrobulbar muscles, heart, and liver of these mice showed varying inflammatory infiltration, interstitial muscle edema, and hepatic vein congestion. The severity of GD + GO in the co-injection group was not related to injection frequency; however, GD and ocular signs in co-injection mice were more severe compared to the pcDNA3.1/TSHR-289(+) group.
Conclusions
We successfully induced a GD + GO mouse model by a repeated co-injection of pcDNA3.1/IGF-1Rα and pcDNA3.1/TSHR-289 plasmids. Injection of pcDNA3.1/IGF-1Rα alone failed to induce GD. Co-injection of two plasmids induced more severe GD + GO than pcDNA3.1/TSHR-289(+) alone.

Clinical significance of IgG4 serum concentration in Graves Disease – a pilot study

Michał Olejarz, Ewelina Szczepanek-Parulska, Aleksandra Hernik, Nadia Sawicka-Gutaj & Marek Ruchala
Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Medicine, Poznan, Poland

Background
Immuglobulin 4 (IgG4) is the least common subtype of Immoglobulin G. However due to its unique characteristic it has been the focal point of many research projects, which eventualy led to the discovery of the sytemic fibro-inflammatory disorder called IgG4-Related Disease. The potential role of IgG4 in the pathogenesis of autoimmune thyroid diseases has been also suggested. However, the amount of evidence is still limited, especially in Graves Disease (GD).
Objective
In this study we aimed to assess the prevalence of patients with high IgG4 GD and the corelations between IgG4 and other clinical, ultrasounographic and biochemical parameters.
Methods
60 patients with GD were recruited. The study group was divided into 3 subgroups: Group 1 – hyperthyroid patients with newly diagnosed GD ($n=29$); Group 2 – euthyroid patients with GD after antythyroid treatment ($n=19$); Group 3 – patients with moderate to sever Graves Orbitopathy (GO) ($n=12$). Only patients who had not been previously treated with thyroidectomy or radioiodine were included in the study. All patients underwent a detailed laboratory assessment and ultrasonographic evaluation. IgG4 serum concentration was evaluated with the ELISA method. High IgG4 GD was defined as IgG4 serum >135 mg/dl.
Results
The prevalence of high IgG4 GD was low among GD patients without orbitopathy (4%) and substantially higher in patients with GO (33%). IgG4 serum concentration was higher in GO group than in the hyperthyroid and euthyroid GD groups (87.9 [61.55; 143.78] vs 31.4 [23.7; 41.7] mg/dl, $P<0.001$ and vs 30.1 [26.95; 79.6] mg/dl, $P=0.015$, respectively). There was no difference in IgG4 levels between the hyperthyroid and euthyroid GD groups, despite massive differences in anti-TSH receptor antibodies (TRAb) (29 [12.92; 6.38] vs 1.93 [0.78; 3.46] $P<0.001$), anti-thyroperoxidase antibodies (TPOAb) (274 [62; 522.75] vs 37 [21.5; 122.5] $P=0.005$). There were no statistically significant correlations between IgG4 levels and thyroid stimulating hormone (TSH), free thyroid hormones, TRAb, TPOAb and anti-thyroglobulin antibodies (TgAb) levels nor with thyroid volume, thyroid echogenicity, intrathyroidal blood flow. Patients with multiple thyroid nodules ($>=3$) had significantly lower IgG4 levels than those with <3 nodules (41.35 [29.5; 91.93 vs 25.7 [23.8; 26.3] mg/dl, $P=0.026$).
Conclusions
Our results suggest that IgG4 serum concentration is associated with the occurence of Graves Orbitopathy. The IgG4 serum concentration seems to be unrelated to TRAb, TPOAb or TgAb levels. Further studies, especially with a longitudinal design, are needed to determine the influence of IgG4 levels on the treatment outcomes and prognosis of GD patients.

A Prospective Comparitive Study on Cardiovascular Dysfunction and its Reversal After Treatment in Patients with Graves and Toxic Multi Nodular Goitre

Muthukumar Sankaran[1], Ravikumar Krishnan[2], Mohammad Salmon[3], Thalavaai Sundarram[4], Dhalapathy Sadacharan[5] & Syed Ibrahim,[1]
[1]Madurai Medical College, Endocrine Surgery, Madurai, India; [2]Royal Care, Endocrine Surgery, Coimbatore, India; [3]Rasipuram Gh, Gen Surgery, Rasipuram, India; [4]Omandurar Med College, Endocrine Surgery, Chennai, India; [5]Madras Med College, Endocrine Surgery, Chennai, India

Cardiovascular dysfunction (CVD) is a well recognized complication in patients with hyperthyroidism and is the major cause of mortality. To date there has been no studies which had clearly evaluated the CVD and its recovery pattern between patients with Graves and Toxic multi nodular goitre(TMNG). Hence we intended to compare treatment outcomes in patients with Graves and TMNG. Patients with hyperthyroidism were grouped into, **Group 1** [$n=133$, age <60 years, proven Graves, **Group 2**[$n=64$, age <60 years, proven TMNG] were evaluated with 2D Echocardiography, at the time of diagnosis(Point A), after achieving euthyroidism(Point B) with anti-thyroid drugs and 6 months after achieving euthyroidism (Point C). 40 patients(**Group 3**), age <60 years, with nontoxic benign thyroid nodules served as controls. All groups were age and sex matched. At point A, CVD was evident in 88/133(66.2%) in Group 1 and 39/64(60.9%) in Group 2. At Point B improvement in CVD occurred in 55/88(62.5%) in Group 1and 22/39(56.4%) in Group 2. At Point C dramatic improvement in CVD occurred in 82/88(93.1%) in Group 1, whereas only 28/39(71.7%) improved in Group 2. Though incidence of CVD was more in group I the improvements in dysfunction parameters were more pronounced in group I after treatment. At Point C there was a significant decrease in all the cardiac dysfunction parameters in Group 1 whereas the same was not observed in Group 2 patients (Table1). Cardiac dysfunction parameters improved significantly in patients with Graves after treatment than in patients with Toxic MNG and hence those patients with Toxic MNGs should be treated more cautiously owing to the increased morbidity due to cardiovascular dysfunction.

TABLE 1 IVS-Interventricular septum LV-left ventricle

CytoFoam core device: an innovative support for immunocytochemical assessment in cytologically indeterminate thyroid nodules

Roberto Novizio[1], Silvia Taccogna[2], rinaldo guglielmi[1], Agnese Persichetti[3] & Enrico Papini[1]
[1]Regina Apostolorum Hospital, Endocrinology and Metabolism, Italy; [2]Regina Apostolorum Hospital, Pathology, Italy; [3]IRCCS-Regina Elena National Cancer Institute, Service of Pharmacovigilance, Italy

Background
Fine needle aspiration (FNA) is the procedure of choice in the evaluation of thyroid nodules. Nodules with indeterminate cytological categories, Bethesda III and IV, pose challenges in clinical practice and are frequently submitted to diagnostic surgery. Immunohistochemistry provides complementary information to cytological findings but its reliable use on FNA samples is hampered by technical problems. CytoFoam Core (CFCS), an absorbent foam device inserted into the needle hub, collects the cytological sample aspirated during FNA and may overcome these difficulties because a formalin-fixed and paraffin-embedded specimen, well suitable for ancillary techniques, is provided.
Aim of the study
To assess diagnostic efficacy of CFCS, compared to traditional cytology, in re-evaluating thyroid nodules classified as Bethesda III. Post-surgical histology was used as reference standard.
Method
Retrospective study on 89 patients with a first indeterminate cytological report referred to Department of Endocrinology of Regina Apostolorum Hospital (Albano L. Rome, Italy) for a second FNA. FNA was performed, after at least one month, under ultrasound guidance with a 23G needle according to the established procedure. Both traditional cytological (TC) smears and a single-pass CFCS specimen were obtained for each patient. On CFCS samples immunocytochemical staining for Galectin-3, HBME-1, and CK-19 were performed. Fifty-one patients underwent surgery and their histological diagnoses were blindly compared to the TC and CFCS reports. Four parameters were evaluated: inadequacy rate, rate of persistent indeterminate (Bethesda III and IV) reports, rate of malignancy in persistently indeterminate nodules, and rate of cancer in lesions cytologically classified as malignant.
Results
Non-diagnostic samples were 6 (11.8%) in TC vs 3 (5.9%) in CFCS ($P=0.4$). Persistent indeterminate samples were 31 (60.8%) in TC vs 19 (37.2%) in CFCS ($P=0.01$). Rate of malignancy in persistently indeterminate nodules was 8/19 (42.1%) in CFCS vs 9/31 (29%) in TC group ($P=0.3$). Nine/51 (17.6%) samples were reclassified as benign by TC vs 21/51 (41.2%) samples by CFCS ($P<0.01$). All benign nodules were confirmed as benign at post-surgical evaluation. Five/51 (9.8%) samples were classified as suspicious for malignancy/malignant in TC group against 8/51 (15.7%) samples in CFCS ($P=0.5$). Post-surgical evaluation confirmed malignancy in all these cases.
Conclusion
CFCS significantly improved diagnostic accuracy of TC in repeat FNA assessment of cytologically indeterminate nodules. CFCS increased the conclusive diagnosis rate and decreased the number of cytologically indeterminate cases.

Sonographic and clinicopathological differences between non-invasive follicular thyroid neoplasm with papillary-like nuclear features (NIFTP) and minimally invasive encapsulated follicular variant of papillary thyroid carcinoma (EFVPTC)

Banu Ertürk[1], Yesim Gaye Güler[2] & Alper Gürlek[1]
[1]Hacettepe University, Endocrinology and Metabolism, Ankara, Turkey; [2]Hacettepe University, Pathology, Ankara, Turkey

Background
Noninvasive follicular thyroid neoplasm with papillary-like nuclear features (NIFTP) is a newly described indolent thyroid tumor with well-defined histopathological diagnostic criteria. Even though the histopathologic features and diagnostic criteria for NIFTP are well-established, preoperative diagnosis using sonographic or fine needle aspiration findings has yet to be confirmed. The aim of this study is to compare the clinical, sonographic, and cytological characteristics of NIFTP with minimally invasive encapsulated follicular variant of papillary thyroid carcinoma (EFVPTC).
Methods
We examined the records of 73 patients who underwent thyroid surgery at Hacettepe University Hospital between 2016 and 2022 with a postoperative diagnosis of NIFTP or EFVPTC. A detailed analysis of patients' medical charts and pathology reports was used to analyze clinicopathological features retrospectively.
Results
The 73-case cohort consisted of 42 NIFTP and 31 IFVPTC cases (median age 54 years, 47 (64 %) women). NIFTP group was consisted of more female sex subjects ($P<0{,}001$). The ultrasound findings for NIFTP and minimally invasive EFVPTC typically demonstrated a circumscribed oval/round nodule with a hypoechoic rim. Presence of halo in nodules was significantly more prevalent in the EFVPTC group ($P<0.001$). 47.6% of the nodules in NIFTP were solid-cystic, 42% solid, and 9.5% cystic. These ratios were similar in EFVPTC (35.5%, 48.4%, and 16.1%, respectively). There were no differences in microcalcification in nodules ($P=0.06$). Metastatic lymph node(s) was found in 8 cases of EFVPTC but none in NIFTP ($P<0.001$). In NIFTP, the prevalence of nodules being TIRADS 2, 3, 4, and 5 was 21,4%, 23,8%, 45,2%, 7,1%, respectively. EFVPTC group had more TIRADS-5 nodules ($P<0{,}01$). The NIFTP and EFVPTC groups showed benign features, with a majority of the patients categorized as Bethesda category III (39,5 % and 25.8%, respectively) ($P<0.02$) or IV (28,5% and 30.2%, respectively). Lobectomy has been performed in only 9% (4/42) of NIFTP cases. Total thyroidectomy was the preferred surgical method in remaining NIFTP and all EFVPTC cases. CK19 staining of nodules in EFVPTC was more prevalent ($P<0.001$). TNM stages of the groups were similar, too. The rates of postoperative hypoparathyroidism were also comparable ($P=0.32$). During follow-up, no recurrence or metastasis was observed in any case.
Conclusions
These results demonstrate that NIFTP and EFVPTC are clinically and sonographically similar, despite being pathologically recognized by well-defined criteria. In our study, the presence of peripheral halo, irregular margins, and CK 19 staining in pathology were more common in EFVPTC, which may support the preoperative diagnosis.

Cytokine levels and the effect of the Covid-19 pandemic on the course of Graves' disease under antithyroid treatment

Göktuğ Sarıbeyliler[1], Yasemin Oyacı[2], Ayşe Merve Ok[1], Hayriye Şentürk Çiftçi[2], Sacide Pehlivan[2] & Sema Yarman[1]
[1]Istanbul University, Endocrinology and Metabolism, Istanbul, Turkey; [2]Istanbul University, Medical Biology, Istanbul, Turkey

Objective
Graves' disease (GD) occurs as a result of genetic and environmental factors that trigger autoimmunity. Some pro-inflammatory cytokines have already been linked to an increased susceptibility of developing GD. Recently, it has been reported that Covid-19 infection and SARS-CoV-2 vaccination trigger the emergence of new GD cases or disease recurrence as environmental factors due to the pandemic. However, there is no data in the literature reporting the effects of this pandemic in GD patients who are newly diagnosed and followed up under medical treatment. Here, we aimed to report the effect of the pandemic (vaccination/infection) on the prognosis while examining the cytokine level changes in patients with newly diagnosed GD and receiving treatment.
Material and method
Between December 2019 and June 2021, 41 newly diagnosed GD patients (30 Female/11 Male) were included in the study. The control group consisted of 38 age and gender matched healthy individuals. Cytokine (TNF-alpha, IFN-gamma, IL-10, IL-13, IL-17, IL-22, IL-23 and IP-10) levels were measured by ELISA method from serum samples at baseline and at 6th and 12th months of antithyroid drug (ATD) treatment.
Results
The mean age of the patients was 41.02 ± 11.6 years. Baseline serum TNF-alpha ($P=0.11$) and IP-10 ($P=0.003$) levels were higher in GD patients than in controls. As seen in the Table below, serum IFN-gamma, IL-13, IL-17, and IP-10 levels were significantly decreased compared to baseline under ATD treatment. In contrast, other cytokine levels did not differ statistically with treatment. Of the patients who had both clinical and hormonal control under ATD treatment, 90% ($n=37$) were vaccinated, and 41% ($n=17$) had Covid-19 infection. In both cases, there was no increase in either ATD doses or TSH receptor antibody levels.
Conclusions
The significant decrease in IP-10, IFN-gamma, IL-13 and IL-17 levels with antithyroid treatment showed that these cytokines may play a role in GD in our population. In addition, it was observed that neither Covid-19 infection nor vaccination adversely affected disease activity in GD patients who were newly diagnosed and whose disease was controlled by ATD treatment.

TABLE 1 Cytokines that change significantly with treatment in GD patients

Cytokines	Baseline	At 6th months of ATD treatment	At 12th months of ATD treatment	p
IFN-gamma (pg/ml)	8.82 (3.64-34.40)	8.57 (3.41-21,12)	7.57(4.56-33.46)	**0.004**
IL-13 (pg/ml)	26.13 (18.12-56.79)	22.68 (18.18-43.26)	25.15 (17.60-43.72)	**0.028**
IL-17 (pg/ml)	28.99±11.74	27.08±11.06	24.60±10.80	**0.001**
IP-10 (pg/ml)	61.27±12.13	50.81±12.33	45.40±17.67	**0.016**

Normative Values for the Hypoparathyroidism Patient Questionnaire (HPQ28) in the General German Population

Martina Blaschke[1,2], Deborah Wilde[1], Maxi Schulz[3], Christoph Herrmann-Lingen[4] & Heide Siggelkow[1,2]
[1]University Medical Center Goettingen, Clinic of Gastroenterology, Gastrointestinal Oncology and Endocrinology, Goettingen, Germany; [2]MVZ endokrinologikum Goettingen, Goettingen, Germany; [3]University Medical Center Goettingen, Institute for Medical Statistics, Goettingen, Germany; [4]University Medical Center Goettingen, Clinic for Psychosomatic Medicine and Psychotherapy, Goettingen, Germany

Introduction
Patients with hypoparathyroidism (hypoPT) suffer from a number of complaints and reduced quality of life (QoL) besides having serum values for disease-specific parameters in the target range. To be able to quantify symptoms in hypoPT patients we lately developed a disease-specific questionnaire, the Hypoparathyroidism patient questionnaire with 28 items (HPQ28). The aim of this study was to present normative values for the HPQ28.
Methods
A representative sample of the German general population ($n=2509$) was tested with the HPQ28. The HPQ28 consists of five scales and three single items with 28 items in total. The five scales indicate different areas of complaints: Pain and cramps (PaC) including 5 items, neurovegetative symptoms (NVS) including 5 items, loss of vitality (Vit) including 6 items, depression and anxiety (DaA) including 5 items, gastro-intestinal symptoms (GIS) including 2 items and two control items for depression. Three items were not attributable to any of the five scales.
Results
Mean age of the healthy population sample was 50 ±18 years. Men (49%) and women (51%) were equally distributed. To investigate influence of age and gender on symptoms and QoL participants were organized into seven age classes. All scales and single items, except for GiS, were affected by age in male and females ($P<0.001$). In addition, all scales and single items were affected by gender ($P<0.001$). Hence, in the general German population females report highly significant more complaints ($P<0.001$) on every scale and single item of the HPQ28 compared to men. Symptoms and complaints also increase in older subjects. Regression analyses proved a linear trend in the different scores. Percentile rank norms are given for all scores and items.
Conclusion
Analysis in the German population sample revealed gender and age dependency of scores and items of the HPQ28. The regression coefficients now allow the

calculation of expected mean scores for each age and gender distribution of any sample of patients.

Graves' Disease in A Patient with Thyroid Hormone Resistance

Esra Çopuroğlu[1], Gökhan Baykal[2], Bilge Dibeklioğlu[2], Narin Nasiroglu Imga[2], Ahmet Dirikoc[1], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Ankara Yildirim Beyazit University Faculty of Medicine Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey

Introduction
While Graves' disease is a common cause of thyrotoxicosis, tyroid hormone resistance (THR) is a rare cause of high thyroid hormones. Coexistence of Graves' disease and THR which can cause quite a lot of difficulties in diagnosis and treatment was reported very rarely in the literature. Here, we report a patient with THR and Graves' disease in whom remission was achieved with medical therapy.
Case
A 38-year-old woman applied to our clinic with sweating and palpitation. Familial history revealed THR in her sister. Her body temperature was 37.2°C, heart rate was 120 beats/minute, respiratory rate was 18 breaths/minute and blood pressure was 120/70 mmHg. In laboratory examinations, thyroid stimulating hormone (TSH) was 0.018 mU/l (0.55-4.78 mU/l), free T4 was 2.64 ng/dl (0.89-1.7 ng/dl), free T3 was 9.05 ng/l (2.3-4.2 ng/l), anti-thyroglobulin and anti-thyroid peroxidase were negative, TSH receptor antibody (TRAB) was positive. Thyroid ultrasonography revealed chronic thyroiditis and technetium 99m scintigraphy showed heterogeneous activity. When laboratory results were examined retrospectively, we saw that in previous 3 years, her TSH, free T4 and free T3 ranged between 0.84-1.75 mU/l, 1.87-2.12 ng/dl and 4.77-5.86 ng/l, respectively. Thus, the patient had the lowest TSH value and highest free thyroid hormones in her life when she applied. With the current laboratory results and imaging findings, Graves' disease was diagnosed. Methimazole and propranolol treatment was started. Methimazole was switched to propylthiouracil due to the development of skin rash. Owing to family history and her previous thyroid hormone profile, THRB gene mutation analysis was requested from the patient. Heterozygous c.1001T>C mutation was detected. Under treatment, her symptoms resolved, TSH returned to normal, free T3 and T4 were followed as close to the upper limit or slightly elevated. The patient's propylthiouracil medication therapy was discontinued after 18 months. At the time of discontinuation her TSH was 0.96 mU/l, free T3 was 6.05 ng/l, free T4 was 1.98 ng/dl, TRAB was negative. At the last visit, 2 years had passed since drug discontinuation and her serum TSH was 0.51 mU/l, free T3 was 4.86 ng/l and free T4 was 1,50 ng/dl.
Discussion
Treatment with anti-thyroid drugs remains the primary choice for Graves' hyperthyroidism complicated by THR. The optimal treatment is to normalize TSH while keeping free thyroid hormones slightly higher than the upper limit. Iodine therapy and surgery are not generally recommended, since they may induce severe hypothyroidism.

History of Goiter in The Mother is Associated with Thyroid Volume, TSH and Thyroid Heterpogeneity in Women at Midlife

Zeynep Dilek Erzengin[1] & Banu Kale[2]
[1]Suleyman Demirel University, Internal Medicine, Division of Geriatry, Isparta, Turkey; [2]Bahçeşehir University VM MedicalPark Pendik Hospital, Endocrinology and Metabolism, Istanbul, Turkey

Family history of thyroid disease (Karger 2010) and family history of goiter (Singer 2011, Knudsen 2003, Gebremichael 2020) were found to be associated with risk of goiter though some did not observe this association (Phitayakorn 2006). On participants of the Isparta Menopause and Health (IMH) Study, we measured TSH ($n=1099$) and thyroid sonographic parameters ($n=994$) including TV, thyroid nodularity (TN) and heterogeneity (TH). Health related factors and history of goiter in the mother were evaluated through a questionnaire. History of maternal goiter was positive if participant recalled the existence of goiter in her mother and negative otherwise. Univariate and multivariate ordinal (for TV and TSH) and binary (for TH, TN) logistic regression was performed to evaluate the significance of history of maternal goiter as a predictor of TSH, TV, TN and TH. Stepwise model selection algorythm was applied. MVA was performed in 2 steps and response variables were also evaluated as predictors for each other in the second step. The age range of IMH study participants was 44-61. Median TV (interquartile range) was 13 (10, 18.75) ml. Median TSH (interquartile range) was 1.1858 (0.7527, 1.9576) uIU/ml. At least one thyroid nodule was present in 540 (54.44) women. Sonographic heterogeneity was present in 347 (34.98) women. $n=170$ (15.47) women had history of goiter in their mother. In univariate analysis, history of maternal goiter tended to predict increased likelihood of greater TV ($P=0.0581$) and predicted reduced likelihood of greater TSH ($P=0.00076$) whereas it was not associated with TN or TH. In multivariate analysis controlling for the effects of health related factors, history of goiter in the mother was found to be an independent predictor of TV (OR = 1.492 (1.083-2.055), $P=0.0144$) and TSH (OR = 0.616 (0.453-0.837), $P=0.0019$) but not of TN and TH. When multivariate models also included the other response variables, history of goiter in the mother remained independently associated with TSH but not with TV, whereas it also predicted the presence of TH (OR = 1.548 (1.076-2.227), $P=0.0185$). History of maternal goiter may have long-term impact on thyroid health of the female offspring. These alterations may be observed even after considerable time lapse at midife. The association between history of maternal goiter and their daughter's TSH may be more robust than the association between history of maternal goiter and daugter's TV.

Is there a paradigm shift for the evaluation and treatment of isthmic thyroid nodules?

Yagmur Babayid[1], Asena Gökçay Canpolat[2], Koray Ceyhan[3], Demet Çorapçioğlu[2] & Mustafa Şahin[2]
[1]Ankara University, Internal Medicine, Ankara, Turkey; [2]Ankara University, Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara University, Pathology, Ankara, Turkey

Introduction
Although the thyroid isthmus seems like a structure that connects bilateral lobes, it is an undiscovered area that needs to be explored. Currently, the data is evolving that the increase in the risk of malignancy is higher in the isthmic nodules, and extrathyroidal extensions and lymph node metastases are more common in isthmic-derived malignant thyroid nodules. Therefore, we aimed to compare the malignancy rate of isthmic and lobar nodules, the ultrasonographic features of isthmic and lobar nodules, and presence of lymph node metastases, distant metastases, and extrathyroidal invasions in malignant isthmic nodules.
Methods
In this retrospective study, we enrolled patients between the ages of 18-80 years, who had thyroid nodule/nodules cytology and/or pathology results from January 2009 to November 2020. 9504 nodules were selected for the analysis of US findings, cytopathology results, and malignancy rates.
Results
A median age of 56 (18-80) years with a Female to male ratio of [7618 (80.2%)/1886(19.8%)] were included in the study. 962 of the nodules were at isthmic localization; whereas 8542 nodules were at lobar localization. 803 nodules were surgically removed and resulted as malignant from histopathological evaluation. The median age of the patients with malignant nodules was 54 (18-80). Of the 803 malignant nodules, 704 nodules were (87.7%) PTC, 46 nodules (5.7%) were FTC, 35 nodules were (4.4%) MTC, 14 nodules 1.7% were Hurtle cell carcinoma, and 4 nodules (0.5%) were anaplastic thyroid carcinoma. 108 of the malignant nodules (13.4%) were located in the isthmus, whereas the majority of the malignant nodules (n:695, 86.6%) were located at the lobar parts (right or left) of the thyroid. When the metastasis patterns of isthmic and lobar thyroid cancers were examined, no significant relationship was found between isthmic and lobar cancers in terms of capsule invasion ($P=0.437$), muscle invasion ($P=0.294$), and lymph node metastasis ($P=0.476$). A significant correlation was found between nodule localization (isthmus-upper-middle and lower lobes) and malignancy ($P<0.0001$). In our logistic regression analysis, isthmic nodule localization was evaluated as an independent risk factor for malignancy (than lobar nodules)(OR: 1.35 95% CI, $P=0.008$). Nodules in the isthmus region were found to have a higher risk of malignancy compared to the lower lobes (OR: 1.88 95% CI, $P=0.005$).
Conclusions
We recommend, nodule localization has to be considered an additional risk factor when performing a Fine Needle Aspiration Biopsy (FNAB).

Evaluation of Factors Determining Iodine Refractoriness in Thyroid Carcinoma

Aslı Erten[1], Zeynel Abidin Sayıner[2], İpek Köroğlu[2], Sibel Oğuzkan Balcı[3] & Ersin Akarsu[2]
[1]Gaziantep Unıversity School of Medicine, Internal Medicine, Gaziantep, Turkey; [2]Gaziantep University School of Medicine, Endocrinology and Metabolism, Gaziantep, Turkey; [3]Gaziantep University School of Medicine, Medical Biology, Gaziantep, Turkey

Introduction
Radioiodine-resistant thyroid carcinoma is an important milestone in the treatment and follow-up of thyroid cancers. The biological defects of iodine uptake in thyroid cancer cells should be well known. In this study, we aimed to evaluate the clinical and pathological features and SLC5A5 gene expression status of iodine-refractory papillary thyroid carcinoma patients.
Material-Method
We studied SLC5A5 expression in 83 papillary thyroid carcinoma patients before radioactive iodine treatment was given. While 32 of these patients were radioactive iodine-refractory, 51 of them were cured with radioactive iodine on the follow-up. Biochemical, histopathological, and radiological data were gathered retrospectively.
Results
While the median $\pm$ SD age in the iodine-refractory thyroid carcinoma group was 56.56 $\pm$ 15.22, it was 46.82 $\pm$ 12.43 in the control group. The median value of the refractory patient's thyroglobulin was 278 (65-724), while it was 3.21 in the non refractory group (0.66–23.7). The mean age of 13 patients with refractory thyroid carcinoma who received chemotherapy was 65.77 $\pm$ 12.58. The mean age of 19 patients who did not receive chemotherapy was 50.26 $\pm$ 13.80. SLC5A5 gene expression increased in the iodine non-refractory PTK group and decreased in the iodine refractory PTK group. All these parameters and statistically significant ($P < 0.05$).
Conclusion
Advanced age (age $>$ 55 years) and a high postoperative thyroglobulin level (278 ng/ml) are effective in the development of iodine resistance in patients with differentiated thyroid carcinoma. In addition, the presence of advanced age in patients with iodine-refractory thyroid carcinoma is associated with the need for chemotherapy. Contrast expression changes in SLC5A5 gene expression may be a guide to better understand the pathophysiological mechanism of RAI refractory disease.

Microscopic Calcifications Isolated from Thyroid Nodule Fine Needle Aspiration Can Serve as Biomarkers of Thyroid Nodule Malignancy

Uri Yoel[1,2], Merav Fraenkel[1,2], Lotem Gotnayer[3], Dina Aranovich[3] & Netta Vidavsky[3,4]
[1]Soroka Medical Center, Endocrinology, Be'er Sheva, Israel; [2]Ben Gurion University of the Negev, Faculty of health sciences, Be'er Sheva, Israel; [3]Ben Gurion University of the Negev, Chemical Engineering, Be'er Sheva, Israel; [4]Ben Gurion University of the Negev, Ilse Katz Institute for Nanoscale Science & Technology, Be'er Sheva, Israel

Background
When US characteristics and the diameter of a thyroid nodule (TN) justify further evaluation to rule out or to establish the diagnosis of thyroid cancer (TC), fine needle aspiration (FNA) biopsy for cytology (FNAC) is indicated. A major limitation of FNAC is the high rate of indeterminate significance (~30%) results, which require further evaluation. Although recently introduced molecular testing contributed to the ability to differentiate benign from malignant TNs, these approaches are costly, and not available worldwide. Punctate calcifications detected within a TN by neck US are considered a high-risk feature for TC. We hypothesized that the small amount of material that remains in the syringe at the end of the FNA procedure contains microscopic calcifications (MCs), that may differentiate benign from malignant TNs, by chemical analysis for composition and morphology.
Aim
To assess the diagnostic potential of MCs within TNs obtained during routine FNAC procedure.
Methods
In this single-center proof-of-concept study, samples were collected between 11/2020 and 12/2022 during FNAC procedures, conducted as clinically indicated. Clinical decisions were made according to the accepted guidelines based on thyroid US and cytological findings. Comparisons between the final diagnosis of a TN as benign or malignant and the results of the thorough compositional and morphological MCs analyses were conducted retrospectively.
Results
Samples from 124 patients were collected and sent for chemical analysis in parallel with the routine cytological evaluation. Samples from 26 patients were used for protocol development, and 35 patients were still under clinical evaluation. The remaining 63 patients underwent full clinical evaluation, and FNA samples from these patients were subject to the MCs isolation protocol. In 52/63 patients (82.5%), FNA MCs were identified. Interestingly, all 11 patients without identifiable MCs were diagnosed with benign TNs. The final study cohort included 30 patients with benign TNs (median age: 54 years [range: 26-76 years], 83.3% females), and 22 patients with TC (median age: 42 years [range: 18-80 years], 63.6% females). Morphologically, while MCs from patients with TC were spherical, MCs from benign TNs were crystals with sharp edges. Regarding elemental composition, zinc was present in 91% and 7% of MCs obtained from patients with final diagnosis of TC and benign TN, respectively.
Conclusion
The presence of zinc in MCs isolated from samples collected during routine FNAC can offer value as a biomarker for TC.

Challenges in the management of endocrine complications after hematopoietic stem cell transplantation – could it be reconstitution Graves' disease?

Iustina Grosu[1], Sabina-Maria Dumitrache[1], Raluca Stan[1], Ana Zubaci[1], Marina Iliescu[1], Mihaela Tarna[1], Cristina Jercan[2], Anca Colita[2,3], Luminita Nicoleta Cima[1,3] & Simona Fica[1,3]
[1]''Elias' Emergency University Hospital, Endocrinology, Bucharest, Romania; [2]Fundeni Clinical Institute, Pediatrics, Bucharest, Romania; [3]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background
The rapid advancements in the field of allogenic hematopoietic stem cell transplantation (allo-HSCT) and better management of acute postprocedural complications have led to increased life expectancy, but at the same time to higher incidences of long-term complications. Conditioning regimens (chemotherapy, total body irradiation), immunosuppresive treatments and immune dysregulation threaten endocrine and metabolic functions, leading to late effects, including hypogonadism and infertility, thyroid dysfunction or steroid-induced diabetes and dyslipidemia, associated with increased cardio-vascular risk. Even though, thyroid function abnormalities are one of the most prevalent conditions encountered after HSCT, Graves' disease is rarely seen, but can appear as a result of immune reconstitution syndrome, either by transfer of pathogenic auto-reactive lymphocyte clone from donor to recipient or by loss of immunotolerance secondary to graft-vs-host disease (GVHD).
Case report
A 20-year old female received an allo-HSCT from a related donor(brother) for acute myeloid leukemia without maturation (M1) in November 2019. The conditioning regimen included cytarabine, idarubicine, etopozide and methyl-prednisolone. In August 2021, the patient developed an active form of cutaneous chronic graft-vs-host disease with morphea-like lesions, for which high doses of methylprednisolone were started. In December 2021, she presented to our departement for premature ovarian failure secondary to chemotherapy and evaluation for other endocrine and metabolic complications. Continuous combined hormone replacement therapy was introduced for menopausal symptoms. Subsequently, the patient developed hematocolpos secondary to vulvovaginal cGVHD for which she underwent dilatation. At the next follow-up in our department, her thyroid function tests revealed a TSH level of 0.059 µIU/ml (0.3-3.6 µIU/ml), fT4 1.08ng/dl (0.8-1.7ng/dl) and fT3 60.7 ng/dl (76.3-220.8 ng/dl). Her thyroid ultrasound was normal. Even though, her thyroid function abnormalities are consistent with the effects of high dose corticosteroids, subclinical hyperthyroidism caused by Graves' disease in connection with a post-transplant immune reconstitution syndrome cannot be excluded, as thyrotropin receptor antibodies were found increased (TRAb = 5.06 UI/l, normal 0-1.75 UI/l). Nevertheless, we were not able to perform TSI for differential diagnosis. Moreover, diabetes mellitus (fasting glucose = 132 mg/dl) and dyslipidemia (total cholesterol = 476 mg/dl, triglycerides = 716 mg/dl) were diagnosed.
Conclusions
As survivorship after HSCT increases and endocrine complications become more frequent, emphasis should be placed on the importance of a long-term multidisciplinary follow-up, in order to recognise and treat endocrinopathies before clinical impact, thus optimizing quality of life. Furthermore, HSCT offers an unique insight into the pathogenesis of autoimmune disease, such as Graves' disease.

A life threatening manifestation of severe hypothyroidism

Shyam Seshadri[1] & Raja Nata[2]
[1]The Queen Elizabeth Hospital, Diabetes and Endocrinology, Kings Lynn, United Kingdom; [2]The Queen Elizabeth Hospital, Cardiology, Kings Lynn, United Kingdom

A 29 year old lady with a past history of seronegative rheumatoid arthritis, Vitamin B12 deficiency, autoimmune hypothyroidism and fibromyalgia who had feeling unwell with a left sided headache for a few days had a fall at home witnessed by her friend. She was noted to be in peri arrest state by ambulance crew on their arrival. Agonal breathing was noted and monitor revealed VF. She was given 5 DC shocks with return of spontaneous circulation and regained consciousness. She was transferred to ITU where her initial obervations showed oxygen saturation of 94% on oxygen with a respiratory rate of 26 and pulse rate of 106 per minute and a GCS of 15 with a glucose of 12.1 mmol/l. Her recent thyroid biochemistry had revealed poorly controlled hypothyroidism with a TSH of 160.41 miu/l. She had a long history of poor compliance with her thyroid medication and the plan prior to her hospital admission was her to have had a supervised levothyroxine adminstration and absorption test to probe for any issues with malabsorption which unfortunately she could not attend. She was intially commenced on iv liothyronine and hydrocortisone along with fluid resucitation and broad spectrum antibiotics as a CTPA showed widepread lung consolidation with however no pulmonary embolism. A bedside echocardiogram showed evidence of moderate to severe LV impairment with an ejection fraction of 35-40% and a small posterior pericardial effusion of maximum size of 1.3 cm. She was commenced on Ramipril. She made good progress and was switched to oral liothyronine and levothyroxine on day 2 of her stay on ITU. Her TSH showed good recovery with a value of 38.9 on day 3 with further improvement to 20.22 on day 5. An ECHO 2 weeks later showed a slight improvement in her LV function with an EF at 45%. The patient was transferred to the medical ward and made steady progress. Serial ECHO showed a reduction in the pericardial effusion with further improvement in LV function. The patient was subsequently well enough and stable to be discharged home. This case highlights the reversibility of cardiac dysfunction induced by severe hypothyroidism with focussed thyroid replacement in a patient with a history of poor compliance with the management of her hypothyroidism. Severe hypothyroidism can cause reduced ventricular filling and decreased cardiac contractility which in turn leads to reduced cardiac output which in the extreme case of severe hypothyroidism can be life threatening.

Resistance to Thyroid Hormone Beta in a 12-Year-Old Patient: Clinical, Laboratory, and Molecular Characteristics

Vera Lozovanu[1], Cristina Alina Silaghi[2] & Carmen Emanuela Georgescu[2]
[1]County Emergency Clinical Hospital, Department of Endocrinology, Cluj-Napoca, Romania; [2]'Iuliu Hatieganu' University of Medicine and Pharmacy, Department of Endocrinology, Cluj-Napoca, Romania

Background
Resistance to thyroid hormone beta (RTHβ) is an inherited syndrome of reduced tissue responsiveness to thyroid hormones (THs). It is driven in 85% of cases by mutations in the thyroid hormone receptor beta (*THRb*). The estimated incidence is 1:40.000 to 1:19.000 live births. We report the clinical, laboratory, and genetic analysis of a patient with this disorder.
Case report
A 12-year-old boy with a history of Attention-Deficit/Hyperactivity Disorder was referred to endocrinological evaluation due to hyperactive, impulsive behavior, insomnia, palpitations, heat intolerance, and perspiration. Physical examination was unremarkable except for resting tachycardia and hypertension. Thyroid function tests (TFTs) showed normal thyroid-stimulating hormone (TSH) of 2.38 uIU/ml (normal range: 0.4-4.0), elevated free thyroxine (fT4) of 2.48 ng/dl (0.7-1.3), free triiodothyronine (fT3) of 10.9 pg/ml (2.4-4.1) and reverse T3 (435 pg/ml; 90-215) levels. He was not taking any medications that could have affected thyroid labs. Repeat TFTs using a different assay showed a similar pattern. Antithyroid peroxidase and TSH receptor antibodies were not detected. Sex Hormone-Binding Globulin (SHBG), a peripheral marker of THs action, was in the euthyroid range. A diffuse cystic goiter was revealed on ultrasound. The magnetic resonance imaging identified a 5 mm hypointense area in a slightly hyperplasic pituitary. His father showed hormonal abnormalities consistent with RTHβ. T3 and Thyrotropin-releasing hormone (TRH) was not available for dynamic tests. A heterozygous missense mutation in the *THRβ* gene (c.1012C>T) was identified. Tiratricol was prescribed thereafter.
Discussions
Elevated serum THs accompanied by unsuppressed TSH are suggestive of RTHβ. However, alternative diagnoses (assay interferences, thyroxine-binding globulin abnormalities, and familial dysalbuminemic hyperthyroxinemia) should be excluded first by measuring free THs with equilibrium dialysis and T4-binding panel. First-degree relatives hormonal testing, a-subunit/TSH ratio, markers of THs action (SHBG, Type I Collagen C-Terminal Telopeptide), pituitary imaging, dynamic tests with T3 and TRH are used to discriminate between RTHβ and thyrotropinoma. As in our patient, a pituitary lesion mimicking thyrotropinoma may appear in RTHβ as an incidental finding; although it can result from thyrotropes enlargement after a longstanding absence of negative feedback. Genetic testing is regarded as the gold standard for definitive diagnosis. *THRβ* c.1012C>T affects a highly conserved amino acid (p.Arg338Trp) in the *THRβ* T3-binding domain and was classified as pathogenic.
Conclusions
In the setting of normal TSH and elevated THs, after ruling-out artifactual laboratory interference, there is a high suspicion for RTHβ. Alternative diagnoses should be excluded as they have completely different management approaches.

Role of thyroid hormones in the development of neurodegeneration in rats

Muhammadjon Mustafakulov[1], Talat Saatov[1], Takhir Ishankhodjaev[1], Ilmira Yalalova[1] & Zulaykho Shamansurova[1,2]
[1]Institute Biophysics and Biochemistry at the National University of Uzbekistan, Metabolomics, Tashkent, Uzbekistan; [2]Tashkent Pediatric Medical Institute, Endocrinology with Pediatric Endocrinology, Tashkent, Uzbekistan

Introduction
Neurodegeneration is one of the most common condition accompanied Diabetes Mellitus, Parkinson's and Alzheimer's diseases. Although its mechanisms intensively studied for many years, some questions of pathogenesis remain unclear. The aim of the study was investigate the effects of thyroid hormones and some neurotransmitters on the cerebral cortex of rats with experimental neurodegeneration.
Materials and methods
Series of experiments were carried out on 45 purebred white rats were divided into 3 groups: control, animals given a neurotoxins such as thiamazole (second group) and AlCl3 (third group) for neurodegeneration models. In the end of experiments rats were sacrified, blood samples taken by cardiac puncture, hippocampus, cortex and other parts of the brain taken separately and homogenised. In blood serum T3, T4, TTG and tau protein concentrations were determined, also in samples from hippocampus, cortex and other part of the brain based on enzyme immunoassay kits. Determination of the content of neurotransmitters aspartate, glutamate, gamma-aminobutyric acid (GABA) level in samples were measured using thin-layer chromatography. The amount of dopamine and noradrenaline in the homogenate of the hippocampus and cortex of the brain determined by column chromatography, and acetylcholine was determined spectrophotometrically.
Results
Rat models with neurodegeneration were obtained 14th day after taken of neurotoxins. Blood serum T3, T4 levels were not significantly differs between the groups and were in normal ranges. Interestingly, in rats with both neurodegeneration models significant decreasing in the level of T3 in the homogenate of the hippocampus and cortex, but not in other parts of the brain were found. Moreover, neurotransmitters level were disturbed i.e. increasing of glutamate and aspartate, GABA level, also decreasing of amount of noradrenaline and dopamine in the homogenates of the hippocampus and cortex of the brain were determined in rats with neurodegeneration. Decreasing level of thyroid hormones locally in hippocampus and cortex of the brain and abnormal neurotransmitters level probably was one of the main causes of the disturbance of cognitive functions in the rats.
Conclusion
Experimental neurodegeneration in rats revealed decreasing of thyroid hormones level locally in the homogenates of the hippocampus and cortex of the brain, which accompanied with disturbed level of glutamate and aspartate, GABA levels, also decreasing of amount of noradrenaline and dopamine, which affected rats cognitive function.

The utility of salivary thyroid hormones in assessment of thyroid function

Nadia Sawicka-Gutaj[1], Piotr Glinicki[2], Kacper Nijakowski[1], Barbara Bromińska[1], Magdalena Ostrowska[2], Alicja Szatko[2], Zuzanna Sobol[3], Konrad Kowalski[3], Paweł Wilk[1], Wojciech Zgliczyński[2] & Marek Ruchala[1]
[1]Poznań University of Medical Science, Department of Endocrinology, Metabolism and Internal Medicine, Poznań, Poland; [2]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland; [3]Masdiag Laboratory, Warsaw, Poland

Introduction
Saliva is an interesting alternative to blood in clinical evaluation of endocrine function. Certain advantages of saliva collection must be considered, when comparing with conventional blood sampling. Vital arguments are that procedure is easy, non-invasive and stress-free. The studies on correlation between salivary and serum thyroid hormones are scarce and contradictory. The goal of our research was to assess if salivary thyroid hormone levels reflect serum concentration.
Methods
This is a prospective study with a consecutive enrollment of patients routinely referred for thyroid hormone's evaluation. We recruited 109 patients with various thyroid disorders. We assessed TSH, ft3 and ft4 concentration in serum with electrochemiluminescence (ECLIA) immunoassays and chemiluminescence immunoassay (CLIA). Serum levels of anti-thyroid antibodies were measure with ECLIA. In saliva, ft3 and ft4 levels were evaluated by the liquid chromatography with tandem mass spectrometry (LC-MS/MS) analytical technique. Venous blood samples were collected in the morning, after an overnight fast. Saliva samples were obtained in the morning into special Salivette® tubes. Saliva was picked up after at least 30 minutes of eating, drinking, smoking, or chewing gum.
Results
There was a consistency between ECLIA and CLIA methods for serum assessment of TSH, ft3 and ft4. In the whole group ($P<0.001$, R 0.575) and in the subgroup with TSH within reference interval ($P<0.001$, R 0.570) salivary ft3 and ft4 were positively correlated. Then we evaluated correlation between serum and salivary hormone concentrations, according to TSH reference ranges. Serum ft4 correlated positively with salivary ft4 in entire group (ECLIA $P<0.001$, R 0.355; CLIA $P<0.001$, R 0.384), in subgroup with TSH within reference interval (ECLIA $P=0.027$, R 0.256; CLIA $P<0.001$, R 0.263) and in one with TSH above normal limit (CLIA $P=0.014$, R 0.712). Adversely, serum ft3 correlated with salivary hormone only in patient with TSH below normal value (CLIA $P=0.017$, R -0.802; ECLIA $P=0.011$, R -0.826). Then we assess how levothyroxine therapy for hypothyroidism influence serum/saliva thyroid hormones correlations. Salivary and serum hormones were correlated only in naïve treatment patients. We evaluated also if anti-thyroid antibodies have an impact on salivary and serum thyroid hormones.
Conclusions
Our study indicated that salivary thyroid hormones to a certain degree mirror levels of their serum equivalents. Even, in patients with anti-thyroid antibodies, but not on levothyroxine treatment, saliva assessment may be of clinical value. Our research provide a basis for future studies concerning usefulness of saliva in evaluation of thyroid function.

Weight Variability with the Treatment of Graves' Disease in Adults

Leonor Lopes[1], Carlos Tavares Bello[2], Clara Cunha[1], Carolina Antunes[1], Clotilde Limbert[1] & João Manuel Sequeira Duarte[1]
[1]Hospital Egas Moniz, Endocrinology, Lisbon, Portugal; [2]Hospital da Luz, Endocrinology, Lisbon, Portugal

Introduction
Graves disease (GD) is a frequent cause of primary hyperthyroidism and often presents with weight loss. Weight gain beyond the premorbid state is often reported and could be a challenge during patient's management. Treatment modalities, disease remission and biochemical parameters at the diagnosis have been described as predictors of weight changes in patients with GD.
Objectives
To evaluate the determinants of weight changes in GD treated patients.
Methods
Retrospective, observational and longitudinal study of patients with the diagnosis of GD and at least six months of follow-up, with available data regarding baseline, premorbid and post-treatment weight. Laboratory and demographic variables, including body mass index (BMI), were also recorded.
Results
The sample included 122 patients (95 females) with a median age at the diagnosis of 48 years-old (IQR 21). Almost 34% of the patients documented some weight loss during the state of hyperthyroidism. Hyperthyroidism was responsible for a mean loss of 5,7 $\pm$ 7,8 kg, with a mean BMI reduction of 0,75 (IQR 3,00) kg/m^2. Moreover, patients with weight loss before treatment presented a lower premorbid BMI (22,4 $\pm$ 2,7 vs 25,1 $\pm$ 4,8 kg/m^2, *P*-value 0,027). On the other hand, after starting treatment, a weight gain was observed in 59,2% of patients, and excessive weight gain (final weight above premorbid weight) in 23,8% of them. Patients with weight gain after treatment were mainly women (78%), with a mean age of 47 $\pm$14,7 years. These patients were also more frequently smokers (*P*-value 0,034) and presented higher prevalence of hypothyroidism after treatment (*P*-value 0,008). All patients considered underweight (BMI <18 kg/m^2) presented a weight gain during treatment (*P*-value <0.001). Curiously, excessive weight gain was more common between individuals that did not lose weight before treatment (*P*-value <0.001). Hypothyroidism after treatment of GD was more prevalent among those with excessive weight gain (*P*-value <0.001). Finally, there was no difference in baseline TSH, TSH-receptor antibody levels, free T4 or free T3 serum levels between patients regardless of their weight changes.
Conclusions
Our analysis shows that GD patients with a lower premorbid BMI presented with a higher weight loss at the diagnosis. Also, excessive weight gain was more common between individuals that did not lose weight before treatment. These results support the evidence that other factors, especially premorbid patient's BMI, may determine weight changes in GD patients, regardless of their analytical serum endocrinological profile and disease management.

Amyloid Goiter, Papillary Thyroid Microcarcinoma and Diffuse Thyroid Lipomatosis – a case report of a rare association

Guilherme V. de Assunção, Liliana Fonseca, André Couto de Carvalho & Cláudia Freitas
Centro Hospitalar e Universitário do Porto, Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal

Introduction
Amyloidosis is a disease characterized by the accumulation of an amorphous proteinaceous material, known as amyloid, in various organs and tissues of the body. Amyloid goiter is a remarkably rare pathologic condition due to thyroid massive amyloid infiltration of amyloid light chain (primary) or amyloid A (secondary amyloidosis) proteins.
Case
54 year-old male, with known history of chronic tophaceous gout medicated with anakinra and prednisolone, obesity (BMI 36.0 Kg/m2), obstructive sleep apnea, heart failure with preserved ejection fraction and an enlarged multinodular goiter. Relevant thyroid nodules were found in the right lobe (4.5 cm, TIRADS 4) and in the left lobe (3.7 cm, TIRADS 2 and 2.6 cm, TIRADS 2). Fine needle aspiration cytology to the TIRADS-4 lesion was non-diagnostic (*Bethesda I*). Sometime later compliants of cervical compressive symptoms such as dysphagia were found. The ultrasound revealed an overall enlargement of the thyroid gland and its nodules with significant tracheal deviation. Thyroid function tests revealed a TSH 0.96 µUI/ml (RR: 0.30 - 3.18) and a T4L 1.57 ng/dl (RR: 1.01 - 1.65) with negative anti-thyroid peroxidase (TPO) and anti-thyroglobulin (TG) antibodies. A total thyroidectomy was performed. The thyroid weighed 125g and consisted of amyloid lesions associated with diffuse lipomatosis and multiple focal and bilateral papillary microcarcinomas (dominant with 2mm). Proper search for systemic amyloidosis was performed without any discovery. At the last follow-up, he had an excellent biochemical response with undetected Tg level and no evidence of amyloid recurrence.
Conclusions
Deposition of amyloid in the thyroid gland is a rare condition. In patients with a rapid enlargement of the goiter and a history of chronic inflammatory diseases, clinicians should suspect of amyloid involvement. This excessive growth can cause compression of the surrounding structures and warrant a total thyroidectomy. Papillary thyroid carcinoma has been rarely associated to amyloid goiter.

Course of Papillary Thyroid Carcinoma Diagnosed in Childhood and Adolescence and Followed Through Adulthood: Experience from a Tertiary Referral Center

Hulya Hacisahinogullari[1], Elif Inan Balci[2], Gulsah Yenidunya Yalin[1], Ozlem Soyluk Selcukbiricik[1], Firdevs Bas[2], Ayse Kubat Uzum[1], Sukran Poyrazoglu[2] & Nurdan Gul[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Endocrinology and Metabolism, Istanbul, Turkey; [2]Istanbul University, Istanbul Faculty of Medicine, Department of Paediatrics, Division of Paediatrics Endocrinology, Istanbul, Turkey

Introduction
Differentiated thyroid cancer accounts for 1.5% of all pediatric malignancies. Papillary thyroid cancer (PTC) is the most common subtype and is associated with more advanced disease at diagnosis compared to adults. The aim of this study was to identify long-term outcomes of pediatric PTC.
Methods
Records of 30 patients with PTC diagnosed in childhood and adolescence and followed up at Istanbul Faculty of Medicine were reviewed retrospectively.
Results
The mean age of 30 patients (21 females, 9 males) at diagnosis was 14,7±2,4 years (range, 7 to 18). Mean duration of follow-up was 126,8±45,2 months. Five patients had history of radiation therapy (RT); mean duration from RT to diagnosis of PTC was 7,2±2,4 years. Mean nodule diameter was 1,54±1,32 cm, and fine-needle aspiration biopsy was Bethesda II in 6,6%, III in 6,6%, IV in 10%, V in 26,6%, and VI in 46,6%. The patients underwent total thyroidectomy ($n=9$), or total thyroidectomy with central lymph node dissection ($n=9$) or total thyroidectomy with central and lateral lymph node dissection ($n=12$). The tumor was located in both lobes in 43,3% of the patients, in left lobe in 30%, in right lobe in 20%, and in isthmus in 3.3%. The mean tumor diameter was 1,56±1,47 cm (range, 0,1 to 6), and was microcarcinoma in 12 of the patients. Histopathological subtype was available in 28 patients (follicular variant $n=13$, classic $n=9$, encapsulated follicular $n=3$, tall cell $n=1$, macrofollicular $n=1$, hobnail $n=1$, diffuse sclerosing $n=1$). Chronic lymphocytic thyroiditis was detected in 10 patients. Six patients had BRAF mutation. There were 5 patients with T2 and 2 patients with T3 disease. At diagnosis, half of the patients had lymph node metastasis to the neck or upper mediastinum (N1a=5, N1b=10), and 2 also had lung metastasis. Of 10 patients with N1b, 7 had multicentric disease and vascular invasion, and 6 had lymphatic invasion. Eight low-risk patients still in remission were treated with only TSH-suppressive levothyroxine. Post-operative radioactive iodine (RAI) treatment was administered to 22 patients [median number of administration was one (range 1-7), median cumulative dose was 150 mCi (range 50 to 1100)]. Sixteen patients had excellent response following single ($n=13$) or multiple (2 for persistent and 1 for recurring disease after 100 months) RAI administrations. Remaining 3 patients had structural incomplete and 3 had indeterminate response.
Conclusions
Although PTC presented at more advanced stage in childhood and adolescence, the response to treatment was fairly good with appropriate management.

Performances of ABEI-based automated immunoassays thyroid function tests

Damien Gruson
Cliniques Universitaires Saint Luc, Laboratory medicine, Bruxelles, Belgium

Background
Diagnosis and monitoring of thyroid diseases rely on thyroid function tests. Testing for Thyroid Stimulating Hormone (TSH) and free thyroxin (FT4) are frontline assays for the diagnosis of hyper- and hypothyroidism. Measurement of TSH receptor autoantibodies (TRAB) is pivotal for the diagnosis of Graves' disease. Our study objective was to determine the performances of ABEI-based automated immunoassays for measurement of TSH, FT4 and TRAb.
Methods
Performances of the Maglumi® 800 TSH, FT4 and TRAb chemiluminescent immunoassays that applies ABEI labels were determined. Imprecision of assays was assessed with control materials. Method comparison was performed with Cobas electrochemiluminescent assays for TSH and FT4 and with Kryptor Compact Plus assay for TRAb. Reference intervals were also confirmed with samples from healthy volunteers.
Results
Between-run imprecision coefficients of variation were 7.1% for concentrations of 3.3 IU/ml for TSH, 4.4% for concentrations of 15.0 pg/ml for FT4 and 2.2 % for concentrations of 3.6 IU/l for TRAb, respectively. Passing-Bablok regression analysis showed a slope of 1.07 and an intercept of -0.06 for TSH, a slope of 1.03 and an intercept of 0.99 for FT4. For TRAb assay, the Kappa coefficient of concordance with the TRAK method was 0.79. Reference intervals were 0.4 – 2.6 IU/ml for TSH and 8.0 to 17 pg/ml for FT4. The 99th percentile of the reference of the TRAb assay was 1.38 IU/ml.
Conclusions
The ABEI-based automated immunoassays showed good analytical performances for the Maglumi® TSH, FT4 and TRAb and our study confirmed reference intervals for those assays.

Radioiodine therapy outcomes in benign thyroid disease at the University Hospital of Wales, UK

Kalyani Nagarajah[1], Elizabeth Jones[2], Justyna Witczak[2], Peter Taylor[2] & Andrew Lansdown[2]
[1]Department of Medicine, University Hospital Llandough,, Endocrinology and Diabetes, Llandough, United Kingdom; [2]Department of Medicine, University Hospital of Wales, Heath, Department of Endocrinology, Cardiff, United Kingdom

Background
Radioiodine therapy (I-131) is commonly prescribed for benign thyroid disease in keeping with recommended guidelines.
Aims
To determine the effectiveness of I-131 in treating benign thyroid disease and the rates of hypothyroidism following treatment and by diagnosis.
Methods
We identified 100 patients who received radioiodine therapy between November 2013 and June 2015 from a database held in the Medical Physics Department at the University Hospital of Wales, Cardiff, UK. Patient group: 18 male, 82 female; mean age: 58 (15-91)y. Mean activity of I-131 administered: 556 (529-572) MBq. Diagnosis: Graves' disease (52%), solitary toxic nodule (15%), toxic multi-nodular goitre (MNG) (21%), subclinical hyperthyroidism (12%). 89% were cured with a single treatment of I-131, 10% required a second therapy and 1% a third. Hypothyroidism: 67% patients became hypothyroid, requiring levothyroxine replacement. Rates of hypothyroidism according to diagnosis: Graves' (49/52 = 94%), solitary toxic nodule (6/15 = 40%), toxic MNG (7/21 = 33%), subclinical hyperthyroidism (5/12 = 42%), X 2 (6, $n=100$) = 40.06, $P<.001$. There was no correlation between development of hypothyroidism and smoking status or age. Median time to hypothyroidism was 4 (1-94) months, mode 2 months. There was no correlation between time to hypothyroidism and smoking status or age.
Conclusions
Most patients who received I-131 were female, and had a a diagnosis of Graves' disease. 89% were cured with following a single treatment of I-131, and overall 67% became hypothyroid, most 2 months following therapy. There was a statistically significant different in the rates of those who became hypothyroid according to diagnosis, with the highest rates of hypothyroidism in those receiving I-131 for Graves' disease.

The iodine study in pregnancy: no correlation between serum thyroglobulin and urinary iodine concentration

Kristýna Žabková[1,2], Jan Krátký[1,2], Jan Jiskra[1,2] & Adéla Krausová[1,2]
[1]Charles University, First Faculty of Medicine, Prague, Czech Republic; [2]General University Hospital, Third Department of Medicine - Clinical Department of Endocrinology and Metabolism, Prague, Czech Republic

Background
Despite obligatory iodination of salt in the Czech Republic, pregnant women with higher demands on iodine intake may be at risk of iodine deficiency with potentially negative consequences for the course of pregnancy and foetal development. Determination of urinary iodine concentration (UIC) is a conventional but not widely available method used to estimate the iodine status. Based on previous studies, serum thyroglobulin (Tg) could serve as a more convenient marker of iodine deficiency in preschool children and adults. This study aimed to investigate the potential use of Tg as a marker of iodine status in pregnancy.

Patients and methods
UIC from the morning urine sample, biochemical thyroid tests — serum concentration of thyroid stimulating hormone (TSH), free thyroxine (FT4), antibodies to thyroid peroxidase (TPOAb) and thyroglobulin (TgAb) and serum thyroglobulin (Tg) were measured, and thyroid ultrasound (US) was performed in 187 pregnant women in the first trimester of pregnancy.
Results
Overall, inadequate iodine supply in the investigated group of pregnant women was found (median UIC 119.2 μg/l). In the group of women taking oral iodine supplements with ≥ 100 μg of elemental iodine daily, the IUC was significantly higher compared to the group of women taking supplements with 100 μg of iodine or no supplements (median IUC 137.85 μg/l vs. 103.50 μg/l, $P = 0.002$). We found no significant correlation between serum Tg and UIC. Serum Tg was significantly higher in euthyroid TPOAb positive women with US pattern of autoimmune thyroiditis as compared to euthyroid TPOAb positive women with normal US and controls (median Tg 25.65, 7.9 and 8.5 μg/l, respectively, $P = 0.0009$).
Conclusions
Serum Tg was no reliable marker of iodine deficiency in pregnant women in our study. In TPOAb-positive women, serum Tg could distinguish between actual autoimmune inflammation of the thyroid gland and simple serum TPOAb positivity, but further studies are needed. The study was supported by the Charles University, project GA UK No. 265221

An unremarkable presentation but signs of Grave danger: Never forget the thyroid function

Jenna Essame[1], David M Williams[1], Ayesha Shaikh[1], Michael Atkinson[1], Maneesh Udiawar[1] & Kusuma Boregowda[1]
[1]Morriston Hospital, Department of Endocrinology and Diabetes, Swansea, United Kingdom

Introduction
Profound thyrotoxicosis commonly presents with heat intolerance, sweating, weight loss, palpitations, tremor, goitre and eye signs in the case of Grave's disease. Typically, thyroid storm is differentiated by marked volume depletion, congestive cardiac failure, cardiac arrhythmias, confusion, nausea and vomiting, often with extreme agitation. The wide-ranging and systemic manifestations associated with profound hyperthyroidism are mediated through the thyroid hormone receptor present in most tissues throughout the body.
Case Presentation
A 16 year old female presented to the emergency department with increasing shortness of breath over the last two months. She had a previous history of surgically-corrected patent ductus arteriosus, bilateral sensorineural hearing loss and depression and anxiety, with no previous history of endocrine disease. She was apyrexial, found to be tachycardic and tachypnoeic with an elevated jugular venous pressure, but no signs of thyrotoxicosis. Her biochemistry was notable for free T3 > 50 pmol/l, free T4 > 100 pmol/l, TSH < 0.01 mU/l, thyroid-stimulating immunoglobulins 27.30 IU/l and a peak NT-proBNP of 29,258 ng/l. She was admitted for further investigation and treatment. Echocardiogram demonstrated biventricular failure with a left ventricular ejection fraction of 35% and severe tricuspid regurgitation associated with right ventricular failure. She was initially treated with carbimazole, propranolol and hydrocortisone. She deteriorated rapidly with increasing breathlessness and became unresponsive requiring prolonged intubation and intensive care unit stay. She was transferred to the specialist tertiary centre to consider mechanical bridging therapy and heart transplant but she recovered with milrinone infusion and was repatriated for continuation of management. She was extubated successfully after 3 weeks and subesquently completed ward-based rehabilitation. On discharge, her hyperthyroidism and decompensated heart failure status resolved, and her most recent echocardiogram observed a left ventricular ejection fraction of 45-49% with trivial-mild tricuspid regurgitation and a NT-proBNP of 179 ng/l. Her free T3 was 6.2 pmol/l, free T4 16.4 pmol/l and TSH < 0.01 mU/l. She was discharged on carbimazole 15 mg once daily.
Conclusion
The key learning points from this case are that severe thyrotoxicosis can present with shortness of breath and no other typical hyperthyroidism symptoms, and patients can present with severe heart failure in the absence of Grave's disease signs and symptoms. Importantly, the treatment of Grave's thyrotoxicosis can resolve cardiac impairment, therefore we recommend assessing thyroid status, an inexpensive test, early in such cases to prevent Grave complications.

Long-Term Effects of Radioiodine Treatment on Thyroid Functions, Thyroid Volume, Nodule Volume and Ultrasonographic Features in Patients with Toxic Adenoma and Toxic Multinodular Goitre

Ilgın Koç[1], Adile Begum Bahçecioglu Mutlu[2], Fatma Avcı Merdin[2], Mine Araz[1] & Murat Erdogan[2]
[1]Ankara University, School of Medicine, Department of Internal Medicine, Ankara, Turkey; [2]Ankara University, School of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey

Background
Radioiodine(RAI) has been used to treat hyperthyroidism for more than seven decades. Effects of RAI treatment on thyroid function tests(TFT), risk of hypothyroidism, gland and autonomous nodule volumes and on ultrasonographic features in toxic adenoma (TA) and toxic multinodular goitre TMNG patients, have been previously studied by ourselves and other. However, studies evaluating ultrasonographic changes in thyroid and toxic nodule volumes usually have a follow-up period less than 36 months. Thus we aimed to study the long-term effects of RAI treatment on thyroid functions, ultrasonographic morphology and volume changes in patients with TA and TMNG.
Methods
Thyroid function tests and ultrasonography (US) reports of patients diagnosed with TA or TMNG between the years 2000 and 2021 were retrospectively analysed.
Results
We included 100 patients ($n = 65$ TA, $n = 35$ TMNG) whom thyroid function and US reports were obtained before and at least 36 months post-RAI. At the end of the median follow-up of 7.3 ± 0.3 years (TA, 6.6 ± 0.5 years; TMNG, 8.5 ± 0.7 years), the mean thyroid volume (TV) reduction in patients with TA and TMNG was mean ± sd, 56.6 ± 3.1% and 51.1 ± 6.7%, respectively. Mean volume decrease of all toxic nodules was 80.5 ± 1.9%. When the TA patients were divided into age groups as < 50 and ≥ 50 years, the TV reduction was significantly higher in younger patients(64.5 ± 4.7% vs 53.1 ± 3.8%, $P < 0.05$). One year after RAI treatment, the maximal volume reduction of the toxic nodules (TN) was 66.5%. The volume of the thyroid and TN was significantly reduced up to 12 years ($P < 0.01$) after RAI treatment. Between 3 and 10 years after RAI therapy, the annual incidence of hypothyroidism was 2.0% and 1.5% in the TA and TMNG groups, respectively. Patients who developed hypothyroidism in both TA and TMNG groups had significantly smaller pre-treatment TV when compared to euthyroid patients [i.e. 51.1 ± 4.7 mL and 21.4 ± 1.8 mL ($P < 0.05$)]. Compared with pretreatment sonography findings, TN were more frequently solid, hypoechoic and macrocalcified in post-RAI ultrasounds ($P < 0.01$).
Conclusions
The volume of thyroid gland and toxic nodules continuously decreases, as the risk of hypothyroidism increases up to 10 years after RAI treatment. Thus, follow up to check thyroid functions should continue. In post-RAI examinations, toxic nodules may show ultrasonographic features suspicious for malignancy. Hence history should include previous RAI treatment and old scintigraphy scans should be evaluated to avoid unnecessary procedures and non-diagnostic biopsy results.

Thyroid status in patients after COVID19 in iodine deficiency region

Mukima Karimova[1] & Zulaykho Shamansurova[1,2,3]
[1]Ferghana Medical Institute of Public Health, Endocrinology, Ferghana, Uzbekistan; [2]Tashkent Pediatric Medical Institute, Endocrinology with Pediatric Endocrinology, Tashkent, Uzbekistan; [3]Institute of Biophysics and Biochemistry, Metabolomics, Tashkent, Uzbekistan

Introduction
Coronavirus infection COVID19 spread by Sars-Cov-2 virus were announced by WHO as a pandemics in the end of 2019. As shown in many studies virus affects whole body, particularly endocrine system. There were information about thyroid disturbances after COVID19 infection. Fergana valley of Uzbekistan is an endemic region with high degree of iodine deficiency. The aim of our study were investigate impact of COVID19 on thyroid function in people living in iodine deficiency region.
Material and methods
Study conducted in 84 people who had no any problems with thyroid gland previously and were admitted and treated from COVID19 in hospital of Fergana region. Patients' clinical and anamnestic data, also data from charts were collected and analyzed. Thyroid gland were observed by palpation, thyroid hormones TSH, T3, free T4, and anti-TPO level were detected by RIA kits, structure of thyroid gland were estimated by ultrasound.

Results
80% of observed people who were suffered from COVID19 were women and 20% were men. Palpation of thyroid gland shown that all of them had enlargement of thyroid gland (5%) or/and nodules (95%). Thyroid gland examination by ultrasound revealed that 30 (35%) patients had I-II degree of thyroid enlargement, 35 (42%) patients had autoimmune thyroiditis, 19 (23%) patients had nodular goitre. When examine the thyroid hormones level were shown that 58% patients were in euthyroid state, 36% patients had subclinical hypothyroidism, and 6% patients had manifest hypothyroidism. It seems that iodine deficiency more predisposed thyroid gland to Sar-Cov-2 virus.
Conclusion
In people who lives in high iodine deficiency region after COVID19 thyroid status were affected in 42% and structure were affected in all patients, where 35% was thyroid gland enlargement and in 42% had autoimmune thyroiditis and 23% had nodular goiter.

Incidence of congenital hypothyroidism in Lithuania: data from the National New-born screening program, 2002-2019

Lina Zabuliene[1], Marius Miglinas[1,2], Deimante Brazdziunaite[2,3], Marija Smirnova[2], Jurgita Songailiene[2,3], Nomeda Bratcikoviene[3,4], Valdas Banys[3], Ernesta Macioniene[1,2], Mykolas Urbonas[5] & Alfgirdas Utkus[2,3]
[1]Faculty of Medicine, Vilnius University, Institute of Clinical Medicine,, Vilnius, Lithuania; [2]Vilnius university hospital ' Santaros klinikos', Vilnius, Lithuania; [3]Faculty of Medicine, Vilnius University, Institute of Biomedical Sciences, Vilnius, Lithuania; [4]Vilnius Tech, Vilnius, Lithuania; [5]Faculty of Medicine, Vilnius University, Vilnius, Lithuania

Background
Congenital hypothyroidism (CH) is one of the most common preventable causes of mental retardation and intellectual disability. The overall incidence of CH ranges from 1 in 3,000 to 1 in 4,000 live births, with variation worldwide among different ethnicity [1]. During the period 1993–2000 the incidence of CH in Lithuanian population was estimated as 1 in 4800 live births [2]. The aim of present study was to determine the incidence of CH among new-borns in Lithuania.
Methods
The study was conducted as a part the nationwide NATRIJOD program aimed to evaluate sodium and iodine status in Lithuania. We retrospectively analyzed the results of neonatal thyroid-stimulating hormone (nTSH) tests from the National new-born Screening Program for congenital hypothyroidism database during the period 2002–2019; this reflected about 18% of the total population. According to the screening methodology, heel-prick blood samples of new-borns were collected on filter paper cards. Results of samples collected more than 48 h after the first feeding were analyzed. The nTSH concentration was measured in dry blood spots (DBS) using a fluorometric enzyme immunoassay (Labsystems). Anonymized results of nTSH tests from 517498 cards were retrieved in total. Inadequately sampled 640 DBS were excluded, data of 516858 live-borns were analysed. New-born screening for CH was based on measuring nTSH using a 10 mU/l cut-off and diagnosis of CH was confirmed after repeated evaluation of new-born.
Results
Total of 100 new-borns were diagnosed with CH during study period. Number of CH each year was different lowest in 2004 – 3 cases with CH and highest in 2008 – 17 cases of CH. The highest incidence of CH in Lithuania was observed in 3 counties – Vilnius (29 cases during 19 years), Kaunas (34 cases during 19 years) and Klaipeda (13 cases during 19 years), where 60% of the country's population live. During the period 2002–2019 the incidence of CH in Lithuanian population was estimated as 1 in 4784 live births.
Conclusions
The overall incidence of CH is low in Lithuania. The study revealed significant geographical variations of CH incidence in Lithuania, depending on population density.

Thyroid hormones resistance, lipid profile and insulin resistance in autoimmune thyroiditis

Celestino Neves[1,2,3], João Sérgio Neves[1,2], Juliana Gonçalves[1,2], Miguel Pereira[1,2] & Davide Carvalho[1,2,3]
[1]Centro Hospitalar Universitário de São João, Department Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]Faculty of Medicine, University of Porto, Porto, Portugal; [3]Institute for Research & Innovation in Health, University of Porto, Porto, Portugal

Introduction
Anomalies of glucose metabolism and insulin resistance are common in patients with hypothyroidism. Some studies suggests that euthyroid autoimmune thyroiditis (AIT) may also be associated with changes of glucose metabolism and insulin resistance. The role of thyroid hormones resistance in this context is still uncertain.
Aim
To evaluate the relationship between thyroid hormones resistance, insulin resistance and lipid profile in euthyroid patients with AIT.
Methods
We evaluated a sample of 40 patients with AIT. We assessed thyroid function tests and calculated the resistance to thyroid hormones [Parametric Thyroid Feedback Quantile-Based Index (PTFQI)]. Thyroid antibodies, lipid profile, high-sensitivity C-reactive protein, B12 vitamin, folic acid, anti-thyroid antibodies, and the insulin resistance indexes [HOMA-IR, HOMA-B, QUICKI (Quantitative Insulin Sensitivity Check Index), HISI (Hepatic Insulin Sensitivity Index), WBISI (Whole-Body ISI) and IGI (Insulinogenic Index)] were also evaluated. We divided patients in two groups: TSH <2.00 μUI/ml and TSH >2.00 μUI/ml. All patients had normal levels of TSH, FT3 and FT4. The statistical analysis was done with the Student's t-test and Pearson correlation. We considered a two-tailed P-value of <0.05 significant.
Results
The mean age was 54.4 $\pm$ 13.6 years and 95 % were female. In the total group, we found a negative correlation between PTFQI and Lp(a) ($r=$-0.37; $P=0.04$). Patients with TSH >2.00 μUI/ml had significant higher levels of PTFQI ($0.912\pm$ 0.072 vs $0.701\pm$ 0.155; $P\leq$ 0.001). Patients with TSH >2.00 μUI/ml had significant higher levels of A1c (5.73 ± 0.35 vs 5.41 ± 0.33 %; $P=0.01$). In the group with TSH <2.00 μUI/ml the following correlation were significant: PTFQI with LDL cholesterol ($r=$-0.44; $P=0.04$), QUICKI with triglycerides ($r=0.48$; $P=0.02$), QUICKI with B12 vitamin ($r=0.69$; $P=0.001$) and IGI with triglycerides ($r=0.46$; $P=0.03$). In the group with TSH >2.00 μUI/ml we found significative correlation between HOMA-B and ApoA1 ($r=$-0.86; $P=0.01$).
Conclusion
In euthyroid patients with AIT, we observed significant interrelationships between thyroid function, thyroid hormone resistance, lipid profile and insulin resistance, which may contribute to increased cardiovascular risk.

A Rare Association of Thyroid Medullary Carcinoma with Paraneoplastic Cushing Syndrome: Effects of Multidisciplinary Approach

Cristina Alexandra Olariu[1], Alexandra Marin[1], Cristina Corneci[1] & Corin Badiu[1,2]
[1]National Institute of Endocrinology, Thyroid Related Disorders, Bucharest, Romania; [2]'C. Davila' University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania

Introduction
Medullary thyroid cancer (MTC) is a neuroendocrine tumor of the parafollicular or C cells of the thyroid gland. While thyroid cancer is increasingly common worldwide, MTC still has a low incidence. We present a case of a seventy-one-years-old woman who presented in our unit after an axillary adenopathy biopsy which tested sparsely positive for KeratinPan, CK7, CEA, TTF1, Chromogranin, Snaptophysin and calcitonin, focal positive for EMA, PAX8, Ki67 30%. Also multiple liver, lung and supraclavicular, axillary tumors were described, the largest supraclavicular adenopathy was 59/35 mm. The evaluation in our clinic, in august described a large thyroid gland with multiple nodules described in both lobes, the largest of them was bulking in the mediastinum, reaching the aortic cross and measured 3.93/3.5 cm, imprecisely delimited from the surrounding tissue, with multiple calcifications and high vascularization, as well as multiple large latherocervical lymph nodes. Calcitonin (177000 pg/ml) and CEA (305 ng/ml) where also elevated suggestive for MTC. The additional evaluation revealed a severe hypokalemia, and high cortisol and ACTH values unsuppressed after high dose Dexamethasone, suggesting associated Cushing. The patient underwent total thyroidectomy with large resection of involved lymph node

compartments, were the TNM classification was pT3b pN1b stage IV B. After hemodynamic rebalancing, and testing of the RET mutation, the patient was started on TKI, Vandetanib 200 mg/day. During one year of treatment with TKI, the patient remained stable, without any new lesions observed on the evolutive CT findings. Biochemical findings revealed an initial lowering of Calcitonin and CEA, then the values started to increase, the patient started developing cognitive impairment and dizziness. The particularity of this case high stage MTC associated with paraneoplastic Cushing make more insidious the progress and worsen prognosis of the disease, by being difficult to predict the effects of bilateral adrenalectomy, chemoembolization of liver metastases or radiofrequency ablation for lung metastases, especially in a patient with clinical decline (diarrhea, cognitive impairment, muscular weakness, dizziness which could be an indicator of disease progression-brain metastases).
Conclusions
The therapeutic approach is always a challenge in metastasized cancer, patients benefitting nowadays from the tyrosine kinase inhibitors, especially RET inhibitors, Vandetanib. The presence of distant metastases, and calcitonin doubling time are the most important prognostic factors in determining survival.

Prevalence and clinico-pathological correlations of BRAF V600E and TERT promoter mutations in differentiated thyroid cancer in Romania
Ruxandra Dobrescu[1], Sorina Schipor[1], Andrei Muresan[1], Dumitru Ioachim[2], Andrei Goldstein[3], Dana Manda[1], Suzana Vladoiu[1] & Corin Badiu[4]
[1]CI Parhon National Institute of Endocrinology, Scientific Laboratory, Bucharest, Romania; [2]CI Parhon National Institute of Endocrinology, Pathology, Bucharest, Romania; [3]CI Parhon National Institute of Endocrinology, Nuclear Medicine, Bucharest, Romania; [4]CI Parhon National Institute of Endocrinology, Thyroid related disorders, Bucharest, Romania

Background
Differentiated thyroid cancer (DTC) encompases a wide spectrum of disease from clinically insignificant micro-tumors to aggressive cancers. The molecular signature can be used to predict tumor behaviour, and the co-existence of BRAF and TERT promoter mutations has been identified as a marker of adverse prognosis, but we have yet no available molecular data for the Romanian population.
Objectives
To determine the prevalence of BRAF V600E and TERT promoter mutations in the Romanian thyroid cancer patients and to evaluate the association between mutational status and the clinical and pathological characteristics used in risk stratification.
Methods
We evaluated 68 tissue samples from 58 patients with DTC followed up in 'CI Parhon' Institute. Paraffin embedded tissue was used to extract genomic DNA, and BRAF V600E and C228T and C250T TERT promoter mutations were detected using Sanger sequencing.
Results
BRAF V600E mutation was present in 21.2% (11/52) patients, significantly correlated with classical papillary carcinoma and aggressive histology subtypes ($\chi2=11.29$, $P=0.023$), but not with age, invasion, TNM stage or ATA risk group. TERT promoter mutations were identified in 17.3% (9/52) of patients, and were associated with advanced age (age $\geq$45years) ($\chi2=3.352$, $P=0.06$), aggressive histological subtypes ($\chi2=9.04$, $P=0.060$) and advanced local tumor stages ($\chi2=4.121$, $P=0.042$). The patients with concomitant BRAF+TERT promoter mutations ($n=5$) presented with clinically aggressive cancer (high risk ATA) ($\chi2=6.019$, $P=0.049$), while 4/5 were radioiodine resistant.
Conclusions
We identified a low prevalence of BRAF V600E mutations, probably related to geographical (iodine deficiency) and ethnic factors, and a high prevalence of TERT promoter mutations probably due to the large proportion of aggressive cancers included. BRAF and TERT promoter mutation status helps identify patients with clinically aggressive cancer who will require intensive management.

The clinical significance of low dose biotin supplements (<300μg/day) in the treatment of patients with hypothyroidism: crucial or overestimated?
Nikolaos Angelopoulos[1], Rodis Paparodis[2,3], Ioannis Androulakis[4], Anastasios Boniakos[5], Spyridon Karras[6] & Sarantis Livadas[7]
[1]AHEPA University Hospital, School of Medicine, Academic Department of Nuclear Medicine, Thessaloniki, Greece; [2]The University of Toledo Health Science Campus, Center for Diabetes and Endocrine Research, Toledo, Greece; [3]Endocrinology, Diabetes and Metabolism Clinics, Private Practice, Patras, Greece; [4]Private Practice, Endocrinology, Diabetes and Metabolism Clinics, Chania, Greece; [5]Private Practice, Endocrinology, Diabetes and Metabolism Clinics, Petroupoli, Greece; [6]Medical School, Aristotle University of Thessaloniki, Laboratory of Biological Chemistry, Thessaloniki, Greece; [7]Athens Medical Center, Endocrinology, Diabetes and Metabolism Clinics, Athens, Greece

Background
In the last decade, the combination of the widespread use of streptavidin-biotin technology and biotin–containing supplements (BCS) in the daily clinical practice, have led to numerous reports of erroneous hormone immunoassay results. However, there are no studies assessing the clinical and biochemical significance of that phenomenon, when treating patients with hypothyroidism. Therefore, a prospective study was designed to investigate the potential alterations in the measurement of thyroid hormone concentrations and clinical consequences in patients with hypothyroidism using low -dose BCS containing less than 300μg/day.
Methods
57 hypothyroid patients on thyroxine supplementation, as a result of hypothyroidism and concurrent use of BCS at a dose <300μg/day for 10 to 60 days were prospectively evaluated. Namely, TSH and free T4 (FT4) concentration measurements were performed, during BC supplementation and 10 days post BCS discontinuation and compared to 31 age-matched patients with hypothyroidism and normal thyroid hormones levels.
Results
A statistically significant increase in TSH and decline in FT4 concentrations was observed after BCS discontinuation. However, on clinical grounds, these modifications were minor and led to medication dose adjustment in only 2/57 patients (3.51%) in whom TSH was notably decreased after supplement discontinuation. Regarding the impact of biotin dose on thyroid hormone levels, no statistical significant correlation was detected between the biotin dose ingested in either TSH (r2= -0.09, $P=0.53$) or FT4 levels (r2 = 0.08, $P=0.52$). Significant increase in TSH levels was revealed only in the subgroup of patients that were taking BCS in doses > 100 μg daily
Conclusion
Our study suggests that changes in thyroid hormones profiling, due to supplements containing low dose biotin, are of minimal clinical relevance and in most cases don't hide the need to adjust the thyroxine replacement dose in patients with hypothyroidism. Larger, well-designed trials are required to further evaluate this phenomenon.

Corticosteroid therapy in dysthyroid orbitopathy: about 53 cases
Sara Charkaoui, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
CHU Ibn Rochd, Department of Endocrinology, Diabetology and Metabolic Diseases, Ibn Rochd University Hospital, Casablanca, Morocco

Introduction
Dysthyroid orbitopathy is an autoimmune disorder that occurs in the context of dysthyroidism. corticosteroid therapy is the main therapeutic option recommended by EUGOGO for the management of moderate and severe active forms.
Goal of the Study
Describe the clinical, para-clinical and evolutionary characteristics of dysthyroid orbitopathy treated by bolus corticosteroid therapy
Materials and Methods
This is a descriptive and analytical study including all patients with dysthyroidism associated with orbitopathy with an activity score (EUGOGO) $\geq$ 3. The protocol consists of the IV infusion of 6 boluses of 500 mg of methylprednisone per week followed by 6 others of 250 mg per week with a cumulative dose not exceeding 7.5g
Results
Our study involved 53 patients with an average age of 44.5 years. With a male predominance of 62%. The average evolution of the orbitopathy was 15.7 months. The most common etiology was Graves' disease in 96% of cases. Among our patients 18 were active smokers. The majority of patients were in biological euthyroidism. The average activity score was 4.9. In our series, 52% of patients had grade 2 proptosis and 48% had grade 3. Optic nerve damage was objectified in 6 patients. On the therapeutic level, 38 had received the entire protocol while 7 patients had interrupted before the appearance of the effects After 1 month, all the patients who had completed the protocol had reported a marked improvement with an average drop in the activity score of 3.5 which

Conclusion
Our study showed the effectiveness of corticosteroid therapy in the management of active dysthyroid orbitopathies at the cost of acceptable intolerance.

Objective
Distant metastases from papillary thyroid carcinoma (PTC) are relatively rare and may be associated with a poor prognosis. Herein, we describe a case report with adrenal and lung metastasis of follicular variant of PTC in the context of the review of the literature.
Case Report
A 52-year-old male presented with complaints of swelling of his neck and cough. He had been diagnosed with multinodular goiter, obesity, pre-diabetes, and hypogonadism. Bilateral multiple pulmonary nodules were detected on thorax CT. The fluoro-deoxyglucose positron emission tomography (18F-FDG PET) revealed an extremely hyperplastic and multi nodular thyroid gland with an increased FDG uptake (SUVmax: 14.2). Increased FDG uptake was present both in pulmonary nodules (SUVmax: 2.3) and also on left adrenal gland (SUVmax: 5.8). Neck ultrasonography showed conglomerated multiple isoechoic, hypoechoic nodules with cystic degeneration and increased vascularity in both lobes. Fine needle aspiration biopsy of the dominant nodule was suspicious for follicular neoplasm with positive immuno-reactivity for TTF-1, PAX8. Magnetic resonance imaging (MRI) of the abdomen demonstrated a centrally necrotic heterogeneous left adrenal mass, measured 75x60x 80 mm. It was nonfunctioning through biochemical evaluation. Biopsy from adrenal gland was compatible with thyroid carcinoma metastasis which was strongly positive for TTF-1, PAX8, thyroglobulin and HBME-1. The patient underwent total thyroidectomy and cervical lymph node dissection. A 12 cm multifocal, follicular variant of PTC with vascular invasion was detected. Tumor invasion was detected in the right jugular vein and trachea. The patient subsequently underwent left adrenalectomy, the tumor size was 10 cm. Histopathology was consistent with metastatic follicular variant of PTC. Postoperatively, the patient was administered 150 mCi of radioactive iodine orally. Whole body scanning after 131I treatment revealed radioiodine uptake in thyroid bed and bilateral lung metastasis.
Conclusions
PTC metastasizes principally to local lymph nodes. Distant metastases are uncommon and associated with poor prognosis. Among such patients pulmonary and skeletal metastases are followed by very rare and sites like brain, kidneys, liver, adrenals, breasts, skin, eyes, and pancreas. Metastasis to adrenal gland is quite rare. Around 20 cases of TPC with adrenal metastasis have been reported to date. Here, we report a rare case of follicular variant PTC with left adrenal metastasis. The patient also had synchronous involvement of the cervical lymph nodes, trachea, right jugular vein and lung. Multidisciplinary care team coordination is essential for accurate diagnosis and treatment plan formulation.

Retrospective analysis of diagnostic and therapeutic management in thyroid cancer patients in 2019- 2021 to assess the possibility of treatment de-escalation

Magdalena Kolton[1], Daria Handkiewicz-Junak[1] & Jolanta Krajewska[2]
[1]M. Sklodowska-Curie National Research Institute of Oncology Gliwice Branch, Gliwice, Poland, Nuclear Medicine and Endocrine Oncology Department, Gliwice, Poland; [2]M. Sklodowska-Curie National Research Institute of Oncology Gliwice Branch, Gliwice, Poland, Nuclear Medicine and Endocrine Oncology Department, Gliwice, Poland

Introduction
In recent years, there has been a significant increase in the detection of thyroid cancer (TC) and a number of thyroid surgeries. Both the ATA 2015 and 2022 Polish guidelines allow sparing treatment in low-risk TC, nevertheless, most patients are qualified for total thyroidectomy.
Material and method
The present study analyzed how often a TC patient opts for sparing treatment and the relationship between the size of the primary focus and risk factors on histopathological examination. The possibility of preoperative evaluation of low-risk cancer was attempted. The stage of the disease, the extent of surgery, and the occurrence of risk features on histopathological evaluation were determined.
Results
A group of 1000 TC patients diagnosed between 2019 and 2021 mainly with thyroid microcarcinoma and low-risk TC was analyzed. It was shown that there was a correlation between the diameter of the tumor infiltration on histopathological examination and the occurrence of risk features. A primary tumor size of 2 cm was defined as safe for qualification for thyroid lobectomy.
Conclusions
There is a limited willingness of low-risk TC patients to undergo lobectomy. It is therefore necessary to educate physicians and patients to convince them to undergo less extensive treatment in low-risk TC.

Predictive factors affecting prognosis in papillary thyroid microcarcinomas

Yusuf Kayhan[1], Leyla Azizova[2], Merve Yilmaz[3], Muhsine Bakış[2], Sema Çapkinoğlu Türk[1], Betül Gündüz[1], Elif Kılıç Kan[1], Aysegul Atmaca[1] & Ramis Çolak[1]
[1]Ondokuz Mayis University, Endocrinology and Metabolism, Samsun, Turkey; [2]Ondokuz Mayis University, Internal Medicine, Samsun, Turkey; [3]Samsun Gazi State Hospital, Endocrinology and Metabolism, Samsun, Turkey

Background
Papillary thyroid microcarcinoma (PTMC) is a papillary thyroid cancer (PTC) type with a maximum diameter of $\leq$ 10 mm. Generally, PTMCs have good prognosis and low mortality risk. However, there are cases of PTMCs showing more biologically aggressive characteristics, such as lymph node (LN) involvement and distant metastasis.
Objectives
Reveal the factors affecting the prognosis and aggressiveness of PTMCs.
Methods
Retrospectively a total of 255 patients over the age of 18 operated on thyroid, at Ondokuz Mayıs University Faculty of Medicine between June 2008 and December 2021, whose pathology results reported as PTMC (maximum tumor diameter of $\leq$ 10 mm), undergoing regular follow-ups for at least 36 months were studied. Age, gender, performed surgical procedure, pathology results, recurrence, distant and lymph node (LN) metastasis, mortality, and follow-up period, tumour histological type, microscopic variant, tumor diameter, bilaterality, focality, tumor localization, presence of capsule of the tumor, capsule invasion in the tumor, parenchymal, lymphatic, perineural, and vascular invasion, necrosis, mitosis, calcification, surgical borders were studied.
Results
The mean tumour size was 5 mm (0.1-10 mm), and multifocality was seen in 137 (53.7%) patients. Capsule invasion was observed in 23 (9%) patients. Vascular invasion was present in 5 (2%) patients, the lymphatic invasion was present in 14 (5.5%) patients, and extrathyroidal invasion was present in 2 (0.8%) patients. Metastatic cervical LN were present in 24 (9.4%) patients. Comparing patients with and without LN metastasis in terms of pathology results, it was observed that lymphatic invasion and calcification presented by the tall cell variant were significantly higher in patients with LN metastasis. In addition, tumor size was larger in those with LN metastasis. Tumor size ($P=0.004$; OR = 1.380; 95% CI = 1.106-1.722) and gender ($P=0.013$; OR:4.233; 95% CI = 1.355-13.226) were found to be the main predictive factors affecting LN metastasis, as a result of the regression analysis. It was observed that LN metastasis were more common in males than females and seen more frequently as the tumour size increased.
Conclusion
Male gender and large tumour size (cut-off 6.75 mm) were found to be the factors associated with LN metastasis. It is recommended that these factors should be considered in the treatment decision, especially in LN-negative patients, regarding

prophylactic central compartment neck dissection. In case of the distant metastasis without regional LN metastasis, further studies on molecular markers are needed.

Epidemiology of thyroid cancer in Tunisia

Selma Mohsen[1], Khiari Hyem[1], Mziou Emna[1], Mehrez Achwak[2] & Berriche Olfa[3]
[1]Institut Salah Azaiez, Medecine Preventive, Tunis, Tunisia; [2]Institut de Nutrition, Tunisia; [3]Institut de Nutrition, Service A, Tunisia

Introduction
In 2020, Thyroid cancer was responsible for 586,000 cases worldwide, ranking in 9th place in terms of incidence. It is also the most common type of cancer of the endocrine system in 2020. According to the literature, thyroid cancer have reported an increase in the incidence worldwide. However, it varies greatly from country to country. The aim of this work was to evaluate the incidence of thyroid cancer and its trend in northern Tunisia between 1990 and 2019.
Materials and Methods
The data source for this study was the population based cancer registry in Northern Tunisia 2010-2014. This registry shelter around the half of the Tunisian population. Trend analysis was performed using JoinPoint software.
Results
Between 2010 and 2014, 1226 cases of thyroid cancer were recorded in Northern Tunisia. The mean age at diagnostic was around 50 years old. The standardized incidence rate was of 1.9/100.000 for men and 6.9/100.000 for women. This cancer ranked 3rd in females and 14th in males. Papillary carcinomas and adenocarcinomas were the most common histological types. This cancer was generally diagnosed at a local stage (44.7% in men and 66.7% in women). The trend of the incidence was significantly upward between 1994 and 2014 for both genders, with a Mean Annual Percent Change of 2.6% in males and 3.1% in females ($P < 0.05$).
Conclusion
The increasing trend in the incidence of thyroid cancer may reflect improved diagnostic techniques but also overdiagnosis which constitute a problem of overtreatment.

Incident gout attack precipitated by primary hypothyroidism: a case report

Najoua Lassoued, Malak Belkhiri, Zantour Baha, Alaya Wafa & Sfar Mohamed Habib
Taher Sfar Hospital University, Endocrinology Department, Tunisia

Introduction
Thyroid hormones in fluence kidney function and thereby might alter serum urate levels, a major risk factor for gouty arthritis. Previous research documented a high prevalence of elevated levels of Uric acid in primary hypothyroid patients. We present the case of an incident gout attack in a patient with primary hypothyroidism.
Case report
A 72-year-old male was hospitalized for a primary hypothyroidism complicated by a rhabdomyolysis. Laboratory examinations reveled a low serum FT4 = 3.67 pg/ml (NR 7–18) and an elevated serum TSH = 46.6 IU/l, eGFR =42. The patient was treated initially with levothyroxine 12,5 µg/day . During his hospitalization, he complained of sudden onset of throbbing pain in the right wrist, rankles and metacarpophalangeal joints in a context of apyrexia. Physical examination disclosed marked deformities of his hands, feet, and synovitis localized to his wrist and ankle on the right side. The squeeze test was positive. There was no Tophi. Serum uric acid was severely elevated 731 umol/l (180-420). Sedimentation rate was normal. Joint X-rays rule out other causes of joint inflammation. Immunological investigation was negative. The diagnosis of a gout attack was finally retained. The patient was therefore referred to rheumatology department.
Conclusion
This case illustrates an incidental gout attack that was precipitated by primary hypothyroidism in a patient who had no history of gout disease. This leads us to check regularly uric acid in patients with hypothyroidism and to check the thyroid status in patients who presents for gout attack.

Multinodular Goitre followed by a new diagnosis of PTEN Hamartoma Tumor Syndrome in an adult patient- A Case report

Aiman Haddad, Tanya Chopra, Elizabeth Hyams, Shivani Joshi, Shivashankar Seechurn & Bara Taufik
Northwick Park Hospital, Endocrine & Diabetes, Harrow, United Kingdom

Introduction
PTEN Hamartoma Tumor Syndrome (PHTS)is a rare genetic spectrum of disorders characterised by multiple hamartomas and increased risk of cancers including thyroid cancer. People with PHTS have an increased lifetime risk of differentiated thyroid carcinoma (DTC), estimated to be about 35% compared to the general population risk of below 1% (1).
Case Presentation
We report a 38-year-old male who presented with a Goitre found on routine examination present for over 2 years. Noticeably, he had unexplained mild learning difficulties and macrocephaly present since childhood. There were no risk factors for thyroid cancer on the first assessment. His thyroid function tests were normal, thyroid ultrasound USS showed a multinodular goitre with a U3 nodule and his fine needle aspiration FNA cytology was in keeping with non-neoplastic Thy2. He was also investigated for new rectal bleeding and found to have multiple bowel polyps on colonoscopy. He underwent diagnostic PTEN genetic testing and was found to have a pathogenic mosaic gene change in the PTEN gene, confirming new diagnosis of PHTS. Given the significant risk of a malignant transformation, he was discussed in the thyroid multidisciplinary team (MDT) meeting, discussing the rationale of prophylaxis thyroidectomy. A previous study favours the rationale of prophylactic thyroidectomy in certain patients with PHTS, particularly in those with developmental delay or who may struggle to adhere to screening guidelines (2). However, another study showed that patients who did not undergo a thyroidectomy also did not develop thyroid cancer during a 10-year follow-up (1). Following MDT decision, our patient underwent a prophylactic total thyroidectomy to reduce his anxiety and avoid the need for ongoing surveillance with USS & FNA.
Conclusion
It is always important to consider hereditary conditions like PHTS when evaluating patients with thyroid nodules. The need for further evaluation despite a non-neoplastic ultrasonographic and cytologic findings has to be guided based on the risk factors for thyroid cancer. Patients with PHTS are at a significantly increased risk of developing DTC and should undergo regular surveillance with consideration of prophylactic total thyroidectomy following MDT discussion.

Hyalinizing trabecular tumor of the thyroid gland. A rare entity with atypical cytological features A case report

Georgios Boutzios[1], Gerasimos Tsourouflis[2], Charikleia Gakioloulou[3], Maria Destouni[3], Sofia Chatzi[1] & Ilias Giovannopoulos[1]
[1]National and Kapodistrian University of Athens, Department of Pathophysiology, Medical School, Athens, Greece; [2]National and Kapodistrian University of Athens, Second Department of Propaedeutic Surgery, Medical School, Athens, Greece; [3]National and Kapodistrian University of Athens, First Department of Pathology, Medical School, Athens, Greece

Introduction
Hyalinizing trabecular tumors are extremely rare and uncommon thyroid tumors, which were first described by Carney *et al*. Until now, their preoperative diagnosis based on cytological characteristics is not possible, because of the lack of specific features and molecular markers.
Case presentation
We present a 38-year-old Caucasian female, non-smoker, with a disease-free medical history, with a right-sided clearly delimited large hypoechoic thyroid lesion measuring 4.2 cm in its greatest dimension as detected by neck sonography. The patient underwent a FNAB, which showed overlapping elongated nuclei, nuclear grooves, pseudoinclusions and stromatic hyaline material between the

cell clusters. The lesion was characterized as suspicious for malignancy (Bethesda Category V). A total thyroidectomy was performed. Histologic examination confirmed a 4.2 cm encapsulated nodule on the right side of the thyroid gland. The tumor cells were polygonal to elongated with eosinophilic cytoplasm and arranged in an alveolar or trabecular pattern, while extensive hyaline material was presented at the stroma. Their nuclei exhibited nuclear grooves and pseudoinclusions. Immunohistochemical staining showed positivity for thyroid transcription factor-1, thyroglobulin and negativity for chromogranin A, calcitonin, carcinoembryonic antigen, cytokeratin 19, HBME-1. These findings were compatible with thyroid hyalinizing trabecular tumor. Treatment of hyalinizing trabecular tumors remains conservative. Patient's follow-up after thyroidectomy remains the same as the one followed after surgical removal of a thyroid neoplasm with low malignant potential.

Conclusion

Novel cytologic features including molecular panels unique for hyalinizing trabecular tumor would be of great value for pre-surgery recognition and prevention of overtreatment with thyroidectomy for treating an almost benign disease.

The relationship of Nodular Goiter Frequency and Iodine Consumption in University Students

Ferhan Mantar[1], Elvan Nur Altuntas Yurttas[1], Ihab Elghorab[2], Ecenur Ozkul[1] & Feriha Goksu[3]
[1]Bahcesehir University, Nutrition and Dietetics, İstanbul, Turkey; [2]King Khalid University, Radiology, Saudi Arabia; [3]Uskudar University, Food Technology, Istanbul, Turkey

Nodular Goiter Disease is very common, its prevalence varies between 26 and 67%. This rate is higher in iodine deficient regions. Recent data indicate that the incidence of both benign and malignant thyroid nodules is increasing. The most important factor in noduler guatr is iodine deficiency. The reported prevalence of nodular disease depends on which population is studied and the methods used to detect the nodules. There are other risk factors that lead to an increased incidence of thyroid nodules. Some factors such as age, gender, genetics and a history of head and neck irradiation are some of these. While these factors cannot be changed, factors such as iodine deficiency, alcohol and smoking are modifiable factors for thyroid nodules. In the study we aimed to determine the frequency of nodular goiter in university students and also to investigate the relationship between the frequency of nodular goiter and dietary iodine consumption. 333 university students participated to our study who were being between the ages of 18-30 and with or without existing thyroid disease. Exclusion criteria were those with diagnosed cognitive dysfunction, pregnant and breastfeeding, odine restriction and who use drugs that could affect thyroid metabolism. Application of the research: As a result of the ultrasonographic imaging, the participants divided into those who have thyroid problems and those who do not. The presence of nodules in those with thyroid problems noted and its relationship with dietary daily iodine consumption by taking daily Food Consumption Frequency Record in both groups investigated. We also demonstrated daily amounts of fiber, some macromicronutrients and also mediterinian diet scores of all participants. We also had information about the smoking and alcohol consumption. The observeted of 333 students, the number of those with nodules is 31 (9.3%) and the number of those who do not is 302 (90.7%). Unpaired/Welch t-test and Two Sample t-test was used to determine the significance level of the relationship between numerical variables. As a result of the analysis, mean iodine consumption was higher in the group without nodules (142.17) than in the group with nodules (121.96). According to the test results, there is a significant difference as statistical between the mean differences. No relationship was found between smoking and alcohol use and the presence of nodules. No statistically significant relationship was found between fiber and the presence of nodules

Cerebral Vascular Accident in a patient presenting with a Thyroid Storm

Ayan Mohamed, Mahamud Bashir, Kirtanya Ramachandran, Lubna Etbinah, Mohammed Mohammed, Juthi Roy & Gideon Mlawa
BHURT NHS Trust, Endocrinology and Diabetes, London, United Kingdom

Thyroid storm is rare life-threatening clinical manifestation of endocrine dysfunction originating from excess level of thyroid hormone leading to hypermetabolic state with an incidence of 0.57-0.76/1000,000. The increase demand of metabolic activity subsequently induces, palpitations, dyspnoea, exercise intolerance and congestive heart failure. Most common cardiovascular manifestation of thyroid storm is tachycardia and atrial fibrillation occurs in up to 15% of patients. In very rare incidence ischemic stroke can co-occur with thyroid storm, whether it is precipitating factor or not is unclear. Without adequate treatment for both thyrotoxicosis and stroke mortality can be as high as 100%, therefore early recognition and management is essential. Herein we present a case of a patient with poorly controlled thyrotoxicosis leading to development of malignant left middle cerebral artery infarct. 58-year-old gentlemen admitted to emergency department with a sudden onset right sided weakness, facial drop, and aphasia with a NIHSS 23/42, His background is hyperthyroidism with poor compliance of medication, DVT, AF, and anaemia. On examination showed low GCS of 11 (E4V1M6), patient was able to track with eyes, no verbal response, with dense right sided weakness ongoing. CT head showed subtle hyperdensity of the left middle cerebral artery and loss of grey-white matter definition within the basal ganglia of the left cerebral hemisphere. Patient was thrombolysed and had thrombectomy, he then developed malignant MCA and underwent decompressive hemicraniectomy which led to an ITU admission where a tracheostomy was also performed. Patient was found to have thyrotoxic storm and was treated with lugols iodine, cholestyramine, iv hydrocortisone, propranolol and high dose propylthiouracil.

Discussion/Conclusion

Thyroid storm is a medical and an endocrine emergency that requires urgent management. Long standing and poorly managed thyroxicosis can cause thyrotoxicosis induced cardiomyopathy leading arrythmias including fast AF as well as heart failure. Fast AF can lead to ischaemic stroke with undesired outcome as demonstrated in this case report. This case highlights the importance of complying with the treatment for thyrotoxicosis as it can cause devastating consequences with severe life threating event with long term effect. In the light of this event, offering definitive treatment (in form of radioactive iodine or thyroidectomy) is vital in to avoid adverse or catastrophic outcome.

Test	Result	Normal value
TSH	<0.01	0.27- 4.2mU/L

Aspects and Evolution of the thyroid gland in Thyroid dyshormonogenesis

Faten Haj Kacem Akid, Samir Mkaouer, Wafa Belabed, Younes Ayadi, Nesrine Dhieb, Mouna Mnif, Nabila Rekik Majdoub, Mouna Elleuch & Mohamed Abid
Hedi Chaker Hospital, Endocrinology Department, Sfax, Tunisia

Introduction

Congenital Hypothyroidism is the principal cause of preventable mental retardation. It is due to Thyroid dysgenesis in 85% of the cases and in 15% to thyroid dyshormonogenesis.

Methods

We conducted a prospective study including 17 patients with familial congenital hypothyroidism due to thyroid dyshormonogenesis other than the features of thyroid gland by ultrasound. Other than the phenotype we evaluated the functionality by thyroid Scintigraphy with Radioactive Iodine. the mean follow up duration and the Evolution of the thyroid gland.

Results

During a long term follow up of 10,11 years [4-24] of 17 patients with congenital hypothyroidism due to thyroid dyshormonogenesis, Sex ratio was 1,83 in favor of male sex. The mean age of diagnosis was 7 year old [1 month-30 years]. Thyroid Gland size was normal in eleven patients, moderate homogenous goiter was present in five patients and One had multinodular gland Isotopic thyroid scan showed Increased Iodine Uptake with a positive perchlorate test in two patients leading to the diagnosis to TPO enzyme defect. Patients were treated with L - thyroxine normalizing TSH levels in 14 patients: baseline mean TSH was 54,92mUI/ml [5,2 -300] and Final TSH levels were 19,17[1,6-43] concomitantly, increasing volume and multinodularity was observed in three out of six patients. Regression of the Goiter was noticed in only one case. Seven out of eleven

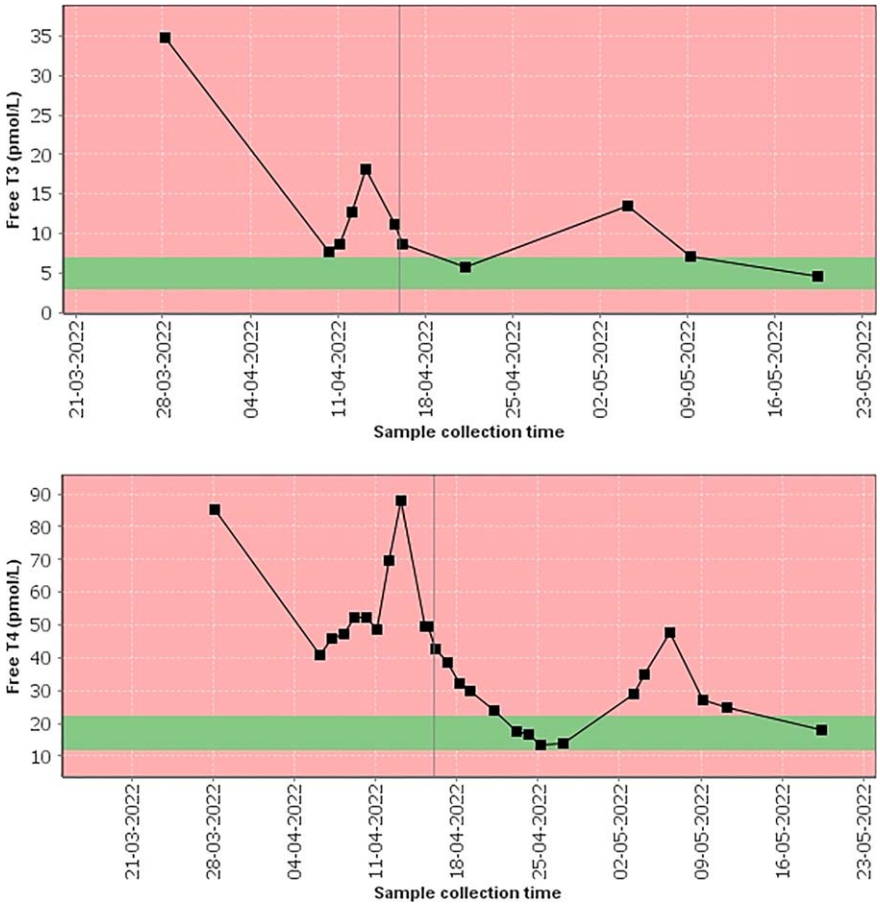

Figure 1 (Abstract P518)

patients, developed a goiter at a mean duration of 13,83 years [2-27], at a mean age 16,71 year old [3-36].

Conclusion

In our study, despite normalization of Tsh levels in our patients, increasing thyroid volume and multinodularity was observed in 52 % suggesting involving other factors than TSH in the development and differentiation of the thyroid gland.

Change in mucosal pigmentation following treatment with radioactive iodine

David Veríssimo[1], Diogo Rombo[2], Teresa Ferreira[2] & Sara Donato[3,4]
[1]Hospital das Forças Armadas, Serviço de Endocrinologia, Portugal; [2]Instituto Português de Oncologia de Lisboa Francisco Gentil, EPE, Serviço de Medicina Nuclear, Portugal; [3]Instituto Português de Oncologia de Lisboa Francisco Gentil, EPE, Serviço de Endocrinologia, Portugal; [4]Nova Medical School, Faculdade de Ciências Médicas de Lisboa, Portugal

Introduction

Treatment using radioactive iodine (RAI) is used in several thyroid diseases, including differentiated thyroid carcinoma (DTC). The most frequent adverse effects include acute gastrointestinal symptoms, sialadenitis, xerostomia, cervical pain, and cervical swelling. Chronic symptoms such as obstruction of the salivary ducts, pulmonary fibrosis or other primary malignant diseases are also described. A single case of change in tongue pigmentation / lingua villosa nigra following treatment with RAI for DTC, was described in a recent case report. We present a similar case of change in tongue pigmentation after treatment with RAI, also associated with nails darkening.

Case report

A 54-year-old black woman followed in our Endocrinology Department for papillary thyroid carcinoma, diagnosed at the age of 47, underwent total thyroidectomy and adjuvant treatment with 100mCi of RAI. Due to pulmonary metastasis, she was treated with a second RAI cycle of 150mCi. At that time, she was medicated with levothyroxine 125 mg/day and was asymptomatic. No relevant laboratory results were observed (hemoglobin 14.1 g/dl, leukocytes 4890x10^3/µL, platelets 374x10^3/µL, TSH $<$0.02 µUI/ml T3 139 ng/dl, antithyroglobulin antibodies $<$40 UI/ml, thyroglobulin 46.3 ng/ml). The treatment was uneventful and post-treatment body scintigraphy did not reveal any uptake, including pulmonary uptake. Two days later, she presented a striated melanonychia, discolored tongue, edema of both hands, generalized joint pain, as well as abdominal pain. These complaints spontaneously reversed over the course of two weeks. One month after the onset of symptoms, on observation, she presented on good condition, afebrile, maintaining a slight swelling of the hands and striated melanonychia on the first fingers of both hands. Her teeth were in good condition and did not presented halitosis. On the dorsal side of the tongue, a diffuse black pigmentation was observed, with discolored areas, but without fissures nor erythema. A salivary gland scintigraphy revealed severe functional and secretory impairment of the left parotid gland and a slight secretory impairment of the submandibular glands. The patient maintained a close follow-up and at the last observation, seven months after RAI treatment, her pain had improved and her tongue had a normal pigmentation, although she maintained striated melanonychia.

Conclusion

We present a case of parotid gland dysfunction associated with lingua villosa nigra as well as other unspecified symptoms, secondary to RAI, similar to a recently described case. However, striated melanonychia was also present and, to our knowledge, it is the first case describing such condition following treatment with RAI.

A case of follicular thyroid cancer in a girl with Graves' disease

Shakhlo Muratova
Republican Specialized Scientific and Practical Medical Center of Endocrinology named after Academician Y. Turakulov, Thyroidology, Tashkent, Uzbekistan

The combination of GD and FTS in children is extremely rare and is poorly understood. RSSPMC of Endocrinology named after Academician Y. Kh. Turakulov, a girl A.M., 12 years 11 months old, living in the Namangan region, was hospitalized for the purpose of diagnosis and correction of treatment. Complaints corresponded to the clinic of HT, also included bilateral protrusion of the eyeballs, lacrimation, reddening of the conjunctiva, feeling of a foreign body in the eyes, blurred vision. Anthropometry revealed severe underweight, BMI 13.9 (BMI z-score = -2.75), secondary short stature (height z-score = -1.31). Pulse 118 beats per minute, blood pressure 130/70 mm Hg. Sexual development according to Tanner 1. The thyroid gland is diffuse on palpation, enlarged to grade 2 (WHO), visible to the eye, stringy, of moderate density, mobile, painless. Peripheral lymph nodes are not palpable. Electrochemiluminescent immunoassays ECLIA from Roche Diagnostics GmbH (Germany) determined overt autoimmune HT. Ultrasound of the thyroid gland - diffuse enlargement of the thyroid gland, volume = 48mm3. Graves' disease, Graves' ophthalmopathy was diagnosed. Thyrostatic therapy was prescribed with the Tab. Thiamazole orally at a dose of 20 mg / day according to a descending scheme under the control of biochemical analyzes and instrumental examination by an endocrinologist at the place of residence. After 2 years, the girl was again admitted to our center with a relapse of GD. Palpation of the thyroid gland revealed nodes in both lobes with a diameter of up to 0.8-1.2 cm, the thyroid gland is mobile, painless, regional lymph nodes are not enlarged. TAB thyroid - Bethesda V. Preoperative preparation was carried out, after reaching euthyroidism, Lugol's solution was prescribed 8 drops 2 times a day and total thyroidectomy (TTE) was performed. Histological examination - follicular thyroid cancer. Conducted radioiodine therapy (RIT) 1200 MBC. Suppressive therapy prescribed. Levothyroxine sodium in a dose. Thyroid status is currently presented in Table 1. There are no complaints. Persistent remission.

Conclusion

GD is a rare pathology in children, FTC is diagnosed even less often. In this case, GD is more often combined with papillary TC. However, this case is an example of the coexistence of autoimmune diseases, Graves' disease, and follicular thyroid cancer in a child who required total thyroidectomy and radioiodine therapy. No matter how extremely rare the combination of GD and FTC in children is, we must remember that this is possible.

Cardiovascular health status among thyroid cancer survivors

Nadjib Kaouache[1] & Nassim Nouri[2]
[1]Béjaïa, Internal medecine, Béjaïa, Algeria; [2]University hospital of Constantine, Endocrinology, Constantine, Algeria

Background

Thyroid cancer have good global prognosis with survival rate exceeding 85% at 5 years. Survivors are exposed to higher cardiovascular morbidity and mortality than the general population. The objective of this study is to quantify the prevalence of cardiovascular health levels in an Algerian cohort of thyroid cancer survivors who were considered free of any classical cardiovascular risk factors or cardiovascular disease

Methods

A cohort of patients followed in the thyroid cancer, and not known or treated for any cardiovascular risk factor or cardiovascular disease, has been screened for cardiovascular risk factors during the period between January 2020 and June 2021. Patients have received a complete evaluated, including three measures of blood pressure, BMI, fasting blood sugar, complete lipid profile, TSH, and FT4, in addition to smoking habits. The prevalence of 6 out of 7 cardiovascular risk factors of the American Heart Association (AHA)'s cardiovascular health (CVH) have been evaluated including nonsmoking, body mass index <25 kg/m^2, physical activity, untreated total cholesterol <200 mg/dl, untreated blood pressure $<120/<80$ mm Hg, and fasting blood glucose <100 mg/dl.

Results

229 patients have been included, median age was 41 years (11-78), median time from diagnosis was 30 months (1-240), 86.5% were females, thyroid cancer type was as fellow respectively; 74%,3% and 12% for papillary, follicular, and medullary thyroid cancer. 83.3% were in stage 1 and 6.6% were in stage 2 according to AJCC 8th edition, and 6.1% had metastasis. All patients were on levothyroxine with median TSH 0.28 at mui/ml. 55.5% of patients have received radioiodine therapy. Only 16.7% have a biological or radiological persistent/recurrent disease. Cardiovascular health level was as fellow; BMI <25 in 28.7% of patients, 59.6% of patients had fasting blood glucose <100d/dl, 64.6% had total cholesterol <200 mg/dl, 33.8% had systolic blood pressure <120 mmhg, 48.1% had diastolic blood pressure <90 mmhg, and 29.2% had blood pressure $<120/<80$ mm Hg, 11% of survivors made physically active and 96.9% were not smoking. no patient had all the factors in the objective

Conclusion

In this cohort of Algerian thyroid cancer survivors, the prognosis of cancer is favorable in most cases but the achievement of cardiovascular health is far from being reached. More efforts must be implemented to improve the cardiovascular health of thyroid cancer survivors.

Primary hyperparathyroidism and papillary carcinoma of the thyroid: about a case

Sara Charkaoui[1], Nassim Essabah Haraj[2,3], Siham El Aziz[2,3] & Asma Chadli[3]
[1]Department of Endocrinology, Diabetology and Metabolic Diseases, Ibn Rochd University Hospital, Casablanca, Morocco; [2]CHU Ibn Rochd, Casablanca, Morocco; [3]CHU Ibn Rochd, Service d'Endocrinologie et Maladie Metabolique, Casablanca, Morocco

Introduction

Primary hyperparathyroidism is a frequent pathology. Its association with non-medullary thyroid carcinoma is rare (2.3–4.3%). The aim of this work is to describe the particularities of this association based on an observation.

Observation

This is a 67-year-old patient who was admitted to the department for exploration of primary hyperparathyroidism discovered during a pathological fracture. Biologically she hada calcemia at 130 mg/l a parathyroid hormone at 1541 pg/l. In the morphological assessment the cervical ultrasound had objectified Presence at the level of the lower edge of the right thyroid lobe and in the extra thyroid of two nodular formations measuring respectively 12.2x11.7x11.3 mm and 18.6x 12.2x 11.5 mm suggesting two parathyroid adenomas, associated with a multi-nodular goiter whose most pejorative nodules are lower left lobe measuring 18.3x 14.5x10 mm classified EUTIRADS 4, upper right lobe measuring 9x8.5x7.1 mm, classified EUTIRAD5. A total thyroidectomy and an adenectomy were performed, with an anatomopathological examination showing the presence of a parathyroid adenoma and a papillary carcinoma of the thyroid classified as pT3b, N1a, Mx. The patient was therefore sent to the nuclear medicine department for additional treatment with radioactive iodine.

Conclusion

The association of papillary thyroid carcinoma and primary hyperparathyroidism has been reported in 2.3–4.3% of patients operated on for primary hyperparathyroidism. Our case showed underlined the interest of concomitant management of parathyroid adenomas and thyroid nodules suspicious on preoperative imaging in order to avoid surgical revision.

Anti-cancer medication related hypothyroidism: Case report

Aygun Huseynova & Valeh Mirzazada
Azerbaijan State Advanced Training Institute for Doctors named after A. Aliyev, Therapy, Baku, Azerbaijan

Here we present a patient who had been on various anti-cancer medications such as tyrosine kinase inhibitors and checkpoint immune inhibitors. Eventually, anti-cancer therapy caused thyroid disfunction. Male, 74 years old, presented with fatigue, somnolence, decreased appetite, diarrhea and depression. His medications included tyrosine kinase inhibitor Axitinib (Inlyta) 5 mg which he has been taking for 1 year and human monoclonal antibody Denosumab (Exgeva) 120 mg since 2016. His family history had diabetes mellitus type 2. He has no family history of thyroid diseases. In 2012 while having routine checkup he was diagnosed with kidney cancer on the right side. He had partial right nephrectomy. However, recurrence occurred in 2015 and he had total right nephrectomy. In 2016 metastasis occurred in the right lung and bones. He was prescribed denosumab (Exgeva) and thyrosine kinase inhibitor pazopanib (Votrient) 800 mg. There was progression of the disease on the pazopanib and the patient had

palliative radiation therapy in 2018 and in 2019. From October 2019 to June 2021 he had therapy with immune checkpoint inhibitor nivolumab (Opdivo) 480 mg. He started treatment with tyrosine kinase inhibitor Axitinib (Inlyta) 5 mg in November 2021 and the dose eventually was raised to 7 mg. During presenting the patient still continued taking the axitinib 5 mg. Thyroid ultrasound showed isthmus size 2 mm, right lobe volume 5 cm^3, left lobe volume 11 cm^3, no nodules presented. The gland had heterogeneous echotexture and normal vascularity. There was no pathology in lymph nodes. The evaluation of thyroid functional tests showed TSH 39.64 μIU/ml (reference 0.35-5.6 μIU/ml), free T4 11.55 pmol/l (reference 7-20 pmol/l), free T3 4.18 pmol/l (reference 3.10-6.80 pmol/l), fasting glucose 100 mg/dl, and HbA1c 5.6%. He undergone repeated laboratory checkup the 6 days after, on 29/09/2022 in another clinic and it showed TSH 34.54 uIU/ml (reference 0.35-5.6 uIU/ml), free T3 5.26 pmol/l (reference 3.1-6.8pmol/l), free T4 10.99 pmol/l (reference 7-20 pmol/l), Ab TPO 0.1 IU/ml (reference <9 IU/ml) and Ab Tg 1 IU/ml (reference 0-4.11 IU/ml). Therapy with levo-thyroxine (L-thyroxine) 25 mg/day was started immediately and gradually raised to 50 mg/day. Since then he is maintaining improvement in his symptoms. Following oncological whole-body 18 F-Fluorodeoxyglucose (FDG) PET/BT showed metastasis in lymph node in left supraclavicular area. Axitinib 5 mg was stopped and Cabozantinib (Cabometyx) 40 mg was prescribed.

A rare association of hyperthyroidism with Darier disease: case report

Hadami Ben Yamna, Marwa Chiboub, Khadija Had, Radhouen Gharbi, Hajer Kandara & Ines Kammoun
National Institute of Nutrition and Food Technology, Department of Endocrinology, Tunis, Tunisia

Introduction
Darier disease, also known as dyskeratosis follicularis, is a rare autosomal dominant genodermatosis characterized by a persistent eruption of keratotic papules. It is caused by mutations in the ATP2A2 gene encoding sarcoendoplasmic reticulum Ca 2+ -ATPase isoform 2 in the endoplasmic reticulum. Since it is expressed in most tissues, other organs besides the skin may be involved in Darier disease. In this case, we report a patient treated for Darier disease who was also diagnosed later with Graves disease.
Case Presentation
We report the case of a 44-year-old male patient, treated for Darier disease since the age of 13, who recently showed nervousness, irritability, weight loss and hand tremors. Initial investigation showed a hyperthyroidism which is confirmed with measurement of a suppressed serum thyrotropin concentration (TSH) at a level of 0, 17 μUI/ml, and elevated free thyroid hormones at a level of at 176 pmol/l. Physical examination showed bilateral exophthalmia, a diffuse homogeneous goiter, systolic hypertension with a blood pressure of 160/80 mmHg, and multiple hyperkeratotic papules, on the chest, upper back, forehead, scalp, nasolabial folds, and ears. Immunological investigation showed positive anti-thyroid stimulating hormone receptor antibody at the level of 41 (normal <1), and positive Thyroid peroxidase antibody (TPO) at the level of 8780 (normal<70). He was treated with two doses of radioactive Iodine-131 (10 mCi than after 7 month 17 mCi) with good evolution. After 2 months, he developed hypothyroidism and is now treated with a dose of 1,5μg/kg/day of levothyroxine.
Conclusion
In conclusion, since intracellular calcium homeostasis is of fundamental importance, Darier disease should be considered a systemic condition that requires screening for other organ dysfunctions like dysthyroidism.

Hypokalemic Thyrotoxic Periodic Paralysis. A case report

Álvaro Mauricio Chávez Villegas, Noemí Jiménez López, Gonzalo Allo Miguel & Miguel León Sanz
University Hospital October 12, Endocrinology and Metabolism, Madrid, Spain

Background
Hypokalemic Thyrotoxic Periodic Paralysis (HTPP) is a rare acquired muscular channelopathy that develops in the context of thyrotoxicosis. It consists of episodes of painless muscle weakness, precipitated by exercise, fasting, or high-carbohydrate meals. Men among ages 20-40 are more frequently affected than woman. Thyrotoxicosis (and its subsequent beta-adrenergic stimulation) increases the activation of the Sodium-Potassium ATPase channels, which leads to hyperpolarization of the muscle membrane and relative inexcitability of the muscle fibers. Peripheric insulin resistance and testosterone have also been described as contributors to the phenomenon, although the complete pathogenesis remains unclear. The degree of hypokalemia usually corresponds with the severity of clinical manifestations. We present one case of Thyrotoxic Periodic Paralysis with severe hypokalemia in the context of thyrotoxicosis.
Case description
A 23-year-old male attends the ER complaining of acute muscle weakness after an extenuating work-out prior to the visit. The symptoms progressively worsen during the night, leading to the development of tetraparesia and generalized paraesthesia. The patient refers at least three previous episodes in the last two years. Neurologic examination confirms proximal weakness in the four limbs, predominantly in lower extremities, with preserved consciousness and normal breathing pattern. Urgent laboratory test reports serum Potassium (K+) of 1.1 mEq/l. EKG shows sinus tachycardia, ST depression and frequent SV extrasystoles. Due to life-threatening risk, continuum cardiologic monitorization and intensive intravenous K+ repletion through central line is initiated in the Intensive Care Unit. After stabilization, patient confirms that he has been suffering from tachycardia, sweating, heat intolerance and distal tremor for several months. The anamnesis was negative for other symptoms or signs of hyperthyroidism. However, lab test shows supressed serum TSH (<0.005 μIU/ml) and elevated Free T4 (5.97 ng/dl), Free T3 (13.75 pg/ml) and positive Thyroid-Stimulating Immunoglobulin (TSI) (7.36 IU/l), confirming the diagnosis of Graves-Basedow Disease. Anti-thyroid medication and beta-blockers are initiated. During the evolution in hospitalization, the clinical manifestations eventually subside, accompanied by progressive normokalemia and overall clinical stability in a period of 5 days.
Conclusion
In the context of Periodic Paralysis, finding of hypokalemia must be an alert about a case of HTPP. Therefore, thyrotoxicosis should be evaluated, particularly in the absence of a family history of periodic paralysis. Monitorization and K+ supplementation must not be delayed. Restoration of euthyroidism is the only preventive measure to eliminate attacks of HTPP.

Preoperative thyroid tumor markers significance - two case reports of misleading values

Ricardo Fonseca, Catarina Roque, Ana Sofia Osório & Sofia Castro Oliveira
Hospital Fernando Fonseca, Amadora, Portugal

Background
Basal tumor markers are valuable in preoperative evaluation of medullary thyroid carcinoma (Calcitonin and CEA), but are insensitive and nonspecific for papilary thyroid cancer (thyroglobulin). Even if their utility is questionable or not recomended in the evaluation of thyroid nodules, in some cases refered to endocrinology department they are available and can be misleading. We present two cases of thyroid nodules with very high preoperative tumor markers.
Case 1
A 67-years old man, with history of hepatocellular carcinoma, had a markedly elevated CEA (188ng/ml; reference range <6.5ng/ml), without an evident diagnose. The calcitonin was measured and the result was 8024ng/l (<14,3ng/l). The patient was referred to endocrinology department to further investigation. The thyroid ultrassonography showed a nodule in the right lobe with 77x52x38mm predominantly solid, mildly hypoechogenic. Fine-needle aspiration was benign, immunohistochemical staining of calcitonin and CEA negative, with high calcitonin in the washout fluid (827ng/l), but incomparably lower than serum. Due to discrepancy in the results a 68Ga-DOTANOC PET was performed with high thyroid nodule uptake (SUVmax 12.6). No locoregional lymph node or distant metastasis were identified in the CT/ultrasonography. A total thyroidectomy was performed, with histological result of medullary thyroid cancer. The calcitonin 6 monts after surgery is 2.6ng/l.
Case 2
A 48-years old women presented with a hypertensive crisis with aortic dissecation. Bone metastatis were incidentally found in CT, mainly in iliac, sternum and spine. Due to non evident primary tumor, a FDG-PET was performed with abnormal uptake in a thyroid nodule (SUVmax 26), bone lesions and also in parotid gland. Thyroid function and serum thyroglobulin (Tg) levels were prescribed and the patient was referred to endocrinology department. The thyroid ultrassonography showed a 30x26x47mm predominantly solid, mildly hypoechogenic, without any suspicious lymph node. Fine-needle aspiration was non-diagnostic. Thyroid function was normal (TSH 2,17mUI/l), but Tg levels were very high (15362 mg/l; reference <77 mg/l). The bone lesions biopsy was compatible with adenocarcinoma, without expression of TTF1, PAX8 or Tg. The patient died due to disseminated intravascular coagulation, and primary tumor was not found in autopsy.

Discussion
Thyroid tumor markers are helpful in postoperative evaluation. Calcitonin is an important marker preoperatively in medullary thyroid carcinoma. However, a very high level as presented in our case isn't pathognomonic of distant metastasis. Preoperative serum Tg levels are nonspecific and can be misleading in cases of distant metastasis without evident primary tumor, as presented in our second case.

A case of Kikuchi-Fujimoto disease with fluctuating thyroid autoantibodies

Kalyani Nagarajah[1], Win Lei Yin[2], Andrew Lansdown[2] & Justyna Witczak[2]
[1]Department of Medicine, University Hospital Llandough, Endocrinology and Diabetes, Llandough, United Kingdom; [2]Department of Medicine, University Hospital of Wales, Heath, Department of Endocrinology, Cardiff, United Kingdom

Introduction
Kikuchi-Fujimoto disease (KFD) is a benign self-limiting disease presenting with fever and lymphadenitis and mostly affecting adults younger than 40 years of age and of Asian descent. Its aetiology and pathogenesis are unknown though KFD often occurs in patients with concomitant autoimmune illness such as autoimmune thyroiditis or lupus erythematosus (SLE). We report a case of a patient with KFD and fluctuating thyroid function and thyroid autoantibody levels.
Case Report
A 35-year-old female patient presented with 4 months history of flu-like symptoms with fever, myalgia and persistent right axillary lymphadenopathy. She had past medical history of Graves' disease diagnosed at the age of 15 when she presented with clinical and biochemical thyrotoxicosis (no treatment was given at that time). Eight years later she became hypothyroid with positive anti- TPO Ab and levothyroxine was commenced at 75 mg. However, after 6 years, her TFTs showed hyperthyroid picture despite gradually reducing and then withdrawing levothyroxine (TSH $<$0.01 mU/l, Free T4 13.3 pmol/l and Free T3 2.6 pmol/l, TSH receptor antibody (TRAb) $<$0.9 U/l, Anti-TPO Ab 615 U/ml). At the time of presentation with lymphadenopathy, she was found to have slightly raised anti-dsDNA levels (51.6 IU/ml) with negative ANA, ENA, negative Crithidia dsDNA and normal ESR (20 mm/hr), TFTs 2 months before were normal. Subsequent biopsy of right axillary lymph node showed necrotizing lymphadenitis with low ki67 score. SLE and other connective tissue disorders were excluded and diagnosis of Kikuchi-Fujimoto lymphadenitis was made. Following her confirmed diagnosis of KFD, she again developed fluctuating thyroid function tests and symptoms, which were alternating between mild hypothyroidism and hyperthyroidism. Her TRAb and anti-TPO at the time were 35.6 U/l and 615 U/ml respectively. Medical treatment was not recommenced as her symptoms were mild clinically and TFTs were not significantly deranged. KFD resolved spontaneously after 3 months and there has been no recurrence since. Her TFTs and antibodies continue to fluctuate (TSH 2.43 mU/l with normal Free T4 and Free T3, thyroid stimulating immunoglobulins 0.8 IU/l and anti-TPO Ab 626 U/ml) which raises the suspicion for presence of blocking and stimulating autoantibodies.
Conclusion
KFD is a rare usually self-limiting disease with unknown aetiology; SLE and autoimmune thyroid dysfunction, especially Hashimoto's thyroiditis is often described in relation to it. Therefore, close follow up of these patients is required. The patient we report developed unusual for KFD significant fluctuations in her auto-antibodies status which are ongoing.

Myxoedma coma and NAFLD secondary to poorly controlled Hypothyrodism

Mohammed Mohammed[1], Ayan Mohamed[2], Bashir Mahamud[2], Mohammed Abumedian[2], Yousif Saeed[2], Awadelgeed Musa[3] & Gideon Mlawa[2]
[1]BHURT, Romford, United Kingdom; [1]BHURT, Romford, United Kingdom; [3]The Princess Alexandra Hospital, Harlow, United Kingdom

Myxoedema Coma with NAFLD secondary to poorly controlled hypothyroidism. Myxoedema coma is defined as severe hypothyroidism leading to decreased mental status, hypothermia, and other symptoms related to slowing function in multiple organs. It can culminate in severe, longstanding hypothyroidism or be precipitated by acute stressors such as infection, and surgery in patients with poorly controlled hypothyroidism. Moreover, there is a strong correlation between poorly controlled hypothyroidism and the pathogenesis of non-alcoholic fatty liver disease (NAFLD). Although the mechanism of how the two interlink remains unclear. Herein we present a case of a patient with poorly controlled hypothyroidism which caused secondary NAFLD and culminated in myxoedema coma.
Case presentation
A 79-year-old woman presented to the emergency department after being confused and less responsive at home. Her background is Hypothyroidism with poor compliance with her medication, Hypertensive, and CVA. No history of alcoholism. On presentation, her vital signs were unremarkable apart from high blood pressure of 191/112. on examination she was disoriented, physical examination was remarkable for periorbital oedema and lower limb oedema. Abdominal ultrasound showed fatty liver, CT Angiogram showed an Enlarged thyroid gland with retrosternal extension. Myxoedema coma was diagnosed, which was treated with hydrocortisone, the loading dose of levothyroxine100 micrograms followed by 50 micrograms daily with an increase of 10 micrograms till reached 100 micrograms and liothyronine 10 micrograms twice per day were given. Over 10 days patient consciousness returned to normal as well liver enzymes.
Discussion/conclusion
Myxoedema coma is a medical emergency that requires urgent management. In our case, the precipitating factor was likely poor compliance with medication for her hypothyroidism. In the case presented here patient abdominal ultrasound showed fatty liver stranding, after excluding organic and other causes of Non-Alcoholic Fatty Liver Disease it was concluded that the most probable cause of NAFLD was due to the patient's severe and poorly controlled hypothyroid. After starting Thyroxine Liver enzymes show marked improvement and return to normal levels. Based on the findings from this case we recommend screening for thyroid dysfunction in the patient that presents with non-alcoholic liver disease.

Test	Result	Normal value
Haemoglobin	108	115 – 155 g/l
ALT	814	$<$33 U/l
AST	232	$<$33 U/l
GGT	68	$<$40 U/l
Bilirubin	14	1 - 21 umol/l

Coexistence of thyroid nodule and Graves' disease: Is it a favorable factor for papillary thyroid cancer?

Yağmur Yatkın Keleş[1], Zeynel Abidin Sayıner[2], İpek Köroğlu[2], sadettin öztürk[2] & Ersin Akarsu[2]
[1]Gaziantep University School of Medicine, Internal Medicine, Gaziantep, Turkey; [2]Gaziantep University School of Medicine, Endocrinology and Metabolism, Gaziantep, Turkey

Introduction
The incidence of papillary thyroid cancer (PTC) in the coexistence of Graves' disease (GD) and thyroid nodule is not known clearly, and the pathophysiology of PTC development in these patients is still unclear.
Aim
The aim of our study is to compare the clinicopathological features of GD patients with thyroid nodule + PTC and patients with euthyroid and non auto-immune thyroid nodule + PTC and investigate the clinicopathological features' of the patients.
Material and Method
Preoperative and postoperative clinicopathological features of 239 patients diagnosed with PTC between 2000 and 2021 were evaluated retrospectively. The patients were evaluated in 2 groups as GD+PTC and only PTC.
Results
There were 99 patients in the group with GD+PTC and 140 patients in the group with PTC without GD. The female gender was higher in the GD+PTC group.

Tumor diameter was smaller in the GD+PTC group (1,45±1,28 cm vs 1,81± 1,34 cm). Multifocal involvement was significantly less in the GD+PTC group compared to the PTC group. Among the histopathological subtypes of PTC, follicular subtype was more common in patients with non-GD PTC. Frequency of tall cell subtype was similar between two groups.
Conclusion
Malign thyroid nodules' ultrasonographic features are not different in patient with GD and PTC. In addition, presence of less multifocality and smaller tumor size in papillary carcinoma patients with Graves' disease may be considered a favorable feature.

Assessment of sleep quality in patients in remission from differentiated thyroid carcinoma: a case-control survey

Abdel Mouhaymen Missaoui[1], Fatma Hamza[2], Siddiqa Soomauroo[1], Khawla Ben Ahmed[2], Wafa Belabed[1] & Mohamed Abid[1]
[1]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Habib Bourguiba University Hospital, Department of Nuclear Medicine, Sfax, Tunisia

Objective
To evaluate the quality of sleep in patients in remission of differentiated thyroid cancer (DTC)
Patients and Methods
Comparative case-control study conducted at the Nuclear Medicine Center of Sfax, Tunisia including 99 individuals divided into 2 subgroups G1 ($n=39$) patients in remission from DTC G2 ($n=60$) healthy control subjects Sleep quality was assessed according to the 7 components of the Pittsburgh Sleep Quality Index (PSQI)
Results
The mean sleep period was significantly shortened in G1 patients (06H:43' vs 07H:05'; $P=0.022$). The duration of sleep in G1 patients was significantly longer than in the control group (41.5±35.4 vs 25.6±21.9 min; $P=0.035$). Subjective sleep quality (component 1), sleep latency (component 2) and sleep duration (component 3) were impaired in both groups. Sleep efficiency (component 4) is significantly lower for patients with DTC ($P=0.000$). G1 patients experience more sleep disturbances (component 5) ($P=0.000$). The use of sleeping pills (component 6) is significantly more frequent in G1. Sleep-related daytime dysfunctions (component 7) are comparable between the two groups. The global PSQI score was significantly higher in G1 (7.7±3.2 vs 5.9±2.8 points; $P=0.049$)
Discussion
Several sleep components are impaired in patients in remission from DTC compared to the general population. These patients frequently suffer from more disrupted and less compensatory sleep than normal subjects. Electro-physiological and neuro-hormonal studies are required to determine the mechanisms of these dysfunctions.

Transition from hypothyroidism to hyperthyroidism following R-CHOP treatment in mantle cell lymphoma patient

Anamarija Zrilic Vrkljan[1], Jelena Andric[2], Mirna Hrabar[2], Ivona Šamle[2], Srecko Marusic[2] & Vlatka Pandzic Jaksic[3]
[1]University Hospital Dubrava, Department of Endocrinology, Diabetes, Metabolism and Clinical Pharmacology, Zagreb, Croatia; [2]University Hospital Dubrava, Department of Endocrinology, Diabetes, Metabolism and Clinical Pharmacology, Zagreb, Croatia; [3]University Hospital Dubrava, Department of Endocrinology, Diabetes and Metabolic Diseases, Zagreb, Croatia

The most common cause of primary hypothyroidism is Hashimoto's disease, while the most common cause of hyperthyroidism is Graves' disease; both conditions are autoimmune diseases. In clinical practice, the switch from hypothyroidism to hyperthyroidism is a rare phenomenon. So far, the etiology and mechanisms of conversion have not been determined. We present a case where we believe the monoclonal antibody rituximab was the primary cause of transition. A 58-year-old male patient presented to the hospital with enlarged neck lymph nodes. After undergoing a number of tests, he was diagnosed with 3 synchronous primary neoplasms: mantle cell lymphoma (B-cell lymphoma), localized colorectal cancer, and localized right kidney cancer. At the same time, he was also diagnosed with diffuse thyroid goiter and hypothyroidism (TSH 67.35 mIU/l, FT-4 3.4 pmol/l), and levothyroxine therapy was begun. First, the patient underwent surgery: a rectosigmoid colon resection and right-sided nephrectomy were performed. Due to the low grade of the lymphoma, the immunochemotherapy treatment was postponed so that the patient could receive capecitabine chemotherapy for colon cancer. At the end of capecitabine chemotherapy, the patient was euthyroid with 175 mg/day of levothyroxine, and R-CHOP (rituximab, cyclophosphamide, hydroxydaunorubicin hydrochloride, vincristin, and prednisone) treatment for mantle cell lymphoma was started. The patient received 8 cycles of therapy within 6 months, which resulted in disease remission; however, at the end of the last cycle, the TSH values were lowered. Levothyroxine dosage was gradually reduced as a result of decreasing TSH levels, and it was completely discontinued 4 years after the end of the R-CHOP treatment. Despite discontinuation of the therapy, the patient's TSH remained <0.005 pmol/l; unfortunately, we missed levels of thyrotropin receptor antibodies (both blocking and stimulating). The patient started losing weight and had exophthalmos, therefore, thyrostatic therapy with thiamazole was started. Initially, the patient responded well to the therapy, but over time there was a relapse of hyperthyroidism, which no longer responded to thiamazole, necessitating a total thyroidectomy. Until now, nine years following the diagnosis of three primary malignant diseases, there have not been any disease relapses. There are a variety of opposing theories described in the literature about how rituximab affects the thyroid. While it is used to treat resistant Graves' orbitopathies, in our patient's case, it appears that rituximab led to the resolution of the hypothyroidism and caused the hyperthyroidism. However, it remains unclear whether chemotherapeutic agents used in combination with rituximab contributed to that transition.

A rare case of rapidly progressive Graves' orbitopathy in an elderly patient with a new-onset hyperthyroidism

Carla Pandozzi, Marta Tenuta, Alessia Cozzolino, Tiziana Feola, Roberta Centello, Alessia Filice, Elisa Giannetta & Andrea M. Isidori
Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy,

Background
Graves' orbitopathy (GO) is the major extrathyroidal manifestation of Graves' disease (GD). Even if usually mild and non-progressive, in its worst forms, GO can represent a major therapeutic challenge, because is not always responsive to the available medical treatments. First line treatment for moderate-to-severe and active GO relies on intravenous (i.v.) methylprednisolone. Optic neuropathy is a sight-threatening complication which can seriously impact the quality of life and should be immediately treated. Here we present a complicated case of worsening and aggressive GO.
Case report
In March 2022 a 78-years-old woman presented to the endocrinological outpatient clinic for newly diagnosed hyperthyroidism. Positive TSH receptor antibodies (TrAb) confirmed GD diagnosis. In medical history: atrial fibrillation on amiodarone therapy (discontinued in June 2021 because of hypothyroidism) and high blood pressure. The third dose of anti-COVID-19 vaccine was received in December 2021. During the first visit, mild ocular involvement was detected, therefore oral prednisone (25 mg per day) was prescribed together with methimazole (20 mg per day) and selenium supplementation. After 40 days, a rapid worsening of the ocular pattern occurred. The eye examination showed bilateral exophthalmos, eyelid oedema, conjunctival chemosis, with a reduced ocular motility and visual acuity. Therefore, i.v. methylprednisolone was planned, with a cumulative dose of 4.5 g in 12 weekly infusions (6 of 0.5 g plus 6 of 0.25 g). Nonetheless, after the second infusion, the orbit MRI showed diffuse hypertrophy of the oculomotor muscles with incarceration of the optic nerves. Considering the severity and evolutionary nature of the GO, in June 2022 the patient underwent urgent orbital decompression surgery, and daily 0.5 g methylprednisolone i.v. was prescribed in the perioperative days. After discharge, treatment with i.v. methylprednisolone was continued and cyclosporine (100 mg daily) was added to the treatment, with a significant clinical improvement, except for visual acuity. From August 2022, scalar therapy with oral prednisone together with ciclosporine was planned up to the maintenance dosage. The latest eye re-evaluation found in right eye only light perception and in left eye a perception of 2/30. Orthoptic rehabilitation was finally planned, although very little chance of recovery.
Conclusions
Although rare, GO can occur in acute and rapidly progressive forms, even in patients with mild hyperthyroidism and low TrAb levels at diagnosis. Since a sudden worsening can arise, GO patients should be carefully and strictly observed, hopefully in a centre equipped for multidisciplinary (both clinical and surgical) management.

Treatment Response With VRDN-001, a Full Antagonist Antibody to IGF-1 Receptor, in Thyroid Eye Disease (TED): Phase 1/2 Clinical Study

Barrett Katz[1], Roger Turbin[2], Kimberly Cockerham[3], Rosa Tang[4], Navdeep Nijhawan[5], Shoaib Ugradar[6], Denis J. O'Shaughnessy[1], Rochelle M. Summerfelt[1], Angela She[4] & Raymond Douglas[7]
[1]Viridian Therapeutics, Inc., Waltham, United States; [2]Rutgers New Jersey Medical School, Department of Ophthalmology, New Jersey, United States; [3]Stanford Department of Ophthalmology at Byers Eye Institute, Stanford, United States; [4]Eye Wellness Center– Neuro-Eye Clinical Trials, Inc., Bellaire, United States; [5]Oshawa Clinic, Oshawa, United States; [6]The UCLA Stein Eye Institute, Los Angeles, United States; [7]Cedars Sinai Medical Center, Los Angeles, United States

Purpose
IGF-1R antagonism reduces TED-related inflammation and proptosis. VRDN-001, a subnanomolar affinity full antagonist antibody to IGF-1R, is being evaluated in a phase 1/2 RCT (NCT05176639) at 3-20 mg/kg. We present results from the first cohort (10 mg/kg) of TED patients.
Methods
Adults with active moderate-to-severe TED with clinical activity score (CAS) ≥ 4 were randomized to 2 infusions 3 weeks apart of either 10 mg/kg VRDN-001 or placebo (3:1). Safety, tolerability, and efficacy through 12 weeks were assessed.
Results
Baseline characteristics were similar between VRDN-001 ($n=6$) and placebo ($n=2$). At 6 weeks, overall responder rate (% of patients with ≥ 2 mm reduction in proptosis and ≥ 2 point reduction in CAS) was 83% (5/6; VRDN-001) vs. 0% (placebo); proptosis responder rate (% of patients with ≥ 2 mm reduction) was 83% (5/6; VRDN-001) vs. 50% (1/2; placebo). At 12 weeks, 80% (4/5) of VRDN-001 responders had maintained both overall and proptosis response. Mean proptosis reduction was 2.4 mm (VRDN-001) vs. 1.0 mm (placebo) at 6 weeks and remained consistent for VRDN-001 at 12 weeks (2.2 mm). MRI analysis at both 6 and 12 weeks confirmed proptosis improvement for all 4 VRDN-001 patients with scans available and showed no improvement in both placebo patients. CAS decreased to 0 or 1 for 83% (5/6; VRDN-001) vs. 0% (placebo) at 6 weeks and was maintained for 80% (4/5) at 12 weeks. Mean reduction in CAS was 4.3 (VRDN-001) vs. 1.5 (placebo) at 6 weeks and remained consistent for VRDN-001 at 12 weeks (4.2). Of the 4 VRDN-001 patients presenting with diplopia, complete resolution occurred for 3 by 6 weeks and all by 12 weeks. VRDN-001 was well-tolerated through 12 weeks. AEs were mostly mild, with no severe or serious AEs reported.
Conclusions
Two infusions of 10 mg/kg VRDN-001 were well tolerated in this cohort of TED patients, and the rapid, clinically meaningful improvement across all efficacy measures by 6 weeks was sustained through 12 weeks. These results were achieved with a lower dose and fewer treatments than in prior RCTs of other anti-IGF-1R antibodies. Results from the additional 3 mg/kg and 20 mg/kg cohorts may extend these findings and define potential VRDN-001 treatment regimens.

Thyroglobulin Point of Care Assay for Rapid Detection of Metastatic Differentiated Thyroid Carcinoma- A Pilot Study

Uri Yoel[1,2], Sagi Angel[3], Emily Bosin[4], Miri Elezra[4], Robert S. Marks[3,5] & Merav Fraenkel[1,2]
[1]Soroka Medical Center, Endocrinology, Be'er Sheva, Israel; [2]Ben Gurion University of the Negev, Faculty of Health Sciences, Be'er Sheva, Israel; [3]Ben Gurion University of the Negev, Biotechnology Engineering, Be'er Sheva, Israel; [4]Soroka Medical Center, Laboratory of Endocrinology, Be'er Sheva, Israel; [5]Ben Gurion University of the Negev, National Institute for Biotechnology in the Negev, Be'er Sheva, Israel

Introduction
Fine needle aspiration (FNA) for thyroglobulin (Tg) measurement (FNA-Tg) and for cytology (FNAC) are recommended for the evaluation of cervical lymph nodes (LN) suspected as differentiated thyroid carcinoma (DTC) metastases. LN proven to represent a metastasis of thyroid origin, change the operation plan, both prior to surgery and while encountering suspicious LN during surgery.
Aim
To assess the diagnostic accuracy of a novel point-of-care assay for Tg (POC-Tg) (PCT Patent Application No. PCT/IL2022/050067), able to detect qualitatively, within minutes, Tg in the needle washout of a suspicious LN.
Methods
Limit of detection for Tg was set at a concentration of 5 ng/ml following needle dilution with 1 mL of 0.9% saline. The POC-Tg was assessed in the FNA clinic when a LN suspected as DTC metastasis was biopsied; and in the operating room (OR) when suspicious LN was found during thyroid surgery. Each LN was evaluated using both the formal method (FNA clinic- FNAC and FNA-Tg; OR- 'frozen-section'), and the POC-Tg. Clinical decisions were made according to the formal evaluation only. The POC-Tg performance was analyzed retrospectively.
Results
FNA clinic: 22 sonographically suspicious LN were tested. Eleven were found to be positive in both our POC-Tg and the formal Tg immunoassay, with final histology reporting metastatic DTC. Ten LN were negative in both our POC-Tg and the standard Tg immunoassay, all with benign cytology. One metastatic LN, as was proven by final histology, was negative in our POC-Tg but showed low detectable Tg in the standard immunoassay.
OR
Four LNs were positive and seven negative in both our POC-Tg, and the 'frozen-section' results.
Conclusion
The diagnostic accuracy of the POC-Tg for LN metastases of DTC origin exceeded 95%, thus might change diagnostic and treatment algorithms.

A Rare Case of Covid-19 Vaccine-Associated Subacute Thyroiditis Causing Thyroid Storm

Zehra Yagmur Sahin Alak, Pinar Uzgec Guller, Metin Güçlü & Sinem Kiyici
University of Health Sciences, Bursa Yuksek Ihtisas Training and Research Hospital, Endocrinology and Metabolism, Bursa, Turkey

Introduction
Subacute thyroiditis (SAT) has been reported after COVID-19 infection and SARS-CoV-2 vaccination. SAT has a mild and self-limiting course. This is the first reported case of thyroid storm following the SARS-CoV-2 vaccine
Case
A 32-year-old female patient had mild anterior neck pain, fatigue, tremor 2 weeks after being administered with the second dose of COVID-19 mRNA vaccine BNT162b2 (Pfizer–BioNTech). Initial biochemical investigations were consistent with thyrotoxicosis (Figure 1). The patient was prescribed a non-steroidal anti-inflammatory drug. After the following two weeks, she developed sweats, palpitations, hand tremor, dizziness, generalized numbness, fever, fatigue, headache and mild vomiting. The physical examination in the emergency department revealed a weak, anxious, agitated woman. She was tachycardic at 127 beats per minute, tachypneic (30 breaths per minute), and mildly hypertensive (140/95 mmHg). However, there was moderate tenderness on palpation of the anterior neck. The diagnosis of thyroid storm was made on a clinical basis according to the Burch and Wartofsky' criteria. She was hospitalized and managed by intensive monitoring, giving propranolol (40 mg$\times$4) and hydrocortisone (50 mg$\times$4, intravenous). Graves' disease couldn't be excluded completely. The sedimentation rate was moderately high (ESR: 47 mm/hr), CRP (3.23 mg)/l) was normal and there were no previously measured values. Propylthiouracil 4x50 mg/day added to treatment. At the 48th hour of the treatment, increased serum liver enzymes (ALT:375 and AST:150 U/l) were detected and antithyroid drug therapy was discontinued. However, the patient responded poorly to the treatment, her thyroid free hormone levels were very high. The patient underwent two plasma exchange procedure. There was no previous history of thyroid disease, upper respiratory tract or COVID-19 infection. She reported neck pain which is typical for subacute thyroiditis developing two weeks after vaccination. Thyroid autoantibodies were negative. Thyroid ultrasound showed diffusely enlarged gland parenchyma with a heterogeneous echotexture and decreased vascular flow. The technetium 99m scintigraphy of thyroid which was performed 4 days after the antithyroid drug discontinuation has revealed a poorly visualized thyroid gland. She was discharged home on oral steroids and a beta-blocker. The changes in her thyroid functions overtime are presented in Figure 1. The patient achieved euthyroid state 1 month after being discharged from the hospital.
Conclusions
We herein present a case of thyroid storm related to SAT -reported for the first time- following SARS-CoV-2 vaccination. Clinicians should be aware of the rare post-vaccine side effects.

Introduction
Adverse pregnancy outcomes have been associated with maternal thyroid dysfunction. However, optimizing the best threshold value to improve maternal and perinatal outcomes and alleviate complications by establishing population-based gestation-specific reference intervals (RIs) instead of using recommended universal cut-off values, especially for thyroid-stimulating hormone (TSH), is still an ongoing debate. The aim of this study was to compare the prevalence and risk of pregnancy outcomes based on established gestation- and laboratory-specific RIs and the recommended criteria.
Methods
We conducted a retrospective study on 2104 pregnant women in different trimesters and their infants. The national neonatal screening program was reached to obtain data on TSH measured in capillary blood. We considered TSH thresholds recommended by Endocrine Society clinical practice 2012 and revised American Thyroid Association (ATA) 2017 guidelines to classify thyroid dysfunction. In addition, trimester-specific and subgroup-specific RIs, which were based on our local population, and published previously by our group, were applied for comparison. Outcomes comprised fetal-maternal complications, including gestational hypertension, gestational diabetes mellitus (GDM), preeclampsia, preterm delivery, low birth weight (LBW $\leq$ 2500 g), and elevated neonatal TSH ($\geq$ 5.5mIU/l).
Results
Maternal hypothyroidism based on subgroup-specific classification was associated with a higher risk of GDM than was euthyroidism (2.8% vs. 7.5%; OR 2.78, 95%CI 1.01-7.62; $P=0.047$), while maternal hypothyroidism based on Endocrine Society 2012 criteria was associated with a higher risk of infants with elevated neonatal TSH (2.3% vs. 6.5%; OR 2.93, 95%CI 1.27-6.79; $P=0.012$) in the first trimester. Based on ATA 2017 guideline, trimester-specific and subgroup-specific RIs, lower median birthweight ($P=0.032$, $P=0.031$, $P=0.01$, respectively) was demonstrated in the hypothyroid women in early pregnancy compared to the euthyroid group. Among those tested in the third trimester, maternal hypothyroidism had significantly higher incidences of LBW (3.2% vs. 14.7%, $P=0.009$; 3.5% vs. 27.3, $P=0.008$; 3.6 vs. 15.4, $P=0.02$; 3.7 vs. 14.8, $P=0.025$; based on four different criteria respectively). The incidence of preterm delivery was also higher in hypothyroid women than in euthyroid women in the third trimester (7.5% vs. 20.6, $P=0.017$; 7.7% vs 23.1, $P=0.017$; 7.6% vs 22.2%, $P=0.02$; based on Endocrine Society 2012 guideline, trimester-specific and subgroup-specific RIs, respectively).
Conclusions
Our data confirmed the adverse impact of maternal thyroid function and provided further evidence for an even stronger relationship between maternal hypothyroidism and pregnancy outcomes in the case of applying different thresholds for TSH in pregnant women.

Pre-operative features of borderline thyroid lesions – outcomes of the sonographic and cytopathological analysis

Agnieszka Żyłka[1], Katarzyna Dobruch-Sobczak[2], Hanna Piotrzkowska-Wróblewska[3], Piotr Góralski[1], Jacek Gałczyński[1], Elwira Bakuła-Zalewska[4] & Marek Dedecjus[1]
[1]Maria Sklodowska-Curie National Research Institute of Oncology, Department of Endocrine Oncology and Nuclear Medicine, Warsaw, Poland; [2]Maria Sklodowska-Curie National Research Institute of Oncology, Radiology Department II, Warsaw, Poland; [3]Institute of Fundamental Technological Research, Polish Academy of Sciences, Department of Ultrasound, Warsaw, Poland; [4]Maria Sklodowska-Curie National Research Institute of Oncology, Department of Pathology, Warsaw, Poland

Objectives
In the 5th edition of the WHO Classification of Endocrine and Neuroendocrine Tumors thyroid tumors are divided into several new categories that allow for a clearer understanding of the cell of origin, pathologic features, molecular classification, and biological behavior. According to this classification there are some borderline nodules -the group of low-risk follicular cell-derived neoplasms - such as noninvasive follicular thyroid neoplasm with papillary-like nuclear features (NIFTP), follicular tumor of uncertain malignant potential (FT-UMP) and well-differentiated tumor of uncertain malignant potential (WDT-UMP). The diagnosis is possible only postoperative based on histopathologic results. In order to raise suspicion of borderline lesions preoperatively, the outcomes of sonographic and cytopathological patterns of thyroid nodules were analysed.
Methods
In the present study we retrospectively analysed thyroid nodules of the 35 patients operated on in 2022 diagnosed with NIFTP, FT-UMP and WDT-UMP in final pathology. Sonographic features of nodules including elastography and contrast-enhanced ultrasound (CEUS) were evaluated by two experienced specialist and the risk of malignancy were assessed according to EU-TIRADS classification.
Results
Final histopathologic results included 35 thyroid nodules (in 30 women and 5 men, age ranged: 20-81, diameter range: 6-55,5mm [mean: 28.7]) diagnosed as NIFTP ($n=7$, 20%), FT-UMP ($n=21$, 60%) and WDT-UMP ($n=7$, 20%). Cytopathological results were categorised as follows: Bethesda II ($n=4$), Bethesda III ($n=2$), Bethesda IV ($n=25$), Bethesda V ($n=3$) and Bethesda VI ($n=1$). On ultrasound most of the nodules were predominantly: solid ($n=27$), ovoid shape ($n=33$), longer than tall ($n=33$), with circumscribed margins ($n=26$), mixed vascularization ($n=30$) and heterogenous echotexture ($n=15$), mildly hypoechoic ($n=16$) or isoechoic ($n=13$). The stiffness of nodules was assessed in the strain elastography either Asteria score 2 ($n=16$) or 3 ($n=11$). On CEUS examination the majority of nodules presented contrast enhanced patterns (comparing with thyroid parenchyma) as: iso- or high, heterogenous and centripetal enhancement with fast or equal wash-in and wash-out. Most lesions were classified on ultrasound as low risk - EU-TIRADS-2 ($n=13$) or intermediate risk – EU-TIRADS-3 ($n=15$), but 7 lesions were assigned to EU-TIRADS-5 characterised as taller than wide ($n=2$), markedly hypoechoic ($n=4$) with circumscribed margins ($n=2$).
Conclusions
Preliminary results indicate that most ultrasound features are typical for benign tumors, but still 20% of lesions were assigned to EU-TIRADS-5 category. Despite the fact, that borderline nodules present indolent disease with minimal risk of recurrence, it should not be underestimated, and the proper management of patients should be introduced.

Concordance between the ACR TIRADS ultrasound criteria, the BETHESDA cytopathology classification and final resection result in evaluation of thyroid nodules – Spanish tertiary hospital experience

Izabela Jalowiecka[1], Sandra Garzón Pastor[1], Olivia Sanz Martínez[2], Encarna Martí Ibor[2] & Carlos Morillas Ariño[1]
[1]Doctor Peset University Hospital, Department of Endocrinology and Nutrition, Valencia, Spain; [2]Doctor Peset University Hospital, Department of Anatomical Pathology, Valencia, Spain

Introduction and Aims
Thyroid lesions constitute a frequent consultation in the area of endocrinology. Fine-needle aspiration (FNA) cytology is a gold standard for the evaluation of thyroid lesions, while ultrasound examination according to various thyroid imaging reporting and data system (TIRADS) criteria is gaining importance in the field. The aim of our study was to compare the sensitivity and specificity of both techniques in patients attended in thyroid lesion unit of our hospital in relation to the final resection diagnosis.
Methods
We conducted a retrospective review of lesions studied in our unit since the introduction of the ACR TIRADS criteria (2018-2021). The evaluation included cases

with Bethesda III to VI category since these had higher probability of having been operated. In the case of Bethesda III cytology a second FNA was conducted and if benign the case was labelled as benign and thus not operated. For the final analysis only the nodules with an ultrasound exam, FNA cytology and final result of histopathology (from thyroidectomy or core-needle biopsy in one case) were taken into consideration.
Results
Overall, 106 FNAs were reviewed from which 80 cases met the inclusion criteria. Out of 80 cases, 59 patients (74%) were women, and the average age was of 54 years. The risk of malignancy in presence of ACR TIRADS 3, 4, and 5 were 27%, 55% and 83% respectively and in case of Bethesda III, IV and V/VI category of 39%, 30%, and 92% respectively. To calculate sensitivity and specificity, we labelled TIRADS 2-3/Bethesda III as benign and TIRADS 4-5/Bethesda IV-VI as malignant. The overall sensitivity and specificity of ultrasound with ACR TIRADS was of 83% and 44%, and FNA of 78% and 36%.
Conclusions
Both FNA and TIRAD system showed similar trends in malignancy prediction. Ultrasound evaluation with TIRAD system demonstrated better concordance with final resection result with the exception of TIRADS 5/Bethesda V-VI group where cytological evaluation had better outcomes. Knowing the limitations of both techniques and the results of our and previous studies we consider advisable the use of both modalities adjunctively.

Introduction
Although ^{18}F-FDG-PET has found wide application in the management of radio-refractory differentiated thyroid cancers (RAI-R-DTCs), alternative radiotracers, including ^{68}Ga-PSMA have been recently evaluated. Prostate-specific membrane antigen (PSMA) is in fact overexpressed in the microvasculature of several solid malignancies including thyroid cancers.
Aim
To compare the diagnostic performance between ^{68}Ga-PSMA-PET and ^{18}F-FDG-PET in detecting metastasis of RAI-R-DTCs
Materials and Methods
12 patients with RAI-R-DTCs underwent radiological evaluation between 2020 and 2022: in particular, CT, FDG-PET and PSMA-PET were consecutively performed over a period of no more than 6 months. The ability of FDG-PET and PSMA-PET in detecting metastases previously identified by CT was evaluated. Next, PSMA uptake (SUVmax) was compared with FDG uptake.
Results
In our population, 7 patients showed no pathological uptake, 4 patients had PET-FDG and PET-PSMA positive lesions and 1 patient had exclusively PET-FDG positive metastasis. Compared to patients without any pathological uptake, patients with PET positive lesions received an higher doses of Iodine-131 (100 vs 150 mCi, *P*-value 0.018) and showed higher thyroglobulin values at ablation (10.2 ng/ml vs 266 ng/ml, p value 0.005). A total of 42 lesions were identified by CT scan: 11 involved the lymph nodes, 17 the lungs, 8 the bones and 2 the liver. Altogether, 9 metastasis were FDG-PET positive (21.4 %), 5 were PSMA-PET positive (11.9%) of which 4 were also FDG-PET positive (9.5%). Therefore, regardless of the tracer used, no differences were found in the rate of metastases detection (9/42 - 21.4% vs 5/42 – 11.9%, *P*-value 0.24). FDG-PET positive lesions were thus subdivided: 3 in lymph nodes, 1 in lungs e 5 in bones. Only one lymph node metastasis was exclusively PSMA-PET positive, while 2 lymph node lesions and 2 bone metastasis were both FDG and PSMA-PET positive. These latter had similar SUVmax values, regardless of the tracer used and the site of the metastasis (median SUVmax values 6.2 vs 3.8 in the case of lymph node lesions and 4.8 vs 6.3 for bone metastasis with *P*-value 0.439 in both cases). None of the liver lesions were identified by PET study. Thus, there was no evidence of a different lesion distribution between the two tracers.
Conclusions
Compared to FDG-PET, PSMA-PET seems not to better detect metastasis in RAI-R-DTCs. Further prospective studies with wider populations are necessary to confirm our results.

Cancer rate and characterstics of nodules with macrocalcification

Fatma Tuğçe Şah Ünal[1], Asena Gökçay Canpolat[1], Atilla Halil Elhan[2], Selim Sevim[3], Serpil Dizbay Sak[3], Rifat Emral[1], Özgür Demir[1], Sevim Güllü[1], Murat Erdogan[1], Demet Çorapçıoğlu[1] & Mustafa Sahin[1]
[1]Ankara University Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara University Faculty of Medicine, Department of Biostatistics, Ankara, Turkey; [3]Ankara University Faculty of Medicine, Department of Pathology, Ankara, Turkey

Aim
The aim of this study was to determine the malignant potential of thyroid nodules with macrocalcifications and to evaluate the role of other sonographic findings in the diagnosis of malignancy in thyroid nodules besides macrocalcifications.
Method
The findings of 8250 patients who applied to our outpatient clinic and underwent thyroid ultrasonography(US) between 2008 and 2021 were retrospectively reviewed. We included a total of 303 patients with 303 macrocalcified nodules (macrocalcification group) and an age- and sex matched group of 220 patients (control group) with the cytopathologic and/or histopathologic data of fine needle aspiration biopsy (FNAB) of thyroid nodules without calcification. Demographic characteristics of these patients, US characteristics of the nodules, and thyroid function tests were recorded. Cytopathological data of FNAB were classified according to BETHESDA.
Results
Overall, 458 (87.6%) of 523 nodules were benign, whereas 65 (12.4%) were malignant. When the macrocalcification and control groups were evaluated separately, 16 (7.3%) of 220 nodules in the control group were malignant, and 49 (16.2%) of 303 nodules in the macrocalcification group were malignant. Malignancy was significantly higher in the macrocalcification group than in the control group. ($P=0.002$) The nodules with macrocalcifications were divided into subgroups with peripheral interrupted calcifications and others according to the type of macrocalcification, and there was no association between peripheral interrupted calcification and malignancy risk. ($P=0.496$) We examined the sensitivity and specificity of the TI-RADS classifications. In the macrocalcification group, the sensitivity of the TIRADS classification was 54.8% (95%CI, 39.9 - 68.8%) and the specificity was 80.3% (95%CI, 74.7- 84.9%).
Conclusions
In our study, the malignancy rate was higher in the macrocalcification group than in the control group. There was no association between peripheral interrupted calcification and malignancy risk. In the macrocalcification group, the classification system TI-RADS had similar sensitivity and specificity as in the study population.

Redifferentiation with Vemurafenib of BRAF-mutated Radioiodine Refractory Differentiated Metastatic Thyroid Cancer in two patients

Chrysoula Koukoula[1], Olga Papalou[1], Aristidis Diamantopoulos[1], Aikaterini Beka[1], Dimitra Baikousi[1], Vasiliki Antonopoulou[1], Georgia Ntali[1], Theodora Stratigou[1], Phoebe Rontogianni[2], Ioannis Datseris[2], Dimitra Vassiliadi[1] & Stylianos Tsagarakis[1]
[1]Evangelismos Hospital, Department of Endocrinology Diabetes and Metabolism, National Expertise Center for Rare Endocrine Diseases, Athens, Greece; [2]Evangelismos Hospital, Nuclear Medicine and PET/CT Department,, Athens, Greece

Radioiodine treatment is the cornerstone of differentiated thyroid cancer (DTC) management. A number of thyroid cancers, however, become radioiodine-refractory (RAIR) and these represent about 60% of advanced DTCs and are responsible for the vast majority of DTC mortality. RAIR DTC has limited therapeutic options, mainly tyrosine kinase inhibitors that are associated with moderate efficacy and considerable toxicity. Reinducing NIS expression (redifferentiation) with the aim of restoring RAI avidity is a promising strategy. To this end, vemurafenib has been used in small clinical studies of BRAFV600E mutated advanced DTC with encouraging results. Two patients with RAIR, BRAFV600E mutant thyroid cancer received vemurafenib for 4 weeks. They had received a total of 400 mCi and 420 mCi ^{131}I respectively, with their latest post-therapeutic scans being negative and with progression of disease (cervical lymphadenopathy and lung metastases). After 4-week therapy with vemurafenib (960 mg BID), they both exhibited positive WBS scans and subsequently each received 200 mCi ^{131}I treatment. Both post-therapeutic WBS showed significant radioiodine uptake in the cervical neck region, and in one of the patients additional uptake in pulmonary nodules. Regarding thyroglobulin levels a different response pattern was observed in these two patients. Specifically, a significant increase in serum thyroglobulin was observed during redifferentiation treatment in one patient, whereas in the other thyroglobulin levels remained stable. Response to treatment was evaluated with imaging and serum thyroglobulin after 6 months, with both patients exhibiting stable disease, with mixed response in different metastatic areas. Vemurafenib treatment was mainly accompanied by Grade 1 or 2 adverse reactions, involving electrolyte abnormalities, skin manifestations and infections that were completely reversible. Redifferentiation reintroduces RAI in the therapeutic quiver of RAIR DTC with optimistic results avoiding the long-term adverse events of TKIs. More studies are needed to define the place of this approach in the management of advance DTC.

Paraneoplastic Subacute Thyroiditis Secondary to Renal Cell Carcinoma

Deniz Cengiz
Ankara Ataturk Sanatoryum Training and Research Hospital, Internal Medicine, Ankara, Turkey

A 52 year old lady presented with a six month history of weight loss and fatigue. Physical examination showed mild abdominal discomfort on the right flank with signs of anemia. Blood pressure was 130/60 mmHg, pulse was 83 bpm regular. Tender goitre or tremor were not present. Laboratory tests revealed tsh: 0.008 mUI/l (0.37-4.45), fT4: 2.12 ng/dl (0.8-1.8), thyroglobulin 40 ng/ml (5-42), TPO-Ab $<$35 IU/ml and TgAb $<$20 IU/ml, sedimentation:72 mm/h, crp: 59 mg/dl with normal renal, liver function test and urine dip. Previous thyroid results dated a year ago were normal. Abdominal computed tomography (CT) and thyroid ultrasound were requested. Ultrasound revealed heterogeneous echogenicity with 10 and 14 mm hyperechoic nodules on the right thyroid gland. Thyroid scan revealed a generalised decreased uptake. Abdominal CT scan revealed a 5x8 cm exophytic right renal mass with necrotic features, another 4x6,1 cm necrotic conglomerate mass which is suspicious of lymphadenopathy in the right renal hilus, pressing the right renal vein and right vena cava inferior were reported. Due to the suspicion of renal cell carcinoma (RCC), requested thorax CT showed 2.8 cm necrotic left hilar lymphadenopathy and 1 cm parenchymal nodule suspicious of metastasis in the left lingula. To assess possible paraneoplastic features, β-hcg, afp and ldh levels were measured and reported as normal. Patient was referred to the urology department for right nephrectomy and lymphadenectomy. Pathology results were consistent with stage four renal cell carcinoma. Patient was transferred to the medical oncology team for chemotherapy and follow-up. Fine-needle aspiration biopsy revealed degenerated follicular cells, multinucleated giant cells and epithelioid changes, consistent with chronic granulomatous thyroiditis. 6 weeks after the nephrectomy, thyroid functions returned to normal with tsh:0.82 mUI/l and ft4:1.78 ng/dl, which was suggestive of a subacute thyroiditis secondary to renal cell carcinoma. Literature review showed only one other similar case (1). RCC is known with its' variety of paraneoplastic features. unique inflammatory and immune-mediated responses(2). Pathophysiological role of IL-6, an inflammatory cytokine which is related to high crp levels as well, is also associated with thyroiditis as well(3).

J – 131 therapy of autonomously functioning thyroid adenoma: the outcome of our 20 – years experience

Zlatko Petrovski
Clinic Hospital Dr. Trifun Panovski, Nuclear Medicine, Bitola, Macedonia

Objective

To investigate the results of J – 131 treatments in patients (pts) with autonomous thyroid adenomas in long period of follow up.

Material and Methods

We enrolled 68 consecutive pts with Plummer's disease (50 females, 18 males, mean age 54,7 yrs, range 21 – 79 yrs) for period 2000 – 2020 yrs. 87%(59/68) pts had a unifocal nodule, while 13% (9/68) pts had multifocal toxic autonomous nodules. Pts stopped antithyroid drugs for at least one month prior to the radioiodine therapy and than we administered a J- 131 activity of 740 -+180 MBq (range 550 – 1150 MBq), based of size and weight of 'hot' nodules and the value of radiiodine uptake. Volumetry was done by ultrasound. The mean duration of follow up was 7,84 yrs.

Results

In 65/68 (95%) pts was administered a single dose, while 3/68(5%) pts needed two doses. 62/68 (91,3%) pts who received a single dose were euthyroid with scintigraphic normalization. The percentage of euthyroid did not significantly change in long term of 20 yrs observation. The recurrent hyperthyroidism was 2,9% (2/68) pts. The cumulative incidence of hypothyroidism was 11,8% (8/68) pts withing 1 – 6,2 yrs. The nodular volume was statistically higher in pts who had recurrent hyperthyroidism over hypothyroidism ($P<0,01$) and euthyroidism ($P<0,02$). The development of hypothyroidism was higher in pts who showed extranodular uptake and after TSH suppression. No differences were observed in the results between unifocal and multifocal nodules.

Conclusions

J – 131 therapy is a simple, safe and 97% effective treatment of autonomous functioning thyroid adenoma after one or more radioiodine doses.

Assesmement of An Artificial Intelligence-Based Decision Support System in The Thyroid Nodule Evaluation in Clinical Practice

Pablo Fernández Velasco[1], Beatriz Torres Torres[1], Paloma Pérez López[1], Katia Benito-Sendín Plaar[1], Daniel De Luis Román[1] & Gonzalo Diaz Soto[1]
[1]University Clinical Hospital of Valladolid, Endocrinology and Nutrition, Valladolid, Spain

Objective

To evaluate the impact of a decision support system (DSS) based on artificial intelligence (AI) -KoiosDS- on ultrasound (US) image analysis and risk stratification in thyroid nodules. Material and methods Retrospective US study of all thyroid nodules with histologic (AP) result from June 2020 to December 2021. Diagnostic performance of US with ACR-TIRADS, by four endocrinologists and DSS, before and after the use of AI was evaluated.

Results

A total of 172 patients (83.1% women) with a mean age of 52.3 ± 15.3 years were evaluated. The maximum nodular diameter was 2.9 ± 1.2 cm, with 10.7% being malignant. 81.4% and 24.5% of the nodules classified by DSS as ACR-TIRADS 3 and 4, respectively, were reclassified into lower risk categories with AI When performing a ROC curve to assess the diagnostic performance of endocrinologists and DSS against the AP diagnosis, a mean increase in the area under the curve (AUC) after the use of AI was observed for endocrinologists (AUC = 0.730 vs. 0.790, $P<0.001$) and DSS (AUC = 0.696 vs. 0.735, $P<0.001$). When evaluating the impact of AI on diagnostic accuracy, we observed an improvement in mean sensitivity (S) (82.75% vs. 88%), specificity (S) (35.25% vs. 50.25%), a high negative predictive value (NPV) (94.5% vs. 96.75%) and an increase in positive predictive value (PPV) (13.5% vs. 17.75%). When analyzing the degree of agreement in the US characteristics, we observed a mean increase in concordance with the use of AI in all ultrasound patterns, especially echogenicity (kappa 0.456 vs. 0.642; $P<0.001$). As well as an improvement in the mean correlation between the endocrinologist's ACR TIRADS scores after the use of AI ($r=0.678$ vs. 0.801, $P<0.001$). When estimating the DSS as a learning tool for the endocrinologists in the first 25 image evaluated by the endocrinologist compared to the last 25, an improvement in the degree of agreement after using the AI was observed in the assessment of all the ultrasound features, particularly echogenicity (kappa 0.474 ± 0.244vs0.698 ± 0.111; $P<0.001$).

Conclusion

The use of AI in an Endocrinology Department was associated with an overall improvement in the diagnostic ability of US, as well as an increase in S, E, NPV

and PPV. AI reclassified more than half of the nodules with intermediate ACR TIRADS into lower risk categories. All US ACR-TIRADS patterns increased the degree of agreement and interindividual variability were reduced with the use of AI. AI proved to be a useful learning tool in the evaluation of thyroid nodule.

Long term effects of 0.1 mg Recombinant Human Thyrotropin-Stimulated fix dose of radioiodine therapy in patients with recurrent multinodular goiter after surgery. A 10 year follow-up study

Nikolaos Angelopoulos[1], Ioannis Iakovou[1], Grigoris Effraimidis[2] & Sarantis Livadas[3]
[1]AHEPA University Hospital, School of Medicine, Academic Department of Nuclear Medicine, Thessaloniki, Greece; [2]Medical School, University of Thessalia, Endocrinology, Diabetes and Metabolism Clinics, Larissa, Greece; [3]Athens Medical Center, Endocrinology, Diabetes and Metabolism Clinics, Athens, Greece

Background
Several treatment options exist after thyroid malignancy has been ruled out in patients with multinodular goiter (MG). Surgery efficiently reduces the goiter size but carries a risk of both surgical and anesthetic complications while in recent years, levothyroxine suppressive therapy has been abounded. I131 therapy is the only nonsurgical alternative; however, the effectiveness diminishes with increasing goiter size and depends on iodine sufficiency in some areas. Recombinant human (rh) TSH approximately doubles the thyroid 131I uptake in patients with nodular goiter. Several studies have proved efficacy of rhTSH stimulated 131I therapy on goiter reduction.
Objective
The objective of the study was to assess the efficacy and safety of 0.1 mg rhTSH as an adjuvant to a fix dose of 131I therapy (11 mci) in patients with recurrence of large multinodular goiter several years after the initial thyrodectomy.
Patients and Intervention
14 (13 females), age 59.14 $\pm$15.44 (range 35-78 years) received 11mciu of I131, 24h after the administration of 0.1 mg rhTSH.
Main Outcome Measures
The primary endpoint was the change in thyroid volume (by ultrasound measurements) as well as in the diameter of the predominant nodule during a follow up period of 10 years. Secondary end points were the alterations in thyroid function and potential adverse effects.
Results
significant decrease in the volume of initial thyroid remnant (32.16$\pm$16.66 ml) was observed from the first reevaluation (at 4 months, 23.12$\pm$11.59 ml) as well as at the end of the follow up period (10 years, 12.62$\pm$8.76ml), $P<0.01$. There was a positive correlation between the decreased thyroid volume at 4 months with the volume of thyroid remnant at the end of the study ($r=0.407$, $P=0.014$). Significant reduction of the dominant nodule was also observed (from 31.71$\pm$10.46 mm in the beginning to 26.67$\pm$11.05 mm).
Conclusions
further investigation is needed since this approach could be attractive in terms of minimizing the potential risks of reoperation in these patient

Microwave ablation therapy in the treatment of benign thyroid nodules: A single center experience

Elif Onder[1], Gulden Anataca[2], Suleyman Sonmez[3] & Hande Peynirci[1]
[1]Health Sciences University Kanuni Sultan Suleyman Training and Research Hospital, Endocrinology and Metabolism, Istanbul, Turkey; [2]Health Sciences University Kanuni Sultan Suleyman Training and Research Hospital, Endocrinology and Metabolism, Istanbul,; [3]Health Sciences University Kanuni Sultan Suleyman Training and Research Hospital, Radiology, Istanbul, Turkey

Aim
Image-guided thermal ablation methods are gaining popularity in recent years for the treatment of benign and malignant thyroid nodules. It has also started to be performed more frequently in our country in the last few years, but few centers have published data on this subject. We aimed to assess the effectiveness and safeness of microwave ablation (MWA) technique in patients with benign thyroid nodules (TNs).
Materials and Methods
This retrospective and single-center study was included 72 patients with 84 benign TNs. Patients aged over 18 years old, diagnosed with USG guided fine-needle aspiration biopsy as benign by the trained pathologists about this subject, who had compression symptoms or cosmetic problems, and patients refusing surgery or at high risk for surgery were included. MWA was performed under local anesthesia. The trans-isthmic approach and moving-shot technique were used during the procedure. The pre-treatment thyroid function tests, nodule volume, cosmetic and symptom scores were compared to the 1 month follow-up. The complications were also noted.
Results
Out of 72 patients, fifty seven (79.1%) were female, and the median age was 50.31$\pm$14.26 years. The initial thyroid-stimulating hormone (TSH) and free thyroxine (T4) levels detected in the normal range before and no significant difference were found during follow-up after the ablation technique. The baseline nodule volume was 16.25 mL, and significantly decreased to 7.40 mL one month after treatment ($P<0.001$). The volume reduction rate (VRR) was 53$\pm$20% in female and 58$\pm$11% in male patients at the end of the 1st month. There was no significant difference with respect to the gender. The pretreatment mean symptom score was 7.09$\pm$1.68, and observed significant improvement after 1 month. The median cosmetic score was 3 (ranged from 1 to 4) before the procedure, and this score reduced significantly to a median of 1 (ranged from 1 to 2) after MWA ($P<0.001$). This technique was generally well-tolerated by our patients. No life-threatening major complications were observed.
Conclusions
In the treatment of benign symptomatic thyroid nodules MWA is considerable option in terms of efficacy and safety. We consider that awareness of thermal ablation methods should be increased in selected patients due to the drawbacks, need for hospitalization, risk of anesthesia, life-long L-thyroxine replacement therapy and therefore economic burden of surgery.

An Fifty Six Gene panel Next Generation Sequencing Study of Follicular differentiated Thyroid Cancer: An Indian Study

Ramesh Bangaraiahgari[1], Ramakanth Bhargav Panchangam[2], Sabaretnam Mayilvaganan[3], Rajesh Bangaraiahgari[4], Udaya Kumar N[5] & Chakrapani Bangaraiahgari[6]
[1]AIMS, Biochemistry, Hyderabad, India; [2]BGH, Endocrine and Metabolic Surgery, Vijayawada, India; [3]SGPGIMS, Endocrine Surgery, Lucknow, India; [4]AIMS, Anatomy, Hyderabad, India; [5]AIMS, Pediatrics, Hyderabad, India; [6]Chakri Neuro Hospital, Neurology, Nizamabad, India

Background
Follicular differentiated thyroid cancer (FDTC) is the most common endocrine cancer, globally. Next-generation sequencing (NGS) in thyroid cancer allows for high-throughput genetic sequencing in short time. This analysis offers useful information on tumor biology. NGS Studies on follicular differentiated thyroid cancer are scanty from South East Asia. In this context, we set out study the pattern of a genetic panel wide somatic mutations in thyroid cancer.
Methods
We selected 20 FDTC cases. All of them underwent total thyroidectomy with neck dissection as needed. Tumour tissue samples extracted and paraffin embedded, were taken from ex-vivo specimen. Sample processing, DNA extraction, cDNA preparation and PCR amplification was performed. Mutation analysis with a thyroid cellular pathway specific 56-gene mutation panel using real-time PCR and ThyroSeq v2 on the Ion Torrent PGM sequencer was employed. Common single nucleotide polymorphisms (SNPs) with a minor allele frequency of >0.05 were excluded. Mutations were also manually checked using the Integrated Genomics Viewer v2.4.10 to filter out false positives.
Results
The analysis found mutations commonly in BRAF (16), CDKN2A (10), NRAS (6), PI3KCA (9), RET (4), RAS (12) and TP53 (3) genes. The common mutations found in the samples was RET (M918T), NRAS (Q61R), BRAF (V600E) and missense mutation in TP53 (c.217 – c.1178). A mutation has also been identified in KMT2D gene in two of the patient samples. BRAF, CDKN2A, PI3KCA were more common in papillary cancer. RAS, NRAS, RET mutations were common in follicular cancer. TP53 and KMT2D were seen only in poorly differentiated cancer.
Conclusions
NGS helps in patient management, providing risk stratification and subtyping of malignancy. It can be used in molecular tumor classification, and molecular prediction of long term outcomes in thyroid carcinoma. More prospective studies are needed for its routine use at clinical level.

Is it necessary to elevate TSH for FDG-PET/CT imaging in differentiated thyroid carcinoma patients with TENIS Syndrome?

Ertan Şahin[1], Zeynel Abidin Sayıner[2] & Umut Elboğa[1]
[1]Gaziantep University Faculty of Medicine, Nuclear Medicine, Gaziantep, Turkey; [2]Gaziantep University Faculty of Medicine, Endocrinology, Gaziantep, Turkey

Objective
We aimed to compare the effectiveness of F-18 fluorodeoxyglucose in positron emission computed tomography (FDG-PET/CT) findings under elevated TSH levels (eTSH) and suppressed TSH levels (sTSH) in differentiated thyroid carcinoma patients with TENIS syndrome (Thyroglobulin-elevated Negative Iodine Scintigraphy).
Methods
A total of 23 patients with differentiated thyroid carcinoma (DTC) who undergone total thyroidectomy and 131I ablation therapy that presenting TENIS Syndrome were included to study. FDG-PET/CT imaging were performed to DTC patients with TENIS syndrome under two hormonal conditions: levothyroxine intake (sTSH) and hormonal withdrawal resulting TSH level $\geq$ 30 μIU (eTSH). PET/CT imaging findings were compared on the patient and lesion basis for two hormonal conditions.
Results
Positive findings were found in 15 patients with eTSH FDG-PET/CT and in 14 patients with sTSH FDG-PET/CT, and sensitivity was found as 65.2% and 60.8% for both imaging, respectively ($P > 0.05$). The number of patients who could detect a lesion with eTSH FDG-PET/CT but could not detect any lesion with sTSH FDG-PET/CT was only 1, and there was no change in the clinical management of other 14 patients. Of the total 56 lesions, 47 could be shown eTSH FDG-PET/CT, while 41 lesions could be detected with sTSH FDG-PET/CT ($P > 0.05$). Similarly, mean SUVmax values were also found to be high and not statistically significant in eTSH FDG-PET/CT imaging.
Conclusions
We concluded that eTSH FDG-PET/CT and sTSH FDG-PET/CT imaging have similar results for detecting recurrent disease in DTC patients with TENIS syndrome. On the other hand, it should be considered that eTSH FDG-PET/CT may provide some additional advantages.

Analysis of curative effect after 131I treatment of familial differentiated thyroid cancer

Yanhui Ji, Danyang Sun & Wei Zheng
Tianjin Medical University General Hospital, Department of Nuclear Medicine, Tianjin, China

Objective
To analysis the clinical pathological characteristics and ^{131}I curative responses of familial differentiated thyroid cancer(FDTC) and sporadic differentiated thyroid cancer(SDTC).
Methods
A total of 112 FDTC patients(79 females, 33males, age(41.3 ± 15.6)) and 1000 SDTC (658 females, 342males, (44.2 ± 13.9)) who underwent ^{131}I therapy in Department of Nuclear Medicine in our hospital between January 2011 and July 2021 were retrospectively enrolled. The clinical pathological characteristics, preablative stimulated thyroglobulin (ps-Tg), preablative stimulated thyroglobulin antibody(ps-TgAb) and response to the ^{131} I therapy (excellent response, indeterminate response, biochemical incomplete response, structural incomplete response) of two groups were analyzed and compared. The clinical pathological parameters included age, gender, pathological type, tumour maximum diameter, bilateral, multifoci, nodules goiter, thyroiditis membrane invasion, lymph node metastasis(LNM), invasion of the surrounding soft tissues, distant metastasis, TNM staging and ATA risk stratification (low-risk, intermediate-risk, high-risk). χ^2test or Fisher exact test and independent-sample t test were used to compare the data between the two groups.
Results
Comparing the SDTCgroup, FDTC group showed higher proportion of bilateral foci (60.71%(68/112) *vs* 38.10%(381/1000), $\chi^2 = 10.899$, $P < 0.001$); thyroiditis membrane invasion 45.53%(51/112) *vs* 25.90%(259/1000), $\chi^2 = 9.899$, $P < 0.01$; distant metastasis:13.39%(15/112) *vs* 6.00%(6/1000). There was a ststistical difference in risk stratification between two groups (high-risk: 17.86%(20/112) *vs* 9.20%(92/1000), intermediate-risk: 67.85%(76/112) *vs* 73.00%(730/1000), low-risk: 14.28%(16/112) *vs* 17.80%(178/1000), $\chi^2 = 6.\ 989$, $P < 0.01$). The response to ^{131}I therapy of SDTC group were higher than that of the FDTC group($t = -2.275$, $P < 0.05$)There were no significant differences in other clinical pathological parameters and ps-Tg and between FDTC group and SDTC group (all $p > 0.05$). Conclusions The FDTC group displays distinct characteristics as increased aggressivess at diagnose and the worse response to ^{131}I therapy.

Effect of Tumor Size on Prognosis in Papillary Thyroid Microcarcinoma

Yusuf Kayhan[1], Leyla Azizova[2], Merve Yilmaz[3], Muhsine Bakış[2], Sema Çapkinoğlu Türk[1], Betül Gündüz[1], Elif Kılıç Kan[1], Aysegul ATMACA[1] & Ramis Çolak[1]
[1]Ondokuz Mayis University, Endocrinology and Metabolism, Samsun, Turkey; [2]Ondokuz Mayis University, Internal Medicine, Samsun, Turkey; [3]Samsun Gazi State Hospital, Endocrinology and Metabolism, Samsun, Turkey

Introduction
Papillary thyroid microcarcinomas (PTMC) are usually detected incidentally. They occur as a result of histological/microscopic examination of a thyroid removed especially for nodular goiter. Generally, the prognosis is good. However, it has been reported that lymph node (LN) metastasis is more common especially in PTMCs with tumor size $>$ 5mm. In this study, it was aimed to show the effect of tumor size on prognosis by comparing clinicopathological data in patients with PTMCs $\leq$ 5mm and $>$ 5mm.
Material-Method
A total of 246 patients aged $>$18 years, who were operated at Samsun Ondokuz Mayıs University Faculty of Medicine between January 2008 and October 2021 and whose pathology was reported as PTMC, were followed for at least 30 months, were included in the study. The patients were divided into two groups. The first group included 131 patients with a tumor size of $\leq$ 5mm, and the second group included 115 patients with a tumor size of 5-10mm. The age, gender, performed surgical procedure, pathology results, recurrence, distant and LN metastasis, mortality, radioactive iodine (RAI) ablation and follow-up periods were recorded. The results were compared between the two groups.
Results
When the groups were compared in terms of pathology results, multifocality ($P = 0.009$), parenchymal invasion ($P = 0.008$), calcification ($P = 0.001$), lymphatic invasion ($P = 0.002$) and presence of metastatic LN ($P < 0.001$) were found to be statistically more significant in those with tumor size $>$ 5mm. RAI ablation therapy was significantly higher in the group with tumor size $>$ 5mm ($P < 0.001$). There was no statistically significant difference between the two groups in terms of follow-up time and recurrence. Distant metastasis and disease-related death were not detected in any of them. There was a significant difference between the groups in terms of tumor type ($P = 0.049$). Tall cell variant was more common in tumor size $>$ 5mm.
Discussion and conclusion
Our findings show that recurrence rates were similar in patients with PTMCs $\leq$ 5mm and $>$5mm, and there was no disease-related mortality in either group. However, in the group with tumour size $>$ 5 mm, predictive values which may be associated with tumor aggressiveness as multifocality, parenchymal invasion, calcification, lymphatic invasion, LN metastasis and the tall cell variant were found to be significantly higher. We conclude that patients with $>$ 5mm PTMK, having these positive predictive factors, should be managed more carefully.

The Efficiency of Ultrasound Surveillance in Papillary Thyroid Cancer Patients with Excellent Response to Therapy

Bercemhan Yazirli[1], Sinem Ardic[1] & Uğur Unluturk[2]
[1]Hacettepe University School of Medicine, Department of Internal Medicine, Ankara, Turkey; [2]Hacettepe University School of Medicine, Department of Internal Medicine, Division of Endocrinology and Metabolism, Ankara, Turkey

Aim
To investigate the efficiency of ultrasound surveillance in detecting papillary thyroid cancer recurrences in Dynamic Risk Stratification (DRS) subgroups.
Methods
The study included 477 patients with papillary thyroid cancer (PTC) who underwent total or completion thyroidectomy and were followed for at least three ultrasound scans (US). The patients were categorized into DRS subgroups based on their first-year therapy response. The reports of consecutive US following the initial assessment were analyzed retrospectively. The US findings of the residual thyroid tissue or lymph nodes were categorized as suspicious, indeterminate, or benign based on European Thyroid Association guideline criteria. The lymph nodes that did not meet these criteria were defined as non-specific lesions. In addition, the positive predictive value (PPV) and negative predictive value (NPV) of the follow-up ultrasound scans were calculated.
Results
The median surveillance time was 76 IQR [58-104] months. Nine recurrences were observed. The recurrence rate was 0.3% in the excellent response group. The maximum time to recurrence after the first-year assessment was one year in the excellent response group (ERG) and two years in the non-excellent response group (NERG). Out of 11 fine needle aspiration biopsies performed for atypical findings in ERG, one revealed metastasis (9.1%). This ratio was 100% for the structural incomplete response group. The cumulative PPV of ERG and NERG were 1.78% and 29.76%, respectively. Given the sole recurrence in ERG subgroup was observed in the first year of assessment, the PPV of the first periodic ultrasound scans was evaluated. It was 7.69% in ERG and 34.78% in NERG.
Conclusion
The findings from the present study suggest that patients with PTC who achieved excellent response may be followed with clinical examination and serum non-stimulated thyroglobulin level.

Does targeting a TSH $\leq$ 2.5 mmol/l improve fertility in euthyroid women?

Ismail Nasri
Dr Nasri Ismail Endocrinologue Diabétologue, Chlef, Algeria

Introduction
hypothyroidism is among the most frequent causes of infertility, our objective is to analyze this population in order to evaluate the effectiveness of treatment with levothyroxine.
Patients and methods
this is a retrospective interventional study from September 2017 to September 2022.
Inclusion criteria
infertility, TSH>2.5 mmol/l
Exclusion criteria
infertility for less than 1 year, age $\geq$ 45 years, other cause of infertility for the woman, spermogram abnormality.
Results
our work brought together 82 patients, 41% of whom presented with primary infertility, with an average age of 33 years. 32% have positive Anti TPO Abs, and 40% have a family history of thyroid disease. 33% of patients have a TSH (2.51-4.5), 51% TSH (4.51-10), 16% a TSH>10. Targeting a TSH $\leq$ 2.5 mmol/l improves the fertility rate by 56% with an average duration of 7 months under levothyroxine. There were 3 cases of abortion or stillbirth, this improvement in fertility is 48% in patients with TSH (2.51-4.5), 62% for TSH (4.51-10), 62% for TSH> 10.56% in patients with positive Anti TPO Ac, and 67% in patients with negative Anti TPO Ac.
Conclusion
our work shows that the use of levothyroxine in patients who consult for infertility with a TSH>2.5 mmol/l clearly improves fertility independently of the level of TSH and Anti-TPO Ac.

Clinical, Laboratory and Imaging Findings in the Selection of Treatment and Determination of Relapse in Subacute Thyroiditis

Ali Aytuğ Kuştaş[1], Fatma Nur Korkmaz[2], Asena Gökçay Canpolat[2] & Özgür Demir[2]

[1]Ankara University Faculty of Medicine, Internal Medicine, Ankara, Turkey; [2]Ankara University Faculty of Medicine, Endocrinology and Metabolic Diseases, Ankara, Turkey

Subacute Thyroiditis (SAT) is a painful, self-limited inflammation of the thyroid gland. Guidelines recommend Non-Steroid Antiinflammatory Drugs (NSAIDs) for mild cases and steroids for moderate to severe cases. Early relapses can be seen in about 9-35%. The aim of this study was to investigate the clinical, laboratory, and imaging findings that may affect treatment selection and predict relapse.
Materials and Methods
Forty SAT patients who applied to the Endocrinology and Metabolic Diseases Department of Ankara University Hospitals between Jan. 2020 – Jan. 2021 were included prospectively. All patients were evaluated with Clinical Categorical Pain Scale; NSAIDs were administered for mild cases (0-1 points) and steroids (Methylprednisolone 32 mg) for moderate to severe cases or cases unresponsive to NSAIDs. After the response, the dosage of methylprednisolone was reduced by 4 mg per 3 days. Methylprednisolone was discontinued if remission was achieved following 10 days of the 4 mg dose. If symptoms increased during or after treatment and relapse was detected, the steroid dose was increased or restarted. NSAID and steroid treatment groups at baseline and patients with and without relapse during follow-up were compared in terms of clinical, biochemical, and imaging findings.
Results
28 (70%) patients received a steroid regimen, and 12 (30%) patients received NSAIDs initially. In the steroid treatment group tenderness on palpation was more prominent (p:0,005), thyroid stimulating hormone (TSH) levels were lower (p:0.007), free T4 and free T3 levels were higher (p:0,003; 0,002), C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were higher ($P<0,001$; 0,004), lymphocyte counts were lower significantly (P:0,046). The unresponsiveness to NSAIDs was 70%. The remission was achieved in 35 patients with methylprednisolone and in 2 patients with NSAIDs. Relapse was observed in 14 of 37 patients (37.8%). Only one of the relapsed patients had NSAIDs as the first-line treatment. Patients who relapsed ($n=13$) and did not relapse ($n=22$) in the steroid group were compared; ESR, and total thyroid gland volume were higher (p:0,012; 0,049) and the duration of successful treatment was longer ($P<0.001$) significantly in the relapsed group.
Conclusions
Steroids might be considered for the first-line treatment instead of NSAIDs in symptomatic patients due to the high unresponsiveness to NSAIDs. ESR and total thyroid volume might be parameters that may predict the relapse in the steroid treatment group. Slower steroid dose reduction particularly in patients with a high risk of relapse may be helpful to prevent relapse.

Predictive factors for sufficient cytological result after first nondiagnostic thyroid fine-needle aspiration biopsy result

Fatma Dilek Dellal Kahramanca[1], Nagihan Bestepe[1], Merve Meryem Kiran[2], hüsniye başer[3], Didem Özdemir[3], Oya Topaloglu[3], Reyhan Ersoy[3] & Bekir Cakir[3]

[1]Ankara City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara City Hospital, Pathology, Ankara, Turkey; [3]Ankara Yildirim Beyazit University Faculty of Medicine, Endocrinology and Metabolism, Ankara, Turkey

Aim
To determine whether there is any factor that can predict sufficient results in second thyroid fine-needle aspiration biopsy (FNAB) after first nondiagnostic cytological result.
Materials and method
Nodules with non-diagnostic result after first FNAB were included and separated into two groups as sufficient (Group-1) and insufficient (Group-2) second FNAB.
Results
Second FNAB was performed on 643 nodules of 443 patients with initial nondiagnostic cytology. The result was diagnostic in 437(68.0%) nodules (Group-1) while it was again nondiagnostic in 206(32.0%) (Group-2). Thyroid autoantibody positivity were similar in groups. Cystic/mixed structure and heterogeneous echogenity were more frequent in Group-2 ($P=0.020$ and $P=0.011$, respectively). Solid structure and isoechoic appearence were more frequent in Group-1 ($P=0.003$ and $P=0.020$, respectively). Border regularity, micro/macrocalcification, taller-than-wide shape, presence of halo were comparable in two groups ($P>0.05$). There were also no significant differences

in terms of nodule dimensions, volume and rate of subcentimeter nodule between two groups($P>0.05$). In multivariate analysis, likelihood of sufficient cytology was 1.943 times higher in isoechoic nodules in comparison to heterogeneous nodules(95 CI:1.253-2.977, $P=0.003$), whereas the effect of nodule structure on sufficient result became insignificant($P=0.432$). Sufficient results group were cytologically distributed as 299 (68.4%) benign, 131 (30.0%) AUS/FLUS, 2 (0.5%) FN/SFN, 1 (0.2%) SFM and 4 (0.9%) malignant. 35 patients in Group-1 and 20 patients in Group-2 underwent thyroidectomy. Malignant histopathology was observed in 12/60(20%) nodules in Group-1 and in 3/37(8.1%) nodules in Group-2 ($P=0.116$)(Table).

Conclusions

Heterogeneous echogenity and cystic/mixt structure were more frequent in insufficient group, but after multivariate analysis, only isoechoic texture was determined to predict sufficient cytological result in rebiopsy. Second biopsy should be done to all nondiagnostic nodules because of comparable malignant histopathology results.

	Sufficient result after nondiagnostic biopsy ($n=437$, 68.0%)	**Insufficient result after nondiagnostic biopsy** (206, 32.0%)	*P*

Does timing of repeat fine needle aspiration biopsy in thyroid nodules alter the adequate or AUS/FLUS cytology result?

Fatma Dilek Dellal Kahramanca[1], Muhammed Sacikara[1], Aydan Kilicarslan[2], Berna Evranos Ogmen[3], Cevdet Aydin[3], Oya Topaloglu[3], Reyhan Ersoy[3] & Bekir Cakir[3]
[1]Ankara City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Yildirim Beyazit University Faculty of Medicine, Pathology, Ankara, Turkey; [3]Ankara Yildirim Beyazit University Faculty of Medicine, Endocrinology and Metabolism, Ankara, Turkey

Aim

To determine whether early repeat fine needle aspiration biopsy(FNAB) has an effect on adequate or atypia of undetermined significance/follicular lesion of undetermined significance(AUS/FLUS) cytology rates in thyroid nodules with inadequate or AUS/FLUS in the first FNAB.

Method

Nodules of patients who underwent repeat biopsy due to insufficient or AUS/FLUS cytology between 2019-2022 were included. Demographic data of the patients and ultrasonographic, cytological and histopathological results of the nodules were recorded. Additionally, the time between the two biopsies was noted. In nodules with two FNAB results, the first was called initial, and the second was called rebiopsy. In nodules with more than two FNAB results, the time between each consecutive results was evaluated separately, and for these nodules, again first result was called initial and the second was called rebiopsy for each biopsy period of the nodule. Seven different paired groups were formed according to the time between two consecutive biopsies;before and after 1 month,45 days,2 months,3 months,6 months,9 months,12 months. The groups were compared in terms of adequate or AUS/FLUS cytological results.

Results

972 nodules of 546 patients who underwent FNAB at least twice were included. The mean age of the patients was 51 ± 12, and the female sex ratio was 79.1% ($n=432$). FNAB was performed 2 times for 573,3 times for 310, 4 times for 73, 5 times for 13 and 6 times for 3 of the nodules. A total of 2984 cytology results were evaluated. Accordingly,1026 (68.8%) of the initial biopsies were inadequate and 466 (31.2%) were AUS/FLUS. Rebiopsy results are shown in the table. There were no differences in adequate or AUS/FLUS rebiopsy results according to the different time interval groups($P>0.05$ for all). When 1026 samples with inadequate initial FNAB were considered as a separate group, to perform rebiopsy before or after any time interval had no effect on adequate or AUS/FLUS results. Similar results were obtained when a subgroup was created for samples with initial AUS/FLUS cytology($P>0.05$ for all). Also, there was no cut-off time for an adequate or AUS/FLUS rebiopsy result.

Conclusions

In patients with inadequate or AUS/FLUS initial biopsy, the rate of adequate or AUS/FLUS cytology results at rebiopsy did not vary with the timing of repeat biopsy. As recommended in the ATA guideline, there is no need to wait 3 months for a repeat biopsy. In patients with suspicious nodules in terms of malignancy, biopsy might be repeated before 1 month.

Table 1 Comparison of the parameters after patients with polycystic ovary syndrome excluded

Rebiopsy	**Initial Biopsy**			**p**
	Inadequate	**AUS/FLUS**	**Total**	<0.001

The role of oxidative stress in Hashimoto's disease

Angelika Buczyńska[1], Iwona Sidorkiewicz[1], Aleksandra Wiatr[1], Agnieszka Adamska[2], Katarzyna Siewko[2], Adam Krętowski[1,2] & Anna Popławska-Kita[2]
[1]Medical University of Bialystok, Clinical Research Centre, Bialystok, Poland; [2]Medical University of Bialystok, Department of Endocrinology, Diabetology and Internal Medicine, Bialystok, Poland

Hashimoto disease, a chronic autoimmune lymphocytic thyroiditis, is the most common cause of hypothyroidism with a prevalence of 10–12% in the general population. Literature data suggests that persistently high levels of oxidative are considered as relevant risk factor in the occurrence and development of autoimmune diseases, including Hashimoto. The DNA and RNA are particularly valuable to the oxidative damage, and guanine is the most prone base to oxidation. Thus, the DNA/RNA repair processes are also activated by the formation of oxidants multiple guanine species, including 8-hydroxyguanosine (8-OHG), 8-hydroxy-2'-deoxyguanosine (8-OHdG), and 8-hydroxyguanine. Thus, the measurement of DNA/RNA oxidative damage, when all three oxidized guanine species; 8-hydroxy-2'-deoxyguanosine from DNA, 8-hydroxyguanosine from RNA, and 8-hydroxyguanine from either DNA or RNA would be quantify, may comprehensively determine the oxidative stress impact on nucleic acids damage and indirectly determine the level of activation of DNA/RNA repair processes. Determining the impact of oxidative stress on the development of autoimmune diseases is of great clinical importance, enabling the determination of new medical targets through the potential antioxidant implementation. Thus, the aim of the study was to evaluate the concentration of DNA/RNA oxidative stress damage products among Hashimoto's patients in comparison to healthy subjects. For the purpose of this study, 50 patients with Hashimoto disease (study group) and 30 healthy volunteers (control group) were enrolled. The DNA/RNA oxidative stress damage products were evaluated using immunoassay method. The DNA/RNA oxidative stress damage products concentration was increased among study group comparing to control group. This may lead to the Hashimoto patients' susceptibility to other diseases, including an increased risk of other autoimmune diseases or cancer. Thus, antioxidant intervention in these patients may bring many promising results, but many research in this field is still needed.

Hypothyroidism in Glycogen Storage Disease Type 1b and Management

Deniz Atikcan, Neslihan Bascil Tutuncu & Ozlem Turhan Iyidir
Baskent University, Endocrinology and Metabolism, Ankara, Turkey

Glycogen storage disease (GSD) type 1 is an autosomal recessive disorder in which there is problem in glucose 6 phosphatase system. Glucose-6-phosphate transport protein deficiency is found in GSD type 1b. There is disorder in glucose metabolism, lack of glucose production in liver. Hypoglycemia, seizures, lactic acidosis, hyperuricemia and hyperlipidemia are some of the components. Affected people may also have short stature, pancytopenia and inflammatory bowel disease. Our aim is to show togetherness of GSD type 1b and autoimmune disorders. Thyroiditis and growth hormone deficiency are some examples of autoimmune disorders, in this case hypothyroidism is detected. A 22 years old woman admitted to our outpatient clinic for evaluation of primary hypothyroidism. She had a history of glycogen storage disease type 1b, Crohn's disease, rheumatoid arthritis, osteopenia, hyperuricemia and pancytopenia. Current medication is levothyroxine, filgrastim, omega-3 acid esters, allopurinol, adalimumab and glycosade. Her height is 152 cm, weight is 66 kg, hepatomegaly is detected. Her biochemical tests confirmed primary hypothyroidism. Current TSH is 7,63 mU/l, anti-thyroid peroxidase antibody 24,3 IU/ml, anti-thyroglobulin <0,9 IU/ml, uric acid 4,2 mg/dl, ALT 36 U/l, haemoglobin 10,8 g/dl, leucocyte 2780/microliter, trombocyte 105.000/microliter. Levothyroxine initiated on 2021 and dose is titrated to 100 µg in a short time and still needs further titration. Thyroid gland's parenchyma is heterogeneous but no thyroid nodule is detected on ultrasonography. Levothyroxine replacement was challenging due to difficulties in titration. The dose needed to be increased to 100 µg/day due to possible problems in absorption of the drug from the intestine. Although attention was paid to the timing of consumption of the raw corn starch, there may also have been interaction with levothyroxine. We present our case to underline the challenges of levothyroxine replacement in those patients with glycogen storage disease revealing thyroiditis and hypothyroidism.

Atezolizumab A PDL-1 Inhibitor Induced Severe Hypothyroidism Related Rhabdomyolysis

Rabia Abul, Selvinaz Erol, Esra Cil Sen, Feyza Yener Ozturk, M. Masum Canat, Hatice Kostek, Begum Kuver, Fatma Doğan İpek & Yuksel Altuntas
Seyrantepe Hamidiye Etfal Eğitim ve Araştırma Hastanesi, Endocrinology and Metabolism, İstanbul, Turkey;

Introduction
Recently, Programmed cell death ligand 1 (PD-L1) inhibitors have been frequently used as promising treatment options for some advanced malignancies. Although immune-related side effects secondary to PD-1 inhibitor treatment are well defined in the literature, data on PD-L1 inhibitors are limited. Thyroid dysfunction was reported in 10% of patients in the clinical study of atezolizumab. We aimed to present a case of severe hypothyroidism-related rhabdomyolysis and acute renal failure in a patient receiving atezolizumab with the diagnosis of metastatic lung cancer.
Case report
A 63-year-old male metastatic lung cancer was admitted to the hospital with complaints of generelized weakness, myalgias, shortness of breath, difficulty in walking. He has been receiving chemotherapy (carboplatin, etoposide, cisplatin) for small cell lung cancer for 2 years. Atezolizumab (PD-L1 inhibitor) was added to this treatment regimen from 3. cycle and total of 7 doses were used. The patient was receiving atezolizumab treatment every 21 days. Last dose of atezolizumab administered two weeks before admission. In the laboratory tests of the patient who did not have a known history of thyroid and kidney disease, cr: 1.6 8 mg/dl(0.7-1.2), ALT:118 U/l(<41) AST:173U/l(<40) CK: 2422 U/l (39-308), TSH: 168Mu/l(0.27-4.2), fT4: 0.3ng/l(8.9-17.1), fT3: 1,23 ng/l(2-4.4), cortisol:12.3 mg/dl (6.02-18.4) were found. In thyroid ultrasound of the patient; The thyroid gland dimensions are normal, the echo pattern is slightly heterogeneous and the echo intensity is decreased, there is no nodul. The patient was hydrated, L-thyroxine replacement was performed (excluding adrenal insufficiency). L-thyroxine treatment was gradually increased to 125 mg. After the treatment, the patient's complaints regressed. In laboratuary tests cr:1.09 mg/dl (0.7-1.2) CK:428 U/l (39-308) decreased, while TSH:63 mU/l (0.27-4.2) was suppressed, increased to fT3:2.2ng/l (2-4.4) and fT4:7.86ng/l (8.9-17.1). Liver function tests decreased to the normal range.
Conclusions
The fact that PD-L1 inhibitors cause severe hypothyroidism, rhabdomyolysis and acute kidney failure shows that the evaluation of thyroid function tests in patients using these drugs is very important. Therefore, we recommend that patients taking PD-L1 inhibitors have their thyroid function tests checked regularly and their creatinine kinase (CK) and creatinine levels should be measured when they show clinical signs of myositis such as myalgia and hypothyroidsm.

Rapidly-Growing Thyroid Mass: is the Diagnosis Always Anaplastic Cancer?

Ekin Yiğit Köroğlu[1], Kubra Turan[1], Feride Pınar Altay[1], Bilgehan Karadayı[2], Aydan Kılıçarslan[3], Oya Topaloglu[4], Reyhan Ersoy[4] & Bekir Cakir[4]
[1]Ankara City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara City Hospital, Radiation Oncology, Ankara, Turkey; [3]Ankara City Hospital, Pathology, Ankara, Turkey; [4]Ankara Yıldırım Beyazıt University Faculty Of Medicine, Endocrinology and Metabolism, Ankara, Turkey

A 87 year old woman admitted with complaints of hoarseness and a palpable mass which she noticed 1 week ago. She had hypothyroidism for 25 years. On examination, there was a hard and fixed palpable 4x4 cm mass on the right side of the neck. In laboratory evaluation, thyroid function tests were normal, thyroid auto-antibodies were positive, calcitonin was normal, C-reactive protein was 224 mg/l and liver and kidney function tests were normal. Thyroid ultrasonography revealed a 27.5x51.1x61.0mm isoechoic nodule containing macrocalcifications and areas of cystic degeneration completely filling the right lobe. Fine needle aspiration biopsy(FNAB) of the nodule was reported as atypia of undetermined significance. In the second FNAB;there were atypical cells with spindle cytoplasm, isolated spindle cells described in fibrin in the cell block with necrosis. The specimen was evaluated as suspicious for malignancy. Lymphoid malignancies were ruled out with flow cytometric analysis. The patient was hospitalized with a prediagnosis of anaplastic thyroid cancer. Neck MRI detected a 9.0x6.5x6.5 cm centrally necrotized mass surrounding right common carotid artery. In 18-FDG-PET-CT scanning, uptake of the lesion was significantly increased and there were multiple metastatic nodules in the lung. A tru-cut biopsy was performed. 'In cytopathologic evaluation, neoplastic infiltration consisting of fascicular shapes was observed within a fibrous stroma. Spindle cells arranged in 'herringbone pattern was observed. A large number of mitotic figures drew attention. In the immunohistochemical study, no staining was detected with TTF-1, CD34, PAX-8, CK-7, p63, SMA, desmin, FL-1, S100, synaptophysin and calcitonin. Staining with vimentin was detected. The Ki-67 proliferation index was 90%. BRAF mutation was negative.' A primary malignant fibrosarcoma of thyroid gland was considered. Because of the advanced age and poor general performance of the patient; chemotherapy and surgery were not considered. 10 sessions of radiotherapy was started. Malignant mesenchymal tumors of thyroid gland comprise 0.3% of all malignant thyroid tumours(1). Fibrosarcomas consist 9.2% of primary malignant mesenchymal tumors of thyroid(2). Although the initial diagnosis that comes to mind in a hard, fixed and rapidly-growing thyroid cancer is anaplastic cancer, malignant mesenchymal tumors like fibrosarcoma should also be considered in differential diagnosis.

Severe post-amiodarone thyrotoxicosis: personalized approach for radical treatment in a life-threatening condition

Marta Opalinska[1], Jacek Pantoflinski[2], Grzegorz Sokołowski[1], Dorota Pach[1], Marta Kostecka-Matyja[1], Katarzyna Żabicka[2], Bartosz Partyński[1], Małgorzata Kieć-Klimczak[2], Anna Sowa-Staszczak[1], Monika Buziak-Bereza[1], Aleksandra Gilis-Januszewska[1] & Alicja Hubalewska-Dydejczyk[1]
[1]Jagiellonian University Medical College, Chair and Department of Endocrinology, Kraków, Poland; [2]University Hospital in Krakow,

Endocrinology, Oncological Endocrinology and Nuclear Medicine Department, Krakow, Poland

Background
Despite increased awareness among cardiologists about the risk of amiodarone's significant side effects, it is still a commonly used antiarrhythmic drug. Amiodarone may induced easy for management hypothyroidism which affect even 25% of patients or less frequent thyrotoxicosis (AIT) which causes a challenge for clinicians. Type 1 of AIT occurs on the basis of pre-existing thyroid diseases such as nodular goiter or latent Graves' disease, type 2 results from destructive thyroiditis, and mixed/indefinite forms combine both pathomechanisms. Initial treatment of AIT includes the use of thioamides accompanied by glucocorticoids and/or perchlorate. Unfortunately, some patients refractory to this treatment may develop life-threatening symptoms. In such cases, an urgent decision must be made on salvage radical treatment. AIT induced exacerbation of cardiac insufficiency and life-threatening arrhythmias causes anaesthesia for thyroidectomy and 131-I (low 131-I uptake) therapy challenging. We aimed to assess the clinical course and results of salvage thyroidectomy or 131-I therapy in patients with life-threatening AIT refractory to medical treatment.
Materials and Methods
75 patients, hospitalized due to severe cardiac insufficiency or arrhythmias associated with AIT between 2014-2022 at a single tertiary center.
Results
In 73 of 75 patients amiodaron was withdrawn at admission. All patients received thiamazole as the best conservative treatment. Glucocorticosteroids were applied in 60, sodium perchlorate in 38, lithium carbonicum in 10 and albumins in 16 patients. The sequence of medications used depended on the individual course of the disease. In the whole group, 20 patients required salvage radical therapy due to the worsening of clinical symptoms. Six patients died during hospitalization before any radical treatment was applied. Further, 6 patients underwent total thyroidectomy. 131-I treatment was carried out in 8 cases (6 patients after rhTSH stimulation). In 4 patients a single dose of 131-I was sufficient. Four patients required repeated 131-I therapy due to thyrotoxicosis recurrence, but the partial response to first 131-I therapy enabled its repetition at the time of cardiac improvement.
Conclusion
AIT may be associated with life-threatening symptoms resulting from the exacerbation of cardiac failure and arrhythmias. The decision on the optimal time for radical AIT treatment is critical and cannot be taken too late. In selected group of patients at high risk of anaesthesia, an 131-I treatment can be considered as an effective therapeutic option. In some patients, the administration of rhTSH may be useful to improve 131-I uptake.

Autoimmune thyroid dysfunction induced by Alemtuzumab

Andrada-Elena Singh[1], Bethany Jones[2], Emad Abdelrahim[1], Harpal S. Randeva[3,4], Tarunya Arun[5] & Pratibha Machenahalli[6,7]
[1]UHCW, General Medicine, Coventry, United Kingdom; [2]UHCW, Coventry, United Kingdom; [3]University Hospitals Coventry and Warwickshire, Endocrinology, Coventry, United Kingdom; [4]University of Warwick, Endocrinology, Coventry, United Kingdom; [5]University Hospitals Coventry and Warwickshire, Neurology, Coventry, United Kingdom; [6]University hospitals Coventry and Warwickshire, Endocrinology, Coventry, United Kingdom; [7]Warwick Medical School, Coventry, United Kingdom

Background
Alemtuzumab is an anti-CD52 monoclonal antibody used in the treatment of relapsing and remitting Multiple Sclerosis (MS). It is a highly effective medication however common side effects of the treatment can include Autoimmune thyroid disease (Graves' disease, Hashimoto's thyroiditis), idiopathic thrombocytopenic purpura, anti-glomerular basement membrane disease, neutropenia, haemolytic anaemia, vitiligo being the most common presentation. This case highlights the importance of thyroid monitoring during treatment with Alemtuzumab.
Case Presentation
A 37 year old lady with a background of MS which was diagnosed in 2017, she was initially treated with IV methylprednisolone with good effect. She was then commenced as an outpatient on the Alemtuzumab, the initial course comprised five infusions in 2018 and a further three infusions were given in 2019. Following the treatment course her MS was stable. She presented to her GP in early 2022 with a picture of hyperthyroidism. Biochemical profile revealed TSH of 0.52 mU/l and T4 of 15.9 pmol/l. She was hence commenced on Carbimazole for hyperthyroidism. The GP referred her back to the Endocrinology clinic due to her background of Alemtuzumab infusions. The Carbimazole was later stopped due to hypothyroidism on repeat blood tests, at this time TSH was 62.03 mU/l. Her medications on presentation to Endocrine clinic were Carbimazole 10 mg OD, Cabergoline 0.25 mg twice a week, Sertraline, and the combined contraceptive pill. She also had a background of Macroprolactinoma on Cabergoline, this had been incidentally picked up on her initial presentation with symptoms of MS. This had been stable following commencing treatment with Dopamine agonist (Cabergoline). A DEXA scan was also performed this showed normal bone density with osteopenia of L3 and L4. On presentation with thyrotoxicosis, she has thyroid antibodies and thyroid ultrasound scan requested. The ultrasound scan showed a normal thyroid appearance, however the TSH receptor antibody levels were elevated at 61.9 U/l.
Discussion
This case report highlights the importance of regular thyroid screening in MS patients who have been treated with Alemtuzumab. In alemtuzumab-induced autoimmune thyroid dysfunction, additional challenges are posed by spontaneous, bidirectional switching between hyperthyroidism and hypothyroidism.

Thyroid and ovarian cancers occurring a decade after treated Hodgkin's disease

Bel Hadj Sliman Chayma, Ben Sellem Dorra, Cherif Syrine, Rokbani Hend, Letaief Bechir & Mhiri Aida
Institute Salah Azaiez, Nuclear Medecine, Tunis, Tunisia

Introduction
Hodgkin lymphoma is a cancer that affects the lymphatic system. Treatment includes chemotherapy and radiation therapy, which can increase the risk of secondary cancers such as thyroid and ovarian carcinomas. We report a case of a patient who developed secondary thyroid and ovarian cancers after being treated for Hodgkin's disease.
Observation
Mrs LS was diagnosed with Hodgkin disease at the age of 34 and was treated with chemotherapy and radiation therapy of the neck and supraclavicular regions, achieving full remission. Ten years later, a full-body CT scan revealed a left latero-uterine pelvic mass of the ovary, which was diagnosed as ovarian small cell carcinoma after surgery. The patient received chemotherapy as adjuvant therapy. At the age of 49, the patient consulted for a left cervical swelling. Cervical ultrasound showed a 10 mm thyroid nodule Tirads 5, with malignant cytology (Beteshda 6). The patient underwent total thyroidectomy and central lymph node dissection. Histology revealed papillary thyroid carcinoma classified as pT1aN1bMx. The patient was referred to nuclear medicine. She received a 30 mCi Radioactive Iodine Treatment. Post-therapy whole-body scan showed mild iodine uptake in the thyroid bed.
Conclusion
The patient's history of receiving radiation therapy for Hodgkin disease may have increased her risk of developing these secondary cancers. This case highlights the importance of long-term follow-up for patients treated by radiation therapy.

Quality of Life in Patients with Papillary Thyroid Cancer Assessed with The Turkish Version of The Thyroid Related Patient-Reported Outcome Questionnaire ThyPRO: A Prospective Single Center Study

Cansu Çıkın Boztuğ, Adile Begum Bahcecioglu Mutlu & Sevim Güllü
Ankara University, School of Medicine, Endcorinology and Metabolism, Ankara, Turkey

Background
Although the survival rate of papillary thyroid cancer is over 95%, the diagnosis of 'cancer' and fear of recurrence may impair the quality of life of patients. There

is no specific scale for patients with thyroid cancer, scales that can be used in the course of all chronic diseases and include the concept of general health are used to evaluate the quality of life in these patients. We aimed to evaluate the validity of the Thyroid Specific Quality of Life Scale, ThyPRO, which was developed for benign thyroid diseases, in patients with papillary thyroid cancer.
Material and Methods
121 participants who applied to Ankara University Faculty of Medicine, Department of Endocrinology and Metabolism between July 2019 and June 2021 and underwent total thyroidectomy for papillary thyroid cancer were included in this study. Patients with comorbidities were excluded from the study. In addition, the ThyPRO and SF-36 questionnaires were applied to all patients. Thyroid function tests of all patients were evaluated.
Results
A significant negative correlation was observed between the ThyPRO fatigue subscale and the SF-36 vitality subscale $r=$-0,546, $P<$0,001). When the ThyPRO anxiety, depression and emotional symptoms subscales were compared separately with the SF-36 mood subscale, significant negative correlations were found for each subscale ($r=$- 0,446, $P<$0,001; $r=$-0,403, $P<$0,001; $r=$-0,545, $P<$0,001). A significant negative correlation was observed between the ThyPRO social life subscale and the SF-36 social function subscale ($r=$-0,378, $P<$0,001). When the ThyPRO daily life subscale was compared with the SF-36 physical role and emotional role subscales, a significant negative correlation was observed ($r=$-0,413, $P<$0,001; $r=$-0,335, $P<$0,001). There was no significant correlation between the ThyPRO general quality of life assessment and SF-36 general health assessment ($P=$0,087).
Conclusions
Favorable outcomes have been observed that the ThyPRO scale can be used to evaluate the quality of life in patients followed up with papillary thyroid cancer. These findings need to be tested with a validity-reliability study in a larger patient population.

The impact of lockdown on thyroid hormone metabolism in patients on levothyroxine replacement therapy residing in Adjara

Liana Jashi[1,2], Tamar Peshkova[1,3], Ketevan Dundua[1,2], Koba Kamashidze[4], Rusudan Kvanchakhadze[2] & Sophio Beridze[1]
[1]Avicenna Batumi Medical University, T'bilisi, Georgia, [2]David Aghmashenebeli University of Georgia, T'bilisi, Georgia, [3]Batumi Shota Rustaveli State University, Batumi, Georgia, [4]University of Georgia, Medicine, T'bilisi, Georgia

Background
The Covid 19 pandemic has significantly changed people's lives. For patients with chronic diseases, social isolation and distancing have become a provocative factor in metabolic control disorders of varying degrees. Patients avoided hospital visits as much as possible due to fear of infection. Also for the representatives of the medical field, the pandemic has become the basis for new ways of consulting patients (remote, teleconsultation). The aim of the study was to investigate the impact of lockdown on thyroid hormone metabolism in patients on levothyroxine replacement therapy residing in Adjara (The study includes the results of two clinics)
Materials and Methods
A retrospective cohort study identified patients who underwent a dispensary at an endocrinology clinic in 2019 and 2021 due to hypothyroidism and were on replacement therapy with levothyroxine. Demographic data of patients' age, sex, and diagnosis were in the history of the disease. TSH and FT_4 level was also assessed, whether there were mid-term examinations and consultations (via social network/telemedicine service).
Results and Discussion
Data from 54 patients were reviewed as part of the study. Average 18 to 55 years, 18 males and 36 females. Of these, 38 patients were diagnosed with chronic autoimmune thyroiditis, in 16 cases with postoperative hypothyroidism. In 2019, patients's TSH ranged from 0.9- 3.2 (norm 0.5 to 5.0 mIU / L) FT_4- 0.8-1.4 (0.7 to 1.9ng / dL). Patients received levothyroxine 100 mg - 150 mg; During the pandemic period, 32 (59%) patients were examined and their thyroid status was stable (using online services), and in 8 (14.8%) cases, iatrogenic thyrotoxicosis was observed (arbitrary dose increase), 11 (20.3%) cases-hypothyroidism (decrease dose); 3 (5%) In the case of the same dose, despite the lack of control, the thyroid profile was stable.
Conclusion
The results of the study show that social isolation and distancing is a risk factors for decompensation of chronic disease, the use of online services for such patients is innovative and useful for the stability of their condition.

Antithyroid Drugs-Induced Angioedema

Amina Al-Qaysi & Sudesna Chatterjee
Milton Keynes University Hospital, Endocrinology & Diabetes Department, Milton Keynes, United Kingdom

Introduction
Anti-thyroid drugs like Carbimazole and Propylthiouracil are widely used in the management of hyperthyroidism. These medications are associated with a spectrum of cutaneous, hematologic, teratogenic and hepatobiliary adverse effects.
Case Report
A 65-year-old lady, known to have asthma on inhalers as needed and no history of allergies. She was diagnosed with Graves' thyrotoxicosis after she presented to her General Practitioner with mood irritability, insomnia, palpitations, and tremor of six months duration. She opted for medical therapy and was commenced on Carbimazole 30 mg per day. The patient developed lightheadedness and tongue swelling after the third dose of Carbimazole that improved with Chlorphenamine. Propylthiouracil was substituted for Carbimazole, she developed throat discomfort after the first dose and dizziness, breathing difficulty, tongue swelling and facial flushing after the second dose of the medication that required Adrenaline treatment in the Emergency Department. This case was discussed in the Endocrinology team meeting, it was felt that thyroidectomy with Potassium Iodide pre-operatively is the most appropriate treatment. She was urgently referred to our Ear, Nose and Throat surgeons and she awaits total thyroidectomy.
Conclusion
The prevalence of the antithyroid drugs-induced angioedema is unknown. While switching the patient from one anti-thyroid medication to another is the usual action in clinical practice. However, the cross-reactivity between these medications is reported to be as high as 50%. We encountered a treatment challenge in this case after the patient developed angioedema to both medications. The slow onset of disease control with radioactive iodine therapy and the risk of transient thyrotoxicosis worsening prevented us from considering this treatment option in this case.

Methimazole induced agranulocytosis - A clinical case report

João Menino[1], Inês Meira[1], Jorge Pedro[1,2,3], Davide Carvalho[1,2,3] & Paula Freitas[1,2,3]
[1]São João Universitary Hospital Center, Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]Faculdade de Medicina da Universidade do Porto - FMUP, Porto, Portugal; [3]i3S - Instituto de Investigação e Inovação em Saúde da Universidade do Porto, Porto, Portugal

Introduction
Antithyroid drugs (ATDs) are generally safe and well tolerated, however, major side effects such as hepatotoxicity and agranulocytosis may occur and patients should be provided information on the major symptoms of these conditions. Although rare, agranulocytosis appears to be more likely with propylthiouracil (PTU) at any dose than with low-dose Methimazole (MMI).
Clinical Case
We describe the case of a 70-year-old woman referred to Endocrinology for persistent Subclinical Hyperthyroidism (SH). Her previous medical history was relevant for dyslipidemia, treated with simvastatin 40 mg, once daily. Sixteen years before, she was evaluated for diplopia and fatigue due to an unknown thyroid dysfunction and was managed with PTU, suspended due an alteration in the white blood cells. There were no other known medical conditions or allergies. On presentation to our clinic, in August 2021, she reported worsening of anxiety with no other symptoms. On examination her thyroid was not enlarged, and no signs of Graves' ophthalmopathy or fine tremors were present. A thyroid ultrasound revealed an enlarged thyroid with a 5mm cystic node. Thyroid function tests revealed low thyroid-stimulating hormone (TSH) 0.252 µUI/ml and normal free thyroxine (fT4) 1.12 ng/dl. MMI 2.5 mg daily was started for symptomatic control. After 2 months, the analytical study showed a maintenance of SH and a decrease in the white blood cell count from 3.92x10^9/l to 2.28x10^9/l. Methimazole was suspended while awaiting anti-thyroid stimulating hormone receptor antibodies (TRAbs) and thyroid scintigraphy. Six days later, the patient presented to the emergency room with a 2-day history of pharyngitis, fever, headache, nausea and vomiting. Blood tests revealed worsened leukopenia 160x10^9/l with severe neutropenia with 0 cells. Broad spectrum antibiotherapy was started. Polyclonal pANCA:AntiMPO antibodies were detected and bone marrow examination revealed severe hypocellularity with rare neutrophils.

Granulocyte-colony stimulating factor was administered for 6 days. The patient was discharged after 12 days with a normal leukocyte and neutrophil count, with the diagnosis of methimazole induced agranulocytosis.
Conclusion
A rare life-threatening side-effect of ATDs is agranulocytosis. Patients with fever or pharyngitis should seek immediate medical help. If granulocytopenia is confirmed, ATD should be suspended. Switching to the other ATD is contraindicated, because a cross-reaction between PTU and MMI has been observed. The onset of agranulocytosis is sudden and patients should be educated for warning signs at time of prescription.

Thyroid nodular disease in a patient with Neurofibromatosis type 1

Ghachem Aycha[1,2], Hamza Elfekih[1,2], Sabbagh Ghada[1], Ghada Saad[1,2], Houd Kenza[1,2], Yosra Hasni[1,2] & Molka Chadli Chaieb[1]
[1]Faculty of Medicine Ibn El Jazzar, University of Sousse, Sousse, Tunisia; [2]Endocrinology-Diabetology Department, Farhat-Hached University Hospital, Sousse, Tunisia

Introduction
Neurofibromatosis type 1 (NF1) is a rare autosomal dominant disease. Patients affected by NF1 have an increased risk of developing tumors other than neurofibromas, especially of endocrine origin, that's why this patients should be screened for endocrine lesions. In this report, we describe a patient affected by NF1 who present a thyroid nodule.
Observation
A 27-year-old woman was admitted in our department for endocrinological evaluations of NF1. She had a family history of NF1, primary hyperthyroidism and autoimmune diseases. The diagnosis of NF1 was made at the age of 3 months when the first skin lesions appeared on her trunk. Her follow-up was irregular. She had cervicobrachial neuralgia revealing bilateral plexiform neurofibroma in the cervical, dorsal, and lumbar region and a suspicious lateral vertebral mass regarding C6 and C7 vertebrae on spine MRI. Bilateral mammary and axillary neurofibromas are found on mammography. On fundus examination, she presented with Lisch nodules without choroidal nodules. She also suffers from chronic gastritis with duodenal polyp on esophagogastroduodenoscopy. The patient had a normal growth and puberty. She was normotensive, plasma methoxylated derivatives and phosphocalcic assessment were normal. She had a grade 1 goiter, with a normal TSH level at 2.15 mIU/l [0,25 - 4,5] and FT4 at 13,7 ng/l [9 - 18]. Anti-thyroid peroxidase and anti-thyroglobulin antibodies were negative. Cervical ultrasound showed initially a multicystic goiter. Two years later, cervical ultrasound identified one right and one left thyroid nodules respectively of 15 x 9 mm and 8 x 5 mm classified as EUTIRADS 3.
Discussion
NF1 is a common heritable neurocutaneous disorder. Central nervous system tumors, pheochromocytoma and optic nerve glioma are known to be associated with NF1. Thyroid nodular disease seems to be underestimated. In literature, there is few cases reporting the presence of thyroid neurofibroma, its possible transformation and even papillary thyroid carcinoma in patients with NF1. These finding highlight the importance of developing a guideline for the screening of thyroid diseases in these patients.

Graves' disease presented simultaneously with subacute thyroiditis - A case report

Ema Lumi[1], Rajmonda Tare[2] & Agron Ylli[3]
[1]Regional Hospital 'Teni Konomi', Endocrinologist, Internal Unit, Korce, Albania; [2]Regional Hospital Elbasan, Endocrinologist, Internal Unit, Elbasan, Albania; [3]Universal Hospital Center 'Nene Tereza', Endocrinologist, Head of Endocrinology and Metabolism department, Tirane, Albania

Introduction
Graves' disease is an autoimmune disease that leads to a generalized over activity of the entire thyroid gland (*hyperthyroidism*). It is caused by TRAb thyrotropin receptor antibodies (TRAb), which bind to receptors on the surface of thyroid cells and stimulate those cells to overproduce and release thyroid hormones. **Subacute thyroiditis** is presumed to be caused by a viral infection or a postviral inflammatory process. It is a self-limited thyroid condition associated with a triphasic clinical course of hyperthyroidism, hypothyroidism, and return to normal thyroid function.
Case
In this article we present a case of a 52-years old women diagnosed with subacute thyroiditis, in the hyperthyroid phase. She was presented with fever up to 38°C, pain and tenderness on the palpation of thyroid, weakness, mild tachycardia and palpitations. Thyroid Ultrasound resulted with enlargement and heterogenous structure in both lobes, difuse hypoechoic parts with no vascularization in the right lobe, but mildly hyper vascularization in the left one. Laboratory findings: TSH = 0.005mIU/ml (n = 0.27-4.7), FT3 = 25.39pg/ml (n = 3.1-6.8), FT4 = 59.53pg/ml(n = 12-22), ESR = 72mm/h (n = 3-20), PCR = 11.15(n = 0.0-5.0), TRAb = 13.24IU/ml (n < 1.22). Covid-19 tested negative. The thyroid scan showed an enlarged gland with heterogeneous trapping. She was treated with prednisone 35 mg/d with tapering dose down to 5 mg/day in 4 weeks, beta-blocker and omeprazole. The pain and fever was resolved after 3-4 days. Four weeks later the inflammatory tests resulted negative. She was feeling much better, but she continued to have weakness. In the follow –up after 6 weeks the patient complained dyspnea. Total blood count was normal, ESR = 29 mm/h, PC r = 2.29 other renal and liver tests normal. Thoracic scan ruled out any pulmonary disease. EKG revealed tachycardia. TSH = 0.005 mIU/ml, FT4 = 100 pg/ml. The patient was started on treatment with methymasole 40 mg / day. Follow-up in 4 weeks, clinically stable, FT3 = 6.86 mIU/ml, FT4 = 17.18 mIU/ml, TRAb = 10 IU/ml, ESR = 24 mm/h, PC r = 2.0. Thyroid ultrasound continued with heterogenic structure, normal vascularization. The treatment with methymasole was tapered down to 20 mg/day. Follow up at 3 months.
Conclusions
The development of Graves' disease and subacute thyroiditis simultaneously is an uncommon condition and only a few cases have been reported. The diagnosis of Graves' disease in these patients is always difficult because of atypical signs and symptoms and the unclear onset time. The causes of the Graves' disease that followed subacute thyroiditis are still unknown. However, Graves' disease should be suspected when a high blood level of thyroid hormone and TRAb persists after subacute thyroiditis.

A rare case of autoimmune thyroiditis with frequent episodes of hashitoxicosis requiring thyroid surgery

Ketevan Dzagania[1] & Natia Vashakmadze[2]
[1]David Tatishvili Medical Center, Endocrinology, Tbilisi, Georgia; [2]Israeli-Georgian Medical Research Centre 'Healthycore', Department of Endocrinology, Tbilisi, Georgia

19 years-old female was diagnosed with thyrotoxicosis for the first time in 2015; Severe hypothyroidism developed after 1 month thiamazole therapy, therefore medication was stopped and the patient was prescribed L-T4 that resulted in improvement of thyroid function tests. L-T4 was finally withdrawn and TSH returned to normal. Since then TSH was constantly monitored and the levels were normal. In 01/2020, the patient was presented with complains about increased heart rate, emotional lability, hand tremors and oligomenorea. Lab tests revealed overt thyrotoxicosis (TSH – 0.001 mIU/ml); Additional studies, performed to clarify the genesis of thyrotoxicosis, revealed increased levels of Anti-Tg antibodies; Antibodies against TSH receptors were negative; the ultrasound of the thyroid revealed the presence of nodules in the gland, in order to clarify the diagnosis, the patient underwent a radioisotope scan of the thyroid gland, which showed decrease in uptake – 0% – consistent with destructive thyroiditis. The patient was diagnosed with transient thyrotoxicosis due to Hashimoto's thyroiditis (destructive form), which did not require pathogenic treatment, therefore, only symptomatic treatment was prescribed (beta-blocker and hydration). The studies conducted after 2 months (03/2020) were consistent with hypothyroidism (TSH – 9.5 mIU/ml, FT4 – at the lower limit of normal). She was given levothyroxine (initial dose – 25 mg); as the result thyroid hormone levels returned to normal. Since the patient has diagnosed with autoimmune thyroiditis and is being treated with levothyroxine, on the back of this, there were very frequent episodes of Hashitoxicosis (at least 6 episodes in recent years) for which it is necessary to reduce the dose of thyroxine or stop therapy completely, after which marked hypothyroidism develops soon. The patient feels thyrotoxicosis and hypothyroidism subjectively, and symptoms are disturbing for her. In addition, the patient plans pregnancy. Considering the frequent episodes of Hashitoxicosis, target level of TSH < 2.5 mIU/l according to patient's pregnancy plans and the patient's will, a shared decision was made for operative treatment – in favor of total thyroidectomy. The patient was recommended to consult a surgeon to plan total thyroidectomy. In addition, the patient has been diagnosed with polycystic ovary syndrome (hyperandrogemenia, hirsutism, oligomenorea); she is on therapy with combined oral contraceptive pills with positive result. Frequent episodes of Hashi-toxicosis with subsequent development of hypothyroidism has negative effect on reproductive system and ovarian function. So, prompt

normalization and stabilization of thyroid function tests after surgery and maintaining TSH below 2.5 mIU/ml is planned for pregnancy.

Etiological profile of hypothyroidism in transition to adult endocrinology

Amine Gueddari, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
UHC Ibn Rochd, Endocrinology and Metabolic Disorders, Casablanca, Morocco

Introduction

Hypothyroidism, congenital or acquired, is responsible for hypometabolism. It is the leading cause of preventable mental retardation in children. Its congenital form is common with 1 in 3500 births. The objective of our work was to describe the characteristics and etiologies of hypothyroidism.

Patients and methods

Retrospective descriptive and analytical study on patients followed for hypothyroidism in transition consultation at the department of Endocrinology and Metabolic Diseases at Ibn Rochd University Hospital in Casablanca. The statistical analysis was carried out by SPSS 25.

Results

We included 23 patients. The average age of patients was 16.6 years with a female predominance in 89% of cases. The average age of diagnosis was 3.6 years. Two patients were diagnosed in the neonatal period. A notion of consanguinity was found in 6 patients, (26% of cases). When the diagnosis was discovered, 9 patients had generalized hypotonia, 7 patients had constipation, 5 patients had delayed psychomotor acquisitions and 2 patients had respiratory disorders. Etiologically, hormone disorders were predominant in 19 patients with positive antithyroperoxidase antibodies in 11 patients. Thyroid dysgenesis was found in 4 patients. All of the patients were put on L-thyroxine with a good clinical evolution in all of our patients.

Conclusion

Hypothyroidism, in case of delayed diagnosis, can have an impact on the neurological development of the child. Hence the systematic neonatal screening and the education of parents and patients on therapeutic observance.

Treatment resistant Amiodarone-induced Thyrotoxicosis in a patient with laminopathy requiring salvage thyroidectomy

David J Tansey[1] & Carla Moran[2]
[1]St. Vincent's University Hospital, Endocrinology and Diabetes Mellitus, Dublin, Ireland; [2]St. Vincent's University Hospital, Dublin, Ireland

Background

Amiodarone induced thyrotoxicosis (AIT) is a potentially catastrophic situation for patients with cardiac disease who are at risk of life-threatening complications. We describe the protracted and challenging journey of a patient with Laminopathy and a significant cardiac history who developed AIT.

Clinical Case

A 53-year-old man was referred with thyrotoxicosis (TSH <0.01mU/l, free T4 61 pmol/l, free T3 8.0 pmol/l) detected following commencement of amiodarone for atrial fibrillation. He had a history of laminopathy (due to LMNA mutation), associated cardiomyopathy and intractable arrhythmia, requiring ICD insertion, atrial and ventricular ablations. Medications included Amiodarone, Mexiletine, Bumetanide, Eplerenone, Bisoprolol, Entresto, Rivaroxaban, and Empagliflozin. Laminopathy was present in numerous relatives, including his mother, who had a history of AIT also. TRAb antibody was <0.8 IU/l. An ultrasound thyroid showed normal sized gland, mildly heterogenous echogenicity and reduced vascularity. He was treated with carbimazole and dexamethasone for AIT but remained thyrotoxic, and developed cardiac decompensation (oedema, SOB) with early myopathy. Second line agents cholestyramine and iodine solution were added, without effect. It was decided that he required salvage thyroidectomy, and he underwent numerous plasma exchanges in preparation for surgery. Following thyroidectomy, the patient recovered well. His thyroid and cardiac symptoms improved, and he was discharged on Eltroxin with follow up.

Conclusion

We describe a rare case of treatment resistant AIT. The case was complicated by the underlying laminopathy, which further increases the risk of myopathy, cardiac arrhythmia and cardiac decompensation in a thyrotoxic patient. Prompt recognition of treatment resistance is required, because the window of opportunity for safe thyroidectomy in such patients is narrow. Options for rendering patients euthyroid in resistant AIT include perchlorate, iopanoic acid, and therapeutic plasma exchange.

Unusual coexistence of primary hyperparathyroidism with graves' disease and papillary thyroid carcinoma: a case report

Baltagi Myriam, Bchir Najla, Bel Hadj Sliman Chayma, Annam Benchhida, Dorra Dorraelguiche, Zouaoui Chadia & Haroun Ouertani
Military Hospital of Tunis, Endocrinology, Tunis, Tunisia

Introduction

Papillary Thyroid Carcinoma (PTC) is the most frequent cancer of the thyroid. PTC may rarely coexist with Primary hyperparathyroidism (PHPT). Furthermore, the association of PTC and graves' disease (GD) has been described and the existence of a link between these entities has long been investigated, but no clear correlation has been established. We report the case of a female patient who suffered from GD, PTC and PHPT.

Observation

A 34-year-old woman consulted our endocrinology department for palpitations, tremors of the extremities and anxiety. Primary hyperthyroidism was diagnosed (TSH <0.01mUI/l, FT4 $=30$ pmol/l). It was related to Graves 'disease considering the presence of positive TSH receptor antibodies at 3.32 IU/ml. The patient was treated with Thiamazole. Furthermore, thyroid Ultrasound revealed a right thyroid nodule measuring 18*10 mm and classified as EU-Tirads 4. Fine needle aspiration was performed revealing malignant thyroid cytopathology (category VI according to the Bethesda system). Hence, surgical treatment was indicated. At the preoperative assessment, hypercalcemia was incidentally discovered (Calcemia $=$ 2,78 mmol/l) and related to a primary hyperparathyroidism (PTH $=$ 60 pg/ml). Cervical ultrasound showed a 7mm left inferior polar parathyroid adenoma, consistent with hyperfixation on parathyroid Scintigraphy. A total thyroidectomy and a left lower parathyroidectomy were performed. the final pathological examination showed a PTC classified as pT2NxMx according to TNM system.

Conclusion

The association of hyperparathyroidism with thyroid pathology has been described in the literature. Further studies are needed to clarify the link between these disorders.

Long-Term Effects of Radioiodine Treatment on Parathyroid Gland Functions in Patients with Benign or Malignant Thyroid Diseases

Fatma Avcı Merdin, Demet Çorapçıoğlu & Mustafa Sahin
Ankara University Faculty of Medicine, Department of Endocrinology and Metabolic Diseases, Ankara, Turkey

Background

Radioiodine (RAI) therapy has been used for a long time in benign and malign diseases of the thyroid gland. During the application of radioiodine treatment, parathyroid glands may also be exposed to radiation due to its close proximity to the thyroid gland. There is interest in the effects of RAI treatment on parathyroid functions in clinical studies. The aim of this study is to evaluate whether the dose of RAI treatment for benign or malignant thyroid diseases has an effect on parathyroid functions in long-term follow-up or not.

Methods

The study sample consisted of 197 patients with or without receiving RAI treatment followed up for benign or malignant thyroid disease. The clinical features, preoperative and postoperative biochemical parameters and postoperative histopathological results of the patients with DTC were examined. Serum calcium, phosphorus, parathormone and 25 OH Vit d3 levels were recorded at the 3rd month, 1st year, 3rd year and 5th year after RAI treatment in all patients with or without receiving RAI treatment.

Results

A total of 197 patients, 189 of whom were diagnosed with DTC, were included in the study. 159 (80.7%) of the patients were female and 38 (19.3%) were male. The mean age at diagnosis was 43 ± 13.4 years. Total thyroidectomy was performed in 179 patients with the diagnosis of DTC and in 6 patients with Graves' disease. While the PTH levels measured in the preoperative period were higher ($P=0.002$) in 92 patients who received RAI treatment at doses of 100 mci and above, the calcium and PTH levels measured after the 1st year of RAI treatment

were found to be lower ($P=0,020$, $P=0.031$). When the patients at 5-years of follow-up after RAI treatment were evaluated, no statistically significant differences were found in terms of serum calcium, phosphorus, parathormone and 25ohvitd3 levels. However, it was found that normocalcemic hyperparathyroidism developed at ten years of follow-up in 2 patients who were treated with RAI.

Conclusions

Although the effect of RAI treatment for thyroid diseases on parathyroid functions seem to be safe in long term follow-up, normocalcemic primary hyperparathyroidism was detected in 2 patients. For this reason, before RAI treatment, patients should be informed about the potential risk of developing abnormal parathyroid function in the future. In addition, patients should be followed-up periodically to control parathyroid function after RAI treatment. Patients should be followed up for low PTH and calcium in the early period and for hyperparathyroidism in the long term.

Plasma Lipoprotein(a) Is Not Associated With Graves' Ophthalmopathy

Cem Sulu[1], Selin Dedeoglu[2], Busenur Gonen[3] & Sait Gonen[1]
[1]Istanbul University-Cerrahpasa, Endocrinology, Metabolism, and Diabetes, Istanbul, Turkey; [2]Eyupsultan State Hospital, Internal Medicine, Istanbul, Turkey; [3]Zonguldak Ataturk State Hospital, Ophthalmology, Istanbul, Turkey

Aim

To investigate the relation of serum lipoprotein (a) (Lp(a)) and other serum lipids with presence of Graves' Ophthalmopathy (GO). We also analyzed the correlation between serum lipids and GO activity.

Methods

A cross-sectional investigation was conducted in consecutive patients with Graves' Disease (GD) who came under the authors' observation to receive antithyroid drug. A stratification was aimed at forming two distinct groups of patients under the same conditions concerning age, gender, alcohol consumption, and smoking. A total of 99 patients, 45 with GO and 54 without GO were included along with 56 HCs. Ophthalmological assessments and serum lipids measurements were performed.

Results

The study groups were similar in age, sex, body mass index, alcohol consumption, and smoking status. The patients without GO had the highest serum Lp(a) (6.7 mg/dl, IQR [3.7-9.9]), followed by patients with GO (5.7 mg/dl, IQR [4.3-9.2]), and HCs (4.7 mg/dl, IQR [3-7.6]). Inter-group comparisons of serum Lp(a) yielded no significant results ($P=0.165$). Serum levels of total cholesterol, LDL-cholesterol, HDL-cholesterol, and triglycerides also did not show any difference between patients with GO, patients without GO, and HCs ($P>0.05$ for all). Serum Lp(a), total cholesterol, LDL-cholesterol, HDL-cholesterol, and triglycerides were not correlated with GO activity ($P>0.05$ for all).

Conclusion

The results of this study indicated no relation of serum Lp(a), total cholesterol, LDL-cholesterol, HDL-cholesterol, and triglycerides with the presence of GO. Further studies with a larger sample size are needed to investigate whether the presence and activity of GO are affected by serum Lp(a) and/or other lipids.

DOI: 10.1530/endoabs.90.P792

Blood ethylenethiourea and disorders of the thyroid gland in Indian mango plantation workers

Manish Kumar[1], Akhouri Sukrit Prakash[2] & Sajjad Ahsan[3]
[1]Chikitsa Clinic, Medicine, Patna, India; [2]Dr Prakash Diabetes Specialities Centre, Diabetes, Patna, India; [3]Diabetes Thyroid & Endocrine Clinic, Medicine, Patna, India

Introduction

A suspected human carcinogen and antithyroid substance, ethylenethiourea (ETU), is produced during the metabolism of ethylenebisdithiocarbamates (EBDCs). These fungicides are sprayed from above or while wearing a backpack. Ethylenethiourea (ETU), a Type II B carcinogen, and antithyroid chemicals are produced when EBDCs are broken down.

Objective

The objective of conducting this research was to compare the occurrence of thyroid problems among EBDC-exposed mango plantation workers with ETU levels.

Method

90 employees between the ages of 20 and 52 who had been exposed to EBDCs directly or indirectly for at least two years each from four plantations that had been heavily reliant on dithiocarbamates over the previous ten years were chosen at random. These workers were most recently exposed 2 to 7 days prior to the start of the investigation. 40 control workers were chosen from an organic farm. These laborers lived at least 40 kilometers from the mango plantations and had no exposure to EBDCs. Weekly and daily applications of EBDCs were made using aerial and backpack spraying, respectively. In addition to or in instead of EBDCs, other fungicides such as chlorothalonil, propanol, and bioethanol were applied. Farmers were primarily exposed through skin contact and breathing. The Statistical Package for Social Sciences (SPSS) for Windows, version 10, was used to perform descriptive statistics, student t-tests, analyses of variance, Fisher's exact tests, Pearson's correlation analyses, and regression analyses.

Results

Despite being well within the normal range, the results showed that exposed workers had greater mean thyroid-stimulating hormone measurements than the control group. Compared to 2 in the control group, 10 of the exposed farmers showed abnormal thyroid ultrasonography results, which were primarily single nodules. Blood ETU levels among the directly exposed, indirectly exposed, and control groups were substantially different ($P<0.002$), although urine ETU levels were not ($P=0.11$; analysis of variance). Environmental ETU levels were below the threshold required for cleanup by the US EPA. A strong direct link between nodule size and blood ETU level in farmers with solitary thyroid nodules was observed.

Conclusion

According to this research, blood ETU is a more accurate biomarker of EBDC exposure than urinary ETU, hence medical surveillance programs for EBDC-exposed personnel should include blood ETU measurement to look for thyroid gland diseases.

Leukopenia A Benign Comorbitidy and Early Sign of Autoimmunity in Hashimoto's Thyroiditis

Lambros Athanassiou[1], Panagiotis Athanassiou[2], Pavlos Tsakiridis[2], Sofia Nikolakopoulou[3], Maria Nikolidaki[4], Dimitra Mathiou[4], Athanasios Fortis[5] & Kostoglou Athanasiou Ifigenia[6]
[1]Asclepeion Hospital, Voula, Department of Rheumatology, Athens, Greece; [2]St. Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece; [3]Asclepeion Hospital, Voula, Covid-19 Department, Athens, Greece; [4]European University Cyprus, Nicosia, Cyprus; [5]Asclepeion Hospital, Voula, Second Department of Internal Medicine, Athens, Greece; [6]Asclepeion Hospital, Voula, Department of Endocrinology, Athens, Greece

Introduction

Leukopenia is a manifestation of autoimmune diseases such as systemic lupus erythematosus (SLE). Leukopenia may be an early sign of autoimmunity and may be a comorbidity in patients with autoimmune Hashimoto's thyroiditis.

Aim

The aim was to present a cohort of 12 patients with autoimmune Hashimoto's thyroiditis who presented with leukopenia.

Methods

A cohort of 12 patients, aged 19-72 y, female, with autoimmune Hashimoto's thyroiditis is described. Patients presented with leukopenia. Leukopenia was defined as a white blood cell count <4000 cells/mm^3.

Results

The white blood cell count remained <4000cells/mm^3 in a period of follow-up of 5-15 years. The white blood cell count varied in long-term follow-up. A female patient aged at diagnosis of Hashimoto's thyroiditis 42 y, developed breast cancer in her left and consequently her right breast at the age of 63 and had to receive chemotherapy. The white blood cell count deteriorated further during chemotherapy, but she was able to finish the therapeutic regimen. In long-term follow up her white blood cell count improved but remained <4000cells/mm^3.

Conclusions

Disorders of white blood cells may accompany autoimmunity. Neutropenia has been described in the context of autoimmune thyroid disease. Idiopathic neutropenia has been described as a benign disorder of granulopoiesis characterized by unexplained reduction in the absolute neutrophil count below

the lower limit of the normal for a prolonged period. It has been divided in primary autoimmune neutropenia characterized by autoantibodies against mature neutrophils and their bone marrow progenitors and chronic immunologic neutropenia characterized by suppression of granulopoiesis. Both disease entities usually display an uncomplicated clinical course with minimal symptoms. Leukopenia and lymphopenia have been described in the context of SLE. Leukopenia characterized by a benign clinical course may be an early sign of autoimmunity and may accompany autoimmune Hashimoto's thyroiditis. In conclusion, leukopenia may be a manifestation of Hashimoto's thyroiditis, especially in female patients and it is characterized by a benign clinical course.

Nivolumab-induced hypothyroidism: a case report

Nagihan Bestepe[1], Yasar Aydogmus[1], Belma Tural Balsak[1], Emre Hafizoglu[2], Kubra Solmaz[1], Oya Topaloglu[3], Reyhan Ersoy[3] & Bekir Cakir[3]
[1]Ankara City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara City Hospital, Medical Oncology, Ankara, Turkey; [3]Ankara Yildirim Beyazit University Faculty of Medicine, Endocrinology and Metabolism, Ankara, Turkey

Introduction
Immune checkpoint inhibitors are relatively new and promising treatments for a variety of solid tumors. Nivolumab is an anti-cancer monoclonal antibody that inhibits anti-programmed death-1 (PD1) and modulates T-cell response. It has been shown to significantly improve survival in many types of cancer, but clinical studies have also reported an increased risk of developing immune-related adverse events. In particular, immune-related adverse events may be related to the endocrine system. It has been reported that approximately 8% of patients treated with PD-1 inhibitors demonstrate hypothyroidism. We present a case of thyroid dysfunction caused by nivolumab.
Case
A 64-year-old male patient was treated with nivolumab for 10 months for tonsillar squamous cell carcinoma. He had no history of thyroid disease. Laboratory studies performed before the administration of nivolumab revealed normal thyroid function with normal levels of anti-thyroid peroxidase and anti-thyroglobulin antibodies. 9 months after starting treatment, the patient's thyroid stimulating hormone (TSH) levels suddenly increased to 57.70 mU/l (normal range 0.55–4.78 mU/l). Free T3 level was 1.65 pg/l (normal range 2.3 - 4.2 pg/l) and free T4 level was 0.24 ng/dl (normal range 0.89–1.76 ng/dl). We suspected nivolumab-induced hypothyroidism in the absence of other possible causes and started thyroid hormone replacement. The patient was followed as euthyroid with L-thyroxine 100 mg/day.
Conclusions
Immunotherapy has demonstrated significant clinical efficacy in many types of cancer. Immune checkpoint inhibitors aim to stimulate the immune system against cancer cells but should not be considered independent of some side effects. Thyroid dysfunction should be considered as a possible immune-related adverse event. Therefore, it is important to evaluate thyroid dysfunction at baseline and before the administration of each dose of nivolumab.

Assessement of Thyroid Function in An Obese Population

Chaima Jemai[1], Manel Jemel[2], Radhouen Gharbi[2], Hajer Kandara[2], Ines Kammoun[2], Olfa Berriche[3], Faten Mahjoub[4] & Henda Jamoussi[4]
[1]National Institute of Nutrition of Tunis, C, Tunisia; [2]National Institute of Nutrition of Tunis, B, Tunisia; [3]National Institute of Nutrition of Tunis, A; [4]National Institute of Nutrition of Tunis, A, Tunisia

Background
Obesity is an expanding pathology in the world and in Tunisia. We conducted this study to assess the thyroid function in a population of obese women and to investigate the relationship of thyroid status parameters with clinical and metabolic parameters.
Methods
This is a cross-sectional retrospective study about 50 obese women carried out at the obesity unit of department A of the National Institute of Nutrition in Tunis. We collected body mass index (BMI), waist circumference (W), serum free thyroxin (FT4) and thyroid stimulating hormon (TSH) levels, fasting glycemia (FG), baseline insulinemia, lipid profile, liver function, and body composition assessed by bioelectrical impedancemetry. We assessed insulin resistance and pancreatic activity by calculating the Homeostasic Model Assessment for Insulin Resistance (HOMA-IR) and the Homeostasic Model Assessment to quantify Beta-cell function (HOMA-B) respectively.
Results
The mean BMI and W were $41,2 \pm 9,3$ kg/m^2 and $120 \pm 17,7$ cm respectively. The mean body fat percentage (BF) was $43,4 \pm 7,1$%. The mean FT4 and TSH levels were $16,6 \pm 4,7$ pmol/l and $2,4 \pm 1$ IU/l, respectively. 2 patients had subclinical hypothyroidism. Glycoregulation abnormalities were noted in 54%. The mean insulinemia, HOMA-IR and HOMA-B were $23,4 \pm 14,8$ mIU/l, $6,5 \pm 5,1$ and $230,4 \pm 162,1$ respectively. 96% ($n=48$) had insulin resistance. TSH was not correlated with cardiometabolic risk parameters nor with BF. FT4 was correlated with age ($r=-0,3$, $P=0,017$), FG ($r=-0,29$, $P=0,019$), insulinemia ($r=-0,42$, $P=10^{-3}$), choesterol ($r=0,24$, $P=0,04$) and high density lipoprotein ($r=0,24$, $P=0,002$). It was not correlated with BF ($r=-0,14$, $P=0,32$).
Conclusion
In our population of obese women, FT4 seems to be more correlated than TSH with cardiometabolic risk parameters.

Congenital Hypothyroidism and Thyroid dyshormonogenesis: Clinical features and genetic findings

Samir Mkaouer[1], Faten Haj Kacem Akid[1], Younes Ayadi[1], Wafa Belabed[1], Rihab Khochtali[1], Bougacha Noura[2], Chaaben Rim[3], Dhoha Ben Salah[1] & Mohamed Abid[1]
[1]Hedi Chaker Hospital, Endocrinology Departement, Sfax, Tunisia; [2]Faculty of Sciences of Sfax, Genetic Department, Sfax, Tunisia; [3]Sfax Faculty of Medicine, Human Molecular and Genetic Laboratory, Sfax, Tunisia

Introduction
Thyroid dyshormonogenesis represents 15% of congenital hypothyroidism. It is a genetic disorder due to a trouble of Thyroid hormones synthesis. it implies many factors involved in this process mainly TPO Enzyme and NIS channel.
Methods
We conducted a prospective study including 17 patients with Congenital Hypothyroidism belonging to 4 consanguine multigenerational Tunisian families. The thyroid dyshormonogenesis was diagnosed based on clinical, biological and imaging exams. We assessed the mean age at diagnosis, clinical phenotype, hormonal and thyroid Autoantibodies, complications and the mean follow up duration. Meanwhile, we performed Audiometry exam to detect neurosensorial hearing defects.
Results
Our study included 17 patients with a sex ratio of 1,83 in favor of male sex. The mean age of diagnosis was 7 years old [1 month-30 years]. The mean TSH at Diagnosis was 54,92mUI/ml [5,2 -300]. The mean follow-up time was 10,11 years [4 to 24 years]. bilateral perceptive deafness was detected in only Three patients. Intellectual disability was severe in four cases and moderate in two. Two patients had fascial dysmorphia. they presented an enlarged saddle nose with a wide anterior fontanel associated with umbilical hernia. Thyroid autoantibodies were negative for all patients except two patients having Subclinical hypothyroidism. Biomolecular study of TG, NIS, PDS was negative for all patients, However segregation with S92STPO gene mutation was detected in all of them with evidence of a founder effect of the Tunisian population.
Conclusions
Congenital hypothyroidism may lead to severe complications which may be preventable if the disease is diagnosed and treated early, therefore the importance of screening for this disease is heightened. The discover of the founder TPO gene mutation will allow to perform genotype correlation that will guide diagnosis and screening.

Anaplastic transformation of papillary thyroid carcinoma in lung metastases:A case report

Zeliha Yarar[1], Yusuf Öztürk[1], Mustafa Kulaksizoglu[1], Mellia Karakose[1], Feridun Karakurt[1], Pembe Oltulu[2] & Seda Tas Ayçiçek[2]
[1]Meram Faculty of Medicine, Necmettin Erbakan Unıversity, Department of Endocrinology and Metabolism, Konya, Turkey; [2]Meram Faculty of

Medicine, Necmettin Erbakan Unıversity, Department of Pathology, Konya, Turkey

Introduction
Anaplastic thyroid carcinoma is a subtype of thyroid carcinomas with an aggressive form. Anaplastic thyroid carcinomas are thought to develop as a result of differentiation of well-differentiated thyroid cancers. Anaplastic transformation of well-differentiated papillary thyroid carcinoma is very rare and most commonly occurs in thyroid gland and regional lymph nodes, whereas occurrence at distant metastatic site is extremely rare. Here we report the case of a patient with papillary thyroid carcinoma presenting with anaplastic transformation of metastases in the lung.
Case Presentation
An 80-year-old man presented with a 1 week history of dyspnea. His medical history included hypertension and papillary thyroid carcinoma, stage PT3N1bM0, for which he underwent total thyroidectomy, santral and lateral neck dissection and received radioactive iodine (RAI) therapy in 2008. 2 years ago, the patient was re-operated for recurrent disease and received second time RAİ therapy. Post-RAI scintigraphy was detected no involvement. Thyroglobulin and anti-thyroglobulin values were negative after RAI therapy. There was no metastasis in the thorax computed tomography (CT) imaging during this period. The patient; who did not come to follow up for 2 years, thorax CT was performed due to shortness of breath. Thorax CT scan showed metastatic nodules, the largest of nodules which 2.4 cm diameter in the lung and tissue densities compatible with recurrence including cystic necrotic areas extending to the pretracheal, right paratracheal, upper mediastinum in the thyroid gland lodge. Laboratory tests revealed TSH:0.94 mU/l (normal 0.27-4.2 mU/l) thyroglobulin:0.52 mg/l (normal 3.5-77 mg/l) anti-thyroglobulin antibody: 14 (normal 0-115 U/ml). Biopsy was performed from the mass in the thyroid lodge and the nodule in the lung. Histologic examination of thyroid mass and lung nodule revealed anaplastic thyroid carcinoma. Immunohistochemical staining for markers showed the presence of paired-box gen 8 (PAX-8) and absence of transcription factor 1 (TTF-1), and thyroglobulin (Tg). Tracheostomy was performed due to tracheal compression. Despite supportive treatment, his condition kept deteriorating and he was followed up in the intensive care unit. Subsequently, the patient died on the 15 th day of hospital admission.
Conclusions
We have described a case of anaplastic transformation of thyroid papillary carcinoma in the lung metastases, 14 years after initial presentation of papillary thyroid carcinoma. Anaplastic transformation of thyroid papillary carcinoma is a rare entity. It should be kept in mind that it can be seen with metastases years after diagnosis and considered in cases with aggressive clinical course.

Idiopathic Intracranial Hypertension and Grave's Disease

Hadjer Zeguir, Safia Achir & Zakia Arbouche
CHU Isaad Hassani de Beni Messous Hôpital, Endocrinology, Beni Messous, Algeria

Introduction
Idiopathic intracranial hypertension (IIH) is characterized by increased intracranial pressure without a detactable cause. Risk factors for the development of this syndrome are obesity and young female population. IIH due to hyperthyroidism is rare in the literature, mentioned in few individual case reports. The exact mechanism of how hyperthyroidism causes IIH is not known. We are reporting the case of a young women with Graves' disease presenting with symptoms of intracranial hypertension and blindness.
Case presentation
A 38 years old obese women with known Graves' disease, treated with monotherapy thiamazole, dose of 30 mg once daily during 3 years. Her condition unexpectedly deteriorated by associated moderate to severe active Graves' orbitopathy, headache, tinnitus, and blindness. Bilateral papillary pallor with blurred edges are found in fundus, the MRI and lumbar puncture showed increased intracranial pressure, but no underlying anatomical cause for the IIH was found. Patient was treated by High-dose systemic glucocorticoids and ventriculoperitoneal shunt. Unfortunately, no improvement of visual function were noticed.
Conclusion
This case report shows the importance of investigating for IIH in a hyperthyroid patient presenting headache associated with visual disturbances by performing a fundus, cerebral MRI angiogram, and CSF pressure measurement in order to preserve the visual function.

Assessment of educational needs of thyroid cancer patients during ablative iratherapy sessions

Abdel Mouhaymen Missaoui[1], Fatma Hamza[2], Siddiqa Soomauroo[1], Khawla Ben Ahmed[2], Wafa Belabed[1] & Mohamed Abid[1]
[1]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Habib Bourguiba University Hospital, Department of Nuclear Medicine, Sfax, Tunisia

Objective
To assess the educational needs of patients with differentiated thyroid carcinoma (DTC) undergoing ablative irradiation therapy (RAI131)
Patients and Methods
Cross-sectional study including 25 patients operated for TDC who integrated the therapeutic education program (TPE) on DTC at the Nuclear Medicine Center, Sfax, Tunisia. An assessment questionnaire was filled by the patients before the RAI session131
Results
Our group consisted of 19 women and 6 men, with an average age of 45.5 ± 15.2 years. This was the first treatment for 52% of the patients. RAI131 is a routine treatment for CDT for 64%. It is only necessary for severe/metastatic forms for 20% of respondents. RAI131 is used to 'destroy the cancer' (40%) and 'limit its spread' (44%). Contraception is recommended during treatment for 40% of patients. Defecation before the treatment was respected by 56%. Good knowledge of the low iodine diet (76%), its duration (56%) and its necessity for the success of the totalization (68%) was reported. Individual and community radiation protection rules were correctly recalled (95.8%). Isolation after RAI131 is essential according to 88% of patients for a duration > 5 days (73.7%). Questions about possible adverse effects of RAI131 were asked by 52% of participants.
Discussion
The success of isotopic totalisation for patients with CDT depends on good therapeutic and dietary preparation. ETP sessions with simulation of the procedure and reminder of the rules of radioprotection are essential.

Prevalence and factors associated with sleep disorders in patients with thyroid cancer

Abdel Mouhaymen Missaoui[1], Fatma Hamza[2], Siddiqa Soomauroo[1], Khawla Ben Ahmed[2], Wafa Belabed[1] & Mohamed Abid[1]
[1]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Habib Bourguiba University Hospital, Department of Nuclear Medicine, Sfax, Tunisia

Objective
To determine the prevalence and factors associated with sleep disorders in patients with differentiated thyroid cancer (DTC)
Patients and Methods
Analytical cross-sectional study of 39 patients followed for DTC at the Nuclear Medicine Center of Sfax, Tunisia. Sleep disorders were evaluated according to the 7 components of the Pittsburgh Sleep Quality Index (PSQI).
Results
The average age of the patients at the time of the survey was 44.5 ± 13.1 with a female predominance (92.3%). Pathological examination revealed a papillary variant in 89.7%. The response was excellent in 58.9% after a cumulative ablative irradiation of 265.9 ± 197 mCi. Patients had a mean disease-free survival of 4.6 ± 3.4 years. Hormone replacement therapy was chosen in all cases with a mean levothyroxine dose of 2.2 ± 0.4 µg/kg/day. The mean TSH at the time of the survey was 0.48 ± 0.89 mIU/l. These patients sleep on average 06 h an 45 minutes per day. The average sleep time was 41.5 ± 35.4 minutes. The average global PSQI score is high (7.7 ± 3.2 points). The prevalence of sleep disorders was estimated at 66.7%. The PSQI score was not significantly correlated with either the dose of levothyroxine prescribed or the degree of TSH suppression.
Discussion
The prevalence of sleep disturbances affects two out of three patients followed for DTC according to our results. This increased prevalence does not seem to be explained by subclinical hyperthyroidism for therapeutic purposes. Advice on lifestyle management during consultations is desirable to preserve the quality of life of this population.

Graves' disease associated with thymic hyperplasia: about a case

Amira Bouchenna & Ould Kablia Samia
Hopital Central de l'Armée Alger, Endocrinology, Alger, Algeria

Introduction
The association between Graves' disease and thymic hyperplasia was first described in 1912. Hundreds of cases have since been described. This rare association doesn't seem fortuitous. We report a case.
Observation
A 30-year-old patient with no particular personal history who consults following the onset of dyspnea with chest tightness. A CT scan of the chest revealed thymic hyperplasia. The preoperative assessment found an hyperthyroidism hence its orientation in endocrinology. A synthetic antithyroid drug treatment is started, and a CT reassessment after euthyroidism is proposed instead of surgery. A decrease in thymic hyperplasia is indeed observed after 3 months.
Discussion
Thymic hyperplasias are rare, except in adolescence. The persistence of a thymic remnant in adulthood raises fears of thymoma. The association of Graves' disease and thymic hyperplasia is to be known, it concerns 38% of patients, its evolution is benign and favorable under medical treatment with antithyroid drugs. What makes it possible to avoid unnecessary surgery, offers simple radiological monitoring.

Effects of semaglutide, PYY3-36, and empagliflozin on the adrenal gland transcriptome in diet induced obese rats

Simon Kloock[1], Marie Oertel[1], Michael Kohlhaas[2], Alexander Nickel[2], Martin Fassnacht[1,2], Ziegler Christian G.[1,3] & Ulrich Dischinger[1,2]
[1]University Hospital Würzburg, Department of Internal Medicine I, Würzburg, Germany; [2]Würzburg University Hospital, Centre for Heart Failure, Würzburg, Germany; [3]University Hospital Carl Gustav Carus Dresden, Department of Internal Medicine III, Dresden, Germany

Background
An activation of the hypothalamic-pituitary-adrenal (HPA) axis is a common observation in obese individuals. GLP-1 agonists, such as semaglutide, and SGLT-2 inhibitors, such as empagliflozin, are well known to be beneficial in obesity, while other incretins, like peptide tyrosine tyrosine 3-36 (PYY 3-36), might be also useful for the treatment of obesity. However, the effect of these substances on the adrenal gland is largely unknown. We directly compared the effects of semaglutide alone and in combination with PYY as well as empagliflozin alone and in combination with semaglutide on adrenal gland transcriptomics.
Methods
High-fat diet (HFD)-induced obese male Wistar rats ($n=50$; mean bodyweight 260g) were randomized into the following treatment groups: semaglutide, semaglutide + PYY3-36, empagliflozin, semaglutide + empagliflozin, and saline. Animals had free access to high- and low-fat diet. After an observation period of 8 weeks, adrenal glands were taken out and evaluated using hypothesis-free RNA sequencing.
Results
Semaglutide and more pronounced semaglutide + PYY3-36 treatment led to weight loss, reduced overall food intake and (less pronounced) high-fat preference compared to saline treated controls. Empagliflozin had only mild effects on body weight. Interestingly, semaglutide + PYY3-36 treatment (compared to saline) led to a high amount of significantly upregulated genes ($n=320$) in the adrenal glands, which was much less pronounced in semaglutide and/or empagliflozin treated animals. Pathway analysis revealed a high number of activated pathways, most prominent among them: PI3K-Akt signaling, insulin signaling, renin-angiotensin system, neuroactive ligand-receptor interaction, adrenergic signalling.
Conclusions
Semaglutide + PYY3-36 combination therapy induces strong changes of adrenal gland transcriptome. Further analyses are necessary to identify exact mechanisms of GLP-1 and PYY based therapies on adrenal gland functionality, potentially leading to new treatment options for adrenal pathologies and for obesity related hypercortisolism.

DOI: 10.1530/endoabs.90.P260

Factored aldosterone can help distinguish mineralocorticoid resistance from aldosterone deficit hypoaldosteronism

Jorge Gabriel Ruiz Sánchez[1,2], Alfonso Calle[2,3], Miguel Angel Rubio Herrera[2,3], Maria Paz de Miguel Novoa[2,3], Emilia Gomez Hoyos[4] & Isabel Runkle[2,3]
[1]Universitary Hospital Fundación Jimenez Díaz, Endocrinología y Nutrición, Madrid, Spain; [2]Universidad Complutense de Madrid. Facultad de Medicina, Madrid, Spain; [3]Hospital Clínico San Carlos, Endocrinología y Nutrición, Madrid, Spain; [4]Universitary Hospital Valladolid, Endocrinología y Nutrición, Valladolid, Spain

Introduction
Hypoaldosteronism can be induced by a deficit of aldosterone production (AldDef) or a mineralocorticoid resistance (MinRes). Experts have proposed to use hyperkalemia-based aldosterone values for this purpose. However, there is no a range of aldosterone values indicating one of this type of hypoaldosteronism. In 2008, Adam W. R.[1] hypothesized that the factored aldosterone (FAldo) could be useful differentiating hypoaldosteronism secondary to MinRes from AldDef. We aimed to determine the accuracy of aldosterone and FAldo values classifying hypoaldosteronism cases as AldDef or MinRes.
Methods
Retrospective study of adult cases of isolated hypoaldosteronism. Data from the aldosterone measurement day were analyzed. The presence of mineralocorticoid-resistance factors (ResF) was used to define hypoaldosteronism as MinRes. The absence of ResF defined hypoaldosteronism as AldDef. FAldo is obtained of the formula: blood aldosterone-ng/dl/(blood potassium-mmol/l– 4.2). FAldo value > 10 is suggestive of MinRes. The area under the curve (AUC) of the receiver operator characteristic (ROC) curve was used for determining the accuracy of aldosterone and Faldo values classifying hypoaldosteronism cases as MinRes or AldDef. Aldosterone values were analyzed both indistinctly from the presence of hyperkalemia and only in those with hyperkalemia. FAldo, since is already an aldosterone value corrected by kalemia, was analyzed indistinctly from the presence of hyperkalemia.
Results
88 hypoaldosteronism cases, age: 74 ± 13 years, 39 (46.4%) were female, 60/88 (68.2%) had MinRes. Mean FAldo values were different between those with and without MinRes (22.7 vs. 7.5 ng/dl/mmol/l, $P=0.007$). Mean Aldosterone values were also different between these groups (19.2 vs. 7.5 ng/dl, $P=0.032$). In the entire cohort, the AUC of FAldo for MinRes was 0.721 (95%CI: 0.61-0.83, $P=0.003$), while AUC of aldosterone values was 0.630 (95%CI: 0.51-0.75. $P=0.065$). During hyperkalemia, the AUCI of aldosterone values was 0.627 (95%CI: 0.48-0.78. $P=0.137$). The cut-off point of FAldo>10 had a sensitivity of 62%, a specificity of 81%, a predictive positive value of 90.2% and a predictive negative value of 43.6% to identify MinRes hypoaldosteronism.
Conclusions
A FAldo > 10 is suggestive of MinRes with a high accuracy. FAldo, indistinctly from the presence of hyperkalemia, seems to be more accurate than aldosterone values measured during hyperkalemia, to identify hypoaldosteronism induced by MinRes as defined by the presence of ResF. Clinicians could use this FAldo to identify etiopathogenic mechanisms in hypoaldosteronism patients.

Define cell-type-specific disease signatures regulating white adipose tissue of women with polycystic ovary syndrome

Congru Li[1], Gustaw Eriksson[1], Haojiang Lu[1], Alana Vannay[1], Eva Lindgren[1], Angelica Hirschberg Linden[2], Qiaolin Deng[1] & Elisabet Stener-Victorin[1]
[1]Karolinska Institutet, Department of Physiology and Pharmacology, Stockholm, Sweden; [2]Karolinska Institutet, Department of Women's and Children's Health, Stockholm, Sweden

White adipose tissue (WAT) is a dynamic and heterogeneous organ composed of different cell types involved in a wide array of biological processes. We know that women with polycystic ovary syndrome (PCOS) suffer from insulin resistance and type 2 diabetes which is associated with pathological white adipose tissue (WAT) function and expansion characterized by hypertrophic adipocytes, altered production and release of lipids and adipokines, and chronic low-grade tissue inflammation. We hypothesize that cell-type-specific WAT dysfunction contributes to insulin resistance and subsequent development of type 2 diabetes in women with PCOS and that treatment aimed at improving insulin sensitivity and reducing androgen excess has the potential to reverse these changes. Because our subcutaneous WAT are frozen and adipocytes are too large and fragile for traditional single-cell sequencing, in order to unravel the cellular complexity, we extracted single-nuclei (sn) from snap frozen WAT from controls ($n=4$) and from hyperandrogenic and insulin-resistant women with PCOS ($n=10$) at baseline and in PCOS after 16 weeks of metformin ($n=6$) or lifestyle management ($n=3$) for snRNA-sequencing using the 10x Genomics protocol. 200 million reads were sequenced from ~5,000 nuclei/sample. Pre-processing and quality control (QC) of the data was performed using CellRanger and Seurat 4.0 was used for downstream QC, filtering, integration, clustering and differential gene expression analyses.
Preliminary results
First we mapped all sequenced cells ($n=109,739$) from all subjects and identified four main canonical cell types based on the expression of known markers: 1) adipocytes ($n=17,896$); 2) adipose stem and progenitor cells (ASPCs) ($n=12,438$); 3) immune cells ($n=15,925$); and 4) vascular cells ($n=20,486$). Subclustering and differential gene expression within each subcluster, pathway- and functional analyses as well as defining the effect of metformin and lifestyle management are ongoing and will be presented.
Summary
These comprehensive analyses will significantly increase our understanding of the cellular complexity and heterogeneity in specific cell types underlying WAT dysfunction in PCOS, and define whether cell-type-specific molecular dysfunctions can be reversed by current first-line treatment.

Are severe obese patients aging faster? The impact of severe obesity on different markers of biological age

Alicja Dudek[1,2], Barbara Zapała[3], Piotr Tylec[1], Karol Ciszek[1], Katarzyna Cyranka[4], Wojciech Zgliczyński[5] & Piotr Major[1]
[1]Jagiellonian University Medical College, Second Department of General Surgery, Krakow, Poland; [2]Department of Endocrinology CMKP, Warsaw,; [3]Jagiellonian University Medical College, Department of Clinical Biochemistry, Krakow, Poland; [4]Jagiellonian University Medical College, Psychiatry Department, Krakow, Poland; [5]Department of Endocrinology CMKP, Warsaw, Poland

Obesity is defined as a state of chronic low-grade inflammation. It is associated with pro-inflammatory activity of visceral adipose tissue, regarded as a neuroendocrine organ that secretes cytotoxins and other pro-inflammatory factors, impairing metabolic pathways. The corollary of these changes is the risk of developing comorbidities. There are many similarities in the mechanisms of ageing and in obesity. The process of ageing leads to the accumulation of pro-inflammatory factors, activation of transcription factors responsible for promoting ageing (NFkB), impaired autophagy, impaired immune system function and increased senescence cells. Telomere length, levels of DNA damage and levels of inflammatory markers are considered hallmarks of ageing. Other markers of biological age are the level of cognitive function and metabolic age. The aim of this prospective cohort study was to assess the markers of premature ageing in people with extreme obesity: telomere length, DNA damage levels, IL-6 levels, cognitive function and metabolic age. All patients were recruited in 2nd Department of General Surgery in Jagiellonian University Medical College from July 2020 to May 2021. 133 patients were included and divided into two groups: SG - the extremely obese group (BMI $>=$ 40 kg/m2 or $>=$ 35 kg/m2 with comorbidity, $n=100$) and CG - the group of healthy volunteers (BMI between 18.5 and 24.9 kgm2, $n=33$). Blood samples were collected for serum and EDTA, DNA material was isolated for PCR telomere length assessment and enzymatic evaluation of 8-OHdG, the Wisocisin Card Sorting Test and the Colour Linkage Test were performed and body composition was analysed by bioimpedance. The SG group showed significantly shorter telomeres compared to CG (3957.4 vs 5191.53 bp) ($P=0.009$), higher IL-6 levels (4.57 vs 1.19) ($P<0.001$) and higher metabolic age (56.18 + -9.85 vs 37.12 + -12.8 years) ($P<0.001$). IL-6 levels were significantly influenced by percentage body fat ($P=0.043$). There were no statistically significant differences in cognitive function or levels of DNA damage in the extremely obese subjects compared to the control group. Obese patients are at a premature stage of ageing in terms of metabolic age and molecular age understood as telomere length. Elevated levels of chronic inflammation associated with body fat may be a factor in premature ageing.

A Novel Nonsense Variant in APOB Related to Familial Hypobetalipoproteinemia: A Case Report

Begum Kuver, Selvinaz Erol, Feyza Yener Ozturk, Esra Cil Sen, M. Masum Canat, Hatice Kostek, Fatma Doğan İpek, Rabia Abul & Yuksel Altuntas
University of Health Sciences Sisli Hamidiye Etfal Training and Research Hospital, Endocrinology and Metabolism, Istanbul, Turkey

Purpose
Hereditary familial hypobetalipoproteinemia (FHBL) is an autosomal dominant disease group characterized by very low levels of lipoprotein including apolipoprotein-B (apo-B). FHBL patients are usually heterozygous and asymptomatic. Patients clinically diagnosed with homozygous FHBL are extremely rare. We aimed to present a 37-year-old adult patient with hepatosteatosis and neurological symptoms who had a homozygous missense c.737A>C (p.Gln246Pro) mutation in the APO-B gene, which has not been described in the literature before.
Case Report
The patient with primary hypothyroidism has the symptoms of ataxia, falling, myalgia, and steatorrhea; Total cholesterol: 21 mg/dl, Triglyceride: 19 mg/dl, HDL: 23 mg/dl, and LDL levels were found to be extremely low. Hepatomegaly was detected, muscle strength was complete, there was no motor deficit, but deep tendon reflexes were globally hypoactive. No pathological finding was detected in cranial MR and EMG. Grade-3 hepatosteatosis was seen in hepatobiliary ultrasonography, FIB-4 index was found to be 0.79. In the lipoprotein electrophoresis: Alpha: %93 (22-53), Beta: %4.4 (38-69) Chylomicron: 023) were detected. Stool evaluation of the patient with steatorrhea was positive for fat, pH:5, carbohydrate negative and stercobilin was normal. The percentage of acanthocytes was %50 and the eye examination was normal. Other laboratory findings; ALT: 48 U/l (<33), AST: 34 U/l (<32), INR: 1.06 (0.8- Prebeta: %1.7 (4-1.25), TSH: 1.8 mU/l (0,27-4.2), Vitamin-E: 1.2 mg/ml (5.5-18), Vitamin-A: 685 ng/ml (300-1000), Vitamin-D: 13 mg/l, APO-B: <20 mg/dl (60-117). MTTP gene mutation wasn't detected, c.737A>C (p.Gln246Pro) variant mutation was detected in the APO-B gene. In a short time with fat-soluble vitamin replacement, there were significant regression in neurological findings. In the first-degree relatives of the patient, a 14-year-old girl (Total cholesterol: 88 mg/dl, LDL: 37 mg/dl, Triglyceride: 47 mg/dl, HDL: 42 mg/dl, APO-B: 28 mg/dl, FIB-4 index: 0.17) and a 19-year-old boy (Total cholesterol: 89 mg/dl, LDL: 33 mg/dl, Triglyceride: 131 mg/dl, HDL: 30 mg/dl, APO-B: 44 mg/dl, FIB-4 index: 0.42) also has hypolipidemia and hepatosteatosis, APO-B heterozygous c.737A>C (p.Gln246Pro) variant mutataion was detected in their gene.
Conclusions
The case we present is the first description of the homozygous FHBL associated pathogenic mutation Apo-B c.737A>C (p.Gln246Pro) variant. Clinical suspicion associated with changes in the patient's lipid profile and subsequent genetic testing are very important in the diagnosis of FHBL. Identifying at-risk young relatives of an individual with FHBL through genetic testing will help identify those who would benefit from prompt initiation of treatment and preventive measures as early as possible.

Investigating the role of deubiquitinases in adrenocortical carcinoma

Victoria Louise Marnet[1,2], Oliver Hartmann[1], Michaela Reissland[1], Nikolett Pahor[1], Laura-Sophie Landwehr[2], Martin Fassnacht[2], Carmina Teresa Fuss[1,2] & Markus Elmar Diefenbacher[1]
[1]University of Wuerzburg, Protein Stability and Cancer Group, Department of Biochemistry and Molecular Biology, Wuerzburg, Germany; [2]University of Wuerzburg, Division of Endocrinology and Diabetes, University Hospital, Wuerzburg, Germany

Adrenocortical carcinoma (ACC) is a rare endocrine malignancy presenting with an incidence of 1 per million per year and an overall 5-year survival rate under 35%. Currently, curative treatment is limited to full surgical resection, while the adrenolytic drug mitotane remains the only approved medical therapy option leaving a huge demand for innovative therapeutic strategies. Genetic alterations observed in ACC commonly lead to activation of Wnt/β-Catenin signaling most frequently caused by mutations in the CTNNB1 gene encoding for the nuclear effector β-Catenin. The key players of Wnt/β-Catenin signaling are known to be under tight control of the ubiquitin-proteasome-system. However, the role of deubiquitinases (DUBs) regarding β-Catenin regulation in ACC remains unknown. Analyzing publicly available data we preselected potentially relevant DUBs linked to patient survival in ACC and Wnt-Signaling. To confirm interesting targets, we performed quantitative PCR in six established ACC cell lines leading us to further investigation of USP10. We observed elevated protein abundance in primary tumor tissue compared to the normal adrenal gland as well as a high portion of USP10 in its active state across all ACC cell lines. Continuing the characterization of USP10 expression and localization, we performed immunohistochemical stainings on Tissue Micro Arrays (TMAs). Subsequential quantification of the TMAs incorporating a manually trained algorithm to distinguish tumor and surrounding tissue confirmed significantly higher USP10 expression in ACC as well as endocrine inactive adenoma compared to normal adrenal gland. Treatment with a Pan-DUB inhibitor, the proteasome inhibitor Bortezomib and a USP10-specific inhibitor led to a reduction of cell growth in ACC cell lines. In summary, we so far found strong indication for dysregulation of USP10 in adrenocortical tumors, therefore making it potential therapeutic target in ACC.

Introduction
Prostate cancer is a neoplasm with high incidence and prevalence in the elderly population in western countries. Androgen deprivation therapy (ADT) has been used in locally advanced or metastatic disease, although most relapse, becoming hormone resistant, which is a poor prognostic event.
Objectives
The aim of this study was to evaluate the association of genetic polymorphisms NOS2, GPRC6A, VKORC1, ARGI and ARGII in prostate cancer, particularly to assess their predictive value for the development of hormone resistance in individuals under ADT therapy.
Methods
107 patients with PCa, aged 67-76 years, were included in this study. Most had PCa at an advanced stage, with 65.5% of patients having metastases at diagnosis. DNA was extracted from whole blood. NOS2, GPRC6A, VKORC1, ARGI and ARGII polymorphisms were detected using real-time PCR with Taqman probes and PCR-RFLP.
Results
Carriers of the NOS2 GG genotype were at higher risk for stage T3-T4. In the case of ARGI in the recessive model, that is, for the CC genotype, there is a 2.6 times greater risk for the existence of a PSA level greater than 20 ng/ml according to the univariate and multivariate analysis.
Conclusions
The ARGII GG genotype in the recessive model was related to early diagnosis of the disease. NOS2 and ARGI polymorphisms are associated with aggressive traits, while the ARGII variant affects earlier onset of prostate cancer.

Risk of Impulse Control Disorders in Cabergoline-Treated Cushing's Disease: A Cross-sectional Study

Cem Sulu[1], Nurdan Gul[2], Sema Ciftci[3], Seher Tanrikulu[4], Feyza Yener Ozturk[5], Hande Mefkure Ozkaya[1], Burc Cagri Poyraz[1] & Pinar Kadioglu[1]
[1]Cerrahpasa Medical School, Turkey; [2]Istanbul University Faculty of Medicine, Turkey; [3]Bakırköy Sadi Konuk Training and Research Hospital; [4]Acıbadem Ataşehir Hospital, Turkey; [5]Sisli Hamidiye Etfal Research and Training Hospital

Aim
To determine the prevalence of impulse control disorder (ICD) in patients with Cushing's disease (CD) treated with cabergoline (CBG) compared to CBG-naive patients with CD.
Methods
We performed a cross-sectional study in patients with CD followed at 5 referral centers based in Istanbul. Eligible patients with CD were those with current CBG treatment for $\geq$ 3 months. Eligible controls were CBG-naive patients with CD that were matched for age and sex to CBG-treated patients. We administered Beck Depression Inventory, Beck Anxiety Inventory, and Symptom Checklist-90-Revised questionnaire to obtain a general measure of psychological distress. To evaluate impulsivity, both self-administered neuropsychological tests (Barratt Impulsiveness Scale, revised version of Minnesota Impulsive Disorders Interview, and Questionnaire for Impulsive-Compulsive Disorders in Parkinson's Disease-Rating Scale) and computerized behavioral tasks (Go/No-Go task, Iowa Gambling task, and Short Penn Continuous Performance Test) were used. All individuals underwent a detailed psychiatric assessment and the ultimate diagnosis of ICD(s), when present, was confirmed by an experienced psychiatrist. The measures of impulsivity and frequency of ICD(s) were compared between groups.
Results
A total of 34 CBG-treated patients with CD and 34 CBG-naive patients with CD were included. The mean age was 45.5 $\pm$ 11.6 in CBG-treated patients and 46.1 $\pm$ 13.5 in CBG-naive patients ($P=0.731$). In each group, 30 patients were female ($P=1.0$). The groups were similar in income, educational level, frequency of smokers, alcohol consumption, size of pituitary adenoma on last imaging study, frequency of hypogonadism and any psychiatric disorder. In CBG user group, the median duration of CBG use was 12 [IQR] 6-26.3 months. The median weekly CBG dose was 2 [IQR] 1-3.5 mg and cumulative dose was 61 [IQR] 30.6-146.4 mg. CBG-treated and CBG-naive patients showed no significant difference in measures of psychological distress and impulsivity. The most common psychiatric disorder in both groups was depression (35.3% vs. 29.2%, $P=0.796$). The frequency of any ICD was 8.8% ($n=3$) in CBG users and 5.9% ($n=2$) in non-users ($P=1.0$). In CBG-treated group, one patient was diagnosed with compulsive gambling (2.9%), one patient was diagnosed with compulsive shopping (2.9%), and another patient was diagnosed with both compulsive shopping and hobbysm (2.9%). In CBG-naive group, one patient with CD had compulsive gambling (2.9%) and one patient with CD had compulsive punding, eating, and hobbysm (2.9%).
Conclusions
Risk of ICDs may not be increased in CBG-treated patients with CD.

Surgical outcomes in acromegaly: The influence of sex and menopause

Ana Carreira, Mafalda Martins Ferreira, Luís Cardoso, Daniela Guelho, Leonor Gomes, Miguel Melo & Isabel Paiva

Centro Hospitalar e Universitário de Coimbra, Endocrinology, Diabetes and Metabolism, Coimbra, Portugal

Introduction
Oestrogens and androgens modulate the effects of growth hormone (GH). Sex differences have been described in acromegaly, with conflicting results in different populations. Additionally, data on sex differences in tumour histopathology are scarce.
Aims
To analyse the influence of sex and menopause status in tumour characteristics and surgical outcomes in patients with acromegaly.
Materials and methods
Retrospective cohort study of patients with acromegaly submitted to transsphenoidal surgery, followed in a tertiary centre from 1988-2021. Postoperative biochemical remission was defined at $\geq$12 weeks by a normalization of insulin like growth factor-1 (IGF-1) and random GH $<$1ug/l or GH nadir $<$1ug/l after a 75-g oral glucose tolerance test. IGF-1 was presented as percent of upper limit of the normal value (%ULN). Differences in tumour size and invasiveness, hormone deficiencies, histopathology and surgical outcomes were compared between sex and pre/postmenopausal status at the time of diagnosis.
Results
We obtained a total of 65 patients: 44 women (12 postmenopausal), 21 men. Mean age at diagnosis in women was 48.1$\pm$12.1 vs 47.9$\pm$13.0 years in men (P=0.933), and mean IGF-1 was 296.3$\pm$126.9 vs 319.2$\pm$1221 %ULN (P=0.497). Pure somatotroph tumours accounted for 68.2% in women vs 71.4% in men, mixed somatotroph-lactotroph 25.0% vs 19.0%, plurihormonal PIT1+ 4.5% vs 9.5%, null cell 2.3% vs 0%. Somatotroph tumours were sparsely granulated in 83.3% of women and densely granulated in 75.0% of men (P=0.001). Postmenopausal women had less macroadenomas than premenopausal (47.1% vs 90.9%, P=0.004), lesser cavernous sinus invasion and suprasellar extension (16.6% vs 61.1%, P=0.016, and 30.8% vs 83.3%, P=0.003) and higher postoperative biochemical remission (52.6% vs 17.4%, P=0.016) and radiological remission at 1-year post-surgery (73.7% vs 27.3%, P=0.003), despite no differences in histopathology. Compared to women, men had a higher prevalence of hypogonadism at diagnosis (57.1% vs 22.7%, P=0.004) and lower rates of radiological remission (11.8% vs 47.6%, P=0.010). Tumour size was similar in men and premenopausal women (23.8 vs 26.0mm, P=0.546) and correlated inversely with age at diagnosis (r=-0.4, P=0.006). Men showed no significant differences regarding tumour invasiveness, postoperative biochemical remission or medical treatment response.
Conclusions
In our cohort men showed a higher prevalence of hypogonadism at diagnosis and lower radiological remission. Premenopausal women showed larger and more invasive tumours than postmenopausal, which may be due to younger age, but also to the oestrogen modulation of GH/IFG-1 axis. Differences in somatotroph tumour histopathology between sex may reflect a different impact of gonadal hormones in tumourigenesis.

Salivary Alpha-Amylase Activity in Patients with Acromegaly: A Preliminary Report

Selvinaz Erol[1], Esra Cil Sen[1], Feyza Yener Ozturk[1], ZMY Kara[2], Zeynep Sarac[3] & Yuksel Altuntas[1]
[1]University of Health Sciences, Hamidiye Etfal Training and Research Hospital, Department of Endocrinology and Metabolism, Istanbul, Turkey; [2]University of Health Sciences, Hamidiye Etfal Training and Research Hospital, Department of Biochemistry, Istanbul, Turkey; [3]University of Health Sciences, Hamidiye Etfal Training and Research Hospital, Department of Internal Medicine, Istanbul, Turkey

Objective
It has been argued that salivary alpha-amylase (sAA) is a potential indirect sympathoadrenal medullary (SAM) system activity marker. This study aimed to look at sAA to assess the sympathetic nervous system in acromegaly patients.
Subjects and Methods
A total of 31 individuals with acromegaly and 30 controls were enrolled in this prospective, single-center investigation. Saliva samples were taken from individuals with acromegaly and controls in the morning and at midnight. SAA activity were measured in patients with acromegaly and controls in the morning and at midnight.
Results
The morning sAA activity in the acromegaly group was 1.76 $\pm$ 0.38 U/ml, while the control group had 2.26 '13; 0.65 U/ml. Morning sAA activity were considerably lower in the acromegaly group ($P<0.001$) when compared to the control group. The midnight sAA activity in the acromegaly group was 1.79 $\pm$ 0.58 U/ml, and the midnight sAA activity in the control group was 2.19 $\pm$ 0.58 U/ml. When the two groups were compared, the midnight sAA activity of the acromegaly group was significantly lower (P=0.002). In addition, morning and midnight sAA activities were found to be similar between acromegaly groups with active and inactive diseases (respectively P=0.54, P=0.63).
Conclusions
This study showed that sAA activity, which is used as an indicator of sympathetic nervous system activity, was decreased in the acromegaly group compared to the control group. Additionally, morning and midnight sAA activity between acromegaly groups with active and inactive disease were similar. Further studies with larger sample sizes are needed to show the link between sympathetic nervous system activity and sAA activity in acromegaly.

Overlapping syndromes - Turner and X-linked Kabuki associated with Short Stature

Nicoleta Chelaru[1], Ioana Vasiliu[2,3], Irina Puscasu[1], Diana-Elena Nita[1], Iuliana-Magdalena Starcea[2,3], Cristina Preda[1,3] & Alexandru Florescu[1,3]
[1]Saint Spiridon County Hospital, Endocrinology, Ia?i, Romania; [2]Saint Mary Emergency Children Hospital, Iasi, Romania; [3]'Grigore T. Popa' University of Medicine and Pharmacy of Ia?i, Ia?i, Romania

Introduction
Kabuki syndrome (KS) is a rare congenital, multisystemic disorder caused by pathogenic variants of KMT2D or KDM6A genes, causing autosomal dominant KS type 1 (more than 80%) and X-linked KS type 2 respectively. The phenotype spectrum is highly variable, consisting of a mixture of any of the five cardinal features (facial dysmorphic features, skeletal defects, dermatoglyphic abnormalities, various degrees of intellectual and growth retardation) with structural disorders comprising ophtalmologic, auricular, dental, cardiac, gastro-intestinal, genitourinary disorders and other conditions such as seizures, autoimmune or endocrine-related disorders (growth hormone deficiency (GHD), hyperinsulinemia, delayed sexual development, early thelarche or diabetes insipidus).
Case report
Our 4-year-old female patient was born prematurely via caesarian section at 32 gestational weeks, with a birth weight of 2300g. She had a history of infantile hypotonia, developmental delay, astigmatism, right renal hypoplasia and medullary nephrocalcinosis treated with Hydrochlorothiazide. At the first assessment in the Endocrinology clinic, she presented prominent, low-set ears, long palpebral fissures, flattened nose, enlarged thorax base, short stature at -3.04 SD according to Romanian synthetic growth charts, at -2.08 SD compared to the target height, healthy weight at 11th percentile and a perfectly normal neuropsychomotor development. The genetic test was positive for a heterozygous complete deletion of the coding regions of KDM6A gene, and the karyotype disclosed a Turner mosaicism 46,X,i(X)(q10)/45,X/46,XX[17]/[14][1]. IGF-1 level was in the normal range, the GH secretion was not stimulated consecutive to glucagon administration.
Discussions
The occurrence of both Kabuki and Turner syndrome has been cited in several case reports, and may express overlapping features, such as short stature, hyperinsulinism or congenital heart diseases. The clinical characteristics of X-linked KS type 2 have been less studied than the 1st type. The females were observed to be less prone to severe phenotypes than male-affected individuals. Short stature is a common feature in patients with KS, not necessarily related to GHD; however, the genotype-phenotype correlations suggest a direct relationship with KMT2D mutations, while short stature is less frequent in the KDM6A group. Turner karyotype serves as an indication for rh-GH therapy, which may significantly improve the prognosis of our patient.

Monitoring serum estradiol levels in clinical practice: a retrospective study in transgender AMAB subjects

Silvia Federici[1,2], Chiara Garofalo[1], Chiara Parazzoli[1,2], Myriam Amer[1,2], Elisa Delle Donne[1,2], Luca Persani[1,2], Stefania Bonadonna[2] & Marco Bonomi[1,2]

[1]University of Milan, Department of Medical Biotechnology and Translational Medicine, Milan, Italy; [2]IRCCS Istituto Auxologico, Department of Endocrine and Metabolic Diseases, Milan, Italy

The Standards of Care version 8 (SOC 8) for transgender and gender diverse people suggest maintaining estradiol (E2) levels between 100-200 pg/ml in Assigned Male at Birth (AMAB) subjects who desire a complete feminization during gender affirmation hormone therapy (GAHT). However, data about estrogen dose therapy and corresponding serum concentrations are scarce, especially regarding gel formulations. Our aim was to retrospectively compare E2 serum levels in AMAB patients undergoing GAHT according to the different formulations and dose used. All subjects were treated with either oral estradiol valerate (OE) or transdermal estradiol gel 0.1% (TDE), according to SOC 8. Three different groups were identified according to the dose of E2 administered: low dose (LD), medium dose (MD), and high dose (HD) [$\leq$ 2, 3-5, $>$6 mg/day for OE and $\leq$ 1, 1.5-2.5, $\geq$3 mg/day for TDE, respectively]. 135 serum E2 measurements were collected among 79 subjects undergoing GAHT. 34.1% of samplings (46/135) were collected in subjects on OE, while 65.9% (88/135) were collected in subjects on TDE. OE was administered in 23.9% of cases at LD, 60.9% at MD and 15.2% at HD, while TDE was administered in 14.6% of cases at LD, 44.9% at MD and 40.4% at HD. Overall, E2 levels showed a wide spreading: 165.8$\pm$264.0 pg/ml (16.7 - 2613.6). Serum levels in patients taking TDE (214.7$\pm$311.6 pg/ml) were significantly higher ($P<0.001$) than those in OE (71.1$\pm$61.6 pg/ml). Stratifying by dose, significance was maintained in MD and HD groups ($P<0.001$), with a trend toward significance for the LD groups (P 0.055). Overall, only 23.7% of the measurements were within the desired range: in subjects taking EO were within, below and above range in 15.2%, 80.4% and 4.3% of cases, while in subjects taking TDE were within, below and above range in 28.1%, 38.2% and 33.7% of cases, respectively ($P<0.001$). No significant differences were found according to the dosage used for each formulation. In conclusion, despite the dosage of GAHT was consistent with the SOC 8 recommendations, E2 levels were often out of target, with patients taking OE showing lower values than those taking TDE. This result could suggest both a greater efficacy of TDE compared with EO at doses typically used and an underestimation of the measured concentration in EO (as found in recent studies), and it should be considered for the interpretation of estradiol values measured in clinical practice.

Predictors of Quality of Life in Treated Hypothyroidism

Bence Bakos[1], Tibor Solymosi[1], Balázs Szili[1], Ágnes Vincze[2], Szilvia Mészáros[1], Richárd Ármós[1], András Kiss[1], Péter Lakatos[1] & István Takács[1]

[1]Semmelweis University, Department of Internal Medicine and Oncology, Budapest, Hungary; [2]Semmelweis University, Department of Haematology and Internal Medicine, Budapest, Hungary

Background

Despite receiving biochemically adequate levothyroxine replacement, many patients with primary hypothyroidism suffer from persistent symptoms and a reduced quality of life (QoL). The underlying causes of this phenomenon are not fully understood, but psychological factors, autoimmune inflammation, and variations in thyroxine conversion have all been suggested as potential contributors. At this time, however, there is no consensus on the root cause.

Methods

In this cross-sectional study we aimed to explore the potential impact of various demographic, anamnestic, psychometric, and laboratory predictors on disease-specific quality of life, as measured by the Thyroid-Dependent Quality of Life questionnaire. To minimize confounding factors, we applied stringent inclusion criteria including a disease duration of at least two years, a stable thyroxine dose and normal TSH level for at least six months, and no significant medical or psychological comorbidities. The assessed psychometric covariates were somatization (Somatosensory Amplification Scale), depression (Patient Health Questionnaire-9), and symptom number (Underactive Thyroid Symptom Rating Questionnaire). Determinants of QoL were assessed using uni- and multivariate linear modeling with robust corrections, as well as mediation analysis.

Results

Our final study sample consisted of 157 patients, of whom 70.7% had Hashimoto's thyroiditis and 29.3% had hypothyroidism of iatrogenic origin (eg. cancer, thyroidectomy, or post-radioiodine treatment). The mean age of participants was 49.5 $\pm$ 14.5 years, average disease duration 11.2 $\pm$ 8.2 years, thyroxine dose 1.2 $\pm$ 0.4 mg/kg body weight, and a TSH level 1.8 $\pm$ 0.9 mIU/l. We found no significant association between QoL and thyroid-specific laboratory parameters, including TSH, FT3, FT4, rT3, anti-TPO, and SHBG. Using a multivariate model we identified somatization (B=-0.59, $P=0.005$), BMI (B=-0.08, $P=0.015$), and symptom number (B=-0.11, $P=0.043$) as the primary determinants of quality of life ($r^2 = 0.34$). Mediation analysis also revealed a significant indirect effect of depression on QoL, mediated primarily by somatization and BMI. In this later model 49% of the variation in symptom number was related to depression and somatization. After adjusting for psychometric factors, etiology had no effect in either analysis.

Conclusions

Our study suggests that psychological factors play a paramount role in determining quality of life of hypothyroid individuals receiving adequate levothyroxine replacement. Our findings do not support the notion that autoimmune inflammation or tissue-level hypothyroidism has a significant influence on QoL.

Management of Thyroid Nodules- a single centre experience/ a district Hospital Experience

Thein Lin Htut[1], Gideon Mlawa[2], Rabia Mahmood[1], Thura Hein[1], Dalya Sadulah[1], Gopika Sreejith[1] & Yasser Latif[1]

[1]Barking, Havering and Redbridge University Hospitals NHS Trust, Romford, United Kingdom; [2]Barking, Havering and Redbridge University Hospitals NHS Trust, Endocrine Department, Romford, United Kingdom

Background

A thyroid nodule is a discrete lesion within the thyroid gland, which can serve as a prelude to a spectrum of conditions ranging from a benign incidental growth to a full-blown invasive carcinoma. Thyroid nodules are very common in adult population. About 15% of the UK population have clinically detectable goitres or thyroid nodules, and the lifetime risk of developing a thyroid nodule is around 5 to 10%. In addition, there is increasing risk of thyroid cancers in the UK, numbers having more than doubled since the 1970s, and estimated to climb to 74% between 2014 and 2035. 1 Therefore, it is crucial to follow a defined protocol for investigation and risk stratification of such nodules, while ensuring judicious use of available resources.

Aim and Method

A retrospective study was undertaken in the East London District Hospital with the aim to assess the management of thyroid nodules in keeping with the guidelines published by British Thyroid Association Guidelines for Management of Thyroid Nodules (2014). We enrolled random patients who had been diagnosed with thyroid nodules on ultrasound imaging of the neck. We collected data from 50 patients, such as U score in their ultrasound reports, how they were followed up and the outcome of follow up. These data were analysed, by tracking their progress to date after being diagnosed with thyroid nodule.

Standards

We compared against the BTA thyroid nodule management guidelines (2014) which recommend that: (1) all thyroid ultrasounds should report U-score on thyroid nodules (2) U1-U2 nodules does not require fine needle aspiration cytology (FNAC) (3) U3-U5 requires further follow up with FNAC.

Result

According to this study, more than three-quarters of the cases appropriately met the standards defined in the BTA guidelines. Nearly ten percent of thyroid nodules were found to be thyroid cancers upon follow up. Less than 2% of ultrasound reports did not include a U score for thyroid nodule identified.

Conclusions

It was deduced that the follow up management plan for thyroid nodule cases was satisfactory within 2022. However, there are still some areas to emphasize for further perfection. It would be beneficial to introduce educational interventions including departmental teaching in order to ensure compliance to latest guidelines, for suitable follow up according to clinical indication, with the ultimate goal of positive impact on patient care.

Introduction/Aim

New oral anticoagulant drugs such as the factor Xa inhibitor rivaroxaban are often preferred to the classic coumarins because they do not need frequent blood-test monitoring and have fever interactions with other drugs and foodstuffs. They are not, however, interaction free. Rivaroxaban is metabolized by oxidative degradation catalyzed by CYP3A4/5 and CYP2J2; it is also a substrate of the P-gp and ABCG2 efflux transporter proteins. CYP3A4 activity enhancers such as phenytoin, carbamazepine, phenobarbital, rifampin, and the herbal antidepressant St. John's wort may decrease the efficacy of factor Xa inhibitors and increase the risk of thrombosis and embolism. We hereby report the case of a patient who presented recurrence of deep vein thrombosis (DVT) complicated with severe pulmonary embolism in spite of treatment with rivaroxaban, associated with the intake of Saint John's wort.

Methods

Review of the patient's record and the relevant literature.

Results

A 54 year old, non-smoker female patient with type 2 diabetes, obesity, sedentarism, hypertension and dyslipidaemia had recurrent episodes of DVT in both calves, and had been diagnosed of factor V Leiden deficiency. Treatment with acenocoumarol was prescribed, but her INR values were erratic; moreover she had several episodes of minor bleeding, and her treatment was switched to rivaroxaban 2.5 mg/12 h + AAS 100 mg/day. The patient remained asymptomatic for two years. Afterwards, the patient was admitted to the Emergency Room with sudden-onset dyspnea, tachypnea, tachycardia, hypotension, diffuse pleuritic chest pain, cyanosis and sincope. She had noticed tenderness, redness and swelling in her right calf during the previous week. Chest auscultation showed disseminated sibilant rales, and her pulse oximetry was 91%. DVT and pulmonary embolism were suspected and confirmed by calf ultrasonography and thoracic CT scan. Intravenous heparin therapy was begun along with support measures, and the patient was discharged on subcutaneous low molecular weight heparin after five days. When questioned again before discharge, she revealed self-medication with a non-prescription St. John's wort (Hypericum perforatum) preparation over the previous 3 weeks, motivated by depressive symptoms related to family issues.

Conclusions

Depression is a frequent comorbidity of DVT and the use of non-prescription herbal antidepressants such as Saint John's wort is often not reported by the patients. Saint John's wort may treble the activity of CYP3A4 and impair the effect of factor Xa inhibitors such as rivaroxaban with potentially serious consequences. The awareness of this interaction among the prescribing physicians is low and should be enhanced.

Introduction

The human fetal adrenals (HFA) produce high levels of steroids. The gland is distinguishable from the 7th gestational week and can be separated in two zones: the fetal zone in the center which correspond of 80 % of the gland and the definitive zone in the periphery. At this time of the development, neural crest cells are reaching the adrenal primordium, producing catecholamines. A third zone, the transitional zone appears later in the early 2nd trimester. The objective of our study is to evaluate the functionality of adrenals after freezing, thawing and cultured in 'hanging drops' for 14 days.

Tissues and Methods

Adrenal tissues from surgical elective abortions at 9-13 weeks of gestation was cut in several fragments of 1mm^3 and cultured in 'hanging drops' either straight after dissection or after vitrification or slow freezing and thawing in a drop of 40 µl of media containing ACTH 1ng/ml or not. Twelve steroids were measured by LC-MS/MS in medium recovered all along the culture and the expression of CYP17 was explored by immuno-histo-chemistry (IHC) after 2 weeks of 3D culture.

Results

Steroidogenesis is persistent after 2 weeks in organotypic culture and ACTH stimulate cortisol, cortisone and corticosterone secretion. After vitrification or slow freezing procedure, steroid secretion was similar. Analysis is in progress to compare the IHC results between the first and the second week of culture and between the tissues that have been frozen and those that have not.

Conclusion

We showed that 1er trimester fetal adrenals can produce steroids after vitrification or slow freezing and 2 weeks in organotypic culture. Adrenals, as gonads, derivate from the mesoderm. Indeed, the optimization of these techniques could help us to enhance the freezing/thawing protocols of immature testicular tissue in the context of fertility preservation of prepubescent youth.

Occurrence of thyroid autoimmunity, metabolic disorders and malignancy in patients with primary, non-syndromic hyperparathyroidism

Efstratios Kardalas, Georgia Ntali, Dimitra Argyro Vassiliadi & Stylianos Tsagarakis

Evangelismos General Hospital, Endocrinology, Metabolism and Diabetes Department, Athens, Greece

Background/aim

Primary hyperparathyroidism (pHPT) is a relatively common endocrine disorder, which is often asymptomatic and thus diagnosed during routine biochemical testing. Emerging scientific data supports the theory that non-syndromic pHPT patients may be at increased risk for thyroid autoimmunity, metabolic disorders and malignancy.

Materials and methods

A cohort of 227 pHPT (61 male and 166 female) and 244 non-pHPT (75 male and 169 female) patients from our endocrinology outpatient clinics was included in the retrospective study. Demographic, clinical and laboratory data of these patients were evaluated retrospectively.

Results

Mean age and body mass index of pHPT and non-pHPT patients were comparable (60.3 vs 58.1 years, $P=0.21$ and 28 vs 27.1 kg/m^2, $P=0.58$). pHPT affected more often female patients (166/227-73%) Autoimmune thyroid disease (AITD) was more prevalent among pHPT patients (78/227 [34.4%] vs 26/244 [10.6%], $P=0.01$). pHPT patients had more often diabetes mellitus (DM) (46/227 [20.3%] vs 23/244 [9.4%], $P=0.026$). On the contrary, obesity ($P=0.24$) and impaired fasting glucose (IFG) ($P=0.36$) were equally observed among the groups. The overall occurrence of cancer was increased among the pHPT patients (59/227 [26%] vs 38/244 [15.5%], $P<0.01$). The most commonly observed malignancy among all patients was differentiated thyroid cancer, which was more prevalent among the pHPT patients (19/227 [8.4%] vs 12/244 [4.9%], $P=0.014$). Regarding other malignancies, pHPT patients exhibited higher malignancy rates (40/227 [17.6%] vs 26/244 [10.6%], $P<0.01$). Among the pHPT patients, breast cancer was more frequent (12/227 patients), followed by lung and uterus cancer (7/227 and 4/227 patients respectively). Among non-pHPT patients, breast, lung and intestinal cancer were more prevalent (9/244, 5/244 and 3/244 patients, respectively). Finally, among pHPT patients, female patients suffered more often from AITD (65/166 [39.1%] vs 13/61 [21.3%], $P<0.01$) and DM (36/166 [21.7%] vs 10/61 [16.4%], $P=0.02$). Additionally, women were more obese (84/166 [50.6%] vs 11/61 [18%], $P=0.01$) and had more often IFG (8/166

[4.8%] vs 2/61 [3.3%]. $P=0.04$) than men. Interestingly, the prevalence of cancer was equal among male and female pHPT patients (16/61 [26.2%] vs 43/166 [25.8%], $P=0.15$).
Conclusions
Non-syndromic pHPT may be associated with increased risk for concomitant thyroid autoimmunity, metabolic disorders and malignancies. Thus, clinicians should be alert and routinely evaluate these patients for the previous mentioned pathological entities.

Role of insulin therapy in weight gain: lessons from islet transplantation in type1 diabetes

Bulois Romain[1], Arnaud Jannin[2], Frédérique Defrance[2], Le Mapihan Kristell[2], Chetboun Mikael[1], Kerr-Conte Julie[2], Pattou François[1] & Marie-Christine Vantyghem[1]
[1]Hospital Center University De Lille, Endocrine Surgery, Lille, France; [2]Hospital Center University De Lille, Endocrinology-Diabetology-Metabolism-Nutrition, Lille, France

Background
Weight gain in type 1 diabetes (T1D) patients has become a clinical problem due to less strict diets and more stringent glycemic targets. Thus, the number of overweight T1D in the USA increased from 3.4% in 1988 to 22.7% in 2007. Hyperinsulinism is involved in the genesis of obesity but in T1D, the impact of insulin therapy in weight gain is not established. Islet transplantation, now reimbursed in France, makes it possible to interrupt insulin. The aim of this work was to study weight evolution in an islet-transplanted population after obtention of insulin-independence and to determine the weight predictive factors.
Methods
monocentric retrospective study comparing the evolution of anthropometric and metabolic parameters before and 1, 3, 5 and 10 years after islet transplantation alone performed between 2003 and 2017, in 41 patients.
Results
The population (21 women, 20 men), aged (median (IQR)) 48 (42-55) years, had a weight of 71.4 (66-78) kg, a BMI of 24.7 (22.9-26) kg/m^2, a body fat percentage (DEXA) of 26.3 (20.0-31.5) %, and a daily insulin requirement of 41.3 (30.5-47.0) IU/day. The median weight loss at 1, 3, 5 and 10 years was 6.6 ($P=0.003$), 4.9 ($P=0.007$), 5.0 ($P=0.043$), and 5.4 kg ($P=0.418$) respectively, and correlated with the decrease in insulin doses ($r^2=0.295$; $P=0.0005$) at 5 years. In the 18/41 patients with a pre-transplantation BMI >25 kg/m^2, 10-year weight loss was permanent, unlike in the 23/41 patients with pre-transplantation normal BMI. The glycemic balance was identical between the 2 groups.
Conclusions
A weight loss is observed with islet transplantation, more marked in initially overweight subjects and correlated with the insulin dose decrease. These results suggest a role of exogenous insulin therapy in the weight gain of T1D patients, that is likely to limit their access to islet transplant, since a BMI below 28-30 is usually required is a favorable factor to gain insulin-independence after islet transplantatin. The latter, however, could be modulated by the level of insulin-sensitivity.

How did COVID-19 pandemic affect the glycemic regulation of patients with type 1 diabetes mellitus and continuous insulin infusion systems? Experience of a single diabetes center

Efstratios Kardalas, Nikolaos Katechakis, Dimitra Argyro Vassiliadi & Stylianos Tsagarakis
Evangelismos General Hospital, Endocrinology Diabetes and Metabolism, Athens, Greece

Background and Aims
The COVID-19 pandemic severely affected the glycemic regulation of adult patients with type 1 diabetes (T1D). The aim of this study was to evaluate the impact of this pandemic on glycemic control in T1D patients with continuous subcutaneous insulin infusion (CSII) systems.
Methods
A cohort of adult T1D patients with CSII was retrospectively evaluated. Data regarding number visits to our diabetes clinics, total daily insulin dose (TDID), blood and estimated HbA1c (b- and eHbA1c), time in range (TIR) (70–180 mg/dl), time below range (TBR) (<70 mg/dl) time above range (TAR)(>180 mg/dl) and coefficient of variation (%CV) in the pre- (March 2018- March 2020) and the pandemic (April 2020- April 2022) were collected.
Results
66 patients were studied (32 females) with mean age 44±12.1 years, mean body mass index [BMI] of 25.1±4 kg/m2 and mean total daily insulin dose (TDID) was 37±4.3 IU. Patients had a moderate glycemic control (mean bHbA1c 7.3±0.9%) while the mean estimated HbA1c (7.15±0.9%) (glucose management indicator or GMI) was slightly lower. Mean sensor use of patients was satisfactory (92.5%) while %CV (34.1±5.5%), which reflects intraday glycemic variability (GV), was marginally higher than normal. The average number of visits in the prepandemic period was 8, with a relatively strong negative correlation between this number of visits and HbA1c ($r=-0.65$) During the pandemic period, both BMI (25.1±4 vs 24.4±3.3 kg/m2, $P=0.11$) and TDID (37±4.3 vs 36.1±3.6 IU, $P=0.33$) remained stable. On the contrary, TIR increased significantly (65.8±8.6 vs 70.2±16.8%; $P=0.026$) while TBR (5.8±4 vs 4.9±3.8%; $P=0.007$) and TAR (28.4±5.4 vs 24.9±3.3%; $P=0.03$) diminished substantially. Furthermore, mean bHbA1c (7.3±0.9 vs 7.15±0.7%; $P=0.01$), eHbA1c (7.15±0.9 vs 6.94±0.65%; $P=0.005$) and %CV (34.1±5.5 vs 31.7±4.1%; $P<0.001$) decreased considerably during the pandemic. Additionally, the average number of visits was reduced to 4 per person in the postpandemic period and this number was moderately and negatively correlated with glycemic control ($r=-0.45$).
Conclusions
Glycemic regulation of adult patients with T1D and CSII improved significantly during the pandemic, despite reduced visits to the diabetes outpatient clinics.

Somatic RET M918T variant can modify the natural history of MEN2 related medullary thyroid carcinoma: a case report and literature review

Nicolas Sahakian[1], Pauline Romanet[2], Nunzia Cinzia Paladino[3], Delphine Mirebeau-Prunier[4], Frederic Castinetti[1] & Anne Barlier[2]
[1]Conception University Hospital - Aix Marseille University, Endocrinology, Marseille, France; [2]Conception University Hospital - Aix Marseille University, Molecular Biology, Marseille, France; [3]Conception University Hospital - Aix Marseille University, Endocrine Surgery, Marseille, France; [4]Angers University Hospital Center, Molecular Biology, Angers, France

Background
Multiple endocrine neoplasia type 2 associated medullary thyroid carcinoma (MTC) is driven by a strong genotype-phenotype correlation, the risk of aggressiveness being defined by the germline *RET* pathogenic variant (American Thyroid Association (ATA) guidelines). Based on this classification, the germline c.2370G>C, p.Leu790Phe (L790F) *RET* variant is considered to be of moderate risk of aggressive MTC, while the germline c.2753T>C, p.Met918Thr (M918T) *RET* variant presents the highest risk. In non-hereditary MTC, the somatic *RET* M918T mutation is also the main driver mutation of tumorigenesis and correlates with a worse outcome.
Patient findings
A 35-year-old woman presented with highly suspicious right thyroid nodule. Preoperative calcitonin and Carcino-embryonic antigen (CEA) were 2300 pg/ml and 21 ng/ml, respectively. Total thyroidectomy with neck dissection revealed a pT3N1b MTC. Genetic screening identified a moderate risk ATA germline *RET*-

mutation (*RET* L790F). As the patient rapidly developed lung and bone metastases, a genetic screening was performed on the MTC: a somatic *RET*-mutation (*RET* M918T) was identified explaining the rapidly aggressive phenotype presented by the patient. At last follow-up, six years after surgery, calcitonin and CEA were 6566 pg/ml and 84.2 pg/ml, respectively. Imaging investigations showed a persistent metastatic disease with cervical-mediastinal nodes, lung and bones metastasis. The patient showed no other manifestation belonging to the MEN2 spectrum. Her family member were screened for the germline variant and all carriers had normal calcitonin and neck ultrasound.

Discussion

We report the case of a double germline and somatic *RET* pathogenic variants, leading to a more aggressive profile than what the germline genetic screening was suggesting. Most of the studies reporting the natural history of MTC associated with *RET* L790F variant are in favor of an indolent disease. A large French multicentric study involving 77 patients with *RET* L790F germline mutation reported no distant metastases. Lymph node invasion was reported in 10/55 (18.2%) operated patients, with an early age of 32 years. After a 89-month follow-up, most of both index and screened patients were cured. On the other hand, several studies reported that patients with somatic *RET*-mutated MTC (mainly *RET* M918T) have a more advanced stage at diagnosis and experienced a worse outcome. The identification of additional somatic RET variant in addition to preexisting mutation in patients with hereditary MTC have been rarely reported and may promote tumorigenesis *in vivo*. Thus, this situation emphasizes the need to think differently when genotype and phenotype don't match in MEN2 related MTC.

Systemic inflammation in paragangliomas and pheochromocytomas

Özge Özer, Merve Apaydin Kayer, Evrim Yilmaz, Medine Nur Kebapci, Aysen Akalin, Belgin Efe, Mustafa Fuat Acikalin & Goknur Yorulmaz
Eskisehir Osmangazi University, Meselik Campus, Turkey

Background

Paragangliomas (PGLs) and pheochromocytomas (PCCs) arise from chromaffin cells. We evaluated the inflammatory markers. The pan-immune-inflammation value (PIV) has recently been used as a new marker. Therefore, we evaluated the PIV association in patients with PGLs/PCCs.

Methods

In the study, the data of 82 patients with PGLs/PCCs who applied between 2005 and 2020 were collected retrospectively from the records. NLR (neutrophil/lymphocyte ratio), PIV (pan-immune-inflammation value), PLR (platelet/lymphocyte ratio) values were calculated with the parameters measured from peripheral blood. These patients were compared with 47 healthy controls.

Results

PIV measurement was found to be higher than that of the control group ($P=0.028$; $P<0.05$). NLR measurement was also statistically significantly different ($P=0.001$; $P<0.01$). According to the ROC analysis, the most appropriate cut-off value for PIV to identify groups is ≥ 296.87.

Conclusion

As far as is known, our study is the first study with PIV in this patient group. This value was found to be significantly higher in the patient group. More studies are needed before it can be used as a marker.

In silico approaches advocates the sensitivity of adrenal gland against EDCs shown in male Wistar rats

Shahzad Ahmad & Sheikh Raisuddin
Jamia Hamdard, Department of Medical Elementology & Toxicology, New Delhi, India

Adrenal gland is a less focused endocrine organ for the endocrine disrupting effect of endocrine disrupting chemicals (EDCs). The effects of two extensively used phthalate esters viz. di-ethyl hexyl phthalate (DEHP) and di-butyl phthalate (DBP) on adrenal gland were observed in Wistar rats in the present study to check the susceptibility of adrenal gland against the exposure of these extensively used plasticizers which are well known EDCs. Wistar rats were divided into seven groups ($n=5$) and received the treatment for fourteen days. Group I was control and received only corn oil which is used as vehicle. Group II, III and IV received daily dose of DEHP of 250 mg/kg-BW, 750 mg/kg-BW and 1500 mg/kg-BW respectively while group V, VI and VII received daily dose of DBP of 100 mg/kg-BW, 500 mg/kg-BW and 1000 mg/kg-BW respectively. The comparative microscopic study of histological slides of endocrine glands i.e. pituitary, pineal, thyroid, parathyroid, adrenal gland and testes revealed the susceptibility of adrenal gland towards the DEHP and DBP. Molecular docking and protein-protein interaction (PPI) studies of DEHP and DBP have been employed using Maestro Schrodinger 9.4 software and STRING database showing the potential of DEHP and DBP to compare the molecular targets of above mentioned endocrine glands. Molecular docking and PPI studies advocates the sensitivity of adrenal gland as second most sensitive endocrine gland after testes by showing promising interaction with biochemical indices of adrenal gland. Therefore, further molecular studies are advised to divulge the molecular targets of EDCs and molecular mechanism underlying through them.

Keywords
DEHP, DBP, phthalate esters, molecular docking, protein-protein interaction

Characterization of RNA expression and clinical outcomes in patients with aggresive pituitary tumors treated with temozolomide

Eva Venegas Moreno[1,1], Pablo Remon[1], Elena Dios-Fuentes[1], Ana Piñar Gutiérrez[1], Juan Manuel Canelo[1,1], Rosario Oliva[2], Miriam Alonso-Garcia[3], Eugenio Cardenas[4], Ariel Kaen[4], Miguel E. G-Garcia[5], David Cano Gonzales[1], Raul M. Luque[5,5] & Alfonso Soto-Moreno[1]
[1]Unidad de Gestión Clínica de Endocrinología y Nutrición. Institute of Biomedicine of Seville (IBIS), Virgen del Rocio Hospital/CSIC/University of Seville, Seville, Seville, Spain; [2]UGC Endocrinología y Nutrición, Virgen Macarena, Seville, Spain; [3]UGC Oncología Medica, Virgen del Rocio, Seville, Spain; [4]UGC Neurocirugía, HU Virgen del Rocio, Seville, Spain; [5]OncObesidad y Metabolismo' del Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Cordoba

Methods

Descriptive retrospective study of the clinical outcomes and RNA expression in aggressive pituitary tumors treated with temozolomide. RNA expression was studied in tumor samples normalized to housekeeping genes including GH, POMC, PRL, αsub, FSH, LH, TSH, sst1, sst2, sst3, sst5, sst5b, sst5c, DR1, DR2T, DR2L, DR4, DR5, Ghrelin, In1-Ghrelin, GOAT, GHRR1b, AVPR1b, GHRH-R, GnRH-R, Ki-67, PTTG1, CRHR1.

Results

Ten patients were treated. 30% (3) prolactinoma, 30% (3) Cushing's disease, 40% (4) NFPT. 30% (3) pituitary carcinomas. Median presentation size was 32 [30-37] mm, historical maximum size 33 [30-37] mm. At presentation, 80% (8) had invasion of the cavernous sinus, and 90% had supra-chiasmatic invasion. 50% (5) ACTH, 10% (1) null cell, 10% (1) GH, 20% (2) PRL and isolated GH, and 10% (1) PRL. Ki-67 greater than 3% in 80% (8), Ki-67>10% in 40% (4). The median number of previous interventions was 2 [2-3]. 60% (6) had received previous radiation therapy, while the rest received it concurrently, with 40% (4) receiving it via the STUPP protocol. The number of cycles received was 17 [6-27]. The RNA expression of Ki67 and PTTG1 was found to be elevated in pituitary carcinomas. The expression of Ghrelin was found to be greatly increased in carcinomas and aggressive tumors, with patients who died having higher levels than survivors. The median maximum size prior to TMZ was 23 [19-30] mm, and at 6 months of treatment, the median maximum size was 17.5 [14-23] mm. A partial response was observed according to RECIST in 40% (4) of cases at 6 months, with one patient achieving partial response criteria after more than 6 months. The median time to maximum response was 0.48 [0.38-1.29] years. Progression was observed in 40% (4) of cases, with a median time to progression from the start of TMZ of 1.61 [1.11-2.32] years. Currently, 50% (5) of patients are not on TMZ treatment, 30% (3) due to progression and complementary treatments, and 10% (1) due to patient relocation. No serious adverse effects were observed, but asthenia was observed in 40% (4) of patients.

Conclusions

The treatment with temozolomide is safe in aggressive pituitary tumors and allows for achieving an initial response and medium-term stability. The

expression of certain RNAs (Ghrelin, PTTG1) may allow for estimating long-term aggressiveness risk and mortality.

Synovial sarcoma in a patient with long-standing acromegalia: Causal vs. coincidental

Ricardo Jose de Leon-Durango[1], Alba Hernandez-Lazaro[1], Borja Santana-Ojeda[1], Carlos Rios-Gomez[1], Claudia Arnas-Leon[1,2], Carmen Acosta-Calero[3], Agnieszka Kuzior[2], Esperanza Perdomo-Herrera[4], Alba Lucia Tocino-Hernandez[5] & Francisco Javier Martinez Martin[1,2]

[1]University Hospital of Gran Canaria Dr. Negrín, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [2]Clinica San Roque, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [3]University Hospital of Gran Canaria Dr. Negrín, Cardiology, Las Palmas de Gran Canaria, Spain; [4]Centro Salud Playa Blanca, Family & Community Medicine, Yaiza, Spain; [5]Centro de Salud Los Gladiolos, Family & Community Medicine, Santa Cruz de Tenerife, Spain

Introduction

Acromegaly is associated with many different types of benign and malign neoplasm, putatively because of the chronic elevation of IGF-1. Colorectal, thyroid and breast neoplasms are well-established associations; there are many other possible ones, such as prostatic and uterine neoplasms, meningioma, leukemia, lymphoma, renal, pulmonary, esophageal and gastric tumors. Also in the context of MEN-1, parathyroid and pancreatic neoplasms are associated with acromegaly. Synovial sarcoma is an infrequent and very aggressive malignant tumor characterized by a specific chromosomal translocation which fuses the SYT gene from chromosome 18 to a homologous gene (SSX1 or SSX2) at Xp11, resulting in the fusion proteins SYT-SSX1 and SYT-SSX2. The presence of IGF-1 receptors in synovial sarcoma is not universal, but has been associated with higher malignancy. Pazopanib, a tyrosine-kinase inhibitor, has been approved for use in synovial sarcoma; the use of IGF-1 receptor inhibitors is undergoing clinical trials. The association of acromegaly and synovial sarcoma has not been reported so far but is plausible from an etiopathogenetic point of view. We hereby report the case of a patient presenting with a synovial sarcoma after long-standing acromegaly.

Methods

Review of the patient's records and of the relevant literature

Results (clinical case)

A 50-year-old patient complained of a painful nodule of about 3 cm in the medial epicondyle of her right elbow. After surgery the pathology diagnosis was synovial sarcoma, and the postsurgical workup only found two apparently unrelated nodules of 3 and 5 mm diameter in her right lung (CT scan). Due to the appearance of her hands, feet and nose, she was referred to our Endocrinology Clinic with the suspicion of acromegaly. The patient did not complain of any symptoms and her appearance had not substantially changed in the last ten years. Acromegaly was confirmed by high IGF-1 and lack of suppression of GH in OGTT. MEN-1 was excluded. An MR scan showed a 17 mm pituitary adenoma with minor stem displacement, not compromising the cavernous or the optic chiasm. Transsphenoidal surgery was performed, with near-normalization of plasma IGF-1, preservation of the pituitary function and no ionic disturbances; the postsurgical workup including digestive endoscopy, mammography and cardiac ultrasonography is forthcoming.

Conclusions

Both acromegaly and synovial sarcoma are infrequent, and their coincidental association is unlikely. On the other hand, acromegaly is associated with many neoplasms via IGF-1 receptor hyperactivation. Synovial sarcoma should be added to the gamut of suspected acromegalia-associated neoplasms.

Pituitary ACTH Secreting Carcinoma or metastasized Small Cell Pulmonary Carcinoma?

Sara Lopes[1], Ana Margarida Monteiro[1], Juliana Sá[1], Catarina Matos[1], Catarina Machado[1], Pedro Ribeiro[2], Rui Almeida[2] & Olinda Marques[1]

[1]Hospital de Braga, Endocrinology, Braga, Portugal; [2]Hospital de Braga, Neurosurgery, Braga, Portugal

Pituitary carcinomas are rare and represent a challenge in clinical practice. Most secondary tumour localizations are intracranial and spinal, followed by liver, cervical lymph node, bone and, rarely, lung. PC frequently exhibit resistance to most usual therapies and the mean survival time is usually <4 years once metastases have been identified. Ectopic ACTH Syndrome is, in up to 50% cases, caused by lung tumours including carcinoids or Small Cell Lung Carcinomas (SCLC). SCLC can secrete ACTH in 1-6% cases. Pituitary metastasis are rare and mainly derived from breast and lung cancers. We report a case of 75 years old men with past history of hypertension, that entered the emergency room with pulmonar tromboembolism (PTE). Two days after he suffered apoplexy of a a previously unknown pituitary macroadenoma. He had elevated ACTH, urinary free cortisol, late serum night cortisol and normal abdominopelvic TC (beyond PTE lesions). He had no cushingoid features. Lab values and adenoma volume improved, but 9 months later he suddenly developed symptoms of hypercortisolism with worsening lab and imaging. He underwent transphenoidal surgery with partial removal. Immunohistochemistry revelead: ACTH adenoma with bone invasion, Ki 40%. He was reoperated and submitted to CyberKnife/SRS for residual left intracavernous adenoma in 3 months. He was clinicaly stable for 8 months, although without remission, under Metirapone therapy. Due to adenoma regrowth, a third surgery with a macroscopically extended removal was performed. Two days after he had basal cortisol 132 mg/dl and severe de novo hypokalemia. 18F-FDG PET-TC showed a suspicious lung nodule and hepatic metastasis. He maintained Metirapone and initiated Ketoconazole. The hepatic biopsy revealed neoplastic cells, Ki 90%, CK CAM5.2, Sinaptofisin, CD56 and Cromogranin A positive; CK7 and CK5/6 negative. It was assumed a probable origin in SCLC. The pulmonary biopsy revealed necrotic tissue. Pituitary histology was reviewed: Sinaptofisin positive, TTF1, napsina A and P40 negative. The results excludes pulmonary origin. Pulmonary oncology group classified the pulmonary lesion as SCLC, T3N0M1c-IVB and patient began chemotherapy with inicial clinical and pulmonar nodule improvement. Subsequent complications as pancitopenia, large haematomas, severe hypokaliemia, SARS CoV 2 infection and Klebsiella sepsis led to chemotherapy interruption and lastly patient's death. A post morten hepatic biopsy immunohistochemistry review showed TTF1 and ACTH negative. The authors conclude this is a rare case of an ACTH secreting Pituitary Carcinoma with fulminant metastatic lung and hepatic disease and highlight for the challenges and difficulties in diagnosing and treating those patients.

AMH in men: Higher serum levels associated with healthy male aging

Veronika Tandl[1], Christoph W. Haudum[1], Katharina Eberhard[2], Barbara Hutz[1], Ewald Kolesnik[3], Albrecht Schmidt[3], Andreas Zirlik[3], Dirk von Lewinski[3], Daniel Scherr[3], Nicolas Verheyen[3], Thomas R. Pieber[1] & Barbara Obermayer-Pietsch[1]

[1]Medical University of Graz, Department of Internal Medicine, Division of Endrocrinology and Diabetology, Graz, Austria; [2]Medical University of Graz, Core Facility Computational Bioanalytics, Graz, Austria; [3]Medical University of Graz, Department of Internal Medicine, Division of Cardiology, Graz, Austria

Anti-Müllerian hormone (AMH), known for its role in fetal development and female reproduction, is also present in adult and elderly men in considerable amounts. In recent years, controversial findings regarding relations to age, other hormones, and BMI (possibly based on a dilutional effect due to higher blood volume) have been discussed. To date, little is known of its clinical relevance in this population. We aimed to further investigate AMH levels in an aging male population and explore their relationship to various health parameters referring to potentially underlying (patho-)physiology. Out of the ongoing prospective BioPersMed cohort (Biomarkers for Personalized Medicine), we included male volunteers with available serum AMH measurements for cross-sectional ($n=379$) and longitudinal analysis ($n=320$) analysis over 3.8 ± 1.2 (max 6.8) years. AMH and metabolic, hormonal, reproductive, and functional muscle parameters, as well as DXA-derived (dual energy X-ray absorptiometry) body

composition were explored. AMH values were log-transformed for the statistical analyses, adjusted R^2 values are given. In our cohort, median age was 59 years (IQR = 13) and median serum AMH levels ranged from 0.07 to 23 ng/ml (median = 4.75; IQR = 4.02). An initial forward stepwise linear regression model included follicle stimulating hormone (FSH), estradiol (E2), total lean mass and mean handgrip values to best explain the variance of AMH levels ($R^2 = 0.217$). There was an inverse relationship of AMH and age ($R^2 = 0.021$; $\beta = -0.004$; $P = 0.003$). In >75% of participants, AMH levels decreased during follow-up. FSH was the most powerful predictor ($R^2 = 0.159$; $\beta = -0.017$; $P < 0.0001$) of AMH. When both age and FSH were included in a model ($R^2 = 0.162$), age was no longer significant ($P = 0.153$), in contrast to FSH ($P < 0.0001$). AMH decreased with BMI ($R^2 = 0.044$; $\beta = -0.01$; $P = 0.002$), but lean mass yielded a better fit ($R^2 = 0.065$; $\beta = -0.008$; $P < 0.001$) than BMI or fat mass. Including both parameters ($R^2 = 0.062$), the relationship with BMI was no longer significant ($P = 0.7$) other than with lean mass ($\beta = -0.007$; $P = 0.006$). E2 was inversely correlated to AMH levels ($R^2 = 0.049$; $\beta = -0.003$; $P < 0.0001$), remaining significant after including potential confounders. The positive relationship of AMH and mean handgrip ($R^2 = 0.009$; $\beta = 0.001$; $P = 0.048$) stayed significant when included in a model with both lean mass and FSH ($R^2 = 0.19$; $\beta = 0.002$; $P = 0.003$). The age-dependent parameters FSH, E2, handgrip strength and lean mass were significantly related to AMH levels. Lean mass, as a proxy of blood volume, was a better predictor than BMI, suggesting some dilution effect. In summary, we found higher AMH levels being an interesting marker for healthy aging in males.

Polycythemia vera and feminizing hormone treatment in an individual Assigned Male at Birth (AMAB): a prickly situation

Chiara Parazzoli[1], Elisa Delle Donne[1], Silvia Federici[1,2], Myriam Amer[1], Luca Persani[1,2], Marco Bonomi[1,2] & Stefania Bonadonna[2]
[1]University of Milan, Department of Medical Biotechnology and Translational Medicine, Milano, Italy; [2]IRCCS, Istituto Auxologico Italiano, Endocrinology Department & Lab of Endocrine and Metabolic Research, Milan, Italy

Introduction
Feminizing hormone therapy (HT) for male-assigned at birth (AMAB) includes estrogens, often in combination with anti-androgens. Several studies have reported an increased incidence of cardiovascular diseases and venous thromboembolism in AMAB receiving estrogens. Indeed, procoagulant changes induced by estrogen-based HT occur in transwomen as well as in cisgender individuals. Therefore, using estrogen in gender-affirming HT is relatively contraindicated in those with a history of thrombosis or thrombophilia. Polycythemia vera (PV) is a chronic myeloproliferative neoplasm characterized by increased erythropoiesis and is a relative contraindication to HT because of its high thrombotic risk.
Case Presentation
We describe a 36-year-old AMAB with PV and gender dysphoria. The patient had suffered clinically significant distress due to gender incongruence with a stable female gender identity since childhood. Indeed, in 2020, a diagnosis of gender dysphoria was made, and the patient expressed her firm will to begin a feminizing transition. However, in 2017, she was diagnosed with JAK2-positive PV and started treatment with low-dose aspirin and phlebotomy every month. Given her younger age and no history of thrombosis, her PV was considered at low risk for recurrent thrombosis. Nevertheless, the use of estrogen in her gender-affirming therapy was initially avoided due to the negative advice of her hematologist. Thus, to reduce her significant dysphoria, low-dose anti-androgen therapy with spironolactone 25 mg/day, preferred for less procoagulant effects, was started in June 2021 and titrated to 50 mg/day with clinical and psychological benefit. After one-year, lower testosterone levels were detected with concomitant improvement in hematocrit (43.5% vs 47.5% pre-treatment) and erythrocyte count (5.3/mm^3 vs 6.2/mm^3), allowing to extend the phlebotomy interval to 3 months.
Discussion & Conclusion
To date, there are no guidelines for gender-affirming HT in PV patients, and to our knowledge, no cases have been reported. Because of the lack of literature, we investigated the thrombosis risk of PV in other hyperestrogenic conditions, such as pregnancy. In patients with low-risk PV during pregnancy, antiplatelet therapy alone appears to be sufficient to prevent thrombotic complications. Therefore, even in our patient, low-dose aspirin helps to control the thrombotic risk. Moreover, anti-androgen therapy also had a beneficial effect by lowering the hematocrit, may be related to the decrease in testosterone levels, which normally increase erythropoietin and erythrocyte production. However, anti-androgen therapy alone could lead to hypogonadism with all its complications. Therefore, in our AMAB with PV we are currently considering combining anti-androgens with low-doses transdermal estrogens.

A case of functional hypercortisolism associated to alcohol abuse in a 43-year-old male

Borja Santana-Ojeda[1], Carlos Rios-Gomez[1], Ricardo Jose de Leon-Durango[1], Alba Hernandez-Lazaro[1], Agnieszka Kuzior[2], Claudia Arnas-Leon[1,2], Carmen Acosta-Calero[3], Paula Gonzalez-Diaz[4], Catherine del Pino Ortiz-Hernandez[5] & Francisco Javier Martinez Martin[1,2]
[1]University Hospital of Gran Canaria Dr. Negrín, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [2]Clinica San Roque, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [3]University Hospital of Gran Canaria Dr. Negrín, Cardiology, Las Palmas de Gran Canaria, Spain; [4]University Hospital of Gran Canaria Dr. Negrín, Emergency Medicine, Las Palmas de Gran Canaria, Spain; [5]Bañaderos Primary Healthcare Center, Family & Community Medicine, Arucas, Spain

Objective
Functional hypercortisolism associated with alcohol abuse is an infrequently diagnosed entity of unknown prevalence. Ethanol elicits hypothalamic over-secretion of CRH with subsequent increase in ACTH and cortisol. It may simulate Cushing's disease both clinically and biochemically but there are no anatomic lesions and the diagnosis is confirmed by normalization of the biochemical pattern after at least 1 month of abstinence from alcohol. We hereby report a clinical case in order to increase the awareness of alcohol-induced functional hypercortisolism.
Methods
Review of the patient's record and of the relevant literature
Clinical Case
A male, 43-year-old patient was referred to our Endocrinology Clinic with suspected Cushing's syndrome, because of the typical phenotype, with central obesity and proximal muscle atrophy, round face, interscapular fat pad, violaceous striae and ecchymosis. These signs had appeared gradually during the last 5-8 years but in the last few months he complained of progressive incapacitating asthenia. The patient showed borderline central obesity (BMI 29.4 kg/m^2), with enlarged liver without palpable lumps, high blood pressure (154/92 mmHg) and inability to stand up from the sitting position without arm support Lab tests; Routine normal except fasting glucose 112 mg/dl, HbA1c 6.2%, triglycerides 368 mg/dl, AST 124 U/l, ALT 98 U/l, GGT 169 U/l, cyanocobalamin <137 pg/ml, folate 2.1 ng/ml, MCV 102 fL, platelets 127000/mm^3, FIB-4 index 4.73. Hormones: Normal except ACTH 57.2 pg/ml, fasting cortisol after 1 mg dexamethasone suppression 18.1 µg/dl; 24-hour cortisol excretion 211 µg. After 14 days the results were similar (61.4 pg/ml, 21.8 µg/dl, 198 µg respectively). Abdominal ultrasonography: hepatomegaly and intense steatosis without nodules: both adrenals were normal. Pituitary MRI was normal. Thoracic/abdominal CT showed no additional findings Petrosal sinus sampling was scheduled but then the patient revealed alcohol abuse for the last 10 years, with usual daily intake of half a liter of rum plus variable amounts of beer, wine and other spirits. The patient was encouraged to abstain from alcohol and treated with vitamin B complex supplements. After 3 months, the Cushing phenotype was largely reversed, the patient could stand up easily, and the biochemical profile was normal (cortisol 1.4 µg/dl after dexamethasone, excretion 32 µg, fasting ACTH 26 pg/ml).
Conclusions
This case illustrates a probably underdiagnosed entity. Alcohol abuse may go unreported and patients may remain in a diagnostic quagmire. When hypercortisolism is unexplained, functional causes such as alcohol abuse, major depression, chronic emotional stress, etc. must be ruled out.

Insulin Pump Therapy in Pregnant Women with type 1 Diabetes: Flash Glucose Monitoring vs Sensor Augmented Pump

Karla Mariaca Riveros, Camila Milad, Daria Roca, Antonio Amor, Marga Giménez, Jordi Bellart & Irene Vinagre
Hospital Clinic Barcelona, Endocrinology and Nutrition, Barcelona, Spain

Objectives
Pregnant women with type 1 diabetes (T1D) are associated with an increased risk of maternal fetal complications. Continuous subcutaneous insulin infusion [CSII] has been shown to improve metabolic control and perinatal morbidity. Few studies have compared the use of CSII with SAP (sensor augmented pump) therapy to flash glucose monitoring (FSL) in pregnant women with T1D. We aim to evaluate the possible differences between both monitoring systems associated with CSII therapy and assess their effect on metabolic control during pregnancy and maternal-fetal morbidity.
Methods
This retrospective cohort study enrolled pregnant women with T1D on CSII treatment at a tertiary hospital between 2018 and 2022. We compared the SAP system (640G pump) with FSL monitoring (ISCI-FSL). Glucometric data of 14 days were obtained at every trimester of pregnancy from the different platforms (Carelink and Libreview); clinical and analytical data were obtained from medical records.
Results
were included 31 pregnant women with a mean age of 35 years and 20 years of T1D evolution. The SAP group ($n=21$) presented a higher percentage of pre-pregnancy control (80% vs 95.2%) and severe hypoglycemia in the 2 years prior to pregnancy (0 vs 28.6%), without significant differences ($P>0,05$). Regarding glycemic control, a longer time under range (<63 mg/dl) was evidenced in the ISCI-FSL group, both in the second (9.7 vs 5.8%, $P=0.044$) and in the third trimester (12.1 vs 5.6%, $P=0.012$), without statistically significant differences in time in range (63-140 mg/dl; 1stTrim 52.8 vs 54.8%, 2ndTrim 52.5 vs 55%, 3rdTrim 61.5 vs 63.9%) or in time over range (>140 mg/dl; 1st Trim 35.8 vs 36.6%, 2ndTrim 37.8 vs 39.2%, 3rd Quarter 26.4 vs 30.5%) between both groups. There were also no differences in HbA1c nor in the rate of severe hypoglycemia by trimester (table). Regarding neonatal complications, no significant differences were found in the incidence of macrosomia, neonatal hypoglycemia, malformations, and perinatal mortality, nor in the rate of maternal complications between both groups.
Conclusions
In this cohort of pregnant women with T1D on CSII therapy, FSL monitoring showed a longer time in hypoglycemia compared to the use of SAP, without finding other differences in metabolic control nor in maternal-fetal complications.

Does the 'obesity paradox' have an expiration date? A bigdata retrospective cohort

Matan Elkan[1], Natalia Kofman[2,3], Sa'ar Minha[2,3], Nadav Rappoport[2,4], Ronit Zaidenstein[1,3] & Ronit Koren[1,3]
[1]Shamir Medical Center (Assaf Harofeh), Internal Medicine A, Zerifin, Israel; [2]Shamir Medical Center (Assaf Harofeh), Department of Cardiology, Zerifin, Israel; [3]Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel; [4]Israeli Ministry of Health, Division of Government Medical Centers, Jerusalem, Israel

Background
Although obesity and overweight are associated with increased morbidity and mortality, higher body mass index (BMI) has been shown to be a protective factor from mortality in patients with acute infectious disease, also known as the 'obesity paradox'. However, it is unknown whether these effects persist at long-term follow-up.
Objective
To investigate the relationship between BMI and mortality after hospitalization with an infectious disease in a five-year follow-up period.
Methods
A retrospective analysis of 25,226 adult patients admitted with an acute infectious disease between the years 2010-2020 to Shamir Medical Center, Israel, was conducted. We compared patients in the following BMI categories underweight 15-18.5 kg/m^2, normal-weight 18.5-25 kg/m^2, overweight 25-30 kg/m^2, obesity class-I 30-35 kg/m^2, obesity class-II 35-40 kg/m^2, and obesity class-III 40-45 kg/m^2, regarding mortality during hospitalization and follow-up.
Results
Patients in different BMI categories were heterogeneous regarding baseline demographics and comorbidities, as well as infectious syndrome at index hospitalization. In-hospital mortality and one-year mortality were higher in underweight and normal-weight patients as compared to all other categories, 22% and 13.2% vs. 7-9% ($P<0.001$) in-hospital, and 31.8% and 20.6% vs. 13-15.6% ($P<0.001$) at one year. Five-year mortality was only significantly higher in the underweight group, 44.4% vs. 30.8%-36.1% ($P<0.001$). In a multivariable logistic regression analysis, adjusted for age, sex, comorbidities, and infectious syndrome, underweight was associated with a significantly increased odds ratio (OR) for In-hospital, one-year, and five-year mortality. While, overweight and obesity were associated with a decreased OR for mortality at all time points. Compared to normal-weight OR for mortality at five years was 0.68 (CI 0.62-0.74 $P<0.001$) in the overweight category, 0.61 (CI 0.55-0.68, $P<0.001$) in obesity class I, 0.71 (CI 0.61-0.83, $P<0.001$) in obesity class II, and 0.71 (CI 0.56-0.89, $P=0.004$) in obesity class III. In a survival analysis model, all categories of obesity were associated with a decreased OR for mortality compared to normal weight, while underweight was associated with increased OR (five-year mortality OR 1.72 CI 1.59-2.07, $P<0.001$).
Conclusions
Our study found evidence of an 'obesity paradox' for up to five years following hospitalization due to infectious causes. Although we did not find a significant univariate association between BMI of 18.5-25 kg/m^2 and five-year mortality, upon multivariate analysis all groups of overweight and obesity were independently associated with decreased mortality compared to this group. Further studies should search for explanations for this counterintuitive phenomenon.

Reduction of urinary albumin excretion with empagliflozin in patients with type 2 diabetes and uncontrolled hypertension

Claudia Arnas-Leon[1,2], Alba Hernandez-Lazaro[1], Borja Santana-Ojeda[1], Carlos Rios-Gomez[1], Ricardo Jose de Leon-Durango[1], Carmen Acosta-Calero[3], Agnieszka Kuzior[2], Jennifer Maria Perez-Rivero[4], Sara Quintana-Arroyo[5] & Francisco Javier Martinez Martin[1,2]
[1]University Hospital of Gran Canaria Dr. Negrín, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [2]Clinica San Roque, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [3]University Hospital of Gran Canaria Dr. Negrín, Cardiology, Las Palmas de Gran Canaria, Spain; [4]Centro Salud Escaleritas, Family & Community Medicine, Las Palmas de Gran Canaria, Spain; [5]Hospital Universitario Insular de Gran Canaria, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain

Introduction
Empagliflozin has a well-established anti-albuminuric effect in patients with T2DM, but in almost all available trials the baseline blood pressure was well controlled with SB $P<140$ mmHg. We analyzed the impact of empagliflozin treatment in patients with T2DM and uncontrolled hypertension, and its relationship with the changes in HbA1c and SBP.
Methods
Retrospective analysis of the albuminuria, SBP and HbA1c data in patients with T2DM and high office blood pressure (SB $P>140$ mmHg) when starting empagliflozin therapy. Post-hoc mediation analyses were performed with SBP and HbA1c changes as mediators in order to quantify their relative contributions to the changes in albuminuria. All included patients gave informed consent. Patients who started or changed antihypertensive medication simultaneously with the onset of empagliflozin therapy were excluded. Data are given as mean ± sd.
Results
Data were obtained from 169 patients (59.8% women, age 64.5 ± 9.3 years) in the visit in which empagliflozin was started (10 mg day in almost all cases), and in a successive visit after 3-6 months. 101 patients were on ACEI or ARB (59.7%). Baseline HbA1c was 8.2 ± 1.6% and the change was -0.7 ± 0.3% ($P=0.011$, paired t-test). Baseline SBP was 167 ± 18 mmHg and the change was 7.3 ± 5.1 mmHg ($P=0.007$, paired t-test). At baseline, 83 (49%), 57 (34%) and 29 (17%);

and successively 98 (58%), 48 (28%) and 23 (14%) had normoalbuminuria (<30 mg/g Cr), microalbuminuria (30-300 mg/g Cr) or macroalbuminuria (> 300 mg/g Cr), respectively. Albuminuria was reduced by 9% (CI 95%: 14%-4%, $P=0.043$) in patients with normoalbuminuria; by 29% (35%-23%, $P=0.002$) in patients with microalbuminuria, and by 38% (47%-29%, $P=0.003$) in patients with macroalbuminuria. The reduction in albuminuria was significantly correlated with those of HbA1c (Pearson's R: 0.18; $P=0.008$) and SBP (Pearson's R 0.26; $P=0.003$). Mediation analyses showed that 16% (CI 95%: 12-20%, $P=0.011$) of the reduction in albuminuria was mediated by HbA1c reduction, and 25% (19-31%, $P=0.004$) by SBP reduction, but 59% was independent of both mediators.
Conclusions
Empagliflozin therapy was associated with a clinically and statistically significant reduction in albuminuria in patients with T2DM and uncontrolled hypertension. Although the reductions in HbA1c and SBP clearly contributed to this effect, much of the reduction in albuminuria seems to be attributable to other mechanisms, most likely the restoration of the tubuloglomerular feedback.

Retinal quantitative traits as prognostic factors for diabetic cardiomyopathy in people with type 2 diabetes: A scoping review

Emmanuel Sandoval Garcia[1,2] & Rubi Stephani Hellwege[3,4]
[1]The University of Edinburgh, Usher Institute, Edinburgh, United Kingdom; [2]Royal Infirmary of Edinburgh NHS Lothian, Acute Internal Medicine, Edinburgh, United Kingdom; [3]Kantonsspital St. Gallen, St. Gallen, Switzerland; [4]The University of Edinburgh, Edinburgh, United Kingdom

Introduction
Heart failure (HF) morbidity and mortality are increasing at an alarming rate in people with type 2 diabetes (T2D). Myocardial dysfunction may develop without ischemic heart disease (IHD), hypertension, or valvular pathologies, and which is defined as diabetic cardiomyopathy (DCM). Although the pathophysiology of DCM is unclear, DCM is initially characterised by myocardial fibrosis, dysfunctional remodelling, and associated diastolic dysfunction, later by systolic dysfunction, and eventually by clinical HF. Retinal quantitative traits have been seen associated with cardiovascular complications in T2D. Previous studies have shown that the presence of narrowing retinal arterioles and decreased fractal dimension – a novel biomarker of microvascular density- have been associated with IHD and HF, independent of well-known cardiovascular (CV) risk factors. A novel paradigm of DCM focuses on pro inflammatory signalling originating from the myocardial microvasculature. Nevertheless, phenotyping the cardiac microvasculature in this population is not feasible in clinical settings. In comparison, the retinal microvasculature can be completely noninvasively and reproducibly evaluated. Currently, there is a paucity about the current evidence about retinal traits and DCM. This scoping review aims to map existing literature and provide a summary of retinal parameters and DCM in people with T2D. This includes risk factors, interventions and identification of research gaps in the literature.
Methods
Electronic databases (MEDLINE, EMBASE, and, Web of Science) were systematically and independently searched following the Joanna Briggs Institute (JBI) guidelines until February 2023. Two independent researchers assessed the literature and conducted the review according to the Preferred Reporting Items for Systematic Reviews and Meta-Analysis guidelines for Scoping Reviews (PRISMA-ScR).
Results
Of the 1072 articles screened, 15 articles met inclusion criteria. The majority were cross-sectional and prospective studies concentrated in North America and Europe. In people with T2D, the presence of moderate and severe retinopathy was associated with heart failure and subclinical left ventricular myocardial dysfunction. Moreover, low retinal vascular fractal dimension was associated with congestive heart failure.
Conclusion
There has been much optimism that quantitative retinal traits may associate with diabetic cardiomyopathy beyond conventional CV risk factors. However, evidence is scarce in people with T2D compared to population-based studies. Clearly, further studies are necessary to understand the potential phenotypes including echocardiographic findings and underlying mechanisms for DCM in people with T2D.

Effects of oral semaglutide on the lipid profile of patients with type 2 diabetes mellitus and obesity: Are they mediated by body weight loss?

Agnieszka Kuzior[1], Borja Santana-Ojeda[2], Ricardo Jose de Leon-Durango[2], Alba Hernandez-Lazaro[2], Carlos Rios-Gomez[2], Claudia Arnas-Leon[1,2], Carmen Acosta-Calero[3], Paula Gonzalez-Diaz[4], Paula Maria Fernandez-Trujillo-Comenge[2] & Francisco Javier Martinez Martin[1,2]
[1]Clinica San Roque, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [2]University Hospital of Gran Canaria Dr. Negrín, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [3]University Hospital of Gran Canaria Dr. Negrín, Cardiology, Las Palmas de Gran Canaria, Spain; [4]University Hospital of Gran Canaria Dr. Negrín, Emergency Medicine, Las Palmas de Gran Canaria, Spain

Introduction
It has been reported that patients with obesity and T2DM treated with oral semaglutide not only have a reduced total caloric input, but they also tend to reduce the proportion of fatty and sweet foodstuffs in an *ad libitum* diet. A modest improvement in the lipid profile of patients with obesity and T2DM treated with oral semaglutide has been reported, but its dependence on weight loss is not well established. We undertook to study the mediation effect of weight loss on the lipid profile changes in these patients.
Methods
We performed retrospective analyses of the lipid profiles of consecutive patients with obesity and T2DM who started oral semaglutide therapy. Data were obtained from the baseline visit and a successive visit, 3-5 months afterwards. Post-hoc mediation analyses were performed in order to quantify the relative contribution of weight loss in the lipid profile changes. Patients who started or changed lipid-lowering medication simultaneously, or refused informed consent were excluded. Data are given as mean $\pm$ sd.
Results
Data were obtained from 48 patients, 31 (65%) women, age 54.4 $\pm$ 11.8 years, T2DM duration 6.7 $\pm$ 2.7 years, BMI 36.6 $\pm$ 5.3 kg/m^2; 43 (90%) had 14 mg semaglutide daily, 3 (6%) 7 mg, and 2 (4%) 3 mg. 29 (60%) of the patents were on statins,12 (25%) on fibrates and 4 (8%) on EPA/DHA supplements. The geometric mean of the total cholesterolemia at baseline was 167 mg/dl, variation coefficient 47%. For HDLc, LDLc and non-HDLc the values were 44 mg/dl, 58%; 82 mg/dl, 49%; 122 mg/dl, 52%, and 207 mg/dl, 68%. The changes in total cholesterol and its fractions (HDLc, LDLc, non-HDLc) were favorable but non-significant (-4.8%, +2,2%, -7.3%, -2.1%) while there was a significant reduction of triglyceridemia from its baseline value 207 $\pm$ 68 mg/dl (-17.6 $\pm$ 11.5%, $P=0.021$). The weight loss was -3.6 $\pm$ 1.5 kg ($P=0.033$). The reductions in weight and triglycerides were positively correlated (Pearson's R: 0.29, $P=0.0023$). The mediation analyses showed that a reduction of 6.4 $\pm$ 7.3% in triglyceridemia was mediated by weight loss, but 11.2 $\pm$ 8.4% was independent of it.
Conclusions
In patients with T2DM and obesity, oral semaglutide significantly improved plasma triglycerides, with a non-significant improvement of total cholesterol and its fractions. The reduction of triglyceridemia was mediated only partially by weight loss, suggesting additional mechanisms, maybe including healthier dietary choices. Oral semaglutide may reduce the need for fibrates and EPA/DHA supplements.

Somatostatin Analogues or Active Surveillance in Sporadic and MEN1 associated Non-functioning Pancreatic Neuroendocrine Tumors

Salvatore Raia[1], Sabrina Chiloiro[1], Maria Grazia Maratta[2], Brigida Maiorano[3], Ernesto Rossi[2], Maria Gabriella Brizi[4], Vittoria Rufini[5], Laura De Marinis[1], Alfredo Pontecorvi[1], Giampaolo Tortora[2], Guido Rindi[6], Giovanni Schinzari[2] & Antonio Bianchi[1]
[1]Fondazione Policlinico Universitario A. Gemelli IRCCS- UCSC, Endocrinology, Rome, Italy; [2]Fondazione Policlinico Universitario A. Gemelli IRCCS- UCSC, Oncology, Rome, Italy; [3]Ospedale Casa Sollievo della Sofferenza IRCCS, Oncology, San Giovanni Rotondo, Italy; [4]Fondazione Policlinico Universitario A. Gemelli IRCCS- UCSC, Radiology, Rome, Italy; [5]Fondazione Policlinico Universitario A. Gemelli IRCCS- UCSC, Nuclear Medicine, Rome, Italy; [6]Fondazione Policlinico Universitario A. Gemelli IRCCS- UCSC, Pathology, Rome, Italy

Introduction
Non-functioning (NF), sporadic and MEN1 associated, G1-G2 pancreatic neuroendocrine tumors (PanNETs) usually display an indolent course. Surgery

is the first-choice treatment for localized tumors >2 cm. Unresectable or metastatic PanNETs expressing somatostatin receptors (SSTRs) are treated with somatostatin analogs (SSAs). The standard treatment for patients with PanNETs ≤ 2 cm is active surveillance (AS). Yet no evidence of the value of SSA treatment exist in such patient population.
Aim(s)
To assess the clinical value of SSAs in patients with PanNETs ≤ 2 cm. Material and methods: Data from patients (pts) NF, G1-G2 PanNETs≤ 2 cm were retrospectively collected. Median progression-free survival (mPFS) and response rate (RR) were analyzed in SSA group and AS group. Results: From June 2007 to June 2022, data from 46 pts were considered: 29 pts, who declined an AS program but had not indication for surgery, entered in the SSA group (21 sporadic and 8 MEN1 associatd PanNET) and 17 in the AS group. At a median follow-up of 64.8 months for sporadic and of 63.9 for MEN1 associated PanNET, no disease progression (PD) was reported in the SSA group, without differences between sporadic and MEN1 associated PanNET. While the PD rate was 23.5 % in the AS group, with a mPFS of 36.2 months.
Conclusion
SSAs therapy showed significant antiproliferative activity in patients with both sporadic and MEN1 associated NF, G1-G2 PanNETs ≤ 2 cm. SSAs treatment delay tumor progression and distant spread in small lesions that sometimes may reveal an unpredictable aggressiveness.

Evaluation with Dynamic Contrast Enhancement (DCE)-MRI in Patients with Acromegaly

Ahmet Toygar Kalkan, Özge Özer, Ugur Toprak, Belgin Efe, Aysen Akalin, Medine Nur Kebapci & Goknur Yorulmaz
Eskisehir Osmangazi University, Meselik Campus, Turkey

Acromegaly is a rare disease with high morbidity and mortality associated with excessive secretion of growth hormone due to adenoma of somatotroph cells in the pituitary gland. In patients with acromegaly, residue may remain after surgical treatment, and disease control is attempted with surgery, medical treatment or radiotherapy for these patients. Pituitary imaging, IGF-1 and GH measurement are used in the follow-ups. Dynamic Contrast Enhancement perfusion MRI provides information about tissue properties at the microvascular level. It provides information and comparison about normal-neoplastic tissue permeability. K-trans transfer constant and increases in neovascularity The K-trans demonstrated by this MRI is the transfer constant and increases in neovascularity. Ve indicates the fractional volume of the extracellular space, increasing in necrosis. Kep is the velocity constant. The IAUC is a data on the interstitial area under curve, fractional blood volume. Since there are also studies showing that GH increases neovascularity, we thought that evaluation with Dynamic Contrast Enhancement (DCE)-MRI could be a clearer guide to the clinician in terms of clarifying the adenoma type during the diagnosis and follow-up of patients with acromegaly.
Material Method
A total of 31 patients including postoperative residual adenoma, 16 diagnosed with non-functioning adenoma (NFA), and 15 diagnosed with acromegaly, were included in the study. MRI Examination was performed with a GE 750W 3.0T MR scanner (2013, GE Healthcare, Milwaukee, WI) using a 16-channel GEM Quiet HNU head coil. Precontrast sagittal and coronal T1 and T2 weighted, postcontrast coronal coronal and sagittal T1, coronal FIESTA sequences after DCE-MRI were taken. MRI images were evaluated by a radiologist with 20 years of experience in neuroradiology. The radiologist was blind to the patients' pathology.
Results
Although the K-transAdenoma and KepAdenoma values were higher in the patients' residual adenomas, the madian values were higher in the acromegaly residues, but no statistically significant difference was found ($P>0.05$). However, a positive correlation was found between the GH values of GH secreting adenomas and K-transAdenoma and KepAdenoma values ($r=0.552$, $r=0.605$, $P<0.05$, respectively).
Discussion
DCE-MRI may be a promising method in the diagnosis and follow-up of acromegaly, since the median values are high in acromegaly residues, although there is no statistical difference, and there is also a positive correlation between GH levels and Ktrans and Kep values in GH-secreting adenomas. Considering the available data together with the relationship between GH and neovascularization, it seems promising to carry out further studies by enlarging the sample.

Background
Steroid synthesis inhibitors, like metyrapone, osilodrostat, and ketoconazole are used as second-line treatment in all types of endogenous Cushing's syndrome (CS). However, a direct comparison of these three drugs is missing. This study aimed to compare these drugs in the short-term therapy of CS.
Design
Retrospective multicenter study involving 15 European centers.
Methods
Patients with CS treated with metyrapone, osilodrostat or ketoconazole as monotherapy for at least 2 weeks were considered eligible. Main outcomes were changes in serum cortisol and 24h urinary free cortisol (24h-UFC) after 2 (T1), 4 (T2), and 12 weeks (T3) of therapy compared to baseline (T0), evaluated as delta (change) percentage from T0 to the different time points. A mixed model was used to explore the data.
Results
Data of 210 patients from 9/15 centers were available. Of the 210 patients (78% females), 158 (75 %) suffered from ACTH-dependent and 52 (25%) from ACTH-independent CS. 83 (40%) patients were treated with metyrapone, 78 (37%) with osilodrostat and 49 (23%) with ketoconazole. No difference in terms of CS subtypes ($P=0.19$) and baseline 24h-UFC (median 295.5µg/24h, 286.0µg/24h and 360.0µg/24h for metyrapone, osilodrostat and ketoconazole, respectively, $P=0.32$) was identified. Median daily starting doses were 750 (range 250-2000)mg, 2 (1-10)mg and 400 (200-800)mg for metyrapone, osilodrostat and ketoconazole, which increased during the treatment for all drugs up to 1000 (250-3000)mg, 5 (1-40)mg and 400 (200-1200)mg, respectively (all $P<0.05$). 24h-UFC significantly decreased in all time points only in the osilodrostat group (-34% in T1, -46% in T2, and -68% in T3, $P<0.001$), being more pronounced at T3 than metyrapone (-37%, $P=0.02$). Under ketoconazole 24h-UFC decreased of -48% at T3. A decrease in serum cortisol was observed at T3 in all groups (metyrapone -7.8%; osilodrostat -39%; ketoconazole -36%). At T3 no significant changes in potassium levels were identified (metyrapone 0%; osilodrostat +2%; ketoconazole -0.6%); and 7 (15%) patients under metyrapone, 6 (10%) under osilodrostat and 0 under ketoconazole were supplemented ($P=0.03$ per trend). At T1, a decrease in

number of antihypertensives was identified in 10% of patients under metyrapone, 22% under osilodrostat and 6% under ketoconazole ($P=0.006$), whereas at T2 and T3 no significant differences were identified. No significant change was observed in Hb1Ac(%).

Conclusion

These preliminary results confirmed the efficacy of all the three drugs in decreasing hypercortisolism. Osilodrostat might act faster in decreasing blood pressure. However, these preliminary results need to be validated in the final cohort.

Importance of HLA in Grave's orbitopathy development in Caucasian population

Magdalena Stasiak[1], Katarzyna Zawadzka-Starczewska[1], Bogusław Tymoniuk[2], Bartłomiej Stasiak[3] & Andrzej Lewinski[1,4]
[1]Polish Mother's Memorial Hospital - Research Intitute, Department of Endocrinology and Metabolic Diseases, Lodz, Poland; [2]Medical University of Lodz, Department of Immunology and Allergy, Lodz, Poland; [3]Lodz University of Technology, Institute of Information Technology, Lodz, Poland; [4]Medical University of Lodz, Department of Endocrinology and Metabolic Diseases, Lodz, Poland

Introduction

Graves' disease (GD), similarly to most autoimmune disease, is triggered by environmental factors in genetically predisposed individuals. Particular HLA alleles increase or decrease GD risk. We have recently demonstrated novel, previously not reported association between a presence of alleles *HLA-B*39:06, -B*37:01, -C*14:02, -C*03:02, -C*17:01, -DRB1*14:01* and GD. These alleles are independent risk factors, with no linkage disequilibrium with other, already reported, high-risk alleles. Up to 2022, no such correlation was demonstrated for Graves' orbitopathy (GO) in Caucasian population.

Material and Methods

We performed *HLA-A, -B, -C, -DQB1* and *-DRB1* genotyping using a high-resolution next generation sequencing method in a total number of 2378 persons including 70 patients with GO, 91 patients with non-GO GD and 2217 healthy controls to compare allele frequencies in GO, non-GO and control groups.

Results

The risk of GO was significantly associated with a presence of *HLA-A*01:01, -A*32:01, -B*37:01, -B*39:01, -B*42:01, -C*08:02, C*03:02, DRB1*03:01, DRB1*14:01* and *DQB1*02:01*. The highest risk of GO was associated with the presence of *HLA-C*08:02* (OR 6.9), *-C*03:02* (8.3), *-DRB1*14:01* (6.2) and *-B*37:01* (OR 4.5). On the other hand, *HLA-C*04:01, -C*03:04, -C*07:02* and *-DRB1*15:02* were demonstrated to be protective alleles. Moreover, correlations between HLA alleles and increased or decreased risk of non-GO GD, but with no impact on risk of GO development, were revealed. The presence of *HLA-B*08:01, -B*39:06, -B*51:01, -C*07:01, -C*14:02, -C*16:02, -C*17:01, -DRB1*01:03, -DRB1*15:02, -DQB1*03:01* was associated with increased risk of non-GO GD, while *HLA-B*07:02, -C*07:02, -A*32:01* were demonstrated to be protective against non-GO GD. The highest risk of non-GO was associated with the presence of *HLA-DRB1*01:03* (OR 8.4), *-B*39:06* (OR 5.6), *-C*17:01* (OR 4.6) and *-C*16:02* (OR 4.2). Additionally, correlations between HLA and clinical risk of GO were found.

Conclusions

These results complemented our previous study, which demonstrated GD high risk alleles, by precise identification and distinction of the groups of GO-related and GO-protective alleles, as well as the alleles strongly related to non-GO GD. The knowledge on HLA-related genetic background of GO and non-GO GD constitutes an important step in a development of personalized medicine, with new possibilities of individual risk assessment and patient-tailored treatment.

Subacute thyroiditis development and its clinical course are HLA-dependent

Magdalena Stasiak[1], Bogusław Tymoniuk[2], Katarzyna Zawadzka-Starczewska[1], Bartłomiej Stasiak[3] & Andrzej Lewinski[1,4]
[1]Polish Mother's Memorial Hospital - Research Intitute, Department of Endocrinology and Metabolic Diseases, Lodz, Poland; [2]Medical University of Lodz, Department of Immunology and Allergy, Lodz, Poland; [3]Lodz University of Technology, Institute of Information Technology, Lodz, Poland; [4]Medical University of Lodz, Department of Endocrinology and Metabolic Diseases, Lodz, Poland

Introduction

Subacute thyroiditis is a thyroid inflammatory disease, triggered mainly by viral factors in genetically susceptible individuals. Up to 2020, only HLA-B*35 was confirmed as SAT-related. However, obviously in HLA-B*35-negative patients, some other genetic background occurs.

Material and Methods

We performed HLA-typing using high resolution NGS method in different groups of patients with SAT and demonstrated the new association between HLA and SAT in the Caucasian population.

Results

In addition to *HLA-B*35*, SAT was proved to be associated with the presence of *HLA-B*18:01, -DRB1*01* and *-C*04:01*. In Caucasians, *HLA-C*04:01* is in a linkage disequilibrium with *HLA-B*35:01/02/03*. Therefore, *HLA-C*04:01* alone cannot be treated as an independent SAT risk factor due to its linkage with the previously described *HLA-B*35*. However, the presence of any of the two haplotypes should be considered as a marker of genetic susceptibility to SAT. No such linkage disequilibrium has been described for *HLA-B*18:01* or *-DRB1*01* so these alleles should be considered new, completely independent SAT risk factors. Moreover, clinical course of SAT also seemed to be HLA-dependent. In regard to US pattern, typically observed multiple hypoechoic blurred lesions were demonstrated to be rarely found in *-B*18:01*-positive patients. In most cases with *HLA-B*18:01* only, unilateral homogenously hypoechoic single SAT area, filling the whole affected lobe and mimicking the large thyroid nodule was observed. This report explained the phenomenon of various US patterns of SAT. Additionally, the risk of SAT recurrence was also reported to be HLA-associated and was significantly higher in patients with co-presence of *HLA-B*18:01* and *-B*35*. In such cases, the steroid treatment should be intensified with slower dose reduction. SARS-CoV-2 is a novel pathogen which can trigger SAT. On the contrary to other viral factors, SAT onset in COVID-19 can be very rapid, and even simultaneous presence of both diseases was described. Our study revealed that this phenomenon can be related to the presence of homozygosity at *HLA-B*35*. COVID-19 vaccination is also a new factor which can induce SAT. We postulated that SAT occurrence after COVID-19 vaccination can be related to a co-presence of *HLA-B*35:03* and *-C*04:01*.

Conclusions

Our study provided the set of four alleles whose assessment allows confirming the genetic predisposition for SAT in almost all patients. HLA-related background seems to play a crucial role in SAT occurrence as well as its typical of atypical clinical course, including cases induced by SARS-CoV-2 and COVID-19 vaccination.

Is Patient Anxiety A Risk Factor for FNAB Sample Adequacy?

Mustafa Can Senoymak, Nuriye Hale Erbatur, İsmail Engin & Arif Yonem
Sultan 2. Abdul Hamid Khan Educational And Research Hospital, Endocrine and Metabolism, İstanbul, Turkey

Aim

Currently, imaging tools are increasing the frequency of thyroid nodules to 50%, and thyroid cancer risk is 7-15%. The most cost-effective, accurate diagnosis method is fine-needle aspiration biopsy (FNAB). However, non-diagnostic (ND) results can delay diagnosis, cause different procedures, raise costs, and distress patients. In addition, FNAB sample adequacy is affected by advanced age, nodule size (<5-10mm), cystic dominating nodules, macrocalcification, and hypo-echogenicity. We aimed to see if situational anxiety was linked to non-diagnostic cytology.

Methods

The prospective cross-sectional study included patients who underwent thyroid fine-needle aspiration at the Endocrinology Clinic of Sultan Abdulhamid Training and Research Hospital between 11/2022 and 02/2023. The State-Trait Anxiety Inventory (STAI) questionnaire and visual analog scale (VAS) for pain assessed situational anxiety and pain in patients just before the procedure. We tested whether the STAI-S score is related to non-diagnostic results.

Results

Of the 119 patients included in the study, 98 were female, and 21 were male. 25 (21%) nodules were non-diagnostic. We divided patients into two groups according to the cytology results: non-diagnostic and others. According to the groups, STAI and VAS scores and other demographic characteristics are given in Table 1. A statistically significant relation was found between the patient's STAI-S score and VAS score and the cytology result of non-diagnostic thyroid nodules ($P=$ 0.001 and $P=0.008$). When we examined the factors associated with the non-diagnostic outcome in multivariate logistic regression analysis, the STAI-S score was found to be again associated with the non-diagnostic outcome. (OR = 1.069, $P=0.02$)

Table 1. Characteristics of the patients, STAI, and VAS scores

Parameters	All patients	Non-diagnostic group	Others	P value
Number of patients	119	25	94	
Age(years)	54.86±12.2	58.64±12.05	53.86±12.15	0,087
Gender(n)				0,38
F	98	19	79	
M	21	6	15	
STAI-S	47.31±12.37	54,80±13.42	45.31±11.34	**0,001**
VAS	2.57±1.51	3(1-6)	2(1-6)	**0,008**
Nodule size(mm)	21.70±0.72	21.60±8.45	21.73±7.68	0.94
Architecture (cyst/solid)	26/93	8/17	18/76	0.16
Boundary (regular/irregular)	18/101	3/22	15/79	0.44
Echogenicity (hypo/iso)	61/58	15/10	46/48	0.37
Macrocalcification (absent/present)	19/100	5/25	14/80	0.54

F: Female, M: Male, STAI-S: Situational State-Trait Anxiety Inventory, VAS: visual analog scale. Independent-Samples T (2 variables) test was used for parametric variables, and data were given as mean±SD. Mann-Whitney test was used for non-parametric variables, and data were shared median (minimum-maximum).

Conclusions

Hence, anxiety level and pain perception during FNAB may be risk factors for non-diagnostic cytology. Reducing anxiety and pain may decrease the incidence of non-diagnostic outcomes.

Adrenal Haemorrhages: A review of cases presenting to University Hospital Southampton over six-year period

Muhammad Umer, Jana Bujanova, Ma'en Al-Mrayat & Hina Aslam
Southampton General Hospital, Endocrinology Department, Southampton, United Kingdom

Introduction
Adrenal haemorrhage (AH) carries high mortality and morbidity. It can be unilateral or bilateral (BAH), trauma or non-trauma (NT) related. The predisposing factors include adrenal tumours, anticoagulation, thrombocytopenia, sepsis, thromboembolic disease, pregnancy, liver transplant and vaccine-induced-immune-thrombocytopenia-and-thrombosis. BAH can result in an adrenal crisis in up to 15%. BAH is usually associated with conditions contributing to adrenal vein spasm or thrombosis.
Aim
The aim of this project was to review management, causes, outcomes and follow-up in patients presenting with AH in our organization between 2017-2022.
Results
We identified 21 patients with AH during this period. Age 19-93 y, mean- 57 y, 19% $<$ 30 y, 52% $>$60 y, 62% males. 20 presented acutely, with one diagnosed electively. 20 were managed conservatively, and 1 required bleeding adrenal artery embolization. 14/21 (66.7%) were non-traumatic, 7/21 (33.3%) were trauma related. 4/21 were bilateral, and 17/21 (81%) were unilateral with slight right-sided predominance. All traumatic bleeds were unilateral. 4/21 bled into a pre-existing adrenal pathology (3/4 adenoma, 1/4 18 cm myelolipoma), 9/21 had other identifiable risk factors or their combinations (3 antiplatelets, 3 antic-oagulation, 6 hypertension, 1 vasculitis, 1 Ehlers Danlos + cocaine, 1 pregnancy, 1 sepsis, 1 diabetes ketoacidosis). All 4 BAH were non-traumatic. Severe hypertension 180-200 mmHg in 3/4 and sepsis from ischaemic foot in 1/4 were the precipitants. 7 required ITU admission, 1 had cardiac arrest, 6 were severely hypertensive (BP $>$180 mmHg), and 2 patients died during admission. 6 cases had profound hypotension on admission (5/6 unilateral, 1/6 bilateral), 2/6 had cortisol checked, and one received Hydrocortisone. Hyponatremia (range 125-133 mmol/l) was noted in 4 cases (19%) and in 50% of BAH. 3 tested for hypoadrenalism, and 2 received Hydrocortisone. 5/21 had cortisol checked, and 4/21 were covered with Hydrocortisone. 7/21 had metanephrines checked, 11/21 patients were referred to the adrenal MDT and 14 had interval imaging during follow-up.
Discussion
The single adrenal vein draining the highly vascular glands makes them sensitive to venous pressure changes and subsequent haemorrhage. Our review demonstrated high prevalence of underlying adrenal pathology and precipitating factors, mainly hypertension, anticoagulants and procoagulant states as main precipitants for NT adrenal bleeds. We observed that testing for adrenal insufficiency and steroid cover in patients with AH could be improved by admitting teams, predominantly in those requiring ITU, those with BAH, and with associated hyponatremia and hypotension. Our aim is to ensure that all patients with AH receive Endocrine input and are tested for potential adrenal insufficiency.

A Case of Ectopic Adrenocortical Cancer Originating from the Pancreas

Alperen Onur İşler [1], Nezih Akkapulu[2], Altan Kavuncuoğlu[3], Büşra Fırlatan[4] & Uğur Ünlütürk[1]
[1]Hacettepe University School of Medicine, Division of Endocrinology and Metabolism, Department of Internal Medicine, Ankara, Turkey; [2]Hacettepe University School of Medicine, Department of General Surgery, Ankara, Turkey; [3]Hacettepe University School of Medicine, Department of Pathology, Ankara, Turkey; [4]Hacettepe University School of Medicine, Department of Internal Medicine, Ankara, Turkey

Background
Ectopic malignancies arising from adrenal rests are extremely rare. Localization has been reported in the retroperitoneum, testis/scrotum, ovary, kidney, anterior abdominal wall, spinal cord, and liver associated with embryological development [1-3].
Objective
This report presents a case of ectopic adrenocortical cancer (ACC) localized to the pancreas. An exciting feature of the case was the simultaneous presence of breast cancer.
Case
A 57 years old female patient was diagnosed with mixed-type breast cancer (lobular and ductal carcinoma) in 2019. After the diagnosis, in addition to the malignant mass in the left breast on CT and FDG PET CT images, a second tumor with well-circumscribed, necrotic, heterogeneous malignant appearance was seen adjacent to the pancreas, in the left paraaortic area, without significant invasion to the environment (SUVmax: 37.7 on FDG PET CT). On abdominal MRI, A 5.2 cm diameter mass with cystic, solid components originating from the pancreatic body and tail junction, growing to posterior and inferior, was observed. The patient did not have features suggestive of hormonal hyperfunction, such as hypertension, electrolyte imbalance, cushingoid appearance, and signs of hyperandrogenism. After the lumpectomy, the mass adjacent to the pancreas was surgically removed. Positive staining with Steroidogenic factor 1 (SF1) was observed in pathology. Ki67 proliferation index was determined as 5%. Neither venous invasion nor capsular invasion was observed. This neoplasm had a diffuse pattern, increased mitosis, and marked nuclear pleomorphism. Regarding p53 mutation in tumor, 5% weak-moderate staining was observed. The tumor was diagnosed with oncocytic-type adrenocortical carcinoma. Mitotane and glucocorticoid replace-ment were added to her follow-up treatment. There was no evidence of recurrence or metastasis in the follow-ups.
Conclusion
This rare case is the first whose ectopic adrenocortical cancer is located in the pancreas. Adrenocortical cancers should also be considered in tumors of non-adrenal areas.

EP3

A rare case of slowly progressing myopathy of unknown origin in a patient with Autoimmune polyglandular syndrome type 1 (APS-1)

Axenia Bondarenko[1], Zhanna Belaya[1], Liudmila Rozhinskaya[1] & Valentin Fadeyev[2]
[1]Endocrinology Research Centre, Moscow, Russia; [2]I.M. Sechenov First Moscow State Medical University (Sechenov University), Moscow, Russia

We report a 53-year-old man. At age 3, the patient was diagnosed with chronic mucocutaneous candidiasis. At age 41 the patient started losing all hair on the body with total boldness. At age 43, he first complained of muscle weakness resulting in difficulty walking, back pain and difficulties holding his head in an upright position. At age 49, he was diagnosed with chronic primary adrenal insufficiency and hypoparathyroidism. Genetic analysis confirmed APS-1 (c.769C$>$T p.R257X mutation in the AIRE gene). The patient received therapy with hydrocortisone 35 mg/day, fludrocortisone 0.5 mg/day, alfacalcidol 0.75-1 mg/day, colecalciferol 15,000 IU/week. On this treatment he had calcium levels within the reference range and no clinical signs of either hyper- or hypocortisolism. However, his muscle weakness gradually, although painlessly, progressed. At age 49 electroneuromyography showed signs of primary muscle damage: high-amplitude motor unit potentials and the absence of spontaneous muscle fiber activity were recorded. According to the results of a PET, specific metabolically active tissue was not identified, but there were described signs of atrophy of the paravertebral muscles, the left lumbar major muscle, and the gluteal muscles on both sides. There was a gradual progression in muscle weakness over time leading to serious difficulties in walking and the ability to maintain his head in the upright position (Fig1). The results of densitometry in the "Total Body" mode show signs of muscle atrophy: limb muscle mass–16793 g (normal range for men $>$19750 g), Baumgarten skeletal muscle index–6.24 kg/m^2 (normal range for men $>$7.26). According to the most recent laboratory tests, an increase in the level of creatine phosphokinase to 411 U/l (normal range, 30-200 U/l), C-reactive protein to 9.8 mg/l (normal range, 0.1-5 mg/l) were detected. Grip strength measurements showed normal performance. When hydrocortisone was replaced with prednisolone, the level of creatine phospho-kinase decreased to 184 U/l, and C-reactive protein decreased to 2 mg/l. No current evidence was found in favor of autoimmune damage to muscle tissue and no other muscle disease was detected.
Conclusion
The clinical case outlines a rare combination of APS-1 and central muscle atrophy of unknown origin, but probably related to mutation in the AIRE gene.

Figure 1. Involuntary position of the patient associated with atrophy of the vertebral muscles

EP4

A case report of a single patient with a dual-functioning incidental adrenal tumor

Milena Lackovic[1], Vladimir Samardzic[1], Bojan Joksimovic[1], Marija Sinik[1], Martina Tomasovic[1], Esma R. Isenovic[2] & Zoran Gluvic[1]
[1]Zemun University Clinical Hospital, Department of Endocrinology and Diabetes, Belgrade, Serbia; [2]"VINČA" Institute of Nuclear Sciences–National Institute of the Republic of Serbia,, Department of Radiobiology and Molecular Genetics, Belgrade, Serbia

Introduction
An undefined lesion detected by imaging methods in one or both adrenals is known as an incidentaloma. The size and capacity of the secretion are evaluated to determine its definitive management. It is extremely uncommon for a mixed adrenal incidentaloma to appear with elevated cortisol and medullar hormone output.
Case report
A 21-year-old woman was admitted to the hospital with intermittent palpitations, headaches, and chest pain. She was already receiving medication for her diabetes and hypertension. The Cushing syndrome symptoms ('moon-face', 'lemon-on-sticks'), with a BMI of 25 kg/m^2, a BP of 140/90 mmHg, and a PR of 75/min, were found during the examination. There was no history of hirsutism, menstruation irregularity, or fractured bones.
Results
Hematology and biochemistry tests, in addition to U&E, were routine. Following a thorough wash-out, additional laboratory tests revealed non-suppressible morning serum cortisol in ODST and HDDT. The levels of dopamine, epinephrine, norepinephrine, and 24-hour urine metanephrines were all increased, as well as the serum CgA. An abdominal MDCT showed a normal left adrenal gland and an enlarged right adrenal gland (36.4×30 mm). No abnormal findings were detected on the pituitary MRI. The patient received an open right adrenalectomy following complete preoperative treatment with alpha and beta blockers. A mixed corticomedullar tumor with no malignant alterations was identified by the histology.
Discussion and Conclusion
A tumor made of chromaffin cells known as a pheochromocytoma exhibits symptoms and signs of elevated sympathetic activity. A cortisol-producing adenoma is the most frequent cause of Cushing's syndrome, which manifests as hypertension, diabetes mellitus, central obesity, proximal muscle weakness, purple striae, bone fractures, and irregular menstruation in females. We describe a rare example of a combined corticomedullar tumor of the right adrenal gland that simultaneously secreted cortisol and medullary hormones.

A case of Conn syndrome presenting as persistent post-partum hypertension

Ei Thuzar Aung, Helmine Kejem , Muhammad Ilyas Khan & Sravan Thondam
University Hospital Aintree, Department of Diabetes and Endocrinology, Liverpool, United Kingdom

Introduction
Conn's syndrome is a well-known cause of secondary hypertension; however, its association with pregnancy is rare. We discuss an interesting case of Conn syndrome presented with severe hypertension 8 weeks post-partum.
Case report
A 34-years-old lady, previously fit and well, presented with severe hypertension (blood pressure–189/115 mmHg) and hypokalaemia (K-2.5 mmol/l) at 8 weeks post-partum. Antenatal records indicated she was normotensive throughout her pregnancy and had an uneventful delivery. She did not have family history of hypertension. She was not on any prescribed or over the counter medications and denied liquorice sweet consumption. Her BMI was 26 kg/m^2 and had no clinical features of Cushing's syndrome. Serum potassium was consistently low (2.5 mmol/l). Repeated measurements of renin and aldosterone showed undetectable renin <5 mu/l and high aldosterone between 828–1224 pmol/l. 24-hour urinary free cortisol was normal at 126 nmol/24 hrs. (reference range <165 nmol/l). Overnight dexamethasone suppression test showed appropriately suppressed cortisol of 18 nmol/l. Urinary met adrenalines were normal. Confirmatory biochemical test was not done as screening tests were strongly positive and patient had persistent hypokalaemia. MRI scan of the adrenals showed a 13×9 mm fat containing left adrenal adenoma. Adrenal vein sampling performed after correcting serum potassium showed a clear left side lateralisation and contralateral suppression (aldosterone/cortisol ration on the left was 18.4 and on the right was 0.3 with lateralisation index >60). She was treated with Ramipril 7.5 mg, Spironolactone 100 mg and Sando-K- 2 tablets twice a day and listed for urgent left adrenalectomy. Her blood pressure and potassium were well controlled on these medications.
Discussion and learning points
Hyperaldosteronism in pregnancy is associated with adverse maternal and foetal outcomes and hypertension is likely to be worsened in this period. Our case highlights an exceptional clinical scenario where Conn's syndrome was likely masked during pregnancy with no evident physiological consequences on mother and foetus. Review of the literature suggests that increased progesterone during pregnancy in some people may mask the effects of hyperaldosteronism 1. Therefore, symptoms are evident in these people after the child birth and women may present with post-partum hypertension1. Clinicians should be aware of the possibility of Conn's syndrome as a cause of post-partum hypertension especially when it is associated with hypokalaemia.

Cushing syndrome due to ACTH-secreting pheochromocytoma

Monica-Mirela Pana[1] & Ancuta Tudorancea[2]
[1]Elias Emergency University Hospital, Endocrinology Departement, Bucharest, Romania; [2]Centre Hospitalier de Blois, Endocrinology and Diabetology Departement, Blois, France

Introduction
Pheochromocytomas are neuroendocrine tumors derived from chromaffin cells which secrete catecholamines. Cushing syndrome due to ACTH-secreting pheochromocytomas is a rare condition and early recognition and treatment is important to decrease morbidity and mortality.Case presentation: We present the case of an 53 years-old man who arrived at the hospital for pain in the right scapula agravated in the last three months with iradiation in the right flanc, heart palpitations, headache and weight loss of 10 kilograms in the last 6 months.

General examination revealed an abdomen without signs of peritoneal irritation, painful in the right flanc, high blood pressure (232/165 mmHg) and tachycardia (128/bpm). Blood tests showed leukocytosis (20 600/mm^3), mild normocytic normochromic anemia with hemoglobine at 10.8 g/dl, hyperglycemia (225 mg/dl) and slightly elevated liver enzymes (ASAT = 94 UI/I, ALAT = 92 UI/I, GGT = 197 UI/I). The computed tomography revealed a large solid adrenal mass measuring 100 mm in the largest diameter with an important vascularization. The patient was trasferred to our department, where he underwent further biochemical testing to establish the functional status of the tumor. Blood tests showed high values for plasma normetanephrines (56.16 nmol/l), urinary normetanephrines (109.39 µmol/24 H), plasma cortisol (2 270 nmol/l), free urinary cortisol (161 nmol/24 H), plasma ACTH level at 22 pg/ml, normal values for 11-deoxycortisol, total testosterone, DHEAS and aldosterone-renin ratio and slightly elevated values for plasma metanephrines (0.54 nmol/l) and urinary metanephrines (2.54 µmol/24 H). Considering the 50 times higher values of plasma and urinary normetanephrines and 2 times higher values of plasma and urinary metanephrines, the diagnosis of pheochromocytoma was established which also associated a secretion of cortisol. A fluorodeoxyglucose-positron emission tomography was performed before the intervention to exclude possible secondary determinations, which revealed an uptake only at the level of the right adrenal tumor. The treatment with alfa and beta blockers was started and the patient was sent to the surgery department for the excision of the adrenal mass. Post intervention the cortisol and the catecholamine values returned to normal.

Conclusion

Considering the ACTH values higher than 20 pg/ml with very high cortisol values before the surgical intervention and the normalization of cortisolemia after the extirpation of the adrenal tumor, we have considered that it was a Cushing syndrome due to ACTH-secreting pheochromocytoma.

Clinical symptoms, imaging and hormonal tests that suggest phaeochromocytoma in a patient with a solitary fibrous tumor incidentally discovered in the adrenal gland

Anna Kurzyńska[1], Andrzej Nowak[2], Magdalena Ulatowska-Białas[3], Marek Sierżęga[4], Łukasz Bobrzyński[4], Elwira Przybylik-Mazurek[1] & Alicja Hubalewska-Dydejczyk[1]

[1]Jagiellonian University Medical College, Chair and Department of Endocrinology, Krakow, Poland; [2]Medical University of Warsaw, Department of Gynecological Endocrinology, Warszawa, Poland; [3]Jagiellonian University, University Hospital, Pathomorphology, Krakow, Poland; [4]First Department of General Surgery, Jagiellonian University, Collegium Medicum, Krakow, Poland

The solitary fibrous tumor is a rare spindle cell neoplasm, originally described in the pleural cavity. However, it can occur in other locations. SFTs that originate from the adrenal gland tissue are extremely rare. To date, only single cases have been described in the literature. We present a case of a 61-year-old Caucasian man with a SFT of the left adrenal gland. The patient was hospitalized in the internal medicine department due to paroxysmal hypertension (up to 190/100 mmHg) and an episode of syncope. An abdominal computed tomography scan was performed, in which a lobular, well-demarcated, 63×66×70 mm, intense post-contrast tumor was described in the left adrenal gland. The overall radiological picture was indicative of a pheochromocytoma. In hormonal tests, slightly elevated normetanephrine and 3-metoxytramine concentrations were found in 24-hour urine collection. Elevated hemoglobin, increased erythrocyte count, and elevated erythropoietin concentration were observed and the suspicion of polycythemia vera was raised. The patient required numerous bloodletting. Genetic tests did not show pathological variants in the *JAK2* gene. The patient was qualified to left adrenalectomy. Pathomorphological examination revealed a SFT with a diameter of 5.5 cm made of a network of interconnecting vessels of different caliber (immunohistochemically: CD31+, CD34+) focally with small visible atypia of endothelial cells, between which bright CD99+ cells were visible, and in part ERG+, bcl2-. The proliferative activity of Ki67 was about 10%. In postoperative follow-up tests 24-hour urinary fractionated metanephrines concentration and the blood count results have returned to normal ranges. The patient remains under regular surveillance. SFTs are usually indolent tumors that do not give certain clinical manifestations. They are extremely rare tumors, which may present with various uncharacteristic symptoms and should be considered in the differential diagnosis of an incidentally discovered adrenal mass.

Metabolic changes in transgender people after gender-affirming hormone therapy

Esteban Sánchez Toscano [1] , Isabel Mateo Gavira[1] & Jesús Domínguez Riscart[2]

[1]Hospital Universitario Puerta del Mar, Endocrinology and Nutrition Department, Cádiz, Spain; [2]Hospital Universitario Puerta del Mar, Pediatrics and Specific Areas Department, Cádiz, Spain

Introduction

Demand for health care for transsexual people has increased exponentially in last years, especially among adolescents and young adults. Gender-affirming hormones (GAHs) are initiated to accommodate secondary sexual characteristics to the desired sex. Published studies about metabolic repercussion of GAHs are heterogeneous and report diverse results. Our objective is to evaluate the effect of GAHs on cardiovascular risk factors in transsexual population treated in our hospital.

Methods

We design a retrospective before-and-after study to evaluate changes in anthropometric parameters, blood chemistry analyses and metabolic comorbidities in transgender population treated with GAHs at least one year in Hospital Puerta del Mar between January 2017 and December 2020.

Results

A total of 227 transgender people were included in the study, 136 (59.91%) transmen and 97 (40.09%) transwomen. GAHs was initiated with median age of 18 (16–23) years old without significant differences between genders. It was detected a significant increase in weight, BMI and systolic and diastolic blood pressure, as well as a worse lipid profile in both genders. Likewise, prevalence of dyslipidemia and hypertension increased in transmen ($P<0.001$ and $P=0.004$, respectively) and transwomen ($P=0.035$ and $P=0.002$, respectively). Glycated hemoglobin increased significantly [32 (31-33) vs 33 (32-37) mmol/mol; $P=0.040$] in transmen and fasting blood glucose [4.66 (4.33-4.88) vs 4.77 (4.38-5.11); $P=0.008$] in transwomen, although it did not translate into a higher risk of prediabetes.

Conclusion

In our setting, there is a higher risk of dyslipidemia and hypertension and a tendency towards weight gain after one year of the THAG in transmen and transwomen. Prevalence of prediabetes did not increase and any new cases of type 2 diabetes mellitus were detected. No cardiovascular events or thromboembolic processes were reported during the study period.

EP9

The role of early postoperative aldosterone in saline infusion test in the prediction of primary aldosteronism remission

Ante Mandic[1], Karin Zibar Tomšić[1], Ivana Kraljevic[1,2] & Darko Kastelan[1,2]

[1]University Hospital Centre Zagreb, Department of Endocrinology and Diabetes, Zagreb, Croatia; [2]University of Zagreb, School of Medicine, Zagreb, Croatia

Objectives

This study aimed to assess the ability of aldosterone in saline infusion test (SIT) to predict biochemical remission of primary aldosteronism.

Methods

We retrospectively analysed 42 patients (19 (45%) females, mean age 49±12 years) with primary aldosteronism who underwent adrenalectomy (after adrenal vein sampling confirmation of unilateral disease) from 2017 to 2022. Aldosterone in SIT was determined on the fifth postoperative day, as well as 6-12 months after surgery, together with the aldosterone-to-renin ratio (ARR). Biochemical remission (complete, partial, or absent) of primary aldosteronism was defined according to the Primary Aldosteronism Surgical Outcomes (PASO) criteria.

Results

On the fifth postoperative day, 28 (66.7%) patients (group 1) had aldosterone in SIT <139 pmol/l, indicating complete biochemical remission; in 11 (26.2%) patients (group 2), aldosterone concentration in SIT was between 139 and 277 pmol/l which is consistent with partial biochemical remission; and 3 (7.1%) patients (group 3) had aldosterone in SIT >277 pmol/l, implicating absent biochemical remission. However, at the follow-up after 6-12 months, in four patients from group 1 ARR and aldosterone in SIT were consistent with partial biochemical remission. Similarly, in nine patients from group 2, and in two patients from group 3, ARR suggested complete biochemical remission. There was no statistically significant difference between these groups ($P=0.646$). Overall, 35 (83.3%) patients in our sample achieved complete biochemical remission, while 7 (16.7%) patients achieved partial biochemical remission.

Conclusions
Our results suggest that early postoperative aldosterone in SIT does not predict biochemical remission of primary aldosteronism.

Hair cortisol measurement in the diagnosis and management of adrenal disorders

Haitham Abu-Lebdeh[1] & Hassan Heshmati[2]
[1]Mayo Clinic, Division of Endocrinology, Diabetes, Metabolism and Nutrition, Rochester, United States; [2]Endocrinology Metabolism Consulting, LLC, Anthem, United States

Introduction
The acute status of the hypothalamic-pituitary-adrenocortical (HPA) axis is routinely assessed by the measurements of cortisol in blood, saliva, and urine. Because cortisol is continuously deposited in the growing hair shaft, hair cortisol can serve as a practical measure of long-term retrospective HPA axis activity. The purpose of this review is to present the relevance of hair cortisol measurement in the diagnosis and management of Cushing's syndrome and adrenal insufficiency.MethodsA systematic search of literature was conducted using the search terms hair cortisol, Cushing's syndrome, adrenal insufficiency, diagnosis, and management.
Results
Adult scalp hair grows at a rate of approximately 1 cm per month. A 1 cm of hair growth would represent total HPA axis activity of the previous 1 month. Therefore, the most proximal 1-cm hair cortisol is the best marker for the recent cortisol production. Longer hair samples can reflect cortisol production over months or years. For the measurement of hair cortisol, a 3-cm sample is taken from the posterior vertex of the scalp. If stored at room temperature and in intact hair, cortisol is stable for more than a year. Commercial kits (e.g., ELISA) can be used for the measurement of hair cortisol. The natural color of hair does not impact hair cortisol levels but excessive shampooing, hair dying, and prolonged exposure to UV light can diminish the cortisol levels. Obviously, baldness prevents the hair collection for cortisol measurement. Hair cortisol can be used as an initial or supportive diagnostic test for Cushing's syndrome with high sensitivity and specificity. The most proximal 1-cm hair cortisol is the best marker of hypercortisolemia. Hair cortisol measurement also helps assessing the natural history of hypercortisolism and adrenal insufficiency by estimating the duration of the disease before diagnosis. Hair cortisol levels may also be useful in the monitoring of disease progression and treatment efficacy of adrenal disorders. However, since hair cortisol levels are not sensitive to the circadian fluctuations of cortisol, they cannot replace blood and salivary cortisol measurements.
Conclusion
Hair cortisol measurement is a new non-invasive approach to assess long-term retrospective HPA axis activity when diagnosing adrenal disorders. The most proximal 1-cm hair cortisol is the best marker of hypercortisolemia and can be used as an initial diagnostic test for Cushing's syndrome. Hair cortisol is also useful in monitoring disease progression and treatment efficacy of adrenal disorders.

Carriers of a pathological variant in CYP21A2 gene– clinical and hormonal status

Sorina Schipor[1], Camelia Procopiuc[2], Cristina Stancu[1], Madalina Vintila[2,3], Andreea Cristiana Brehar[2], Andrei Muresan[1], Dana Manda[1], Andra Caragheorgheopol[1], Dumitrica Alina Elena[1], Luminita Udrea[1], Suzana Vladoiu[1] & Iuliana Gherlan[2,3]
[1]National Institute of Endocrinology "C. I. Parhon", Research Department, Romania; [2]National Institute of Endocrinology "C. I. Parhon", Paediatric Department, Romania; [3]University of Medicine and Pharmacy "Carol Davila", Romania

Introduction
21-hydroxylase deficiency (21OHD) is an autosomal recessive disorder and the diagnosis is confirmed by the presence of at least two biallelic pathogenic variants. The phenotype is determined by the less deleterious variant. The relevance of hormonal assessment to distinguish between heterozygote carriers of pathologic mutations and non-carriers or genetically defined 21OHD patients is still a matter of debate. Identifying the heterozygous genotype is important in adult life for a correct genetic counselling and a personalized approach of future pregnancies.
Materials and methods
We selected a group of Romanian paediatric patients with hyperandrogenism manifested as premature pubarche, accelerated growth, apocrine body odour, and seborrhoea in childhood ($n=19$) and hirsutism, oligomenorrhoea and acne in adolescence ($n=12$). 17OH-progesterone levels were measured by ELISA (reference values <2 ng/ml). MLPA and Sanger sequencing were used to establish CYP21A2 gene mutational status. All patients gave their informed consent for the study.
Results and discussion
After molecular analysis we identified 17 carriers of a pathologic variant in CYP21A2 gene (carrier-group) and 14 patients with genetic confirmation of 21OHD (21OHD-group). The pathologic variants identified in the carrier-group were V282L (35.71%), P31L (28.57%), P454S (21.43%), R92* (7.14%) and I173N (7.14%). We also identified 3 patients with heterozygous Q319* mutation but MLPA also revealed heterozygous duplication of CYP21A2 gene so we excluded them from the analysis. Patients included in 21OHD-group were homozygous or compound heterozygous for pathologic variants identified in the carrier-group and the diagnosis was non-classic or simple-virilizing form of 21OHD. 17OH-progesterone levels were significantly lower in carrier-group vs 21OHD-group (median 2.06 ng/ml vs 20 ng/ml). For the carrier-group the values are slightly increased or high-normal compared to kit reference values.
Conclusion
Clinically manifested hyperandrogenism with or without a concomitant increase of 17OH-progesterone could be a criterion for investigation of possible heterozygous carriers of a pathologic variant in CYP21A2 gene in paediatric population.

Myocardial Infarction with non-obstructed coronaries: uncommon presentation of pheochromocytoma

Jorge Henrique Carmona Alexandrino [1,2], Marta Almeida Ferreira[1], Diogo Ramalho[1], Diogo Santos Ferreira[2], Gualter Santos Silva[2], João Gonçalves Almeida[2] & Maria João Oliveira[1]
[1]Centro Hospitalar Vila Nova de Gaia/Espinho, Endocrinology, Gaia, Portugal; [2]Centro Hospitalar Vila Nova de Gaia/Espinho, Cardiology, Gaia, Portugal

Background
Pheochromocytoma (PHEO) is a rare neuroendocrine tumour, classically presenting with hypertension, palpitations and headaches. Some patients have atypical presentations. We report a case of Myocardial Infarction with non-obstructed coronaries (MINOCA) as the key to unravel the diagnosis of PHEO.
Clinical case
A 53-year-old man with type 2 diabetes mellitus and hypertension (under gliclazide MR 60 mg id, bisoprolol 5 mg id, ramipril 5 mg id and atorvastatin 40 mg id), presented in the emergency room with nausea, vomiting, retrosternal crushing pain and palpitations. Over the past year he had frequent hyperadrenergic spells: excessive sweating, thoracic pain, headaches, tremor, pallor, sometimes accompanied by systolic blood pressure over 200 mmHg. Six months earlier, his echocardiogram showed left ventricular hypertrophy and his myocardial perfusion test (scintigraphy) showed abnormalities in the inferior-apical wall, but coronary angiography excluded obstructive coronary disease. CT scan chest revealed a 27 mm left adrenal nodule not typical of an adenoma. Clinical examination was unremarkable with a blood pressure of 107/68 mmHg.. His electrocardiogram showed sinus rhythm with T wave inversion in aVL and elevated troponins: 224 ng/l at baseline and 253 ng/l after 3 h (normal <14 ng/l). Bedside echocardiography was suggestive of stress cardiomyopathy. New coronary angiography showed normal coronary arteries. Patient was managed as MINOCA and underwent Cardiac MRI which revealed mild left ventricle hypertropohy and mild biventricular systolic dysfunction, but no signs of oedema or fibrosis. The clinical evolution was favourable, without symptomatic recurrence. Systolic dysfunction recovered and the patient was discharged (stopped beta-blocker). After discharge, he continued to have daily hyperadrenergic spells. Further investigation revealed raised urine metanephrine 569 µg/24h (<349), noradrenaline of 207 µg/24 h (<89), adrenaline 200 µg/24 h (<19), and plasma metanephrine 346.7 pg/ml (<89). Abdominal CT scan confirmed left adrenal nodule 3 cm compatible with PHEO. We slowly titrated doxazosin which managed to control the spells. MIBG scintigraphy revealed fixation on the left adrenal mass. The patient will undergo laparoscopic left adrenalectomy.
Discussion
This case illustrates the importance of thorough history taking and investigation for the underlying aetiology of an atypical chest pain. Even though the patient presented with

classical symptoms over a year, the diagnosis remained elusive. Cardiac complications are an uncommon presentation of PHEO. Early recognition of PHEO is crucial to improve clinical outcomes among these patients.

Evaluating the diagnostic capacity of the saline infusion and captopril challengetests for primary aldosteronism

Isabella Mantellini Gonzalez [1], Sime Rogic Valencia[1], Inés Borrego Soriano[1], Paula Vázquez Pérez[1], Rosa María García Moreno[1], Arturo Lisbona Catalán[1], Gumersindo Fernández Vázquez[1], Oscar Moreno Domínguez[1], Beatriz Barquiel Alcala[1], Miriam Zapatero Larrauri[1], María Luisa González Casaus[2], Irene Aguilera García[1], Alexa Pamela Benítez Valderrama[1], Ines Lobo[1], Cristina Álvarez Escolá[1], Patricia Martin Rojas-Marcos[1] & Paola Parra Ramírez[1]
[1]Hospital Universitario La Paz, Endocrinología y Nutrición., Madrid, Spain; [2]Hospital Universitario La Paz, Análisis Clínicos, Madrid, Spain

Introduction
Primary aldosteronism (PA) is the most common cause of secondary hypertension. Guidelines recommend a confirmatory test in the majority of suspected cases: oral sodium loading, saline infusion test (SIT), captopril challenge test (CCT), or fludrocortisone suppression test. The SIT and CCT are most commonly used in clinical practice to study autonomous aldosterone secretion.
Objectives and Methods
We compared the CCT's diagnosis performance to that of the SIT. A retrospective study of PA confirmatory tests was conducted at Hospital Universitario La Paz (Madrid, Spain). Tests performed between 2019 and 2022 were included. All cases underwent confirmatory tests (CCT or SIT) according to the clinician's preference or the patient's characteristics and comorbidities. Antihypertensive medications were changed or discontinued for the confirmatory test following the guidelines. Dietary sodium intake was unrestricted. For CCT, patients received 50-mg captopril orally at 9 AM. The SIT involved the infusion of 2L of 0.9% saline IV over 4 hours. Both tests were performed in a seated position. The results of the different tests were compared.
Results
60 confirmatory tests were performed: 27 CCT and 33 SIT (Table 1). In comparison to CCT, the SIT got more indeterminate results (7.4% vs 39.4%, P 0.014). Age, gender, history of hypertension or hypokalemia, renin and aldosterone determinations (screening and during tests), urine aldosterone (if studied), presence of an adrenal nodule, or 1mg dexamethasone suppression test (if studied) did not differ between groups. Some patients with indeterminate results underwent a second confirmatory test. CCT was performed on 6 patients with non-conclusive SIT, with 5 definite results (2 positives and 3 negatives) and 1 indeterminate. On the other hand, the only patient who had an indeterminate CCT and underwent a SIT, also obtained an inconclusive result.
Conclusion
In diagnosing or ruling out PA, the CCT (50 mg) was more accurate than SIT. For the vast majority of patients with an indeterminate SIT, the CCT yielded a conclusive result.

Paraganglioma mimicking a tumor of the liver in an elderly patient

Monica-Mirela Pana[1], Anca Sirbu[1,2], Miruna Maria Popa[1,2] & Simona Fica[1,2]
[1]Elias Emergency University Hospital, Endocrinology Department, Bucuresti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology Department, Bucaresti, Romania

Introduction
Paragangliomas are neuroendocrine tumors that are derived from the embryonic neural crest cells. Because the paraganglia are widespread through the body, paragangliomas can be found in unusual anatomic locations and the diagnosis can be hard to establish. Case presentationWe present the case of an 72 year-old, hypertensive woman who arrived at the hospital for pain in the right hypochondrium. General examination revealed an abdomen without signs of peritoneal irritation, high blood pressure (170/80 mmHg) and tachycardia (110/bpm). Blood tests showed minimum leukocytosis and slightly elevated liver enzymes. Routine abdominal ultrasound revealed a mass measuring 34/32 mm in the caudate lobe of the liver. Consequent computed tomography described a well-defined liver mass measuring 40/34 mm, adjacent to caudate lobe, para-aortic. The patient underwent endoscopic ultrasound-guided fine needle aspiration, without complications, to establish the tumor type. The histopatology examination revealed compact cell nests with vesicular nuclei, absent mitoses and amphophilic cytoplasm, without well defined boundaries. Imunohistochemical testing found negative results for keratins and positive staining for S-100 in sustentacular cells and positive results for cromogranin A and synaptopysin in chief cells, with a Ki 67 of 1-2%, being established the diagnosis of paraganglioma. The patient was trasferred to our department, where she underwent further biochemical testing to establish the functional status of the tumor. Blood tests showed high values of plasma normetanephrines (1127.99 ng/l), slightly elevated values for metanephrines (124.92 ng/l) and normal values for methoxytyramine. Chromogranin A couldn't be measured because the patient was receiving proton pump inhibitors. After establishing the diagnosis of secretory paraganglioma, the patient started the treatment with alfa and beta blockers and was sent to a surgery department.ConclusionThe reported case is interesting because of the age of the patient and the way the diagnosis was established. Most paragangliomas are diagnosed in younger people, mostly in their third to fifth decade. Even if the majority of sympathetic paragangliomas are located in the abdomen, given the rarity of the tumor, the diagnosis can be missed without a degree of suspicion and further investigations. In our case the diagnosis was established after biopsy, which is **contraindicated** in a patient suspected of having paraganglioma because of the associated risks like severe hypertension, hemorrhage or fibrosis at the intervention site and because the aspirates can be difficult to distinguish from other neoplasms.

A single center experience of extraadrenal paragangliomas–clinical and molecular analysis

Anna Kurzyńska, Marta Opalinska, Anna Skalniak, Ewelina Rzepka, Aleksandra Gilis-Januszewska, Elwira Przybylik-Mazurek & Alicja Hubalewska-Dydejczyk
Jagiellonian University Medical College, Chair and Department of Endocrinology, Krakow, Poland, Krakow, Poland

Paragangliomas are rare neuroendocrine neoplasms that arise from chromaffin tissue commonly located in the adrenal medulla, pre-aortic and paravertebral sympathetic plexus or skull base. About 30% of paragangliomas have a genetic basis. They may be associated with autosomal dominant inheritance of variants in the gene encoding succinate dehydrogenase or may coexist in genetically determined endocrine syndromes. The study aim was to analyse clinical and molecular data of patients with extraadrenal paraganglioma from one clinical center in 2016-2021.
Materials and Methods
In all paraganglioma patients (29 cases), the age of diagnosis, clinical symptoms, location, 24-hour urinary fractionated metanephrines concentration, serum concentration of chromogranin A, the largest dimension of the lesion, and distant metastases were evaluated. Molecular analysis for pathogenic variants in *SDHB*, *SDHC*, *SDHD*, *RET*, *MEN1*, *MAX*, and *VHL* genes was performed using next-generation sequencing methods.
Results
22 women and 7 men were enrolled. Patients were divided into four subgroups according to location, head and neck - 7 patients, thorax - 3 patients, abdomen - 15 patients, and pelvis - 4 patients. The median age of diagnosis for each group was: head and neck 62 years (range 43 - 70), chest 45 years (range 34 - 52), abdomen 58 years (range 18 - 73), pelvis 45.5 years (range 20 - 72). The most common symptom was hypertension, affecting 93.1% of the patients. Tachycardia was present in 27.6% of the study group. The study showed the highest urinary fractionated normetanephrine concentration in patients with paragangliomas with pelvic location (P=0.016)–median 6134.1 µg/24 h (range 1053.8 - 12650.9) [ref. range 88.0 - 440.0]. There was no significant difference in serum concentration of chromogranin A between groups. Molecular alterations within the genes analysed were found in 5 patients: 3 pathogenic variants within the *SDHD* gene were identified, 1 variant of uncertain significance (VUS) in *SDHD* and 1 VUS in *SDHB*, respectively. Molecular alterations were observed in 71.4% of patients with paragangliomas with head and neck localization and were not identified at

other locations. Distant metastases were found in 14.3% of the patients in paragangliomas of the head and neck region, 33.3% of the thorax, 6.7% of the abdomen, and 25.0% of the pelvis.
Conclusions
The pelvic location of the paraganglioma was associated with a statistically higher urinary fractionated normetanephrine concentration. Pathogenic variants within the genes analysed found in the study group involved patients with localization in the head and neck region.

Adrenal venous sampling in tertiary centre from 2015. to 2022

Nino Matas[1], Karin Zibar Tomšić[2], Lana Sambula[3] & Anja Barac Nekic[2]
[1]Clinical Hospital Centre, Internal Medicine, Zagreb, Croatia; [2]CHC Zagreb, Internal Medicine, Zagreb, Croatia; [3]General Hospital Koprivnica, Internal Medicine, Koprivnica, Croatia

Background
Adrenal venous sampling (AVS) is considered the gold standard for differentiating an aldosterone- producing adenoma (aPA) from bilateral adrenal hyperplasia (BAH)
Objective
The aim of this study is to present our experience with this method in our hospital.
Methods
We performed a retrospective analysis of 105 patients who underwent the AVS protocol at our centre between 2015 and 2022 for PA.
Results
AVS was performed 115 times in 105 patients, and in 20 patients AVS was performed 2 times. AVS was successful in 86 patients (82%). Among them, 66 patients were female (63%) and median age of all our patients was 53 years (20-75). In 62 patients (65%), the potassium level was lower than 3.6 mmol/l. The main reason for work-up was arterial hypertension in 42 patients (40%). AVS result and CT scan were compatible in 59 patients (60%). According to AVS, APA was diagnosed in 58 (55%) patients, BAH in 37 (35%) patients and in 10 (10%) patients the diagnosis was inocclusive. Surgery was performed in 46 (44%) patients and 58 (56%) patients were treated with medication. Complete biochemical remission was seen in 20 (84%) patients and partial biochemical remission in 2 (8%) patients. 2 (8%) patients had subclinical Cushing's syndrome and did not show biochemical remission. Complete clinical remission was seen in 13 (38%) patients, partial clinical remission in 18 (53%) and 3 (9%) patients had no clinical remission. AVS was more successful in the last 4 years than in the years before (83% vs 69%).
Conclusion
Our results show a high rate of successfully performed AVS. Prolonged hypertension could be one of the reasons for partial biochemical remission.

Adrenal lesions in patients with familial adenomatous polyposis

Joaquin de Carlos [1], Lucia Zabalza[2], Susana Oquiñena[2], Ana Irigaray[2] & Emma Anda[2]
[1]Hospital de Zumarraga, Endocrinology, Zumarraga, Spain; [2]Hospital Universitario de Navarra, Pamplona, Spain

Introduction
Familial Adenomatous Polyposis (FAP) is an autosomal dominant disease classically characterized by the development of hundreds or thousands of adenomas in the rectum and colon during the second decade of life. Almost all patients will develop colorectal cancer (CRC) if not identified and treated at an early stage. It is a multisystem growth disorder so there is an increased risk of developing extraintestinal manifestations. In this context, an increase in adrenal pathology compared to the general population has been described. We aimed to report the frequency, functional characteristics and progressions of adrenal lesions in FAP patients.
Materials and Methods
Prospective study, selecting 17 living patients diagnosed and registered with APC mutations under follow-up from the Digestive Department of the Hospital Universitario de Navarra (HUN) with current or past follow-up in the Endocrinology Department. Radiological tests, clinical, and analytical variables were analyzed.
Results
The study population included 12 men (64.7%) and 5 women (35.3%), with a mean age of 47 years. The median age at diagnosis of FAP was 28 years, with a mean follow-up time of 16 years. All patients had an abdominal imaging study (CT or MRI), detecting lesions in 5/17 (31.25%). All were incidental findings presented as non-functioning adenomas in the analytical tests performed. The study consisted of the overnight 1mg dexamethasone suppression test, catecholamine/metanephrine determination, adrenal androgen production, and if appropriate, screening of primary hyperaldosteronism. None showed significant growth during follow-up (defined as changes in the size of ≥ 2 mm were considered clinically significant). No major endocrinological alterations (defined as nodular disease or thyroid carcinoma, thyroid autoimmunity, diabetes, obesity) were detected when comparing both groups. There were also no differences in gender, age or time since diagnosis.
Conclusion
Adrenal lesions are common in patients with FAP who undergo abdominal imaging. They appear to follow a benign and slowly progressive course, presenting clinically and analytically as non-functioning lesions.

Insulin Signaling in Hyperactivation of the HPA Axis in Metabolic Diseases

Diana Cozma[1,2], Panagiota Siatra[1,2], Ioannis Oikonomakos[2], Stefan Bornstein[1,2,3], Cynthia Andoniadou[1,3] & Charlotte Steenblock[1,2]
[1]Technical University of Dresden Medical School, Dresden, Germany; [2]University Clinic Dresden, Medical Clinic 3 - Molecular Endocrinology, Dresden, Germany; [3]King's College London, Guy's Hospital, London, United Kingdom

Stress can lead to an increase in body fat and obesity as main clinical conditions preceding the metabolic syndrome. In metabolic stress, hyperactivation of the hypothalamic-pituitary-adrenal (HPA) axis has been observed, resulting in increased steroidogenesis and alteration of cortisol secretion[1]. This increased sensitivity of the HPA axis may be related to the development of comorbidities or severe illness in patients with metabolic diseases and *vice versa*. Disorders of the HPA axis, e.g., Cushing's disease, resulting from overproduction of ACTH, share similar clinical symptoms with metabolic diseases. The molecular signaling mechanisms that cause such changes in the HPA axis under metabolic stress remain elusive. Previous studies indicate a role of insulin in the regulation of adrenal steroidogenesis by upregulating the transcriptional activity of NR5A1[2]. Here, we study the molecular mechanisms to insulin-induced hyperactivation of the HPA axis and characterize the molecular changes that lead to altered cortisol secretion. We generated non-adherent spheroids from primary adrenocortical cells *in vitro* and treated these with insulin. This resulted in an increase of spheroid diameter over time compared to control, indicating greater cell expansion following insulin treatment. Similarly, repeating this experiment with adherent primary anterior pituitary stem cell colonies, we observed an increase in colony size when treated with insulin compared to control. This indicates that the stem cell populations of the adrenal and pituitary gland are responsive to insulin stimulation, likely leading to increased proliferation. This is complementary to our previous studies where we revealed increased secretion of aldosterone in insulin-stimulated adrenocortical cultures[3]. To identify signaling pathways related to insulin stimulation, we performed bulk RNA sequencing of *in vitro* primary cultures of adrenocortical and pituitary cells with and without insulin treatment. Analysis of these data sets reveals specific signaling pathways that are candidates in regulation of metabolic stress *in vivo*. Using mouse models of obesity and diabetes along with genetic lineage-tracing studies, we aim to decipher the role of these pathways on HPA axis stem/progenitor cells during metabolic stress. The outcomes will pave the way for a better understanding of HPA axis activity during metabolic stress adaptation, and the role of the HPA axis in patients suffering from metabolic diseases.

Introduction
Congenital adrenal hyperplasia (CAH) is a group of autosomal recessively inherited disorders that are characterised by inactivating mutations at various steps of adrenal steroidogenic pathways causing defective cortisol biosynthesis. 21-Hydroxylase enzyme deficiency (21-OHd) constitutes more than 95% of all CAH cases.
Material & Methods
Medical records of patients with all forms of CAH from 19 adult endocrinology clinics located at six different geographical regions of Turkey are evaluated in this multicentre study. Findings of 21-OHd CAH cases ($n=181$) eligible for analysis are given.
Findings
There were 101 (55.8%) classical and 80 (44.2%) nonclassical 21-OHd CAH cases. General features of cases can be found in Table. More patients in nonclassical CAH group were married and had children. Reconstructive genital surgery was performed in 54 (78.3%) of classical CAH females and 42 (77.8%) of them had no children. Data about genetic analysis were reached in 120 cases (57 classical CAH, 63 NCAH). V281L mutation was detected in 21 (33.3%) of 21-OHd NCAH patients.
Discussion
Interpretation of findings of this study will improve our knowledge about CAH and will inevitably result in better health service.

Increased sclerostin concentration in patients with primary adrenal insufficiency

Aleksandra Zdrojowy-Welna, Jowita Halupczok-Żyła, Justyna Kuliczkowska-Płaksej, Aleksandra Jawiarczyk-Przybyłowska & Marek Bolanowski
Wroclaw Medical University, Department of Endocrinology, Diabetes and Isotope Therapy, Wrocław, Poland

Background
Sclerostin is a protein secreted by osteocytes, that inhibits Wnt/ βcatenin signaling and was suggested to play a role in glucocorticoid-induced osteoporosis in mice. In humans data are inconsistent. Patients with primary adrenal insufficiency need lifelong replacement therapy with glucocorticoids and mineralocorticoids, which may influence their bone quality.
Aim
The aim of the study was to evaluate sclerostin concentrations, densitometry parameters, and trabecular bone score in patients with primary adrenal insufficiency in comparison to control group.
Materials and Methods
We included 29 patients (62% females) with diagnose of autoimmune primary adrenal insufficiency (mean age 49.7±11.7 years, mean duration of the disease 13.2± 13.6 years) and 33 healthy subjects (adjusted with age, sex and body mass index). Bone mineral density at the femoral neck, lumbar spine, total body and

trabecular bone score were evaluated. Serum sclerostin concentrations were measured.
Results
Mean serum sclerostin concentration was significantly higher in patients with adrenal insufficiency than in control group (44.7±23.5 vs 30.7±10.4 pmol/l, $P=0.006$). There were no significant differences in densitometry parameters (Tscore, Z-score, bone mineral density) and trabecular bone score in patients with adrenal insufficiency and control group. There was a negative correlation between trabecular bone score and the duration of adrenal insufficiency and age, also a negative correlation between femoral neck and total densitometry parameters and 24-hour urine cortisol. Sclerostin concentration correlated positively only with free thyroxine concentration ($R=0.486$, $P=0.009$; no significant correlation with serum TSH), there were no significant correlations with any other clinical or biochemical parameters.
Conclusions
The sclerostin concentration was higher in patients with primary adrenal insufficiency in comparison to control group. This finding needs further studies.

Aldosterone/direct renin ratio (ADRR) in the screening of patients with primary aldosteronism

Alicja Szatko[1], Dorota Leszczynska[1], Barbara Badura[2], Szymon Barczak[2], Kinga Filipek[2], Justyna Hempel[2], Magdalena Ostrowska[1], Lucyna Papierska[1], Wojciech Zgliczyński[1] & Piotr Glinicki[1]
[1]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland; [2]Centre of Postgraduate Medical Education, Students' Scientific Group affiliated to the Department of Endocrinology, Warsaw, Poland

Background
Primary aldosteronism (PA) is the most common endocrine cause of secondary hypertension. It occurs in 5%-10% of hypertensive patients. PA is a group of disorders associated with semi-autonomous hypersecretion of aldosterone. Laboratory diagnosis in patients with suspected PA consists of screening tests aimed at determination of serum/plasma aldosterone concentration, direct renin concentration (DRC) and calculation of the aldosterone/direct renin ratio (ADRR). The aim of the study was to assess the usefulness of aldosterone and direct renin concentrations using the immunochemiluminescent method (CLIA, LIAISON XL® analyzer, DiaSorin, Italy) and to use the ADRR ratio as a screening test in the biochemical diagnosis of patients with suspected primary aldosteronism.
Methods
Patients were divided into 2 groups: 1. Patients with primary aldosteronism ($n=35$) 2. Patients with adenoma + hypertension ($n=200$) Serum aldosterone concentration, direct plasma renin concentration and aldosterone/DRC ratio (ADRR ratio) were determined in all patients. Aldosterone and direct renin concentrations were determined by immunochemiluminescent assay (CLIA) on a LIAISON XL® analyzer (DiaSorin, Italy). The ADRR is shown as ng/dl/μIU/ml.
Results
Serum aldosterone levels in patients with PA ranged from 9.92 to 100 ng/dl. Aldosterone levels were <10 ng/dl in 2 patients, between 10-15 ng/dl in 6 patients, and >15 ng/dl in 27 patients. The optimal cut-off for aldosterone was 13.8 ng/dl (AUC 0.8816; $P<0.0001$). Sensitivity and specificity for serum aldosterone concentration for patients with PA were 79% and 82%, respectively. DRC in patients with PA was in the range of 0.5–10.1 μIU/ml. The optimal cut-off for DRC in patients with PA was 4.22 μIU/ml (AUC 0.9466; $P<0.0001$). Sensitivity and specificity for DRC were 83% and 94%, respectively. The aldosterone/renin ratio (ADRR) was calculated from the aldosterone concentration and DRC. The optimal cut-off point discriminating PA patients from adenoma hypertensive patients was 3.85 ng/dl/μIU/ml (AUC 0.9843; $P<0.0001$), achieving 94% sensitivity and specificity.
Conclusion
Determination of aldosterone and renin levels using the CLIA method and the use of the ADRR ratio show a high diagnostic value as a screening test for patients with PA.

Clinical presentation and cardivascular events in primary hiperaldosteronism

Natasa Vujacic[1,2], Jasmina Ciric[1,2], Vladan Zivaljevic[2], Nikola Slijepcevic[2] & Milos Stojanovic[1,2]
[1]Endocrinology Clinic, Deparment of Endocrinology,Diabetes and Metabolic Disorders, Beograd, Serbia; [2]University Clinical Centre of Serbia, Clinic for Endocrine Surgery, Beograd, Serbia

Introduction
Primary aldosteronism (PA) is characterized by symptoms caused by hypertension and hypokalemia. Some cardiovascular events are found to be more common due to the additional negative effect of aldosterone. The aim of the study was to analyse clinical characteristics of the PA due to adenoma (APA) and to compare the frequency of cardiovascular diseases with those found in adrenal Cushing' syndrome (CS) and adrenal adenoma associated with essential hypertension (A+HT). Material and method: The study group of PA included 40 patients (25 females, 15 males). The study groups (CS $n=20$; A+HT $n=40$) did not differ by age and sex.
Results
The mean systolic and diastolic arterial pressures were significantly higher in PA group than A+HT group ($P=0.004$; $P=0.002$; respectively) and all had hypokalaemia. PA was more common in younger women (20-40 years 24% vs 6.7%) and older men (>60 years 8% vs 60%). The most common symptoms of PA were evenly distributed: muscle weakness, pain, cramps, tingling (45%), headache, brain fog (32.5%) and fatigue (20%). Patients younger than 50 years suffered from muscle paresis (10%) and EPH-gestosis (7.5%). Only patients older than 50 years suffered from cardiovascular complications: atrial fibrillation 15%, cerebrovascular insult 3%, myocardial infarction 7.5%, angina pectoris 6%, chronic heart failure 7.5%, and aortic aneurysm 5%. Chronic renal failure was found in 20% of patients. There were no significant differences in the presence of cardiovascular and cerebrovascular events between groups.
Conclusion
We found a higher tendency for cardiovascular, renal and cerebrovascular events in PA that was not significant.

Background
Glucocorticoid (GC) formulations are widely used as anti-inflammatory treatment, and synthetic GC, e.g. prednisolone, is the cornerstone treatment of polymyalgia rheumatic (PMR) and giant cell arteritis (GCA). Long-term pharmacological GC treatment may induce adrenal insufficiency (GIA). Adrenal function is, however, not routinely assessed after discontinuation of long-term GC treatment, and it is unknown, if hydrocortisone replacement is beneficial. This study aims to generate evidence-based guidance for the management of GIA due to long-term GC treatment.
Methods
The REPLACE study is a multi-centre, randomised, double-blinded, placebo controlled 1-year study. Participants are patients diagnosed with PMR and/or GCA, who have been in GC free remission for 2-12 weeks after long-term prednisolone treatment. Eligible patients undergo an ACTH test, and group assignment depends on the cortisol response: In both RCT and control groups a fasting, standardized baseline visit includes patient reported outcome (PRO), physical and psychological health. Patients in the RCT are randomized to either hydrocortisone or placebo for 1 year with repetition of baseline investigations at 6 and 12 months.
Outcomes
Primary outcome: Health related quality of life associated with adrenal insufficiency assessed by the Addison's disease-specific quality-of-life questionnaire (AddiQol-30).
Secondary outcomes: Using a study smartphone application (app), participant-reported information about intercurrent illness or stress, and symptoms attributable to adrenal insufficiency, are reported daily. Furthermore, ecological momentary assessments of the Multidimensional Fatigue Inventory, General Fatigue scale, are reported in the app in both stressed and unstressed conditions.

Exploratory outcomes: Additional questionnaire-based HRQoL (CushingQoL, SF-36v2, Single item Sleep Quality Scale and the International Physical Activity Questionnaire-S7S); incidence of adrenal crisis; cardiovascular health (blood pressure, arterial stiffness and coagulation markers); body composition and muscle function (DXA scan and physical tests); bone and calcium metabolism; glucose homeostasis; possibly normalization of adrenal function; and biomarkers of GC sensitivity and action.

Ethics and dissemination

The REPLACE study is in accordance with the Declaration of Helsinki; registered at EudraCT (2020-006121-65) and publications will be according to the International Committee of Medical Journal Editors recommendations.

Funding

The REPLACE study is funded by the Novo Nordisk Foundation as part of a collaborative grant entitled "DOUBLE EDGE–Characterization and mitigation of adverse effects of glucocorticoid treatment" (NNF20OC0063280).

Status: Recruiting.

Addison's disease with preserved glucocorticoid function in the Type 1 diabetes population: a diagnosis not to miss during routine diabetes follow-up

Zoe Bond, Razan Ali Rashid, Simon Pearce, Catherine Napier, Anna Mitchell & Yaasir Mamoojee

Royal Victoria Infirmary, Newcastle upon Tyne Hospitals NHS Foundation Trust, Department of Endocrinology and Diabetes, United Kingdom

Background

Prevalence of Addison's disease (AD) among patients with Type 1 diabetes mellitus (T1DM) is estimated at 0.2%, whilst prevalence of T1DM among patients with AD can be up to 14%. Residual adrenal function in patients with established AD may be present in up to 30% of cases but its clinical significance is not fully clear.

Aims

To evaluate the prevalence of AD with preserved glucocorticoid function in patients with T1DM at Newcastle Diabetes Centre. To describe the demographics, clinical presentation and investigations that led to the diagnosis of AD with preserved glucocorticoid function in these patients.

Methods

Review of electronic records for patients with T1DM registered at our centre and diagnosed with AD and/or prescribed steroids and fludrocortisone regularly.

Results

12 out of 2704 patients had a diagnosis of AD. The prevalence of AD in our T1DM population is 0.6%. 3/12 (25%) patients with AD demonstrated preserved or relatively preserved glucocorticoid function. All 3 patients had chronic, intermittent hyponatraemia with hyperkalaemia. Random cortisol level in 2 patients were 205 nmol/l and 479 nmol/l while the third patient was established on longterm immunosuppressant steroid therapy. The latter achieved a peak cortisol of 179 mmol/l on Short Synacthen Testing, suggesting preserved glucocorticoid function. None of the patients reported weight loss but fatigue was a commonly reported symptom.

Conclusions

AD with preserved glucocorticoid function, albeit a rare entity, is most likely to be encountered during routine follow-up in the T1DM clinic in patients with intermittent hyponatraemia or hyperkalaemia. Clinicians should be alert to investigate for AD in these patients. A random cortisol measurement may miss AD with preserved glucocorticoid function. In selected cases, clinicians should consider checking transtubular potassium gradients, serum bicarbonate, renin, aldosterone and ACTH levels, if short Synacthen test results are normal.

Endocannabinoids in patients with adrenal incidentalomas. A new prognostic biomarker?

Chrysoula Mytareli[1], Fani Athanasouli[1], Athina Karampela[1], Petros Papalexis[1], Vasiliki Siampanopoulou[1], Alexandros Lafioniatis[1], Marina Mantzourani[2] & Anna Angelousi[1]

[1]Athens Medical School, National and Kapodistrian University of Athens, Unit of Endocrinology, First Department of Internal Medicine, Laikon General Hospital, Athens, Greece; [2]Athens Medical School, National and Kapodistrian University of Athens, First Department of Internal Medicine, Laikon General Hospital, Athens, Greece

Background

The majority of adrenal incidentalomas (AIs) are benign non-functioning adrenocortical adenomas (NFAIs), yet not clinically silent. Possible autonomous cortisol secretion (PACS) can also be diagnosed in up to 50% of patients. Endocannabinoids (ECs) have recently been studied regarding their role in the hypothalamo-pituitary-adrenocortical (HPA) axis; however, data are scarce in humans.

Aim

We aimed to assess hair EC [anandamide (AEA) and 2-arachidonoylglycerol (2-AG)] levels in patients with AIs compared to controls and their association with the hormone profile of these patients.

Methods

Forty-four patients diagnosed with AIs (32 NFAIs and 12 PACS) and 44 controls (without AIs in computerized tomography), referred to the Endocrinology Unit of the 1st Department of Internal Medicine of Laikon Hospital between June 2020 and July 2021, were recruited. Patients with serum cortisol (F) levels between 1.8 and 5 μg/dl post 1mg dexamethasone suppression test (1mg-DST) were classified in PACS group, whereas those with F levels < 1.8 μg/dl in NFAI group. Basal (8:00 am) F, adrenocorticotropic hormone (ACTH), dehydroepiandrosterone sulfate (DHEA-S) as well as 24-h urinary free cortisol (UFC) were also analysed. Hair samples were collected according to Society of Hair Testing guidelines and EC levels were measured by liquid chromatography tandem-mass spectrometry. Statistical analysis was conducted using SPSS version 28.

Results

The age, sex and body mass index as well as the prevalence of hypertension, dyslipidemia, diabetes mellitus type 2 and bone disease did not differ significantly between the groups. Significantly decreased hair AEA and 2-AG levels were found in patients with AIs compared to controls ($P<0.001$ and $P=0.002$ respectively) as well as between NFAI or PACS and controls ($P<0.001$ or $P=0.002$ and $P=0.038$ or $P=0.02$ respectively). Among the AI patients, EC levels were found lower in PACS group compared to NFAI, although not statistically significantly. AEA hair levels were negatively correlated with F levels post 1 mg-DST ($r_s=-0.257$, $P=0.033$), but not with F, ACTH, UFC or DHEA-S levels.

Conclusion

Data regarding the interaction between glucocorticoids (GCs) and ECs are scarce, contradictory and analysed mainly in animal models. In humans it seems that the chronic exposure to GCs has an inhibitory effect on the circulating EC levels. Our data showed that patients with AIs presented lower EC levels compared to controls enhancing the hypothesis of the suppressive effect of chronic hypercortisolism on hair EC levels. The role of ECs on HPA axis merits a more thorough analysis in larger human studies.

Optimal application of captopril challenge test in the diagnosis of primary aldosteronism

Wenzhan Chen, Nan Chen, Shuang Yu, Rui Zeng, Li Chen, Changliu Xu, Yanbing Li, Haipeng Xiao & Xiaopei Cao

The First Affiliated Hospital of Sun Yat-Sen University, Department of Endocrinology, Guangzhou, China

Objective

To evaluate the optimal parameters and the cut-off points of captopril challenge test (CCT) in the diagnosis of primary aldosteronism (PA) using chemiluminescence immunoassays (CLIA).

Methods

Patients with clinically suspected PA who admitted to our hospital between July 2021 and December 2021 were recruited. Both supine and upright aldosterone to renin ratio (ARR) were calculated in all the participants and 21 healthy volunteers. CCT was performed in all those ARR ≥ 25 and the first two out of three ARR < 25. Blood samples were drawn before, 1 h and 2 h after oral 50mg captopril for the measurements of plasma renin concentration (PRC) and plasma aldosterone concentration (PAC). PRC was measured by CLIA while PAC was measured by both CLIA and liquid chromatography-mass spectrometric (LC-MS/MS). ARR before CCT, at 1 h post-CCT and 2 h post-CCT were calculated. The suppression percentage of PAC and increasing percentage of PRC were also calculated. PA was established according to criteria. Informed written consent was obtained from all participants. This study was registered in chictr.org.cn (identifier, ChiCTR2100047984).

Results
Blood samples of 112 suspected PA patients and 21 healthy volunteers were collected to measure PAC using both CLIA and LC-MS/MS. A positive correlation ($r=0.804$, $P<0.001$) was observed between the two assays. CCT were performed in 45 with ARR $\geq$ 25 and 43 with ARR $<$ 25. Data were analyzed in 43 confirmed PA patients and 45 essential hypertension patients. Compare to the PAC, suppression percentage of PAC and increasing percentage of PRC, ARR at 2 h post-CCT presented the largest area under the receiver operating characteristic curve either PAC was measured by LC-MS/MS or by CLIA. The optimal CLIA-specific cut-off of 2 h post-CCT ARR was 26.0, with a sensitivity and specificity of 95.3% and 93.3%, respectively. Moreover, the specificity achieved to 97.8% when combining 2 h post-CCT ARR $>$ 26.0 with 2 h post-CCT PAC $>$ 15.000 ng/dl.
Conclusion
CLIA presents well correlation with LC-MS/MS in PAC measurement. 2 h post-CCT ARR is the most efficient parameter in PA diagnosis using CCT. The optimal cut-off point for 2 h post-CCT ARR is $>$ 26.0 in our study. The diagnosis is more specific when combining 2 h post-CCT ARR $>$ 26.0 with 2 h post-CCT PAC $>$ 15.000 ng/dl.

Metanephrines work-up in patients diagnosed with incindentaloma - the influence of commonly used drugs on results interpretation

Joanna Kokoszka[1], Marta Opalinska[2], Magdalena Kolasa[1], Monika Szewczyk[1], Katarzyna Sitarz[3], Jolanta Bugajska[4], Joanna Berska[4], Krystyna Sztefko[4] & Alicja Hubalewska-Dydejczyk[2]
[1]University Hospital in Krakow, Endocrinology, Oncological Endocrinology and Nuclear Medicine Department, Krakow, Poland; [2]Jagiellonian University Medical College, Chair and Department of Endocrinology, Krakow, Poland; [3]University Hospital in Krakow, Kraków, Poland; [4]Jagiellonian University Medical College, Clinical Biochemistry Department of Pediatric Institute, Krakow, Poland

Introduction
Due to the frequent occurrence of adrenal incidentalomas, diagnosis of their hormonal activity is a significant clinical concern. Approximately 7-10% of adrenal tumors are pheochromocytomas, which even in silent form can lead to hemodynamic instability during surgery. According to the ESE and ENSAT guidelines in any case of adrenal tumors greater than 1 cm pheochromocytoma should be excluded based on plasma metanephrines level and urinary metanephrines excretion. Such approach can be challenging in patients with significant comorbidities or when patients are on drug which interfere with analytical measurement.
Aim of the study
The aim of this study was to evaluate the effect of selected drug on metanephrines excretion in urine in patients with incidentaloma.
Materials
1,102 patients with incidentalomas confirmed by CT or MR were included in the study. Patients with a clinical or biochemical diagnosis of Cushing's or Conn syndrome as well as patients very likely having pheochromocytoma were excluded. In all patients, 24-hour urinary excretion of normetanephrine, metanephrine and 3-methoxytyramine were measured by high performance liquid chromatography (HPLC) with electrochemical detection. The information on concomitant medication (β-blockers, Ca-blockers, loop diuretics, thiazide diuretics, potassium-sparing diuretics, α-blockers, ACE inhibitors/aniotensin II receptor antagonists, metformin, other antidiabetic drugs, lipid lowering drugs, proton pump inhibitors, levothyroxines, thyreostatics, antidepressants, neuroleptics, benzodiazepines, glucocorticosteroids, B receptor agonists and M-receptor antagonists) from each patient were collected.
Results
The analysis showed that urine excretion of normetanephrine was significantly higher in patients (without medication vs medication) using β-blockers (288.9 vs 332.3 μg/24 h, $P<0.0001$), Ca-blockers (282.6 vs 333.8 μg/24 h, $P<0.0001$), loop diuretics (299.4 vs 374.5 μg/24 h, $P<0.0001$), α-blockers (299.3 vs 352.7 μg/24 h, $P=0.0001$), non-metformin antidiabetic drugs (301.0 vs 366.15 μg/24 h, $P=0.0001$) and neuroleptics (305.4 vs 384.3 μg/24 h, $P=0.0307$). Urinary metanephrine excretion was higher in patients taking α-blockers (109.2 vs 136,9 μg/24 h, $P<0.0001$) and was lower in patients taking non-metformin antidiabetic drugs (114.3 vs 99.3 μg/24 h, $P=0.0247$), antidepressants (114.3 vs 97.7=8 μg/24 h, $P=0.0207$) and glucocorticosteroids (114.6 vs 94.8 μg/24 h, $P=0.0043$) . Urinary 3-methoxytyramine concentration was higher in patients taking thiazide diuretics (191.8 vs 264.5 μg/24 h, $P=0.0031$), antidepressants (195.2 vs 317.9 μg/24 h, $P=0.0005$) and M-receptor antagonists (198.3 vs 284.6 μg/24 h, $P=0.0292$). The other drugs had no significant effect on the results of urinary excretion of catecholamines.
Conclusion
Many of the commonly used drug groups significantly affect the results of 24-hour urine collection of fractionated methanephrines. Interpretation of these results should be adjusted and take into account the effect of the drug groups used on the results obtained and individualized in the clinical context.

Novel high resolution mass spectrometry profiling of free cortisol, cortisone, 6β- and 18-hydroxycortisol for the evaluation of glucocorticoid and mineralocorticoid disorders

Gregori Casals[1,2,3,4], María Antonieta Ballesteros[5], Angielys Zamora[6], Irene Martínez[1], Montserrat Ruiz[7], Guillermo Fernández-Varo[1,2,4], Mireia Mora[2,3,7], Manuel Morales-Ruiz[1,2,3,4] & Felicia A Hanzu[2,3,7]
[1]Hospital Clínic de Barcelona, Biochemistry and Molecular Genetics, Barcelona, Spain; [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [3]Universitat de Barcelona, Barcelona, Spain; [4]CIBEREHD - Center for Biomedical Research Network; [5]Hospital Universitari Son Espases, Servicio de Análisis Clínicos, Palma, Spain; [6]Gregorio Marañón General University Hospital, Clinical Chemistry, Madrid, Spain; [7]Hospital Clínic de Barcelona, Endocrinology and Nutrition, Barcelona, Spain

Introduction
Urine free cortisol measurements are routinely performed to evaluate hypercortisolism. Despite their analytical inaccuracy, immunoassay-based methods are frequently used. Advances in liquid chromatography high resolution mass spectrometry (LC-HRMS) facilitate the incorporation of powerful diagnostic tools into clinical laboratories with high analytical specificity that also allow simultaneous quantification of different metabolites and untargeted compound identification, which may be helpful to identify other clinically relevant metabolites or drugs.
Objectives
The aim was to validate a simple routine LC–HRMS method to quantify simultaneously cortisol, cortisone, 6β-hydroxycortisol, and 18-hydroxycortisol in human urine. In addition to the key role of urine cortisol measurements in Cushing's syndrome, the cortisol/cortisone ratio (11βHSD2 activity) is a sensitive marker for the apparent mineralocorticoid excess syndrome, the 6β-hydroxycortisol/cortisol ratio is a marker for CYP3A activity, and 18-hydroxycortisol levels are useful in the evaluation of primary hyperaldosteronism, especially familial forms.
Methods
Urine extraction was liquid-liquid with dichloromethane, chromatographic separation was performed by micro-LC and detection used accurate masses of steroids and simultaneous high resolution full scan acquisition. Validation included the assessment of linearity, matrix effect, accuracy, imprecision, selectivity, carry-over and comparison with a GC-MS method. We also quantified the 24-h urine excretion of the four steroids by LC-HRMS in 60 samples of patients with clinical suspicion or follow-up for hypercortisolism. The cross-reactivity of the measured steroids with commercial cortisol immunoassays (Liaison and Atellica) was also investigated.
Results
The analytical method was free of matrix effect and presented acceptable analytical performance. Cortisol concentrations in the urine of patients significantly correlated with cortisone and 6β-hydroxycortisol but not with 18-hydroxycortisol. Patients with antisteroidogenic drugs presented reduced CYP3A4 activity as assessed by the 6β-hydroxycortisol/cortisol ratio. The urines of patients without antisteroidogenic drugs ($n=41$), metyrapone ($n=12$), ketoconazole ($n=4$) and osilodrostat ($n=3$) presented, respectively, 6β-hydroxycortisol/cortisol ratios of 4.1 ± 0.5, 2.2 ± 0.5, 1.5 ± 0.6 and 0.1 ± 0.1 ($P<0.05$). In contrast, no differences were observed between these groups in the 11β-HSD2 activity calculated as the ratio cortisol/cortisone. Finally, cross-reactivity with 6β-hydroxycortisol and cortisone was demonstrated in cortisol immunoassays, which presented significantly higher urine cortisol results in comparison with LC-HRMS.
Conclusion
A rapid and accurate routine LC-HRMS method was validated, which is useful for routine evaluation of hypercortisolism and other disorders of glucocorticoid and mineralocorticoid metabolism. Cross-reactivity with 6β-hydroxycortisol may impact cortisol immunoassay reliability to monitor hypercortisolism medical therapies.

A new LC-MS/MS method for simultaneous determination of six steroids in urine for the diagnostic workup of primary aldosteronism

Nora Vogg[1], Lydia Kuerzinger[2], Hanna Remde[2], Sabine Kendl[2], Martin Fassnacht[2] & Max Kurlbaum[2]
[1]University Hospital Erlangen, Institute of Experimental and Clinical Pharmacology and Toxicology, Erlangen, Germany; [2]University Hospital Würzburg, Department of Internal Medicine I, Division of Endocrinology and Diabetes, Würzburg, Germany

Background
The diagnostic workup of primary aldosteronism (PA) is challenging and the current screening tool, aldosterone-renin ratio, is increasingly challenged. Due to interference with immunoassays and the general high variability of plasma aldosterone levels false-positive as well as false-negative results are probably more frequent than previously assumed. Therefore, we aimed at the establishment of a reliable LC-MS/MS method to analyze aldosterone and related steroids in human urine to facilitate diagnostic workup.
Methods
450 µl urine were treated with β-glucuronidase/arylsulfatase by *Helix pomatia* and purified by off-line solid phase extraction before analysis. Chromatographic separation was carried out using an Agilent 1290 Infinity LC system equipped with binary pump, autosampler and thermostatted column compartment and a Waters Acquity® HSS PFP 1.8 µm (2.1×50 mm) column with an eluent consisting of 5 mM ammonium formate as phase A and methanol as phase B. A Sciex QTRAP 6500 mass spectrometer was used for detection of the steroids aldosterone (Aldo), tetrahydroaldosterone (THAldo), cortisol (F), 18-oxocortisol (18-OxoF), 18-hydroxycortisol (18-OHF) and 18-hydroxycorticosterone (18-OHB). Multiple reaction monitoring in positive ion mode and stable isotope labeled internal standards allowed for quantification. Complete validation will be performed according to FDA and EMA guidelines.
Results
Calibration ranges of 0.2-30 ng/ml (Aldo and 18-OHB), 1-150 ng/ml (THAldo), 2-300 ng/ml (F and 18-OHF), and 0.1-15 ng/ml (18-OxoF) have been established. First 24-h urine samples from 18 patients with PA were successfully included in the validation process and mean values were obtained as follows: cortisol 63.4 µg/24 h [IQR:27.7-95.5], Aldo 12.9 µg/24 h [IQR: 6.2-22.1], 18-OxoF 4.5 µg/24 h [IQR: 0.4-5.8], 18-OHF 123.4 µg/24 h [IQR: 21.2-138.0], 18-OHB 8.0 µg/24 h [IQR: 2.6-13.1] and THAldo 67.1 µg/24 h [IQR: 30.4-100.5].
Conclusions
We herein describe a liquid chromatography tandem mass spectrometry method for the simultaneous quantification of six steroids in human urine, which are currently validated according to FDA and EMA guidelines for application in patient care. Prospectively, the method may contribute to an optimization of the diagnostic workup of PA.

The adrenal glands mass and hypertension with elevated levels of aldosterone: is there an association?

Darya Malakhava[1] & Volha Shyshko[1,2]
[1]Belarusian State Medical University, Endocrinology, Minsk, Belarus; [2]Minsk City Clinical Endocrinology Center, Endocrinology, Minsk, Belarus

Introduction
The effect of aldosterone levels on the severity of arterial hypertension was established in many studies. Changes in the level of aldosterone can lead to disorders of the cardiovascular, nervous, excretory systems. One of the factors affecting the fluctuation of aldosterone is the presence of adrenal gland mass.
Aim
To check for a correlation between the identified adrenal masses and the severity of arterial hypertension against the background of elevated aldosterone.
Materials and Methods
The study included 702 cases with changes in aldosterone levels between 2003-2022. Group 1 included 378 patients without identified formations in the adrenal glands; group 2-324 patients with identified formations. The analysis was carried out according to: gender, the severity of hypertension, the presence/absence of mass in the adrenal glands, the size of the formations.
Results and Discussion
Changes in aldosterone levels are more common in women (75.13% (284), 79.94% (259) in groups 1,2, respectively, compared with men (24.87% (94), 20.06% (65)) in groups 1, 2 respectively), ($P<0.05$). In group 1, blood pressure was measured in 326 patients, of which: normal 8.28% (27), elevated 23.62% (77), stage 1 25.46% (83), stage 2 42.64% (139); in group 2, BP was measured in 319 patients, of which: normal 7.84% (25), elevated 2.82% (9), stage 1 37.30% (119), stage 2 52.04% (166). Adrenal formation was detected in 46.15% (326) of them in the right 36.20% (118), in the left 50.92% (166), in both 12.88 (42), 53.85% (378) were not detected. In group 2, formations of the right adrenal gland that were less than or equal to 1 cm accounted for 5.08% (6), more than 1 cm 94.92% (112); formations of the left adrenal gland that are less than or equal to 1 cm were 10.84% (18), more than 1 cm 89.52% (148). The change in fluctuations in the level of aldosterone in comparison of the two groups: aldosterone in group 1 is increased by 28.25% (87), normal 70.45% (217), decreased by 1.3% (4). Aldosterone in group 2 increased by 15% (45), normal 84% (252), decreased by 1% (3).
Conclusions
1. Changes in aldosterone levels are more common in women than men in both groups. 2. In both groups, there is an increase in BP. 3. An increase in BP to stages 1,2 is more common in group 2. 4. Formations in the left adrenal gland are more common. 5. Formations are more often larger than 1 centimeter.

Exploring experiences of patients with Adrenal insufficiency (AI) in managing adrenal crisis using parenteral hydrocortisone: A qualitative study

Aldons Chua[1], Martin Cartwright[2], William Drake[1] & Sofia Llahana[2]
[1]St Bartholomew's Hospital, Endocrinology, London, United Kingdom; [2]City University of London, School of Health Sciences, London, United Kingdom

Background
Adrenal insufficiency (AI) poses a significant health burden on patients, their families, and the healthcare system. Cost of illness for this patient population is four times higher than the general population. Hospital admissions due to adrenal crisis (AC) form a considerable proportion of this cost. Almost 1 in 200 patients die from AC. One in 12 patients with AI are hospitalised at least once a year following an acute AC episode if not treated promptly with parenteral hydrocortisone. Previous studies reported barriers to patient self-management at patient- and clinician- or service-level such as inadequate knowledge from patients and healthcare professionals, illness perceptions, delays in treating adrenal crisis. Out of hospital treatment of an adrenal crisis involves administration of hydrocortisone sodium phosphate (Efcortesol–liquid ampoule) or hydrocortisone sodium succinate (Solu-Cortef–powder vial) which require up to 20 sequential steps to prepare and administer intramuscularly. This can present significant challenges for patients whose health status is already severely compromised due to adrenal crisis.
Research Questions
What are the experiences of patients with AI on the management of an adrenal crisis? What are the barriers and enablers to managing adrenal crisis with the current hydrocortisone injection device?
Methods
This is a Qualitative research study using semi-structured 1:1 online interview for data collection. Adult patients with primary or secondary adrenal insufficiency and with a history of having experienced an adrenal crisis in the past 3 years are recruited via Pituitary Foundation and Addison's Disease Self-Help Group in the UK. The study is underpinned by the COM-B (Capabilities, Opportunity, Motivation–Behaviour) behaviour change Model. A convenience sampling approach will be adopted aiming to recruit 12-15 participants by end of March 2023. Interviews will be conducted online via a secure University Zoom account, transcribed verbatim and will be analysed using deductive thematic analysis with COM-B as the framework for analysis.
Outcomes
The aim is to provide an understanding on the experience and perception of patients with AI in managing AC with the use of hydrocortisone injection device. Identifying and understanding the barriers and enablers in managing AC, will inform guidance for further improvements in patient self-management strategies in preventing and managing AC.

Hereditary and sporadic pheochromocytoma: Comparison of clinical and biological features

Rania El Amel [1], Hanae Rachedi[1], Rami Imane[1], Siham Rouf[2] & Hanane Latrech[2]
[1]Endocrinology-Diabetology and Nutrition Department Hospital University Centre of Mohammed-VI, Oujda, Morocco; [2]Endocrinology-Diabetology and Nutrition Department Hospital University Centre of Mohammed-VI, Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy Mohammed First University , Oujda, Morocco

Introduction
Pheochromocytoma is a rare neuroendocrine tumor derived from the adrenal medulla characterized by a high potential of production of catecholamines. The majority of pheochromocytomas are sporadic. However, recent studies show an increasing incidence of hereditary forms.
Patients and methods
This is a retrospective descriptive study including 30 patients with pheochromocytoma followed-up in the Endocrinology-Diabetology and Nutrition Department of the University Hospital Center of Mohammed-VI-Oujda in Morocco.
Results
Among 30 patients with pheochromocytoma, 22 cases (13 females and 9 males) had a sporadic form, and 8 patients (6 females and 2 males) had an hereditary form, associated with multiple endocrine neoplasia type 2 in 7 patients and Von Hippel-Lindau disease in only one case. Hereditary forms were confirmed genetically in 5 patients. The mean age was lower in the hereditary group compared with the sporadic group (35.4 ± 12.5 years vs 51.8 ± 17.1 years respectively). Hypertension was noted in 15 cases with sporadic pheochromocytoma, 8 of which had cardiovascular complications ; however, in the hereditary group, only one case had hypertension without cardiovascular repercussions. Menard triad, was more frequent in the sporadic cases (63.6% vs 37.5%). Hereditary pheochromocytomas, compared to the sporadic forms, had lower 24-hours urinary metanephrines (2.51 vs 44 times upper limit of normal), represented mainly by elevated normetanephrines compared to metanephrines in both groups.
Conclusion
Hereditary pheochromocytomas are becoming more and more frequent. A genetic testing should be offered to patients with pheochromocytoma to allow a more rigorous follow-up with avoiding recurrence and for an early detection of the disease in relatives, in purpose to reduce morbidity and mortality given the risk of additional tumors.

EP32A

Clinical case of apparent mineralocorticoid excess

Anastasiia Lavreniuk, Nurana Nuralieva, Marina Yukina, Nadezhda Platonova, Ekaterina Troshina & Rustam Salimkhanov
Endocrinology Research Centre, Moscow, Russia

Background
Apparent mineralocorticoid excess (AME) is an autosomal recessive disorder, caused by a homozygous or compound heterozygous mutation in the 11β-hydroxysteroid dehydrogenase type 2 (*HSD11B2*) gene. Mutated HSD11B2 does not inactivate cortisol, which has a similar affinity to mineralocorticoid receptors (MR) but approximately 100 times higher plasma level, than aldosterone. Excessive stimulation of MR leads to severe childhood hypertension, hypokalemia, metabolic alkalosis, low plasma renin activity and aldosterone level.
Clinical case
A male patient was born weighing 2,6 kg at 36 weeks of gestation from healthy consanguineous parents. At 1 year of age, laboratory data revealed hypokalemia (2,2 mmol/l), without the effect of intravenous potassium infusions. At 2 years of age, he presented hypertension, polyuria, polydipsia, hypokalemia, and metabolic alkalosis. AME was suspected and spironolactone treatment was started. At 12 years of age, due to lack of permanent effect of MR antagonists (spironolactone 200 mg/day, eplerenone 50 mg/day), the dexamethasone was added. The diagnosis was confirmed in the Department of hereditary diseases in the Endocrinology Research Centre (ERC) by identifying the homozygous mutation c.911A > G (p.His304Arg) in *HSD11B2* gene. In 2022, at 19 years of age, the patient was admitted to the adult department of ERC with uncontrolled hypertension, polyuria, polydipsia, and distal muscular weakness. He received eplerenone 50 mg/day, dexamethasone 1 mg/day, potassium supplements, amlodipine 5 mg/day. Potassium level was 2,2 mmol/l on admission. We changed eplerenone to spironolactone 150 mg/day, decreased the dose of dexamethasone to 0.5 mg/day, and replaced amlodipine with enalapril 20 mg/day. Thus, we achieved normalization of the blood pressure (BP) and potassium levels. Taking into account the long intake of glucocorticosteroids, we performed dual-energy X-ray absorptiometry and revealed bone mineral density below the expected range for age (Z-score: femoral neck -2.7 SD, L1-L4 -2.5 SD). In addition, secondary hyperparathyroidism due to vitamin D deficiency and high bone turnover markers (osteocalcin - 175.5 ng/ml, C-terminal Type I Collagen Telopeptide 4.1 - ng/ml) were detected. We recommended cholecalciferol and antiosteoporotic therapy (alendronic acid 70 mg/week, calcium carbonate 500 mg/day).
Conclusion
The goal of treatment is to control BP and correct electrolyte disturbance. We consider MR antagonists (high doses might be used) or amiloride/triamterene to be the first line treatment. Dexamethasone suppress endogenous cortisol secretion, but also reduces potassium level and has major adverse effects with long-term therapy. Thus, low-dose dexamethasone therapy should be initiated only when MR antagonists and other antihypertensive agents are low effective.

DOI: 10.1530/endoabs.90.EP32A

EP33

A case of Merkel cell carcinoma in the CNC 1 (Carney complex 1) gene positive family with a rare component of the Carney complex

Fidan Nasrullayeva, Fırat Bayraktar, Mehmet Çağrı Ünal & Gökçen Güngör Semiz
Dokuz Eylul University Faculty of Medicine, Department of Internal Medicine Division of Endocrinonology and Metabolism, Turkey

Introduction
CNC (Carney complex) is a rare inherited autosomal dominant syndrome characterized by prominent pigmented lesions on the skin and mucosal surfaces, cardiac and noncardiac myxomatous tumors, and multiple endocrine neoplasms. About 70% of cases have a family history, while the remaining 30% occur sporadically as a result of de novo mutation. Two genetic loci linked to CNC have been found: the CNC1 gene on chromosome 17q22-24, which encodes the regulatory subunit (R1a) of protein kinase A (PRKAR1A) and is responsible for 2/3 of cases, and the CNC 2 gene is responsible for 1/3 of cases. The "CNC2" gene encoding the PKA (protein kinase A) catalytic subunit located at 2p16. Because clinical manifestations vary even within families, so-called "sporadic" cases require careful clinical evaluation by first-degree family members. Major, complementary and suggestive or possibly associated with CNC, but not diagnostic criteria for the disease are used for diagnosis. Endocrine neoplasms due to adrenal, pituitary gland tumors, or testicular tumors are the most common systemic manifestations of CNC.
Case
A 63-year-old female patient diagnosed with operated Merkel cell carcinoma was examined for primary hyperparathyroidism.The patient had hypercalcemia, hypophosphatemia and elevated parathormone since 2018, and the last corrected Ca-11.5 (8.8-10.6 mg/dl), P -2.4 (2.8-4.1 mg), PTH -146 (14-72 pg/ml), vitamin D-10.2 (30-100 ng/ml), 24-hour urinary calcium was 167.75 (100-300 mg). The bone mineral density was reduced. Ultrasound revealed parathyroid adenoma and multinodular goiter (MNG). Parathyroid scintigraphy revealed increased activity uptake. PRKAR1A gene mutation was positive in 2 daughters and 1 granddaughter of the patient, and her granddaughter had been operated for bilateral adrenal cushing. The patient had a nonfunctional pituitary microadenoma and bilateral adrenal nodular hyperplasia. The patient was operated for parathyroid adenoma and the pathology was compatible with adenoma. In the pathology of the nevus removed from the patient's neck who had congenital nevi, was found melanocytic nevus. PRKAR1A gene mutation was negative. Other genetic analyzes associated with CNC could not be performed. Carney complex was considered in the patient because the patient had 1 major (bilateral adrenal nodular hyperplasia), 1 complementary (positive PRKAR1A gene mutation in first-degree relatives) and criteria suggestive of CNC (congenital nevi, MNG, family history of Cushing's syndrome).
Conclusion
The highest risk of death in CNC is associated with heart disease, particularly cardiac myxomas and complications of cardiac surgery. Other causes of death include metastatic or intracranial psammomatous melanotic schwannoma, carcinoma, or metastatic tumors.

Incidental diagnosis of bladder paraganglioma: A case report

Kalboussi Chanez, Annam Benchhida, Bchir Najla, Zouaoui Chadia & Haroun Ouertani
Military Hospital of Tunis, Endocrinology, Tunis, Tunisia

Introduction
Paraganglioma is a rare neuroendocrine neoplasm which tends to develop in the extra-adrenal glands. Paraganglioma in the bladder is extremely rare and accounts for 0.06% of all bladder tumors Herein we report a case of paraganglioma that was mistaken for urothelial carcinoma and revealed by an intra-operative hypertensive crisis with bradycardia.
Case presentation
A 48-year-old woman was referred to the urology department for intermittent terminal hematuria. The medical history included primary hypothyroidism and uterine Fibroids. On examination the patient appeared well built, normotensive with a heart rate of 78 bpm. Orthostatic change in blood pressure was not documented. Urinalysis revealed full field RBC and urine culture was negative. Ultrasound and Computerized tomography urogram revealed a 2.5-cm solid mass confined to the posterior wall of the bladder and an additional focal liver lesion that the dynamic enhancement pattern recall a hemangioma Decision was made to go for transurethral resection of tumor. Early during the resection, her blood pressure started to raise up to 220/110 mmhg and her heart rate decreased to 35 bpm So the procedure was held. Post operatively, her blood pressure was observed for 24 hours and showed tendency toward hypotension. Her heart rythm was monitored for 24 hours and it was normal. The pathological picture of the resected biopsy confirmed the diagnosis of Paraganglioma of urinary bladder. The 24-hour urine study revealed elevated levels of norepinephrine (0.5 nmol/l), epinephrine (0.16 nmol/l). MIBG scintigraphy detected a mass confined to the bladder without any obvious multicentricity. Six months later, the patient underwent radical removal of the tumor after being treated with a 10 day course of α and B blockade and adequate hydration. Post surgical MIBG scan didn't detect any functional lesion. In twenty-five months follow-up, patient's blood pressure, urinary VMA and epinephrine remained normal.
Conclusion
Urinary bladder paraganglioma is an extremely rare entity. The classical triad of episodic hypertension, hematuria and post-micturition syncope is virtually diagnostic, but is very rare. Our patient presented with hematuria but no hypertension. The correct preoperative identification of paraganglioma is important. However, it is often overlooked because of its rareness. Unsuspected ones may result in intraoperative hypertensive crises, as in our case, and greatly increase the perioperative mortality forcing the surgeon to terminate cystoscopic tumor resection. This case highlights variable presentation of paraganglioma, importance of having a high index of clinical suspicion for early recognition and prompt management.

A patient guide for pregnancy in 21-hydroxylase deficiency

Ann-Christin Welp, Hanna F. Nowotny & Nicole Reisch
LMU Klinikum München, Medizinische Klinik and Poliklinik IV, Munich, Germany

Background
Affected patients with classic congenital adrenal hyperplasia due to 21-hydroxylase deficiency (CAH) are often insufficiently informed about disease-specific aspects of reproduction. Reasons for lower fertility rates in female patients with CAH are hormonal dysregulations, anatomical changes resulting from virilized genital surgeries and psychosocial and psychosexual factors. Fecundity, however, is comparable to the normal population. Male patients with CAH also have comparable fecundity under optimal therapy, but testicular adrenal rest tumors (TART) and adrenal androgen excess can negatively affect spermatogenesis. As long as optimal therapeutic control is achieved, course and outcome of pregnancies is not affected.
Objective
Due to the discrepancy between fertility and fecundity in patients with classic CAH, our aim was to develop a patient guide that informs female and male patients with CAH about disease-specific aspects of fertility and pregnancy. It can also be used for patient education by nurses and physicians.
Design and Methods
In order to develop the most detailed and helpful patient guide for CAH patients of childbearing potential, a literature research was conducted. The research included the basics of CAH, fertility and fecundity in male and female CAH patients, prenatal dexamethasone therapy and important factors to consider before and during pregnancy. The information was summarized and used to develop expert-based patient guidelines.
Results
Two separate leaflets were developed addressing sex-specific aspects of reproduction for both male and female patients with classic CAH. Based on the DSD-Life study, which demonstrated lower birth rates in patients with CAH and an impairment in psychosocial and psychosexual functioning, patients are now educated about factors that may affect fertility and fecundity. Further considerations during pregnancy planning are also addressed. The brochure also contains information on clinical check-ups during pregnancy.
Conclusions
A leaflet containing information on disease-specific aspects of reproduction was developed for CAH patients. It aims to convey information on optimal treatment, genetic counselling and prenatal dexamethasone therapy in order to prevent unjustified worries, uninformed decision-making and suboptimal treatment. The extent to which the developed brochures are helpful for patients with classic CAH needs to be evaluated and assessed in future studies.

Adrenal incidentaloma revealing a cystic pheochromocytoma

Talbi Dounia, Cheibete Zakaria, Kaoutar Elmoatamid, Kaoutar Rifai, Iraqi Hinde & Mohamedelhassan Gharbi
Hospital Ibn Sina, Endocrinology, Rabat, Morocco

Introduction
Pheochromocytomas are rare neuroendocrine tumors producing catecholamines, they are usually unilateral. However, they can be located bilaterally. They still pose several problems in their diagnosis if they are associated with an adrenal cyst, which is the case in our patient.
Case Report
A 34-years-old male patient, his medical and family histories were non specific, admitted to the emergency room for lumbar pain, with no other associated signs, Abdominal computed tomography showed a well-demarcated cystic mass 86*76 mm with a thick wall in the region of the right adrenal gland and a left adrenal nodule of 15*18 mm, 24 hrs urine metanephrine and normetanephrine were significantly elevated metanephrine: 4.81 mg/24 h (0.04-0.30), normetanephrine : 8,73 mg/24 h (0.07-0.46). After adequate medical blockade and hydration, bilateral adrenalectomy has been performed endoscopically, The postoperative course was simple.Anatomopathological analysis showed a right cystic pheochromocytoma, and a left pheochromocytoma with no sign of malignancy.A genetic study was performed was without particularities. The evolution was favorable under replacement therapy with 30 mg/d of hydrocortisone.
Discussion
Pheochromocytoma is a tumor arising from adrenomedullary chromaffin cells that commonly produce one or more catecholamines: Epinephrine, Norepinephrine and Dopamine. Pheochromocytoma can present as cystic lesions, which may mislead the diagnosis. Pheochromocytoma should be considered in patients presenting with non specific symptoms and an incidental cystic adrenal mass, even in the absence of hypertension. A typical solid pheochromocytoma can be easily diagnosed with available diagnostic methods. However, it is difficult to diagnose cystic pheochromocytoma since it structurally resembles a benign adrenal cyst. Structural imaging may be inconclusive. Functional imaging like MIBG scan is essential to prove the presence of sympatho-adrenal tissue.
Conclusion
In any patient presenting with abdominal pain, and adrenal cystic lesion, pheochromocytoma should be suspected, because it is a rare entity and is mostly asymptomatic, and complete with a genetic study in case of bilateral involvement.

Giant Cystic Asymptomatic Pheochromocytoma

Ozlem Kanburoglu Meletli, Cigdem Birinci, M. Cuneyt Bilginer, Hulya Coskun, Irfan Nuhoglu, Ozge Ucuncu & Mustafa Kocak
Karadeniz Technical University Faculty of Medicine, Department of Endocrinology and Metabolism, Trabzon, Turkey

Introduction
Giant and cystic catecholamine-secreting tumors are usually asymptomatic and detected incidentally during imaging. A simple mobilization of the tumor can cause the release of catecholamines into the blood and is therefore associated with high morbidity and mortality. Here, we aimed to present a patient with a 13 cm mass in the left adrenal gland and diagnosed as giant cystic pheochromocytoma.
Case Report
A 62-year-old male patient presented with left flank pain and frequent urination for 6 months. Abdominal computerized tomography (CT) showed a 133*78 mm

non-adenoma mass with a density of 50 HU (Hansfield Unit) and containing cystic-solid areas in the left adrenal gland. There were no symptoms or signs suggestive of pheochromocytoma such as headache, palpitation, flushing, excessive sweating and chest pain. He had type 2 diabetes and coronary artery disease for 7 years, but he did not have hypertension. On examination, blood pressure and pulse measurements were normal. Ambulatory blood pressure measurements were also normal. In laboratory results, plasma metanephrine level was 975.66 pg/ml ($<$90) and normetanephrine was 1204.42 pg/ml ($<$180), urine metanephrine was 4162.77 µg/24 h(50-250) and normetanephrine was 6170.14 µg/24 h (100-500). Hyperaldosteronism and Cushing's screening tests were normal. F-18 FDG PET/CT was performed to rule out malignant pheochromocytoma, no metastasis was detected. Adequate alpha blockade was achieved with doxazosin and left adrenalectomy was performed by an experienced surgical team. No perioperative blood pressure fluctuation was observed. On pathological examination, tumor size was 13.5*8.9*8.7 cm and weight was 274 grams. Macroscopically, it was a well-circumscribed brown mass containing cystic areas with multiple septations. In microscopic examination, there was no atypical mitotic activity, no significant pleomorphism and no increase in cellularity. There was no extraadrenal and vascular invasion, but capsule invasion was present. In the immunohistochemical examination, there was staining with chromogranin A and synaptophysin, and the ki-67 index was $<$1%. The diagnosis of pheochromocytoma was confirmed, and he was followed closely due to the large size of the tumor and capsule invasion.

Conclusion

Giant cystic pheochromocytoma is a rare entity and is mostly asymptomatic. Pheochromocytoma should be considered in the differential diagnosis of retroperitoneal tumors in patients with nonspecific symptoms and adequate therapy should be given to increase perioperative safety. It should be noted that the only curative treatment of such tumors is surgical resection.

Bilateral pheochromocytomas-recurrence and adrenal insufficiency rate related to surgical technique and genetic status

Sofia-Maria Lider-Burciulescu[1,2], Monica Livia Gheorghiu[1,2], Tomulescu Victor[3] & Corin Badiu[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucureşti, Romania; [3]Ponderas Academic Hospital, Bucureşti, Romania

Introduction

Bilateral pheochromocytomas (PHEOs) most often occur as components of hereditary syndromes: MEN2A, VHL disease or neurofibromatosis. The best surgical technique in such cases is yet disputed between cortical sparing or total adrenalectomy. Two important complications are related to each surgical technique: adrenal insufficiency (AI) or recurrence-which one is more harmful for the patient?

Aim

To evaluate the complications (recurrence, AI) rate reported to surgical technique and to genetic status.

Material and Methods

We retrospectively retrieved data of 103 patients diagnosed with PHEOs in a tertiary centre from Romania and identified patients with bilateral disease.

Results

We identified 11 (10.6 %) patients with bilateral disease; 8 synchronous, 3 metachronous. Mean age at diagnosis was 32$\pm$24 y.o; 3 (27.3%) patients had pediatric age at diagnosis; 6 women, 5 men. Eight patients presented with benign PHEO, 3 with malignant disease at diagnosis. Two had adrenergic pattern, 7 noradrenergic, 2 no info. Mean tumor diameter was 47.8$\pm$3 mm. Seven patients had hereditary disease - MEN2A (5), VHL (2), 4 no info. Median follow-up duration was 9 (1-41) years. The patients' outcome reported to surgical technique: 5 had cortical sparing-(3 developed AI and 1 recurrence); 3 patients had total adrenalectomy-(both had AI, 1 recurrence); 1 patient had total unilateral adrenalectomy-contralateral tumor impossible to operate (1 recurrence); 2 no info (1 exitus, 1 lost to follow-up). The outcome reported to genetic status: from 5 patients with MEN2A, 1 had recurrence after total adrenalectomy. In patients with VHL we found 2 recurrences at 7 (bilateral) and 24 years (unilateral), at the same patient after subtotal adrenalectomy. The rest four patients without documented mutations had no recurrence. Overall, in our cohort we found a **27.2 % recurrence rate** (2 patients-3 recurrences, 1 MEN2A, 1 VHL) after 1 total adrenalectomy, 1 cortical sparing. **50 % of patients with cortical sparing had AI and 100% of patients with total adrenalectomy had AI**.

Conclusion

Cortical sparing does not always assure a normal cortical function. There are some factors that should be evaluated before choosing the proper surgery technique including tumor size, the ability to secure vascular supply to the remaining adrenal cortex and the likelihood of a predisposing mutation leading to high risk of recurrence/malignancy in the future. Patients with RET mutation have a higher risk of recurrence and multiple tumors in the same adrenal, therefore, total adrenalectomy is the best option for them.

"Adrenal Giants" Review of adrenal masses $\geq$ 10 cm detected and treated during a 10- year period at the University Hospital Southampton NHS Foundation Trust, United Kingdom

Chloe Galides, Matthew Hayes, James Douglas, C Richard W, Simon crabb, Thomas Chance, Alexander King, Ma'en Al-Mrayat & Jana Bujanova
University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom

Introduction

The aim of this project was to review all adrenal masses $\geq$ 10 cm managed in our organisation over a 10-year period (2012-2022).

Results

20 adrenal masses $\geq$ 10 cm in maximal diameter were identified (range 10-32 cm, average 16.6 cm, 6 above 20 cm and one above 30 cm). Age at presentation was 17-80 y (mean 56.3 y, 50% F). Duration of symptoms: 1 day-18 months, mean 7.5 months with 6 presenting acutely. Follow-up period: 1 month-122 months, mean 35 months. Aetiology: 11/20 Adrenocortical carcinoma (ACC), 2/20 presumed ACCs, 7/20 as follows: 15 cm malignant melanoma (MM) metastasis (met) presenting 6 years post pT1N0M0 skin MM excision; growing MM metastasis (12 cm) despite immunotherapy; renal cell carcinoma (RCC) met in metastatic RCC (4 cm ipsilateral and 13 cm contralateral adrenal met); 10 cm pheochromocytoma [PASS 12, pT2(R0)N0M0] presented with acute coronary syndrome; 18 cm myelolipoma presented with acute abdomen due to intralesional haemorrhage; 13 cm adrenal cyst and 29 cm well-differentiated retroperitoneal liposarcoma. 17/20 (85%) had malignant aetiology. 11/20 (55%) alive at time of abstract submission. ACC in 13/20: 7/13 found to have hormonal hypersecretion (4 cortisol, 1 oestradiol, 1 combined cortisol, aldosterone & androgens). 2/13 presented with symptoms of hormone excess (gynaecomastia, severe hypertension), 11/13 with abdominal pain. 9/13 had surgery [2/9 surgery + mitotane, 2/9 surgery + mitotane + locoregional metastases control (with met resection, ablation, radiotherapy)], 1/13 mitotane only, 2/13 symptom control only (analgesia, laxatives). ACC staging at diagnosis: Stage 2: 6 patients (with three progressing to stage 4 within 6 months-3 years; 3 remain alive); Stage 3: 4 patients (one died within a month post diagnosis, 3 progressed to stage 4; 2 remain alive); Stage 4: 3 patients (all died within 4 months). Median overall survival of ACC cohort 20.0 months (95% CI 5.6 to 34.4).

Discussion

Some adrenal masses can reach huge proportions before their presentation. ACC was detected in 65%. Even at stage 2 at diagnosis, mortality and risk of progression to metastatic disease was very high. Prognosis at stage 4 at diagnosis is extremely poor and all died within 4 months post presentation. Ipsilateral adrenal metastases in RCC can occur in 6-29% especially in pT3, but bilateral adrenal or contralateral metastases are rare. Large 13 cm contralateral RCC met in our patient was therefore unusual. Significant size of adrenal MM metastases at diagnosis and their resistance/escape from immunotherapy suggest that adrenal microenvironment might be a 'sanctuary site' as suggested in our two melanoma cases and literature.

Effects of high-dose atorvastatin treatment on adrenal steroidogenesis in type 2 diabetes patients

Ameni Terzi[1], Nadia Khessairi[1], Ibtissem Oueslati[1], Meriem Yazidi[1], Hammami Bassem[2], Fatma Chaker[1], Feki Moncef[2] & Melika Chihaoui[1]
[1]Rabta, Endocrinology, Tunisia; [2]Rabta, Biochemistry, Tunisia

Introduction

Statins are widely used to prevent cardiovascular diseases. Nonetheless, reducing cholesterol, the main substrate for steroidogenesis, may impair cortisol production. The aim of our study was to assess the effect of high dose statin therapy on cortisol and dehydroepiandrosterone-sulphate (DHEA-S) levels in type 2 diabetes male patients.

Methods

This was a single-center, prospective study, during the period march 2021 - July 2022, including 60 men with type 2 diabetes mellitus, aged between 40 and 65

years, statin-free, and in whom the indication of a treatment with high dose of statin was indicated. The patients had two visits, before and six months after the daily intake of 40mg of atorvastatin. During each visit, they underwent a clinical examination and a fasting blood sample was collected for biological and hormonal measurements including cortisol and DHEA-S.
Results
The median age was 58 years (IQR: 52-62). The median body mass index was 29.5 kg/m^2. The prevalence of asthenia, anorexia, and orthostatic hypotension increased significantly after statin intake from 35%, 12%, and 17% to 38%, 23%, and 18%, respectively. A decrease of 51.1% in median LDL-cholesterol was noted after statin administration. The median serum cortisol level was 289 nmol/l (IQR: 242-384) before and 301 nmol/l (IQR: 236-357) after atorvastatin intake ($P=0.371$). The median DHEA-S level decreased significantly from 4.5 µmol/l (IQR: 2.8-6.1) to 3.8 µmol/l (IQR: 2.6-5.6) after statin intake ($P=0.005$). The reduction of DHEA-S was significantly correlated with the reduction of LDL-cholesterol ($r=0.262$, $P=0.043$).
Conclusion
Long-term high-dose atorvastatin treatment in patients with type 2 diabetes did not impair serum cortisol levels but reduced DHEA-S levels.

The role of CRH test in predicting the efficacy of unilateral adrenalectomy in Bilateral Macronodular Adrenal Hyperplasia

Irene Tizianel[1], Mario Detomas[2], Timo Deutschbein[2,3], Scaroni Carla[1] & Filippo Ceccato[1]
[1]University-Hospital of Padova, Endocrine Unit-Department of Medicine DIMED, Padova, Italy; [2]University Hospital, University of Würzburg, Würzburg, Germany, Department of Internal Medicine I, Division of Endocrinology and Diabetes, Würzburg, Germany; [3]Medicover Oldenburg MVZ, Oldenbur, Germany

Background and Aim
Bilateral Macronodular Adrenal Hyperplasia (BMAH) is a rare form of adrenal Cushing's syndrome (CS). The treatment of choice in patients with BMAH and overt CS is bilateral adrenalectomy (B-Adx), which however implies lifelong glucocorticoid and mineralocorticoid replacement therapy. Unilateral adrenalectomy (U-Adx) has been proposed as an alternative to B-Adx, especially in case of clearly asymmetric adrenal size. Our aim was to determine predictive factors (e.g. gender, age, mutation status, response to dynamic tests) for remission after U-Adx in BMAH patients.
Patients and Methods
BMAH patients undergoing U-Adx for overt CS were considered eligible. Overt CS was defined as urinary free cortisol (UFC) $\geq$2 times the upper limit of normality (ULN) and unsuppressed serum cortisol after overnight 1-mg dexamethasone (DST). After U-Adx, BMAHremission was defined as UFC$<$ ULN without additional therapy. BMAHactive were patients with UFC$>$ULN who required medical therapy or additional surgery for B-Adx. 9 patients were mutated in ARMC5 gene,12 were wild-type, while 2 have not been studied. We compared patients considering therapeutic outcome (BMAHremission vs BMAHactive), gender, ARMC-5 mutational status, baseline UFC ($\geq$2 or $>$3 times the ULN), overnight 1-mg DST (50-138 or $>$138 nmol/l), and the delta ACTH increase to CRH (positive test response: $>$50%).
Results
Twenty-three patients with U-Adx for overt CS were enrolled (69% females, mean age 55 years). According to genetic workup, 9 patients were ARMC5 mutated (wild type, $n=12$; no genetic workup, $n=2$). After U-Adx, 17 patients (74%) had remission for at least 18 months. BMAHremission and BMAHactive groups were comparably distributed regarding gender ($P=0.621$), UFC ($P=1.000$), overnight 1-mg DST ($P=1.000$), and ARMC5 status ($P=0.611$). The CRH test was performed in 15 patients (65%). Absence in ACTH response to CRH was observed in 6 patients (BMAHactive after U-Adx, $n=3$; recurrence after initial remission, $n=2$; CS in remission, $n=1$. The other 9 patients showed a positive test response, (BMAHremission after U-Adx at last follow-up, $n=8$; recurrence after initial remission, $n=1$). A significant correlation between ACTH response to CRH and positive outcome after U-Adx was found ($P=0.011$).
Conclusions
Remission rate from overt CS after U-Adx was higher in patients with a positive ACTH response during the CRH test (8/9 (89%) vs 1/6 (17%) in non-responders). We therefore suggest to perform the CRH test during the preoperative diagnostic workup for estimating the therapeutic outcome of U-Adx

Circadian fluctuations of acylcarnitines and sphingomyelins when measured in serum and in dried blood spots

Valentina Bissi[1], Ilaria Improta[1,2], Greta Galante[1], Lorenzo Tucci[1,2], Valentina Vicennati[1,2], Uberto Pagotto[1,2], Guido Di Dalmazi[1,2] & Flaminia Fanelli[1]
[1]Center for Applied Biomedical Research, Department Of Medical and Surgical Sciences, Alma Mater Studiorum - Bologna University, Bologna, Italy; [2]S. Orsola-Malpighi Polyclinic, Bologna, Italy

Background
Acylcarnitines and sphingomyelins are key players of lipid metabolism at cytosolic, vesicular and cell membrane level. Their metabolism was found deranged in diseases of the hypothalamus-pituitary-adrenal axis. Little information is available about levels of these compounds in the bloodstream and their circadian fluctuations. Dried blood spots (DBS) allow multiple autonomous and painless collections per day. However, poor biological validation data are available about lipid measurement in DBS.
Aim
To evaluate acylcarnitine and sphingomyelin levels and daily variations in paired serum and DBS collections.
Methods
Three women and three men aged 26-50 y were enrolled. All were healthy, normal weight and followed a Mediterranean standardized diet for one week, ending with the collection day. Serum and DBS were obtained 30 min before and 2 h after breakfast (7.30), lunch (13.30) and dinner (19.30). Forty acylcarnitines and 15 sphingomyelins were quantified by flow injection - tandem mass spectrometry.
Results
Twenty-four acylcarnitines were undetectable, 6 were only detectable in serum, 2 only in DBS and 8 in both; mean levels ranging 0.104-40.5 µM in serum and 0.160-21.8 µM in DBS. Four acylcarnitines were higher ($P<0.001$), whereas carnitine was lower ($P=0.003$) in DBS vs serum. Direct correlations between DBS and serum levels were observed for 7 analytes (P: $<$0.0001-0.019), with strongest correlations displayed by carnitine ($R=0.797$), butyrylcarnitine ($R=0.714$) and propionylcarnitine ($R=0.686$). Serum propionylcarnitine, valerylcarnitine, octanoylcarnitine, dodecanoylcarnitine and tetradecenoylcarnitine showed significant daily variations (P: 0.002-0.038), with positive quadratic or negative linear trend. Butyrylcarnitine, acetylcarnitine and hexadecanoylcarnitine showed significant daily variations in DBS (P: 0.009-0.037), with negative linear trend. All sphingomyelins were detectable, ranging 0.197-119.9 µM in serum and 0.281-136.5 µM in DBS. Five and 6 molecules were higher and lower in DBS vs serum, respectively (P: $<$0.001-0.026). Nine sphingomyelins displayed direct correlations between DBS and serum levels (P: $<$0.0001-0.028), with strongest correlations displayed by sphingomyelins(SM)-OH-C22:2 ($R=0.790$), SM-C16:1 ($R=0.760$) and SM-C20:2 ($R=0.690$). No analyte fluctuations were found in serum, whereas significant daily changes were observed in DBS for 11 sphingomyelins (P: $<$0.001-0.036), mostly with negative linear trend. Strongest variations were observed for SM-OH-C16:1, SM-C20:2, SM-C24:0, SM-OH-C24:1, SM-C26:0 and SM-C26:1.
Conclusion
Despite significant correlations between serum and DBS levels, acylcarnitines and sphingomyelins showed different patterns of circadian fluctuations in the two matrices. This may depend on the different distribution of individual molecules in soluble and cellular bloodstream fractions. Further studies are necessary to establish the relevance of serum and DBS measurements for the characterization of circadian rhythm imbalances.

EP43

The effect of long-term treatment of glucocorticoid in adipogenesis/-turnover in epididymal cells

Rafael Salgueiro & Fabio Bessa Lima
University of Sao Paulo, Human Physiology, Sao Paulo, Brazil

Cushing syndrome is a comorbid condition resulting from long-term exposure to glucocorticoids (GC). It affects body fat composition in various parts of the body. Since each fat depot has a distinct response to glucocorticoid exposure, we wanted to understand adipose tissue turnover. In order to reproduce the disease state, we used a rodent model recapitulating Cushing syndrome. We inserted subcutaneous mini pumps in the dorsal area of rats to infuse Dexamethasone at a rate of 187.5 µg/day, for 4 months. Dexamethasone is a synthetic analog of human cortisol. We collected different fat depots. We observed that total epididymal (EP) fat weight was proportionately lower as the total body weight of the animal. Similarly, the

adipocyte size and volume were negatively redistributed. We also found that exposure to Dexa for 48 hrs, decreased incorporation of glycerol, fatty acids and lipids. There was an increase of glycerol release, from epididymal adipocytes, which likely resulted in decrease in lower EP mass. We then explored the mechanism of adipocytes turnover in Dexa treated animals. We found that adipogenesis and apoptosis pathways were altered resulting in the redistribution of the fat. We observed that EP tissue had lower phosphorylation of caspase 3, 8 and 9 in Dexa treated compared to untreated group, while adipocytes from Dexa-induced rats showed upregulation of adipogenic markers, as PPARγ, CEBPα, and SREBP1. However, pre-adipocytes derived from Dexa treated animals revealed lower lipogenesis. The resistance to incorporate lipids might be affecting the commitment of those cells to matured. In summary, the mature adipocytes from EP fat tissue have higher adipogenic markers and low activation of cell death pathways which could explain the phenotype of Cushing syndrome.

Implementation of a new adrenal venous sampling (AVS) protocol for primary aldosteronism: early data from a single tertiary centre

Deirdre Green[1], Vanessa Farnan[1], Tara McDonnell[1,2], Sabah Abdelfadil[3], Karen Heverin[3], Claire Carthy[1], Shari Srinivasan[3], Arnold Hill[4,5], Neal Dugal[4,5], Martina Morrin[6], Ruth Dunne[6], Douglas Mulholland[6], Amar Agha[1,2], Mark Sherlock[1,2] & Michael O'Reilly[1,2]
[1]Beaumont Hospital, Endocrinology, Dublin, Ireland; [2]Royal College of Surgeons in Ireland, Endocrinology, Dublin, Ireland; [3]Beaumont Hospital, Chemical Pathology, Dublin, Ireland; [4]Beaumont Hospital, Surgery, Dublin, Ireland; [5]Royal College of Surgeons in Ireland, Surgery, Dublin, Ireland; [6]Beaumont Hospital, Radiology, Dublin, Ireland

Primary aldosteronism (PA) is the most common cause of endocrine hypertension. Following biochemical confirmation of aldosterone excess, adrenal venous sampling (AVS) is the gold standard investigation to lateralise the source of aldosterone hypersecretion in patients deemed suitable for potential adrenalectomy. AVS has been performed for all suitable patients with a diagnosis of PA in Beaumont Hospital since implementation of a new protocol involving collaboration between Endocrinology, Chemical Pathology and Interventional Radiology in 2021. We aimed to review the outcome of all AVS procedures in Beaumont Hospital between November 2021 and December 2022, with a focus on rates of successful cannulation and the incidence of unilateral versus bilateral disease. We identified 13 patients with PA who were referred for AVS between November 2021 and December 2022. Median age was 46 [IQR 37–51 years] and 38.5% were female. Patients had hypertension for a median of 15 years [IQR 6–25 years]. 53.8% had a history of hypokalaemia. Confirmatory testing with saline suppression test was performed in 10 of 13 cases. The median post saline suppression aldosterone level was 498.5pmol/l [IQR 442 -732pmol/l]. Imaging reported a unilateral adenoma in 61.5% of cases, with a median adenoma diameter of 2 cm [IQR 1.05–3.05 cm]. Sixteen AVS procedures were performed, as 3 patients required a repeat procedure. Bilateral adrenal vein cannulation was successful in 10 of 16 cases [62.5%]. Results of one patient who was successfully cannulated were disregarded as she had taken oral Prednisolone the day prior to the procedure. All patients were discussed at a multidisciplinary team meeting. Unilateral hypersecretion was confirmed in 3 of 9 cases [33.3%]. Out of 5 patients with bilateral disease on AVS, 2 had a unilateral adenoma on imaging. One patient was referred for repeat procedure due to discordant results. AVS is the gold standard means of differentiating unilateral from bilateral forms of PA. Early success rates within the first 12 months in Beaumont Hospital are in line with accepted international standards and will continue to improve with accumulated experience and case throughput. AVS has helped to identify patients suitable for adrenalectomy in our centre, while inappropriate adrenalectomies have also been avoided in a subset of patients.

A rare case of a juxta-adrenal schwannoma presenting as an adrenal mass

Ariadna Prats Custal [1], Theodora Michalopoulou Alevras[1,2,3], Cristina Franco Borras[1], Carlos Jareño Martinez[1], Marc Vallve Bernal[3,4], Laura Nevot Muro[4], Anna Magarolas Aixalà[5], Laia Martinez Guasch[1,2,3], Silvia Näf Cortes[3,6] & Ana Megia[1,2,3]
[1]Hospital Universitari Joan XXIII, Endocrinology and Nutrition, Tarragona, Spain; [2]CIBER, CIBERDEM, Tarragona, Spain; [3]Universitat Rovira i Virgili, Tarragona, Spain; [4]Hospital Universitari Joan XXIII, Anatomical pathology, Tarragona, Spain; [5]Hospital Universitari Joan XXIII, Radiology, Tarragona, Spain; [6]Hospital Universitari Joan XXIII, General Surgery, Tarragona, Spain

Background
Retroperitoneal Schwannomas are rare and generally benign tumors originating from the neural sheath. In particular, juxta-adrenal schwannomas may be misdiagnosed as adrenal tumors due to their location and radiological characteristics.
Case Presentation
A 40-year-old female patient referred to our outpatient clinic owing to a left suprarenal mass of 35 mm incidentally discovered in an enhanced CT. She was asymptomatic and the clinical examination was unremarkable. The mass had an absolute wash-out of 80% in the enhanced CT and presented 36UH in the non-enhanced CT. In the MRI the lesion was hypointense on T1 sequences, with a slight loss of signal on out-of-phase sequences, with a heterogeneous signal on T2 sequences, diffusion restriction and progressive enhancement after intravenous contrast administration. Therefore, showing indeterminate characteristics. The FDG-PET-CT revealed a slightly hypermetabolic mass (SUVmax 5.14), without uptake in the MIGB-123I scintigraphy. The hormone evaluation ruled out a hypersecretory adrenal mass. The MRI performed after 8 months of follow-up showed a growth of 2 mm. She was diagnosed with an indeterminate adrenal mass and underwent laparoscopic adrenalectomy. After the surgery, she presented among the complications, a chylous fistula that resolved with drainage, parenteral nutrition, and a low-fat diet. The histopathological and immunohistochemistry findings reveal a juxta-adrenal cellular schwannoma. It was a rounded, well-defined, and non-encapsulated lesion of 3.5*2.7*2 cm diameter, located in the surrounding adipose tissue of the adrenal gland without contacting it. It had a cellular "Antoni A" pattern, no necrosis, occasional mitosis figures, and lymphoid aggregates at the periphery of the lesion. The cells were positive for Vimentin, S 100 and SOX10, and the Ki-67 index was 5%. In the follow-up CT at 6 months, there were no signs of recurrence.
Conclusion
Juxt-adrenal Schwannomas should be included in the differential diagnosis of adrenal incidentalomas. Being a mass next to the adrenal gland with indeterminate radiological features, often it is misdiagnosed as adrenal carcinoma or atypical adenoma. Complete surgical resection is the treatment of choice and histology and immunohistochemistry confirm the diagnosis.

Acute Bilateral Non-Traumatic Adrenal Haemorrhage; a case series

Muhammad Saqlain, Fayad Ali, Singhan Krishnan & Sidrah Khan
Hinchingbrooke Hospital, North West Anglia NHS Foundation Trust, Endocrinology and Diabetes, Huntington, United Kingdom

Adrenal haemorrhage is a serious condition that can result in adrenal insufficiency, shock, acute adrenal crisis, and mortality if not managed with adequate treatment. Hereby we present two cases of non-traumatic bilateral adrenal haemorrhage highlighting their management during the acute phase.Case 1: 57 year old female presented due to chest pain, palpitations and troponin rise with a background history of antiphospholipid syndrome on anticoagulation. She was treated as acute myocarditis. A CT abdomen was done after an episode of abdominal pain which showed bilateral adrenal haemorrhage. She remained haemodynamically stable with no drop in haemoglobin levels. Anticoagulant effect of warfarin was reversed with intravenous phytomenadione and dried prothrombin complex. She developed an acute left leg DVT after a couple of days and was managed on the lines of catastrophic antiphospholipid syndrome treated high dose of prednisolone and mycophenolate mofetil. Subsequent short synacthen test done after weaning of prednisolone confirmed adrenal insufficiency and she has maintained on replacement hydrocortisone. Repeat cross-sectional imaging was planned in three months to confirm resolution and exclude underlying adrenal pathologyCase 2: 55 year old male presented with right sided flank pain for one week. There was no history of trauma, weight loss, anticoagulation use and clinically no evidence of infection or sepsis. A CT abdomen showed bilateral adrenal enlargement with features in keeping with haemorrhage and small retroperitoneal rupture on the right. Given the haemodynamic stability along with stable serial haemoglobin levels, it was adjudged that non-surgical conservative management is appropriate in this case. Due to the bilateral nature of the disease he was started on replacement hydrocortisone which was subsequently stopped post a normal short synacthen test. Due to extensive past history of smoking a CT chest was conducted that showed 2 right lung lesions. His imaging was discussed in the local Lung and Adrenal MDT with a plan for short interval CT for the lung lesions followed by diagnostic investigation if required.

Biochemical test for hyperfunction and repeat cross sectional adrenal imaging was planned after 3 months of the acute phase.In conclusion, bilateral adrenal haemorrhage can be secondary to various aetiologies. These cases can be managed conservatively if there is no evidence of persistent bleeding and haemodynamic instability. Further investigations after resolution of bleeding is required to determine the functional status and reassess the lesion on imaging.

Primary hypoadrenalism and thyroiditis in metastatic renal carcinoma in Pembrolizumab (PD-1inhibitor) and Axitinib (VEGFR inhibitor) therapy

Serafino Lio[1], Concetta Paolello[2] & Stefano Lamon[2]
[1]Endocrine Section, Dpt Internal Medicine, Oderzo Hospital, AULSS 2.Marca Trevigiana, Oderzo-TV, Italy; [2]Oncology Section, Dpt Internal Medicine, Oderzo Hospital, AULSS 2.Marca Trevigiana, Oderzo-TV, Italy

The association of immune checkpoint inhibitors (ICIs) and tyrosine kinase inhibitors (TKIs) are widely and to with good effect used in the treatment of many neoplasms. Much evidence of endocrine side effects has been reported for both ICIs and TKIs especially to the pituitary and thyroid functions; however, there are few records of primary adrenal insufficiency. We report the case of a 44-year-old soldier, examined for elevated hematocrit findings. Abdominal ultrasound and thoracoabdominal CT scan revealed a left renal tumor with bilateral pulmonary nodules and right iliac lytic lesion. Underwent left nephrectomy, histology revealed a renal clear-cell renal Ca with variant renal vein invasion by sarcomatoid cells (grade 4). pT3a. Adjuvant therapy with pembrolizumab and axitinib was started. Eight weeks later fT4 serum levels were elevated (2.15 ng/dl) with suppressed TSH (0.07 mUI/l) (normal range: 0.8-1.8 and 0.35-4.6, respectively). The endocrinologist advised TPOAb and TRAb resulted present and absent, respectively; a pseudonodular picture is was detected on ultrasound and a diffuse hypocaptation is was found on thyroid scintigraphy, suggestive of thyrotoxic-onset thyroiditis. Therapy with bisoprolol alone was started; after 4 months the hyperthyroidism evolved into hypothyroidism and therapy with L-thyroxine was started. At the same time, the pituitary-adrenal axis was also studied with evidence of normal cortisol (13.5 mg/dl) and elevated ACTH serum levels (128 pg/ml) (normal range 6-28 and 0.0-46.0, respectively) suggestive of primary hypoadrenalism and cortisone acetate was started; the anti21OH Abs were negative. The patient maintained a good quality of life and given the good response of the tumor, documented by a CT scan, the oncological therapy was continued. To the restaging CT scan after 10 months of therapy, despite the excellent clinical conditions of the patient and good hormonal compensation, the presence of a right adrenal lesion of 1.6 cm was instead detected, with increased glucose metabolism on PET/CT scan 18F-FDG with clearly reduced subcentimeter lung lesions on CT scan, and nonhypermetabolic on PET/CT scan, and disappearance of the right iliac lytic lesion. Right adrenalectomy was performed. Histology revealed a clear cell renal Ca metastasis. In conclusion : 1. Immune-mediated thyroiditis with transient hyperthyroidism appeared after 8 weeks of therapy followed by hypothyroidism; 2. primary hypoadrenalism, negative for Ab21OH, appeared after 4 months of therapy; 3. good clinical, pulmonary and bone response to therapy with pembrolizumab and axitinib was obtained, but appearance at 10 months of right adrenal lesion as a heterogeneous response to therapy.

Chronic hypopituitarism as a rare first presentation of euvolaemic hyponatraemia

Calvin Coe, Edward Jude & Susan Mathew
Tameside and Glossop Integrated Care NHS Foundation Trust, Endocrinology and Diabetes, United Kingdom

Background
Hyponatraemia is the most common electrolyte abnormality encountered in hospitals and has been independently associated with increased morbidity and mortality[1]. An appropriate work-up with guideline-based investigations and management is, therefore, crucial to allow accurate diagnosis and optimisation of patient care.
Case Presentation
A 49-year-old with no significant past medical history presented with 2 weeks of persistent nausea and lethargy, alongside worsening headaches. Sodium levels were 116 mmol/l on admission, without an apparent acute cause. Further assessment revealed secondary hypothyroidism and unrecordable cortisol levels, in keeping with hypopituitarism. Urgent MRI scanning was performed to exclude pituitary apoplexy; this ruled out haemorrhage but demonstrated a solitary pituitary lesion, likely having caused chronic pituitary failure and insidious development of hyponatraemia.
Outcome
Commencing glucocorticoid replacement therapy caused a rapid correction of sodium levels and the resolution of the patient's symptoms. Growth hormone, thyroxine and testosterone replacement were initiated, and the patient reported substantially improved quality of life, feeling 'like a new person'. Follow-up scans revealed shrinkage of the lesion, with no operative intervention necessitated.
Discussion
This case describes a rare cause of hyponatraemia and highlights the importance of maintaining open differential diagnosis for patients, given the variety of potential aetiologies. Studies have shown that misdiagnosis of chronic hypopituitarism occurs frequently; often due to poor compliance to diagnostic criteria such as those for the syndrome of inappropriate ADH hormone secretion (SIADH)[2]. Local audit of hyponatraemia work-up revealed deficiencies in comparison to the latest ESE guidelines. A subsequent literature review of published UK audits on hyponatraemia demonstrated country-wide issues with guideline adherence. When combined with the significant benefits an accurate diagnosis provided this patient, our research gives evidence to highlight a need for further work to raise awareness of hyponatraemia investigation and management amongst clinicians, in order to ensure optimal patient outcomes.

Rare case of Munchausen Syndrome in endocrinology: artificial hypokalemia

Lizaveta Aboishava[1], Anna Eremkina[1], Vitaly Ioutsi[1], Ekaterina Bibik[1], Svetlana Mirnaya[2] & Natalia Mokrysheva[1]
[1]Endocrinology Research Center, Moskva, Russia; [2]LLC "SSMC No1", Moskva, Russia

Introduction
An atypical manifestation of disease combined with inconsistent results of examination, long history of multiple past health care services without effect requires to consider factitious disorders.
Case report
A 46 year-old woman was suffering from episodes of severe hypokalemia (K+ 1.9 - 3.4 mmol/l (ref. 3.5-5.1 mmol/l) and hypertensive crises up to 240/145 mm Hg for 4 years. She stated that there was no clear provoking factor for these episodes and the hypertension was resistant to multicomponent treatment. Previous exams showed normal levels of aldosterone and renin, but elevated normetanephrine in 24-hour urine (1548 mg/24 h (ref. 35-445 mg/24 h)) and normal metanephrine. During the last years, the patient underwent 11 different imaging studies, including MRI of the abdomen, scintigraphy with SPECT/CT with In-111 and with MIBG, PET/CT with 68Ga-DOTA-TATE that were negative and ultrasound endoscopy and CT of the abdomen, that showed conflicting results and suspicion for two 3 mm tumors in the descending part of the duodenum or adjacent head of the pancreas. At admission, there was also slightly increased level of normetanephrine (708 mg/24 h) and normal metanephrine. During the first days of hospitalization, the patient developed severe progressive hypokalemia despite IV potassium infusions and spironolactone treatment. Blood pressure monitoring showed hypotension and no episodes of hypertension, thus antihypertensive therapy was stopped. The 24-hour urine collection also demonstrated

(Abstract EP49)

	Days of hospitalization							
	1	2	3	4	5	6	7	8
Na+, mmol/l (136-145)	136.5	137.3			137.6	139	134.8<	137.1
Cl-, mmol/l (98-107)	87.5<	92.2<			106.4	99	101.5	99.7
K+, mmol/l (3.5-5.1)	2.23<	2.46<	<2	2.9–3.3	3.27<	3.56	3.97	4.01

a high potassium level (174 mmol/24 h (25-125)). The patient denied taking any additional drugs, but diuretic abuse was suspected. The high-performance liquid chromatography–high resolution tandem mass spectrometry of the patient's serum sample confirmed the presence of torasemide. The patient was advised to consult a psychiatrist which she refused.

Conclusion

Munchausen Syndrome can be difficult to diagnose and should be suspected in cases of atypical presentation. Diagnosis should be guided by clinical reasoning as multiple laboratory and imaging studies can lead to incidental findings. Liquid chromatography–mass spectrometry can be an invaluable tool to uncover artificial disorders.

Autonomic Cortisol-Secreting Adrenal Mass Containing Extramedullary Hematopoiesis Foci

Ozlem Kanburoglu Meletli, Cigdem Birinci, M. Cuneyt Bilginer, Hulya Coskun, Irfan Nuhoglu, Ozge Ucuncu & Mustafa Kocak
Karadeniz Technical University Faculty of Medicine, Department of Endocrinology and Metabolism, Trabzon, Turkey

Introduction

Extramedullary hematopoiesis (EMH) is most commonly seen in reticuloendothelial system tissues such as liver, spleen and lymph nodes. Rarely, it can be detected in non-hepatosplenic atypical localizations such as the adrenal glands. Although the underlying mechanism is not clearly elucidated, it is suggested that the adrenal glands have hematopoietic activity in the fetal period and EMH may develop from the remains here due to chronic anemia. We aimed to present a case of myelodysplastic syndrome (MDS) presenting with an adrenal mass that secretes autonomic cortisol and contains EMH foci.

Case Report

A 67-year-old female patient was diagnosed with MDS 5 years ago and erythropoietin treatment was started due to anemia. In the abdominal magnetic resonance imaging (MRI) performed 4 years ago, a 33*25 mm adenoma with signal loss in the external phase sequence was detected in the right adrenal gland. Cortisol level was not suppressed in the 1 mg dexamethasone suppression test (DST) performed for hypercortisolemia. As a result of further investigations (Table 1), autonomic cortisol hypersecretion originating from adrenal adenoma was considered. Pheochromocytoma and hyperaldosteronism tests were normal. It was decided to follow-up because there was no indication for treatment. No significant change was observed in adenoma size and clinic in 3-year follow-up. However, in the control abdominal MRI performed at the end of the 4th year, it was observed that there was a minimal increase in the size of the lesion and heterogeneous signal loss that was not present in the previous imaging. PET CT was performed to exclude malignancy since collision tumor was prediagnosed in MRI findings, no metastasis was detected, then laparoscopic right adrenalectomy was performed. Microscopic and immunohistochemical examination revealed an cortisol-secreting adrenocortical adenoma containing EMH foci. She was referred to the hematology department due to the development of adrenal EMH due to MDS and chronic anemia.

Conclusion

The development of EMH foci due to MDS in a stable autonomic cortisol-secreting adrenocortical adenoma is not a common condition, therefore our patient is a rare case in the literature. It should be kept in mind that EMH may develop in atypical localizations in hematological diseases.

Table 1 Laboratory findings

Parameter	Result	Reference Range
Cortisol	14.39 μg/dl	
ACTH*	9.6 ng/l	<46
Mid-night Salivary Cortisol	1.19 ng/ml	0.7-2.2
Urine Free Cortisol	19.22 μg/24 h	3.5-45
2 mg DST (Liddle test)	4.92 μg/dl

A primary adrenal lymphoma with a puzzling evolution: A case report

Abdel Mouhaymen Missaoui[1], Fatma Hamza[2], Siddiqa Soomauroo[1], Khawla Ben Ahmed[2], Wafa Belabed[1] & Mohamed Abid[1]
[1]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Habib Bourguiba University Hospital, Department of Nuclear Medicine, Sfax, Tunisia

Introduction

Primary adrenal lymphoma (PAL) is a very rare entity. Less than 200 cases have been reported. Its evolution is unfavourable even under treatment. We report a case of PAL with a falsely reassuring course unmasked by 18F-FDG PET-CT.

Observation

This is a 48-year-old female patient hospitalized with altered general condition, weight loss, fever and cytopenias. The initial thoraco-abdomino-pelvic CT scan revealed two large bilateral adrenal tumour masses (18×13.7×9.8 cm on the left, 10×9.7×5.5 cm on the right). An adrenal insufficiency was confirmed and treated. CT-guided adrenal biopsy concluded to be a diffuse large cell B lymphoma. The patient received 4 courses of chemotherapy (R-CHOP). Post-chemotherapy thoraco-abdomino-pelvic CT scan showed moderate regression of the adrenal masses (12.7×11×7 cm on the left, 9×8×6.2 cm on the right) with an estimated partial response of 62% (Cheson criteria). In view of the discrepancy between radiological improvement and persistence of clinical alteration, a complementary 18F-FDG PET-CT scan ruled in favour of a metabolic progression (Deauville score = 5): two intense hypermetabolic adrenal foci (SUVmax = 20. 68 on the left, 15.12 on the right) with locoregional invasion of the psoas (SUVmax = 12.64), external oblique (SUVmax = 17.45) and pectoralis major (SUVmax = 6.93) muscles. The patient died 6 months later.

Discussion

18F-FDG PET-CT has become the reference imaging technique for the evaluation of lymphoma extension and therapeutic response. Our case illustrates this superiority since the therapeutic response described on PET-CT was more compatible with the actual clinical evolution of the patient.

EP52

Hyperpigmentation leading to depression in Addison's disease: Case report

Faryal Masood
Dow University Ojha Campus, National Institute of Diabetes and Endocrinology, Karachi, Pakistan

Addison's disease (AD) occurs when 90% of the cortex of Adrenal Glands is affected. Most common causes of AD are autoimmune destruction, tuberculosis, hemorrhage due to meningococcal meningitis, metastatic cancers and adrenoleukodystrophy. AD is associated with other autoimmune disorders e.g., vitiligo, type-1 diabetes or hypothyroidism. Due to non-responsiveness of adrenals to Adrenocorticotrophic hormone (ACTH), α-melanocyte stimulating hormone levels increases and its pro-hormone peptide pro-opiomelanocortin production is strongly increased causing bronze pigmentation of exposed parts of the body. Other features include fatigue, lethargy unintentional weight loss, depression, irritability, vomiting, and loss of libido.

Case presentation

A 35 year old female house wife presented in the Endocrinology department with complaints of nausea, vertigo with tiredness, lethargy with mood swings from severe depression to irritability with yelling and beating her kids at times, hallucinations at night that she will die soon and whose going to take care of her children having unintentional weight loss and darkening of knuckles, palmar creases, lips and oral mucosa and tongue for the past 3 yrs. Treated with different antiemetics and antipsychotics. Different health care providers were unable to diagnose though features were suggestive of the disease and confirmed by labs.

ACTH > 1250 pg/ml (10-60).
Serum cortisol 8 am 4.2 (5-23).
Sodium 128 mEq/l (136-146).
TSH :7.5 ulU/ml (0.4-4.2).
FT4:0.4 ng/dl (0.8-2.37).
FBS :80 mg/dl (<100).
HB: 8.8 gm/dl (12-15).
TPO antibodies positive.

Hypothyroidism also cause depression. It co-presents with AD, a condition known as Schmidt syndrome (part of Autoimmune polyglandular syndrome). Depressive symptoms were the initial and devastating presentation of patient initially being misdiagnosed, as it did in this case. Neuropsychiatric symptoms were due to pigmentation of her face and hands and was desperate to remove them by creams or lotions because her brother was getting married, so was depressed and reluctant to face the guests with darkened patches. Neuropsychiatric symptoms that occur in AD were related to normal to mildly low glucose levels and hyponatremia which may cause brain damage. Decreased glucocorticoids also effect brain and cognitive function. Resulting in an increase in neural excitability, leading to an enhanced ability to detect sensory input, and precipitate hallucinations as well as lower the threshold for psychosis.

Conclusion

AD should always be kept in mind by physicians while treating a psychiatric patient (especially in cases of depression and psychosis) who have no past or family history of psychiatric illness or who fail medical therapy for depression.

Metabolic syndrome and primary bilateral macronodular adrenal hyperplasia

Alexandra Abegão Matias, Bruno Bouça, Olga Gutu, Joanna Prokop, Teresa Sabino & José Silva-Nunes
Hospital Curry Cabral, Endocrinology, Diabetes and Metabolism, Lisbon, Portugal

Introduction
Primary bilateral macronodular adrenal hyperplasia (PBMAH) is a rare entity. Up to 1/3 of patients with incidental bilateral adrenal nodules presents biochemical evidence of hypercortisolism responsible for obesity, diabetes mellitus (DM), arterial hypertension or dyslipidemia. Its insidious course and nonspecific signs explain the underdiagnosis of this entity.
Objective
To describe the case of a patient with metabolic syndrome (MS) with hypercortisolism and diagnosis of PBMAH and its evolution after unilateral adrenalectomy.
Clinical Case
A 73-year-old man was referred to an Endocrinology consultation in 2013 due to incidental bilateral adrenal nodules detected in a vascular study. It is a patient with DM diagnosed at 52 years old without insulin therapy and HbA1c of 6.4%, class II obesity (weight 103 kg, Body Mass Index 36.1 kg/m^2), high blood pressure under 4 classes of antihypertensive drugs and mixed dyslipidemia. He presented a serum cortisol level post-1 mg dexamethasone suppression test and post-low dose dexamethasone suppression test of 2.70 and 2.60 µg/dl, respectively, and an aldosterone at 4 h after saline suppression test of 7 ng/dl. The urinary free cortisol measurement was 27.0 and 40.3 µg/24 h (4.3-176.0), serum cortisol (8 h) 12.50 µg/dl (4.82-19.50), ACTH (8 h) 6.61 pg/ml (ND-46) and DHEA-SO4 97 µg/dl (104.9-256.1). He performed a non-radiocontrast-enhanced computed tomography that showed a nodular thickening of the right adrenal with 24 mm and of the left adrenal with 20 mm. He maintained medical treatment due to clinical stability. In 2016 due to worsening of glycemic control, he needed insulin therapy in increasing doses (maximum 96 U/day) with a maximum HbA1c of 9.8% in December 2020. He was proposed for surgery and performed a scintigraphy of the adrenal cortex with 131 I-norcholesterol, which showed bilateral adrenal cortex hyperfunction. In 2021, he underwent right adrenalectomy with histological examination compatible with PBMAH. Three months after surgery he improved his glycemic profile (HbA1c 6.4%) and he had a 16.7% reduction in total daily dose (TDD) of insulin (80 U/day), maintaining his weight (103 kg) and his antihypertensive therapy.
Conclusion
In this clinical report, PBMAH seems to have contributed to MS previously known and the worsening of DM which is reinforced by the reduction of TDD of insulin after unilateral adrenalectomy. Considering the potential for improvement of comorbidities after surgery, there should be a high index of suspicion in the presence of MS and bilateral adrenal nodules.

DOI: 10.1530/endoabs.90.EP53

The overproduction of interleukin-6 in pheochromocytoma and its impact on systemic inflammation compared to other types of adrenal tumors

Taweesak Wannachalee, Sirinart Sirinvaravong, Pornrumpa Pengkhum & Alisa Uasuwannakul
Mahidol University Siriraj Hospital, Medicine, Bangkok, Thailand

Background
The circulating inflammatory markers and cytokines are associated with unfavorable cardiovascular and metabolic outcomes in patients with primary hypertension. Few reports demonstrated that some adrenal tumors can produce various markers of inflammation, acute phase protein and cytokines, contributing to hemodynamic and metabolic disturbances.
Objective
We aimed to study the differences in the levels of inflammatory parameters and interleukin-6 (IL-6) in adrenal tumors, and their effects to clinical presentations and outcomes.
Methods
We prospectively collected the data of 20 patients with primary aldosteronism (PA), 20 patients with pheochromocytoma (PHEO), 8 patients with mild autonomous cortisol excess and 8 patients with non-functioning adrenal adenoma in Siriraj hospital. The demographic and clinical data, radiographic finding, hormonal status, intraoperative and postoperative outcomes, and follow-up data were evaluated in this study. Inflammatory markers (complete blood count, c-reactive protein (CRP), prealbumin) and IL-6 were measured in all patients, and compared between each group.
Results
Patients with PHEO had significantly higher IL-6 levels than those with other adrenal tumors (4.4 vs 2 pg/ml, $P=0.003$). 8/20 (40%) of patients with PHEO had elevated of IL-6 than normal reference range. Of these patients with IL-6 secreting PHEO, 50% had history of unexplained fever, 88% had weight loss, and all patients had anemia. Only two patients with PA had mild elevation of IL-6, and no systemic inflammatory manifestation was demonstrated in these patients. Median size of IL-6 secreting PHEOs were larger than non-IL-6 secreting PHEO (11 cm vs 5.4 cm, $P=0.1$). Patients with PHEO had lowest prealbumin levels ($P=0.004$). No significant difference in CRP levels and white blood count levels was found among adrenal tumors. Diabetes was seen in 13(65%) patients with PHEO and significantly higher than other groups ($P<0.001$). Hospital length of stay after surgical resection was significantly longer in patients with IL-6 secreting PHEO (20 days vs 8 days, $P=0.008$). Postoperatively, IL-6 levels gradually returned to normal.
Conclusions
Adrenal tumors, especially PHEO, had the elevation of inflammatory markers and IL-6, and subsequently produced systemic inflammatory response and increased postoperative complications.

Effect of long-term atorvastatin treatment on serum vitamin D levels in type 2 diabetes patients

Ameni Terzi[1], Elyes Kamoun[1], Meriem Yazidi[1], Hammami Bassem[2], Nadia Khessairi[1], Ibtissem Oueslati[1], Fatma Chaker[1], Feki Moncef[2] & Melika Chihaoui[1]
[1]Rabta, Endocrinology, Tunisia; [2]Rabta, Biochemistry, Tunisia

Introduction
Statins are widely used in primary and secondary prevention of atherosclerotic cardiovascular diseases. The effects of statins on vitamin D are unclear. The reduction of cholesterol synthesis, a substrate for vitamin D synthesis and the decrease of LDL, the major carrier of vitamin D in the blood, can affect vitamin D metabolism. We aimed to evaluate the effect of high dose statin therapy on serum vitamin D levels.
Methods
This was a single-center, prospective study, including 60 men with type 2 diabetes mellitus, aged between 40 and 65 years, statin-free, in whom the indication of a high dose statin treatment was indicated. The patients had two visits, before and six months after the daily intake of 40 mg of atorvastatin. During each visit, they underwent a clinical examination and a fasting blood sample was collected for biological and hormonal measurements including parathormone and vitamin D.
Results
The median age was 58 years (IQR: 52-62). Twenty-seven (45%) were obese. Thirty-one patients (52%) had hypertension. Twenty percent of participants were on metformin, 12% on insulin, and 3% on sulfonylureas. The median of LDL-cholesterol decreased significantly after statin intake from 1.1g/l (IQR: 0.9-1.4) to 0.6 g/l (IQR: 0.5-0.7), $P<10^{-3}$. Before statin administration, the median of corrected calcemia, phosphoremia and parathyroid hormone were respectively 2.3 mmol/l (IQR: 2.3-2.4), 1 mmol/l (IQR: 0.9-1), and 6.6 pmol/l (IQR: 4.9-10.2) and did not change significantly after statin intake. The median level of vitamin D was 37.4 nmol/l (IQR: 26.1–52.7) before atorvastatin therapy and 40.5 nmol/l (IQR: 26.3–56.1) after statin intake ($P=0.828$).
Conclusion
Long-term high dose atorvastatin treatment in patients with type 2 diabetes mellitus did not affect serum vitamin D levels and calcium homeostasis.

What is the diagnostic serum ACTH threshold in adrenal Cushing?

Aishwarya Naveen[1], Muna Guma[1], Yaasir Mamoojee[1], Richard Bliss[2], Jason Ramsingh[2] & Peter Truran[2]
[1]Royal Victoria Infirmary, Endocrinology and Diabates, Newcastle upon Tyne, United Kingdom; [2]Royal Victoria Infirmary, Endocrine Surgery, Newcastle upon Tyne, United Kingdom

Background
Diagnostic work-up for Cushing Syndrome (CS) can be challenging and is based on clinical and biochemical assessments. Once steroid excess is biochemically

confirmed, the diagnostic serum ACTH threshold for determining ACTH-independent Cushing is debatable. A threshold of less than 15 ng/l has been adopted in our regional guidelines.
Aims
To investigate serum ACTH levels in patients with proven adrenal Cushing and to assess the clinical utility of 24-hour UFC and urine steroid profiling (USP) in the work-up for CS.
Methods
All patients undergoing unilateral adrenalectomy from January 2019 to February 2022 at the RVI were included. Data extracted: demographics, preoperative biochemical assessment, radiological & histological findings, post-operative short Synacthen test (SST)
Results
27 patients had unilateral adrenalectomy for CS. F:M was 8:1 with a mean age of 59 years at diagnosis. 16 patients had a left-sided adrenal lesion, 10 had a right-sided one and 1 patient had bilateral lesions. Pre-operative random ACTH levels were <5, 5-9 and 10-12 in 56%, 37% and 7% of patients respectively. 22 patients had CS confirmed on either dynamic testing (20) or 24-hr UFC (1) or USP (1). The other 5 patients all failed their SST soon after surgery, thereby confirming previous adrenal Cushing. 24-hr UFC was elevated in only 36% of patients. USP was diagnostic in 25% of cases. Atrophy of the adrenal cortex was observed in 48% of resected adrenal glands. 3 patients passed their SST relatively soon post-surgery and histological examination in 2 out of these 3 cases demonstrated focally expanded or nodular adrenal cortex. 1 out of these 3 patients demonstrated ongoing steroid excess on biochemical retesting.
Conclusions
Majority of patients with adrenal Cushing have a random serum ACTH level of $<$ 10 ng/l. Pre-operative diagnostic yield from 24-hr UFC and USP is poor. Post-operative failed SST confirms prior ACTH-independent Cushing. For those patients who pass their SST soon after surgery, reassessment for steroid excess is warranted, especially if histology does not demonstrate atrophy of adrenal cortex.

Adrenal venous sampling in patients with hyperaldosteronism

Ana María Moyano-Sánchez , Angel Rebollo-Román, M[a] del Carmen Serrano Laguna, Paloma Moreno-Moreno & Maria Angeles Galvez Moreno
Hospital Universitario Reina Sofía, Ugc Endocrinología Y Nutrición, Cordoba, Spain

Objective
Adrenal venous sampling (AVS) is a reliable procedure to differentiate if in patients with primary aldosteronism (PA) aldosterone production is unilateral or bilateral and guide treatment of these patients. Our objective was to describe their characteristics and the outcomes of the AVS.
Methods and patients
Observational longitudinal clinical study between July 2020 and November 2022 in patients who underwent AVS in our Hospital.
Results
21 patients included. 24 AVPs performed. Mean age: 56.1 ± 12.66 years. 52.4% women. Reason of PA screening: 38.1% resistant high blood pressure (HBP), 23.8% HBP and adrenal adenoma and 38.1% HPA and hypokalemia. 90.5% patients with an adenoma in the CT: 28.6% in the right gland, 57.1% in the left and 4.8% in both. 9.5% of patients without adenoma in CT. 70.8% of catheterization of both adrenal glands was successful.35.3% with no lateralization. Among the 11 successful AVS with lateralization, in 9 of them AVS lateralization matched the image. In 1 patient AVS lateralized to the opposite side. In 1 patient AVS showed left lateralization although no adenoma was seen in CT. 29.2% unsuccessful AVS: Most of them (85.7%) because of inadequate right adrenal vein catheterization.
Conclusion
– In spite of the limited number of AVS performed in our center, AVS is successful in most of the patients in our series. As previously described, inadequate right adrenal vein catheterization is the main cause of unsuccessful AVS.– In most patients AVS lateralization results matched the side of the adenoma in the CT image if it was present.

Unusual "Square Wave" Presentation of Severe Prolonged Hypercortisolemic Followed by Eucortisolemic Phases in Patients with Cyclical Cushing Syndrome

Kevin Yuen[1], Elizabeth Smith[2], Frank Jesus Cossio[3] & Monica Rodriguez[4]
[1]Barrow Neurological Institute, Neuroendocrinology, Phoenix, United States; [2]Midwestern University, Arizona College of Osteopathic Medicine, Glendale, United States; [3]University of Arizona College of Medicine, Phoenix, United States; [4]Barrow Neurological Institute, Neuroendocrinology and Neurosurgery, Phoenix, United States

Background
Cyclical Cushing syndrome (CCS) is a rare variant of Cushing syndrome (CS) characterized by periodic cycles of cortisol excess. Diagnosis of CCS is difficult because cortisol excess occurs unpredictably and often limited to short periods. We present 2 unusual cases where the patients developed severe prolonged life-threatening "square wave" hypercortisolemic phase followed by eucortisolemia, both phases extending $>$ 3 months. Case 1: A 75 year old male presented with acute atrial fibrillation, 9 kg weight loss over 3 months, facial plethora, leg edema, muscle weakness, hypertension, hyperglycemia, hypokalemia of 2.6 mEq/l and had UFC 20 $\times$ ULN, ACTH 3 $\times$ ULN and 11 PM cortisol 66 μg/dl. High-dose dexamethasone did not suppress his cortisol, no gradient on IPSS, and CT chest/abdomen/pelvis and ^{68}Ga-DOTATATE PET/CT studies did not reveal an ACTH source. Due to his clinical deterioration, ketoconazole was started. After 3 weeks of treatment, cortisol deficiency developed and ketoconazole was stopped. For the following 3 months thereafter without ketoconazole, UFC, 8 AM cortisol and LNSCs remain normalized with resolution of majority of symptoms enabling the patient to gradually increase his physical activity. Case 2: A 61 year old female presented with 3 kg weight loss over 2 months, muscle weakness, edema, spinal compression fractures, uncontrolled hypertension and hyperglycemia, hypokalemia of 2.2 mEq/l, UFC 5 $\times$ ULN, 8 AM ACTH 2 $\times$ ULN and 11 PM cortisol 63.2 μg/dl. Due to her severe comorbidities, she was treated with IV etomidate followed by ketoconazole. No gradient was found on IPSS, and CT chest/abdomen/pelvis and ^{68}Ga-DOTATATE PET/CT studies failed to reveal an ACTH source. After 5 months, 8 AM ACTH, UFC, 8 AM cortisol and fasting glucose normalized. Because she had some side effects to ketoconazole, the drug was stopped after 2 months. After 4 months being off ketoconazole, UFC, cortisol, LNSCs and blood pressure remain normalized.
Discussion
These two cases highlight the importance of identifying and effectively treating severe prolonged "square wave" hypercortisolemic phase of CCS, and to closely monitor for eucortisolemia development. During the eucortisolemic phase, close monitoring is recommended for re-emergence of hypercortisolemia by self-checking glucose, blood pressure, weight and PM salivary cortisol assessments so that treatment can be promptly instituted if and when hypercortisolemia resurfaces. To our knowledge, severe prolonged "square wave" hypercortisolemia followed by eucortisolemia has not been reported in CCS. Herein, we describe a new variant of presentation of severe cortisol excess of this entity.

Adrenocortical Oncocytoma: A bout 7 cases

Mouna Mezoued[1,2], Bessaid Khadidja[3] & Malha Azzouz[3]
[1]Algiers Faculty of Medicine - Ziania, Endocrinology, El Biar, Algeria; [2]Bologhine Hospital, Endocrinology, Algeria; [3]Bologhine Hospital, Endocrinology, Alger, Algeria

Introduction
Adrenal oncocytomas are rare and usually present as incidentally detected masses. The aim of this study is to evaluate the clinical characteristics of a series of patients with adrenal oncocytoma.
Material and Methods
we retrospectively collated all patients admitted to Bologhine Hospital between 2010 and 2020 for adrenal masses and who underwent surgery and a diagnosis of adrenal oncocytoma at the anathomo-pathological study ($n=07$). Demographic, clinical, secretory, radiological and pathological characteristics were evaluated.
Results
Of these 07 patients, 71.4% ($n=5$) were women and 28.6% ($n=3$) were men. They were between 27 and 49 years old ($37.7 \pm$). Four (57.1,%) of the masses were secretory. The masses had a mean length of 91 mm (70-130 mm). Three (42.9%) oncocytomas were classified as benign and the others as having uncertain malignant potential according to Lin-Weiss-Bisceglia criteria. The patients were followed for 36-96 months, no local recurrence and no distant metastasis were detected.
Conclusions
Because there are no clinical and imaging features to differentiate adrenal oncocytomas from other types of adrenal masses, they should be kept in mind in the differential diagnosis of adrenal masses, especially those of large size and those suspected of being adrenal carcinoma.

A pheochromocytoma revealing a neurofibromatosis type 1: A case report

Karimi Meryem, Hajar Azagouagh, Ikrame Qasdi, Nawal Moussaid, Kaoutar Rifai, Iraqi Hinde & Mohamedelhassan Gharbi[1]
Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction
Neurofibromatosis type 1(NF1) is an autosomal dominant genodermatosis that affect multiple organs. It represents one of the most frequent genetic diseases. The diagnosis is primarily clinical and is based on the NIH criteria (National Institutes of Health) established in 1988,and revised in 2021. We report a case of male patient with NF1 revealed by a pheochromocytoma.
Case Report
A 26-years-old man patient with no previous medical history, who presented at the age of 6 the appearance of coffee-like spots, neurofibromas and diffuse lentigines. The evolution was marked by abdominal pain more accentuated in the right hypochondrium. Abdominal CT scan showed a well-limited adrenal tissue mass $50\times57\times40$ mm, with tissue density (49 units in C-). Plasmatic metanephrines were elevated. The eye fundus showed Lich nodules. Brain MRI showed an unidentified bright object related to his disease. Right Surrenalectomy was performed after medical preparation with doxasocin. Histopathological study reveled an agressive pheochromocytoma.
Discussion
NF1 is a disease with heterogeneous clinical expression. On the clinical level, it presents a polymorphic profil, with coffee-like spots, plexiform neurofibromas, axillary and/or inguinal lentigines, Lich nodules, subcutaneous and cutaneous neurofibromas. Pheochromocytoma is a rare disease in NF1, affecting 1 to 15% of NF1 patients, according to studies, This diagnosis must be suspected in a subject with NF1 subject in front of clinical signs of hypertensive flare-ups (sweat flare-ups, palpitations, headaches, anxiety, agitation); minor signs such as malaise, weight loss, abdominal or lumbar pain are also possible. The diagnosis of pheochromocytoma is based on plasma and/or urine metanephrines and on abdominal imaging as in the case of our patient. Screening is recommended every 5 years from the age of 35.
Conclusion
NF1 is a disease with heterogeneous clinical expression: some NF1 carriers present an uncomplicated profil; but others develop rare complications that can affect every system of the human body, such as pheochromocytoma which is one of these complications.

Pheochromocytomas, a series of 68 cases

Sidi Mohamed Aghrabatt, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Faculty Of Medicine And Pharmacy, Casablanca, Morocco

Introduction
Pheochromocytoma is a rare endocrinopathy, most often benign. Early and multidisciplinary management of this disease allows to avoid its dreadful complications.
Objective
To describe the epidemiological, clinical and biological characteristics of patients with pheochromocytoma.
Patients and Methods
Retro-prospective descriptive study, including patients hospitalized in the Endocrinology Department of CHU Ibn Rochd of Casablanca from 1996 to 2022. Data analysis was done by SPSS software.
Results
The mean age was 47.3 years, the sex ratio was 1.07. The main symptom was hypertension followed by Menard's triad. Cardiac and/or renal complications were found in 29% of patients. The location of the tumor was adrenal in the majority of cases (94%). The management was essentially surgical preceded by a medical preparation. A delay in diagnosis with an incidental finding was found in 28%. The anatomo-pathology was benign in the majority of cases with 7 cases of malignant pheochromocytoma. Death was recorded in 7 patients.
Conclusion
Pheochromocytoma is a rare and often benign endocrinopathy. Our work shows the delay of the diagnosis at the stage of complications of this pathology.

Consanguineous marriage and 5 triple a syndrome

Sadettin Öztürk[1], Eren Imre[2] & Tahsin Özenmis[3]
[1]Dr. Ersin Arslan Education Reserach Hospital, Gaziantep, Turkey; [2]Basaksehir Cam and Sakura City Hospital, Endocrinology and Metabolism, İstanbul, Turkey; [3]Dr. Ersin Arslan Education Reserach Hospital, Endocrinology and metabolism, Gaziantep, Turkey

Aim
Triple-A Syndrome (TAS) is a rare autosomal recessive disorder characterized by three cardinal symptoms: alacrimia, achalasia and adrenal insufficiency due to ACTH insensitivity. The disease is caused by mutation in the AAAS gene on chromosome 12q13. Mutations in AAAS were identified in more than 90% of individuals and families with TAS. The aim of this study is to discuss the clinical, laboratory and molecular genetic analysis results of 5 patients with TAS.
Materials and Methods
Five triple A syndrome patients from the same family who were genetically diagnosed were included in our study. Clinical, laboratory and genetic findings of the patients between 2018-2022 were obtained retrospectively.
Results
All of the patients were Syrians and relatives, 3 of them were siblings from the same family and 2 of them were cousins. The first admission of all patients was with achalasia findings. Esophagosgastromyotomy (dor funduplication) was performed in three patients and esophageal balloon dilatation was performed in 2 patients due to dysphagia. The first diagnosis of triple A syndrome(TAS) was made when she applied to the emergency room with dysphagia, nausea and vomiting and was examined in the intensive care unit, while achalasia was diagnosed and the diagnosis was made when she entered adrenal crisis in the follow-up. Then, people with similar symptoms in the family were examined and a total of 5 patients were diagnosed with TAS. All patients had alacrima, adrenal insufficiency and achalasia diagnoses. In addition, 2 had hyperreflexia, 4 had learning difficulties, 4 had hypernasal speech, 3 had muscle weakness, 3 had delayed speech, 2 had excessive sweating, 3 had thenar/hypothenar atrophy, and 3 had short stature. In all patients, AAAS gene was sequenced with sanger sequencing and c.1432C>T (p.Arg478*) mutation was detected in both alleles (homozygous).
Conclusion
Diagnosis of adrenal insufficiency is of vital importance in both the diagnostic and therapeutic stages of achalasia while examining and treating achalasia. Although these two diseases seem to be two different entities, the fact that they were detected in one patient at the same time is important in terms of recognizing and treating the neurological and other findings of triple A syndrome, especially alacrima. At the same time, it increases the incidence of genetic diseases in societies where consanguineous marriages are common. Therefore, the prevalence of consanguineous marriages in some regions of Syria and Turkey, diagnosis and treatment of genetic diseases are of particular importance.

Adrenocortical vascular network and hormonal output after daidzein application in a rat model of the mild andropause

Jovana Cukuranovic Kokoris[1], Miodrag Djordjevic[2], Marko Miler[3], Jasmina Živanović [3], Jelena Marković-Filipović [4], Dobrila Stanković Đorević[5], Rade Čukuranović[1], Verica Milošević[1], Branko Filipović[3] & Vladimir Ajdžanović [3]
[1]University of Niš, Faculty of Medicine, Department of Anatomy, Niš, Serbia; [2]University of Niš, Faculty of Medicine, Department of Surgery and Anesthesiology with Resuscitation, Niš, Serbia; [3]Institute for Biological Research "Siniša Stanković"– National Institute of the Republic of Serbia, Belgrade, Serbia; [4]University of Novi Sad, Faculty of Sciences, Novi Sad, Serbia; [5]University of Niš, Faculty of Medicine, Department of Microbiology with Immunology, Niš, Serbia

Soy isoflavone daidzein exerts some beneficial effects in different ageing-related, chronic diseases and may represent a promising alternative to classical estrogenization of the prostate cancer suffering subjects. The aim of this study was to examine the effects of daidzein on the adrenocortical vascular network and hormonal output in a rat model of the mild andropause. Adult (3 months old) Wistar rats were divided into sham-operated (**SO**; $n=7$), orchidectomized (**Orx**; $n=7$) and daidzein treated orchidectomized (**Orx+D**; $n=7$) groups. Daidzein (30 mg/kg b.m./day) was administered subcutaneously for three weeks, while the **SO** and **Orx** groups received the vehicle alone. Adrenocortical vascular network properties were identified using Novelli histochemical staining, vascular endothelial growth factor (VEGF) immunostaining and the newCast stereological

software. Blood concentrations of aldosterone, corticosterone and DHEAS were measured by immunoassays. Volume densities of blood vessels and VEGF depots within the adrenal cortex were not significantly changed after daidzein treatment, although there was a tendency of decrease of these parameters. On the other hand, daidzein application increased ($P<0.05$) blood concentration of aldosterone by more than 2.5 times and 41%, in comparison with the same parameter in sham-operated and orchidectomized group, respectively. Corticosterone concentration in daidzein-treated, orchidectomized rats showed a tendency of elevation ($P>0.05$) compared to the both **SO** animals and orchidectomy alone. DHEAS blood concentration after daidzein application remained at the level of the **Orx** group, which in both cases ment elevation ($P<0.05$) by around 80% in comparison with the same parameter in **SO** group. We conclude that daidzein significantly increases aldosterone and to some lower extent corticosterone output in a rat model of the mild andropause, without significant rearrangements of the entire adrenal cortex vascular network.

Cushing's Syndrome due Primary bilateral macronodular adrenal hyperplasia–a case series from a tertiary hospital

Juliana Gonçalves[1,2,3], Helena Urbano Ferreira[1,2,6], Jorge Pedro[1,2,3], Davide Carvalho[1,2,3] & Paula Freitas[1,2,3]
[1]Centro Hospitalar Universitário de São João, Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]Universidade do Porto, Faculty of Medicine, Porto, Portugal; [3]Universidade do Porto, Instituto de Investigação e Inovação em Saúde (i3S), Porto, Portugal

Primary bilateral macronodular adrenal hyperplasia (PBMAH) is a rare cause of Cushing's syndrome (CS). It is a highly heterogeneous disease with multiple adrenal macronodules and variable levels of cortisol excess. The pathogenesis is complex and different mechanisms such as aberrant hormone receptors, local production of ACTH in adrenal tissues and genetic mutations have been identified. The approach is not well established. Nine patients with PBMAH who are currently followed in our department were identified. Six of them were females and the median age at diagnosis was 49.0 (range 33-64) years. All patients were investigated as a result of adrenal incidentalomas, with the exception of one patient that was studied for overt CS. At the time of diagnosis, two patients did not have clinical manifestations of CS. The most frequent signs were abdominal obesity (4/7), ecchymosis (3/7) and moon face (3/7). Median BMI was 28.2 (range 24.3–32.3) kg/m^2. All patients had hypertension, eight had dyslipidemia and seven had abnormal glycaemic metabolism (diabetes (3/7) and prediabetes (4/7)). Two cases had hypokalaemia (3.10 mEq/l). Median morning plasma cortisol after 1 mg dexamethasone overnight suppression test was 22.2 (range 1.60–27.60) µg/dl and median cortisol after low-dose dexamethasone suppression test (2 mg/day for 48 hours) was 14.4 (range 1.10-24.4) µg/dl. Median 24-h urinary free cortisol was 200.7 (range 59.4–520.1) µg/24 h [1.48 (range 0.34–3.80)-fold ULN]. Median late-night salivary cortisol was 0.73 (range 0.64–2.70) µg/dl [2.20 (range 2.00–8.13)-fold ULN]. Mean matinal ACTH level was 1.83 ± 1.58 pg/ml and median DHEAS was 17.6 (range 3.8–90.0) µg/dl [ref. 35.4-256]. Primary aldosteronism had been diagnosed in one patient (aldosterone-to-renin ratio 7.26 ng/µg). Only one case had several nodules on one adrenal with an apparently normal contralateral gland. Median largest nodule size was 30.5 (range 20.0–39.0) mm. In two of four patients had found pathogenic mutations in the ARMC5 gene. Seven patients were screened for aberrant receptors: in three cases all tests were negative; in four patients had at least one test with a partial response (glucagon test was the most frequently positive). Seven patients underwent unilateral adrenalectomy. However, only two remain free of hypercortisolism (median follow-up 4.2 y). One patient underwent unilateral adrenalectomy recently. Two patients are under annual active surveillance and their comorbidities are controlled (median follow-up 7.5 y). PBMAH is a heterogeneous and challenging disease in terms of treatment. Unilateral adrenalectomy may be an option. However, patients are rarely free of hypercortisolism and require monitoring and management of comorbidities.

EP65

Bilateral primary aldosteronism prediction by Integer scoring system

Lana Sambula[1], Nino Matas[2], Anja Barac Nekic[3] & Karin Zibar Tomšić[3]
[1]General Hospital Koprivnica, Koprivnica, Croatia; [2]General Hospital Dubrovnik, Dubrovnik, Croatia; [3]University Hospital Centre Zagreb, Zagreb, Croatia

Background
Adrenal venous sampling (AVS) is the gold standard to differentiate patients with unilateral primary aldosteronism (UPA) from those with bilateral disease (BPA). As this is an invasive method, there are a lot of different scoring systems developed for primary aldosteronism (PA) subtyping. Integer scoring system is one of those established for BPA subtyping.
Objective
The aim of this study was to evaluate the efficiency of using the online Integer scoring system in predicting BPA, as a possible surrogate for AVS.
Methods
We performed a retrospective analysis of 105 patients (66 female, median age at diagnosis 53 years (20-75)) treated for PA in our center between 2015 and 2022. AVS was bilaterally successful in 86 (82%) patients. According to AVS, 52 (60%) patients were diagnosed as UPA and 34 (40%) as BPA. The Integer score was calculated based on serum potassium level (<3.9 mmol/l - four points, 3.5-3.9 mmol/l - three points), sex (female sex - one point), imaging finding on CT (absence of nodules during computed tomography - three points), baseline plasma aldosterone concentration (<210 pg/ml - two points) and baseline aldosterone to renin ratio (<620 - two points). The result above 8 was considered as predictive for BPA.
Results
Of 34 patients diagnosed with BPA using the AVS, the Integer score was diagnostic in 9 of them, giving a positive predictive value of 26%. The negative predictive value was 96%, sensitivity 82% and specificity 67%.The median score for BPA subtyping in our patients was 4 with a range from 3.5 to 6.
Conclusion
Our results suggest that Integer scoring system is not applicable for PA subtype prediction in our center and that each center should determine their own score. To the extent that each center does not have a scoring system, AVS remains the only diagnostic method for subtyping PA.

DOI: 10.1530/endoabs.90.EP65

Overview and factors that impact quality of life in patients with Cushing's syndrome

Miruna-Viorela Nacu[1], Carmen Sorina Martin[1,2], Anca Sirbu[1,2], Carmen Barbu[1,2] & Simona Fica[1,2]
[1]Elias Hospital, Department of Endocrinology, Diabetes Mellitus, Nutrition and Metabolic Disorders, Bucharest, Romania; [2]"Carol Davila" University of Medicine and Pharmacy, Department of Endocrinology, Diabetes, Nutrition and Metabolic Disorders, Bucharest, Romania

Background
Quality of life (QoL) has become a useful outcome in recent studies among different specialties. In Cushing's syndrome, elevated cortisol levels result in a decreased QoL, the cause for this impairment being multifactorial. More studies are necessary to find modifiable factors where doctors could intervene and thus improve QoL.
Objective
To evaluate QoL in a group of Romanian patients with Cushing's syndrome. Design: We performed a cross-sectional study, administering three standardized questionnaires (EuroQol-5D, CushingQol and a recently developed one, specific for Cushing's disease, QoL-CD) to 24 patients (mean age 52.46 ± 11.39 years) with both Cushing's disease ($n=16$) and syndrome ($n=8$). The questionnaires were administered by telephone in march 2022.
Results
There was no difference between the two aetiologies when evaluating gender, age, body mass index, serum cortisol at diagnosis and remission status. The most affected domain was the one referring to pain/discomfort, where 66.7% patients reported problems. Mobility was the second most affected dimension (41.7%), followed by anxiety/depression and usual activities (each 37.5%). The least impaired domain was self-care. Patients with Cushing's syndrome reported a significantly higher degree of impairment in almost all of the investigated domains compared to the healthy Romanian population: mobility (41.7 vs 17.22, $P=0.0047$), pain/discomfort (66.7 vs 26.99, $P=0.0001$), usual activities (37.5 vs 15.81, $P=0.009$) and anxiety/depression (37.5 vs 17.22, $P=0.0249$). Patients with obesity reported lower QoL in the psychosocial subscale (51.16 vs 69.72, $P=0.048$) of the CushingQol questionnaire, but not in the physical one, compared with those without obesity. The presence of depression (31.25 vs 65.75, $P<0.001$) and anxiety disorder (27.78 vs 62.50, $P=0.012$) was associated with lower scores. Other conditions, such as cardiac ischemic disease and dyslipidaemia, were also associated with poor QoL. Remission status did not influence any of these scores. In the QoL-CD questionnaire, patients with diabetes reported impairment in domains concerning mental status ($P=0.020$) and general health ($P=0.043$). Depressive disorder was linked with problems in general health and emotional health domains. The overall scores from this questionnaire were

negatively correlated with those of the CushingQol questionnaire (rho = -0.874, $P < 0.001$). The same correlation was found when analysing related domains such as emotional health and the psychosocial subscale from the CushingQol (rho = -0.710, $P = 0.002$).

Conclusions

Improving the control of conditions such as obesity, diabetes and psychiatric disorders could result in better QoL for these patients. The use of QoL-CD is feasible and helpful in real clinical setting.

Effect of glucocorticoid replacement dose on bone mineral density in patients with Addison disease: A cross-sectional Tunisian-based study

Khouloud Boujelben, Dhoha Ben Salah, Hamdi Frikha, Mouna Elleuch, Mouna Mnif, Fatma Mnif, Nadia Charfi, Nabila Rekik Majdoub, Faten Haj Kacem Akid & Mohamed Abid

Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction

Addison disease (AD) is associated with high risk of decreased bone mineral density (BMD) and osteoporosis. Causes are complex, including lifelong glucocorticoid replacement therapy. Several studies have pointed a significant relationship between glucocorticoid dose and low BMD in patients with AD. The aim of our study is to assess the impact of glucocorticoid replacement dose on BMD among Tunisian patients with AD.

Patients and Methods

We conducted a descriptive and analytical cross- sectional study that included 50 patients with AD taking glucocorticoid replacement therapy for at least 5 years and followed at the Endocrinology department of Hedi Chaker University hospital, Sfax,Tunisia, from March 2020 to July 2021. BMD was evaluated using dual-energy X-ray absorptiometry (DEXA), at the lumbar spine (L1-L4) and femoral neck sites. The relationship between glucocorticoid dose and BMD was assessed.

Results

Patients had a mean age of 49.5 ± 13.9 years (18-78 years) and a disease duration with a mean of 13.9 ± 8.7 years (5-35 years) and 80% were women. None of the participants reported having spontaneous or traumatic fracture. All patients were treated from diagnosis with hydrocortisone (HC), distributed in two daily doses in 67% of patients. Twelve percent of patients received fludrocortisone as mineralocorticoid replacement. Average daily HC dose at the time of AD diagnosis was 25.7 ± 9.1 mg (15-50 mg) corresponding to 0.47 ± 0.21 mg/kg (0.18-1.08 mg/kg) and an average daily dose adjusted for body surface area of 16.29 ± 7.54 mg/m^2 (15.6-37.94 mg/m^2). During follow-up, the average daily HC dose was 27.4 ± 6.7 mg (15-42.1 mg) corresponding to 0.388 ± 0.128 mg/kg (range, 0.175-0.711 mg/kg) and a mean dose per body surface area of 14.836 ± 4.658 mg/m^2 (7.486-31.460 mg/m^2). Mean cumulative hydrocortisone dose was 374.636 ± 283.821 mg (60–1184, 94 mg). Low BMD (less than 2 standard deviations [SD] of the mean value of an age-matched reference population) was depicted in almost half of patients (48%). Twelve (24%) patients had osteoporosis. As well, osteopenia was recorded in 24% of patients. Patients with osteoporosis were older ($P = 0.018$) receiving higher mean daily dose than normal BMD ((26.5 ± 8.3 mg/day vs 25.6 ± 6.3 mg/day, $P = 0.9$). Mean cumulative HC dose was higher in patients with osteopenia/osteoporosis than those with normal osteodensitometry but without significant correlation (462.2 ± 373.2 mg vs 344.6 ± 245.5 mg, $P = 0.48$).

Discussion

Glucocorticoid replacement therapy during AD is associated with low BMD requiring better therapeutic adjustment of HC doses.

Health state utility value of Cushing syndrome patients after bilateral adrenalectomy–systematic literature review and mapping to EQ-5D

Fabian Schmidt[1], Alberto Pedroncelli[2], Muriel Marks[3], Dominik Szewczuk[4], Agnieszka Kalinowska[5] & Grzegorz Binowski[5]

[1]Recordati Rare Diseases, Puteaux, France; [2]Recordati AG, Basel, Switzerland; [3]World Alliance of Pituitary Organizations, Zeeland, Netherlands; [4]MAHTA, Warsaw, Poland; [5]MAHTA INTL., Warsaw, Poland

Background

Bilateral adrenalectomy (BLA) is a treatment option for patients suffering from endogenous Cushing syndrome (CS). It consists of the surgical removal of both adrenal glands. Even though BLA offers immediate control of cortisol excess, given the risk of adrenal insufficiency, it requires life-long glucocorticoid and mineral corticoid replacement. It may lead to perioperative and long-term complications which affect patients' quality of life (QoL). Health state utility values are essential parameters in cost-effectiveness models and should be established with a systematic literature review (SLR). The generic EQ-5D is the preferred QoL instrument by health technology assessment bodies.

Objectives

The main objective of the SLR was to identify relevant utility data of adult patients with endogenous CS after BLA to enable performing cost-effectiveness estimation in this therapeutic area. Another goal was to provide clinicians and researchers with a better understanding of the impact of BLA on patients' QoL.

Methods

The search was conducted using electronic databases, Embase® and MEDLINE. Eligibility criteria were based on the population, interventions, comparators, and outcomes (PICO) framework. The search terms included EQ-5D, other recommended measures like HUI 1-3, SF-6D, SF-36 and other instruments which, if no relevant EQ-5D data were available, could be mapped onto EQ-5D. The quality of full-text publications was assessed using a validated checklist provided in the literature.

Results

Out of 146 records identified, 5 unique studies were eligible for inclusion. Four studies assessed the QoL of CS patients after BLA using SF-36 and one using SF-12. All included studies demonstrate consistently that CS patients after BLA had lower QoL scores compared to the general population. The most impaired domains of SF-36 were bodily pain, general health, vitality and social functioning. Both physical and mental composite score of SF-12 were deteriorated. As no EQ-5D values were identified, SF-36 and SF-12 outcomes were mapped to EQ-5D-3L using published and validated regression models. EQ-5D values as estimated for different mapping models were oscillating between 0.5 and 0.7, with median value equal to 0.65. Reference population norms for EQ-5D-3L values, matched to CS patients by age, ranged from 0.85 to 0.97, depending on the country of origin.

Conclusions

Despite control of CS, CS patients after BLA have impaired QoL. The utility value of their health state, mapping SF-36 and SF-12 results to EQ-5D, is approximately 0.65. This relatively low value may be attributable to comorbidities, especially adrenal insufficiency.

Introduction

Osilodrostat and Metyrapone are two CYP11B1 inhibitors used for the treatment of patients with Cushing syndrome. Despite their common suspected mechanism of action, the comparison of serum steroid profiles determined in HPLC-MS/MS in patients treated by either Osilodrostat or Metyrapone for an ACTH-dependent Cushing syndrome identified higher levels of 11-deoxycortisol and androgens in patients treated by Metyrapone than in those treated by Osilodrostat (*F. Bonnet-Serrano and al., EJE, 2022*). This suggested a potential inhibitory effect of Osilodrostat on other steroidogenic enzymes than CYP11B1. The objective of this study was to understand the mechanisms underlying the differences observed in treated patients in clinical routine by comparing the effect of both drugs on the steroid secretion profile of adrenocortical carcinoma cells *in vitro*, exposed to either Osilodrostat or Metyrapone.

Methods

H295R cells were incubated for 72 hours with five different concentrations of Osilodrostat or Metyrapone (0.05 µM, 0.1 µM, 0.5 µM, 1 µM and 5 µM). A profile of ten steroids was measured in the supernatant using HPLC-MS/MS analysis. Cell viability after drug exposure was evaluated by Crystal Violet assay.

Results

Half-decrease in cortisol and corticosterone levels was observed with only 0.05 µM of Osilodrostat (from 270 to 114 nmol/l and from 12.9 to 4.0 nmol/l,

respectively) vs 0.5 μM of Metyrapone (from 267 to 118 nmol/l and from 11.9 to 5.6 nmol/l, respectively). These inhibitions also induced an increase in upstream steroids, 11-deoxycortisol and 11-deoxycorticosterone. Thus, Osilodrostat had a higher inhibitory effect on CYP11B1 and CYP11B2 than Metyrapone, as suggested by the higher 11-deoxycortisol/cortisol and 11-deoxycorticosterone/-corticosterone ratios, respectively. Androstenedione levels showed a slight increase $\leq$20% with Osilodrostat while no variation was observed with Metyrapone. The same experiment and analysis will be performed using different concentrations and exposure durations to better characterize the effect of both drugs on steroid precursors and androgens pathway.

Conclusion

Osilodrostat induced a stronger inhibition of CYP11B1 and CYP11B2 activities than Metyrapone in H295R cells, resulting in a higher decrease in cortisol and corticosterone levels. The comparison of the steroid profile and the expression of steroidogenic enzymes in basal and treated conditions should also give us interesting insights in the action of these drugs on adrenocortical cells. This study would therefore, help to better understand the molecular cause of the adverse effect observed in treated patients, especially hyperandrogenism.

Glycerophospholipid circadian profiles in serum and dried blood spot in healthy subjects

Greta Galante[1], Valentina Bissi[1], Ilaria Improta[1,2], Lorenzo Tucci[1,2], Valentina Vicennati[1,2], Uberto Pagotto[1,2], Guido Di Dalmazi[1,2] & Flaminia Fanelli[1]

[1]Center for Applied Biomedical Research, Department Of Medical and Surgical Sciences, Alma Mater Studiorum - Bologna University, Bologna, Italy, Bologna, Italy; [2]S. Orsola-Malpighi Polyclinic, Bologna, Italy

Introduction

Lipidomics is an emerging approach to characterize circadian rhythm alterations due to diseases of the hypothalamus-pituitary-adrenal axis. Glycerophospholipids are membrane structural constituents and key players in cell signalling, homeostasis and inflammatory and immune responses. Among blood derivatives, serum may reflect the soluble fraction, whereas dried blood spot (DBS) may reflect the cell membrane fraction of these lipids. However, little information is available about individual glycerophospholipid distribution among different blood derivatives as well as about their circadian fluctuation.

Aim

To compare glycerophospholipid levels and their variation during the daytime as assessed in serum and DBS.

Methods

Six normal-weight healthy adults (3 males, 3 females) aged 26-50 y were enrolled. For 7 days, ending with the observation day, subjects had a Mediterranean diet standardized in composition and time. Subjects underwent six paired venepunctures and finger-pricks to obtain serum and DBS, respectively, at pre-established times: 30 min before and 2 hours after breakfast (7.30), lunch (13.30) and dinner (19.30). Ninety glycerophospholipids were quantified by flow injection - tandem mass spectrometry.

Results

Eighty-four metabolites were detected both in serum (mean minimum concentration: 0.117 μM, phosphatidylcholine-diacyl (PC-aa)-C24:0; mean maximum concentration: 413.7 μM, PC-aa-C34:2) and DBS (mean minimum concentration: 0.284 μM, PC-acyl-alkyl(ae)-C44:3; mean max concentration: 218.6 μM, PC-aa-C34:2). Among these, 41 analytes were higher and 35 lower in basal serum vs DBS (P: $<$0.001-0.046). Further 1 and 4 metabolites were only detected in serum and DBS (mean range concentration: 0.746-2.40 μM), respectively; 1 was not detectable. Levels of 75 glycerophospholipids significantly correlated between DBS and serum (P: $<$0.0001-0.040). Highest correlations were found for PC-aa-C34:4 (r=0.933), PC-aa-C32:2 (r=0.912) and PC-aa-C34:3 (r=0.909). Significant variations along the six time points were observed for serum PC-ae-C32:1, lysoPC-a-C16:0, lysoPC-a-C16:1, lysoPC-a-C17:0, lysoPC-a-C18:1, lysoPC-a-C18:2, lysoPC-a-C20:3 and lysoPC-a-C20:4 (P: $<$0.001-0.031), showing a positive linear or quadratic trend. The latter three compounds showed a parallel fluctuation in DBS (P: 0.001-0.014). Forty-six other glycerophospholipids showed significant variations in DBS along the six time points (P: $<$0.001-0.049), mostly with negative linear trend. Strongest variations were found for PC-aa-C24:0, PC-ae-C30:0, PC-ae-C36:0, PC-ae-C38:0, PC-ae-C38:1 and lysoPC-a-C26:0 (all P: $<$0.001).

Conclusions

In our healthy cohort, significant differences in serum and DBS glycerophospholipid levels were observed. DBS displayed daily variations of a much larger panel of glycerophospholipids than serum. This is consistent with the presence of the cellular fraction in DBS. DBS may therefore represent a convenient and more informative tool to study glycerophospholipid involvement in diseases related to circadian rhythm imbalance.

Small Cell Neuroendocrine Carcinoma of the Larynx: A Case Report

Farah Elgharroudi, Nawal El Ansari & Ghizlane El Mghari
CHU Mohammed VI, Endocrinology, Marrakech, Morocco

We report a case of small cell neuroendocrine carcinoma of laryngeal localization. The involvement of the larynx still exceptional. We present in this paper the radiological, pathological and therapeutic aspects of this tumor that was diagnosed in a 48-year-old man. A 59 years old male patient, chronic smoker, with 10 packs per year; without any particular medical history. he consulted for a rapidly progressive cervical swelling since one year, associated with dysphonia. The whole evolving in a context of apyrexia and alteration of the general state (asthenia, weight loss considered very important not quantified with a preserved appetite).There was no dysphagia, no dyspnea, no carcinoid syndrome or other paraneoplastic syndromes. The patient consulted an ear nose and throat physician, who ordered a cervicothoracic computed tomography showing thickening of the right vocal chord with two nodular lesions measuring 8$\times$10 mm for the largest one, with multiple cervical ADPs visible in the jugulocarotid artery, measuring 23 mm on the right and 15 mm on the left, with necrotic content. Rigid laryngoscopy under sedation revealed a regular submucosal thickening of the right vocal cord extending superiorly. With presence of jugulo-carotid adenopathies. The anatomopathological study of the biopsy showed: an undifferentiated carcinoma, largely necrotic, infiltrating the fibrous tissue with vascular emboli at the level of the labelled specimen. A second specimen of the right vocal cord discreetly reworked by fibrosis without neoplastic localization at this level is associated. This morphological aspect must make us eliminate an aerodigestive primary. With immunohistochemical complement morphological aspect and immunohistochemical profile in favor of an infiltrating small cell neuroendocrine carcinoma (anti AE1/AE3: diffuse positivity/anti chromogranin A: diffuse and intense positivity/anti synaptophysin: diffuse positivity of moderate intensity/anti -KI67: estimated at 60%). Complementary tests showed a very high carcinoembryonic antigen level of 156.4 ng/ml, i.e. 26 times normal. The tumor extension assessement showed secondary iliac osseous lesions. The octreoscan was not performed due to lack of reagent. Given the histological nature of the tumor which contraindicates surgical treatment, the case was discussed with the oncologists with the decision to stop the investigations and to refer the patient for urgent radio-chemotherapy.Keywords: larynx, small cell neuroendocrine tumor, endoscopy, radiology, pathology, treatment.

Characteristics of Hypertension in patients with pheochromocytomas

Sahar Abidi, Sabrine Mekni, Sawsen Essayeh, Wafa Ben Hilel, Cherchir Faten, Nadia Mehuirgui, Ibtissem Ben Nacef, Imen Rojbi & Karima Khiari
Charles Nicolles Hospital, Endocrinology Department, Tunis, Tunisia

Introduction

Pheochromocytomas are rare catecholamine-secreting tumors presenting with various clinical manifestations. Hypertension is the most common finding in pheochromocytomas. It can be either persistent or paroxysmal. Study Design: We conducted a retrospective study of 34 patients who were admitted into the endocrinology department of Charles Nicolle hospital, with a diagnosis of a pheochromocytoma from January 2005 to November 2022.

Results

Twenty one patients (64%) had a family history of hypertension. Nine patients (27%) had diabetes and eight patients (25%) had dyslipidemia. Twenty six patients (77%) had hypertension. The median of years with hypertension was 3.5 years IQR (1-5,7). The mean number of used antihypertensive drugs was 2.4 $\pm$ 1.3 [extremes:1-6]. Two patients had coronary disease and one patient had heart failure. An ultrasound myocardium imaging was practiced in 22 patients. Myocardial amyotrophy was detected in 36% of cases (eight patients). Five patients had electric EKG abnormalities. Hypertensive retinopathy, microalbuminuria and chronic kidney disease were detected in 18, 93 and 20% of cases, respectively. Surgical treatment was performed in 27 cases (93%). Fifteen (56%) patients were cured of their hypertension after surgery.

Conclusions

Pheochromocytomas are considered as one of the most common causes of curable hypertension. Early diagnosis of theses tumors is important, owing the possibility of curing hypertension and preventing its lethal complications.

«Non-classical» pheochromocytoma, clinical case

Anna Motrenko[1], Larisa Gurevich[2], Timur Britvin[3] & Irena Ilovayskaya[1]
[1]Moscow Regional Research and Clinical Institute (MONIKI), Neuroendocrine Unit, Department of Endocrinology, Moscow, Russia; [2]Moscow Regional Research and Clinical Institute (MONIKI), Department of Pathoanatomical, Moscow, Russia; [3]Moscow Regional Research and Clinical Institute (MONIKI), Department of Surgical Endocrinology, Moscow, Russia

Neuroendocrine neoplasias (NENs) are a heterogeneous group of tumors that differ in appearance, growth patterns, and clinical symptoms and develop from neuroendocrine cells and, accordingly, unusually similar cytological characteristics. Pheochromocytoma is considered as not epithelial type of NENs. We would like to present a clinical case of pheochromocytoma with difficulties in laboratory diagnosis and morphological verification. Female patient P., 60 years old, for 10 years, she was observed by a cardiologist with arterial hypertension (Grade 3) and chronic heart failure (NYHA Clase III), antihypertensive therapy with 3 standard preparations has been repeatedly adjusted without sufficient clinical response. On treatment, patient had blood pressure up to 200/100 mm Hg accompanied by sweating, episodes of flushes of heat to the face. CT of the abdominal organs incidentally detected a left adrenal tumor size 46×41×45 mm (native density +14+52 HU). Daily urine: normetanephrine 471 mg/day (30–440), metanephrine 60 mg/day (30–440); chromogranin A 23.6 nmol/l (0.54–3). Laparoscopic left adrenalectomy was performed. According to the histological examination of the adrenal tumor, predominantly formed from the structure of a solid and alveolar with the presence of an angiomatous component of large cystic dilated vessels, from small monomorphic tumors cells with a narrow cytoplasm and a rounded nucleus, which in structure most of all resemble the structure of neuroendocrine tumors of the small intestine, "typical carcinoids". The minor component of the structure, characteristic of "classical" pheochromocytomas, was formed from alveolar structures from larger cells with abundant light cytoplasm, with nuclear and cellular polymorphism. When a tumor is detected, invasion of vessels into the tumor and local invasion of capsules. Considering the fact that the tumor has a non-specific structure for pheochromocytes, differential diagnosis was carried out between pheochromocytoma and metastases of intestinal NET or other localizations. Immunohistochemical detection of chromogranin A expression foci, a higher density in areas of a “typical” pheochromocytoma, as well as synaptophysin and CD56, revealed focal uneven expression of vimentin, as well as focal serotonin expression mainly in areas of a “carcinoid structure”. There is no expression of pan-cytokeratin, TFF-1, CDX-2. The average Ki67 2-8% (max 11%).

Conclusion

Pheochromocytoma of the adrenal gland "carcinoid-like" structure. After operation, the patient noted the normalization of blood pressure without preparations. This clinical case demonstrates the diversity of the clinical course and histological picture. Based on this, to establish an accurate diagnosis, we need detailed approach with a mandatory Immunohistochemical study to determine further tactics of treatment and monitoring.

Malignant pheochromocytoma : A therapeutic challenge !

Chtioui Sara, Ahmed Boukhalfa, Sana Rafi, El Mghari Tabib Ghizlane & Nawal El Ansari
Mohammed VI University Hospital Center, Department of Endocrinology, Diabetes, Metabolic diseases and Nutrition, Marrakech, Morocco

Introduction

Pheochromocytomas are rare catecholamine-producing neuroendocrine tumors that are usually benign, but which may also present as or develop into a malignancy. Predicting such behavior is notoriously difficult and there are currently no curative treatments for malignant tumors.

Case Report

A male patient aged 23 years old who was investigated for headaches, flushing and palpitations. The patient presented with classic clinical features of NF-1, *café-au-lait* spots and skin nodules. Laboratory tests revealed elevated catecholamine levels in the 24-h urine collection. Computed Tomography Scan revealed a mass measuring 10×8.2×9.4 cm in the left adrenal gland and pulmonary metastases. He was operated on and histological examination confirmed the diagnosis of pheochromocytoma with a Pass score of 9. After surgery, urinary catecholamines were high and there were diffuse pulmonary and liver asymptomatic metastases in Octreotide scan uptake. The I131 MIBG scan revealed the progression of pulmonary and liver metastases and revealed bone metastases. Radionuclide treatment with use of 131-I MIBG is indicated.

Discussion

Pheochromocytomas are tumors of the adrenal medulla and extra-adrenal chromaffin tissue that secrete catecholamines, resulting in hypertension, whether sustained or paroxysmal, and other symptoms of increased production of catecholamines. They may be classified as sporadic or familial. Most of the pheochromocytomas are sporadic. Familial predisposition is seen mainly in patients with multiple endocrine neoplasia type 2, neurofibromatosis Type 1 (NF-1), von Hippel-Lindau disease and familial carotid body tumors .laparoscopic adrenalectomy (LA) has gained field in the surgery of the adrenals and nowadays it is the procedure of choice. A long-term follow-up is required to monitor for recurrence in patients with genetic predisposition. I-131 MIBG therapy has been widely used for metastatic or unresectable MIBG-avid pheochromocytomas and paragangliomas. Several groups have tried single or repeated therapy with a variable dose of I-131 MIBG.

Conclusion

The association of a malignant pheochromocytoma with neurofibromatosis type 1 although very rare should be known as pheochromocytoma and its metastases may be totally asymptomatic as in the presented case.

Impact of long-term atorvastatin use on renal function in type 2 diabetes patients

Ameni Terzi[1], Nadia Khessairi[1], Meriem Yazidi[1], Ibtissem Oueslati[1], Hammami Bassem[2], Fatma Chaker[1], Feki Moncef[2] & Melika Chihaoui[1]
[1]Rabta, Endocrinology, Tunisia; [2]Rabta, Biochemistry, Tunisia

Introduction

Statins are widely used in primary and secondary cardiovascular prevention. They have been described to improve renal function. We aimed in this study to evaluate the effect of high dose atorvastatin therapy on renal outcome in type 2 diabetes patients.

Methods

This was a single-center, prospective study, including 60 men with type 2 diabetes mellitus, aged between 40 and 65 years, statin-free, in whom the indication of a high dose statin treatment was indicated. Renal clearance was higher than 60 ml/mn/1.73 m^2 in all patients. The patients had two visits, before and six months after the daily intake of 40 mg of atorvastatin. During each visit, they underwent a clinical examination and a fasting blood sample was collected for biological measurements including creatinine.

Results

The median age was 58 years (IQR:52-62). The median duration of diabetes was 81 months (IQR: 26-132). Thirty-one patients (52%) had hypertension. The median weight was 86.5 kg (IQR: 78-94). Twenty-seven patients (45%) had a diabetic nephropathy; a microalbuminuria in 23 cases (38%) and a macroproteinuria in 4 cases (7%). Glomerular filtration rate (GFR) was between 60 and 89 ml/mn/1.73 m^2 in 16 patients (27%) before and 12 (20%) after statin use while GFR $\geq$ 90 ml/mn/1.73 m2 was observed in 44 (73%) before and in 48 (80%) after atorvastatin treatment. Serum creatinine levels decreased significantly from 74.5 µmol/l (IQR: 69.8-82.5) to 70.8 µmol/l (IQR: 64.9-78.3) ($P=0.001$). Creatinine clearance increased significantly from 100 ml/mn/1.73 m^2 (IQR: 88-110) to 105 ml/mn/1.73 m^2 (IQR: 93- 120) after atorvastatin therapy ($P=0.001$).

Conclusion

Long-term high-dose atorvastatin use improved renal function in type 2 diabetes patients.

VCAM-1 concentration in patients 6 months after SARS-Cov2 infection

Aleksandra Jawiarczyk-Przybyłowska, Justyna Kuliczkowska-Płaksej, Aleksandra Zdrojowy-Wełna, Katarzyna Kolačkov, Agnieszka Zembska & Marek Bolanowski
Wroclaw Medical University, Department and Clinic of Endocrinology, Diabetes and Isotope Therapy, Wroclaw, Poland

Objectives
The excessive production of pro-inflammatory cytokines has been previously reported in the severe form of COVID-19. The cytokine storm is responsible for the induction of an inflammatory endothelial cell phenotype which is associated with the shedding of adhesion molecules. VCAM-1 is an endothelial adhesion protein that belongs to the immunoglobulin superfamily. Pro-inflammatory cytokines lead to the induction of VCAM-1 in the endothelium of blood vessels which is crucial for the recruitment, adhesion, and migration of leukocytes. The level of the soluble form of VCAM-1 (sVCAM-1) was shown to be increased in patients with severe COVID-19 and was associated with disease progression and mortality.
Aim
To assess VCAM-1 concentration in patients 6 months after the mild SARS-Cov2 infection (without hospitalization) in comparison to the control group as well as biochemical, hormonal, and anthropometric parameters, considering the influence of sex.
Material and Methods
The study group included 53 patients with a history of COVID-19 and 87 healthy subjects in the control group. Anthropometric parameters were measured. VCAM-1 concentration as well as hormonal (testosterone, insulin, morning cortisol) and biochemical parameters (glucose, alanine transferase, asparagine transferase, lipids) were measured.
Results
The statistically higher VCAM-1 concentrations were observed in the control group in comparison to the COVID-19 group (830, 342 ng/ml vs 772, 509 ng/ml, $P=0.03$). No statistically significant differences in C-reactive protein concentrations were observed between the groups. Significant positive correlations were observed between VCAM-1 and alanine and aspartate aminotransferases as well as with HDL-concertation in the COVID-19 group, although we did not observe significant differences in the concentration of aminotransferases and HDL cholesterol between both groups.
Conclusions
Based on the results of our study, it can be concluded that, at least 6 months after mild COVID-19 infection, there is no strong evidence of endothelial dysfunction in COVID-19 survivors. Surprisingly, we observed a significantly higher concentration of VCAM-1 in the apparently healthy control group.

Primary bilateral macronodular adrenal hyperplasia: Is unilateral adrenalectomy enough?

Mariana Lopes-Pinto[1], Mafalda Pinho Fialho[2], Ema Paula Ricca Lacerda Nobre M Caetano[1,3], José Rocha[1] & Ana Paula Barbosa[1,3]
[1]Centro Hospitalar Universitário Lisboa Norte, Endocrinology, Diabetes and Metabolism, Lisbon, Portugal; [2]Centro Hospitalar Universitário Lisboa Norte, Pathology Department, Lisbon, Portugal; [3]Lisbon School of Medicine, Lisbon, Portugal

Introduction
Primary Bilateral Macronodular Adrenal Hyperplasia (PBMAH) represents $<2\%$ of causes of Cushing's Syndrome (CS). Clinical course is insidious, with adrenal bilateral macronodules and gradual cortisol excess, only rarely presenting with overt CS. The pathophysiology remains unclear, however, hyperactivation of the cAMP/PKA pathway, in 77-87% of cases through aberrantly expressed G-protein coupled receptors (GPCRs), has been described. Despite being a benign entity, PBMAH associated hypercortisolism may require aggressive management.
Objectives
To present a case of PBMAH diagnosed due to hypertension and overt CS, successfully treated with unilateral adrenalectomy.
Case Report
A 34-year-old woman presented with progressive weight gain, facial hair growth and headaches for 14 months. She had been diagnosed with prediabetes and hypertension, which motivated additional study. She had round plethoric face and hypertrichosis, dorsocervical and supraclavicular fat pads and easy bruising. Her weight was 66.5 kg with a body mass index of 24.4 kg/m^2. Laboratory evaluation showed a 9 am serum cortisol of 46.1 µg/dl (*n*:6.2-18), with circadian rhythm, as demonstrated by the measurement of salivary cortisol at 8 am and 11 pm; ACTH <1 pg/ml and 24 h urinary cortisol 6825 µg/24 h (*n*:124-581). Serum cortisol after 1 mg dexamethasone suppression test was 37.9 µg/dl, while salivary cortisol kept circadian rhythm. Androgen and mineralocorticoid hypersecretion were excluded. Adrenal CT scan documented evident bilateral adrenal enlargement with multiple hypodense macronodules which reached a maximum diameter of 67 mm and 49 mm. Considering a PBMAH diagnosis, the stimulation tests to assess aberrant receptors were performed following *Lacroix et al* protocol, but there was no evidence of positive response. The patient initiated metyrapone, controlling the hypercortisolism with 250 mg twice daily. Unilateral adrenalectomy of the largest adrenal gland was considered and uneventfully performed. Histopathologic evaluation revealed an adrenal cortex macronodular hyperplasia, compatible with the PBMAH diagnosis. After surgery, blood pressure returned to normal levels, allowing antihypertensive medication to be suspended two weeks afterwards, and 24 h urinary cortisol normalized. The patient also reported improved well-being and weight loss was documented. One month after surgery, she remained on hydrocortisone replacement, under close surveillance.
Discussion and Conclusions
In this case, secondary hypertension evaluation revealed hypercortisolism and documented adrenal macronodules favouring PBMAH diagnosis. Despite being frequent, aberrant receptors were not present, precluding targeted medical treatment. Unilateral adrenalectomy may offer clinical and biochemical benefits while avoiding hormone replacement, nevertheless, long term follow-up is required since disease recurrence has been reported with this approach.

Preoperative management of Pheochromocytoma with fluctuation of Blood Pressure: A case report

Zahra Ismail[1,2], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]CHU Mohamed VI, Departement of Endocrinology, Diabetes and Metabolic Diseases, Marrakech, Morocco; [2]Mohamed VI University Hospital Center, Department of Endocrinology, Diabetes and Metabolic Disease, Marrakech, Morocco

Introduction
Pheochromocytoma is a rare tumor of chromaffin cells localized in the adrenal gland. It is responsible of secretion of catecholamines in a supra physiologic amount, leading to hypertension. Some patients may present with hypotension despite having high circulating levels of catecholamines. The challenge is to stabilize blood pressure by medication in cases with fluctuation of blood pressure.
Case presentation
49-year-old woman suffered from recurrent right hypochondrium pain and paroxystic headache, palpitations and sweats. She has no history of hypertension and no family history of pheochromocytoma. Urinary 24-h excretion levels of epinephrine, norepinephrine, and dopamine, were highly increased. Abdominal CT Scan showed a right adrenal mass measuring 71×86 cm, discreetly enhanced after injection of PDC and with areas of cystitis and necrosis. After being hospitalized, monitoring of blood pressure and heart rate showed an extreme fluctuation with systolic pressure peaks reaching 210 mmHg and systolic pressure nadir reaching 70 mmHg; and the HR fluctuates from 65 to 120 beats/min. Doxazosin was orally administrated starting by a dose of 1 mg/day, then 2 mg/day, 10 days before surgery. However, the patient kept the fluctuations until day 6 of treatment. Intravenous fluids were introduced 3 days before surgery. Right adrenalectomy was performed through laparotomy with two incidental high BP episodes during surgery. Histological examination confirmed the Pheochromocytoma. BP and HR remain stable after adrenalectomy.
Discussion
Hypotension and BP fluctuation are rare phenomena in patients with pheochromocytoma. The mechanisms by which hypotension and BP fluctuation occur in these patients despite an increase in catecholamine level remain unclear. There is no consensus concerning management of hypotension and BP fluctuation. The Endocrine Society recommend a preoperative blockade (by α-adrenergic receptor blockers as the first choice) for all patients with hormonally functional pheochromocytoma despite the BP status. Some studies showed a beneficial effect of treatment with a combination of intravenous norepinephrine and doxazosin on BP fluctuation. Adrenalectomy should be performed after stabilization of BP.
Conclusion
We presented a case of Pheochromocytoma in a patient who had an important BP and HR fluctuations. The preoperative preparation must be delicate with a close monitoring of BP.

Impact of glucocorticoid replacement therapy on anthropometric parameters in patients with Addison disease

Khouloud Boujelben, Dhoha Ben Salah, Hamdi Frikha, Mouna Elleuch, Nadia Charfi, Fatma Mnif, Mouna Mnif, Nabila Rekik Majdoub, Faten Haj Kacem Akid & Mohamed Abid
Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction
Inappropriate glucocorticoid replacement therapy results in higher mortality rates in patients with Addison disease (AD), predominantly due to higher prevalence of cardiovascular diseases, disturbed glycometabolic state and altered anthropometric parameters. The aim of this study was to assess the impact of life-long corticosteroid exposure on anthropometric parameters in patients with AD.
Patients and Methods
This Tunisian cross-sectional study was conducted in the Endocrinology department of Hedi Chaker University hospital, Sfax, Tunisia, from March 2020 to July 2021, including 50 patients followed for AD for at least 5 years. Anthropometric parameters during clinical controls and at time of the study were recorded. Predictive factors of altered anthropometric parameters were assessed.
Results
Patients had a median age of 49.5 ± 13.9 years (18-87 years) and a disease duration with a mean of 13.9 ± 8.7 years (5-35 years). The mean hydrocortisone dose was 27.4 ± 6.7 mg/day. The mean cumulative dose was 374.636 ± 283.821 mg. The average weight was 72.5 kg (62-107 kg). Seventy percent of patients developed progressive weight gain that was more marked during the first-year follow-up with a mean of 7.4 kg. Average body mass index (BMI) was 28.1 kg/m^2 (21.2-45.8 kg/m^2). Overweight and obesity were recorded in 48% and 26% of patients, respectively. There was no significant correlation between BMI and disease duration nor glucocorticoid replacement dose. Mean waist circumference was 107 ± 11.8 cm (65-121 cm) for woman and 105.1 ± 9.6 cm (64-119 cm) for men. Android fat distribution was depicted in 60% of patients vs only 12% at time of diagnosis. Those patients received higher daily glucocorticoid dose (26.1 ± 7 mg/day vs 24.6 ± 6.1 mg/day, $P = 0.7$). As well, android fat distribution was significantly correlated with cumulative glucocorticoid dose (452.2 ± 301.7 mg/day vs 241.1 ± 264.2 mg/day, $P = 0.02$).
Conclusion
Conclusively, patients with AD taking long-term glucocorticoid therapy may experience altered anthropometric parameters. Consequently, it seems crucial to ensure regular monitoring of those patients in order to reduce cardiovascular complications.

Successful management of adrenal Cushing's syndrome associated with androgen co-secreting adenoma during pregnancy: a case report

Luis Antonio Rodriguez Arrieta[1], Juan Carlos Hoyos Valdelamar[2], Johnayro Gutierrez Restrepo[1], Ana Milena Mejía Sanjuanelo[3], Myriam Vanessa Rueda Galvis[1] & Hugo Rafael Corrales Santander[4]
[1]University of Antioquia, Endocrinology, Colombia; [2]Hospital Universitario del Caribe, Gastrointestinal surgery and digestive endoscopy, Cartagena, Colombia; [3]University of the North, Internal Medicine, Barranquilla, Colombia; [4]National University of Colombia, Endocrinology, Bogotá, Colombia

Introduction
Adrenal Cushing's syndrome during pregnancy is rare, and few cases have been reported. It is infrequent to identify pregnant women with adenomas that have cortisol and androgen co-secretion. The diagnosis and treatment of excess cortisol during pregnancy is challenging when the patient does not want a pregnancy interruption.
Case Report
38-year-old woman with arterial hypertension for four years. During her working days, she remained upright constantly and presented back pain. As part of the approach to this pain, they requested a simple chest tomography without evidence of alterations in the thoracic spine or mediastinum, but with the incidental finding of a 35-mm right adrenal lesion, for which they requested a contrasted abdominal tomography with an adrenal gland protocol. Due to administrative delays, she could not have a timely evaluation of endocrinology. At the time of the initial evaluation, she attended at 14 weeks of gestation, a high-risk pregnancy due to advanced maternal age and pre-pregnancy hypertension. When evaluating this adrenal lesion, hypercortisolism was confirmed by two results with more than 2 to 3 times the reference value of free cortisol in 24-hour urine and adrenocorticotropic hormone less than 5 pg/ml, in addition, hyperandrogenism of adrenal origin with elevated values of 17 hydroxyprogesterone (1633 ng/dl VR: 10-120 ng/dl) and total testosterone (242 ng/dl VR: 0-50 ng/dl), excess aldosterone and catecholamines were ruled out. Pharmacological treatments for Cushing's syndrome are contraindicated during pregnancy, and the patient rejected the possibility of voluntarily terminating the pregnancy; she decided to undergo resection by oncological surgery. At 22 weeks of gestation, she had a 3.5 × 3.0 × 2.5 cm adrenal adenoma resected laparoscopically without complications with subsequent remission of hypercortisolism and hyperandrogenism. Oral prednisolone was started due to adrenal insufficiency due to the slowdown in the activity of the left adrenal gland. The 38-week pregnancy was terminated by cesarean section with a healthy female neonate. The evolution was good in the follow-up one month and three months after the end of the pregnancy. However, she continued with oral corticosteroid replacement requirements and is under surveillance, awaiting a possible recovery of the hypothalamic-pituitary-adrenal axis.
Conclusion
Adrenal adenomas identified during pregnancy are a challenge, drugs are a contraindication in this scenario, and surgical resection can be performed when there is a qualified interdisciplinary team.

Black adrenal adenoma mimicking an oncocytoma–a case report

Helena Urbano Ferreira, Juliana Gonçalves, Sandra Belo, Davide Carvalho & Paula Freitas
São João Universitary Hospital Center, Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal

Introduction
Black adrenal adenomas are rare and benign. They are named after their black appearance, due to lipofuscin pigment. Most frequently black adenomas are associated with ACTH-independent Cushing's syndrome. They can also cause primary hyperaldosteronism or be nonfunctioning. Unlike most other adrenal adenomas, black adenomas exhibit high Hounsfield units (> 30) on CT, and high standard uptake value on FDG-PET.
Case presentation
A 67-year-old woman was diagnosed with lung cancer (adenocarcinoma). For staging purposes, she underwent thoraco-abdominopelvic CT and FDG-PET/CT scans. The CT scan identified a 14 mm nodule of the left adrenal gland, with spontaneous density of 34 Hounsfield units, and the PET/CT scan showed high uptake on the left adrenal gland (maximum standardized uptake value 5.3), but no significant uptake on the pulmonary nodule. Due to high suspicion for metastasis, she underwent an adrenal biopsy. Histological findings were suggestive of an adrenal oncocytoma (oncocytic cells, intracytoplasmic lipofuscin pigment, nuclear anisocarysosis, binucleation, prominent nucleolus and nuclear pseudoinclusions). She underwent an upper right lobectomy and was restaged to pT1bN0R0. The adrenal nodule was initially on active surveillance, but due to increasing dimensions to 20 mm on a follow-up CT-scan, she underwent a left adrenalectomy. No hormonal study was performed prior to the biopsy or surgeries. Macroscopically, a dark, homogeneous, well delimited lesion of 1.8 × 1.8 × 1.5 cm was identified on the surgical specimen. The histological exam was compatible with an adrenal cortex black adenoma, with a conventional Weiss score of 2. Eleven days after the adrenalectomy, the patient presented to the emergency room with fatigue, abdominal pain, hypotension, and hyponatremia. She had *rubeosis faciei* and abdominal fat deposition, but no other stigmata of Cushing's syndrome. Occasional serum cortisol was 1.8 µg/dl and 1.5 µg/dl, at 5 A.M. and 7 A.M. respectively. A diagnosis of acute adrenal insufficiency was made, and the patient received intravenous hydrocortisone, which was weaned to a physiologic oral dose during one week of hospitalization. The onset of adrenal failure after unilateral adrenalectomy with an intact contralateral adrenal gland, led the medical team to presume a previously undiagnosed endogenous hypercortisolism in relation to the adrenal black adenoma. Recovery of the axis has not been assessed yet.
Conclusion
Black adenomas are benign but present with features suggestive of malignancy on both PET and CT scans. They can be associated with hypercortisolism and

hyperaldosteronism. This case highlights the importance of performing hormonal studies despite high suspicion for primary or secondary malignancy.

Primary adrenal insufficiency in the context of small-cell neuroendocrine prostate cancer

Francisca de Brito Marques[1], Helena Magalhães[2], Joana Lima Ferreira[1], Francisco Simões de Carvalho[3] & Ana Paula Marques[1]
[1]Pedro Hispano Hospital, Matosinhos Local Health Unit, Matosinhos, Endocrinology; [2]Pedro Hispano Hospital, Matosinhos Local Health Unit, Matosinhos, Medical Oncology, Portugal; [3]Pedro Hispano Hospital, Matosinhos Local Health Unit, Matosinhos, Endocrinology, Portugal

Introduction
The small-cell neuroendocrine prostate carcinoma (SCPC) is rare, highly aggressive and usually transforms from prostate adenocarcinoma (PAC) after androgen deprivation therapy (ADT).
Case Report
A 66-year-old man had a three-year history of high-grade PAC with high burden disease (abdominal lymph node and bone metastasis) at presentation (09/2019). On the initial staging evaluation, the CT scan documented a 20 mm left adrenal nodule compatible with adenoma. No assessment for hormone excess was performed. He initiated long-term ADT and completed six cycles of palliative chemotherapy with docetaxel. He had good clinical, biochemical (PSA decreased from 18.84 to less than 1 ng/ml) and imaging responses on conventional exams, with best response stable disease. Nineteen months after diagnosis, the left adrenal nodule grew to 29 mm and a de novo 13 mm right adrenal nodule was documented. After additional seven months, dimensional progression (on the left to 46 mm; on the right to 17 mm) and features suspicious for malignancy were observed. An MRI confirmed bilateral adrenal metastasis with further progression after six months (on the left to 50 mm; on the right to 45 mm). Analytically there was evidence of hypocortisolism, and the Endocrinology Department was consulted. Clinically he complained of moderate asthenia, anorexia, and low normal blood pressure for four months. On physical examination was noted mucocutaneous hyperpigmentation and the blood pressure was 110/70 mmHg. Further endocrine studies confirmed primary adrenal insufficiency: morning cortisol 6.7 µg/dl, ACTH 765.80 pg/ml, unmeasurable DHEA-s and aldosterone, high plasma renin activity; normal-high potassium; normal sodium and fasting glucose. Functional pheochromocytoma was excluded. He was started on hydrocortisone at supraphysiological doses, with marked clinical improvement. The 18F-FDG PET/CT revealed enlarged nodular adrenal glands with moderate tracer uptake and slight prostate heterogeneous tracer uptake, with no other abnormal foci. The adrenal mass biopsy revealed a small-cell neuroendocrine carcinoma; immunohistochemical staining was positive for CK AE1/AE3, synaptophysin, chromogranin and PSA (negative for CK7, CK20, MelanA and TTF1); Ki67 $>$ 50%. It was decided to start cisplatin and etoposide.
Discussion
We describe an exceptional rare case of bilateral adrenal metastasis causing adrenal insufficiency, from a prostate cancer that possibly transformed from PAC to SCPC after ADT. Indeed, adrenal insufficiency is uncommon in the context of bilateral adrenal metastasis and the adrenal glands are unusual sites of metastatic prostate cancer. The SCPC usually presents mixed with classic PAC and carries a poor prognosis with rapid disease progression and limited survival.

Addison disease in type 2 auto immune polyglandular syndrome

Rihab Laamouri[1,2], Mansour Sarah[1] & Racolta Niculina[1]
[1]Civil Hospital of Colmar, Endocrinology Department, Colmar, France; [2]Faculty of Medicine of Strasbourg, Strasbourg, France

Introduction
Autoimmune polyglandular syndrome APS type 2 is a rare polygenic disease associationg endocrine autoimmune affection but also other auto immune diseases. The chronology is variable. We report in this context a case of APS associating a Hashimoto thyroiditis, a premature ovarian deficiency and an Addison disease revealed later.
Case Report
A 33 year-old women consulted in 2018 for asthenia and spaniomennorrhea. The diagnosis of peripheral hypothyroiditis was retained. Antibodies Ab anti thyroperoxydase were positive. It was a Hashimoto thyroiditis. The patient was treated with levothyroxine. Menstrual disturbance persisted. Gonadic assessment was performed showing low oestradiol and an elevated FSH. Premature ovarian insufficiency was retained. Iatrogenic causes were excluded in anamnesis. There were no signs for genetic causes as a dysmorphic syndrome. A auto immune origin is the most probable etiology. She was treated with oesro-progestatif hormonal therapy. Four years later, she consulted the emergency department for asthenia, abdominal pain and vomiting. Hyponatremia with kaliema at the upper range were objectified. Peripheral adrenal insufficency was confirmed by a low cortisol at 66 nmol/l (n $>$ 138 nmol/l) and an elevated ACTH at 440 pmol/l. She was treated with parenteral hydrocortisone HC relayed with oral HC 25 mg divided into 2 doses. Aldosteron level was low. A treatement with Fludrocortisone was associated. CT Scan showed atrophic adrenal glands without calcifications. The Ab anti 21 hydroxylase were positive at 6.6 U/ml (n $<$ 0.4). Type 2 APS was retained. In the screening for the other auto immune affection, there was no signs of vitiligo, no chronic diarrhea, ab anti transglutaminase were negative. No diabetes. No arthralgia or other signs of systemic affection. Normocytaire anemia was present, vitamine B12 was normal but ab anti parietal cell were positive. A gastroscopy was prescribed searching for gastric atrophia as part of Biermer disease. The patient were referred for a genetic study. Results are pending.
Comments and Conclusions
APS type 2 is a genetic disease, implicating several genes, as genes coding to class II major histo-compatibility complex, Cytotoxic T Lymphocyte Associated Antigen-4 and others. The presence of two auto immune gandular affections, must incitate clinicians to look for other auto immune affection either endocrinopathie or systemic diseases. As shows our case report, the disease may appear at any time. So that, auto immune screening should not be overlooked during follow up, especially addison disease which is a life threatining affection.

Late-onset 21-hydroxylase deficiency: A case report

Loubna Guissi, Ali Halouache, Khaoula Gorgi, Kaoutar Rifai, Hinde Iraqi & Mohamed Elhassan Gharbi
Ibn Sina University Hospital, Department of Endocrinology and Diabetology, Rabat, Morocco

Introduction
Partial 21-hydroxylase deficiency is a genetic autosomal recessive disorder responsible for accumulation of the precursor upstream of the enzyme block, 17-hydroxyprogesterone (17OHP), and excessive androgen production.
Observation
A 29-year-old woman consulted for hirsutism with a Ferriman–Gallwey score of 25. There were no signs of Cushing syndrome and no abnormalities of sexual development. The Laboratory results revealed testosterone level of 0.76 ng/ml with elevated Δ4 androstenedione to 4.5 ng/ml. Cortisol level was comfortable at 180 ng/ml and 17OHP was elevated to 6 ng/ml and then to 14.6 ng/ml after Synacthen test confirming 21-hydroxylase deficiency. Pelvic ultrasound and adrenal CT scanning were normal.
Discussion
Partial 21-hydroxylase deficiency is responsible for more than 95% of late-onset congenital adrenal hyperplasia. It is distinct from the early so-called "classic" form due to a complete or major block and which results in virilization of a female child and/or syndrome of salt depletion. It usually reveals itself at puberty, sometimes years later. The most frequent reason for consultation is hirsutism, and justifies a Synacthen test with 17OHP in all cases of hirsutism with biological hyperandrogenism. The diagnosis is based on a 17OHP level above 10 ng/ml after stimulation. Management should include a molecular study of the CYP21B gene and a family investigation should be proposed.

Addisonian crisis unmasked by levothyroxine replacement in a patient admitted with suspected septic shock

Sanjali Ahuja[1,2], Gideon Mlawa[1], Robert English[1,2], Miriam Lowe[1,2], Alaina Khan[1,2] & Maisha Hayat[1,2]
[1]Queen's Hospital, United Kingdom; [2]Barts and The London School of Medicine and Dentistry, Queen Mary University of London, Charterhouse Square Campus, United Kingdom

Hypothyroidism due to autoimmune aetiology can be associated with other autoimmune conditions such as Type 1 Diabetes Mellitus (T1DM) and primary adrenal insufficiency. Ruling out primary adrenal insufficiency is important in any patient with suspected autoimmune hypothyroidism.
Case
43-year-old female complaining of general lethargy, sore throat, and neck pain. She was found to be hyponatraemic (Na + 130) after being reviewed by the GP and was advised to attend Accident and Emergency. The patient was admitted with suspected septic shock and severe hyponatremia (Na 112). Her background includes PCOS, recently diagnosed hypothyroidism, and Acalculous Cholecystitis. In her first admission, she was found to be hypothyroid and was started on levothyroxine replacement. 6 weeks after starting treatment, she was admitted once more with severe lethargy, hyponatremia with low cortisol. She underwent further testing including a short synacthen test which showed a suboptimal response. Adrenal antibodies were positive. During her inpatient stay she was treated with IV hydrocortisone and then discharge home on oral hydrocortisone and fludrocortisone. She remains stable and her sodium level has normalized.
Discussion
Autoimmune polyendocrine syndrome II consists of autoimmune hypothyroidism, primary adrenal insufficiency, and/or T1DM (Smith & Gerritis 2019). Levothyroxine replacement augments liver corticosteroid metabolism, consequently precipitating an adrenal crisis in an individual with low cortisol (Betterle et al 2004). It is therefore important to keep a high index of suspicion of primary adrenal insufficiency in patients with autoimmune hypothyroidism. It is also important to ensure sufficient testing is carried out to allow for appropriate glucocorticoid replacement to be given prior to levothyroxine replacement in affected individuals.
Conclusion
Ruling out adrenal insufficiency prior to thyroxine replacement in a patient with hypothyroidism is vital given the co-existence of these autoimmune conditions.

The VON Hippel-Lindau Disease, report of two cases and literature review

Benabdelatif Katia[1], Aicha Lachkhem[2], Khaldi Hassiba[2], Bensalah Meriem[3] & Ould Kablia Samia[2]
[1]Central Military Hospital, Endocrinology, Algeria, Endocrinology, Algiers, Algeria; [2]Central Military Hospital, Endocrinology, Algeria, Endocrinology, Algiers, Algeria; [3]Central Military Hospital, Endocrinology, Algeria, Endocrinology, Alger, Algeria

Background
Von Hippel–Lindau (VHL) is a rare, autosomal dominant syndrome characterized by the development of highly vascularized tumors in multiple organs. VHL affects approximately 1 in 35,000 live births. Tumors associated with VHL include hemangioblastom of the retina and central nervous system, pheochromocytomas, endolymphatic sac tumors of the middle ear, and epididymal or round ligament cysts. In 80% of patients, VHL disease is familial caused by mutations in the *VHL* gene and in about 20% of cases results from de novo mutations. Penetrance is 90% by the age of 65 years, with the mean age at diagnosis being 26 years.
Case Report
We reported two cases of VHL disease reveled by different clinical presentation: pheochromocytoma and cerebellus hemangioblastoma, at different age 48 and 26 years old. Both had the complete spectrum of disease included cerebellus hemangioblastoma, retinal hemangioblastoma, pheochromocytoma, pancreas tumors and renal cell carcinoma.
Conclusion
The von Hippel-Lindau disease is a familial cancer predisposition syndrome. Regular follow-up, early detection and management of tumors reduce morbidity and mortality.

Descriptive analysis of pheochromocytomas and paragangliomas in the southern area of Granada

Javier García, Enrique Redondo, Maria Dolores Aviles Perez, María del Carmen Andreo-Lopez, Elena Martínez & Pablo J López- Ibarra Lozano San Cecilio Clinical University Hospital, Endocrinology and Nutrition, Granada, Spain

Introduction and Objectives
Pheochromocytomas and paragangliomas are rare neuroendocrine tumors derived from enterochromaffin tissue, mostly catecholamine-producing, adrenal gland (PCC) or extra-adrenal paraganglia (PGL). We were struck by the high incidence of these in our health care area, so we decided to study them. The aim of this work is to evaluate the clinical characteristics and epidemiological factors of patients diagnosed with PCC or PGL.
Material and Methods
Retrospective descriptive observational study analyzing patients diagnosed with PCC or PGL at the Hospital Universitario Clínico San Cecilio of Granada from 01/01/2018 to 31/122021. Clinical, radiological and pathological variables are measured. The analysis was performed with SPSS 15.0.
Results
18 cases were diagnosed in 4 years, which is equivalent to a mean incidence of 10.27 cases/1000000 people/year, which is higher than the figure described in the literature (2-8 cases/1000000 people/year). 15 were PCC and 3, PGL, 72.2% were women, with a mean age of 49.17 ± 15.59 years. The 61.2% were diagnosed by compatible symptoms, 27.8% were incidentalomas and 11.1% by screening in mutation carriers. The mean size measured by CT was 45.22 ± 23.02 mm. Tc-99m MIBI scintigraphy was also performed in 72.2% of cases, with positive uptake in 76.9%. Chromogranin A was elevated in 80%. Genetic test was performed in 76.5%, 5 of them had mutations. Sixteen of the 18 were operated by laparoscopy and alpha and beta blockade was performed in all of them and previous embolization in 2 of them.
Conclusions
Our suspicion about the high incidence of these tumors in our area is confirmed. We see that the diagnostic form is very varied. We found 38.46% of hereditary forms, in agreement with what has been described in the literature, 83.3% presenting some predictive factor of greater aggressiveness. We did not find any case with metastasis.

EP89

Pheochromocytomas: presentation and diagnosis

Sahar Abidi , Sabrine Mekni, Sawsen Essayeh, Cherchir Faten, Wafa Ben Hilel, Nadia Mchuirgui, Ibtissem Ben Nacef, Imen Rojbi & Karima Khiari
Charles Nicolles Hospital, Endocrinology Department, Tunis, Tunisia

Introduction
Pheochromocytomas are rare, mostly benign catecholamine-producing neuroendocrine tumors. Clinical manifestations are heterogenous, including persistent or paroxysmal hypertension, sweating, palpitation and headaches known as Menard triad. Diagnostic approach is based on demonstration of catecholamine excess and tumor localization. Our study aimed to describe clinico-biological and radiological features of pheochromocytomas.
Methods
We conducted a retrospective study including 34 patients with pheochromocytoma, who were admitted into the endocrinology department of Charles Nicolle hospital from 2005 to 2022. Data were extracted from medical records.
Results
The mean age at diagnosis was 48.1 ± 14.3 years [extremes:14-72] with a sex ratio (F/M) of 2.4. Hypertension, diabetes, coronary disease and chronic kidney disease were detected in 77, 27, 6 and 20% of cases, respectively. Screening for pheochromocytoma was motivated by adrenal incidentalomas, resistant hypertension, hypertension at a young age and Menard triad in 59, 12, 18 and 12% of cases, respectively. The median (IQR) metanephrine level was 200 (112.5-1369.5) µg/day and median (IQR) normetanephrine level was 1233.5 (565-5199.3) µg/day. On computed tomography, 53% of cases had a right adrenal tumor. Only one patient had bilateral tumors. Mean tumor size was 49.4 ± 22.6 mm [extremes :10-100]. I-123 MIBG scintigraphy was performed in only nine patients with positive uptake.
Conclusion
Pheochromocytomas presentation is highly variable and can mimic other diseases. Because of cardiovascular complications, pheochromocytomas represent a potentially lethal condition, thus requiring early identification and management.

Multifocal paraganglioma due to SDHB mutation: On purpose of one clinical case

Pablo Ferreira-Ocampo, Sandra Carolina Doejo Marciales, Solange Fabiola Barra Malig, Remy Edward Astuñague Condori, Pablo Lois Chicharro, Francisca Almodóvar Ruiz, Juan José Gorgojo Martínez & Helena Requejo Salinas
Hospital Universitario Fundación Alcorcón, Endocrinology, Metabolism and Nutrition, Alcorcón, Spain

The mutations of succinate dehydrogenase subunits (SDHA, SDHB, SDHC, SDHD) are linked with a predisposition to develop pheochromocytoma and paraganglioma, often in diferent locations of the body. With greater acces to genetic tests, current estimations suggest that 40-50% of pheocromocytoma and paraganglioma cases are inherited and half of them are due to SDH mutations. These mutations can be associated with other tumours like renal carcinomas, gastrointestinal stroma tumours and pituitary adenomas. Affectation of subunit B is described with the most probability of malignant illness in the type 4 paraganglioma syndrome. We report a case of a patient who presented with multifocal paraganglioma and prolactinoma secondary to SDHB mutation, followed in our center in Alcorcon (Madrid) in the year 2022.
Case Report
24 year old woman with no medical background and no remarkable familiar history. Derived after finding of pituitary macroadenoma on MRI (23×14×17 mm imprinting optic chiasma) in the context of amenorrhea and elevated serum prolactine (266 ng/ml). This study also inform a incidental lesion in left yugular región inferior to craneal base, that could be a 34 mm tympanic glomus. With normal visual field testing, Cabergoline is initiated to manage hyperprolactinemia and reduce macroadenoma volume. Posterior hormone study only detected subtle elevation of noradrenaline and normetanefrine in 24 hours urianalysis. MIBI-scintigraphy was negative in the possible glomus but there was pathologic deposit in the mid abdomen which was described in a subsequent body CT as another 30 mm intrabdominal paraganglioma. Confirmed these two hypermetabolic nodules in a 18-FDG PET imaging with high expression of somatostatin receptors in a Octreoscan. We decided to first resect the abdominal nodule with previous alfa-blocking with Doxazosine, confirming histological and inmunohistochemical characteristics of sympathetic paraganglioma. The genetic study demonstrated that the patient bear the mutation c166_170CCTCA of the SDHB gene. Surgery of the yugular lesion was dismissed, opting for radiotherapy. Currect prolactine and catecholamine values are normal. Genetic screening of the patient's family still pending.
Conclusion
Mutations causing the pheochromocytoma/paranganglioma can be linked with pituitary adenomas, specially the SDH ezymatic complex. Genetic screening should be performed in all patients with these two entities alongside with a mangement in accordance with practice guidelines.

EP91

Connshing syndrome: A case of late appeal and dilemmas in the diagnosis

Evgeniia Kolpakova, Arina Krainyaya, Alla Tskaeva, Marina Yukina, Nadezhda Platonova & Ekaterina Troshina
Endocrinology Research Centre, Institute of Clinical Endocrinology, Moscow, Russia

Introduction
Connshing syndrome is a rare disease characterized by mixed overproduction of mineralocorticoids and glucocorticoids from adrenal adenoma. We will describe a clinical case that illustrates a rare combination of aldosterone-cortisol co-secreting formation of the left adrenal gland against a background of bilateral macronodular adrenal hyperplasia, and the role of diagnostic methods in determining appropriate tactics for patient treatment.
Case Description
In January 2022, 49-year-old male was admitted to the Endocrinology Research Centre with complaints of increased blood pressure of 220/110 mm Hg, despite multicomponent antihypertensive therapy. According to the hormonal profile, primary hyperaldosteronism was confirmed (aldosterone 2770 pmol/l was increased, renin 0.5 mU/l, and hypokalemia was 2.71 mmol/l against a background of discontinuation of drugs that affect the renin-angiotensin system). ACTH-independent hypercortisolism was confirmed (cortisol in saliva in the evening was 60.33 nmol/l, dexamethasone suppression test was negative (cortisol was 238.8 nmol/l in the morning), ACTH in the morning was 4.88 pg/ml) . Once spironolactone (250 mg per day) was introduced in addition to moxonidine (0.6 mg per day), nifedipine (90 mg per day), doxazosin (6 mg per day), the patient's blood pressure and potassium was stabilized. As a result of MSCT of the abdominal cavity, the formation 30×35×41 mm in the left adrenal gland and the formation is 32×18×17 mm in the right adrenal gland were observed. The density was 17 HU in the native phase in the left adrenal gland, the absolute washout coefficient was 93%, the density was 9 HU in the native phase in the right adrenal gland, the absolute washout coefficient was 72%. To lateralize the side of aldosterone hyperproduction, adrenal vein sampling was performed. Unilateral hyperproduction of aldosterone on the left was confirmed (selectivity coefficient on the left was 27.5, on the right was 4.2 (both more than 3.0). The lateralizing gradient on the left was 2.8 (more than 2.0). Taking into account hypercortisolemia, a calculation was carried out on plasma normetanephrine levels. Laparoscopic left-sided adrenalectomy was performed in August of 2022. After surgical treatment, spironolactone was discontinued, but the patient was forced to take multicomponent antihypertensive therapy due to nephropathy (C3bA3) and a long history of arterial hypertension due to untimely treatment.
Conclusion
Primary hyperaldosteronism is associated with increased cardiovascular risk, and hypercortisolism increases the risk of developing diabetes mellitus and osteoporosis. This case demonstrates the consequences of a late diagnosis of the mixed overproduction of mineralocorticoids and glucocorticoids caused by adrenal adenoma.

A case of a black adrenal adenoma with autonomous cortisol secretion

Catarina Cidade-Rodrigues[1], Francisca de Brito Marques[2] & Isabel Palma[3]
[1]Centro Hospitalar do Tâmega e Sousa, Endocrinology, Penafiel, Portugal; [2]Hospital Pedro Hispano, Unidade Local de Saúde de Matosinhos, Endocrinology, Porto, Portugal; [3]Centro Hospitalar Universitário do Porto, Endocrinology, Diabetes and Metabolism, Porto, Portugal

Introduction
Adrenal incidentalomas are a frequent finding (1.4-7.3% on abdominal CT) and increasingly common with age, obesity, diabetes and hypertension. When approaching adrenal masses, clinicians should exclude malignancy and hormonal hypersecretion. Black adrenal adenomas (BAA), first reported in 1938, are rare benign adrenocortical tumours with black/brown appearance, containing lipofuscin. Most are non-functional, rarely inducing hypercortisolism. We present a case of a woman with a BAA and autonomous cortisol secretion(ACS), with great response to surgery.
Case Report
Female, 58 years-old. Referred to the Endocrinology consult in February 2019 for a left adrenal incidentaloma, diagnosed in 2017, in a colon cancer follow-up CT. She complained of insomnia but denied headaches, hypertensive crisis, spells, proximal muscular weakness, weight gain, hirsutism, previous cardiovascular events. Medical history: arterial hypertension, type 2 diabetes *mellitus*, dyslipidemia, depression, and colon carcinoma treated with right colectomy in 2017. Medication: perindopril, indapamide, amlodipine, metformin, dulaglutide, empagliflozin, insulin glargine, lorazepam, venlafaxine, mirtazapine, amissulpride, rosuvastatin and ezetimibe. No relevant family history. Physical examination: round facies and supraclavicular fat pads. Weight 68.5 kg, height 1.50 m, BMI 30.4 kg/m2. BP 120/80 mmHg, HR 95 bpm. No hirsutism, *acantosis nigricans*, abdominal striae or bruising. Initial workup showed urinary free cortisol 129.6 and 118.24 µg/24 h, cortisol after 1 mg dexamethasone 13.1 and 16.9 µg/dl, urinary free cortisol in spot urine 36.2 nmol/mmol Cr, late-night salivary cortisol 0.278 µg/dl and 0.258 µg/dl, ACTH < 5.00 pg/ml. Plasma and urinary metanephrines, aldosterone-renin ratio, TSH, creatinine and potassium were normal. HbA1c 10.9%, total cholesterol 127 mg/dl, triglycerides 333 mg/dl, LDL-c 23 mg/dl. CT: Nodule in the left adrenal gland, 25 mm, density not compatible with adenoma. MRI: Solid oval nodule in the left adrenal gland, 25 mm, absence of fat content. Osteodensitometry: lumbar spine T-score -3.4.
Diagnosis
Adrenal adenoma with ACS and multiple comorbidities (hypertension, hypertriglyceridemia, diabetes and osteoporosis).
Treatment
Left adrenalectomy in June 2021. Histology: cortical adrenal adenoma. Abundant pigment suggesting a black adenoma. Follow-up: She lost 13 kg and suspended insulin and most hypertensive agents. Transient hypocortisolism, treated with hidrocortisone. HbA1c 6.3%, morning cortisol 3.4 µg/dl, ACTH 39.5 pg/ml, total-cholesterol 122 mg/dl, triglycerides 363 mg/dl, LDL-c 38 mg/dl.
Discussion
This case highlights the importance of treating hypercortisolism to effectively control its comorbidities, cardiovascular risk factors and quality of life. In our patient, ACS originated from a BAA. Functional BAAs usually exceed 20 mm in diameter, which was the case of our patient. After surgery, there was marked

improvement of hypercortisolism-associated conditions. Therefore, early detection of Cushing syndrome in adrenal incidentalomas is essential, especially when multiple comorbidities are present and undercontrolled with medication.

Adrenal Venous Sampling in a patient with bilateral adrenal adenomas and Cushing's syndrome

Christina Limniati[1], Vasileios Nikolaou[2], Magdalini Georgiadou[2], Maria Vellios[3], Aikaterini Moustaka[3], Parthena Rizopoulou[3] & Charalampos Tsentidis[1]
[1]General Hospital of Nikea, Department of Endocrinology, Diabetes and Metabolism, Nikea, Greece; [2]General Hospital of Nikea, Department of Radiology, Nikea, Greece; [3]General Hospital of Nikea, Hormonal Laboratory, Nikea, Greece

Introduction
Adrenal Cushing's syndrome accounts for 15-20% of all the causes of endogenous hypercortisolism, mainly due to unilateral adenomas and adrenal cancer. Approximately 9-17% of patients with ACTH-independent Cushing's syndrome have bilateral adrenal adenomas. Subsequently, their management is quite demanding. The main difficulty lies in distinguishing between a functional and a non-functional adrenal mass, since this cannot be reliably achieved by routine imaging and laboratory tests. Although adrenal-venous-sampling(AVS) is a widely used method for the diagnosis of primary hyperaldosteronism, it's utility in distinguishing bilateral or unilateral cortisol overproduction, has only been evaluated by a few studies.
Case Report
A 68-year-old man, was referred to our department due to severe osteoporosis and vertebral fractures. The patient had a history of 4.5 cm right adrenal adenoma known for the past 15 years. At that time, according to the clinical evaluation and laboratory findings, no adrenal dysfunction was detected and the possibility of malignancy was ruled out. For this reason, despite medical recommendations, he did not wish to be operated on. However, 3 years ago, a slight increase in the size of the adenoma (5.5× 5.4 cm) and a marginally increased urinary-free-cortisol (UFC) 160 μg/24 h (20-90) were found. During the next months he reported low back pain, steadily worsening proximal muscle wasting and weakness, while the diagnosis of severe osteoporosis and vertebral fractures was made. Upon his arrival at our department, he had typical signs of hypercortisolism. New imaging and laboratory tests were performed. The Computed-Tomography (CT) showed the known adenoma, as well as the presence of a 1 cm adenoma in the left adrenal gland. Both, baseline and overnight 1 mg Dexamethasone-suppression-test (DST), cortisol and ACTH values, established the diagnosis of Cushing's syndrome. The patient underwent adrenal-venous-sampling (AVS), to determine the location of cortisol hypersecretion, because bilateral adrenalectomy was extremely likely. Adrenaline was used as reference hormone for Selectivity-Index(SI) and Lateralization- index (LI), and the results were compatible with hypersecretion of the right adenoma, therefore a right adrenalectomy was performed. The patient's postoperative course was satisfactory, with a gradual improvement of all the affected metabolic factors(especially bone metabolism). He continues to need hormone replacement with hydrocortisone one year after surgery.
Conclusion
Adrenal venous sampling (AVS), in patients with Cushing's syndrome and bilateral adrenal adenomas, is a useful tool, for distinguishing between bilateral and unilateral cortisol hypersecretion. However, the results require careful evaluation, along with clinical, biochemical and imaging findings. Larger studies are needed, to establish a specific method of performing and interpreting this test.

Case report: Management of Mild Autonomous Cortisol Secretion

Sanaa Bammou, Ekoundzola Joel Rudy, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
Mohamed VI University Hospital Center, Department of Endocrinology, Diabetology, Metabolic Diseases Nutrition, Marrakesh, Morocco

Introduction
Mild autonomous cortisol secretion (MACS) is a term used to describe biochemical evidence of abnormal cortisol secretion in patients with adrenocortical adenomas (ACA), but without the classical external manifestations of overt Cushing's syndrome (CS).
Materials and Methods
In this study, we report a case of patient who presents mild autonomous cortisol secretion among incidentally discovered adrenal masses; followed in unit of the endocrinology, diabetology, metabolic diseases and nutrition department of the Mohammed VI University Hospital of Marrakesh.
Case Report
A 68-year-old woman with a history of well-controlled hypertension and diabete presents to our department for etiological assessment of an adrenal incidentaloma.. adrenal scan confirms a diagnosis of an incidental right adrenal nodule measuring 27× 26 mm is also identified having an density of 33UH and washout >50%, the patient's physical examination is unremarkable and she does not have any overt Cushingoid features or midline back pain or paroxysmal attacks. Biochemical investigations revealed a morning cortisol following 1 mg of dexamethasone is 2 μg/dl .A normal serum potassium and methoxylated derivatives in urine are normal. A diagnosis of a mild autonomous cortisol secretion was made and given the relatively mild degree of cortisol excess and well-controlled Comorbidities a conservative management is chosen, she should undergo annual clinical reassessments. If she develops new or worsening cortisol-related comorbidities, she should undergo further biochemical testing and reconsideration of adrenalectomy.
Discussion
Mild autonomous cortisol secretion is a term used to describe biochemical evidence of abnormal cortisol secretion in patients with ACA, but without the classical external manifestations of overt CS, such as central muscle weakness, adipose tissue redistribution, and skin fragility. Various terms have been used to describe MACS, such as "subclinical Cushing's syndrome" and "subclinical hypercortisolism"; however, the term "subclinical" is inaccurate, as these patients present with higher prevalence of adverse cardiovascular risk factors, such as diabetes mellitus type 2 (DM2), hypertension, dyslipidemia, obesity, increased rates ofcardiovascular disease, metabolic bone disease, and highermortality rates, when compared with patients with nonfunctioning adrenal tumors (NFAT). The management of patients with an incidentally discovered adrenal adenoma who do not have overt Cushing's syndrome but who have MACS is more controversial as the available studies comparing outcomes of adrenalectomy vs conservative management have been generally small, observational in nature, and heterogeneous.
Conclusion
Future studies with adequate randomization and follow-up to assess adverse clinical endpoints are needed to determine the optimal management and follow-up of patients with MACS.

Primary hyperaldosteronism and renal failure: Diagnostic challenges, a case study

Bessaid Khadidja , Mouna Mezoued & Malha Azzouz
Bologhine Ibn Ziri, El Hammamet, Algeria

Introduction
The diagnosis of primary hyperaldosteronism (PAH) is based on the realization of the renin aldosterone ratio (RAR). The presence of renal insufficiency (RI) in a hypertensive patient complicates this diagnosis by affecting various biological assays.
Observation
We report the case of 25-year-old female, with a personal history of primary hypothyroidism, hypertension diagnosed at age 21 and severe renal insufficiency developed during a pregnancy carried to term at the age of 22. Creatinine clearance was 24 ml/min with a tendency to hypokalaemia. Computed tomography of the adrenal glands revealed a 17 mm left adrenal adenoma. The biological assessment showed an excess of aldosterone (2481 pmol/l) with an unsuppressed renin activity (16.02 mIU/l). The RAR came back positive at 154.69 ($n<64$). The diagnosis of Conn's syndrome was retained. The patient underwent left adrenalectomy with improvement in blood pressure and renal function.
Discussion
The interpretation of the RAR in the context of renal failure is difficult with few data in the literature. It has been previously reported that the RAR is higher in renal failure with a risk of false positives. Recent work has shown that renal insufficiency is on the contrary responsible for a reduction in the RAR by an

increase in renin with a risk of false negative results. In renal impairment, lower RAR thresholds should be considered.

Retrospective Evaluation and Characteristics of Bilateral Adrenal Masses Followed Up in the Endocrinology Clinic of Ondokuz Mayıs University Hospital Between 2008 and 2022

Sema Çapkinoğlu Türk, Betül Gündüz, Yusuf Kayhan, Elif Kılıç Kan, Aysegul Atmaca & Ramis Çolak
Ondokuz Mayıs University - Faculty of Medicine, Endocrinology and Metabolic Diseases, Samsun, Turkey

Background
Adrenal incidentalomas are defined as clinically silent adrenal masses >1 cm in size and are detected in up to 10% of patients during imaging procedures performed for unrelated conditions. 17% and 23% of incidentally detected adrenal lesions were reported to be bilateral. The bilateral adrenal tumors include metastasis, lymphoma, neuroblastoma, pheochromocytoma, adenoma and myelolipoma. Non-neoplastic bilateral adrenal masses include infectious processes and hematomas.
Methods and Design
A retrospective review of all patients with bilateral adrenal masses who are detected in Ondokuz Mayıs University Endocrinology Clinic from 2008 to 2022 was performed. Gender, patient and diagnosis age, diameter and HU of each masses, follow- up time, imaging type, basal cortisole, ACTH, DHEAS and 17-OH Progesterone level, 1-mg dexametahasone supression test (DST) and 2-day-2 mg DST, DHEAS, 17-OH Progesteron, plasma Aldosteron(PA), plazma Renin activity(PRA), PA/PRA ratio, Saline Infusion Test, adrenal venous sampling, 24-hour-urine catecholamines and if operated, type and localization is reported.
Results
In this study, 222 patients was involved. The median age of all patients was 62.22 (range 51-72 years) and median diagnosis age was 57.58 (47-67 years). 50.2% ($n=127$) was women and 42.8% ($n=95$) was men. 120 patients (54.1%) had non-functional adenomas while 10 (4.5%) had cushing, 4 (1.8%) had pheochromocytoma, 8 patients (3.6%) had primary hyperaldosteronism, 1 (0.5%) had myelolipoma, 7 (3.2%) had other metastatic malignancies, 17 had mild autonomous cortisol secretion (MACS) and 55 (24.8%) was not properly followed. 191 patients (89.3%) didn't have any operation, while 10 (4.7%) underwent right, 9 (4.2%) left and 4 (1.9%) bilateral adrenalectomy. The operation types were 18 (78.3%) laparoscopic and 5 (21.7%) open. 23 patients that underwent adrenalectomy had a follow up of median 16 (0-187) months, while the remaining 191 (0-122) patients had a follow-up of median 5 months (P: 0.031). Diameter of right adrenal was 40 mm for the operated ($P<0.001$). Left adrenal diameter was 22 mm for the operated group(P: 0.032). 208 patients who had 24-hour-urine catecholamines sample, 4 (17.4%) were elevated in the operated group and 3 (1.6%) were elevated in the non-operated (P: 0.003). The diagnosis for the masses were also statistically significant in the operated group ($P<0.001$).
Conclusion
Most of the bilateral masses were non-functional. Cortisol and aldosterone secretion are the main causes of functional adenomas. No cases of primary adrenal malignancy were diagnosed besides that metastatic malignancies. Mass diameter for both sides and follow up time were increased in the operation group.

Exogenous hypercortisolism after long-term transcutaneous use of clobetasol propionate in the treatment of psoriasis (a clinical case)

Ina Darashkevich[1], Tatsiana Mokhort[2], Olga Martinkevich[3], Ina Cossack[3], Lola Nikonova[1], Tatiana Litvinova[3] & Marina Ershova[3]
[1]Grodno State Medical University, Grodno, Belarus; [2]Belarusian State Medical University, Minsk, Belarus; [3]Grodno University Clinic, Grodno, Belarus

The use of topical corticosteroids in the treatment of dermatosis, which includes psoriasis, is a common approach. With local use of corticosteroids, an increase in the concentration of corticosteroids in the area of the inflammatory process is noted, therefore local corticosteroids are believed not to have a suppressive effect on the function of the adrenal glands.
Purpose
To demonstrate a side effect of hypercortisolism after uncontrolled long-term use of clobetasol propionate in the treatment of psoriasis.
Materials and Methods
The patient's salivary cortisol levels, as well as repeated study of cortisol and ACTH in blood plasma were determined. The patient underwent a biochemical blood test and glucose level was determined. MRI of the pituitary gland with contrast and CT scan of the adrenal glands were performed.
Results and Discussion
A 42-year-old female patient, who has been suffering from a common form of psoriasis for more than 10 years, complained of weight gain of 15 kg over the past year and stretch marks on the skin. For the last 1.5 years, she has been using clobetasol propionate 0.5 mg/g (25 g) and applied to the skin daily (without doctor's recommendations). Approximate equivalent doses of the drug in terms of prednisolone amounted from 36 mg to 72 mg per day. On examination matronism, "Cushingoid" body features, wide purple striae on the skin, psoriatic plaques on the entire surface of the body and skin of the forearms were revealed. Biochemical examination revealed hypoproteinemia and hypoalbuminemia and hyperglycemia. A hormonal study showed a suppressed level of plasma cortisol of 18.6 and 5.78 (normal value is 166-507 nmol/l), salivary cortisol (once) at 23:00 - 0.11 (normal value is 0.2-4.0 pg/ml) while maintaining a normal level of ACTH - 23.0 and 21.1 (normal value is 7.2-63.3 pg/l). Contrast-enhanced MRI of the pituitary gland (data on the adenoid pituitary gland were not obtained) and CT scan of the adrenal region (no structural sampling was identified) were performed. After the abolition of clobetasol propionate clinical signs of adrenal insufficiency were noted (hyperkalemia - 5.9 mmol/l., hypoglycemia - 2.9 mmol/l, a decrease in blood pressure to 85/70 mm Hg., the level of cortisol - 0.01 nmol/l). Thus, exogenous hypercortisolism was diagnosed. Secondary adrenal insufficiency due to long-term use of glucocorticoids was revealed. Replacement therapy with prednisolone 7.5 mg/day was prescribed; during the follow-up period (1 year), the daily dose of prednisolone decreased to 5 mg per day.
Conclusion
Clobetasol propionate has a marked inhibitory effect on the hypothalamic-pituitary-adrenal axis.

Adrenal insufficiency secondary to steroid withdrawal: A Case Report

Qetevan Gvazava[1,2], Nino Zavrashvili[1,2], Ketevan Chanturishvili[1,2], Natia Margvelashvili[1,2] & Natia Shonia[1,2]
[1]Tbilisi Institute of Medicine, Endocrinology, Tbilisi, Georgia; [2]David Tvildiani Medical University, T'bilisi, Georgia

Introduction
Glucocorticoids are widely used for their anti-inflammatory and immunosuppressive properties. Prolonged administration of synthetic glucocorticoids is one of the most common cause of ACTH deficiency and consequent adrenal insufficiency. Exogenous glucocorticoids interfere with and suppress HPA axis and abrupt steroid withdrawal leaves body susceptible to adrenal insufficiency. Symptoms can range from adrenal crisis to nonspecific complains of fatigue, nausea and unexplained fever. Moreover, clinical picture of adrenal insufficiency can be obscured by patient's concomitant conditions. Timely diagnosis and treatment is essential for patients with adrenal insufficiency.
Case Report
We present a case of 45 year old female, who presented to the ER with nausea, vomiting, increasing fatigue and dysuria. On further examination, patient was found to be hypotensive and had fever. Patient's medical history was significant for motor vehicle trauma that left her paraplegic and type 2 diabetes mellitus controlled with metfromin. Diagnosis of complicated UTI was made by clinical and laboratory findings and appropriate antibiotic therapy was started. Patients

condition slightly improved but she remained hypotensive and febrile. Endocrine consultation for diabetes mellitus, revealed that patient started taking dexamethasone for Covid-19 infection that improved her energy and continued to take it irregularly for 6 months without proper medical supervision. Two weeks before presentation to the ER, patient abruptly stopped taking dexamethasone. Diagnosis of adrenal insufficiency secondary to steroid withdrawal was suspected, IV hydrocortisone was started empirically with close monitoring. Patient's condition began to improve, she became afebrile and more active, her blood pressure and electrolytes stabilized. After a week, patient was discharged home with detailed plan of steroid tapering and frequent follow-ups.

Conclusion

Steroid withdrawal and adrenal insufficiency is rare and under diagnosed condition. Diagnosis of this condition remains a challenge for clinicians, as, patients may present to the ER with vague, nonspecific symptoms. While hypotension, gastrointestinal symptoms and electrolyte abnormalities are common presenting manifestations, fever as an additional possible sign of adrenal insufficiency should be kept in mind. Considering that clinical picture of adrenal insufficiency can vary greatly, it is important to take detailed medical history and to keep a high level of suspicion. Adrenal insufficiency can be life-threatening; therefore, it is crucial to diagnose and treat this disorder in time. When adrenal crisis is suspected, treatment should not be postponed for detailed diagnostic workup. Proper patient education and close monitoring of steroid tapering cannot be understated.

Cardiovascular repercussions of glucocorticoid replacement therapy in patients with Addison disease

Khouloud Boujelben, Dhoha Ben Salah, Hamdi Frikha, Faten Haj Kacem Akid, Mouna Mnif, Fatma Mnif, Nadia Charfi, Nabila Rekik Majdoub, Mouna Elleuch & Mohamed Abid

Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction

Glucocorticoid replacement therapy may result in long-term morbidities, including cardiovascular diseases which can increase cardiovascular risk. The study was aimed to assess the impact of life-long glucocorticoid replacement therapy on cardiovascular parameters in patients with Addison disease (AD).

Patients and Methods

This cross-sectional study was conducted assess cardiovascular events in patients followed for AD for at least 5 years, in the Endocrinology department of Hedi Chaker University hospital, Sfax,Tunisia, from March 2020 to July 2021.

Results

The mean age of patients was 49.5±13.9 years (18-78 years) with glucocorticoid replacement duration of 13.9 ±8.7 years (5-35 years). High blood pressure (52%) and diabetes mellitus (52%) were the most prevalent family histories. No patient had hypertension or carbohydrate metabolism disorder at the time of AD diagnosis. Average body mass index (BMI) was 28.1 kg/m^2 (21.2-45.8 kg/m^2). Overweight and obesity were recorded in 48% and 26% of patients, respectively. Carbohydrate metabolism disorder was depicted in 38% of patients after a mean glucocorticoid replacement duration of 17.5±5.4 years. Among those patients, 31.6% developed type 2 diabetes. Patients with diabetes type 2 diabetes had longer duration of glucocorticoid use (19.8 ±9.9 years vs 13.2 ±8.4 years, P=0.1) and higher daily and cumulative glucocorticoid dose (27.5±5 mg/day vs 25.6 ±6.9 mg/day, P=0.4; 506, 2±277, 2 mg vs 355, 4±282, 9 mg P=0.1) than those with normoglycemia, but without significant correlation. Sixteen percent of patients developed hyperlipidemia after a mean glucocorticoid replacement duration of 13.6 years (mixed dyslipidemia in 5 patients, isolated hypercholesterolemia in one patient, hypertriglyceridemia in 2 patients and low HDL-cholesterol level in 5 patients). As well, patients having disturbed lipid balance had higher daily glucocorticoid dose but without significant difference (26.5±7.1 mg/day vs 25.6±6.7 mg/day,P=0.7). Hypertension occurred in 14% of patients after a mean glucocorticoid use duration of 9.5 years (2-21 years) and two patients developed coronary artery disease. There was no significant correlation between hypertension and cumulative hydrocortisone dose nor duration of glucocorticoid replacement therapy. Metabolic syndrome was noted in 24% of patients and its occurrence was significantly correlated with daily hydrocortisone dose (26.9 ±6.6 mg/day vs 22.3 ±5.9 mg/day, P=0.04).

Conclusion

Our results underline the importance of close monitoring of cardiovascular risk factors in patients with AD in order to reduce cardiovascular repercussions of long-term glucocorticoid replacement therapy.

EP100

Delayed partial primary hypoadrenalism following therapeutic and imaging radiation exposure of the adrenal glands

Genevieve Tellier[1], Rhiannon Berkeley[1], Catrin Searell[2], Ffion Wood[2] & Anthony Wilton[1]

[1]Betsi Cadwaladr University Health Board, Endocrinology, Bangor, United Kingdom; [2]Betsi Cadwaladr University Health Board, Clinical Biochemistry, Bangor, United Kingdom

A 73 year old female presented with a 5-year history of fatigue, anorexia and weight loss of 15 kg. Her primary care physician recorded a 09:00 h cortisol of 163 nmol/l. Previous medical history was one of abdominal diffuse B-cell lymphoma 9 years earlier treated with 6 cycles of R-CHOP (rituximab, cyclophosphamide, doxorubicin and prednisolone) followed by CT-guided radiotherapy. Medications were transcutaneous buprenorphine 20 mg/hour, aspirin 75 mg od and omeprazole 20 mg od. Examination confirmed a weight of 40.8 kg (55 kg 5 years earlier), signs of weight loss and supine blood pressure 180/90 mmHg with no postural drop. Pigmentation was absent. The initial impression was one of opiate-induced hypoadrenalism. Investigations at 09:00 h confirmed cortisol 268 nmol/l, ACTH 149.6 ng/l, fT4 11.0 pmol/l, fT3 5.2 pmol/l, TSH 1.75 mU/l, FSH 88.6 IU/l, LH 21.5 IU/l, prolactin 251 mU/l, IGF-1 9.5 nmol/l, sodium 136 mmol/l, potassium 4.1 mmol/l, creatinine 39 mmol/l and eGFR >90 ml/min suggesting a diagnosis of primary hypoadrenalism but adrenal antibodies were negative. Further investigations at 09:00 h confirmed cortisol 244 mmol/l, ACTH 273.3 ng/l, DHEAS <0.3 umol/l, androstenedione <0.4 nmol/l, testosterone <0.4 nmol/l, plasma renin activity 0.2 nmol/l/hour, aldosterone 337 pmol/l, followed by a Short Synacthen test with cortisol levels 404 nmol/l and 419 nmol/l at 30 and 60 minutes respectively. Review of previous imaging identified 12 CT scans (3 pre-treatment and 9 post-treatment) which confirmed a decreased adrenal size latterly. Treatment with replacement dose of hydrocortisone resulted in resolution of symptoms and weight gain of 7.4 kg over 2 months. Repeat plasma renin activity and aldosterone respectively on treatment were 0.7 nmol/l/hour and 99 pmol/l supine and 0.7 nmol/l/hour and 144 pmol/l standing. We interpret the results as indicating decreased cortisol synthesis (in the zona fasciculata) and DHEAS, androstenedione and testosterone (in the zona reticularis) with preservation of aldosterone synthesis (in the zona glomerulosa) of the adrenals. The zona fasciculata and reticularis cells comprise 75% and 10% of the volume of the adrenal cortex and their loss would explain the decreased adrenal size and impaired steroid synthesis pattern. Acute effects of therapeutic radiation on the appearance and function of the adrenal glands have been reported but not so chronic. We postulate that the combination of therapeutic radiation with superimposed imaging radiation caused the loss of adrenal cell mass and the steroid synthesis abnormities recorded and possible mechanisms of such.

EP101

Aggravation of depressive symptoms after biochemical cure of Cushing syndrome

Sandra Arbunea-Ghenoiu[1], Alexandra Piser[1], Cristina Capatina[1,2] & Catalina Poiana[1,3]
[1]C.I.Parhon national Institute of Endocrinology, Pituitary and Neuroendocrine Pathology, Bucharest, Romania; [2]Carol Davila UMPh, Endocrinology, Bucharest, Romania; [3]Carol Davila UMPh, Pituitary and Neuroendocrine Pathology, Bucharest, Romania

Introduction
Endogenous Cushing syndrome (CS), is associated with significant morbidity (metabolic, cardiovascular, bone, psychiatric complications among others). Most complications tend to improve if hypercortisolism is controlled but some are only partially reversible or even experience temporary exacerbation.
Patients and Methods
We report 2 cases of adrenal Cushing Syndrome (CS). The first is a 72 years-old female with CS caused by bilateral macronodular adrenal hyperplasia (complicated by diabetes mellitus, arterial hypertension and osteoporosis), treated by bilateral adrenalectomy. The second patient was a 45 years- old female with CS caused by left adrenal adenoma complicated by arterial hypertension and diabetes mellitus, treated by left adrenalectomy.
Results
In the first case the postoperative evolution was complicated by severe gastrointestinal candidiasis (discovered after repetitive episodes of adrenal insufficiency despite adequate replacement with gluco- and mineralcocorticoids) and severe depressive symptoms. These necessitated starting antidepressive medication (tianeptine) with slow control of symptoms over 18 months. In the second case postoperatively the only significant symptom occurring during adequate replacement during the initial months was very severe invalidating depression, slowly improving over several months under treatment with mirtazapine and fluoxetine.
Conclusions
Shortly after successful control of hypercortisolism in certain patients exacerbation or occurrence of serious psychological/psychiatric problems is possible so all patients should be evaluated and followed closely by the endocrinologist which should promptly liaise to psychiatric team whenever needed.

DOI: 10.1530/endoabs.90.EP101

The coexistence of primary adrenal insufficiency and systemic diseases: About two cases

Dorra Dorraelguiche, Bchir Najla, Annaam Ben Chehida, Salma Salhi & Zouaoui Chadia
Haroun Ouertani Military Hospital, Endocrinology, Tunia, Tunisia

Introduction
The majority of systemic diseases result from an autoimmune process. Primary adrenal insufficiency (Addisson's disease AD) is also frequently caused by an autoimmune process. Their association is rare but can be seen in the framework of autoimmune polyendocrinopathies. We report 2 observations associating an autoimmune adrenal insufficiency with a systemic disease.
Observation 1
We describe the case of a 50-year-old patient initially admitted to the intensive care unit for vomiting, diarrhea and acute dehydration. Physical examination showed melanoderma and hypotension at 80/60 mm hg.A baseline blood sample revealed hyponatremia (127 mmol/l) and hyperkalemia (5.6 mmol/l). Thus,Acute adrenal insufficiency was suspected. The patient immediately received intravenous hydrocortisone hemisuccinate with hyperhydration. The diagnosis of AD was confirmed by a low plasma cortisol level (50 nmol/l) in the face of high adrenocorticotropin hormone (ACTH) level = 1250 pg/ml). Concerning the etiological investigation, the detection of BK in the sputum analysis was negative, the chest X-ray was normal and the adrenal glands were eutrophic in the Computed tomography. However, the anti 21 hydroxylase antibodies were positive. In the framework of the search for other autoimmune diseases, we found a thyroid autoimmunity with positive ATPO of 412 UI/ml. Antinuclear antibodies, anti SSA, anti SSB and anti R052 were also positive. The patient was referred to the department of internal medicine for management of a Goujerot Sjogren syndrome in the context of very likely systemic lupus erythematosus.
Observation 2
We report the case of a 27-years-old patient who was diagnosed three years ago with Behçet's disease (BD) on the basis of the symptoms of BD triad, which included recurrent oral and genital aphthous, arthralgia and iritis. Recently, he consulted in our endocrinology department for recurrent hypoglycemia. The baseline cortisol level was low(152 nmol/l) and the adrenal insufficiency was confirmed by a stimulation test. ACTH level was high which indicated Addison's disease.
Discussion
Gougerot-Sjogren's syndrome is a systemic disease associated with a humoral immune response. The coexistence with AD has been reported in the literature. Several mechanisms could explain this association such as thrombosis of adrenal vessels,hemorrhage due to anti-phospholipid syndrome,vasculitis or direct organ involvement by an autoimmune process BD pathophysiology is controversial with conflicting data.It is believed that BD disturbs the regulation of immune system. Furthermore, few studies correlate BD with AD and found partially dysfunctional adrenal glands in BD patients.

Introduction
Pregnancy is characterized by increased secretion of estrogens and cortisol. Estrogen is used to prepare the maternal environment for the fetus. Cortisol induces a state of immunosuppression to avoid loss of the fetus, which, by definition, is at least partly a foreign organism. Parturition is characterized by estrogen and cortisol withdrawal. It leads to a rebound in immunity and may be accompanied by the development of autoimmune disease. Autoimmune thyroid disease is observed postpartum and may be related to this rebound in immunity. Rheumatoid arthritis (RA) is a systemic inflammatory autoimmune disease.
Aim
The aim was to present the cases of two female patients who developed RA postpartum after the birth of their second child.
Methods
The cases of two female patients aged 40 and 42 years, respectively, who developed RA postpartum after the birth of their second child are described.
Results
The patients went into menopause immediately following the birth of their second child. RA was RF(+) anti-CCP antibody (+) and led into hospitalization of the patients for a month following parturition. Corticosteroids were administered followed by methotrexate. In long-term follow up both patients required the addition of a biologic agent and are now in remission on treatment with methotrexate and a biologic agent at the age of 79 and 81 years, respectively.
Conclusions
Oestrogen and cortisol withdrawal may have led to the development of RA immediately postpartum in the cases described herein. The development of RA postpartum has been previously reported. Amongst a large cohort of RA patients 2 were reported to develop RA postpartum. RA flare has also been reported postpartum. Additionally, autoimmune thyroid disease is known to occur postpartum, an incidence, which may also be related to steroid hormone withdrawal. In conclusion, estrogen and cortisol withdrawal may reverse the immunologically beneficial maternal profile and may lead to the development of postpartum clinical autoimmune disease.

When pheochromocytoma occurs in the elderly: A case report

Fatima Toulali, Asmae El Hafiani, Lamya Echchad, Kaoutar Rifai, Iraqi Hinde & Mohamedelhassan Gharbi
Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction
Pheochromocytoma is a rare neuroendocrine tumor. It is usually diagnosed in subjects between 40 and 50 years of age. The occurrence of pheochromocytoma in the elderly is much rarer and has its own particularities. We report the case of a 70-year-old female patient with invasive pheochromocytoma.
Case presentation
A 70-year-old female patient with a history type 2 diabetes for 18 years on oral antidiabetics and insulin. The history of his disease goes back to a few months with an

important weight loss, and the installation of a menard triad made of headaches, sweats and palpitations. Exploration showed a suspicious adrenal mass on abdominal CT. Urinary methoxylate assays showed very high levels of metanephrines and normetanephrines. The patient underwent a laparoscopic right adrenalectomy. Pathological examination was in favor of an invasive pheochromocytoma. During the follow-up, the methoxylated derivatives assay was negative.
Discussion
Pheochromocytoma is a benign tumor that develops at the expense of chromaffin cells and secretes catecholamines. Clinical signs are dominated by permanent or paroxysmal hypertension. It rarely occurs in elderly subjects and symptoms may be more subtle and less specific in this age group. In our patient, pheochromocytoma was revealed by weight loss and Menard's triad. It is also more common in the elderly to develop multiple or malignant pheochromocytomas. In our patient the anatomo-pathological examination showed an invasive pheochromocytoma. A meticulous clinical examination and a regular medical follow-up are essential for the detection of pheochromocytoma in the elderly subject.

Clinical and biological features of late-onset congenital adrenal hyperplasia

Nassim Ben Hadj Slama, Taieb Ach, Ghada Saad, Gorchene Asma & Asma Ben Abdelkarim
University Hospital of Farhat Hached Sousse, Endocrinology, Sousse, Tunisia

Introduction
21-hydroxylase deficiency represents 95% of congenital adrenal hyperplasia. The non-classical form manifests in women mainly by hirsutism, menstrual disorders, or infertility. We present three patients' cases.Observations: Patient N.C., 17 years old, who presented with hirsutism beginning at the age of 8 years and progressively worsening after puberty. The patient had her menarche at the age of 9 years, with short and irregular menses. Her BMI was at 27 kg/m^2. Her height was at 166 cm (+1DS), her BP was at 11/8 cm Hg. She had severe hirsutism with a Ferriman-Gallwey score of 35, and she had signs of virilization such as clitoral hypertrophy (Prader 1). Biochemical hyperandrogenism was found with a total testosterone =1.1 ng/ml, S-DHEA=5370 ng/ml, and 4-androstenedione=7 ng/ml. ACTH was high at around 95 pg/ml. Baseline cortisol level was at 220 ng/ml. Baseline 17OH progesterone was 13.6 ng/ml. An abdominal CT scan did not show adrenal hyperplasia. Patient A.F., 18 years old, presented with peripubertal hirsutism. She has a sister with a classic form of congenital adrenal hyperplasia. Her menarche occurred at the age of 12, with irregular menses leading up to a 2-year secondary amenorrhea. On examination, BP was 12/8 cm Hg. Her height was at 152 cm (-1DS), and BMI was at 31 kg/m^2. She had severe hirsutism with a Ferriman-Gallwey score of 31. She did not show signs of virilization. Total testosterone =0.4 ng/ml, S-DHEA =2650 ng/ml, and 4-androstenedione was high at 6.1 ng/ml. ACTH was at 20 pg/ml. 17O-Progesterone response to standard dose synacthen stimulation test was as follows: T0: 11 ng/ml, T30: 42 ng/ml, and T60: 42 ng/ml. Microcystic ovaries were present on pelvic ultrasound. Patient S.B., 22 years old, who presented with post-pubertal-onset hirsutism and dysmenorrhea She had a family history of diabetes. Her menarche occurred when she was 14 years old. On examination, her BP=11/7, BMI:28 kg/m2, height: 155 cm, Ferriman-Gallwey score: 26, no signs of virilization. Total testosterone: 1.1 ng/ml Baseline 17OH-progesterone level: 34 ng/ml.
Discussion
In the late-onset form of congenital adrenal hyperplasia, the clinical presentation is that of peri- or postpubertal hyperandrogenism. Hirsutism is the most common manifestation. It may be associated with signs of virilization or short stature due to premature closure of the epiphyseal plate. Menstrual disorder and anovulation are related to the permanent production of estrogens due to the aromatization of hypersecreted adrenal androgens. PCOS may be present in some cases.

Comparison of The Clinical Course, Mortality and Morbidity Rate of the Covid 19 Disease in Patients with Cushing'' s Syndrome and Patients with Non-functional Incidentaloma

Narmin Huseynli[1,2] & Abdulla Serkan Yener[3]
[1]Dokuz Eylül Universitesi Hastanesi, İzmir, Turkey; [2]Dokuz Eylul University, Turkey; [3]Dokuz Eylül Üniversitesi Hastanesi, Turkey

Objective
Subclinical Cushing's Syndrome is defined as the condition of detecting moderate autonomic cortisol secretion, and it has many conditions such as diabetes, obesity, hypertension, osteoporosis, cardiovascular events, thromboembolic disease, dyslipidemia and immunosuppression comorbidities and with mortality having a relationship shown. Declared a global pandemic COVID-19 infection rapidly spreading with symptoms characterize andmortal one who can watch is a disease. COVID-19 in patients, especially respiratory have a failure in patients steroid in treatment is used in a certain phase when used steroid this treatment in the patient group important to prognosis extent of benefit provides many in the study shown. Subclinical Cushing Syndrome diagnosed patients infected with COVID 19 when, present endogenous cortisol of the height contribution to prognosis completely unknown. Endogenous cortisol height, during treatment applied with cortisol similar effect being or hypercortisolemia caused by immunosuppression status clinical disease your course to worsen are likely to contribute. This The aim of the study endogenous hypercortisolemia condition COVID-19 in patients prognosis whether your contribution that you are not is research.
Materials and Methods
Dokuz Eylul University, Faculty of Medicine, Department of Internal Medicine, Endocrinology in the Department of Science adrenal incidentaloma and Subclinical Cushing Syndrome follow-up and treated, 18 over age, (n=415) of patients biochemical examinations and viewing methods back records facing down examined, the same in time 01.01.2020- 01.10.2222 between COVID-19 testing to the results has been reached. This patientin groups COVID-19 course of illness and mortality rate was compared. Incidentaloma detected patients Subclinical Cushing Syndrome and non-functional adrenal incidentaloma in the form of patients divided into two groups. Sublinic Cushing Syndrome and non-functional incidentaloma diagnosed 1 mg of patients DST result cut off value is accepted as 1.8 µg/dl was done. Both among the group nominal variables that with square test compared.All analyzes SPSS (24.0) with the program done.
Results
In this study, we have done due to adenomas autonomous cortisol secretion there was no significant difference in the frequency of transmission of COVID-19 in patients who were diagnosed with the disease compared to the patients who did not produce hormones. At the same time, a 1 mg DST result of >1.8 µg/dl was not found to be associated with a complicated course in patients with COVID-19 positivity. However, in our study, it was found that the risk of developing complications in the course. of the COVID-19 disease increased 2.17 times in patients with SCS compared to patients with NFA.

Acute adrenal insufficiency revealed by a convulsive crisis

Chayma Besrour, Ibtissem Ben Nacef, Sabrine Mekni, Sawsen Essayeh, Nadia Mchirgui, Imen Rojbi & Karima Khiari
Charles Nicolle Hospital, Endocrinology, Tunis, Tunisia

Introduction
Adrenal insufficiency is defined as a deficit in the functioning of the adrenal cortex. The acute form represents a diagnostic and therapeutic emergency, but the clinical presentation is sometimes misleading.
Observation
We report the case of a 57-year-old patient with a personal history of vitiligo, who was suffering for two months from asthenia with abdominal pain and vomiting, then he presented with a generalized tonic-clonic convulsive seizure requiring his urgent transport to the neurology department. His blood pressure was at 100/70 mmHg and the Glasgow score at 14/15. Biology showed severe hyponatremia at 119 mmol/l with hyperkaliemia at 6 mmol/l. Hormone assay confirmed the diagnosis of acute adrenal insufficiency in the presence of cortisolemia <5 µg/dl with a high ACTH level at 102.6 ng/l. The patient was immediately put on hydrocortisone sodium succinate with a marked improvement. Complementary adrenal CT showed bilateral adrenal atrophy in favor of the autoimmune origin of the adrenal insufficiency.
Discussion
Acute adrenal insufficiency is a rare pathology but which involves the vital prognosis in the short term. It must always be suspected, particularly in the face of evocative ionic disorders or a clinical manifestation not explained by another pathology. It is mainly a therapeutic emergency, even without a positive diagnostic certainty.

Adrenocortical Carcinoma presenting as florid Cushing's Syndrome

Quazi Islam[1], Eleni Armeni[1,2], Ammara Naeem[1], Munachiso Nwokolo[1], Kalyan Shekhda[1], Efthimia Karra[1], Bernard Khoo[1], Dipesh Patel[1], Saroj Kumar Sahoo[1] & Ahmed Yousseif[1]
[1]Royal Free Hospital, London, United Kingdom; [2]National and Kapodistrian University of Athens, 2nd Department of Obstetrics and Gynaecology, Aretaieio Hospital, Athens, Greece

Introduction
Adrenocortical Carcinoma (ACC) is a rare endocrine neoplasm with poor prognosis, and an estimated incidence of approximately 2.5/1,000,000 patients. The functional state of these tumors varies from non-secretory (20%) to non-secretory. The latter category is subdivided into glucocorticoid-producing (45%) or glucocorticoid-androgen producing (45%) or androgen-producing only (10%). We report a case of a 35-year-old lady who initially presented with symptoms of Cushing's Syndrome and underwent adrenalectomy, with post-operative histology compatible with adrenocortical Carcinoma.
Case presentation
Health problems started 5 years ago, when she was diagnosed with Type 2 Diabetes Mellitus, on treatment with oral agents, at that time she underwent sleeve gastrectomy resulting to improved glycemic control and weight loss for the next 4 years. After this time, she started gaining weight again and her glycemic control deteriorated. A few weeks later, she was admitted to the hospital with complaints of diarrhea. Imaging with a Computed tomography of the abdomen and pelvis showed an incidental 30 mm left medial limb adrenal nodule with central focus of calcification with absolute washout of 76% is consistent with adrenal adenoma. A smaller 10 mm left adrenal nodule is also compatible with a lipid rich adrenal adenoma. Biochemical assessment showed failure to suppress adrenal function (overnight dexamethasone suppression test: pre-test cortisol 9 am 695 nmol/l, post-test cortisol 9 am 587 nmol/l; paired ACTH was suppressed to $<$1.5 ng/l pre-test; low-dose dexamethasone suppression test, post-test 227 nmol/l). The remaining biochemical screen showed raised 24-hour urinary free cortisol of 699 nmol/l (range 0-125 nmol/l/24 h), whereas levels of metanephrines, dehydroepiandrosterone, renin and aldosterone were not elevated. At this point, she started on Metyrapone 250 mg 8-hourly as well as hydrocortisone replacement dose, which resulted in an improvement of her glycemic control. The clinical and biochemical findings were discussed in the adrenal multidisciplinary meeting, which advised elective robotic adrenalectomy was made. The surgery was un-eventful with good pos-surgical recovery. Post-surgical histology report was compatible with a multinodular adrenocortical neoplasm, the largest with potentially aggressive behavior (Modified Weiss score: 3/9). Immunohistochemistry showed that the lesion is diffusely positive for inhibin and patchy positive for synaptophysin. Staining for calretinin and chromogranin is negative. MIB1 rate is $<$1%. The follow-up CT scan showed no evidence of recurrence.
Discussion
The radiological features of the lesion were not suggestive of ACC. The Surgical decision was made based on secretory nature of the nodule. It might be advisable to revise the radiological diagnostic criteria in future with emerging new radiological techniques.

It hit two targets with one arrow. A case report of Cushing's syndrome as a contributing cause for osteoporosis and thrombosis in a 64-year-old female

Marina Iliescu[1], Marius Mitrache[1,2], Raluca Stan[1], Ana Zubaci[1], Sabina Dumitrache[1], Iustina Grosu[1], Mihaela Tarna[1], Alexandra Bancu[1], Horatiu Dinu[3], Sergiu Barsan[4], Luminita Cima[1,2] & Simona Fica[1,2]
[1]Elias Emergency University Hospital, Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Elias Emergency University Hospital, Physical Medicine and Rehabilitation, Bucharest, Romania; [4]Elias Emergency University Hospital, Cardiology, Bucharest, Romania

Cushing's syndrome, whether it is ACTH-dependent or ACTH-independent, causes many complications due to chronic exposure of tissues to a glucocorticoid excess. Some of these are arterial hypertension, obesity, osteoporosis, coagulopathies, impaired glucose tolerance and diabetes. We present a case of Cushing's syndrome diagnosed in a 64-year-old female that was referred to the Endocrinology Department from the Physical Medicine and Rehabilitation Department due to multiple vertebral compression fractures and low T score in DXA scan in order to receive anti-osteoporotic treatment. Our patient was known with a history of arterial hypertension grade 3, dyslipidemia, chronic cigarette smoking, lumbar spinal stenosis managed via surgical intervention 3 months prior to our endocrine hospitalisation, left hip arthroplasty, uterine fibroid, intestinal occlusion, multinodular goiter. Physical examination showed an obese patient with central fat distribution, facial and thoracic telangiectasias, high blood pressure, and a systolic murmur. During the screening for endocrine causes of osteoporosis, hormonal tests revealed normal values, except an inadequate supression of 8 am cortisol level after 1 mg overnight of dexamethasone. Subsequent investigations revealed a supressed basal level of ACTH, modified circadian rhythm of cortisol secretion and inadequate supression of cortisol level after 2$\times$2 mg of dexamethasone. Further examinations were made and CT scan showed a mass of 38/35/34 mm in the left adrenal gland with imagistic characteristics suggestive of adenoma. Same CT scan also revealed a pulmonary embolism and massive thrombosis of inferior vena cava. After completion of anticoagulant therapy and remission of thrombosis, left adrenal surgical excision was successfully performed. After this surgical intervention, the patient was initiated with anabolic therapy for severe osteoporosis using a parathyroid hormone analog. The particularity of this case was represented by the cumulative factors leading to both osteoporosis and a procoagulant state. Both postmenopausal status and glucocorticoid excess, as seen in Cushing's syndrome, are contributing to low bone mineral density and osteoporosis. Also, low mobility after previous surgical intervention and hipercortisolism pilled up to coagulation disorders in our patient.

Relationship between megaloblastic anemia and ischemic stroke in a patient with adrenocortical carcinoma

Imane Boubagura, Neima Hassan, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
Department of Endocrinology, Diabetology and Metabolic Diseases, University Hospital of Marrakech, Marrakech, Morocco

Introduction
The prevalence of megaloblastic anemia in the adult population is poorly documented, but in the elderly, it has been clearly shown that the prevalence of macrocytic anemia increases after the age of 65 years especially in men. The most frequent etiology of vitamin B12 and folate deficiency is malabsorption. They have an action in the conversion of homocysteine to methionine: an increase in homocysteinaemia is currently considered a cardiovascular risk factor. Stroke can result from traditional cardiovascular risk factors, as well as from cancer-induced factors, including hypercoagulability.
Case Report
We report the case of a 65-year-old patient, without any pathological history, diagnosed with a left adrenal cortical mass in the left adrenal space, irregular in shape, fairly well limited, isodense with spontaneous contrast (33UH), measuring 9 cm, with an absolute wash out of 25% and relative to 11%. Associated with an alteration of the general state.With a broken cortisol cycle in the biological assessment with a midnight cortisol level of 12, a negative minute braking and a FU of 4 times normal. The patient presented macrocytic anemia and thrombocytopenia with vitamin B12 deficiency. In our case, the etiology of vitamin B12 deficiency was nutritional deficiency. After 4 days, the patient presented an ischemic stroke of the right middle cerebral artery. The patient was put on anticoagulant treatment and intramuscular hydroxocobalamin treatment at the rate of one ampoule per day for one week, then one ampoule per week for one month, then one ampoule per month continuously. The evolution was marked by an improvement of the anemia and thrombocytopenia and the progressive resumption of the motricity of the left hemisphere and speech. The patient was scheduled for left adrenalectomy after medical preparation.
Discussion
Cobalamin deficiency is common in adults, especially in elderly subjects (more than 20%), but is often unknown or even unexplored, mainly because of frustrating clinical manifestations. Nevertheless, the potential seriousness of its complications, particularly neuropsychiatric, but also hematological, invites to systematically search for it. Moreover the diagnosis of cancer increases the risk of stroke in some cases. This has been found to occur over time after a cancer diagnosis, and is more common in people with cancer.
Conclusion
Hyperhomocysteinemia may be a modifiable risk factor for cardiovascular disease, independent of other risk factors, but its direct causality remains controversial. Megaloblastic anemia associated with a neoplastic context constitutes a criterion for suspicion of thromboembolic pathology or ischemic stroke.

Coexistence of adrenocorticotropic hormone-dependent Cushing's syndrome and papillary thyroid carcinoma

Bel Hadj Sliman Chayma, Bchir Najla, Cyrine Chehaider, Annam Benchhida, Zouaoui Chadia & Haroun Ouertani
Military Hospital of Tunis, Endocrinology, Tunis, Tunisia

Introduction
Papillary thyroid carcinoma is one of the most prevalent endocrine tumors. Adrenocorticotropic hormone (ACTH) dependent Cushing's syndrome is a rare disease. We report a rare case of coexistence of papillary thyroid carcinoma and ACTH-dependent Cushing's syndrome.
Observation
A 59-year-old man, was admitted to our endocrinology department for exploration of bilateral adrenal incidentalomas discovered in an abdominal CT scan done in the process of exploring portal hypertension. The patient was asymptomatic. The physical examination showed hypertension but no catabolic signs. Hormonal investigation revealed normal methoxylated derivatives plasmatic catecholamines, aldosteronemia and reninemia measurements. Diagnosis of ACTH-dependent cushing's syndrome was made on the basis of lack of plasma cortisol response to low-dose dexamethasone suppression test at 126 nmol/l (above 50 nmol/l) and high plasmatic ACTH levels at 34 pg/ml (above 20 pg/ml). In order to locate the hypersecretion of ACTH (Cushing disease or an ectopic tumor), the patient underwent a High-dose Dexamethasone Suppression test. Cortisol level decreased greater than 50% after 8 mg of dexamethasone, suggesting Cushing disease. Pituitary MRI was normal. Therefore, we performed a body scan that showed a large thyroid nodule. Complementary cervical ultrasound showed an Eu-tirads 5 nodule. Fine needle aspiration was performed but was inconclusive (category III according to the Bethesda system). The patient underwent a total thyroidectomy. The pathological examination identified a papillary carcinoma of the thyroid.
Conclusion
There are few case reports on the coexistence of thyroid papillary carcinoma and ACTH dependent Cushing's syndrome. The co-occurrence of two endocrine tumors with different origins is rare. Common physiopathology must be investigated.

Rare etiology of a voluminous adrenal incidentaloma: ganglioneuroma

Hind Ouakrim, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
Chu Mohamed Vi Marrakesh - Drh, Marrakesh, Morocco

Introduction
Ganglioneuroma (GN) is a benign, well-differentiated nerve tumor composed of mature sympathetic ganglion cells and nerve fibers, and most commonly located in the posterior mediastinum and retroperitoneum. GN's are rarely found in the adrenal gland. This tumor is usually asymptomatic and, in the majority of cases, detected incidentally. The diagnostic confirmation is histologic. We report a case of adrenal GN revealed by an adrenal incidentaloma.
Observation
A 50-year-old man, with no history of comorbidities, who consulted for intense left back pain evolving for 4 months. An abdominal CT scan was performed and showed a left adrenal mass measuring 68*83 mm with a spontaneous density of 37UH. An endocrine workup, including urine catecholamine and cortisol levels and a 1 mg overnight dexamethasone suppression test, was normal. Because of the tumor size, A left adrenalectomy was performed, with no related complication. Histological analysis was in favor of a neuroganglioma, no evidence was found for the malignancy. No recurrence was detected during the follow-up visits.
Discussion
GN is a rare benign tumor of neuroectodermal origin, developed from the sympathetic nervous system. It develops along the sympathetic chains, hence its cervical, mediastinal, retroperitoneal or pelvic localization. Adrenal localization is rare. It is composed of mature ganglion cells and a stroma with nerve cells associated with a schwannian contingent, in contrast to neuroblastoma and ganglioneuroblastoma which are composed of more immature ganglion cells with a higher potential for progression. Ganglioneuroma is most often found in children and young adults. The mode of revelation is often incidental, because retroperitoneal ganglioneuromas are usually asymptomatic. However, sometimes abdominal pain, palpation of an abdominal mass, or compression of nearby organs lead to the diagnosis, as in the case of our patient. The treatment remains surgical and consist in the removal of the tumor. The diagnosis of certainty will only be made after a histological study of the surgical specimen. Local recurrence is exceptional, but the possibility of malignant transformation into a ganglioneuroblastoma is possible, which explains the interest of prolonged surveillance.
Conclusion
Ganglioneuroma may sometimes be similar to other adrenal malignancies. Careful evaluation with endocrine tests and imaging procedures is necessary to provide an accurate diagnosis. Definitive diagnosis can be made by histological examination. The prognosis is very good with surgical removal.

EP113

A case of autoimmune polyglandular syndrome type 2 unmasked after treating subclinical hypothyroidism

Mahamud Bashir, Ayodeji Oyesanya, Mohammed Mohammed, Ayan Mohamed, Lubna Etbinah, Kirtanya Ramachandran & Gideon Mlawa
BHRUT, London, United Kingdom

Background
Autoimmune polyglandular syndrome type 2 is an autoimmune disorder that affects many hormone-producing (endocrine) glands. It is characterized by the presence of Addison's disease along with autoimmune thyroid disease and/or type 1 diabetes. The initial presentation can be varied but some patient maybe present with subclinical hypothyroidism and later develop Addisonian crisis. The pathogenesis of Autoimmune polyglandular syndrome type 2 remains unclear, although it may occur due to combination of genetic and environmental factors and affects women more than men. Here we present a patient that who was treated for subclinical hypothyroidism which led to adrenal failure.
Case
46 years Caucasian lady Attended an accident and emergency collapse with a 2-week history of general lethargy and dizziness. She was initially reviewed by her General Practitioner after complaining of tiredness, and weight loss. She had blood tests including a thyroid function test which showed evidence of subclinical hypothyroidism. FT4 16 (pmo/l), TSH 14.70 (Mu/l) She was started on Levothyroxine. 2 months after starting the treatment she became more symptomatic with lethargy and dizzy spells and when she attended Accident and Emergency department she collapses as she was hypotensive BP 80/50. She was given iv fluids, blood test revealed low cortisol of 55. She was started on hydrocortisone initially 100 mg i.m/iv and then 50 mg every 6 hours. Her short synacthen test is below in table 1. A further blood test revealed positive adrenal antibodies. She was discharged home on oral hydrocortisone and fludrocortisone and levothyroxine.
Discussion/conclusion
Subclinical hypothyroidism may be part of polyglandular syndrome Type 2. This consists of hypothyroidism with either adrenal failure or type 1 diabetes. Ruling out adrenal insufficiency is important before starting thyroxine replacement to avoid the life-threatening Addisonian crisis. We recommend carrying out 9 am cortisol followed by a short synacthen test if a 9 am cortisol is low before starting levothyroxine replacement.

Table 1 Short Synacthen Blood test results

Time	Cortisol
9 am	5
9:30 am	5
10 am	5

DOI: 10.1530/endoabs.90.EP113

EP114

The importance of under-treating adrenal failure in order to allow normal adrenal function following unilateral adrenalectomy for Cushing's syndrome

Kavita Narula[1], Kate Lazarus[2], Asjid Qureshi[1], Fausto Palazzo[2] & Karim Meeran[2]
[1]London North West University Healthcare NHS Trust, United Kingdom; [2]Imperial College Healthcare NHS Trust, United Kingdom

A 26-year-old woman presented to the Endocrine clinic with features of Cushing's syndrome (CS). Investigations revealed a non-suppressible cortisol in low dose Dexamethasone suppression test with a suppressed ACTH, and two positive 24-hour urine cortisol collections, indicating CS. CT imaging revealed a left adrenal adenoma of 3.4 cm. Following a left adrenalectomy, she was discharged on once daily Prednisolone 3 mg. She was well for a year except for

one occasion where she reported forgetting to take her Prednisolone and started vomiting. She did not seek medical help. This resolved after she had her Prednisolone dose the following day. On review a year later, a Short Synacthen test (SST), showed a suboptimal response (Table 1). As we were certain that the right adrenal was intact, we planned to gradually reduce the prednisolone dose, to assess for recovery of endogenous cortisol production. Administering a replacement dose of glucocorticoids during the perioperative period helps to preserve normal physiological function, while also reducing potential risks of adrenal crisis. While corticosteroid therapy is commonly used for patients with CS undergoing adrenalectomy, there is no clear consensus on the best approach. A general strategy involves administering steroids both intraoperatively and postoperatively, starting with intravenous administration followed by oral administration, and then gradually tapering the dosage to allow recovery of the HPA axis and endogenous cortisol production. There is limited evidence how best to do this. We have found use of a Prednisolone tapering regimen alongside clinical assessment can help the weaning process. She is currently being weaned down to 1 mg Prednisolone. Patients with adrenal CS have reduced cortisol secretion due to negative feedback on the HPA axis. This leads to a decrease in ACTH release. Reduced ACTH stimulation to both the adrenal cortex surrounding the lesion and the contralateral, often atrophic adrenal gland, results in adrenal insufficiency and need for glucocorticoid replacement therapy. However, patients undergoing unilateral adrenalectomy will have adrenal reserve in the contralateral adrenal gland and should be able to recover endogenous cortisol production. This can be stimulated by deliberately reducing the dose of prednisolone to aid ACTH secretion. Life-long glucocorticoid replacement therapy may be avoided in such patients.

Table 1

Dates & Prednisolone dose	Baseline cortisol 0 minutes (nmol/l)	Cortisol 30 min (nmol/l)	Cortisol 60 min (nmol/l)	ACTH (ng/l)
02/12/22 Prednisolone 2 mg	187	189	218	130
11/10/22 Prednisolone 2 mg	125	137	135	76.4
27/07/22 Prednisolone 3 mg	59	76	81	78.5

Adrenal adenomas in untreated Klinefelter syndrome is a frequent finding : Case report

Hadami Ben Yamna, Bchir Najla, Salma Abadlia, Annam Benchhida, Chedia Zouaoui & Haroun Ouertani
The Principal Military Hospital of Instruction of Tunis, Department of Endocrinology, Tunis, Tunisia

Introduction
Adrenal adenomas development has been partially explained by aberrant adrenal expression of some hormone receptors. Klinefelter's syndrome is a common cause of hypergonadotropic hypogonadism, which is characterized by increased serum LH level. In this case, we report a patient with Klinefelter syndrome, who was later diagnosed with a non secreting adrenal adenoma.
Case presentation
We report the case of a 57 years old patient, diagnosed with Klinefelter syndrome since the age of 34. He was treated with testosterone replacement therapy for only four years than stopped consulting. The patient was meanwhile treated for hypertension, atrial flutter and heart failure. He also had a history of hypokalemia. He presented to the emergency department for palpitations with dyspnea. Physical examination showed an obesity with BMI at 37.5 kg/m^2. Blood pressure was EKG showed supraventricular tachycardia. Pulmonary embolism was suspected and a CT angiography was conducted, and a right adrenal tumor mesuring 13 mm was discovered. His plasma cortisol level was suppressed to 17 nmol/l after the 1-mg dexamethasone suppression test. Plasmatic normetanephrine and metanephrine levels were normal (respectively 0.52 nmol/l and $<$0.10 nmol/l). His plasma aldosterone concentration and renin activity were 29.9 pg/ml and 3.9 mUI/l, respectively, with a normal aldosterone to renin ratio (17). He was diagnosed as having a non secreting adrenal tumor.
Conclusion
Since untreated Klinefelter syndrome is characterized by increased serum LH, a possible contribution to adrenal tumors development is suggested. It has been described that some patients with untreated Klinefelter's syndrome, later develop primary aldosteronism.

Pheochromocytoma associated with von Hippel-lindau disease

Sevgul Faki[1], Unzile Arifoglu[2], Bilge Dibeklioğlu[3], Altuğ Tuncel[4], Müge Keskin[3], Abbas Ali Tam[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara City Hospital, Departments of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Yıldırım Beyazıt University, Faculty of Medicine, Departments of Endocrinology and Metabolism, Ankrara, Turkey; [3]Ankara City Hospital, Departments of Endocrinology and Metabolism, Ankara, Turkey; [4]Ankara City Hospital, Department of Urology, Ankara, Turkey

Von Hippel-Lindau (VHL) syndrome is a pathological condition that causes various clinical symptoms and is difficult to diagnose. The most common pathological lesions are hemangioblastomas of the central nervous system, retinal angiomas, renal clear cell carcinomas, and pheochromocytomas. Here we reposrt a case of likely to be VHL due to his family history.
Case
A 33-year-old male suffering from hypertension and a history of hemangioblastoma operated in 2019. The patient had an endoscopic examination after developing nausea, vomiting and weight loss. His endoscopic biopsies include grade 2 neuroendocrine tumors NET). the patient refer to endocrinologist. The father of the patient died at age of 40 due to brain tumor and his brather was operated due to retinal and cerebral hemangioblastoma (in 2013) since that date the familyhad been followed up in the department of neurosurgery with suspicion of VHL. His plasma free metanephrines and urinary metanephrines was high and a computer tomography scan, MIBG and MRI scan of the abdomen showed a solid mass in the lower pole of the lenf kidney at 2.5$\times$2 cm, pancreatic cysts and right adrenal mass at 36$\times$40 laparascopic adrenalectomy and parsiel nefrectomy was performed. The Pathological examination revealed renal cell carcinoma and *pheochromocytomas* with a low PASS score. The contro plasma free metanephrines and urinary metanephrines were withen normal range.
Conclution
Since pheochromocytomas can have low activity, the classical symptoms may be missing. The absence of symptoms can make it difficult to diagnose pheochromocytoma and Even if we couldn't perform the genetic examination there is a strong association between pheochromocytoma and VHL syndrome, and pheochromocytoma is an important feature in the clinical classification of VHL syndrome. The family history of retinal or central nervous system hemangioblastoma (Hb) exists, only one Hb or visceral lesion (renal tumours, pancreatic cysts or tumours, pheochromocytoma, papillary cystadenomas of the epididymis) is required to make the diagnosis of VHL and Due to the risk of pheochromocytoma, the radyologıc sxanning and biochemical tests shoud performed.

17 Alpha Hydroxylase Deficiency in congenital adrenal hyperplasia revealed by a ruptured cerebral aneurysm

Chtioui Sara, Sana Rafi, El Mghari Tabib Ghizlane & Nawal El Ansari
Mohammed VI University Hospital Center, Department of Endocrinology, Diabetes, Metabolic Diseases and Nutrition, Marrakech, Morocco

Background
A 17 alpha-hydroxylase deficiency (17OHD) is a rare form of congenital adrenal hyperplasia (CAH). Congenital adrenal hyperplasia (CAH) is a group of disorders resulting from defect of one of enzymes necessary for biosynthesis of cortisol.
Case Report
A 33-year-old female suffered from 17OHD. She presented with primary amenorrhea, lack of secondary sexual characteristics, and hypertension complicated by ruptured cerebral aneurysm. Laboratory tests showed hypokalemia, low levels of androgens, corticosteroid, and high levels of adrenocorticotropic hormone, 11 Deoxycorticosterone and progesterone. Due to the severe initial presentation with signs of malignancy in adrenal imagery, the decision was to realize left adrenalectomy and to discuss the primary amenorrhea previously. The clinical manifestations, imaging and laboratory results appeared to be consistent with a diagnosis of CAH in the patient, due to the observed 17α hydroxylase deficiency. The patient is putted on corticosteroids (dexamethasone) with normalization of adrenocorticotropic hormone, normal kaliemia and blood pressure.
Discussion
The classical presentation of 17OHD is hypertension,hypokalemia, and delayed puberty with lack of secondary sexual characteristics in a female of pubertal age group. Our patient had all the classical features. The diagnosis of 17OHD is based on clinical, biochemical, and molecular features. In our case, biochemically, there were decreased concentrations of DHEA, androstenedione, testosterone,

estradiol, and cortisol, and increased concentrations of 11 Deoxycorticosterone and ACTH.
Conclusion
17OHD is a rare disease associated with primary amenorrhea and hypertension. This case shows the importance of vital signs measurement, medical history and commitment to a systematic approach.

Coexistence of Gilbert's disease, thyroid nodule, parathyroid adenoma, and Cushing's syndrome: A rare presentation

Bel Hadj Sliman Chayma, Bchir Najla, Dorra Dorraelguiche, Annam Benchhida, Zouaoui Chadia & Haroun Ouertani
Military Hospital of Tunis, Endocrinology, Tunis, Tunisia

Introduction
Gilbert syndrome is a common autosomal dominant hereditary condition characterized by intermittent unconjugated hyperbilirubinemia in the absence of hepatocellular disease or hemolysis. Multiple endocrine neoplasia (MEN) is defined by the association of a neoplasia or hyperplasia of at least two endocrine glands and caused by multiple mutations. Rare cases of atypical MEN were reported in the literature. We report the case of a patient with a history of gilbert's disease, toxic thyroid nodule and primary hyperparathyroidism who was found to have Cushing's syndrome
Observation
It is a 60-year-old man, diagnosed at the age of 37 with Gilbert's disease revealed by a jaundice. At that time, an hyperthyroidism due to a toxic thyroid nodule was diagnosed and treated by surgery. At the age of 42, he was diagnosed with primary hyperparathyroidism (calcemia = 2.77 mmol/l, PTH = 148 pg/ml) caused by a left lower parathyroid adenoma. He underwent a parathyroidectomy. During the work-up for multiple endocrine neoplasia, a 2 cm left adrenal nodule was discovered on an adrenal scan. Initial investigations had revealed a non-secreting adenoma and regular surveillance was carried out. Given the later appearance of hypertension and hypokalemia, a hormonal evaluation was performed again. The results of the hormonal investigation revealed normal levels of methoxylated derivatives of plasmatic catecholamines, as well as normal levels of aldosterone, renin, and the aldosterone-renin ratio in the plasma. However, blood cortisol after a Low-dose Dexamethasone Suppression Test was elevated at 137 nmol/l and ACTH levels was high (86 pg/ml). Diagnosis of ACTH-dependent Cushing's Syndrome was retained. MRI of the pituitary gland revealed an arachnoid cyst. Body scan did not show any abnormalities.
Conclusion
Gilbert's disease, toxic thyroid nodules, parathyroid adenoma, and Cushing's disease are all separate medical conditions that may have different causes, symptoms and treatments. It is possible that they can be associated in some cases, but we could not confirm whether the patient had this multiple endocrine dysfunction as a coincidence or they had a common etiology.

Intermittent cushing's syndrome: diagnostic challenges

Imane Boubagura, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
Department of Endocrinology, Diabetology and Metabolic Diseases, University Hospital of Marrakech, Marrakech, Morocco

Introduction
Cushing's syndrome (CS) is typically characterized by faciotronic obesity with signs of protein hypercatabolism, which may be iatrogenic or endogenous (adrenal or ATCH dependent). We report a case of CS of unusual presentation.
Case Report
We report the case of a 45-year-old patient, referred for etiological assessment and management of an atypical cushing syndrome.
– Symptomatology dates back to 2007, by the appearance of abdominal pain with vomiting and asthenia treated as acute adrenal insufficiency.
– The exploration was then completed by the realization of a biological assessment of the adrenal cortex (17 total urinary cetosteroids = 3.95 mg/24 h (normal between 4.9 and 14)), and a radiological exploration made of thoraco-abdominal CT scan and pituitary MRI: without abnormalities.– In addition, the patient reports the appearance since 2007 of facial erythrosis, skin fragility, with progressive weight gain, with stretch marks and asthenia, evolving intermittently, this symptomatology complicated 3 months ago by the worsening of the intensity, significant asthenia, muscle weakness, myalgias, muscle cramps, spinal bone pain, hair loss, with erythematosquamous lesions and ecchymosis more evident at the level of the MI, no melanoderma, no acne, no seborrhea.
– Urinary free cortisol was 50.7 μg/24 h, with an 8-hour cortisol level of 6.4 μg/dl.
– No other signs of pituitary insufficiency or hypersecression werw reported.
– For confirmation of cushing's syndrome: Braking not done (because of IS), CLU not done (patient under hydrocortisone), cortisol cycle was performed (no disruption of the circadian cycle).
– Etiological workup: Biological: hypophysogram:ACTH = 2.96, hypogonadotropic hypogonadism. Radiological: adrenal CT scan(no abnormalities), octreoscan (no abnormal fixation in favor of ectopic cushing), brain MRI (arachnoidocele pushing back the pituitary gland).
Discussion
Diagnostic hypotheses: This is most likely a cushing's disease with an apoplectic pituitary adenoma responsible for arachnoidocele, in view of the progressive onset of intermittent cushing's syndrome, hypogonadism of central appearance, and the negativity of the rest of the workup although the ACTH is low that can be explained by braking of the corticotropic axis by CTC in the long term (equivalent of 7.5 mg of prednisone for 12 years).
Conclusion
This case illustrates an atypical and confusing presentation of CS highlighting the clinical polymorphism of this disease and the resulting diagnostic difficulties.

Primary Aldosteronism and Cortisol Cosecretion in a Patient with Adrenal Adenoma

Nino Zavrashvili[1,2], Natia Shonia[1,2], Ketevan Chanturishvili[1,2], Qetevan Gvazava[1,2] & Natia Margvelashvili[1,2]
[1]Tbilisi Institute of Medicine, Endocrinology, Tbilisi, Georgia; [2]David Tvildiani Medical University, Endocrinology, Tbilisi, Georgia

Background
Primary aldosteronism (PA) is a group of disorders characterized with inappropriately high adrenal aldosterone production, suppressed renin and hypertension. Prevalence of PA is approximately 5-10% in people with hypertension and up to 20-50% in those with resistant hypertension. PA is associated with increased cardiovascular and cerebrovascular morbidity and mortality rates compared with patients with essential hypertension when matched with age, sex and blood pressure. PA is commonly caused by an adrenal adenoma, unilateral or bilateral adrenal hyperplasia (BAH), or in rare cases adrenal carcinoma or inherited conditions of familial hyperaldosteronism. The cause of PA dictates the optimal treatment strategy- curative surgery (unilateral adrenalectomy) or mineralocorticoid receptor blockade. Corticotropin (ACTH)-independent hypercortisolism is relatively rare condition, diagnosed in <5% of patients with adrenal tumors or hyperplasia, while mild autonomous cortisol secretion (MACS) is common, affecting up to 50% of patients with unilateral adrenal adenomas. ACTH independent hypercortisolism can present with overt features of Cushing Syndrome (CS) or as MACS. Laparoscopic adrenalectomy is the treatment of choice.
Case presentation
We present a case of a 45 year old man with 10 year history of hypertension and spontaneous hypokalemia first documented 5 years ago. He was treated with Perindopril, Amlodipine, Indapamide, Nebivolol and potassium supplements. Laboratory workup planned at our clinic confirmed the diagnosis of primary aldosteronism. Adrenal CT revealed 14 mm left adrenal adenoma (-20 HU). Further evaluation with dexamethasone suppression test, ACTH and DHEA-S confirmed MACS. Considering the cosecretion of cortisol with aldosterone, adrenal venous sampling (AVS) was no longer required and the patient was advised about unilateral adrenalectomy.
Conclusion
In conclusion, in patients with large aldosterone-producing adenomas, the possibility of MACS should be evaluated as the identification of aldosterone and cortisol co-secreting neoplasms will require specific approach.

Cushing's disease in children: about a case

Aicha Bouzid[1] & Kolli Meriem[2]
[1]Laboratory of Endocrinology and Metabolism Algiers 1, Algiers, Algeria; [2]Endocrinology Department of the EPH Bologhine, Algiers, Algeria

Cushing's disease (CD) is rare in paediatric practice but requires prompt investigation, diagnosis and therapy to prevent longterm complications. We report the case of a young 12-year-old patient who presented with probable Cushing's disease complicated on the bone level by osteopenia. Cushing's syndrome seems to have been evolving for 2 years, i.e. at the age of 10, manifesting itself by a weight gain of 20 kg in 18 months. Clinically, she presents clear signs of hypercortisolism with faciotroncular obesity, large and colored stretch marks and amyotrophy of the lower limbs. The biological exploration returns in favor of an ACTH-dependent Cushing syndrome. Endogenous hypercortisolism was confirmed by a negative weak braking test on plasma and urinary cortisol and etiologically ACTH is high confirming ACTH-dependent hypercortisolism, strong braking on plasma and urinary cortisol is positive in favor of of hypothalalmohypophyseal origin. The hypothalamic-pituitary MRI does not find any pituitary adenoma but highlights a small cystic formation with sediment in hyposignal, evoking a Rathke's pouch cyst. The cervicothoraco-abdominal scanner is without anomalies. Catheterization of the inferior petrous sinuses showed a Centro peripheral gradient without lateralization. The diagnosis of CS has remained a challenge in clinical practice, with limited sensitivity and specificity of laboratory and imaging tests. For this reason clinical examination, and sometimes long-term observation, can be key to correct diagnosis.

EP122

Primary Aldosteronism due to Adrenal Adenoma

Nazi Tchelidze[1] & Natia Vashakmadze[2]
[1]University of Georgia, Tbilisi, Georgia; [2]Israeli-Georgian Medical Research Centre "Healthycore", Endocrinology, Tbilisi, Georgia

A patient, 24 y/o male, presented with the regular occurrence of severe hypertension for past two years: 150-170/100 mmHg. He complained of occasional vertigo, fatigue, and rare muscle cramps. The laboratory findings showed marked hypokalemia–2.7 mmol/l. Thyroid function tests, creatinine, magnesium levels were normal. Heart US showed septal thickening. He had been taking spironolactone 50 mg/day according to the prescription of his cardiologist for the last 2 weeks. Based on patient's history, clinical presentation, and lab findings, primary aldosteronism was suspected. We recommended withdrawing spironolactone and temporarily replacing it with verapamil and measuring the levels of aldosterone and renin in 4 weeks after withdrawal. The levels of aldosterone and renin were measured after a month of withdrawal of spironolactone. Renin levels were completely suppressed: <1 ng/l (normal range 1.7-23.9 ng/l), and the aldosterone/renin ratio was markedly increased: >218. Aldosterone levels were borderline elevated: 218 ng/l (normal range 11.7-236 ng/l), probably due to hypokalemia which could not be fixed even with a high-dose potassium therapy. We did not conduct confirmatory tests as diagnosis of primary aldosteronism was evident. The CT scan with contrast was performed that revealed 1 cm adenoma in the left adrenal gland. Due to patient's young age, presence of hypertension, hypokalemia and high aldosterone/renin ratio, the diagnosis of Conn's syndrome (primary aldosteronism caused by aldosterone-producing adenoma) was indubitable. AVS was not recommended. The patient had been prepared for surgery with 50 mg spironolactone therapy. His potassium was normal and blood pressure normalized after 2 weeks of spironolactone therapy. A laparascopic adrenalectomy was performed in September 2022. Spironolactone was withdrawn after the surgery. Potassium level in blood in two weeks postoperatively was 4.7 mmol/l, blood pressure decreased (120/75 mmHg to 130/90 mmHg). Prompt improvement in blood pressure indicates that most probably he had short duration of aldosteronism and process was completely reversible. He was recommended to monitor his blood pressure regularly without any additional treatment.

Congenital adrenal hyperplasia due to 21-hydroxylase deficiency

Chtioui Sara, Ilham Midhat, Sana Rafi, El Mghari Tabib Ghizlane & El Ansari Nawal
Mohammed VI University Hospital Center, Department of Endocrinology, Diabetes, Metabolic Diseases and Nutrition, Marrakech, Morocco

Introduction
Congenital Adrenal Hyperplasia (CAH) are any of several autosomal recessive diseases resulting from mutations of genes for enzymes mediating the biochemical steps of production of mineralocorticoids, glucocorticoids or sex steroids from cholesterol by the adrenal glands (steroidogenesis).
Case Report
We describe a case report of a 20 year-old female with congenital adrenal hyperplasia (CAH). The 20-year-old female patient was born with genital ambiguity. She was brought up as a girl. Karyotype test result was 46,XX, and laboratory examination showed a high value for 17-hydroxyprogesterone 17OHP (259.4 ng/ml ng/ml), and Dehydroepiandrosterone sulfate (9136 ng/ml) with elevated adrenocorticotropic hormone ACTH (377 ng/l). MRI examination showed atrophic uterus and ovaries. Computed adrenal tomography showed and increased bilateral adrenal glands. The examinations were consistent with the diagnosis of adrenal hyperplasia due to 21 hydroxylase deficiency. The patient is putted on corticosteroids (Oral hydrocortisone) and antiandrogens .The hormonal monitoring showed efficiency of treatment(Decreased 17OHP, DHEA S, ACTH and testosterone).
Discussion
The majority of virilized 46,XX infants will prove to have CAH. CAH is also the most common disorder of sex development. Simple virilizing 21-hydroxylase deficiency is usually diagnosed in female patients shortly after birth owing to genital ambiguity (CYP21 mutation). Mild forms of 21-hydroxylase deficiency in females are identified later in childhood due to precocious pubic hair, partial or complete fusion of labioscrotal folds, and phallus enlargement to clitoromegaly, and are often accompanied by accelerated growth and skeletal maturation due to excess and postnatal exposure to adrenal androgen, either not treated or inadequately treated. 46,XX CAH is a rare case. Management of the patient is based on substantial examination, and the patient's preference has an important role in deciding the type of treatment. In this case, all examinations were consistent with a diagnosis of CAH and the patient has a tendency to identify as female so the operation (clitoroplasty) will be done.

Young man with back pain, is it Cushing's

Aida Kanaan[1,2], Rajinder Gupta[1,3] & Daniel Kannappan[1,3]
[1]Royal Albert Edward Infirmary, Diabetes and Endocrinology, Wigan, United Kingdom; [2]Wrightington, Wigan & Leigh NHS Foundation Trust, Appley Bridge, United Kingdom; [3]Wrightington, Wigan & Leigh NHS Foundation Trust, Diabetes and Endocrinology, Appley Bridge, United Kingdom

Introduction
Cushing's syndrome is rare disease with annual incidence 2/ million. It carries a high mortality rate if untreated. ACTH independent Cushing's with Adrenal adenoma is responsible for 10% of cases. This is a case of a young gentleman with back pain, vertebral fracture, in presence of left adrenal incidentaloma, normal MRI pituitary, and hormonal profile indicative of possible non-detectable central pituitary lesion, diagnosis of likely adrenal Cushing's was established. Left adrenalectomy was performed with smooth recovery, histopathology has confirmed a benign nature of adrenal adenoma.
Case presentation
37-year-old gentleman presented in A&E with chest pain, radiating to the back. PMH: hypertension on triple therapy. Family history: non-significant In view of chest pain, he had a CT Aortogram to rule out aortic dissection, this showed left adrenal incidentaloma and T7 vertebral body collapse. In view of left adrenal mass and vertebral fracture he had further investigations to rule out cortisol excess. At this point overight dexamethasone suppression test was arranged.
Investigations
CT angiogram: left adrenal mass 3.4 cm, 5 HU likely benign adenoma. MRI Spine: subacute **T 7 vertebral** body fracture. **FSH 7.9** U/l **LH 3.7** U/l **Testosterone 5.3** nmol/l. Normal Prolactin, Thyroid, IGF1 and random cortisol. In view of left adrenal mass, he was referred to Endocrine clinic. Ongoing vision disturbance and weight gain was reported. On Examination: BP 137/69 BMI 35.9, evident abdominal striae. He failed to suppress high dose overnight dexamethasone suppression test. [cortisol 123 nMol/l with ACTH 19 (0-46 ng/l)], and low dose dexamethasone suppression test [(72 nMol/l with ACTH 9)]. Bone densitometry: Lumbar spine Osteopenia **T-score -1.9 Z-score -1.8**. Elevated UFC (107 nmol/l), and UFC excretion index (25 nmol/24 hours). MRI pituitary: normal.
Differential Diagnosis
1.Established Cushing's disease diagnosis with possible left adrenal driven etiology. 2.On the other hand, he had inappropriately low FSH and LH for an

extremely low testosterone level, and his ACTH was not suppressed. There is a possibility of small pituitary adenoma which is non-detectable on pituitary MRI.
Treatment
1. Metyrapone
2. laparoscopic left adrenalectomy
Outcome
Metyrapone was stopped and his post-operative low dose dexamethasone suppression test confirmed his Cushing's has now been cured. Histopathology: benign adrenal adenoma. Reduced anti-hypertensive medications to one medicine
Future Plan
1. Blood pressure and osteopenia monitoring - expected to improve.
2. Monitor for possible post-operative corticotrope tumor growth and adrenal insufficiency.
3. Gonadotrophin and testosterone re-assessment.
4. Genetic test to rule out MEN.

Application of untargeted metabolomics in primary hyperparathyroidism

Marta Wielogórska-Partyka[1], Beata Podgórska[1], Karolina Mocarska[1], Joanna Godzień[2], Julia Siemińska[2], Michał Ciborowski[2], Gabriela Kozłowska[2], Małgorzata Szelachowska[1], Agnieszka Adamska[1], Anna Popławska-Kita [1], Janusz Dzieciol[3], Adam Krętowski[1,2] & Katarzyna Siewko[1]
[1]Department of Endocrinology, Diabetology and Internal Medicine, Medical University of Bialystok, Bialystok, Poland; [2]Clinical Research Centre, Medical University of Bialystok, Poland; [3]Department of Human Anatomy, Medical University of Bialystok, Bialystok, Poland

Background
The excessive secretion of parathormone by parathyroid glands is a common disorder known as hyperparathyroidism. With a prevalence of 0.1-0.4 percent in the general population and 2-4 percent in post-menopausal women, primary hyperparathyroidism is the third most frequently reported endocrine disorder. According to estimates, the prevalence of primary hyperparathyroidism has escalated in recent years, probably due to the increasing rate of parathormone and calcium measurements. Evaluation of whether patient with hyperparathyroidism requires parathyroidectomy assumed important place in endocrinology practice. Metabolomics is a relatively new field of science serving a source of novel potential biomarkers. This new important 'omic' approach delivers biochemical information associated with the regulation of specific gene transcripts.
Objective
The aim of the study was to explore metabolic differences in plasma metabolome between patients with primary hyperparathyroidism and healthy individuals.
Methods
A retrospective, single-center study was performed on 28 patients with primary hyperparathyroidism and 30 healthy volunteers. Two complementary liquid-phase separation methods, capillary electrophoresis combined with TOF (CE-TOF-MS) and liquid chromatography coupled with QTOF (LC-QTOF-MS), were used to obtain metabolic fingerprints of plasma samples. A filtering and QA procedure, followed by uni- and multivariate analysis were applied to the acquired data. All included patients underwent the endocrine work-up aimed to study the hormonal and electrolyte status of primary hyperparathyroidism.
Results
Untargeted metabolomics has been successfully applied to track differences in plasma metabolome between PHPT patients and healthy subjects regardless of the technique used. The application of two complementary liquid-phase separation methods significantly increased metabolite coverage. The observed differences in metabolic profiles were subtle but amounted to more than 250 metabolic features: 36 CE/MS, 91 LC/MS for pos mode, and 127 LC/MS for neg mode. More than 20% of noted features were steroid hormone sulfates and vitamin D3 derivatives.
Conclusions
The most significant differences were observed between anionic metabolites detected by LC-MS, followed by cationic compounds measured by CE-MS, while the weakest differences were observed for cationic molecules detected via LC-MS. Presented results show that application of untargeted metabolomics in patients with primary hyperparathyroidism may help to understand the pathogenesis of primary hyperparathyroidism and to discover new biomarkers in easy-to-obtain biological samples. However, a larger cohort is necessary to search for potential biomarkers due to subtle changes in the levels of metabolites in patients with primary hyperparathyroidism.

DOI: 10.1530/endoabs.90.EP125

EP126

Diagnostic efficiency of the fine needle aspirate parathyroid hormone assay in parathyroid adenomas

Celia Gallego Díaz[1], Virginia Hernando Jiménez[1], Manuel J Caballero[2], Guillermo Martínez-de Pinillos[1] & Eyvee Arturo Cuellar Llocl la[1]
[1] Hospital Universitario Nuestra Señora de Valme, Sevilla, Spain; [2]Hospital Universitario Puerto Real, Puerto Real, Spain

Objective
Evaluate the utility of analytical determination of parathyroid hormone assay in fine-needle aspirate as a diagnostic test for parathyroid adenoma in patients with primary hyperparathyroidism.
Material and Methods
retrospective observational study of 58 patients diagnosed with primary hyperparathyroidism in our hospital who underwent ultrasound-guided FNA of lesions compatible with parathyroid adenoma with determination of PTH in fine-needle aspirate (PTHL). A cut-off point for PTHL of 100 pg/ml was considered positive.
Results
70.7% of the sample was female and the mean age was 59.2 ± 13.3 years. Fifty-eight lesions were punctured with a mean diameter of 12.78 ± 11.55 mm, and no procedure-related complications were recorded. Sestamibi-Tc99m gammagraphy showed no uptake in 85.9% of cases, intra-thyroid adenoma was suspected in 8.6% of cases and in 74.1% there was discordance between localization tests (ultrasound, gammagraphy, 4D parathyroid CT). The mean PTH_L value was 3399.7 ± 7776.2 pg/ml, and 74.1% of cases were considered positive. Until the analysis was performed, 31 patients had undergone surgery and the result of the surgery was concordant with the localised lesion by PTHL in 83.9% of the cases. The determination of PTHL ($\geq$ 100 pg/ml), in our series, has a sensitivity of 93%, a positive predictive value of 100%, a specificity of 100% and a negative predictive value of 60%. Two false negative cases were observed with PTHL values of 9 and 72 pg/ml.
Conclusion
PTH measurement in FNA aspirate is an affordable and useful diagnostic test to confirm the location of parathyroid adenoma. Further studies are needed to establish a standardised cut-off point for PTHL. This technique could be established as a complementary or safe alternative test in cases with difficult localisation or discordant localization tests.

Key factors associated with impaired glucose metabolism in primary hyperparathyroidism

Ekaterina Bibik[1], Alina Elfimova[1], Anna Gorbacheva[1], Ekaterina Dobreva[1], Elena Karaseva[1], Nikolay Gins[1], Anna Eremkina[1] & Natalia Mokrysheva[2]
[1]Endocrinology Research Centre, Department of Parathyroid Pathology, Moscow, Russia; [2]Endocrinology Research Centre, Director, Moscow, Russia

Background
Primary hyperparathyroidism (PHPT) can present with not only classic complications like bone and kidney pathology but also with different metabolic disorders and cardiovascular diseases. The prevalence of diabetes mellitus type 2 (DM2) in patients with PHPT is higher than in general population but the mechanism of carbohydrate metabolism alteration in PHPT remains unclear.
Aim
The aim of this study is to estimate parameters associated with impaired glucose metabolism in patients with PHPT using a method of machine learning–decision tree.
Material and Methods
The study included clinical data of 307 patients with PHPT. None of the included patients received drugs that affect mineral metabolism. We assessed age, PHPT duration, the presence of prediabetes or DM2, serum calcium, phosphorous, iPTH, osteocalcin levels, BMI. Decision tree (DT) is a classic supervised machine-learning method used for solving classification problems. DT consist of decision nodes and end nodes. Decision nodes contain decision rules, end nodes–value of target variable with Gini index characterized quality of classification. DT was built in Python using library Scikit-learn. The Bayes theorem was used to determine the conditional probability of impaired glucose metabolism in PHPT.
Results
55 patients with PHPT had prediabetes/DM2 (17.9%). They were older (60 [55;70] vs 58 [50;66] years, $P = 0.011$), had higher BMI (32.7 [28.1; 39.4] vs 27.2 [24.2; 30.4] kg/m^2, $P < 0.001$) and lower serum osteocalcin levels (33.1 [20.8; 51.8] vs 48.1 [34.0; 76.3] ng/ml, < 0.001) compared to those without carbohydrate metabolism disorders. Thus, DT was built using these parameters (age, the presence of obesity, osteocalcin

level). To form a decision rule, a terminal leaf node with the prevailing class 1 (presence of prediabetes/DM2) and the lowest Gini index were identified. The absence of obesity in combination with osteocalcin >36.8 ng/ml in patients with PHPT was less often associated with impaired glucose metabolism (OR = 0.04, 95% CI [0.01-0.17]). Vice versa, obesity with osteocalcin level ≤ 36.8 ng/ml can be the potential marker of hyperglycemic state in PHPT. The probability of carbohydrate metabolism disorders in such patients is 19.8%.

Conclusion

Patients with PHPT and obesity with osteocalcin level less than 36.8 ng/ml should be considered as the risk group of prediabetes and DM2. In such patients extensive evaluation of carbohydrate metabolism is preferred.

Height loss is almost 5 times more correlated with trabecular bone score than with bone mineral density. Study on over 900 patients (2023)

Dan Peretianu[1], Adrian Sirbu[2], Serban Motoiu[1], Catalin Gavrila[2], Mihaela Stanciu[3] & Aurelian E Ranetti[4]

[1]Medical Center Povernei, Endocrinology, Bucharest, Romania; [2]SANA Medical Center & SANA Monitoring, Osteoporosis, Bucharest, Romania; [3]Victor Papilian Faculty of Medicine, Endocrinology, Sibiu, Romania; [4]Carol Davila Military Hospital, Endocrinology, Bucharest, Romania

Aim

To show that height loss is more correlated with vetebral micoarchitecture than with Bone Mineral Density (BMD).

Material and Method

A. DEXA: made with a GE-Lunar Prodigy Pro # 500074. Vertebral microarchitecture was investigated by Trabecular Bone Score (TBS). TBS software: TBS iNsight®, version 3.0.2.0.

B. Patients. 902 patients, 844 (93.6%) women, 58 men. Only 42 under 50 years. Age average: 65.79 years. Women: 65.56 years, men 69.15 years.

C. Height measurement. At the time of DEXA analysis, each patient's height was measured (centimetres). Patients were asked to appreciate the difference in height compared to a previous age to which they can relate.

D. Statistical analysis. Student tα test was used for differences. Linear correlation test (r) was used for correlations.

Results

1. Diagnosis of osteoporosis. BMD scores led to the classic diagnosis of osteoporosis (score $<$ -2.5) in only 28.38% of patients. TBS T scores suggested the diagnosis of osteoporosis in 71.95% of patients (Table). The concordant diagnosis of osteoporosis by the intersection of BMD and TBS scores occurred in only 24.06% of patients.

2. Decreasing height. a. Average: 3.58 cm. Women loss height = 3.58 cm, Men loss height = 3.41 cm. Individual maximum loss was 12 cm (woman, 66 y). Average maximun loss at 8th decade = 7.5 cm. Minimum mean loss was at <45 years = 0.8 cm. **b. Correlations between height decrease and DEXA values.** The correlation of the decrease in height with BMD T score was "r" = 0.0724, $P<0.05$. The correlation of height decrease with TBS was r" = 0.3592 $P<0.001$. The value "r" for the correlation with TBS was 4.96 times higher.

Conclusions

1. Vertebral compression is correlated with age, higher in women than in men.

2. Patients lose up to 12 cm, beginning with the 6th decade of life, maximum average in 8th decade.

3. TBS is more correlated with vertebral microarchitecture and decrease in height with age compared to BMD, since the correlation "r" between TBS values and height decrease vs the correlation between height decrease and BMD is almost 5 times higher.

		BMD-T score			
		Normal	Osteopenia	Osteoporosis	Total

Prediabetes is associated with lower trabecular bone score (TBS): Comparison of TBS according to the prediabetes phenotype

Yong Jun Choi, Kyounghwa Ha, Dae Jung Kim & Yoon-Sok Chung

AJOU University School of Medicine, Endocrinology and Metabolism, Suwon, South Korea

Objective

Diabetes mellitus (DM) is known to be associated with a lower trabecular bone score (TBS) and an increased risk of fracture. However, little is known regarding whether it is associated with poor bone results in pre-diabetic individuals. Despite the fact that both IFG and IGT are characterized by insulin resistance and β-cell dysfunction, the metabolic abnormalities are quite distinct between the two disorders. Impaired fasting glucose (IFG) was marked by dysfunctional insulin secretion and decreased hepatic insulin sensitivity. In contrast, impaired glucose tolerance (IGT) was related with decreased whole-body insulin sensitivity, followed by a decline in β-cell function. We examined if TBS differed depending on the prediabetes phenotype.

Methods

This was a cross-sectional analysis of baseline data collected from 30- to 64-year-old participants in the Study of the Cardiovascular and Metabolic Diseases Etiology Research Center (CMERC) Cohort Study. A whole-body dual-energy X-ray absorptiometry (DXA) scan and an oral glucose tolerance test were performed. Excluding those with diabetes, liver cirrhosis, chronic kidney disease, or cancer, as well as those on osteoporosis drugs, steroids, or thyroid hormones, or who had ever received hormone replacement treatment, we enrolled 3.276 individuals. Subjects were classified as having normal glucose tolerance (NGT), isolated IFG, isolated IGT, or combined IFG and IGT (IFG + IGT). Statistical analyses were conducted by dividing into three groups (male, premenopausal women and postmenopausal women).

Results

Males with isolated IGT exhibited a lower TBS after adjusting for age, weight, vitamin D, Hba1c, cigarette smoking, and alcohol intake (1.466 vs 1.494, $P=0.040$). However, statistical significance disappeared when visceral fat was additionally adjusted for. In premenopausal women, patients with isolated IFG had a lower TBS than those with NGT (1.493 vs 1.513, $P=0.044$), and statistical significance was preserved even after visceral fat was further adjusted. There were no significant differences in TBS among groups of postmenopausal women.

Conclusion

Similar to diabetics, prediabetics have decreased TBS levels compared to NGT people. However, there were gender disparities in the association between TBS and prediabetes. Insulin resistance with visceral fat may have a greater impact on TBS in men, but disruption in insulin secretion may have a greater impact on TBS in premenopausal women.

Tension-free thyroidectomy (TFT) with medial approach to the recurrent laryngeal nerves and parathyroid glands helps to achieve a low rate of permanent postoperative hypoparathyroidism

Ilya Sleptsov[1], Roman Chernikov[1], Alexander Pushkaruk[1], Konstantin Novokshonov[1], Ilya Sablin[1], Natalia Timofeeva[1], Tillo Tilloev[1] & Yana Osokina[2]

[1]Saint Petersburg State University Hospital, Endocrine Surgery, Saint Petersburg, Russia; [2]North-Western State Medical University named after I.I. Mechnikov, Saint Petersburg, Russia

Background

Hypoparathyroidism is one of the most important complications of total thyroidectomy. Its treatment with the use of recombinant parathyroid hormone (PTH) is limited now, therefore the prophylaxis of post-surgical hypoparathyroidism is very important. A method of tension-free thyroidectomy (TFT) was proposed in 2021. TFT uses unusual medial approach to the recurrent laryngeal nerves (RLN) and parathyroid glands (PG), together with several principles decreasing traction applied by the surgeon to these anatomical structures.

Method

117 consecutive patients underwent total thyroidectomy with the use of TFT technique (there were 468 PGs at risk). In 46 (39.3%) cases patients additionally underwent central neck dissection with preservation of the thymus horns and their blood supply, in 13 cases–lateral neck dissection. Indications for surgery were thyroid cancer ($n=56$; 47.9%), follicular neoplasia ($n=25$; 21.4%), Grave's disease ($n=27$; 23.1%), nodular toxic goiter ($n=7$; 5.9%), nodular nontoxic goiter ($n=2$; 1.7%). Mean thyroid volume was 69 ml ($\pm$58 ml). Mean diameter of the thyroid nodule was 42 mm ($\pm$64 mm). Intraoperative neuromonitoring was

used in all the cases (5 mV). Calcium and PTH levels were measured on the day of surgery and on the day 1. In cases where PTH level dropped, additional calcium and PTH tests were performed on the 14th, 30th, 90th postoperative days. Laryngoscopy was used in all the cases prior and after surgery to evaluate vocal folds mobility.
Results
Unintentional complete PG removal occurred in 1 case (0.2% of PGs at risk), a fragment of parathyroid tissue was unintentionally removed in 14 cases (3.0% of PGs at risk). Hypoparathyroidism occurred in 12 patients (10.2%). In 7 out of these patients PTH level started to rise on the first postoperative day. In all the cases PG function has restored in the next 90 days, thus the rate of permanent hypoparathyroidism was 0%. Only in 2 cases hypoparathyroidism occurred in patients with unintentionally removed PG fragments, which means that the main reason for hypoparathyroidism was ischemia. An additional benefit of TFT was the low rate of RLN palsy which was registered in 2 cases (unilateral palsy; 0.9% of 234 RLNs at risk). In both cases RLN function restored, therefore the rate of permanent RLN palsy was 0%.
Conclusion
This initial study shows that TFT gives an opportunity to achieve the low rate of permanent complications such as hypoparathyroidism and RLN palsy.

Hypercalcemic hyperparathyroidism after bariatric surgery–primary or tertiary? Case report

Katerina Zajickova
Institute of Endocrinology, Clinical Endocrinology, Prague 1, Czech Republic

Bariatric surgery significantly reduces obesity-related comorbidities. Secondary hyperparathyroidism (SHPT), due to calcium malabsorption and vitamin D deficiency, has been frequently reported, however, in patients after bariatric surgery. Whether chronic SHPT after bariatric surgery could ultimately evolve into tertiary hyperparathyroidism has not been clarified. Here, we report a 59-old-woman who presented with osteoporosis (T score at the lumbar spine -4.1 and T score at the distal radius -2.5). Mild primary hyperparathyroidism (PHPT) was documented in the laboratory work up: total calcium 2.65 mmol/ l (normal ranges 2.15-2.55 mmol/l) and parathyroid hormone (PTH) 8.9 pmol/l (normal ranges 1.58-6.03 pmol/l). MIBI scintigraphy revealed a left upper enlarged parathyroid gland which was removed. Histopathology was reported as parathyroid hyperplasia. Postoperatively, hypercalcemia persisted. The patient then underwent PET-CT with fluorocholine which showed weak activity in the left lower parathyroid gland. An enlarged parathyroid gland was not, however, found during the second surgery. The patient underwent left hemithyroidectomy to remove a potential intrathyroidal parathyroid gland but none was seen on postoperative histopathology and hypercalcemia continued. The patient had a history of laparoscopic gastric banding for obesity 10 years prior to her presentation with PHPT. To reduce hypercalciuria and to improve calcium absorption, hydrochlorothiazide and vitamin D supplementation were started, followed by oral ibandronate. After a year of treatment bone mineral density at the lumbar spine significantly improved (by 22%) whereas serum calcium and PTH have not changed. Although we do not have a histologic correlate, a combination of inaccurate parathyroid imaging, multiglandular parathyroid disease and complicated parathyroid surgery together with a significant bone mineral density improvement might be indirectly suggestive of tertiary hyperparathyroidism in a patient with a history of bariatric surgery. Longstanding SHPT may contribute to the development of hypercalcemic, i.e. tertiary, hyperparathyroidism. In a patient presenting with hypercalcemic hyperparathyroidism and a history of bariatric surgery, multiple parathyroid gland disease with tertiary hyperparathyroidism should be considered. Supported by MH CZ - DRO (Institute of Endocrinology - EÚ, 00023761).

Comparison of the prediction powers of hypercalciuria tests for nephrolithiasis in patients with asymptomatic primary hyperparathyroidia

Melek Özkan[1,2] & Serkan Yener[3]
[1]Dokuz Eylül University Hospital, Internal Medicine, İzmir, Turkey; [2]Dokuz Eylül Üniversitesi Hastanesi, Internal Medicine, Izmir, Turkey; [3]Dokuz Eylül University Hospital, Endocrinology and Metabolic Diseases, İzmir, Turkey

Objective
One of the ways to predict nephrolithiasis,which is one of the surgical indications in patients with asymptomatic primary hyperparathyroidism,is to detect hypercalciuria.A calcium excretion of >400 mg/day in 24-hour urine, >4 mg/kg/day calcium excretion in 24-hour urine or a fractionated calcium excretion (FECa) >0.010 guide us in the detection of hypercalciuria and therefore nephrolithiasis.The aim of our study is which of these three tests is more useful in predicting nephrolithiasis and therefore in determining the indication for surgery in asymptomatic patients.
Materials and Methods
Biochemical examinations and imaging methods records of patients diagnosed with primary hyperparathyroidism ($n=271$) at Dokuz Eylul University Hospital Endocrinology and Metabolic Diseases Department between 2016-2022 were retrospectively analyzed and the predictive power of the aforementioned hypercalciuria screening tests for nephrolithiasis was compared.
Results
Median age at diagnosis was 56,adjusted calcium 10.9 mg/dl,estimated glomerular filtration rate 95 ml/min, 25-OH (hydroxy) vitamin D 17 ng/ml,phosphorus 2.8 mg/dl,parathormone 156 pg/ml,adenoma size (maximum) 12 mm and fractionated calcium excretion was 0.016 of the patient included in our study. There was no significant difference in adjusted calcium, phosphate, parathormone and 25-OH vitamin D levels between patients with and without nephrolithiasis.A significant difference was found in terms of median age at diagnosis,urinary calcium and fractionated calcium excretion. There was a significant difference between categorical variables in terms of urinary calcium >400 mg/day and urinary calcium >4 mg/kg/day. According to univariate analysis results, phosphorus ($P=0.017$), 24-hour urinary calcium ($P=<0.05$), urinary calcium >400 mg/day ($P=0.002$),urinary calcium >4 mg/kg/day ($P=0.003$) and fractionated calcium excretion ($P=0.005$) were significant in terms of nephrolithiasis.According to the results of univariate analysis,we determined that male gender increased the probability of nephrolithiasis by 2 times.It was determined that low phosphorus increased the probability of nephrolithiasis 1.8 times, urinary calcium excretion >400 mg/day 3.2 times,urinary calcium excretion >4 mg/kg/day 2.3 times and fractionated calcium excretion 16.3 times. According to the results of multivariate analysis,we found that fractionated calcium excretion ($P=0.007$) was significant in terms of nephrolithiasis and it was found that it increased the probability of nephrolithiasis 20.7 times.There were no significant findings in terms of gender,age at diagnosis, adjusted calcium,phosphorus,estimated glomerular filtration rate and parathormone.
Conclusions
As a result of our study,all three hypercalciuria tests were found to be significant in terms of predicting nephrolithiasis.However,the most valuable of these tests,which is also the aim of our study,was found to be fractionated calcium excretion.

The Russian Registry of primary hyperparathyroidism, the latest update

Anna Eremkina[1], Alina Elfimova[1], Anastasiia Miliutina[2], Elena Kovaleva[1], Anna Gorbacheva[1], Ekaterina Bibik[1] & Natalia Mokrysheva[3]
[1]Endocrinology Research Centre, Department of the Parathyorid Glands Pathology, Moscow, Russia; [2]Endocrinology Research Centre, Department of Epidemiology of Endocrinopathies, Moscow, Russia; [3]Endocrinology Research Centre, Director, Moscow, Russia

Introduction
Primary hyperparathyroidism (PHPT) is one of the most common endocrine disorders. No major epidemiological research has been previously conducted in the Russia. This served as the basis for the creation of the Russian online registry of PHPT with accessibility from various regions of the country.
Aim
Aim of this study was to estimate the clinical profile, surgical and medical therapy of the patients with different forms of PHPT.
Material and Methods
The cross-sectional, observational study was carried out at the Endocrinology Research Centre (Moscow,). The present study explored retrospective data from 6003 patients submitted to the Registry between 12.12.2016 and 25.10.2022 (http://pgpt.clin-reg.ru/) from 81 regions of the Russia.

Results
The median age was 59 [60; 66] years with a female: male ratio of 11.7:1. Symptomatic PHPT was observed in 73.5% of patients while asymptomatic form - in 26.5%. The predominant clinical manifestation was the combination of skeletal and renal complications (41.7%), while isolated disorders were noted in 35.9 and 22.4%, respectively. There was a difference between symptomatic and asymptomatic patients in age (60 [53; 67] vs 54 [45; 62] years, $P<0.001$). Serum iPTH, albumin adjusted and ionized Ca levels were higher in symptomatic patients ($P<0.001$ for all), hypophosphatemia was also more typical for the symptomatic PHPT ($P<0.001$). Cardiovascular disease was recorded in 48% of patients, more frequent in the symptomatic group ($P<0.001$). 811 patients (14%) had a suspicion for hereditary PHPT, however a genetic analysis was conducted in 183 cases revealing the mutations in *MEN1, CDC73, RET* genes in 107, 6 and 2 cases, respectively. As expected, the PHPT manifestation in MEN-1 group was earlier 33 [26; 48] compared to sporadic disease 59 [52; 66] years ($P<0.001$), average duration of disease before diagnosis was 0 [0; 4] vs 0 [0; 2] years ($P=0.055$). Surgical treatment has been performed in 3206 (53%) of patients with remission achievement in 87%, the relapse or persistence after surgery were recorded in 13%. Parathyroid carcinoma was verified in 101/2666 (4%) of cases, atypical adenoma in 53/2666 (2%), adenoma in 2227/2666 (84%), hyperplasia in 285/2666 (11%). Drug therapy was prescribed in 2889 (48%) of patients, with a predominance of cholecalciferol prescription.
Conclusion
The detection rate of PHPT has increased in recent years in the Russia, which is associated with start of online registration. However, the majority of patients remained symptomatic that indicates delayed diagnosis and requires further modifications of medical care.

Variations in plasma free 25-hydroxyvitamin D concentrations during intermittent fasting are independently correlated with amino acid intake among meat and non-meat eaters

Spyridon Karras[1], Theocharis Koufakis[1], Lilian Adamidou[2], George Dimakopoulos[3], Eirini Melidou[1], Paraskevi Karalazou[4], Katerina Thisiadou[4], Pantelis Zebekakis[1], Kali Makedou[4] & Kalliopi Kotsa[1]
[1]Medical School, Aristotle University of Thessaloniki, AHEPA University Hospital, Division of Endocrinology and Metabolism, First Department of Internal Medicine, Thessaloniki, Greece; [2]AHEPA University Hospital, Department of Dietetics and Nutrition, Thessaloniki, Greece; [3]BIOSTATS, Ioannina, Greece; [4]AHEPA General Hospital, School of Medicine, Aristotle University of Thessaloniki, Laboratory of Biochemistry, Thessaloniki, Greece

Background
Data on the effects of different dietary patterns on free 25-hydroxyvitamin D [25(OH)D] and vitamin D binding protein (VDBP) concentrations are scarce. Our objective was to prospectively assess changes over time in these parameters and possible correlations with diet composition among overweight adults who followed a pescatarian Orthodox intermittent fasting (OF) regimen and controls who followed a low-fat 12:12 diet for 7 weeks.
Methods
Total and free 25(OH)D, parathyroid hormone, VDBP, and anthropometric data were evaluated in 59 Orthodox fasters and 46 controls at three time points: at baseline, 7 weeks after the implementation of diets, and 5 weeks after the participants returned to their typical eating habits (12 weeks from baseline). The intake of amino acids for both diets was evaluated at all time points and possible associations with longitudinal changes in markers of vitamin D homeostasis were explored.
Results
Free 25(OH)D concentrations increased in both groups during the study. At 7 weeks, Orthodox fasters had higher concentrations than controls (9.52 ± 4.97 vs 4.96 ± 2.08 ng/ml, $P=0.003$). In the OF group, VDBP concentrations increased at 7 weeks compared to baseline values (286.37 ± 86.90 vs 230.11 ± 58.46 μg/ml, $P=0.004$), followed by a decrease at 12 weeks compared to 7-week measurements (234.66 ± 57.82 vs 286.37 ± 86.90 μg/ml, $P=0.032$). In contrast, a decrease in VDBP concentrations of controls was observed at 7 weeks compared to baseline (206.94 ± 40.01 vs 277.70 ± 76.01 μg/ml, $P=0.008$), followed by an increase at 12 weeks compared to 7-week values (290.12 ± 76.28 vs 206.94 ± 40.01 μg/ml, $P=0.014$). An increase in amino acid intake between baseline and 12 weeks was independently correlated with higher free 25(OH)D values at 12 weeks for both groups.
Conclusion
Our findings suggest that diet composition can affect free 25(OH)D concentrations, through variations in amino acid intake, independently of exposure to sunlight, and provide novel mechanistic insights into the future planning of vitamin D supplementation strategies and food fortification policies.

Acquired Parathyroid Hormone Resistance–a Possible Disease

Grzegorz Świder
Holy Family Hospital, Department of Internal Medicine & Endocrinology, Rudna Mala 600, Poland

Introduction
Acquired PTH Resistance (Acquired Pseudohypoparathyroidism) appears to be an extremely rare disease.
Case Report
A 19-year old man with history of brain medulloblastoma treated by surgery, radiotherapy and chemotherapy 9 years earlier was admitted to hospital in 2019 due to new-onset hypocalcemia. Patient presented with muscle cramps in legs, a tingling sensation in hands and feet, numbness around the mouth, and memory disturbances. Previously serum calcium levels were normal. Until the age of 10, psychophysical development was normal. Family history of calcium or PTH abnormalities was negative. Physical examination revealed positive Trousseau's sign, alopecia, lower limbs paresis, and mental retardation most likely due to the brain cancer. The biochemical evaluation showed low level serum calcium and ionized calcium as follows: 7.9 mg/dl and 0.98 mmol/l, high level phosphorous: 6.8 mg/dl, high level PTH: 780 pg/ml, normal level 25OHD3: 70 ng/ml, low level calcium diurnal urine collection: 41 mg/24 h.There were no other endocrinopathies nor renal and liver failure. Ultrasound examination showed no evidence of nephrolithiasis or nephrocalcinosis and x-ray scans revealed no signs of osteodystrophy. There were no cerebral calcifications. Treatment with calcium carbonate and alphacalcidol was initiated. The symptoms of tetany equivalents subsided and the level of calcium stabilized. PTH levels remained high despite calcium and magnesium normalization. The PTH resistance, probably acquired, was recognized. In the 4-year follow-up, the course of the disease was improved and the doses of vitamin D and calcium carbonate were significantly reduced.
Discussion
Genetic causes of PTH resistance become apparent in early childhood. At discharge, we suggested an acquired form of PTH receptor resistance, perhaps antibody or mutation related. We have no scientific methods to confirm this. Spontaneous improvement of the clinical course and alleviation of disorders in the last 4 years, may also speak in favor of an immunological mechanism. Uremic patients may develop antibodies against the PTH receptor[1]. Since the report in NEJM in 2021, we know that an acquired variant of the pseudohypoparathyroidism is possible[2]. The mechanism of the disease in the described patient is unknown, however, drug immunization cannot be ruled out despite the use of old-generation cytotoxic drugs. Tyrosine kinase and immune checkpoint inhibitors were not used. Therefore, further research is needed.

Background
Infection with the human immunodeficiency virus (HIV) predisposes to endocrine disorders, manifesting as a metabolic phenotype that affects the entire adipose-musculoskeletal unit (AMS). The present cross-sectional study aimed to investigate differences in irisin and adiponectin concentrations between people living with HIV and healthy controls, as well as to explore potential correlations between the levels of the aforementioned adipokines and markers of calcium homeostasis.
Methods
46 HIV-infected individuals (all men), with a mean age of 52.85 ± 8.48 years and a body mass index (BMI) of 25.76 ± 2.65 kg/m^2 and 39 healthy controls (all men) with a mean age of 45.44 ± 9.17 years and a BMI of 28.44 ± 6.29 kg/m^2 were included in the study. Anthropometric data, adipokine levels, 25-hydroxyvitamin D [(25(OH)D)] status and parathyroid hormone (PTH) concentrations were evaluated in the two groups. The Mann Whitney U test was used to assess differences between the HIV group and the control group. Pearson's correlations and partial correlations for the relationship between adiponectin, irisin, and PTH levels were examined. The results were adjusted for several confounders, including 25(OH)D levels, body fat, muscle mass, and mean exposure to ultraviolet B radiation during the previous 45 days before blood sample collection.
Results
The HIV group had a lower body fat mass (20.76 ± 6.18 vs 33.55 ± 7.60 kg, $P <$ 0.001) and a higher muscle mass (59.09 ± 8.13 vs 50.71 vs 12.08 kg, $P = 0.009$) compared to the control group. Mean adiponectin concentrations were significantly lower in the HIV group compared to the control group: 5868 ± 3668 vs 9068 ± 4277 ng/ml, $P = 0.011$. The same was applicable to irisin concentrations: 8.31 ± 8.17 (HIV) vs 29.27 ± 27.23 (controls) ng/ml, $P = 0.013$. A statistically significant and negative correlation was observed between irisin and PTH in the control group (r=-0.591; $P = 0.033$). In contrast, no significant correlation was observed between PTH and irisin in the HIV group ($P = 0.898$).
Conclusion
Our results suggest a possible down-regulation of the inverse relationship between PTH and irisin in HIV patients and highlight that AMS dyshomeostasis could be involved in the development of skeletal and adipose HIV-related morbidities.

Histomorphometric parameters of parathyroid glands after 60 days of sodium benzoate administration

Vitaly Morozov[1] & Vladyslav Luzin[2]
[1]Belgorod State National Research University, Human Anatomy and Histology, Belgorod, Russia; [2]State Establishment LPR "Sent Luke Lugansk State Medical University", Human Anatomy, Operative Surgery and Topographical Anatomy, Lugansk, Russia

Sodium benzoate (the food additive E211) is widely used as a preservative in the food and pharmaceutical industries. A direct correlation between sodium benzoate intake and the development of sensibilization, nephrotoxicity and hepatotoxicity, disorders of puberty, and genotoxicity has been established. However, the literature does not provide data on changes in morphometric parameters of parathyroid glands after long-term use of sodium benzoate. The aim of this work is to study the effect of 60-day sodium benzoate administration on the histomorphometric parameters of the parathyroid gland in rats. The experiment was performed on 18 white male mature rats divided into three groups. In group 1, animals were injected daily with 1 ml of sodium chloride through a feeding tube for 60 days, in groups 2 and 3, rats were injected with 1 ml of sodium benzoate solution at a dose of 500 mg/kg and 1000 mg/kg, respectively. Histological samples were prepared according to the standard procedure, sections were stained with hematoxylin-eosin and subjected to morphometry. Statistical analysis of the numerical data was performed using the Statistika 5.1 license program. In group 2, we observed a decrease by 1.47% ($P > 0.05$) in the largest size of parathyroid gland in comparison with group 1. The smallest size of the parathyroid gland decreased by 0.84% ($P > 0.05$), the number of nuclei of chief cells per unit section area decreased by 3.58% ($P > 0.05$), the mean diameter of chief cell nuclei decreased by 5.12% ($P < 0.05$), and functional index (number of nuclei of chief cells per unit section area*mean diameter of chief cell nuclei/20) decreased by 5.17% ($P < 0.05$). In group 3, changes in morphometric parameters of the parathyroid gland became more intense. The largest size of parathyroid gland decreased by 2.45% ($P > 0.05$), the smallest size of the parathyroid gland decreased by 2.65% ($p > 0.05$), the number of nuclei of chief cells per unit section area decreased by 5.27% ($P < 0.05$), the mean diameter of chief cell nuclei decreased by 10.12% ($P < 0.05$), and the functional index decreased by 8.11% ($P < 0.05$). 60-day intake of sodium benzoate causes dose-dependent changes in the histomorphometric parameters of the parathyroid glands in rats, which are indicative of their hypofunction.

Clinical characteristics of sporadic and MEN1-associated primary hyperparathyroidism in young patients

Lizaveta Aboishava, Alina Elfimova, Anna Gorbacheva, Rustam Salimkhanov, Anna Eremkina, Elena Karaseva & Natalia Mokrysheva
Endocrinology Research Centre, Moscow, Russia

Introduction
Primary hyperparathyroidism (PHPT) is commonly the most early manifestation of multiple endocrine neoplasia syndrome type 1 (MEN1), but it can also occur in young patients without any inherited disorders. The aim of our study was to compare the clinical characteristics of PHPT in young patients with MEN1 syndrome and with sporadic disease.
Patients and Methods
The study included 72 patients with MEN-1 associated PHPT and 168 patients with sporadic disease. All patients were tested for MEN1 mutations. Electronic medical records were used to analyze clinical data of each patient. Patients who had sufficient data at the time of manifestation of PHPT (before the first surgery) were included.
Results
Both groups consisted mostly of young patients and there was no significant difference in the age of manifestation: 31 [25; 39] in the MEN1-group vs 34 [29; 37] in sporadic PHPT ($P = 0.308$). We did not receive a difference in preoperational levels of parathormone (145.2 pg/ml [98.7; 227.0] in MEN1 group and 152.07 pg/ml [113.90; 241.38] in sporadic PHPT, $P = 0.248$, as well as in albumin-corrected total blood calcium, phosphorus, and daily calciuria ($p > 0.05$ for all)). Also, no statistical difference was found in postoperative levels of PTH ($P = 0.605$) and total blood calcium ($P = 0.466$). Our groups did not differ in the prevalence of nephrocalcinosis/nephrolithiasis (59% in the MEN1group and 63% in the sporadic PHPT, $P =$ 0.615). Bone mineral density less than -2.0 SD (Z-score) was found more often in MEN1group: 54 vs 34% in sporadic patients, $P = 0.031$. There were significant differences in the preoperative number of the parathyroid (PT) tumors at the time of the primary surgery (95% of patients with sporadic PHPT and 41% of patients in the MEN1 group had only one PT tumor preoperatively, $P < 0.001$). Differences were also obtained by histological characteristics of the PT tumors (the frequency of adenoma, hyperplasia, and carcinoma occurrence ($P < 0.001$)), recurrence of PTHT after the surgery (36% of patients in MEN1 group and 1% in sporadic PHPT, $P <$ 0.001), and family history of other endocrine neoplasia (69% of patients in MEN1 group and 18% in the sporadic PHPT, $P < 0.001$).
Conclusion
Number of PT tumors, their histological characteristics, recurrence rate and family history should be taken into consideration when evaluating young patients with PHPT.

Differential diagnosis between classic primary-, normocalcemic- and secondary hyperparathyroidism based on PFI and WI

Antonis Polymeris, Stavroula Psachna, Dimitrios Ioannidis, Dimitrios Lilis, Maria Drakou & Peter Papapetrou
"Sismanogleio-Amalia Fleming" Hospital, Department of Endocrinology, Metabolism and Diabetes Mellitus, Athens, Greece

Introduction
Patients with primary hyperparathyroidism (PHPT) present high calcium and PTH levels while some patients present also high PTH levels but normal calcium levels (NHPT) and such patients be considered as having normocalcemic hyperparathyroidism. On the other hand vitamin D deficient patients develop secondary hyperparathyroidism (SHPT). Sometimes normocalcemic- and secondary hyperparathyroidism coexist. Therefore in clinical settings it is very difficult to distinguish primary hyperparathyroidism and normocalcemic hyperparathyroidism from secondary hyperparathyroidism.
Aim
The aim of our case control study is to differentiate these entities using the parathyroid functional index (PFI = PTH × Ca devided by P) and the Wisconsin Index (WI = PTH × Ca).

Patients and Methods
Twenty seven patients with PHP, 15 patients with NPHPT, 38 patients with SHPT and 47 apparently healthy (NC) were included. All patients had normal renal function. In all participants serum calcium, phosphorus, PTH and albumin were measured and corrected calcium, PFI and WI were evaluated.
Results
The PHPT group had the highest PFI compared to NHPT group ($P=0.02$) and also to the other two groups (SHPT and NC, all $P<0.0001$). The WI was higher in the PHPT group compared to SHPT group ($P<0.0001$) and to NC group ($P<0.0001$). WI was also higher in the NPHPT group compared to NC group ($P<0.0001$). In the healthy individuals (NC group) the highest values of PFI (18.41) and of WI (20.81) were taken as cut-off values and based on this sensitivity and specificity of the two indexes were evaluated and are presented in the following table.
Conclusion
PFI and WI can be useful in the differential diagnosis of hyperparathyroidism. It seems that the PFI performs slightly better than the WI in distinguishing patients with PHPT and NHPT from healthy individuals, whereas the WI distinguishes only patients with PHPT from healthy individuals.

	PHPT	NHPT	SHPT
PFI Sensitivity (%)	100	100	100
Specificity (%)	100	100	63.2
WI Sensitivity (%)	100	97.9	97.9
Specificity (%)	100	93.3	73.7

Patient with Ia pseudohypoparathyroidism and the novel mutation in the GNAS gene

Anna Gorbacheva[1], Rustam Salimkhanov[1], Tatyana Pogoda[1], Viktor Bogdanov[1], Victoriya Zakharova[1], Anna Eremkina[1], Svetlana Mirnaya[2], Galina Melnichenko[1] & Natalia Mokrysheva[1]
[1]Endocrinology Research Centre, Moscow, Russia; [2]LLC "SSMC №1", Moscow, Russia

Introduction
Pseudohypoparathyroidism (PHP) is an orphan disease caused by a mutation in the *GNAS* gene encoding the α-subunit of G-protein. PHP is characterized by multihormonal resistance. A correlation between the genotype and phenotype of patients with *GNAS* mutations hasn't yet been described.
Clinical Case
Patient T., 19 years old male, admitted to our Centre with general weakness and overweight. Hypocalcemia, hyperphosphatemia, increased serum PTH, TSH and psychomotor retardation were first detected at the age of 8 months, however, the diagnosis was clinically made at age of 2 years. The patient's elder brother died at the age of 4 years for unknown reason (symptoms consistent with PHP), the mother, elder sister and her 2 daughters were healthy. From 2003 to 2008, the patient received alfacalcidol 1.2 mg daily without normocalcemia achievement. Further alfacalcidol was replaced with cholecalciferol 25,000 IU daily. At the same time, levothyroxine was prescribed. At the age of 4 years, the patient was diagnosed with diabetes insipidus followed by desmopressin therapy. At admission, T.'s consciousness was clear, however, he was partially oriented in space and time. T. had II stage obesity (BMI - 36.73 kg/m^2). There were a posture disturbance, shortening of the metatarsal bones of 1,2,4,5 fingers of both hands, shortening and deformation of 4 toes (phenotype of Albright hereditary osteodystrophy). Laboratory tests revealed normocalcemia - 2.16 mmol/l (2.15-2.55), normophosphatemia - 1.33 mmol/l (0.74-1.52), normocalciuria - 3.7 mmol/d (2.5-8), increased serum PTH -102.4 pg/ml (15-65). 25(OH) vitamin D was above 150 ng/ml. We temporarily discontinued cholecalciferol and prescribed alfacalcidol 0.75 mg daily with achievement of normocalcemia, normophosphatemia. Brain MRI visualized symmetrical zones of calcification in the subcortical nuclei and nuclei dentati of cerebellum. Nephrocalcinosis/nephrolithiasis were excluded. Given the lack of evidence for the diabetes insipidus a trial withdrawal of desmopressin was carried out, and the plasma and urine osmolality, blood serum electrolytes remained within the laboratory reference range. The typical MRI signal of the neurohypophysis was preserved. *GNAS* gene sequencing showed a novel heterozygous mutation, whose pathogenicity was proved.
Conclusion
PHP is caused by complex genetic and epigenetic defects. As a result, the path to diagnosis can be long and difficult. Determining the pathogenicity of novel GNAS mutations will improve understanding of gene function and expected clinical manifestations.

EP141

Risk factors of hypoparathyroidism after total thyroidectomy: A prospective study

Souha Kallel[1], Mohamed Amin Chaabouni[1], Faten Haj Kacem Akid[2], Majdi Trigui[1], Hamdi Frikha[2], Mohamed Abid[2] & Ilhem Charfeddine[1]
[1]Habib Bourguiba Hospital, Department of Otolaryngology (ENT) Head and Neck Surgery, Sfax, Tunisia; [2]Hedi Chaker Hospital, Department of Endocrinology, Sfax, Tunisia

Objective
Identify the risk factors of hypoparathyroidism (hypoPT) after Total thyroidectomy (TT).
Patients and Methods
Our study is a randomised clinical trial. It enrolled patients who underwent total thyroidectomy at the department of ENT surgery at Habib Bourguiba Hospital in Sfax between November 2020 and august 2021. We studied age, gender, type of surgery, duration of surgery, vitamin D level, magnesium level, histopathological exam, inadvertent resection of parathyroid gland, central neck dissection (CND) and the impact of prophylactic supplementation with oral calcium and vitamin D.
Results
Forty-seven patients were recruited for this study. They were divided into two groups: group 1: with prophylactic supplementation (24 patients) and group 2: without prophylactic supplementation (23 patients). We studied the impact of the risk factors on day one parathormone level. There were 19 patients with transient postoperative hypoparathyroidism. There was not a significant difference between the two groups regarding Day 1 PTH level. The results of univariate analysis showed a significant relation between transient hypoPT with severe hypovitaminosis D ($P=0.001$), operative time($P=0.01$), CND ($P=0.03$) and accidental resection of parathyroid gland ($P=0.04$). Multivariate analysis did not show any relation of hypoPT with any risk factor. The prophylactic supplementation allowed to significantly reduce the occurrence of biological and clinical hypocalcaemia.
Conclusion
In multivariate logistic regression we did not identify any independent risk factor. This explains the difficulty to predict the occurrence of such a complication. For that, prophylactic postoperative supplementation with oral calcium and vitamin D seems to be a safe choice to prevent postoperative hypocalcaemia.

Chronic hypoparathyroidism: Predictors of complications according to the Russian Registry

Elena Kovaleva[1], Alina Elfimova[1], Anna Eremkina[1] & Natalia Mokrysheva[2]
[1]Endocrinology Research Centre, Department of Parathyroid Disorders, Moscow, Russia; [2]Endocrinology Research Centre, Director, Moscow, Russia

Background
Chronic hypoparathyroidism is a relatively rare disease associated with various complications. The analysis of large databases of patients with chronic hypoparathyroidism is a necessary tool to enhance quality of medical care, as well as to determine the therapeutic approaches and prognostic markers of the disease.
Aims
To describe complications associated with chronic hypoparathyroidism and determine predictors of their development according to the Russian Registry.
Materials and Methods
The cross-sectional, observational, continuous study based on the Russian Registry of patients with hypoparathyroidism was carried out including 708 patients from 64 regions of the Russia. ROC-analysis was used to find cut-off points of predictors positively associated with complications.
Results
Nephrolithiasis was confirmed in 34.6%, nephrocalcinosis - in 11.7% of cases, 24.9% of patients met the criteria of CKD 3a-5 stages (glomerular filtration rate (GFR)-EPI less than 60 ml/min/1.73 m^2). The predictors of renal complication were non-target 24 h urinary calcium level ($P=0.033$, U-test, Benjamini-Hochberg correction $P_0=0.004$) and upper-reference range serum calcium level ($P<0.001$, U-test, $P_0=0.05$). Patients with preserved renal function took significantly lower doses of alfacalcidol - 1.00 μg/day [0.75; 2.00] vs 1.50 μg/day [1.00; 2.00] compared with patients with an GFR less than 60 ml/min/1.73 m^2 ($P=0.033$, U-test, $P_0=0.025$). Differences in doses of calcium carbonate weren't obtained ($P=0.270$, U-test). ROC-analysis revealed cut-off points of serum calcium level associated with the risk of GFR less than 60 ml/min/1.73 m^2: 1.97 for albumin-adjusted (AUC=0.651), 2.12 for total (AUC=0.610) and 1.08 for ionized (AUC=0.637) calcium levels. The cut-off point

for the decreasing GFR was duration of hypoparathyroidism–14.5 years, with a 3.58-fold increased risk. Also the excess of 24 h urinary calcium level more than 4.02 mmol/day was associated with an increased risk of structural disorders in the kidneys (AUC = 0.594). The cataract was confirmed in 47% patients, 82% of them had postsurgical hypoparathyroidism. The longer duration (10.5 years [6.0; 17.0] vs 6 [4.0; 9.0]) of hypoparathyroidism was associated with more frequent cataract ($P <$ 0.001, U-test, $P_0 = 0.004$) and this does not depend on medicaments and their doses. ROC-analysis showed cut-off points of serum ionized calcium level of 1.03 mmol/l, if it is not reached, the risk of developing cataracts increases (AUC = 0.652). The cut-off point for the development of cataracts was duration of hypoparathyroidism–10.5 years, with a 4.39-fold increased risk.

Conclusions

Hypoparathyroidism is associated with higher risks of renal stone formation, decreased GFR, cataract - especially in patients with longer duration of disease. The non-target serum calcium level was associated with renal and ophthalmological complications.

Primary hyperparathyroidism in pregnancy: A case report

Justina Bieliauskienė
Lithuania University of Health Sciences, Hospital of Lithuanian University of Health Sciences, Kaunas Clinics, Endocrinology Department, Kaunas, Lithuania

Introduction

Despite its rarity, the most common cause of hypercalcemia in pregnancy is primary hyperparathyroidism (PHPT). This disorder increases the risk of miscarriages, premature birth, intrauterine growth restriction, severe pancreatitis, preeclampsia, and neonatal hypocalcaemic tetany if not diagnosed and properly managed.

Case

A 31-year-old woman with 13 weeks of pregnancy and acute pancreatitis was admitted to the Obstetrics department. Since the 6th week of pregnancy, she has suffered from intense nausea, vomiting, and great general weakness. To find the cause of acute pancreatitis, the calcium level was measured, and severe hypercalcemia albumin-corrected at 3.5 mmol/l was found. Hypophosphatemia 0.61 mmol/l, hypomagnesemia 0.36 mmol/l, hypokalemia 2.27 mmol/l, anemia Hb 89 g/l, parathyroid hormone (PTH) 32.37 pmol/l, vitamin D 74.5 nmol/l, normal renal function, and hypercalciuria in 24-h urine at 15.42 mmol/l are also found in the laboratory. Abdominal-pelvic ultrasound revealed no kidney calcification and confirmed no abnormalities in the fetus. A neck ultrasound revealed a $3.1 \times 1.1 \times 2.4$ cm hypoechogenic mass under the left thyroid lobe, which looked more like an enlarged lymph node than a parathyroid gland, so the mass was aspirated with a fine needle. From the start of the hospitalization and while waiting for the puncture results, a large amount of infusion therapy was administered, lowering the calcium level to 2.8 mmol/l. Other electrolyte imbalances were also corrected. Cytology results confirmed a parathyroid gland, and a parathyroidectomy was performed in the 15th week of pregnancy. After surgery, PTH was 0.61 mmol/l, and the lowest albumin-corrected calcium level was 2.2 mmol/l on the 4th day after surgery. Calcium, magnesium, and vitamin D supplements were administered to prevent the symptoms of hypocalcemia. The patient complained of mild numbness in her arms for two days following surgery. The calcium level normalizes rapidly after surgery, and the mother and fetus were both in good health when the patient was released from the hospital for follow-up care. Postoperative pathology suggested a parathyroid adenoma.

Conclusions

The diagnosis of PHPT in pregnancy is difficult due to the physiological changes in pregnancy that can mask the clinical symptoms of hypercalcemia. When pregnant women have intensive digestive disorders, fatigue, polyuria, and muscle weakness, calcium levels should be measured to rapidly establish appropriate treatment and reduce the risk of maternal and fetal complications. Surgery is the first choice of PHPT treatment and it is the safest during the second trimester of pregnancy.

Differences in the clinical, laboratory, and operative variables between pre-menopausal and post-menopausal primary hyperparathyroid women: a single-center experience

Phulrenu Chauhan[1], Aasim Maldar[1], Murad Lala[2], N. F. Shah[1] & Manoj Chadha[1]

[1]P. D. Hinduja Hospital and Medical Research Centre, Department of Endocrinology, Mumbai, India; [2]P. D. Hinduja Hospital and Medical Research Centre, Department of Oncosurgery, Mumbai, India

Introduction

Primary hyperparathyroidism (PHPT) is an endocrine disorder wherein enlargement of one or more of the parathyroid glands causes autonomous overproduction of the parathyroid hormone (PTH), which leads to high serum calcium levels.

Objective

Comparison of clinical, laboratory, and operative variables between premenopausal (pre-M) and postmenopausal (post-M) women with PHPT.

Materials and Methods

A retrospective analysis of the data of female patients who underwent surgery for PHPT at a single centre, from January 2011 to December 2020, was done. Patients with familial PHPT and secondary hyperparathyroidism were not included.

Results

Of the 130 women with PHPT, 44.6% were pre-M and 55.4% were post-M. A significantly higher number of pre-M females were symptomatic compared to post-M females (pre-M vs post-M, 84.5% vs 68.1%, $P = 0.031$). Renal calculi were more common in pre-M women (34.5% vs 18.1%, $P = 0.032$), while rest of the clinical features of bone disease, gastrointestinal manifestations, proximal myopathy and neuropsychiatric manifestations were comparable between the two groups. Proportion of women with osteoporosis (6.7% vs 19.4%, $P = 0.071$), hypertension (13.8% vs 34.7%, $P = 0.012$) and diabetes mellitus (3.5% vs 16.7%, $P = 0.033$) was lesser in the pre-M group. Elevated serum alkaline phosphatase levels were significantly more prevalent in the pre-M group (37.9% vs 20.8%, $P = 0.032$). Mean serum calcium (12.35 ± 1.28 vs 11.96 ± 1.22 mg/dl, $P = 0.079$), median serum PTH (334 vs 239 pg/ml, $P = 0.051$), and median weight of the operated adenomas (1.75 vs 1.45 g, $P = 0.075$) were also higher in pre-M females. The proportion of ectopic adenomas and multiple adenomas, pre-surgery adenoma localization rates, and disease cure rates did not differ according to the menopausal status. Occurrence of post-surgery hungry bone syndrome was higher in the pre-M women (15.5% vs 1.4%, $P = 0.008$).

Conclusion

The majority of women with PHPT are post-M, but symptomatic presentation is more common in pre-M females. The severity of the disease, and occurence of hungry bone syndrome appears to be more in pre-M women, however, imaging and operative variables generally did not significantly differ between the two groups.

Hypocalcaemia induced dilated cardiomyopathy

Jan Drugda[1], Filip Gabalec[1], Markéta Hegarová[2] & Petr Lupínek[2]
[1]University Hospital Hradec Králové, 4th Department of Internal Medicine, Hradec Králové, Czech Republic; [2]Institute of Clinical and Experimental Medicine, Cardiology Department, Prague, Czech Republic

Introduction

Dilated cardiomyopathy is the third most common reason for heart failure and transplantation worldwide. The etiology of dilated cardiomyopathy often remains unclear, but in certain cases we can discover the cause, which can then contribute to better and more causal treatment.

Observation

We present a case of a 47-year-old man without any significant comorbidities in his medical history. In 2015 he underwent two hemithyroidectomies with a neck lymph node dissection due to a multifocal papillary thyroid cancer. The second hemithyroidectomy was complicated by a left-sided recurrent nerve paresis and severe postoperative hypocalcaemia caused by the accidental parathyroid removal. The surgery was followed by a radioiodine ablation and levothyroxine suppressive treatment. The radioiodine had to be reapplied twice because of a persistent biochemical incomplete response. From the beginning it was very difficult to achieve adequate calcium substitution mainly because of a previously documented noncompliance of our patient. He was repeatedly intolerant to calcium and vitamin D supplements and therefore adjusted doses himself. In 2020 he was hospitalized due to signs of a heart failure and was diagnosed with dilated cardiomyopathy. Chronic hypocalcaemia and the uncompensated post-operative hypoparathyroidism were considered as the most probable cause. Patients heart failure progressed rapidly, which led to LVAD (left ventricular assist device) implantation as a bridge for heart transplantation. Therefore, restoring normocalcaemia became a priority. We started newly available rhPTH (1-84) therapy, that successfully normalized calcium levels. Concerning the thyroid cancer, the thyroglobulin is still rising and newly there is a paratracheal thyroid residuum visible on the PET/CT scan, which will require surgical intervention.

Therefore, the heart transplantation is being postponed. However, according to the latest echocardiography there is an improvement of ejection fraction (from less than 20% to 30-35%) with a partial reverse myocardial remodelling and reduction of the end-diastolic diameter of the left ventricle.
Conclusion
Hypocalcaemia induced dilated cardiomyopathy is a rare condition but previous case reports suggest its potential reversibility after a timely hypocalcaemia correction. In our case there is a slight improvement, however not enough to prevent him from the heart transplantation which is now being postponed due to the planned surgery of the thyroid residuum. The non-compliance has contributed significantly to the severity of his condition.

EP146

The calcium-to-phosphorus ratio in the diagnosis of parathyroid disorders

Cherchir Faten, Ibtissem Oueslati, Arige Abid, Emna Aloui, Meriem Yazidi & Melika Chihaoui
La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia

Introduction
The diagnosis of primary hyperparathyroidism and hypoparathyroidism is still challenging because of the increasing frequency of non-classical presentations. The calcium-to-phosphorus ratio (Ca/P) (CPR) is an inexpensive biochemical marker that could be useful to diagnose parathyroid disorders.
Aim
The aim of this study was to assess the performances of CPR in the diagnosis of primary hyperparathyroidism and hypoparathyroidism.
Methods
This was a single-center, cross-sectional study including 32 patients with PHPT, 32 patients with hypoparathyroidism, and 32 controls. Total serum calcium (mg/l), serum phosphorus (mg/l), and parathyroid hormone (PTH) (ng/l) levels were recorded for all the participants. The diagnostic performance of the CPR was evaluated using the receiver operating characteristic (ROC) curve to define cut-off points. Sensitivity and specificity were calculated.
Results
The mean CPR was 1.58 ± 0.39 in patients with hypoparathyroidism, 5.37 ± 1.28 in patients with primary hyperparathyroidism, and 2.94 ± 0.49 in controls ($P < 10\text{-}3$). It was positively correlated with the PTH level ($r = 0.618$, $p < 10\text{-}3$). However, CPR was not correlated with age, body weight, and body mass index. CPR had an area under the ROC curve of 0.977 (95%-confidence interval: 0.941-1) in the diagnosis of primary hyperparathyroidism with an optimum cut-off level of 3.70, providing a sensitivity of 94% and a specificity of 100%. The area under the ROC curve of CPR in the diagnosis of hypoparathyroidism was 0.987 (95%-confidence interval: 0.969-1). A CPR level below 1.99 was defined to identify patients with hypoparathyroidism with a sensitivity of 97% and a specificity of 91%.
Conclusion
Our results demonstrated the accuracy of CPR as a reliable tool for the diagnosis of both primary hyperparathyroidism and hypoparathyroidism.

Long-term outcomes of parathyroidectomy in patients with primary hyperparathyroidism from patient's perspective

Dmitrii Buzanakov[1], Roman Chernikov[1], Sergey Efremov[1], Inna Gladkova[1], Tatiana Ionova[1], Tatiana Nikitina[1], Ilya Sleptsov[1], Anna Zolotoukho[2], Kirill Bubnov[2], Vladimir Skvortsov[2], Arina Vinogradova[2] & Vladimir Rusakov[1]
[1]Saint Petersburg State University Hospital, Saint Petersburg, Russia; [2]saint Petersburg State University, Saint Petersburg, Russia

Background
A parathyroidectomy (PTX) is the preferred standard treatment for patients with primary hyperparathyroidism (PHPT). the assessment of the surgery success from patient's perspective is important to provide patient-centered care.
Aim
We aimed to evaluate QoL changes in PHPT patients during 2-years follow-up after PTX and to identify preoperative predictors of meaningful QoL improvement after surgery.
Materials and Methods
The single-center observational prospective study was carried out from September 2019 to October 2022. All the patients underwent routine PTX. The objective success of surgery was confirmed by pathology confirmation of hyperfunctioning parathyroid tissue and postoperative normalization of Ca^{2+} and p-PTH. Patients filled out generic and specific QoL questionnaires–RAND SF-36 and PHPQoL before surgery, at 3, 12 and 24 months after PTX. To evaluate QoL changes after surgery GEE method with adjustment to gender, age, baseline QoL, clinical type of PHPT and level of hypercalcemia was applied. Binary logistic regression and χ^2 were used to explore the association between preoperative variables and whether the patient had experienced meaningful QoL improvement in ≥ 9 points by PHPQoL total score.
Results
A total of 72 PHPT patients (median age–53.1 ± 9.9 years, 94.4% females) who had objective surgery success were included in the analysis. From the total 70.8% patients had «symptomatic» PHPT, 29.2%–"asymptomatic" PHPT; mild hypercalcemia was detected in 65.3% patients, moderate or severe hypercalcemia–in 34.7% patients. During the entire follow-up period there was significant improvement in QoL after surgery by all scales of SF-36 questionnaire ($P < 0.01$), excluding bodily pain, and by the PHPQoL total score (GEE, $P < 0.001$) as compared with their preoperative values. Meaningful QoL improvement by PHPQoL total score (QoL response) was reported in 61.1% patients (QoL responders); the proportion of QoL responders was similar in patients with "symptomatic" and "asymptomatic" PHPT (60.8% vs 61.9%, $p > 0.05$). Among preoperative variables, including type of PHPT ("symptomatic" or "asymptomatic"), Ca^{2+}, p-PTH, disease duration, presence of comorbidities, patient's age and education along with QoL parameters, only mental component of QoL by PHPQoL was significantly predicting of QoL response after surgery (OR = 0.927, 95%CI = 0.874-0.984, $P = 0.013$).
Conclusions
Successful PTX was accompanied with remarkable QoL improvement for at least 24 months after surgery in both "symptomatic" and "asymptomatic" PHPT patients. Mental QoL component was the only one factor significantly predicting QoL response after surgery. This finding suggests that patients without overt clinical manifestation or prominent hypercalcemia, but with derangement of mental health may benefit from PTX.

Efficacy and safety of Cinacalcet therapy for patients with primary hyperparathyroidism: A retrospective observational study

Håkon Johnsen & Atul Kalhan
Royal Glamorgan Hospital, Diabetes and Endocrinology, Ynysmaerdy, United Kingdom

Introduction
Cinacalcet therapy remains the only alternative to elective parathyroidectomy (EP) for lowering serum calcium (Ca) in patients with primary hyperparathyroidism (PHPT). National Institute of health and Care Excellence (NICE), UK support use of cinacalcet in symptomatic patients with PHPT who decline surgery (or deemed unfit for surgery), if serum Ca levels > 2.85 mmol/l. The limitation in wider use of cinacalcet remains cost effectiveness apart from limited data related to its long term efficacy and safety.
Objective
To evaluate long term safety & efficacy of cinacalcet in patients with PHPT.
Methodology
We carried out a retrospective observational study of all patients with a biochemically confirmed diagnosis of PHPT who were initiated on cinacalcet therapy in Cwm Taf healthboard. The clinical records were accessed and with a focus on noting the indication, duration, dose and side effects of cinacalcet. Biochemical results were analysed for Serum Ca, Phosphate, PTH (pre and post cinacalcet therapy) and a note was made of relevant radiological investigations.
Results
We identified a total of 56 patients with PHPT who received cinacalcet therapy from September 2013 to January 2021. Cinacalcet use was observed to be associated with a reduction of mean serum calcium level by 0.4 mmol/l ($P < 0.001$; CI 0.369- 0.484). There was a decrease in mean serum PTH level by 3.6 mmol/l ($P < 0.001$; -1.6914 to -5.438; $n = 17$). The adverse drug reactions (ADR) encountered in this study were mainly gastrointestinal (GI) symptoms such as nausea, vomiting and abdominal discomfort. 5 of the patients discontinued cinacalcet due to GI side effects. Mild hypocalcaemia was noticed in 2 of the patients.
Discussion
Our retrospective observational study results show a significant as well as sustained reduction in serum Calcium and PTH levels with use of cinacalcet in patients with PHPT. This therapy is generally well tolerated with no long term safety concerns. The threshold for offering cinacalcet therapy should be lowered in patients with PHPT considering significant reduction in serum calcium and PTH levels which may translate into improved intermediate to long term secondary outcomes.

The daily calcium profile in patients with chronic hypoparathyroidism depending on different 25(OH) vitamin D level

Elena Kovaleva[1], Anna Eremkina[1], Alina Elfimova[1], Elena Karaseva[1], Anna Gorbacheva[1], Lizaveta Aboishava[1] & Natalia Mokrysheva[2]
[1]Endocrinology Research Centre, Department of Parathyroid Pathology, Russia; [2]Endocrinology Research Centre, Director, Russia

Introduction
Chronic hypoparathyroidism is a rare disease, which usually treated with active forms of vitamin D and oral calcium. Supplementation with native vitamin D can be useful both for achieving "non-skeletal" effects of vitamin D and for a more stable serum calcium profile.
Aim
The aim of this study was to estimate the daily serum calcium and 24-hour urine calcium levels in patients with chronic hypoparathyroidism depending on different 25(OH) vitamin D (25(OH)D) values.
Methods
40 patients with chronic hypoparathyroidism (38 with postsurgical and 2 with idiopathic) were involved in the study. All patients were divided in two groups, matched on sex and age, according to the median level of 25(OH)D in the total group (1–with 25(OH)D <35.0 ng/ml; 2 - with 25(OH)D ≥ 35.0 ng/ml). To assess the variability of calcium during the day, the measurement of the total calcium (Ca_{total}) was carried out every 2 hours within 24 hours, albumin - once in the early morning (to calculate albumin-adjusted calcium, Caadj). All patients received conventional treatment with active metabolites/analogues of vitamin D (alfacalcidol, calcitriol) and calcium supplements.
Results
Serum 25(OH)D level was significantly higher in group 2 (28.45 ng/ml vs 44.15 ng/ml, $P<0.001$, U-test). There were no significant differences between groups by Ca_{total}, Ca_{adj} levels and daily calciuria. Patients with serum 25(OH)D level $\geq$ 35.0 ng/ml had significant tendency to achieve more often the target levels of Ca_{total} (128 vs 149 measurements during the day, $P=0.049$, χ^2). However, this tendency disappeared for Ca_{adj} ($P=0.517$, χ^2). The frequency of hypercalcemia by Ca_{adj} was significantly lower in patients with 25(OH)D ≥ 35.0 ng/ml ($P=0.006$, χ^2), but not for Ca_{total} (a trend, $P=0.042$, χ^2). As regards hypocalcemia, there were no significant differences by Ca_{adj} ($P=0.581$, χ^2) and it tends to lower frequency by Ca_{total} ($P=0.023$, χ^2).
Conclusion
The additional administration of native vitamin D in patients with chronic hypoparathyroidism may have some advantages, related to the general concept of worldwide vitamin D deficiency and better disease control. In this study, we did not confirm statistically significant differences for chronic hypoparathyroidism in the calcium profile depending on different 25(OH)D levels. But we obtained some promising statistical further studies are required.

Low 25(OH) vitamin D levels are associated with Long COVID syndrome in COVID-19 survivors

Luigi Di Filippo[1], Stefano Frara[1], Fabrizio Nannipieri[2], Alice Cotellessa[3], Massimo Locatelli[3], Patrizia Rovere-Querini [4] & Andrea Giustina[1]
[1]Institute of Endocrine and Metabolic Sciences, Università Vita-Salute San Raffaele, IRCCS Ospedale San Raffaele, Milan, Italy; [2]Clinical Research, Abiogen Pharma, Pisa, Italy; [3]Laboratory Medicine Service, IRCCS Ospedale San Raffaele, Milan, Italy; [4]Division of Immunology, Transplantation & Infectious Diseases, Università Vita-Salute San Raffaele, IRCCS Ospedale San Raffaele, Milan, Italy

Low vitamin D levels were consistently reported as a risk factor for worse outcomes in hospitalized COVID-19 patients. Emerging evidences suggest that in 50–70% of COVID-19 survivors several post-COVID symptoms can be observed up to 3 months after acute-disease, representing a novel clinical condition defined Long-COVID syndrome. To date, the predisposing factors for this syndrome are still poorly understood. We retrospectively aimed at evaluating the influence of 25(OH) vitamin D levels on Long-COVID occurrence in patients previously hospitalized for COVID-19, re-assessed 6-months after discharge. Long-COVID was defined based on the National Institute for Health and Care Excellence-guidelines and approximately 500 patients were re-evaluated after the first pandemic-wave. While excluding patients with therapies/comorbidities affecting bone metabolism, and/or those admitted in ICU during hospitalization, only 50 Long-COVID patients were eligible for enrolment and compared in an age, sex, comorbidities and acute-disease characteristics-matched 1:1 ratio with non-Long-COVID patients. 25(OH) vitamin D was measured at hospital-admission and after 6-months. Median 25(OH) vitamin D levels were 14.7 and 20.6 ng/ml, at hospital-admission and at 6-month follow-up, respectively. At admission, vitamin D deficiency (25(OH) vitamin D <20 ng/ml) was found in 71 patients, and, at 6-month follow-up, in 46 patients. We observed lower 25(OH) vitamin D levels, evaluated at follow-up visit, in Long-COVID group than those without (20.1 vs 23.2 ng/ml, $P=0.03$). No statistically significant differences were observed regarding prevalence of vitamin D deficiency between those with and without Long-COVID. Regarding the different affected health areas evaluated in the entire cohort, we observed lower 25(OH) vitamin D levels in those with neurocognitive symptoms at 6-month visit (n.7) as compared to those without (n.93) (14.6 vs 20.6 ng/ml, $P=0.042$). In patients presenting vitamin D deficiency both at admission and at follow-up (n.42), those affected by Long-COVID (n.22) were characterized by lower 25(OH) vitamin D levels, evaluated at follow-up, compared to those not affected (n.20) (12.7 vs 15.2 ng/ml, $P=0.041$). In multiple regression analyses, lower 25(OH) vitamin D levels, evaluated at follow-up, resulted as the only variable significantly associated with the Long-COVID occurrence ($P=0.016$, OR 1.08-CI 1.01-1.15). In conclusion, COVID-19 survivors with Long-COVID have lower 25(OH) vitamin D levels as compared to matched patients without Long-COVID. Moreover, lower vitamin D resulted as an independent risk factor for the occurrence of this syndrome. Our data suggest that evaluating vitamin D levels in COVID-19 patients after hospital discharge and improving their vitamin D status when needed may be helpful in reducing the burden of COVID-19 sequelae.

Evaluation of the efficacy and safety of long-term Cinacalcet in primary hyperparathyroidism

Isabel Huguet, Iciar Martin Timon, Inmaculada Moreno-Ruiz, Vanessa Triviño Yannuzzi, Maria Llavero, Olalla Meizoso-Pita, Manuel Angel Gargallo Fernandez & Cristina Sevillano-Collantes
University Hospital Infanta Leonor, Endocrinology, Madrid, Spain

Introduction
Cinacalcet is a positive allosteric modulator of the calcium sensing receptor successfully used to decrease serum calcium in primary hyperparathyroidism (pHPT) patients in the short-term, but long-term data are scarce. In this single-centre retrospective analysis, we investigated the efficacy and safety of cinacalcet in pHPT patients who received more than 5 years of treatment.
Methods
Statistical analysis was performed using free online software (www.socscistatistics.com) and Excel database statistics functions; a non-paired t-test was used in the analysis of pre-treatment biochemistry in low vs high dose cinacalcet therapy, and a paired t-test was used for the analysis of pre- vs post-treatment biochemistry. A P-value of <0.05 was considered statistically significant.
Results
21 patients (81% females) were treated for a mean of 7.3 years (SD 1.74). Patients were commenced on cinacalcet due to increased surgical and/or anaesthetic risk (8), persistent/recurrent disease (4) and patient unwilling to undergo surgery (3). 6 patients received cinacalcet since adenomas were not localized preoperatively. Initial dose was 30 mg/day in 76% of cases, with the remainder starting at 60 mg/day. Baseline calcium levels did not differ between the two different starting dose groups (11.35 mg/dl vs 11.84 mg/dl: P 0.06). 47% remained on same dose and 42% increased dose during follow up. Serum calcium level decreased significantly at 3 months (11.47 mg/dl vs 10.7 mg/dl; $P<0.05$), with 66% reaching serum calcium <10.5 mg/dl. Compared to basal levels, at last appointment calcium decreased significantly (11.47 mg/dl vs 9.7 mg/dl; $P<0.05$), phosphorus increased significantly (2.57 mg/dl vs 3.2 mg/dl; $P<0.05$). There was a non-significant decrease in PTH (217 pg/ml vs 191 pg/ml; $P=0.1$). 3 patient developed adverse events (myalgia, headache and no-specified), all of which could be managed without a definitive withdraw of treatment (temporal stop 2, decrease dose 1). 6 patients died during follow up, 5 of them were initially classified as "increased surgical and/or anaesthetic risk". One death could be related to HPP: pancreatitis, with calcium levels of 12.5 mg/dl probably due to temporal suspension of the treatment of unknown reason, with previous excellent calcium control. The rest of exitus were due to age related diseases. 2 patient developed hip fracture during treatment with cinacalcet.
Conclusion
Cinacalcet seems effective in lowering serum calcium and PHPT patients in the long-term. The high mortality of our study seems to be related to the fact that cinacalcet is mainly used in patients who are poor surgical candidate.

Incidental hypercalcemia during denosumab treatment for osteoporosis: rebound phenomenon or occult primary hyperparathyroidism

Lakshminarayanan Varadhan[1], Elizabeth Adams[2], Nishita Padmanabhan[1] & Zoe Paskins[2]
[1]University Hospitals of North Midlands NHS Trust, Diabetes and Endocrine Department, Stoke on Trent, United Kingdom; [2]Haywood Hospital, Rheumatology Department, Stoke on Trent, United Kingdom

Introduction
Denosumab is an important treatment option for osteoporosis. Rebound hypercalcemia on discontinuation of denosumab is well documented. Denosumab can increase PTH, peaking within 2-4 weeks of administration and subsiding thereafter, therefore making diagnosis of primary hyperparathyroidism (pHPT) difficult.The aim of our case series is to review the calcium fluctuations in relationship to timing of denosumab administration and identify the possibility of rebound hypercalcemia during denosumab treatment.
Methods
A retrospective case-series analysis of patients discussed at metabolic bone multidisciplinary meeting due to elevated calcium on denosumab treatment (2019-2022) was conducted. Calcium was checked as part of standard care during denosumab treatment, and if elevated led to subsequent PTH measurement. Based on the timing of calcium measurement to denosumab administration, the hypercalcemia was classified as *pre-denosumab* (taken preceding denosumab administration), *post-denosumab* (within 3 weeks of administration of denosumab) or *mid-denosumab* (typically between 3 weeks post administration and 2 weeks before next injection)
Results
$n=16$; all patients had normal calcium preceding denosumab initiation. The patterns identified were:

A. *One-off pre-denosumab hypercalcemia*: ($n=3$): Elevated calcium noted only once; all were on a pre-denosumab sample. 2 of these had a high PTH on post-denosumab both of which normalized on subsequent pre-denosumab sample; one had persistent PTH throughout.
B. *Persistent pre-denosumab hypercalcemia*: ($n=2$). These patients had elevated calcium on more than one occasion on pre-denosumab samples. One patient had elevated PTH, but on post-denosumab sample.
C. *Likely pHPT*: ($n=5$): These patients had high calcium not only in pre but also in the post denosumab samples. 4 had elevated PTH.
D. *Inconclusive*: ($n=6$). These patients had documented hypercalcemia in pre and mid-denosumab samples but normal readings post-denosumab, therefore likely pointing towards calcium lowering effect of denosumab. 4 had documented high PTH.

Conclusion
Incidental hypercalcemia can be commonly encountered during denosumab treatment. A significant proportion of these patients may represent 'rebound' hypercalcemia and less likely to be true pHPT (groups A,B). The normal calcium readings preceding denosumab initiation, timing of the elevated reading (pre-denosumab being elevated) and a lack of consistent PTH raise (normal PTH despite being on Denosumab) may support the likelihood of this phenomenon during denosumab treatment. The possibility of pHPT being unmasked or incidentally idenfied needs to be considered too (groups C,D). This case series depicts the complexities and uncertainties of identifying an aetiology for high calcium during denosumab treatment and hence the need for multi-disciplinary approach and long term prospective studies.

Phosphocalcium profile and prevalence of osteoporosis in patients with cushing's disease at diagnosis

Hanae Rachedi[1], Rania El Amel[1], Dounia Zerrouki[1], Nabila Zeryouh[1], Hanae Bakmizi[1], Siham Rouf[2] & Hanane Latrech[2]
[1]Endocrinology, Diabetology and Nutrition Departement, University Hospital Center Mohammed VI, Oujda, Morocco; [2]Department of Endocrinology, Diabetology And Nutrition, Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy, Mohamed I University, Oujda, Morocco

Introduction
Cushing's disease represents the most frequent etiology of endogenous cushing's syndrome. It is a severe condition associated to many comorbidities and increased mortality that occurs a long-term management to optimize these patients outcomes. This study aims to describe the phosphocalcium profile and to assess the prevalence of osteporosis in patients with cushing's disease.
Materiels and Methods
Retrospective and descriptive study, including 17 patients with cushing's disease hospitalized in the Endocrinology-Diabetology-Nutrition department of university hospital center Mohammed VI of Oujda between 2016 and 2022, we had excluded the cases where a bone densitometry was missing. Statistical analysis was performed by SPSS version 21 software.
Results
The average age was 34.8 ± 10.8 years, with a clear female predominance (70.6%). The average time to consultation after onset of symptomatology in our patients was 3.2 ± 3 years. The mean level of phosphorus in our series was 32.3 ± 4.5 mg/l, 5.8% of our patients had hypophosphatemia. On the other hand, none of our patients had hypocalcemia with a mean value of calcemia at 93.8 ± 3.1 mg/l. The mean vitamin D level in our series was 16.2 ± 7.9 ng/ml, hypovitaminosis D was described in 94.1% of the patients, of which 31.2% had vitamin D deficiency, while 62.9% were vitamin D deficient. Eighteen percent of our patients had osteoporosis, with a predominance of the lumbar spine in all patients. Osteopenia was found in 53% of the patients in our series, with involvement of the lumbar spine in all cases, 30% of whom had involvement of the lumbar spine associated with the femoral neck.
Discussion-Conclusion
Cushing's disease leads to many complications that heavily impact on life's quality and survival of affected patients. Cushing osteopathy is one of the most severe ones, in fact, the risk of fracture increases immediately with the onset of the disease, hence the need for rapid management in order to limit these complications and optimize the survival of these patients.

Bone mineral metabolism in young hemodialyzed women with prolonged amenorrhea

Manish Kumar[1] & Pankaj Hans[2]
[1]Chikitsa Clinic, Medicine, Patna, India; [2]Patna Medical College Hospital, Medicine, Patna, India

Introduction
Since chronic renal failure is accompanied with bone abnormalities, the term renal osteodystrophy has become widely accepted. In women, chronic renal failure is commonly accompanied by endocrine problems that cause irregular menstruation. The majority of investigations on renal osteodystrophy, however, have not considered the potential impact of these hormonal imbalances on the etiology of the bone changes observed in these patients.
Objective
In the current study, the bone mineral metabolism in a group of young hemodialyzed women with persistent amenorrhea was assessed and contrasted with women of comparable age and menstrual cycle
Method
The study included 70 women, of which 30 had persistent amenorrhea, which is the lack of menstrual blood for more than five months, and 40 had regular menstrual cycles. All patients underwent a bone mineral density (BMD) analysis that simultaneously assessed various biochemical parameters, intact parathyroid hormone (iPTH), sexual hormone measurements including total estradiol, follicle-stimulating (FSH), and luteinizing hormone, and markers of bone resorption such as the procollagen type 1 cross-linked carboxy-terminal telopeptide (ICTP). Unpaired observations were compared using the Student's t-test between two groups of data (two-tailed). The linear regression technique was used to compare two variables. P values below 0.04 were regarded as significant.
Result
Both groups had comparable levels of serum iPTH, calcium, and phosphorus. Amenorrheic women had greater serum levels of alkaline phosphatase. Despite being normal when compared to non-uremic women, the total serum estradiol levels in amenorrheic women was substantially lower than that of women who regularly menstruate. The amenorrheic women had considerably greater serum levels of FSH and ICTP. Compared to dialysis patients who had regular periods, the trabecular BMD in the lumbar spine was likewise considerably lower in amenorrheic women. Significant correlation was seen in the amenorrheic group between lumbar spine BMD and total estradiol levels.

Conclusion
These results demonstrated that when compared to regular menstruation women on dialysis, persistently amenorrheic young women on dialysis have reduced trabecular BMD and signs of accelerated bone resorption. It is yet to be determined how these findings may affect the course of uremic osteodystrophy in its natural state.

A case with late-onset Ornithine Transcarbamylase Deficiency as a possible cause of osteoporosis

Sena Ilin, Serife Mehlika Kuskonmaz, Gönül Koç, Sevde Nur Fırat, Tülay Omma & Cavit Çulha
Ankara Research Hospital, Endocrinology Department, Ankara, Turkey

Introduction
Ornithine transcarbamylase deficiency (OTCD) is a urea cycle disorder that causes the accumulation of ammonia, which can lead to neurocognitive problems in patients[1]. Here we report a 21-year-old man who was diagnosed with OTCD during investigation for secondary osteoporosis.
Case
The patient applied to the Endocrinology department complaining of widespread muscle-joint pain, shortening in height, nausea/vomiting attacks followed by protein-rich nutrition and weight loss (8 kilograms in 5 months). His personal history was otherwise unremarkable. He had a brother with osteoporosis diagnosed of 17 while being investigated for avascular necrosis of the hip. Bone mineral density measured with dual X ray absorptiometry showed a lumbar Z score-3.4 and a femur neck Z score of -2.2 concluded. Scoliosis was observed on X ray and no fracture is detected computed tomography. No hypogonadism was detected in laboratory tests performed for secondary osteoporosis. 1 mg dexamethasone suppression test was normal. Celiac markers, ANA and the enzymatic test for Gaucher's disease were negative. Serum calcium, phosphorus, magnesium and alkaline phosphatase, 24-hour urinary calcium, parathormone, and 25OH vit-D values and anterior pituitary hormones, were found to be within the normal limits as well as abdominal ultrasonography. The patient had suffered learning difficulties since childhood, protein intolerance and the development of nausea and vomiting attacks after consuming foods rich in protein. Serum ammonia test revealed hyperammonemia. Genetic tests showed hemizygote c.206A > G (p.Gln69Arg) mutation in OTC gene. The patient is given a protein poor diet which resulted in significant improvement with clinical symptoms and a decrease in nausea and vomiting.
Discussion
Osteoporosis was reported previously in lysinuric protein intolerance which is a member of the family of urea cycle defects[2]. In the present case, OTCD may be a possible cause of osteoporosis. Although the mechanism is not fully understood the low-protein content in diet, the decrease in amino acid activity can cause decreased collagen synthesis, leading to a decrease in bone density[3].

The role of osteoprotegerin and sclerostin in bone metabolism in children with congenital adrenal hyperplasia

Gülay Karagüzel[1], Esra Erkul[1], Yüksel Aliyazıcıoğlu[1], Ercüment Beyhun[1] & Bircan Sönmez[1]
[1]Karadeniz Technical University, School of Medicine, Trabzon, Turkey

Aim
Serum sclerostin levels as an indicator of bone resorption in children with congenital adrenal hyperplasia (CAH) have not been evaluated to date. The aim of this study was to determine the role of osteoprotegerin (OPG) and sclerostin in bone metabolism in children with CAH.
Methods
Thirty-one patients (19 girls, 12 boys) with CAH (aged 11.6 ± 3.7 years) and 31 healthy children (age- and sex-matched) as controls were included in the study. The patients were using glucocorticoids (GC) for at least six months. Serum levels of OPG, sclerostin, calcium, phosphate, alkaline phosphatase, parathormone, and 25-hydroxy vitamin D were assessed in patients and controls. Bone mineral density was measured by dual energy X-ray absorptiometry (DEXA) of the lumbar spine.
Results
In patients with CAH and controls, the mean lumbar spine bone mineral density were 0.841 ± 0.220 and 0.852 ± 0.202 ($P > 0.05$), respectively, and 70% of the patients and 68% of the controls were pubertal. Serum levels of calcium, phosphate, alkaline phosphatase, and parathormone were not found different in the groups ($P > 0.05$). Serum OPG levels of the patients were significantly higher than the controls ($P < 0.001$). Serum sclerostin levels were higher in pubertal patients than the pubertal controls ($p < 0.05$), but there is no significant difference in prepubertal patients and controls ($P > 0.05$). A positive correlation was found between serum OPG and sclerostin levels in patients, while there was a negative correlation between serum OPG and sclerostin levels in controls. Serum 25-hydroxy vitamin D levels of the patients and controls were 19.2 ± 7.5 ng/ml and 14.2 ± 4.8 ng/ml, respectively ($P < 0.05$).
Conclusions
The role of sclerostin in bone metabolism was investigated for the first time in patients with CAH by the present study. Increased OPG levels in the patients were considered as a compensation mechanism against the tendency of increased bone resorption in these patients. As stated in the literature, serum sclerostin levels decreased with increasing age in healthy children, but the expected decrease was not observed in the pubertal period in the patient group. This can be considered as a finding of increased susceptibility to bone resorption in patients with CAH. In addition, the concomitant increase in serum sclerostin and OPG levels in the patients may be associated with increased bone turnover in CAH, especially in the pubertal period.

Evaluation of biochemical markers of bone metabolism in patients with secondary hyperparathyroidism and chronic kidney disease

Natalia Karlovich & Tatsiana Mokhort
Belarusian State Medical University, Endocrinology, Minsk, Belarus

The diagnostic possibilities of using biochemical markers of bone metabolism in patients with secondary hyperparathyroidism (SHPT) and chronic kidney disease (CKD) have not yet been adequately evaluated. The aim of the study: To evaluate biochemical markers of bone metabolism in patients with various stages of CKD, their relationship with SHPT and bone mineral density.
Materials and Methods
The study included 452 patients with various stages of CKD and 60 persons of the comparison group without CKD aged 20 to 70 years. Serum levels of parathyroid hormone (PTH), vitamin D (25(OH)D), calcium (Ca), phosphorus (P), alkaline phosphatase (AP), osteocalcin (OC), collagen type 1 crosslinked C-telopeptide (CTX) were determined by enzyme immunoassay. Bone mineral density of the lumbar spine (LS), proximal femurs (PF), femoral necks (FN), radius (R), distal part of the radius (R33%) was assessed by double X-ray absorptiometry (DXA). A neural network algorithm for clustering patients was applied to identify a cluster of patients with optimal bone tissue parameters.
Results
The incidence of osteoporosis in patients with CKD ranged from 13.8% in LS, PF, FN to 28.2% in radius. Incidence of osteoporosis increased up to 20% in patients with CKD 4-5. PTH is a major factor of BMD loss in CKD patients, maximum frequency of osteoporosis was noted in patients with SHPT and CKD5. A significant relationship was established between the OC, CTX, ALP and PTH, as well as with the presence of osteoporosis. OC, CTX, ALP progressively increase

with exacerbation of renal failure, which is a consequence of a violation of both bone metabolism and degradation and elimination in conditions of reduced renal function. Population-wide reference intervals OC, CTX are not applicable in patients with CKD 4-5. Using a neural network algorithm, we proposed reference intervals for osteocalcin: CKD 4 - 55-125 pg/ml, CKD 5 before dialysis - 35-235 pg/ml, dialysis - 70-550 pg/ml; for CTX: CKD 4 - 0.3-1.2 pg/ml, CKD 5 before dialysis - 0.7-2.3 pg/ml, dialysis - 0.7-2.5 pg/ml.
Conclusion
The detection of low BMD in patients with SHPT and CKD in some cases requires clarification of bone metabolism. Estimation of OC, CTX, ALP can be used for such purpose. When interpreting the results of the assessment of OC, CTX, the specific reference intervals in CKD 4-5 should be taken into account.

Atypical parathyroid adenomas and parathyroid carcinomas: Are there any differences?

Jesús Machuca Aguado[1], Pablo Rodríguez de Vera Gómez[2], Pablo Ferreira Ocampo[3], Álvaro Gutiérrez Domingo[1], Miguel Ángel Idoate Gastearena[1] & Tomás Martín Hernández[2]
[1]Hospital Universitario Virgen Macarena, Pathology, Sevilla, Spain; [2]Hospital Universitario Virgen Macarena, Endocrinology and Nutrition, Sevilla, Spain; [3]Hospital Universitario Fundación Alcorcón, Endocrinology and Nutrition, Alcorcón, Spain

Introduction
Parathyroid carcinoma (PC) is a very rare neoplasm, which has histopathological features different from those of atypical parathyroid adenomas (APA). However, the clinical course of both tumour types is similar, with the exception of the unusual metastases of the carcinoma. With this study we aim to identify those clinical-analytical and anatomopathological variables that allow us to differentiate PCs from APAs.
Material and Methods
Retrospective observational clinicopathological study of a cases series diagnosed with PC and APA in the period 2000-22. The classic histological criteria of invasion of adjacent structures, vascular permeation, perineural infiltration and/or development of metastases were used to diagnose PC. Adenomas with atypical cytoarchitectural features, but without features of invasiveness or metastasis were considered APA. Immunohistochemistry for parafibromin, PGP 9.5 and galectin-3 was performed. Post-surgical tumour recurrence was determined by detection of disease on imaging and/or by elevation of parathormone (PTH) in blood.
Results
A total of 17 patients with a mean age of 59.6 years were studied. 41.2% ($n=7$) were classified as PC, of which one had distant metastases, and the remaining 58.8% ($n=10$) as APA. No statistically significant differences were observed between PC and APA in the variables of age, sex, pre-surgical blood tests [PTH ($P=0.5$) and calcemia ($P=0.5$)], ultrasound characteristics, percentage of post-surgical cure ($P=0.3$) and recurrence of hyperparathyroidism ($P=0.6$). The case of metastatic PC showed no differential histopathological features. Immunohistochemically, 29.4% ($n=5$) showed loss of parafibromin, of which 2 corresponded to APA and 3 to PC. No differences were observed in the expression of PGP 9.5 ($P=0.5$) or galectin-3 ($P=0.7$) between PC and APA. The group of tumours not expressing parafibromin were associated with age (74 ± 13.3 vs 54.36 ± 16.3 years, $P=0.04$), higher frequency of bone fractures (40% ($n=2/5$) vs 0% ($n=0/12$), $P=0.07$), capsular invasion (100% ($n=5/5$) vs 58.3% ($n=7/12$), $P=0.06$), infiltration of adjacent structures (100% ($n=5/5$) vs 33.3% ($n=4/12$), $P=0.05$) and loss of PGP 9.5 expression (80% ($n=4/5$) vs 16.7% ($n=2/12$), $P=0.02$).
Conclusion
No analytical or clinical behavioural differences were observed between PCs and APAs. Interestingly, loss of parafibromin is associated with locally more aggressive tumour behaviour.

Primary hyperparathyroidism: A rare form of presentation

Marta Vaz Lopes[1], José Vicente Rocha[1], Carolina Peixe[1], Mariana de Griné Severino[1], Ana Coelho Gomes[1] & Maria Joao Bugalho[1,2]
[1]Hospital de Santa Maria, Centro Hospitalar Lisboa Norte EPE, Serviço de Endocrinologia, Lisboa, Portugal; [2]Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal

Introduction
Primary hyperparathyroidism (PHPT) is characterized by parathyroid hormone (PTH) overproduction, causing hypercalcemia. The most common cause is a parathyroid adenoma. PHPT most frequently presents as asymptomatic hypercalcemia or with nonspecific symptoms. Less frequently, it presents with the classical manifestations of bone disease and nephrolithiasis. Acute pancreatitis (AP) as the initial manifestation of PHPT has been reported rarely. Hypercalcemia can cause AP by leading to pancreatic calculi and ductal obstruction, and by activating trypsinogen to trypsin, causing pancreatic autodigestion.
Case Report
A 37 year-old man was admitted to the hospital due to AP. Initial tests revealed elevated amylase and lypase levels (164U/l [NR 13-53U/l] and 106U/l [NR 13-60U/l], respectively), hypercalcemia (14.9 mg/dl [NR 8.6-10.2 mg/dl]), hypophosphatemia (1.9 mg/dl [NR 2.5-4.5 mg/dl]) and acute kidney failure. Further investigation showed elevated serum PTH (1241 pg/ml [NR 14-72 pg/ml]), suggesting PHPT. During hospitalization, the patient was treated with IV fluids and pamidronate 90 mg. On discharge, calcemia was 10.3 mg/dl, amylase was 34U/l, lypase was 66U/l and renal function was normal. The patient denied any previous history of bone disease, nephrolithiasis or other symptoms of hypercalcemia. Renal ultrasound excluded kidney stones. To evaluate for the presence of multiple endocrine neoplasia syndromes types 1 and 2, pituitary function, calcitonin and plasma metanephrines were measured, which were normal. 99mTc-Sestamibi scintigraphy identified a 15 mm right inferior parathyroid nodule, therefore the patient underwent right inferior parathyroidectomy. Intraoperative PTH level decreased to 7 pg/ml. Histology revealed a parathyroid adenoma as the etiology of PHPT. The patient was discharged under calcium carbonate and cholecalciferol treatment (6000 mg + 1600UI per day). Laboratory tests in the first postoperative appointment showed normal PTH, calcium and phosphorus values (71 pg/ml, 9.7 mg/dl and 3.2 mg/dl, respectively). Levels remain normal after having suspended calcium and cholecalciferol therapy (59 pg/ml, 9.6 mg/dl and 2.7 mg/dl, respectively). There has been no recurrence of pancreatitis.
Discussion and Conclusions
AP in patients with PHPT is uncommon (estimated prevalence: 1%-13%), however this can be the initial manifestation of PHPT. While hypercalcemia causes under 1% of AP cases, in patients where calcemia is elevated, investigation of endocrine causes such as PHPT should be prompted.It is also important to note that although histology in this case suggested parathyroid adenoma, the patient presented with severe hypercalcemia ($>$ 14 mg/dl) and very high serum PTH ($\geq$ 10-12 times the upper limit of normal), which are potential predictive factors of parathyroid carcinoma (versus benign causes of PHPT). Therefore, close monitoring will be required.

Ectopic parathyroid adenoma of the upper jugulo-carotid region

Moncef Sellami[1], Ayadi Sirine[1], Noura Salem[1], Zouche Imen[2], Faten Haj Kacem Akid[3], Mohamed Abid[3] & Ilhem Charfeddine[1]
[1]Habib Bourguiba University Hospital, Department of Otorhinolaryngology, Head and Neck Surgery, Sfax, Tunisia; [2]Habib Bourguiba University Hospital, Department of Anesthesiology, Sfax, Tunisia; [3]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction
Ectopic location of the parathyroid glands has been described in 10-15% of patients with hyperparathyroidism. Upper cervical localization is exceptional and may be missed by preoperative localization techniques. We report a rare case of parathyroid adenoma of the upper jugulo-carotid region.
Observation
A 41-year-old woman with no notable pathological history presented diffuse osteoarticular pain. Physical examination showed a right superior jugulo-carotid swelling of 3 cm of the main axis, firm, painless and mobile, without any other associated neck swelling. The laboratory workup revealed a serum calcium level of 2.7 mmol/l, an elevated parathyroid hormone level of 1109 ng/ml, and normal renal function. The neck ultrasound showed an oval 32 mm long axis, a heterogeneous upper right jugulo-carotid mass, and a normal thyroid gland. The technetium-99m-MIBI scan showed no hyper-fixation. The cervicothoracic scan showed a mass on the right neck with heterogeneous enhancement. Intraoperative exploration revealed a firm yellowish right jugulo-carotid mass of a 3 cm long axis that was easily dissected. A frozen section examination revealed a

parathyroid adenoma, and this diagnosis was confirmed by the final anatomopathological examination. The postoperative course was marked by the normalization of PTH and improvement in patient quality of life.
Conclusion
The ectopic upper neck location of parathyroid adenomas is exceptional (less than 1% of adenomas). Sestamibi scintigraphy is of major importance help in the location of parathyroid glands but may be negative for the detection of these high cervical adenomas.

Sialolithiasis revealing hyperaparthyroidism: A case report

Moncef Sellami[1], Mohamed Amine Chaabouni[1], Majd Werda[1], Faten Haj Kacem Akid[2], Mohamed Abid[2] & Ilhem Charfeddine[1]
[1]Habib Bourguiba University Hospital, Department of Otorhinolaryngology, Head and Neck Surgery, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction
Primary hyperparathyroidism is associated with lithiasis, but this has been universally considered to refer to kidney lithiasis. Sialolithiasis as a comorbidity or result of primary hyperparathyroidism is uncommon. We report a rare case of submandibular lithiasis in a child and discuss the etiological assessment of this condition.
Materials and Methods
We report a rare case of submandibular lithiasis in a child revealing primary hyperparathyroidism.
Results
A 13-year-old child with no previous history was referred for episodes of right painful submandibular swelling evolving for 1 month. Physical examination revealed a firm and mobile right submandibular swelling measuring 3 cm. Upon intraoral examination, a 5 mm hard mass was felt over the right floor of the mouth area. A neck ultrasonography showed a hypoechoic enlarged submandibular gland associated with a 5 mm intracanal stone causing dilatation of the submandibular duct associated with an hyperplasia of the inferior right parathyroid gland measuring 1.5 cm. The phosphocalcic evaluation and parathormone dosage concluded to a primary hyperparathyroidism. The patient had an intra-oral removal of stone under local anesthesia. The spectrophotometric analysis of the stone confirmed its phosphocalcic nature. An excision of the parathyroid adenoma was performed. Histological findings revealed a parathyroid adenoma. The clinical course was marked by clinical and biological improvement.
Conclusion
Salivary lithiasis is common. An etiological investigation is necessary in children and in recurrent forms to identify the possibility of hyperparathyroidism.

Evaluation of ultrasonography and 99mTc-sestamibi scintigraphy in the preoperative imaging study in Primary Hyperparathyroidism

Amelia Oleaga[1,2], Alejandra Santamaría[1], Fernando Goñi[1,2], Cristina Moreno[1], Ana Izuzquiza[1], Javier Espiga[1], Vanessa Arosa[1], Andoni Monzón[1], Miren Josune Rodríguez-Soto[1], Jon Izquierdo[1], Natalia Iglesias[1], Jon Garai[1], Laura Calles[1], Iñigo Hernando[1], Aitzol Lizarraga[1,2], Estíbaliz Ugarte[1] & Miguel Paja[1,2]
[1]University Basurto Hospital, Endocrinology and Nutrtion, Bilbao, Spain; [2]Basque Country University, Bilbao, Spain

Introduction
Minimally invasive surgery has become the standard surgical procedure in Primary Hyperparathyroidism (PHP). Targeted parathyroidectomy is associated with a shorter operative duration, a lower risk of complications and a greater patient satisfaction. This approach is dependent on precise localization of the abnormal gland. 99mTc-sestamibi scintigraphy and ultrasonography are acceptable imaging modalities to detect parathyroid adenoma prior to operation but discrepancies exist with regard to diagnostic accuracy. 18F-fluorocholine positron emission tomography has shown promise results but its availability is only in a few centres. The aim of the present study was to evaluate the efficacy of 99mTc-sestamibi scintigraphy and ultrasonography in surgery for primary hyperparathyroidism.
Subjects and Methods
This is a retrospective observational cohort study in 117 patients diagnosed of PHP who were operated on between January 2017 and January 2022. There were 28 males and 89 females, age range: 35-87 years. All patients underwent ultrasonography and 99mTc-sestamibi scintigraphy before surgery. Surgical procedure was neck exploration ($n=42$) or selective parathyroidectomy ($n=75$), according to imaging localization. Statistical analyses used SPSSv20.0 software. Approval of the ethics and research committee was obtained for the study.
Results
Demographic, preoperative, interventional and cure data were compared according to ultrasonography and 99mTc-sestamibi scintigraphy results, distinguishing 3 patient groups: concordant $n=68$, discordant $n=26$, negative $n=23$. Gland weight $P=0.03$ in ultrasonography, and gland size in 99mTc-sestamibi scintigraphy ($P=0.02$), but no concomitant thyroid pathology rates, differed significantly between the positive and negative imaging results groups. In the 117 patients, sensitivity was 68% and PPV 81% for ultrasonography, and respectively 74% and 78% for 99mTc-sestamibi scintigraphy. Both modalities were concordant in 68/117 (58%) and in 58 consistent with surgery result (sensitivity 53%). Histopathological analysis showed: 109 adenomas, 1 carcinoma, 5 multiple adenomas. In 2 patients no lesion was shown. In 110 out of 117, calcemia and PTH were normalized one and six months after surgery.
Conclusion
The performance of associated ultrasonography and 99mTc-sestamibi scintigraphy could be the ideal practice to precisely localize parathyroid lesion in patients with PHPT. Combining both techniques can reduce surgical morbidity.

Effect of calcium and vitamine D supplementation on parathyroid glands function after total thyroidectomy

Mohamed Amin Chaabouni[1], Souha Kallel[1], Majdi Trigui[1], Faten Haj Kacem Akid[2], Hamdi Frikha[2], Mohamed Abid[2] & Ilhem Charfeddine[1]
[1]Habib Bourguiba Hospital, Department of Otolaryngology (ENT) Head and Neck Surgery, Sfax, Tunisia, 2Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Aim
The purposes of our study are to study the effect of systematic calcium and vitamin D supplementation on parathyroid glands function after total thyroidectomy.
Patients and Methods
We conducted a prospective cohort study, including patients undergoing total thyroidectomy. Patients were randomly divided into two groups: group 1: with prophylactic supplementation (24 patients) and group 2: without prophylactic supplementation (23 patients). For each patient, undergoing total thyroidectomy, the assessment includes Ca; PTH in preoperatively and at day 1 and day 30 on postoperative.
Result
The mean PTH on day1 for group 1 was 12.7 pg/ml $\pm$ 10.7 and 17.4 pg/ml $\pm$ 7.5 for group 2. The difference was not statistically significant ($P=0.09$; Student's T-test for independent sample). The mean PTH at day 30 for group 2 was 23.4 pg/ml $\pm$ 15.7 and 25.7 pg/ml $\pm$ 9.7 for group 1. We did not notice any difference in mean PTH between the two study groups. ($P=0.54$; Student's T test for independent sample)
Conclusion
Calcium and vitamin D supplementation has no inhibitory effect on PTH on D1 and D30 and therefore does not in any case delay the resumption of parathyroid glands function. In addition, it appears in our study that this supplementation improves parathyroid function at 1 month.

EP165

PFI and WI before and after loading with vitamin D in vitamin D deficient patients

Antonis Polymeris[1], Stavroula Psachna[1], Dimitrios Ioannidis[1], Dimitrios Lilis[1], Maria Drakou[1] & Peter Papapetrou[1]
[1]Sismanogleio-Amalia Fleming Hospital, Department of Endocrinology, Metabolism and Diabetes Mellitus, Athens, Greece

Aim
To evaluate the change in PFI (Parathyroid Function Index) and WI (Wisconsin Index) after loading with vitamin D in patients with vitamin D deficiency.

Patients and Methods
In 41 vitamin D deficient patients ($25(OH)_2D < 17.16 \pm 6.07$ ng/ml, mean $\pm$ SD) the PFI (PTHxCa devided by P) and the WI (PTHxCa) were evaluated before and after 3 month loading with Vitamin D 50.000 IU per week for the first 6 weeks and 25.000 IU per week for the next 6 weeks.
Results
$25(OH)_2D$ increased significantly ($P < 0.0001$) and PTH decreased significantly ($P = 0.001$) after 3 month loading with vitamin D while serum calcium and phosphorus showed no change ($P = 0.16$ and $P = 0.19$ respectively). PFI and WI decreased significantly after loading from 17.9 ± 8.2 (mean $\pm$ SEM) to 13.3 ± 7.4 and from 20.4 ± 8.3 to 14.5 ± 6.9, $P = 0.001$ and $P = 0.0008$ respectively. Considering a $25(OH)_2D$ level as the best between 20-50 ng/ml and taking as cut-off value of $25(OH)_2D$ 20.2 ng/ml, the analysis showed for the PIF sensitivity 68.3% and specificity 36.6%, and for the WI sensitivity 68.3% and specificity 53.7%.
Conclusion
PFI and especially WI can potentially be used as indicators of adequate vitamin D loading along with a remeasurement of vitamin D considering that most of the commercial Vitamin D assays overestimate its serum levels.

Giant parathyroid adenoma: Report of two cases

Houas Jihene[1], BelHadj Miled Heyfa[1], Ghammam Monia[1], Ben Arfi taissir[1], El Omri Malika[1], Bellakhdher Mouna[1], Hasni El Abed Yosra[2], Meherzi Abir[1], Kermani Wassim[1] & Abdelkefi Mohamed[1]
[1]ENT Department and Neck Surgery of Farhat Hached Hospital, Sousse, Tunisia; [2]Endocrinology Department Farhat Hached Hospital, Sousse, Tunisia

Introduction
Primary hyperparathyroidism is a common disease. It is generally caused by a solitary parathyroid adenoma. Adenomas weighing more than 3.5 g are classified as giant. These giant parathyroid adenomas constitute a rare clinical entity.
Patients and Methods
We report two cases of giant parathyroid adenoma observed in our department of otorhinolaryngology and cervicofacial surgery.
Results
Case 1: A 54-year-old woman was referred to our ENT department for the management of recent hypercalcaemia. She had no previous medical history. She complained of mild constipation, muscle weakness, nausea and intermittent abdominal pain for one month. Cervical examination did not find any palpable masses. Biologically, there was severe hypercalcaemia at 5.59 mmol/l and a PTH level of 2268 pg/ml. SPECT-CT revealed a right parathyroid adenoma measuring $6 \times 2.7 \times 2$ cm in the anterior mediastinum with minimal cervical expression. The patient was managed urgently in the intensive care unit with hyperhydration, forced diuresis and bisphosphonates. The patient underwent double team surgery (cervicofacial surgery and vascular surgery). The parathyroid adenoma was successfully removed by a transcervical approach. Final pathology confirmed the diagnosis of a giant parathyroid adenoma. Post-operative management was straightforward. Her serum calcium and PTH levels normalized rapidly. The patient is currently asymptomatic and normocalcaemic.
Case 2: The patient is 70 years old, diabetic, coronary and chronic renal failure(on haemodialysis since 2019). She had been suffering from diffuse bone pain for a year with functional impotence, especially in the two lower limbs. A parathyroid workup revealed a blood calcium level at the upper limit of normal and an elevated PTH level of 1160 pg/ml even after correction of hypovitaminosis D. Scintigraphy found two MIBI-binding sites, one of which is large and projects below the left lower pole. MRI and CT scan found a 4 cm calcified left basicervical mass extending into the upper mediastinum. The patient underwent a subtotal parathyroidectomy with removal of the subthyroidal lower laterotracheal mass. The postoperative follow up was straightforward. The PTH was back to 35 pg/ml on postoperative day 3 with a blood calcium level of 2.05 mmol/l. Pathological examination concluded to a giant parathyroid adenoma associated with hyperplasia of the remaining parathyroids. The evolution was marked by a regression of bone pain.
Conclusion
Giant parathyroid adenomas are usually solitary. Their treatment is surgical but would require medical preparation. The main post-operative complication is hypocalcaemia. Parathyroid carcinoma remains the main differential diagnosis and can only be ruled out by definitive pathological examination.

Cholecalciferol supplementation effect on vitamin D metabolism parameters in hospitalized covid-19 patients

Arina Mikhailova, Daria Lagutina, Ksenia Golovatuk, Alena Chernikova, Elena Yu. Vasilieva & Tatiana Karonova
National Medical Research Centre named after V.A. Almazov of the Ministry of Healthcare of Russia, Saint-Petersburg, Endocrinology, Saint Petersburg, Russia

Background
Recent studies demonstrated clinical benefits of cholecalciferol supplementation among COVID-19 hospitalized patients. However, features of vitamin D metabolism in the acute phase of SARS-CoV-2 infection remain unclear.
Aim
to estimate the level of 25(OH)D and 1,25(OH)2D as well as oral bolus cholecalciferol supplementation effect on the dynamic of vitamin D metabolites in hospitalized COVID-19 patients.
Materials and Methods
A total of 44 hospitalized patients with confirmed COVID-19 were included in the randomized single-center open-label study. Patients in the Group 1 ($n = 22$) received cholecalciferol bolus supplementation at a total dose of 100,000 IU on the first and the eighth days of hospitalization. Patients from the Group 2 ($n = 22$) did not receive cholecalciferol supplementation. Serum 25(OH)D and 1,25(OH)2D levels were estimated for each group on the first and the ninth day of hospitalization. There were no differences in demographic, clinical, laboratory and instrumental patientŝ baseline characteristics, as well as in the total dose of concomitant corticosteroid therapy by the 9th day of hospitalization.
Results
On the ninth day of hospitalization 25(OH)D serum level demonstrated the 45.8% rise in the Group 1, while in the Group 2 there was a decrease in the 25(OH)D level by 17.9%. At the same time, dynamic evaluation of the 1.25(OH)2D level did not show any differences between the groups, while pairwise comparison on the first and on the ninth day of hospitalization revealed a significant increase in the active metabolite concentration ($P < 0.001$) in both groups. It was also no significant correlation between the 25(OH)D and 1,25(OH)2 D level at both time points.
Conclusion
Such vitamin D metabolism parameters in the acute period of COVID-19 may be associated with the 1α-hydroxylase activity alteration. Thus, the increase in serum 1.25(OH)2D level despite of vitamin D status dynamic during the hospitalization could be explained either by the COVID-19 course or by the concomitant corticosteroid therapy.

EP168

Menses-associated decline of serum calcium in hypoparathyroid women

Svetlana Mirnaya
LLC "SSMC №1", Moscow, Russia

Some hypoparathyroid women report the appearance or intensification of hypocalcemia symptoms at the time of menses. It is still unknown whether this is the result of premenstrual syndrome or fluctuations in serum calcium levels. Studies have not found a relationship between fluctuations in levels of sex hormones and serum calcium and phosphorus and it appears probable that they affect neuromuscular excitability through a separate mechanism. Alterations in serum calcium levels during the menstrual cycle are not always detected [Graham WP.; Gordan GS.; Loken HF.; Blum A; Halden A (1964). Effect of Pregnancy and of the Menstrual Cycle on Hypoparathyroidism. The Journal of Clinical Endocrinology & Metabolism, 24(6), 512–516. doi:10.1210/jcem-24-6-512. Saha S, Goswami R. Menstruation associated hypocalcemic symptoms and serum calcium in patients with idiopathic hypoparathyroidism. BMC Endocr Disord. 2014 Mar 21;14:28. doi: 10.1186/1472-6823-14-28.]. But in some patients menses-associated hypocalcemic symptoms correlate with a decline of serum calcium [L. E. Mallette. Case Report: Hypoparathyroidism with Menses-Associated Hypocalcemia Am J Med Sci 1992; 304(1):32-37]. I have studied two patients with chronic postoperative hypoparathyroidism who have experienced muscle stiffness, numbness and paresthesia chiefly during menses. It was accompanied with the significant decline (0.20-0.38 mmol/l) of albumin-adjusted calcium levels after onset of menses.
Case 1. Patient B, 18-year-old. An improvement in well-being during menses has been achieved with an increase in the calcium supplementation dose by 500 mg and alfacalcidol by 0.5 mg. The patient was recommended to increase the dose of calcium and alfacalcidol from the 2nd to the 7th day of menses.

Case 2. Patient D, 36-year-old. Patient was prescribed oral contraceptive in the 63/7 regime, and the hypocalcemic symptoms significantly decreased, the level of serum calcium remained stable. Further research is required to determine the mechanism of serum calcium decline and the possible effect of sex hormones on symptoms of hypocalcemia in chronic hypoparathyroidism.

Deep vein thrombosis revealing primary hyperparathyroidism

Arige Abid[1], Ibtissem Oueslati[1], Mayssa Bouzidi[2], Meriem Yazidi[1], Mounir Lamloum[2] & Melika Chihaoui[1]
[1]La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia; [2]La Rabta University Hospital, Department of Internal Medicine, Tunis, Tunisia

Introduction
Primary hyperparathyroidism is a common endocrine disease. Its association with inflammatory and thrombotic events was rarely reported in the literature. The pathophysiological mechanisms of this association remain uncertain. Herein, we report a case of hypercalcemia secondary to primary hyperparathyroidism revealed by a deep vein thrombosis.
Observation
A 65-year-old patient was referred to our department for primary hyperparathyroidism. The patient was admitted to the department of internal medicine for a deep vein thrombosis in the left lower limb. On physical examination, he had a body weight of 68 kg, a height of 165 cm, a body mass index of 24.9 kg/m^2, a blood pressure of 12/08 cmHg, and a heart rate of 57 beats/min. Other systemic and regional examinations did not show any abnormalities. Potential causes of vein thrombosis were excluded. Biological investigations showed a total calcium level of 3.3 mmol/l, a phosphorus level of 0.49 mmol/l, a creatinine level of 60.9 mmol/l, a PTH level of 163 ng/l, albumin level of 43 g/l, a 25 hydroxyvitamin D of 20.2 ng/ml, and a calciuria of 0.21 mmol/24 h. The diagnosis of primary hyperparathyroidism was established. Cervical ultrasound and Sestamibi scan showed a left inferior parathyroid nodule measuring 12.5 × 7 mm. Bone mineral density scan revealed osteoporosis. No other complications were observed. The patient was treated with saline intravenous hydration, zoledronic acid, and a therapeutic dose of low-molecular-weight-heparin. Then, he underwent a left inferior parathyroidectomy. The postoperative course was simple with a total calcium level of 2.25 mmol/l.
Discussion
Thrombotic events were reported in a few patients with primary hyperparathyroidism. This association may be explained by direct activation of prothrombotic factors and hemoconcentration. Even though hypercalcemia is a rare cause of thrombotic events, it should be considered in the clinical evaluation of patients with deep vein thrombosis in the absence of evident causes.

Brown tumors complicating hyperparathyroidism

Mustapha Asfour, Antonio Nfad, Yassine Errahali, Sanae Chakdoufi, Jade Issouani & Ahmed Anas Guerboub
Rabat, Endocrinology Diabetology Nutrition, Rabat, Morocco

Introduction
Brown tumor or osteitis fibrocystica is a benign bone lesion reflecting an abnormality of bone metabolism in the context of hyperparathyroidism. It can affect the entire skeleton, including the pelvis, ribs, clavicles and extremities. Involvement of the maxillary bone is very uncommon. We present a case of multiple brown tumors with an unusual maxillo-mandibular localization, revealed by a disorder of phosphocalcic metabolism and tertiary hyperparathyroidism. This case reminds us of the difficulty to establish a correct diagnosis in patients with an osteolytic process of the maxilla and the necessity to look for hyperparathyroidism in front of a giant cell lesion given the insidious character of this endocrinopathy.
Observation
32 year old female patient with the following history
– Chronic kidney disease at dialysis stage
– HTA under ARB II
– Viral hepatitis C
– Left femoral per trochanteric fracture
History of the Disease
The history of the disease began 2 years ago with the appearance of a maxillo-mandibular bone tumor that had been surgically resected with a brown giant cell tumor at the anapath, and whose etiological exploration revealed hyperparathyroidism:
• PTH 668 pg/ml (11×N) and normocalcemia 99 mg/l
• Localization test : a right parathyroid nodule of 17 mm on CT scan
The patient was operated, the procedure consisted in a para thyroidectomy with simple postoperative course and the result of the anapathy was a parathyroid hyperplasia.
Nevertheless, the evolution was marked by the recurrence of her maxillomandibular tumor, which progressively increased in volume, reaching facial deformation and oral obstruction, making feeding difficult.
With a probable tertiary hyperparathyroidism
• PTH more than 20×N and normocalcemia at 98 mg/l
• MIBI scintigraphy with pathological parathyroid of the posterior inferior face of the left lobe of the thyroid.The patient was referred to our training for further treatment. Functionally she shows a deep asthenia.
Clinical Examination
Voluminous mass of the facial mass, painless on palpation, obstructing the oral cavity and causing a tooth separation and intermittent gingivorrhagia. Painless right tibial bone swelling on palpation causing no functional impotence. We are faced with a biologically confirmed hyperparathyroidism initially secondary to kidney failure which has become autonomous with the appearance of a parathyroid nodule marking the transition to tertiary hyperparathyroidism.
Conclusion
The diagnosis of hyperparathyroidism avoids the need of surgery for brown maxillary tumors that should regress after removal of the parathyroid lesion.

Approach to a Mediastinal Parathyroid adenoma: A case report

Ömer Sönmez[1], Gamze Beydağı[2], Kaan Akcay[2] & Nalan Alan Selçuk[2]
[1]Yeditepe University Hospital, School of Medicine, Istanbul, Turkey; [2]Yeditepe University Hospital, Nuclear Medicine, Istanbul, Turkey

Ectopic mediastinal parathyroid adenoma is a rare cause of primary hyperparathyroidism (PHPT), which is reported in 1-1.5% of patients. We present you a case of a 22-year old male, who was suffering from severe itchiness which significantly interferes with his daily activities of life. His laboratory results were suggestive of PHPT (Table 1). His initial scans, including Technetium-99m (Tc-99m) Sestamibi (Mibi) did not reveal any abnormality. Subsequently, increase of PTH level along with new onset nausea and fatigue were observed, due to which further investigation was required. His neck and head Ultrasonography (USG) was normal. Second Tc-99m Mibi illustrated an anterior mediastinal mass in the thymic area with focal atypic activity, which is suggestive of a potential ectopic parathyroid adenoma. To accurately localize the adenoma, choline Positron Emission Tomography-Magnetic Resonance Imaginging (PET-MRI) and choline PET-Computer Tomography (CT) were ordered. The images of PET-CT were correlating with the data obtained from the parathyroid scintigraphy. It is recommended to perform parathyroidectomy to PHPT patients, who are diagnosed at 50 years or younger regardless of existence of other surgery indications. Consequently, the patient underwent parathyroidectomy and left thymectomy. Histopathological examination has confirmed the diagnosis. His follow-up blood results were within normal limits and symptoms were resolved (Table 1). The most challenging aspect of the management of PHPT is establishing the accurate localization of the hyperfunctioning adenoma. In addition to that, localization has a huge impact on the success of parathyroidectomy. Although there are many techniques such as USG, Tc99m-Mibi, parathyroid four-dimension CT, PET and MRI, no universally recommended algorithm exists. The most commonly used method is concordant application of USG and Tc99m-Mibi. The reported case had been succesfully treated following useage of Tc99m-Mibi and choline PET-CT to establish the accurate location of the adenoma. We strongly believe that our approach with a multimodality imaging strategy provides valuable information to the physicians.

Table 1 Pre- and post-operative laboratory values

Dates	PTH (pg/ml)	Total calcium (mg/dl)	Phosphorus (mg/dl)	Calcium excretion in 24 hours urine collection (mg/day)

Epidemiological characteristics of cardiovascular diseases in primary hyperparathyroidism according to the Russian Registry

Ekaterina Dobreva , Anna Eremkina, Anna Gorbacheva, Ekaterina Bibik, Elena Kovaleva, Nikolay Gins & Natalia Mokrysheva
Endocrinology Research Center, Moskva, Russia

Objective
Primary hyperparathyroidism (PHPT) is associated with a higher incidence of different cardiovascular diseases (CVD), but the prevalence of CVD in PHPT remains unclear.
Aim
To evaluate the prevalence of CVD in PHPT according to the RussianPHPT Registry.
Materials and Methods
The Registry includes a database of patients with PHPT available at the Endocrinology Research Centre (Moscow) since 2007, which was transferred to the online platform in 2017. New cases of the disease, as well as dynamic monitoring, are recorded through an electronic form by medical professionals. The data of the included patients were entered into the register by 247 endocrinologists from 81 regions of the Russia. Data are given as medians, unless otherwise noted.
Results
Data from the Registry was uploaded on September 1, 2022. The study included 4892 patients with PHPT. 2308 (47.2%) of them had their cardiovascular history filled in. Among them the most frequent cardiovascular complication was arterial hypertension (AH) (up to 96%), while left ventricular hypertrophy was present in 5.8% of patients. A history of coronary artery disease (CAD) was diagnosed in 20.1%, calcification of the structures of the heart and/or blood vessels was observed in 2.7% of patients. Patients with a mild course of PHPT were significantly younger (62 vs 68 years, $P<0.001$) and had lower concentrations of parathyroid hormone (PTH) (118 vs 141 pg/ml, $P<0.001$) , total calcium, (2.67 vs 2.75 mmol/l, $P<0.001$) and higher GFR (84 vs 76 ml/min/1.73 m^2) than patients with symptomatic PHPT. In patients with mild PHPT, the frequency of CVD was significantly lower than in the patients with symptomatict PHPT: for all CVD 37.9 vs 46%, $P<0.001$, for AH 36.5 vs 51.6%, $P<0.001$ and for ischemic heart disease 4.4 vs 11.9%, $P<0.001$, respectively. Patients with AH were statistically significantly older, had higher serum PTH levels (149 vs 138 pg/ml), and lower GFR compared with normotonic patients. Patients with CAD were also older than those without CAD and had higher ionized calcium levels(1.4 vs 1.37 mmol/l, $P=0.006$), and lower GFR.
Conclusion
There is a high incidence of CVD in PHPT. The severity of PHPT is associated with higher incidence of all CVDs but most often with AH and ischemic heart disease in particular.

The effect of Immune Checkpoint Inhibitors (ICIs) in Bone Metabolism: A case series analysis

Vasiliki Siampanopoulou[1], Anna Angelousi[1], Athina Karampela[1], Petros Papalexis[1], Alexandros Lafioniatis[1], Chrysoula Mytareli[1], Dimitrios Ziogas[2], Helen Gogas[2] & Evanthia Kassi[3,4]
[1]Athens Medical School, National and Kapodistrian University of Athens, Unit of Endocrinology, First Department of Internal Medicine, Laikon General Hospital, Athens, Greece; [2]Athens Medical School, National and Kapodistrian University of Athens, First Department of Internal Medicine, Laikon General Hospital, Athens, Greece; [3]Athens Medical School, National and Kapodistrian University of Athens, Department of Biological Chemistry, Athens, Greece; [4]Athens Medical School, National and Kapodistrian University of Athens, Unit of Endocrinology, First Department of Propaedeutic and Internal Medicine, Laikon General Hospital, Athens, Greece

Background
Immune checkpoint inhibitors (ICIs) constitutes a novel treatment for patients with melanoma. Endocrine-related adverse effects are now a distinctive clinical entity of ICIs, with hypophysitis and thyroiditis being the most common. Recent consensus doesn't suggest routinely screening of bone mass indexes in patients on ICIs since data in the literature are scarce.
Methods
Data regarding bone disease were retrospectively analysed in 118 patients with melanoma treated with ICIs who were referred to our unit for endocrine-related adverse events. Only patients with available data of bone density in two sites (left femoral bone and lumbar spine), as defined by Dual energy X-ray absorptiometry (DXA) before as well as after ICIs treatment were included in the study. Biochemical markers associated to bone remodelling such as calcium, phosphorus, alkaline phosphate, 25-OH vitamin D and parathormone levels were also registrated. Ten-year probability of fracture score (FRAX score) adapted to Greek population was also calculated. DXA was assessed at least one year post-ICIs interruption (median follow up: 2.5 years).
Results
Six patients (all females, median age: 70.5 years) fulfilled the criteria of inclusion in this case series. Five patients had been treated with systemic monotherapy with an anti-PD1 agent (nivolumab ($n=4$) or pembrolizumab ($n=1$)). The last patient had received combination therapy with anti-PD1 plus anti-CTLA4 (nivolumab plus ipilimumab) therapy. At baseline before any treatment, 2 (33.3%) patients presented with normal bone density, 3(50%) with osteopenia and the last one (16.6%) with osteoporosis treated with calcium replacement and bisphosphonates (ibandronic acid). Baseline levels of biochemical bone metabolism markers were within the normal range except for 25 OH vitamin D levels which was deficient in all 6 patients necessitating the initiation of replacement with cholecalciferol with a median dose of 2000 units administered daily. No bone fracture was diagnosed radiologically during ICIs treatment. None of the patients presented any difference in the T score, the BMD or the FRAX score during the follow-up post- ICIs treatment.
Conclusions
Bone disorders are rarely searched in patients treated with ICIs thus data in the literature are rare. Our case series analysis showed no difference of T score, BMD levels or of the FRAX score in 6 patients with melanoma before and after receiving ICIs in a median follow up of 2.5 years. No osteoporotic fracture was detected neither. Further large-scale analyses with longer follow-up are required in order to assess the effect of ICIs on bone metabolism.

Predictive factors of Hungry Bone Syndrome after surgical management of Primary Hyperparathyroidism

Rania El Amel[1], Lamiae Zarraa[1], Soumiya Berrabeh[1], Yousra Laalaoua[1], Siham Rouf[2] & Hanane Latrech[2]
[1]Endocrinology-Diabetology and Nutrition Department Hospital University Centre of Mohammed-VI, Oujda, Morocco; [2]Endocrinology-Diabetology and Nutrition Department Hospital University Centre of Mohammed-VI, Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy Mohammed First University, Oujda, Morocco

Introduction
Primary hyperparathyroidism (PHP) is a common endocrine disease, and its most effective treatment is surgery. Hungry bone syndrome (HBS) is one of the complications that can occur after parathyroidectomy, and that can cause severe and prolonged hypocalcemia. The aim of this study was to determine the risk factors for HBS in patients who underwent parathyroidectomy for PHP.
Patients and Methods
This is a retrospective descriptive and analytic study of 48 patients with primary hyperparathyroidism followed-up in the Endocrinology-Diabetology and Nutrition Department of the University Hospital Center of Mohammed-VI-Oujda in Morocco, from which 36 patients underwent parathyroidectomy, and were included in this study.
Results
Out of the patients included in the study, 3 cases (8.3%) had HBS, and 33 cases (91.7%) didn't develop HBS. Compared to patients who didn't have this complication, these patients had a lower age (43.33 ± 16 vs 54.6 ± 10.7 years). A feminin predominance was observed in both groups. The preoperative biological analysis demonstrated: higher serum levels of calcium (135.4 ± 8.2 vs 120.1 ± 27.4 mg/l), of PTH 1-84 (1423 ± 1209.6 vs 413.56 ± 379.5 pg/ml), of ALP (436.2 ± 281.6 vs 178.61 ± 103.9UI/l) and lower levels of phosphorus (16.7 ± 1.5 vs 21.57 ± 5.9 mg/l) and of vitamin D (6.3 ± 1.7 vs 11.8 ± 6.3 ng/ml) in the HBS group. A significant association was found between higher preoperative levels of ALP ($P=0.04$) and PTH 1-84 ($P<0.001$) and the occurrence of HBS. Cervical ultrasound showed no difference in number of adenomas between the 2 groups (1 localisation). Bone densitometry indicated osteoporosis in the 3 cases of HBS.
Conclusion
Based on these readily obtainable parameters and the results of our study, higher preoperative ALP and PTH 1-84 levels, were significantly associated with a greater risk of development of the hungry bone syndrome following parathyroid surgery.

Electronic health record with decision support as a tool to improve quality of care for women with postmenopausal osteoporosis

Olga Derevyanko[1], Tatiana Rumyantseva[2], Alexandr Balashov[2] & Dmitry Fomin[2]
[1]Fomin Clinic, Endocrinology and Metabolic Disorders, Moscow, Russia; [2]Fomin Clinic, Moscow, Russia

Background and Aims
Awareness and knowledge about any disease is the first step to prevent and treat it. Osteoporosis is a worldwide health problem. Osteoporosis is characterized by decreased normal bone density. More than 8.9 million fractures worldwide annually are caused by osteoporosis; these fractures are a significant cause of morbidity and mortality. Evidence suggests that the modification of several lifestyle habits, diagnostics, prevention and treatment could assist in lowering the incidence of osteoporosis. The aim of our study was to explore the quality of osteoporosis care experienced by women in Russia in Fomin Clinic in 17 cities in Russia and how it could be improved with the help of Electronic Health Record with decision support.
Methods
244 Electronic Health Records of women aged 56.4 before and after the start of the decision support (52 и 54 respectively) were analyzed and rated on a 100-point scale(diagnostics using FRAX and dual-energy x-ray absorptiometry (DXA) (lumbar spine and hip), nutrition, physical activity, drugs recommendations were evaluated by both experts and artificial intelligence). The decision support system based on Guidelines of Russian Association of Osteoporosis, National Osteoporosis Foundation and Endocrine Society.
Results
The average score before using decision support was 43, and after doctors started to use it the average score after 6 months of using became 81.
Conclusions
Electronic Health Record with decision support is great tool wich improves quality of care for postmenopausal women and refines the diagnosis and treatment of osteoporosis in different cities in Russia.

EP176

Hypophosphatasia: recurrent fractures and a suppressed alkaline phosphatase level - can we make the connection?

Najeeb Shah & Jonathan Thow
York & Scarborough NHS Foundation Trust, Diabetes & Endocrinology, York, United Kingdom

Case
A 66-year-old female was referred to the Endocrinology clinic for suspected osteoporosis after a right femoral shaft fracture. As the site was atypical and the injury was low energy, a pathological fracture was suspected. There was a history of recurrent fractures sustained after the age of 30 years and were either spontaneous or from low-energy impacts (Table 1). Growing up, she was told that "there was something wrong with her bones" and required regular physiotherapy. She reported having a "funny" walk and the inability to run. She also described life-long myopathic symptoms. She could only walk for 10-15 yards with a stick before needing to rest. She took paracetamol and a buprenorphine patch for chronic pain and was on doxazosin and losartan for hypertension. She underwent a left hemiarthroplasty for NOF and an intramedullary nail to fix the right femoral shaft fracture. Her mother suffered recurrent fractures. Her grandson was diagnosed with a skeletal deformity in utero, which was deemed incompatible with life. Apart from a waddling gait, there were no clinical abnormalities. The relevant initial blood tests are listed in Table 2. Myeloma screen, tumour markers and creatine kinase were normal. Interestingly, the ALP was suppressed (chronically) with normal calcium and vitamin D and raised phosphate levels. DEXA scan was inconclusive due to spinal degeneration and metalwork in both hips. Congenital osteopathy was suspected, and a genetic screen revealed compound heterozygosity for pathogenic variants c.400_401delinsCA (p.Thr134His) and c.571G>A (p.Glu191Lys) in the HPP gene confirming ***Hypophosphatasia***.
Outcome
Vitamin D and physiotherapy were commenced, and she was accepted for Asfotase alfa therapy in a specialist metabolic bone clinic.
Learning points:
• Hypophosphatasia results from mutation(s) in the tissue non-specific ALP encoding gene with reduced activity of ALP and defective mineralisation of bone and teeth.
• Suspect hypophosphatasia in cases of recurrent fractures, myopathic symptoms, poor dentition, and suppressed ALP in the presence of normal calcium levels, especially if there is a family history of skeletal problems.

Table 1 Fracture history.

Fracture
Right elbow
Sternum
Left foot
Left ulna
Left neck of femur (NOF)
Left humerus
Right femoral shaft

Maxillary brown tumor revealing primary hyperparathyroidism: A case report

Chayma Besrour, Ibtissem Ben Nacef, Sabrine Mekni, Sawsen Essayeh, Nadia Mchirgui, Imen Rojbi & Karima Khiari
Charles Nicolle Hospital, Endocrinology, Tunis, Tunisia

Introduction
Primary hyperparathyroidism is an asymptomatic endocrine disorder in 80% of the cases. The bone manifestation represents the late stage of the disease and the brown tumor represents an exceptional and rare lesion.
Observation
We report the case of a 73-year-old patient, with a medical history of type 2 diabetes, followed in the oto-rhino-laryngology department for a gingival tumor. A biopsy was performed and the anatomopathological examination was in favor of a reparative granuloma. She was referred to our department for further exploration. The calcium phosphate balance showed an hypercalcemia at 3.37 mmol/l, an hypophosphatemia at 0.53 mmol/l and a high PTH at 451 pg/ml, suggesting primary hyperparathyroidism. The thyroid ultrasound showed no parathyroid nodules, with suspicious adenopathies and the parathyroid scintigraphy revealed a lower right parathyroid adenoma. Complementary thoraco-abdomino-pelvic CT scan revealed two retro-thyroid masses (left 34×16×53 mm and right 29×16 mm) with a lytic lesion type Ib Lodwick of the left iliac bone of 19 mm corresponding to a second brown tumor. As for the assessment of the complications of the hypercalcemia; the electrocardiogram showed a regular sinus rhythm at 60 bpm without shortening of the QT interval, the bone densitometry did not find osteoporosis and the renal ultrasound did not show any lithiasis. The patient was proposed for parathyroid surgery.
Discussion
Nowadays, it is rare that a brown tumor of the maxilla is the circumstance of discovery of hyperparathyroidism. But this lesion must always lead to a calcium level assessment, because the treatment is etiological and the tumors regress spontaneously after parathyroid surgery.

EP178

Development of parathyroid adenoma suggesting tertiary hyperparathyroidism in a patient with a renal transplant history

Anastasios Stofas[1] & Amalia Patereli[2]
[1]School of Medicine, National and Kapodistrian University of Athens, Greece, 1st Department of Pathology, Greece; [2]Agia Sofia Children's Hospital, Athens, Greece, Pathology Department, Greece

Introduction
Tertiary hyperparathyroidism (THPT) is not uncommon in patients with secondary hyperparathyroidism after successful renal transplantation. It occurs

up to 25% of these patients one year after transplantation despite renal function improvement. It can be developed due to the autonomous function of at least one parathyroid gland and leads to overproduction of parathyroid hormone (PTH). Tertiary hyperparathyroidism mostly reveals diffuse or nodular pattern of chief cell hyperplasia of the parathyroid glands which eventually leads them to adenomatous transformation. The THPT results in significant metabolic complications and symptoms, especially in patients who have had kidney transplants and are taking immunosuppressive therapy. Related symptoms include pruritus, severe osteodynia, pathologic fractures, memory loss, concentration difficulties and feelings of depression.
Case Report
A 35-year-old female who was known to have secondary hyperparathyroidism and a history of renal transplantation was admitted to our hospital due to hypercalcemia on routine blood tests. The patient underwent superior and inferior right parathyroidectomy and left inferior parathyroidectomy. Histological examination showed an adenoma measuring 3.6 cm. of the right inferior parathyroid gland and hyperplasia of the left inferior and right superior parathyroid glands, suggesting THPT. The level of serum and serum calcium were normalized after the surgery.
Conclusion
Patients with THPT commonly have significant symptoms and metabolic complications that improve after parathyroidectomy. Parathyroidectomy is the current recommended intervention to cure the disease. Successful surgical treatment results in a dramatic reduction in PTH levels and improvement of clinical symptoms especially bone pain. It is also associated with better patient survival. However, Cinacalcet is an alternative medical treatment for subgroup of patients in whom surgery is deemed inappropriate. Determining the optimal treatment for the individual patient is challenging for nephrologists and endocrine surgeons.

EP179

Primary hyperparathyroidism by an ectopic mediastinal subpericardial parathyroid adenoma

Rahal Amel[1,2]
[1]Medecines, Endocrinology, Algiers, Algeria; [2]Hopital Bologhine Ibn Ziri, Endocrinology, Algiers, Algeria

Introduction
Primary hyperparathyroidism is frequent; it can be ectopic in 11 to 25% of cases, the mediastinal position is the most frequent ectopic position, but the intrapericardial position is exceptional.
Clinical Case
A 58 year old woman with primary hyperparathyroidism complicated by severe osteoporosis. The CT scan and parathyroid scintigraphy reveals a 17 mm parathyroid adenoma in the mediastinal aortopulmonary position. After a first thoracic surgery which was unsuccessful, the patient was treated with injectable then oral bisphosphonates, while waiting for the second surgery done after two years, a second surgery was performed with extirpation of an adenoma between the ascending aorta and the trunk of the pulmonary artery, after opening the pericardium under the aorta. After surgery the patient developed signs of hypocalcaemia immediately after surgery, PTH dropped by more than 50% (from more than 200 to 99 pg/ml), the histological study was in favor of an ectopic parathyroid adenoma. The evolution was marked by a normalization of the phosphocalcic balance.
Discussion
Among the ectopic forms of hyperparathyroidism, the intrapericardial position of a parathyroid tissue is exceptional and difficult to operate, hence the need to entrust the patient to an experienced surgeon.

DOI: 10.1530/endoabs.90.EP179

EP180

Vitamin D in Primary Hyperparathyroidism: status and its effects on Primary Hyperparathyroidism

Rania El Amel[1], Yousra Laalaoua[1], Soumiya Berrabeh[1], Lamiae Zarraa[1], Hanae Rachedi[1], Siham Rouf[2] & Hanane Latrech[2]
[1]Endocrinology-Diabetology and Nutrition Department Hospital University Centre of Mohammed-VI, Oujda, Morocco; [2]Endocrinology-Diabetology and Nutrition Department Hospital University Centre of Mohammed-VI, Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy Mohammed First University, Oujda, Morocco

Introduction
Low levels of vitamin D are commonly seen in patients with primary hyperparathyroidism (PHP). The aim of this study was to determine the vitamin D status and to evaluate its relation with primary hyperparathyroidism severity.
Patients and Methods
This is a retrospective descriptive study including 48 patients with primary hyperparathyroidism followed-up in the Endocrinology-Diabetology and Nutrition Department of the University Hospital Center of Mohammed-VI-Oujda in Morocco. Clinical, biochemical, and densitometric presentation, were compared among patients with vitamin D insufficiency (group 1) and deficiency (group 2).
Results
The mean age of our patients was 55.60 $\pm$11.4 years, with a clear female predominance (77% of cases). The average vitamin D level was 12.06$\pm$7.4 ng/ml, 18 cases (37.5%) had vitamin D insufficiency, and 29 cases (60.4%) had vitamin D deficiency, while only one case (2%) had normal level of vitamin D. The discovery of primary hyperparathyroidism was mainly by an incidental finding of hypercalcemia in these patients. Bone densitometry indicated osteoporosis, osteopenia, and was normal in 53.12%, 28.12% and 18.75% of cases respectively. Ten percent of patients had renal failure, and 35.6% had urolithiasis as complications. We observed that patients who had vitamin D deficiency had higher levels of serum calcium (134.06 $\pm$ 25.60 vs 118.57$\pm$21.31), and PTH 1-84 (468.05$\pm$536 vs 362.04$\pm$432.9) comparatively to those who had vitamin D insufficiency. Also, urolithiasis was twice as common in those with vitamin D deficiency. Post-operative severe hypocalcemia was only seen in those who had vitamin D deficiency before surgery. Therefore, no difference in clinical presentation and severity, in bone mineral density, and the prevalence of renal failure were noted between the two groups.
Conclusion
Vitamin D deficiency worsens the profile of hyperparathyroidism. For this reason, a systematic preoperative screening is necessary in order to prevent its complications.

EP181

Late-onset hypoparathyroidism following total thyroidectomy

Ayesha Mashadi, Elaine Soong & Khin Swe Myint
Norfolk & Norwich University Hospital, Diabetes and Endocrinology, Norwich, United Kingdom

Background
Post-operative hypoparathyroidism is a known complication of total thyroidectomy. It can either be transient or long-term requiring lifelong treatment. Delayed presentation of hypoparathyroidism occurring after several years of surgery is rare, with only a few cases reported in literature but can be life-threatening.
Presentation
We report a case of a 70-year-old female presenting with features of hypocalcaemia (tinnitus and tingling in her fingertips) that required hospital admission. Following were her blood.
Results–
She was treated with IV calcium gluconate, and subsequently discharged with Calvive 1gm OD and Alfacalcidol 0.5 mg BD and followed up in the metabolic bone clinic. She had a total thyroidectomy for a multinodular goitre 12 years ago, wherein she developed transient hypocalcaemia in the immediate post-operative period which resolved spontaneously. Therefore, a diagnosis of late-onset hypoparathyroidism following total thyroidectomy was confirmed.
Discussion
Hypoparathyroidism causes hypocalcaemia, hyperphosphatemia and generally has very low or undetectable PTH levels. In our case, her PTH was "normal" likely due to the remaining parathyroid tissue compensating for hypocalcaemia. Late-onset hypoparathyroidism is rare, but a few cases have been reported previously. It is likely caused by either progressive atrophy of the parathyroid glands, scar tissue formation leading to hypovascularization and progressive ischaemia, or arteriosclerotic changes leading to infarction or atrophy of the remaining parathyroid tissue. British Association of Endocrine and Thyroid Surgeons (BAETS) guidelines advise checking calcium levels within 12 hours postoperatively, but there was minimal guidance found on whether calcium levels need to be re-checked annually. Although our patient was relatively well, there have been cases reported where patients present with seizures due to late-onset hypoparathyroidism.

Tests	Results	Normal reference range
Adjusted calcium	1.75 mmol/l	2.20 - 2.60 mmol/l
Phosphate	1.61 mmol/l	0.80 - 1.50 mmol/l
25-hydroxy Vitamin D	57 nmol/l	50–120 nmol/l
PTH	1.8 pmol/l	1.6-6.9 pmol/l
Magnesium	0.85 mmol/l	0.7–1.0 mmol/l
eGFR	89 ml/min/1.73 m^2	

Conclusion
In patients with a history of thyroidectomy, we recommend an annual blood test for bone profile and PTH along with a thyroid function test.

DOI: 10.1530/endoabs.90.EP181

EP182

Brown tumors in patients with secondary and tertiary hyperparathyroidism

Mohamed Masmoudi, Chaima Zitouni, Wadii Thabet, Ezer Chebil, Mehdi Hasnaoui & Khelifa Mighri
Taher Sfar Hospital, ENT Department, Mahdia, Tunisia

Introduction
Brown tumors result from the destruction of bone occurring especially in regions where bone resorption is rapid with hemorrhage and repa-rative granulation tissue replacing the normal tissue. This bone lesion can affect any part of the skeleton. It results from uncontrolled hyperparathyroidism in patients with chronic renal failure.
Objective
The aim of this report is to describe the management and the evolution after treatment of brown tumors in patients with chronic renal failure.
Method
This is a retrospective study including 5 patients with chronic renal failure who developed brown tumors due to secondary or tertiary hyperparathyroidism. This study was carried out from 2008 to 2022.
Results
The average age was 38 years predominantly males (sex ratio (M/F) = 1.5). The tumor was located in: the mandible (1 case), the maxilla and the mandible (1 case), the sternum (1 case) and the femora (2 cases). The mean serum calcium level was 1.90 mmol/l. The mean phosphoremia level was 2.20 mmol/l. The mean PTH level was 1500 pg/l. All patients had subtotal parathyroidectomy. Histologic examination of the gland showed parathyroid hyperplasia in all cases. No patient underwent intervention on the tumor. The evolution after surgery was favorable in all cases, with clinical and radiological stabilization of bone lesions in 2 cases and spontaneous regression without recurrence in 3 patients.
Conclusion
Patients with chronic renal failure may develop brown tumors in advanced stages of the disease as a result of uncontrolled hyperparathyroidism. Treatment is based on reducing the levels of PTH, either through medical management, or surgery.

EP183

Severe hypocalcemia during respiratory alkalosis reveals a case of Pseudohipoparathyroidism type 1B

Catarina Roque[1], Ricardo Fonseca[1], Ana Sofia Osório[1], Sofia Oliveira[1] & Catarina Machado[2]
[1]Hospital Prof Dr Fernando Fonseca, Endocrinology, Lisbon, Portugal; [2]Hospital de Braga, Genetics, Braga, Portugal

We present a case of Inactivating PTH/PTHrP signalling disorder (IPPSD) revealed in aduthood in the context of respiratory alkalosis caused by covid-19 infection that led to worsening of the preexisting hypocalcemia and intensification of the usual hypocalcemic symptoms. A 39 year old female with history of subclinical hypothyroidism and bilateral cataracts was admited due to hypoxemia in the context of severe covid-19 infection with bilateral pulmonary infiltrates. She was visiting a Neurologist because of chronic complaints of tingling and cramping, with no visible pathology on the exams so far performed (apart from the basal ganglia calcifications on the brain CT from 2010). On admission she was hypotensive, tachypneic, feverish and complained of paresthesia and acral cramping. Metabolic alkalosis (pH 7.48, pCO2 31 mmHg, pO2 62 mmHg, K^+ 2.97 mmol/l, Na^+ 133 mmol/l, Ca^{2+} 0.5 mmol/l) worsened the eletrolyte imbalance leading to severe symptomatic hypocalcemia with prolongued QT segment (500 ms) on the ECG. The initial calcemia (Ca^{2+}) was 3.9 mg/dl [8.6-10], P (Phosphate) 4.0 mg/dl [2.5-4.5], 25OH-vitamin D 13 ng/ml, Mg 1.8 mg/dl [1.6-2.6], 1.25(HO)2 vitamin D was normal, PTHI 190 pg/ml [15-65]. After 48 h Ca^{2+} was 6.4, P 6.1, 25OH-vitamin D 18 ng/ml; the patient was discharged with Ca^{2+} of 9.2, P 4.5 and 25OH-vitamin D of 24 ng/ml with the suspition of IPPSD given the protracted history of paresthesia, cataracts and intracerebral calcifications sugesting long standing hypocalcemia. During follow up PTHi ranged 190-347 pg/ml [15-65], Ca^{2+} 6.1-9.2 mg/dl, P 2.7-5.1 mg/dl, 25OH-vitamin D 21-34 ng/ml and she remained assymptomatic and compliant with calcitriol 0.5 mg q12 h, 1500 mg of calcium carbonate 5 times daily and 22400UI colecalciferol montly. Thyroid antibodies were negative and the US normal; the TSH maintained the same subclinical pattern fluctuating from 3 to 8.8 mUI/l. The gonadal axis were not afected. The patients has a BMI of 32 kg/m^2 though it is not possible to confirm if obesity started at a young age. Hand X-ray showed no brachydactily nor subcutaneuous ossification. Given the clinical suspition for Pseudohipoparathyroidism type 1B, GNAS sequencing was performed but no mutation was found. Nevertheless this clinical IPPSD subtype is more often associated with metilation errors so genetic examination was performed with metilation probes and the genetic mutations were identifyed. Clinical and biochemical manifestations are usually unnoticed during childhood; diagnosis is often delayed owing to lack of recognition of the syndrome. Genetic counseling may facilitate the diagnosis at an early age and prevent the patients from misleading follow-ups or diagnosis and/or engaging extensive unnecessary investigations.

A case of a giant parathyroid adenoma associated with a secondary hyperparathyroidism in a hemodialysis patient

Houas Jihene[1], BelHadj Miled Heyfa[1], Ghammam Monia[1], Kechiche Jawaher[1], El Omri Malika[1], Bellakhdher Mouna[1], Hasni El Abed Yosra[2], Meherzi Abir[1], Kermani Wassim[1] & Abdelkefi Mohamed[1]
[1]ENT Department and Neck Surgery of Farhat Hached Hospital, Sousse, Tunisia; [2]Endocrinology department Farhat Hached Hospital, Sousse, Tunisia

Introduction
Secondary and tertiary hyperparathyroidism (HPT) usually result from parathyroid gland hyperplasia that produces excess parathyroid hormone (PTH). Collectively, secondary and tertiary HPT comprise a minority of the patients diagnosed with HPT. Due to the relative rarity of these conditions and common underlying disease pathology, they are frequently discussed and researched together. While the disease processes are related, secondary and tertiary HPT are two distinct and separate entities.
Patients and Methods
We report a case of a giant parathyroid adenoma associated with a secondary hyperparathyroidism in a hemodialysis patient observed in our department of otorhinolaryngology and cervicofacial surgery.
Observation
The patient is 70 years old, diabetic, coronary and chronic renal failure, and has been on haemodialysis since 2019. She had been suffering from diffuse bone pain for a year with functional impotence, especially in the two lower limbs. A parathyroid workup revealed a blood calcium level at the upper limit of normal and an elevated PTH level of 1160 pg/ml even after correction of hypovitaminosis D. Scintigraphy found two MIBI-binding sites, one of which is large and projects below the left lower pole. MRI and CT scan found a 4 cm calcified left basicervical mass extending into the upper mediastinum. The patient underwent a subtotal parathyroidectomy with removal of the subthyroidal lower laterotracheal mass. The postoperative follow up was straightforward. The PTH was back to 35 pg/ml on postoperative day 3 with a blood calcium level of 2.05 mmol/l. Pathological examination concluded to a giant parathyroid adenoma associated with hyperplasia of the remaining parathyroids. The evolution was marked by a regression of bone pain.
Conclusion
Tertiary HPT is classically caused by hyperplasia of all four glands, though some reports indicate that over 20% of patients may have single or double adenomas as the underlying pathology. Management is essentially based on surgical treatment.

Comparison of biochemical values in asymptomatic and symptomatic urolithiasis

Nurcan Ince[1], Kubra Turan[2], Husniye Baser[2], Neslihan Çuhacı Seyrek[2], Didem Özdemir[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Artvin State Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Yıldırım Beyazıt University Faculty of Medicine, Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey

Background
Primary Hyperparathyroidism (PHPT) is a common endocrine disorder that is characterized by hypercalcaemia and elevated or inappropriately normal serum levels of parathyroid hormone. Most often, the presentation of PHPT is asymptomatic. PHPT can manifest with osteoporosis and hypercalciuria as well as with vertebral fractures and nephrolithiasis, both of which can be asymptomatic. Our aim in this study; to determine the frequency of kidney stones in patients operated for primary hyperparathyroidism and to compare the biochemical values of symptomatic and asymptomatic patients with kidney stones.
Methods
It was planned to include patients who had undergone parathyroidectomy, who applied to Ankara Yıldırım Beyazıt University Atatürk Training and Research Hospital between December 2006 and January 2019 and to Ankara City Hospital Endocrinology and Metabolic Diseases Clinic between February 2019 and November 2021.
Results
Of 886 patients who were operated for primary hyperparathyroidism, 15.9% (n: 141) were male. 189 (%21.3) patients had symptoms at the time of diagnosis. Diffuse body pain (37%), flank pain (22.2%), fatigue (11.6%), dyspepsia (6.9%), polyuria and polydipsia (4.2%) were the most common symptoms. Of the patients, 45.6% (*n*:388) had osteoporosis, 24.6% (*n*:253) had osteopenia, and 30.3% (*n*:257) kidney stones. Urinary symptoms were present in 133 (16.5%) patients. Genetic analysis was performed on 83 patients. 7.2% of the patients who underwent genetic analysis were men-1. The mean age of the patients was 53.6±11.9 (18-85) years. The mean preoperative total calcium of the patients was 11.1±1.1 (6.3-18.6) mg/dl. The mean preoperative phosphorus was 2.6±0.7 (0.7-9.0) mg/dl. The mean preoperative 24-hour urinary calcium of the patients was 380.5±198.2 (24-1438) mg/24-hour. The mean preoperative 24-hour urine phosphorus was 797.9±350.4 (30.2-3798) g/24 hour. 257 patients with kidney stones were divided into two groups according to urinary symptoms. 70.2% (*n*:92) of 131 patients with urinary symptoms and 82.7% (*n*:91) of 110 patients without urinary symptoms were women. The proportion of women was significantly higher in the group without urinary symptoms (*P*:0.035). The median age was significantly higher in the group without urinary symptoms compared to urinary symptoms group (54.7 years vs 51.5 years, *P*:0.039). osteoporosis rate, total calcium value, phosphorus value, parathormone value, 24-hour urinary calcium and 24-hour urine phosphorus value were similar for the two groups.
Conclusion
Patients with symptomatic nephrolithiasis were younger and more male dominated.

A rare etiology of primary hyperparathyroidism

Houas Jihene[1], Bergaoui Emna[1], Ghammam Monia[1], Naouar Maroua[1], El Omri Malika[1], Bellakhdher Mouna[1], Hasni El Abed Yosra[2], Meherzi Abir[1], Kermani Wassim[1] & Abdelkefi Mohamed[1]
[1]ENT Department and Neck Surgery of Farhat Hached Hospital, Sousse, Tunisia; [2]Endocrinology department Farhat Hached Hospital, Sousse, Tunisia

Introduction
Parathyroid cysts are a rare clinical and histological entity, with less than 300 cases reported in the literature. They constitute 0.5% of all parathyroid pathologies and 1% of all cystic lesions in the cervical region. Parathyroid cysts can give rise to a varied symptomatology by the local or hormonal repercussions.
Case
We report the case of a 65-year-old patient with no pathological history who presented for bone pain with functional impotence of the lower limbs. Cervical examination noted a right basicervical tumefaction of 1.5 cm that is firm and mobile on swallowing. The biological assessment objectified an hypercalcemia at 2.43 with an hyperparathyroidism at 2406 pg/ml. Ultrasound evocated 2 necrotic lower lobe thyroid nodules. The parathyroid scintigraphy doesn't show any fixation. Cervical scan showed a cystic lesion at the level of the lower part of the right thyroid lobe and another heterogeneous one on the left side. A para thyroidectomy of the lower right parathyroid gland, which had a large cystic component, was performed associated with left para thyroidectomy. Histopathological examination revealed a right lower parathyroid cyst with hyperplasia of the parathyroid parenchyma of both parathyroid glands. Postoperative follow-up showed a normalization of the calcium and parathyroid hormone levels.
Conclusion
Parathyroid cycts often involved the lower parathyroid glands, with a predominance on the left side. They can be functional or non-functional, depending on their association with hypercalcemia. The clinical manifestations are various. Some cases of carcinoma arising from parathyroid cysts have been reported suggesting that the surgical removal of all cysts should be strongly considered.

Hyperparathyroidism Jaw Tumour Syndrome in Pregnancy: A rare coexistence

Sofia Lopes, Alice Monsanto, Mafalda Ferreira, Mara Ventura, Luísa Ruas, Patrícia Oliveira & Isabel Paiva
Coimbra Hospital and Universitary Centre, Endocrinology, Diabetes and Metabolism, Coimbra, Portugal

Introduction
Only <1% of cases of primary hyperparathyroidism (PHPT) occur during pregnancy. PHPT increases risk of complications such as miscarriage, premature birth and life-threatening maternal hypercalcemic crises. Hyperparathyroidism Jaw Tumor Syndrome (HPT-JT) is a rare inherited cause of PHPT, resulting from CDC73 gene mutations. There are a few reports described about HPT-JT in pregnancy. Although parathyroidectomy is the definite treatment for PHPT, given the scarce evidence on the management of PHPT in pregnancy, questions regarding its safety arise. Additionally, medical therapies such as bisphosphonates, cinacalcet or calcitonin are not recommended, as there is no proven safety.
Objective
We present the case of a woman with HPT-JT, who became pregnant while awaiting surgical treatment.
Clinical Case
A 19-year-old woman with a history of repeated miscarriages and urolithiasis was referred to an Endocrinology appointment due to hypercalcemia of 12.4 mg/dl (8.8-10.6). The remainder study revealed serum PTH of 950 pg/ml (9-72), phosphataemia of 2.2 mg/dl (2.9-5.0), 25-OH Vitamin D of 27 ng/ml (30-100) and normal urinary clearance calcium/creatinine ratio. Cervical ultrasound showed a right inferior parathyroid adenoma. The genetic study identified a CDC73 gene pathogenic variant, confirming the diagnosis of HPT-JT. The clinical situation was explained to the patient, namely the risks associated with pregnancy. Despite this, while awaiting surgical treatment, a 5-week pregnancy was diagnosed, in the context of an episode of abdominal pain. In this patient, we opted for close surveillance and conservative treatment with increased oral hydration and restriction of calcium in the diet, delaying surgery to the postpartum period. Pregnancy complications included: an episode of acute renal colic pain at week 10 of pregnancy, which was treated conservatively; a threatened preterm labor at week 28, that responded positively to bed rest. During pregnancy, calcemia values between 12.7-13.2 mg/dl and PTH between 678-882 pg/ml. Spontaneous vaginal delivery occurred at 39 weeks and 3 days, with a birth weight of 2920g. There were no evident changes in fetal development. Our patient currently awaits postpartum reassessment.
Conclusions
The fact that the patient had become pregnant prior to surgical treatment raised major approach challenges, given the rarity of the clinical situation, the risk of maternal-fetal adverse effects and the scarcity of therapeutic options in pregnancy. Although parathyroidectomy constitutes the definitive treatment for PHPT, the type of treatment during pregnancy is complex and must be individualized, taking into account additional factors such as the severity of hypercalcemia and the risk of post-surgical complications.

22q11.2 deletion syndrome diagnosed in the context of a seizure in adulthood

Francisca de Brito Marques, Francisco Simões de Carvalho & Joana Lima Ferreira
Pedro Hispano Hospital, Matosinhos Local Health Unit, Endocrinology, Matosinhos, Portugal

Introduction
The 22q11.2 deletion syndrome or DiGeorge syndrome (DGS) is rare and the diagnosis in adults is uncommon. The phenotype is highly heterogeneous and of variable severity, including hypoparathyroidism and epilepsy.

Case Report
A 26-year-old man was admitted in the emergency room for inaugural tonic-clonic seizure. He had history of cognitive impairment and learning difficulties. Neurologic examination, brain CT and basic analysis were irrelevant. He was started on an anti-epileptic drug. He was followed up in Neurology and Internal Medicine outpatient clinic. Brain MRI was normal. Electroencephalography showed generalized epilepsy. Laboratory tests revealed total Ca^{2+} 5.7 mg/dl [8.9-10.0], P- 5 mg/dl [2.3-4.7], PTH 8.4 pg/ml [15.0-68.3] and 25-OHD 14 ng/ml. He was started on oral calcium and cholecalciferol supplements with no improvement. At the age of 30, he was referred to the Endocrinology clinic. Accompanied by his mother, he had no history of cervical surgery or irradiation, heart disease or recurrent infections. He had dental plaque due to enamel hypoplasia and had had surgery for spastic flat feet. Family history was irrelevant. He had significant difficulty in noticing typical symptoms of hypocalcemia, but he admitted frequent paresthesia and tiredness in lower limbs since childhood. He had slight facial dysmorphia and normal stature. He was hemodynamic stable, and Trousseau's sign was present. He was started on calcitriol and calcium supplements were adjusted. Symptoms improved for the first time and blood tests revealed clear analytical improvement. Anti-epileptic medication was stopped without new seizures. The remaining study showed normal 24-hour urine calcium, intermediate hyperglycemia and autoimmune thyroiditis; morning cortisol, total testosterone and femur radiographs were normal. The suspicion of DGS was confirmed by genetic study. Complementary evaluation documented mild aortic insufficiency, and there was no evidence of kidney or ophthalmologic alterations. Skin lesions were evaluated by Dermatology and psoriasis and generalized candidiasis were diagnosed. During follow-up, due to poor therapeutic adherence, serum calcium levels have been below target. Currently, however, adherence has improved with maternal support (total Ca^{2+} 8.24 mg/dl).
Discussion
We report a case of DGS diagnosed in the context of a seizure in an adult, but with systemic manifestations since childhood in addition to hypoparathyroidism. We highlight the role of Endocrinology in the correct diagnosis and treatment of this complex patient, with control of hypocalcaemia and its complications and guidance for other comorbidities that also require chronic multidisciplinary follow-up.

Multiple brown tumors mistaken for bone metastases: Bone scintigraphy and 99m-Tc sestamibi imaging findings

Maali Ben Nasr, Wassim El Ajmi, Ali Sellem & Hatem Hammami
The Military Hospital of Tunis, Nuclear Medicine, Tunis, Tunisia

Introduction
Brown tumors or osteitis fibrosa cystica are benign bone tumors complicating uncontrolled primary or secondary hyperparathyroidism. They may behave aggressively and can be destructive. Their osteolytic aspect may be misinterpreted as skeletal metastases.
Methods
A 37-year-old female patient with chronic renal failure on dialysis, presented with pain and swelling of her left knee for 10 days, with no associated trauma. She gave history of tubulo-papillary carcinoma on renal graft, four years after her renal transplantation, treated with transplantectomy since 2015.
Results
X-rays revealed no fracture, but multiple osteolytic lesions were found in the tibias and the right pubic bone. In view of the suspicion of bone metastases, a whole body computed tomography (CT) was performed, revealing renal osteodystrophy as well as multiple osteolytic and mixed lesions within the costal grid, the dorsal spine and the right pubic spine evoking bone metastases. MRI of the knee revealed a lesion of the 1/3 upper left tibia measuring $46 \times 41 \times 76$ mm blowing the cortex, suggestive of brown tumor. Bone scan showed intense, symmetrical and diffuse uptake of the skull, facial bones and mandible. There was increased and diffuse radiotracer uptake in the dorsal spine and several foci of moderately increased uptake within the costal grid and the right pubis. These lesions were previously described on the CT scan however this appearance suggested a metabolic origin. The patient underwent biopsy from the left tibial lesion which showed histiocytic proliferation with large number of osteoclastic giant cells compatible with a brown tumor. The biological workup revealed hyperparathyroidism with elevated parathyroid hormone (PTH) at 1100 pg/ml (reference range; 15-65 pg/ml). ^{99m}Tc- sestamibi scintigraphy was done which localized a left inferior parathyroid adenoma. Radiopharmaceutical uptake was also noted within several brown tumors.
Discussion and Conclusion
Brown tumors are rare skeletal manifestations of hyperparathyroidism. They can be monostotic or rarely polyostotic with preferentially affecting sites such as skull, jaw, phalanges, pelvis, clavicles, femur and ribs. These tumors give a pseudometastatic radiological appearance. Therefore, they should be considered in the differential diagnosis of osteolytic lesions to avoid unnecessary interventions.

Denosumab in the treatment of fracturary osteoporosis: the double effect on bone and glycemic metabolism

Ines Cosme[1], Ema Nobre[1,2] & Ana Paula Barbosa[1,2]
[1]Hospital Santa Maria, CHLN EPE, Fracturary Osteoporosis Outpatient Clinic, Lisbon, Portugal; [2]Lisboa Faculty of Medicine, Lisbon, Portugal

Background
Denosumab (Dmab) is a human monoclonal antibody with an anti-reabsorptive bone effect, used in osteoporosis treatment. It is also suggested that Dmab may improve glucose tolerance through the reduction of hepatic insulin resistance. Some studies have suggested that insulin sensitivity and glycemia can influence bone metabolism.
Aims
To evaluate the relationship between bone turnover markers (BTM) and insulin resistance and glycemia in fracturary osteoporotic patients treated with Dmab.
Methods
Retrospective study of a cohort of osteoporotic patients treated with Dmab for at least 6 months. BTM (CTX - serum C-telopeptide of type I collagen, P1NP - serum procollagen type 1 N-terminal propeptide, BALP - bone alkaline phosphatase and osteocalcin), fasting glycemia and insulin were measured at baseline (T0) and after Dmab treatment (T1). Insulin resistance was estimated using homeostasis model assessment of insulin resistance (HOMA-IR) at T0 and T1. Adequate statistical studies were used, statistical significance was considered for $P<0.05$. Results are expressed as mean $\pm$ SD.
Results
Included 18 patients, 15 postmenopausal women and 3 men, with a mean age 75.5 ± 9.1 years old, treated with Dmab for 23.7 ± 10.1 months. It was observed a reduction of BTM levels after Dmab (BTM T0 vs T1 were: CTX 0.35 ± 0.18 vs 0.14 ± 0.13 ng/ml, $P<0.01$; P1NP 43.7 ± 16.0 vs 21.1 ± 9.7 ng/ml, $P<0.01$; BALP 13.9 ± 5.2 vs 8 ± 2.0 µg/l, $P<0.01$; osteocalcin 17.9 ± 6.9 vs 10.0 ± 4.0 ng/ml, $P<0.01$). After Dmab (T0/T1), fasting glycemia ($98.6 \pm 23.6/93.6 \pm 18.5$ mg/dl, $P=0.04$), fasting insulin ($10.8 \pm 5.3/9.4 \pm 4.8$ µU/ml, $P=0.1$) and HOMA-IR ($2.5 \pm 0.5/2.3 \pm 1.4$, $P=0.43$) decreased. There were no associations between HOMA-IR, insulin or glycemia and each BTM at T0 and T1.
Conclusions
In this group of fracturary osteoporotic patients, Dmab reduced significantly BTM and glycemia. These results may suggest that Dmab can be a good option treatment for patients with diabetes and insulin resistance, both known factors contributing to osteoporotic fractures. Studies with more patients can validate these preliminary results.

Severe calcific uremic arteriolopathy lessions and acute hypocalcemia after parathyroidectomy for secondary hyperparathyroidism in haemodialysis patients: Case series

Ioana Hristov[1], Aciobanitei Elena[2] & Danila Radu[3]
[1]Elytis Hospital Iasi, Endocrinology, Iaşi, Romania; [2]Mediss Center Targu Neamt, Nephrology and Dialysis, Targu Neamt, Romania; [3]Universitatea de Medicină şi Farmacie "Grigore T. Popa" din Iaşi, Surgery, Iaşi, Romania

Introduction
Calcific Uremic Arteriolopathy (CUA) is a rare but severe complication of end-stage kidney disease with one year survival rates between 45-55%. Extensive skin ulcers and concomitant painful purpura are the clinical features and diagnosis criteria as defined by Hayashi. Parathyroidectomy treatment for hyperparatiroidism is reserved for patients with inadequate response to calcimimetics, persistent elevated PTH > 800 pg/ml or calciphylaxis and it has been shown to provide

benefits for all-cause mortality in secondary hyperparathyroidism patients.
Method
Case series of five patients (3 females and 2 males) with a mean age of 51 ± 5.3 years old with end stage kidney disease and hemodialysis programme duration of 9.5 ± 2.7 years. Due to persistent high serum iPTH levels was 1400 ± 270 pg/ml after calcimimetics medication, sub -total parathyroidectomy was indicated in all 5 cases. We evaluated calciphylaxis lessions and iPTH dynamic levels for the next 12 months.
Results
CUA with painfull skin ulcers has occurred in 2 cases, the patients aged 46 and 49 years old, males and with a hemodialysis history of 8 respectively 11 years. The iPTH levels before parathyroidectomy were > 1400 pg/ml in both cases, and they had severe post-surgery hypocalcemia 1.48 mmol/l and 1.53 mmol/l with iPTH levels between 120 and 250 pg/ml. The outcome after surgical debridation, antibiotherapy, discontinuation of anti-vitamin K and nutritional support was favorable with complete skin ulcers remission and stable calcium levels of 1.8-2.1 mmol/l.
Conclusions
The calciphylaxis lessions are rare, especially after parathyroidectomy, when calcium levels are lower and iPTH levels are reduced. Guidelines for CUA therapy are currently lacking and these particular cases show that long term evolution of hyperparathyroidism especially with very high levels of PTH need accurate management .Also the associated severe hypocalcemia is an aggravating factor, as correction with calcium supplements may lead to calciphylaxis lesion progression.

Features of diagnosis and management of parathyroid cysts

Yuriy Aleksandrov[1], Artem Dyakiv[1] & Yury Patrunov[2]
[1]Yaroslavl State Medical University, Surgery, Yaroslavl, Russia; [2]Yaroslavl State Medical University, Ultrasound, Yaroslavl, Russia

The retrospective experience of diagnosis and treatment of 18 people with true parathyroid cysts was studied. Clinical features, ultrasound results, laboratory parameters, surgical aids and subsequent dynamics were studied. All patients were women aged 35 to 77 years. Parathyroid cysts had no clinical manifestations, hyperparathyroidism and compression syndrome were absent. All parathyroid cysts were discovered accidentally during an ultrasound examination of the neck. Often the reason for contacting surgeons was a referral to FNAB due to an erroneous diagnosis of thyroid nodules. Ultrasound data showed that all the cysts were located on the neck, two of them fell behind the collarbone. Most of the cysts (14) were located in the projection of the lower third of the thyroid lobes and below the thyroid gland. The cysts were visualized as rounded or oval formations with clear contours, an echogenic capsule, the absence of a solid component and anechoic contents with distal pseudo-amplification of the echo. Ultrasound criteria included cases of reliable location of cysts outside the thyroid gland, as well as a tendency to increase due to one of the diameters. When determining the size of cysts, their diameter ranged from 10 to 120 mm. Elevated levels of PTH and Ca^{++} in the blood were not detected in any patient. In all cases, a crystal clear colorless liquid was obtained using FNAB, which was one of the diagnostic criteria. When determining the level of PTH in the cystic fluid, a very high (more than 1000 pg/ml) concentration of the hormone was observed in all cases. Cystectomy was performed in 4 cases together with thyroid surgery (thyroid adenomas and nodular goiter). In 10 cases (dimensions more than 30 mm (average volume more than 4 ml), sclerotherapy was performed), in 4 cases - aspiration of cystic contents. The results were tracked 3 months and 1 year after the manipulations. Since all parathyroid cysts were functionally inactive, PTH levels after aspiration, sclerotherapy and cystectomy were not determined. The level of Ca^{++} in the blood after aspiration and sclerotherapy was not determined, and after surgery was measured 24 hours after the intervention. According to ultrasound and laboratory tests, a positive result was obtained in all cases. It was concluded that the presented protocol of examination and treatment of patients is optimal, and the choice of treatment method depends on the size and activity of cysts, as well as on the presence of concomitant pathology.

Parathyroid carcinoma: A case report

Ben Salem Maram, Marwa Chiboub, Wafa Ben Hilel, Manel Jemel & Ines Kammoun
National Institute of Nutrition, Department of Endocrinology, Tunis, Tunisia

Introduction
Parathyroid carcinoma is an uncommon cause of primary hyperparathyroidism. It is responsible of 0.4% to 5% of all cases of primary hyperparathyroidism. Parathyroid carcinoma has a high probability of local recurrence, regional node and distant metastasis and the preoperative diagnosis is challenging.
Case presentation
We report a case of a 66-year-old female patient with medical history of hypertension and chronic kidney failure. She was diagnosed with primary hyperparathyroidism and underwent cervicotomy for an ectopic suprasternal and a right paratracheal parathyroid nodule and histopathology confirmed the diagnosis of parathyroid hyperplasia. One year later, she consulted for persistent hyperparathyroidism with malignant hypercalcemia. Sestamibi parathyroid scintigraphy confirmed hyperfunctioning parathyroid tissue in the right thyroid bed and in the mediastinal area. The cervical MRI revealed an ectopic mediastinal nodule of 11.8 mm. Multiple endocrine neoplasia was excluded. The patient underwent surgical removal of the lower right parathyroid and the mediastinal nodule and histological examination of the specimen confirmed the diagnosis of parathyroid carcinoma with clear cell and on-cocytic features. Postoperative calcium and parathyroid blood levels remained high. The presence of pulmonary metastasis was confirmed after practicing a total body scintigraphy and the patient was referred to oncology for chemotherapy.
Conclusion
Parathyroid carcinoma is a rare tumor. The severity of this pathology is due to the severe hypercalcemia aggravating the mortality and to the risk of local recurrence and distant metastases justifying the prolonged monitoring to improve the prognosis of the disease.

Completely intra-thyroidal parathyroid adenoma: A rare entity

Manash Baruah[1], Bubul C Roy[2], Upasana M Baruah[3], Anup K Das[4], Ashok K Bhuyan[5] & Pankaj Patawari[1]
[1]Apollo Excelcare Hospital, Endocrinology, Guwahati, India; [2]Apollo Excelcare Hospital, Head & Neck Surgery, Guwahati, India; [3]Apollo Excelcare Hospital, Radiology, Guwahati, India; [4]Arya Wellness Centre, Pathology, Guwahati, India; [5]Gauhati Medical College, Endocrinology, Guwahati, India

Introduction
Intra thyroidal parathyroid adenoma is an uncommon presentation of primary hyperparathyroidism (PHPT). Herein we report such a patient who had recurrent hypercalcemia after a classical parathyroid exploration.
Case presentation
45 year old female, home-maker had a long standing history of weakness, back and lower limb pain, loss of appetite. Preliminary evaluation at secondary care level revealed hypercalcemia (18.3 mg/dl) with high intact parathyroid hormone (iPTH, 1244.0 pg/ml). 99mTc SestaMiBi scan revealed left inferior parathyroid adenoma for which she underwent left inferior parathyroidectomy elsewhere. Post operatively her symptoms of hypercalcemia returned within few weeks and further evaluation revealed high iPTH(251.10 pg/ml) with hypercalcemia (10.4 mg/dl). Repeat MiBi scan revealed suspected parathyroid adenoma in relation to lower pole of left lobe of thyroid suggesting failed surgery. HR-USG neck revealed no parathyroid adenoma in usual locations and a left lobe thyroid nodule which roughly corresponded to the isotopic activity. USG guided FNAC was non contributory. Patient was subjected to re-exploration by a parathyroid surgeon. Left hemi-thyroidectomy was done and the intrathyroidal mass was removed. Pre-operative iPTH of 1988 pg/ml came down to 55.9 pg/ml within 4 hours of surgery. Intra-opeartive imprint smear showed small clusters of tumor cells with normal to moderate cytoplasm and round to oval nuclei. HPE showed a well circumscribed tumour within left lobe of thyroid with an incomplete fibrous capsule surrounded by thyroid tissue without any capsular or vascular invasion. There were polygonal cells with moderate amount of clear cytoplasm and round to oval hyperchromic nuclei and mild anisocytosis. Post-operative hypocalcemia (6.9 mg/dl) was managed with intravenous calcium and magnesium and oral calcitriol. Patient continues to be on oral calcium plus calcitriol supplement at the 7th post operative week of the second surgery.
Discussion
In a large series of > 10,000 parathyroid exploration for PHPT, 1.2% were partially intrathyroidal while only 0.7% were truly intrathyroidal[1]. Most reported cases were typically diagnosed due to persistent disease post-exploration[2].
Conclusion
Intrathyroidal parathyroid adenoma is a rare cause of PHPT and should be considered as a potential cause for a unsuccessful parathyroid exploration.

Primary Hyperparathyroidism and colon cancer: Incidental association or causal link?

Lamya Echchad, Khaoula Gorgi, Kaoutar Rifai, Hinde Iraqi & Mohamed El Hassan Gharbi
Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction
Hypercalcemia is often observed in patients with cancer, secondary to the production s of parathyroid hormone (PTH)-related peptides. However, the association of primary hyperparathyroidism (pHPT) and colon cancer is rarely reported.
Case
We present the case of a 76 years old female patient, who was operated one year ago of for a low-grade colorectal adenocarcinoma. As part of her routine workup of her disease she underwent a phosphocalcic assessment which showed hypercalcemia at 120 mg/l, hypophosphatemia at 19 mg/l, an elevated PTH above 300 pmol/l and a 24-hour calciuria of 350 mg/day.The parathyroid Sestamibi scan was performed and the findings were suggestive of a left inferior parathyroid focus. The patient underwent a left inferior parathyroidectomy and the anatomopathological examination was in favor of a parathyroid adenoma.
Discussion and Conclusion
Calcium is considered as a potential anticarcinogenic, these findings can be explained by two possible mechanisms. Firstly, it neutralizes the promoter activity of fatty acids and bile acids in colorectal carcinogenesis. Secondly, calcium is believed to reduce crypt cell hyperproliferation so a decreased level of calcium can lead to hyperproliferation of the colorectal mucosa. In primary hyperparathyroidism the increase in PTH activates 1,25(OH)2D and promotes calcium absorption in the intestine. As a result, the level of calcium in the lumen is decreased, which leads to an elevated risk of colorectal cancer.

Depot medroxyprogesterone acetate (DMPA)-associated early-onset osteoporotic fracture with ALPL gene mutation: Challenges and Limitations in the era of molecular diagnostics

Yotsapon Thewjitcharoen, Soontaree Nakasatien, Sirinate Krittiyawong, Veekij Veerasomboonsin & Thep Himathongkam
Theptarin Hospital, Diabetes and Thyroid Center, Bangkok, Thailand

Background
Recent advances in next-generation sequencing technology have greatly increased the number of Variants of Uncertain Significance (VUS) encountered in clinical practice. Herein, we present difficulty in diagnostic path and challenges in a premenopausal woman with an unusual fracture history and osteoporosis.
Clinical Case
A 37-year-old Thai woman with no known underlying disease was diagnosed with osteoporosis (a BMD Z-score of -2.6 at femoral neck) after having developed left proximal fracture femur from a slip and fall accident 6 months earlier. The patient came to see us for further treatments of early-onset osteoporosis. Additional history revealed that intramuscular DMPA injection was continuously used for 7 years as a hormonal contraceptive. Initial work-up for secondary osteoporosis at that time showed only low serum TSH level, vitamin D insufficiency (17 ng/ml), slightly elevated plasma iPTH level (70.5 pg/ml) with normal plasma alkaline phosphatase (ALP). The patient was started on a weekly oral bisphosphonate for 4 months before whole exome sequencing to investigate monogenic bone disorders revealed a rare heterozygous variant c.1069C>T (p.Arg357Trp) of the *ALPL* gene which could cause adult-onset hypophosphatasia (HPP). However, this variant was classified as VUS by the ACMG guidelines. Based on the very low allele frequency from gnomAD, the possibility of pathogenicity of this variant could not be excluded. However, additional testing revealed normal plasma pyridoxal 5′-phosphate (an ALP substrate) together with her history of prolonged use of DMPA which could have adverse bone effects from hypoestrogenism and its glucocorticoid effect did not support the diagnosis of HPP. Extended family members testing to determine whether the variant is shared by other unaffected individuals showed the patient inherited this variant from her mother and her brother without history of fracture also carries this variant. As a result, the possibility of HPP had been disregarded. At follow-up 3 months later, she developed avascular necrosis (AVN) of previous screw fixation at left femoral head and total hip arthroplasty was performed uneventfully.
Conclusions
Identification of rare *ALPL* VUS challenges in deciphering the clinical relevance whether this patient has HPP and bisphosphonate should be discontinued. The underrepresentation of non-European ancestry groups in current genomic databases complicates interpretation of their genetic test results. The patient's clinical presentation remains the most important context for interpreting sequencing results. Our case also highlights the fracture risk from long-term use of DMPA which is widely used as progestogen-only contraceptive method in low and middle-income countries.

Body mass index as predictor of bone mineral density in postmenopausal women

Snjezana Popovic Pejicic[1,2], Nina Pejicic[2], Gabrijela Malesevic[1,2] & Valentina Soldat Stankovic[1,2]
[1]University of Banja Luka, Faculty of Medicine, Banja Luka, Bosnia and Herzegovina; [2]University Clinical Centre of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina

Introduction
In order to detect the subjects at risk for osteoporotic fractures, one should actively search for them, primarily in a group of postmenopausal women, considering clinical risk factors. Body mass index (BMI) is a well-known, significant predictor of bone mineral density (BMD) of entire skeleton.
Aim
The aim of this study was to examine relationship between BMI and BMD in a group of postmenopausal women.
Methods
The study involved a group of 100 postmenopausal women, aged 46 to 70 years. (59.08 ± 6.07). All subjects had their body mass and body height measured and BMI calculated. BMD was determined by DXA method (dual energy X-ray absorptiometry) by Lunar Prodigy Advance Unit. BMD was measured at central skeleton (lumbal spine and both hips). According to densitometry finding, the criterion for osteoporosis is T score less than –2.5 SD. BMI values were correlated with total T score values of the lumbal spine and both hips, as well as total T score values of spine and hip.
Results
Results have shown that BMI was normal in 18% subjects, 1st grade obesity was found in 52%, 2nd grade obesity in 23%, 3rd grade obesity in 7% of subjects. Median BMI value was found in 28.27 ± 4.12. Median lumbal spine T score was– 2.19 SD ± 1.25, and hip T score–1.11 SD ± 0.95. A statistically significant positive correlation ($r = 0.01$) was found between BMI and BMD of the hip, whereas between BMI and BMD of lumbal spine there was no statistically significant correlation. There was a statistically significant correlation ($r = 0.01$) between BMD values of lumbal spine and hip.
Conclusion
In postmenopausal women BMI is more important predictor of hip BMD, as compared to spine BMD. BMD of hip is increased with the increase of BMI and height in postmenopausal women due to considerable endocrine function of fat

tissue which produces leptin and other bioactive peptides which have a protective role in bone structure. A lack of correlation between BMI and BMD of spine in postmenopausal women might be due to predominant effect of lack of estrogen and faster bone metabolism in spinal region.

Porphyria presenting as osteoporosis

Nuriye Hale Erbatur, Gönül Koç[2], Serife Mehlika Kuskonmaz[2] & Cavit Çulha[2]

[1]Health Sciences University Sultan Abdulhamid Han Training and Research Hospital, Endocrinology and Metabolism, İstanbul, Turkey; [2]Ankara Training and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey

Introduction

Secondary osteoporosis is defined as bone loss caused or exacerbated by other clinical disorders. Secondary osteoporosis can be due to a wide range of medical disorders, including endocrine disorders and genetic disorders. We are presenting a clinical case which the patient diagnosed as acute intermittent porphyria while being investigated for secondary osteoporosis.

Clinical Case

41-year-old female patient applied with bone and back pain, itchy dark-colored lesion in the abdomen, abdominal pain during menstruation and nonspecific neurological complaints such as numbness in the arms and headache. The patient had anxiety was using sertraline for the treatment. On physical examination, brown spots were seen on the skin in the lower abdominal quadrants. In laboratory examinations, there was no hypogonadism, parathyroid and thyroid functions were normal. In 24-hour urine analysis, uroporphyrin was detected as 96.92 μg/24 h (0-33 μg/24 h). Bone mineral density (BMD) showed a *Z* score of −2.6 for L2 to L4, −2.7 for the femoral neck and -2.6 for total hip. Her FRAX score showed low risk of osteoporotic fracture. Genetic examination was performed for porphyria due to its clinical compatibility ant the patient was a heterozygote for an exon 9 (NM_000190) *HMBS* variant. The patient was evaluated as acute intermittent porphyria with clinical and genetic results. Antiresorptive treatment was not started due to the low risk of fracture. She was followed up with vitamin D and calcium.

Conclusion

In any patient evaluated for osteoporosis, secondary causes may have contributed to the condition. Various causes of osteoporosis, such as mild asymptomatic hyperparathyroidism, celiac disease, metabolic and genetic disorders, may be clinically unclear. Intensive research is particularly needed in all premenopausal women and men with atraumatic fractures or BMD below 1 SD of same-age control subjects. Porphyria should be kept in mind in patients with atypical abdominal pain or atypical neurologic findings.

Table 1 Laboratory findings of the patient

Laboratory test	Patient's values	Reference range
Creatinine (mg/dl)	0.61	<1.2
ALP(U/l)	96	<98
FSH (mIU/ml)	4.7	1.5-12.4
LH (mIU/ml)	12.14	1.7-8.6
Estradiol (ng/dl)	213.3	30-400
TSH (Uu/ml)	1.26	0.27-4.2
FT4 (ng/dl)	1.3	0.89-1.76
PTH (ng/l)	27.5	15-65
25-OH-D(μg/l)	21.84	30-80
Serum calcium (mg/dl)	9.67	8.8-10.6
Serum phosphorus (mg/dl)	2.7	2.6-4.5
AFP (μg/l)	1.78	0-7

FSH: Follicle-Stimulating Hormone; LH: Luteinizing hormone; TSH: Thyroid-stimulating hormone; FT4: Free thyroxine; PTH: Parathyroid hormone; 25-OH-D: 25-hydroxy vitamin D; AFP: alpha-fetoprotein

Osteoporosis in a patient with Glycogen Storage Disease Type I

Ozlem Iyidir[1], Tugce Ilayda Turer[2] & Deniz Atikcan[1]

[1]Baskent University, Endocrinology and Metabolism, Ankara, Turkey; [2]Baskent University, Faculty of Medicine, Ankara, Turkey

Glycogen storage disease type 1 is a rare autosomal recessive disorder. Osteoporosis is one of the long term complications. However factors associated with low bone mass has not fully understood. Metabolic derangements that occur with poor control may contribute to bone disease. Low bone mass could be caused by hypogonadtropic hypogonadism, a unique issue identified in GSD. Herein we report a patient with GSD type 1, osteoporosis and hypogonadotropic hypogonadism. A 20 years old man admitted to our outpatient clinic for evaluation of osteoporosis after femur fracture in 2021. He had a history of Glycogen Storage Disease type 1a that is diagnosed in infancy with recurrent hypoglycemia. He is currently managed with Glycosade however he has suboptimal metabolic control. He has multiple hepatic adenomas stable for two years on serial abdominal MR scans. He previously underwent a right lobe partial liver resection for probable hepatocellular carcinoma and pathology showed hepatic adenoma. On physical examination his height was 158 cm and weight was 54 kg. He has tanner 3 pubic hair and stage 4 genitalia. His biochemical tests confirmed hypogonadotropic hypogandism, other pituitary hormones were normal. His BMD at L1-L4 was 0.420 with a *Z* score of -6.0. At age 17 years he was evaluated for low bone mass. According to his medical records he underwent spontaneous puberty however his bone mineral density (BMD) at lomber vertebrae was 0.436 g/cm^2 and Z score -5.3 at that time. Vitamin D replacement was started nevertheless he did not use it regularly. Since there was not evidence for use of conventional osteoporosis treatment in Glycogen storage disease related osteoporosis we intended to treat his hypogonadism first. In 2021 at the age of 19 he was started on transdermal testosteron. After a year with transdermal testosteron his hepatic adenomas were stable in MR imaging. His bone mass ameliorated (L1-L4 BMD 0.648 g/cm^2 and *Z* score -4.7) despite his poor metabolic control. Hypogonadotropic hypogonadism may be an important factor contributing to bone loss in patients with GSD. Testosteron replacement may restore bone mass. GSD type 1 patients are at risk for potential malignant transformation of hepatic adenomas, testosterone therapy should be carefully monitored.

Cortisone-induced osteoporosis: A dreaded complication of prolonged corticosteroid therapy

Siddiqa Soomauroo[1], Raida Ben Salah[1], Faten Haj Kacem Akid[2], Mohamed Abid[2] & Zouheir Bahloul[1]

[1]Hedi Chaker University Hospital, Department of Internal Medicine, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction

Cortisone-induced osteoporosis (CO) is the most frequent complication of corticosteroid therapy. It is the first cause of secondary osteoporosis. The aim of this study is to clarify the characteristics of CO.

Patients and Methods

We report a retrospective study of 39 cases of CO among 128 cases of osteoporosis during a 15-year period. The diagnosis of CO was based on a bone densitometry (BMD) of more than -1.5 standard deviations.

Results

Thirty-nine cases of CO were collected. Its frequency is 30.5% of the total osteoporosis series and 85.7% of secondary osteoporosis. There were 34 women (87.5%) and 5 men (12.5%). The average age at diagnosis was 59 years. CO was more frequent in younger subjects with a significant correlation ($P=0.011$). All our patients received long-term systemic corticosteroid treatment. The average cumulative dose of corticosteroid therapy (CT) was 26 g of prednisone (extremes 0.4-65 g). The average duration of CT was 14.5 years (extremes 2-18 years). The indications for CT were: systemic disease in 33 cases, haematological disease (3 cases), dermatological disease (2 cases) and uveitis (1 case). BMD showed a mean vertebral T-score of -2.78 standard deviations. In addition to vitamin and calcium therapy in all patients, bisphosphanates were administered in 23 patients and strontium ranelate in one case.

Conclusion

CO is the main cause of secondary osteoporosis in our series.

A Late Diagnosed Neurofibromatosis Case During Preoperative Evaluation For Scoliosis

Ceyda Dinçer Yazan, Anna Abbasgholizadeh & Dilek Gogas Yavuz
Marmara University Faculty of Medicine, Endocrinology and Metabolism, Istanbul, Turkey

Objective
Neurofibromatosis type 1 is an autosomal dominant inherited neurocutaneous condition characterized with multipl cafe-au-lait spots, neurofibromas, predisposition to malignancies, and the incidence of disease is 1:3000. Patients are diagnosed according to diagnostic criteria and 97% of the patents meet the criteria before 8 years of old. Diagnosis and follow-up of patients for manifestations of neurofibromatosis is important for early diagnosis and treatment of malignancies.
Case
Twenty-one year old female patient admitted to neurosurgery outpatient clinic with complaint of scoliosis. She was consultated to endocrinology clinic for low bone mineral density levels and osteoporotic findings in vertebral x-ray examination. In physical examination she was short statured and she had growth retardation. She had multipl cafe-au-lait spots and scoliosis. On right lower limb, she had a brown lesion and after consultation with dermatology clinic it was considered as plexiform neurofibroma. Her bone mineral density level (BMD) in L1-L4 was 1.006, z score was -0.7, femur neck BMD was 0.669 z score was -2.1. Her osteocalcin level was 21.5 ng/ml (9-42), c-telopeptide was 0.23. Hypophysial hormones were evaluated and her IGF-1 level was found to be low according to age reference range. Insulin tolerance test was performed and her growth hormone was found to be 0.206 when her blood glucose was 36 mg/dl. In family history, her mother and brother were also learnt to have multiple cafe-au-lait spots and in physical examination her mother had cutaneous neurofibromas. Neurofibromatosis diagnosis was confirmed after genetic consultation and genetic test. Hamartomatous lesion in both basal ganglia and thalamus and in right frontal lobe were found in cranial magnetic resonaunce imaging (MRI). In abdominal MRI, neurofibromas in right coxofemoral articulation and right acetabulum were found. Her urine metabolites were examined for pheochromacytoma and found in normal levels. Follow-up visits were planned and she was concultated to relevant departments. Her mother and brother were also diagnosed as neurofibromatosis.
Discussion and Conclusion
Patients with neurfibromatosis have a high predisposition to develop both benign and malign tumours. Although most of the manifestations effect the nervous system, multiple organs and tissues can be affected. Patients can present with different clinical symptoms to different clinics so being aware of the different clinical manifestations of the disease is important for prompt diagnosis.

Gayet Wernicke's encephalopathy: An exceptional complication of primary hyperparathyroidism

Mouna Elleuch[1], Siddiqa Soomauroo[1], Dhouha Ben Salah[1], Abdel Mouhaymen Missaoui[1], Souhir Maalej[1], Nadia Charfi[1], Fatma Hamza[2], Khadijah Moalla[3], Mouna Mnif[1], Fatma Mnif[1], Nabila Rekik Majdoub[1], Mariem Dammak[3], Fadhel Guermazi[2], Faten Hadj Kacem[1] & Mohamed Abid[1]
[1]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Habib Bourguiba University Hospital, Department of Nuclear Medicine, Sfax, Tunisia; [3]Habib Bourguiba University Hospital, Department of Neurology, Sfax, Tunisia

Introduction
Gayet Wernicke's encephalopathy (GWE) is a severe encephalopathy secondary to acute thiamine (vitamin B1) deficiency which may lead to severe sequelae or death if the diagnosis is delayed. We report the first case in the literature of an association between GWE and primary hyperparathyroidism (PHP) in a man.
Observation
He was a 57 years old man, with a personal history of hypertension and primary infertility, who presented with incoercible vomiting, asthenia and fever. Biological finding revealed hypokalaemia (2.7 mmol/l), renal failure (creatinine clearance = 29 ml/min), hypophosphaemia (0.45 mmol/l), hypercalcaemia (4.02 mmol/l) with electrical findings on the elctrocardiogram (QT shortening) requiring an emergency haemodialysis session. PHP was diagnosed with a serum parathyroid hormone (PTH) level of 570 pg/ml (8.7 times upper limit of the range). Cervical ultrasound showed a plunging cystic mass with some parietal calcifications, measuring 40 × 56 × 90 mm and largely necrotic. Parathyroid MIBI scan showed fixation in the periphery of the mass. Parathyroid carcinoma is the most likely diagnosis. The evolution was marked by the appearance of epileptic seizures, followed by an alteration in his state of consciousness. Cerebral MRI showed bilateral and symmetrical signal abnormalities of the mamillary, hypothalamic, medial thalamic bodies and the periaqueductal white matter and around the third and the fourth ventricule (V3 and V4) in FLAIR hypersignal, moderate Diffusion hypersignal in accordance with an EGW. The patient was treated with intraveinous thiamine followed by oral thiamine 100 mg once daily as maintenance dose with favourable outcome.
Conclusion
Although EGW is a known complication of alcoholism, it should be noted that it can occur regardless of this addiction so as to avoid delaying the diagnosis of a curable cause of hypercalcaemia.

Multiple Endocrine Neoplasia type 1: A case report

Chayma Besrour, Sawsen Essayeh, Sabrine Mekni, Imen Rojbi, Nadia Mchirgui, Ibtissem Ben Nacef & Karima Khiari
Charles Nicolle Hospital, Endocrinology, Tunis, Tunisia

Introduction
Wermer syndrome or multiple endocrine neoplasia type 1 (MEN1) is a rare hereditary disease characterized by the presence of generally benign tumors of the endocrine glands.
Observation
We report the case of a 68-year-old patient with a family history of a sister having a primary hyperaldosteronism and a personal history of primary hyperaldosteronism who was referred to our department for the exploration of asymptomatic hypercalcemia. The biological assessment showed an hypercalcemia at 2.96 mmol/l, an hypophosphoremia at 0.71 mmol/l and a high PTH at 220 pg/ml with a normal creatinine level at 83 µmol/l and a normal vitamin D level at 43 ng/ml in favor of the diagnosis of primary hyperparathyroidism. Cervical ultrasound showed a left upper parathyroid nodule of 1.5 x 1 cm but which had no scintigraphic correspondence. The cervico-thoracic scanner showed a double localization of ectopic parathyroid adenoma. The association of primary hyperaldosteronism with primary hyperparathyroidism falls within the scope of MEN1. Therefore, the patient benefited from a subtotal parathyroidectomy given the significant risk of recurrence.
Discussion
The particularity of our case is that MEN1 was revealed at an advanced age by the association of primary hyperaldosteronism with primary hyperparathyroidism. Hence the need to always be vigilant in front of any endocrine neoplasia. In addition to early diagnosis, multidisciplinary care and follow-up are mandatory and for life.

Atypical parathyroid adenomas, a challenging diagnosis and management - Case Report

Raluca Stan[1], Sabina Dumitrache[1], Ana Zubaci[1], Marina Iliescu[1], Mihaela Tarna[1], Iustina Grosu[1], Luminita Cima[1], Cristina Stefan[2], Cosmin Giulea[1] & Simona Fica[1]
[1]Elias Emergency University Hospital, Endocrinology, Bucharest, Romania, [2]Mercury Medical Center, Endocrinology, Tulcea, Romania

Introduction
Primary hyperparathyroidism is typically caused by a parathyroid adenoma (80-85% of the cases). Very rare causes are represented by parathyroid carcinoma and atypical parathyroid adenoma (0.5-1.5% of the cases). Atypical parathyroid adenomas have atypical histological features, not sufficient to be considered a carcinoma, and have an uncertain malignant potential and risk of recurrence. We report the case of a 66-year-old man referred from another medical center for severe hypercalcemia (14.41 mg/dl) with normal serum phosphate (3.24 mg/dl) and elevated PTH (1376 pg/ml - 20 fold of the normal level). The patient mentioned bilateral gonalgia and bone pain for 5 years. His personal history revealed permanent atrial fibrillation, class II congestive hearth failure and bilateral nephrolitiasis. Laboratory evaluation showed a highly elevated serum calcium (13.7 mg/dl), and PTH (1128 pg/ml) with normal serum vitamin D level, confirming the diagnosis of primary hyperparathyroidism. Screening for multiple endocrine neoplasia was negative. The cervical ultrasound revealed the presence

of a 4.13/2.27 cm hypoechoic image, posterior to the left thyroid lobe, which deviated the trachea, suggestive of a left inferior parathyroid adenoma. Cervical CT scan revealed a 2.6/3.5/5.7 cm nodular heterodense process in contact with the left thyroid lobe. T scores of right femur (-1.1 SD) and distal radius (-1.3 SD) on osteodensitometry showed osteopenia. The patient received intravenous furosemide and bisphosphonate therapy to control the hypercalcemia before he was referred to the surgery department for left inferior parathyroidectomy. After surgery PTH levels dropped significantly (24.83 pg/ml), but 4 months after surgery PTH levels increased (387.5 pg/ml) with normal calcium level (8.9 mg/dl). Histopathological exam concluded to atypical features of the adenoma that were suggestive but not diagnostic of parathyroid carcinoma.
Conclusion
The diagnosis and management of the atypical adenoma is still challenging because there are no specific guidelines for the follow-up of patients after parathyroid surgery. Although low, there is a risk of recurrence that can occur many years after initial presentation, so long-term yearly monitoring of calcium concentrations after the surgery is recommended. Once the histopathological diagnosis has been confirmed, studies suggest that immunohistochemistry may be a good approach in differentiating between benign and malignant parathyroid masses.

EP205

Hypercalcaemia as the first manifestation of lymph node tuberculosis

Rahal Amel[1,2]
[1]Medecines, Endocrinology, Algiers, Algeria; [2]Hopital Bologhine Ibn Ziri, Endocrinology, Algiers, Algeria

Introduction
Tuberculosis is a granulomatosis with systemic manifestations. Pulmonary involvement is usually in the foreground. Rarely, hypercalcaemia initiates the pathology. The incidence of hypercalcaemia in tuberculosis varies according to studies and regions between 2 and 25%, with the highest incidences in the most isolated countries and those with the highest calcium and vitamin D intakes.
Clinical Case
This is the case of our patient known for basedow's disease treated by iratherapy; 3 years after stabilization of her hyperthyroidism she presents a frank hypercalcemia. The hormonal exploration is in favour of an extra parathyroid hypercalcaemia. Cervical ultrasound revealed a granulomatous left supra-clavicular adenopathy which was punctured in favour of lymph node tuberculosis. 3 months after the start of anti-tuberculosis treatment, the blood calcium level was normalized.
Conclusion
In tuberculosis, hypercalcaemia is due to extrarenal synthesis of 1,25(OH)2-vitamin D3 by granuloma macrophages with 1-alpha hydroxylase activity. Within the granulomas, the binding of 1,25(OH)2-vitamin D3 to its specific receptors modulates the immune response and decreases the inflammatory response that causes tissue damage.

EP206

Severe PTH-dependent Hypercalcemia Secondary to Atypical Parathyroid Adenoma

Ariana Maia[1], Liliana Fonseca[1], Ana Luísa Viveiros[2], João Neves[2] & Helena Cardoso[1]
[1]Hospital Geral de Santo António, Endocrinology, Porto, Portugal; [2]Hospital Geral de Santo António, Internal Medicine, Porto, Portugal

Introduction
Hypercalcemia is not uncommon in clinical practice and may present as a life-threatening emergency. Its main aetiologies are primary hyperparathyroidism (80% parathyroid adenomas; 20% multiglandular hyperplasia, $<1\%$ parathyroid carcinomas) and hypercalcemia of malignancy, with or without presence of bone metastases.
Case Report
We present a case of a 77 years-old male, submitted to a subtotal gastrectomy at the age of 73 due to a perforated duodenal ulcer and a partial right nephrectomy due to clear cell renal carcinoma limited to the kidney at the age of 74, under annual surveillance. Admitted for severe hypercalcemia associated with acute chronic low back pain in the last two months, gait imbalance, loss of strength in the lower limbs, anorexia, weight loss of 3 kg, polyuria and polydipsia. He was dehydrated, with temporal-spatial disorientation and confusion. Cranial-CT was normal, and EMG showed an axonal sensory-motor peripheral polyneuropathy with sensory predominance. His blood tests revealed PTH 1392 pg/ml, ionized calcium 2.29 mmol/l, total calcium 4.06 mmol/l phosphorus 0.81 mmol/l, vitamin D 20 nmol/l, alkaline phosphatase 193 U/l, Creatinine 1.78 mg/dl. Cervical ultrasound suggested a parathyroid adenoma and TC-99 Sestamibi scintigraphy corroborated parathyroid adenoma/hyperfunctioning left upper parathyroid tissue. Abdominal / pelvic CT excluded renal lithiasis and local recurrence of the renal neoplasm, however exposed focal lytic lacunar lesions in the lumbar vertebral, the largest in L3, suggestive of lytic metastasis and signs of bone demineralization. Bone biopsy of the vertebral lesion showed marked hypocellularity, edema and fibrosis, without osteoclasts or malignant cells. Protein electrophoresis and urinary immunofixation was not suggestive of monoclonal gammopathy. He underwent surgical excision of the parathyroid with $2.6\times1.5\times1$ cm and pre-op PTH 661.0 pg/ml and at 15 min 130.0 pg/ml whose anatomopathology confirms a non-capsulated parathyroid gland or only partially covered by a thin capsule, consisting of proliferation of principal cells without cytological atypia, rare figures of mitosis and necrosis, and with no images of vascular or perineural invasion.
Discussion
Despite considering the hypotheses of tumour hypercalcemia due to PTHrP or secondary to osteolytic metastases, PTH values do not favour them. The case raises the possibility of an Atypical Parathyroid Adenoma. Only long-term follow-up with surveillance of local recurrence and distant metastases will allow a correct diagnosis.

Primary hyperparathyroidism revealed by multiple brown tumors: A case report

Fatima Toulali, Kamel Farah, Khaoula Gorgi, Diehah Isselmo, Kaoutar Rifai, Iraqi Hinde & Mohamedelhassan Gharbi
Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction
Primary hyperparathyroidism revealed by multiple brown tumors is rare. We report the case of a patient with primary hyperparathyroidism on parathyroid adenoma discovered in front of multiple brown tumors.
Case Presentation
A 72-year-old female patient, who presented for 6 months a functional impotence of both lower limbs with paraparesis, associated with bone pain from where the realization of a phospho-calcium assessment returning in favor of an hyperparathyroidism. The diagnosis of localization confirmed the presence of a parathyroid adenoma. It also showed the presence of bone masses at the level of the scapulae, right clavicle, at the level of the costal, dorsal vertebrae with a medullar compression. A bone biopsy was performed showing an aspect in favor of multiple brown tumors. The patient underwent a medullary decompression surgery as well as a parathyroid surgery after normalization of the phospho-calcium balance. The postoperative course was simple with a good evolution.
Discussion and Conclusion
A brown tumor is a benign bone lesion caused by localized and rapid osteoclastic turnover resulting from hyperparathyroidism. Hyperparathyroidism revealed by multiple brown tumors is rare, few cases are reported in the literature and they are rarely described in the axial skeleton as in our patient's case. Its diagnosis is often difficult in the presence of polyostotic lytic lesions with hypercalcemia mimicking bone metastases. Bone manifestations are rarely revealing of the disease since they are present only at a late stage and are seen in only 2% of cases.

EP208

Post-surgical hypoparathyroidism with teriparatide treatment

Carla Rodríguez Rodríguez, Cristina Lorenzo González & Elena Márquez Mesa
Endocrinología, San Cristóbal de La Laguna, Spain

Post-surgical hypoparathyroidism occurs as inadvertent removal or irreversible damageparathyroid disease, irreversible or permanent causing decreased action of parathormone leading to hypocalcemia and hypophosphatemia.
Clinical Case
A 52-year-old woman referred from our outpatient clinics due to severe hypocalcemia symptomatic; hand and foot cramps, and hyperphosphatemia:

albumincorrected calcium. (5.52 mg/dl and phosphate of 6.6 mg/dl). She presents a history of total thyroidectomy in 2021 due to Grave's disease with severe exophthalmos, which therefore performed a post-surgical hypoparathyroidism. During successive revisions in queries, it persists hypocalcemia despite increasing the dose of your usual treatment: calcium carbonate 6 tablets/day, levothyroxine 100 mg every 24 hours, Calcitriol 0.5 mg 3 tablets daily day, Vitamin D 25000ui monthly. Admission for intravenous calcium replacement was decided, in addition to oral contributions of the same and calcitriol. Dose reduction of intravenous calcium was attempted multiple times to achieve its complete withdrawal but returned to symptomatic hypocalcemia. During admission, a study was started to rule out causes of calcium absorptive deficit, discarding it and modifying the calcium formula to calcium pidolate for a better absorption. A nephrological study was performed to rule out causes of excessive losses due to urine that would justify the poor response to treatment, without detecting kidney disease chronicle. Given the therapeutic failure, other therapeutic alternatives were reviewed, deciding start treatment with Teriparatide (rH-PTH) 20 mg every 24 hours, assessing various satisfactory clinical studies, and proceeding in accordance with the literature and with the consent of the patient to start treatment without specific indication. It was obtained satisfactory response with decreased phosphate levels and elevated calcium in blood; Laboratory tests on discharge: calcium corrected for total protein 8.24, phosphate 3.5, allowing withdrawal of intravenous calcium gluconate and allowing home discharge with this outpatient treatment: Teriparatide 20 mg every 24 hours, Calcitriol 0.5 mg every 12 hours, calcium pidolate 1 over every 8 hours, levothyroxine 100 mg every 24 hours. In the following check-ups, the patient has maintained calcium and phosphate levels within range without any symptoms, maintaining the same treatment with Teriparatide 20 mg every 24 hours.
Conclusions
PTH replacement therapy with rh,,PTH regulated mineral homeostasis of calcium and phosphate metabolism towards normality in this patient.

EP209

Hungry bone syndrome after Graves' disease surgery in children

Rahal Amel
Hopital Beloghine, Endocrinology, Algiers, Algeria

Although rare in children, Graves' disease remains the major cause of hyperthyroidism. Positive diagnosis is easy, but management can be extremely problematic.
Case Report
We report the case of a 13 year old female patient treated for Graves' disease since 4 years; non compliant to treatment; after adjustment of therapy and achievement of euthyroidism; a surgical cure is programmed. 24 hours after surgery, severe hypocalcaemia appeared, requiring parenteral treatment with injectable calcium for 1 month. The elements in favour of hyngry bone are a non-elevated phosphorus as well as osteopenia on bone densitometry. After 1 month of treatment with injectable calcium associated with oral calcium substitution and 1 alphacalcidal; the phosphocalcic balance improves and the treatment with injectable calcium is stopped.
Discussion
Hyperthyroidism in children is characterized by an increase in bone resorption which is reversed after total thyroidectomy where resorption decreases and bone absorption increases leading to bone hungry syndrome and severe hypocalcaemia. For this reason, it is important to assess bone damage by BMD prior to thyroidectomy to predict the risk of hungry bone syndrome and ensure adequate management

Primary hyperparathyroidism and papillary thyroid carcinoma: Incidental association or causal link?

Boutheina Mohamed Ali, Moctar Mohamed, Mariem Cheikh, Kaoutar Rifai, Iraqi Hinde & Mohamedelhassan Gharbi
Ibn Sina Hospital, Rabat, Morocco, Endocrinology, Morocco

Introduction
Primary hyperparathyroidism is a frequent pathology, its association with papillary thyroid carcinoma is rare.
Case Report
A 53 year old patient was admitted for management of primary hyperparathyroidism. The biological work-up showed a blood calcium level of 120 mg/l, parathyroid hormone (PTH) 4 times the normal range and hypophosphatemia. Cervical ultrasound showed a right parathyroid nodule with thyroid nodules classified Tirads 4, MIBI scintigraphy had objectified 2 right upper and lower parathyroid adenomas. The patient benefited from a right parathyroidectomy with isthmolobectomy, the anatomopathological study concluded to a parathyroid adenoma with main cells associated with a papillary carcinoma of the thyroid.
Discussion
The association between primary hyperparathyroidism and papillary thyroid carcinoma has been reported in 2.4-4.3% of patients with primary hyperparathyroidism. For some, this association could be explained by the embryological origin and shared genes. This observation illustrates the interest of the "check up" of the thyroid before any parathyroid surgery for a better management.

Parathyroid gland locations during surgery

Mohamed Masmoudi, Chaima Zitouni, Wadii Thabet, Ezer Chebil, Mehdi Hasnaoui & Khelifa Mighri
Taher Sfar Hospital, ENT Department, Mahdia, Tunisia

Introduction
Typically, there are 4 parathyroid glands in humans: 2 superior parathyroid glands usually located near the crico-thyroid joint, and 2 inferior parathyroid glands near the inferior pole of the thyroid gland. However they can be variable in number and location. Awareness of their potential location is crucial for the operating surgeon.
Objective
The purpose of this study is to describe parathyroid gland locations found during surgery.
Material and Methods
A retrospective study including 81 cases of hyperparathyroidism, operated between 2001 and 2021.
Results
The mean age was 53.2 years. Our study included 67 cases of secondary hyperparathyroidism and 14 cases of primary hyperparathyroidism. All patients, having secondary hyperparathyroidism, underwent subtotal 7/8 parathyroidectomy. In the majority of cases (80.6%), the parathyroid glands were found in their usual locations, without intraoperative challenges. Intrathymic localization was noted in 5 cases (thymectomy was performed in these cases). Two parathyroid glands were superposed in 5 cases. Parathyroid glands were located in the recurrent laryngeal nerve's entry point into the larynx, in 3 cases. In cases of primary hyperparathyroidism, intraoperative difficulties were noted in 4 cases: prevertebral parathyroid gland (1 case), latero-tracheal parathyroid gland (2 cases) and parathyroid gland located between the trachea and the esophagus (1 case).
Conclusion
A knowledge of the unusual anatomic locations of parathyroid glands is crucial to operative success during parathyroid surgical exploration. Preoperative imaging can also helpful in the guidance of the surgical procedure.

Severe proximal myopathy revealed a primary hyperparathyroidism: about a case and literature review

Benabdelatif Katia, Aicha Lachkhem, Abdelkader Yahi, Amira Bouchenna & Ould Kablia Samia
Central Military Hospital Algiers, Endocrinology, Algiers, Algeria

Introduction
Proximal myopathy presents as symmetrical weakness of proximal upper and/or lower limbs. There is a broad range of underlying causes including drugs, alcohol, endocrine and metabolic myopathies such as primary hyperparathyroidism.
Observation
We describe a 48-year-old male, hospitalised in neurology departement for exploration of severe proximal myopathy. Cliniquely, he presented progressive debilitating muscle weakness, severe muscle wasting and recurrent muscle spasms over 6 months. He also had bone pain, anorexia and weight loss. He had a

symmetrical proximal myopathy and muscle wasting marked in upper limbs. Biological explorations found a hight level of calcium 3.12 mmol/, hypophosphoremia 0.71 mmol/l, PTH 175 pg/ml, hight 24-hour urine calcium 851 mg/j, wich is suggestive of primary hyperparathyroidism. The creatine kinase (CK) levels was elevated of 637 U/l (30-200). Parathyroid ultrasound and SESTAMIBI scintigraphy localised a hyperfunctioning right inferior parathyroid adenoma of 16 mm. The levels of PTH inside the adenoma was 4070 pg/ml. Bone mineral density indicate an osteopenia (low bone density). He underwent successful parathyroidectomy following treatment with hyperhydration and intravenous pamidronate . There was resolution of muscular spasms, weight gain and normalisation of his calcium, PTH and and CK levels. The histopathological examination confirmed the parathyroid adenoma.

Conclusion

Severe proximal myopathy is a rare complication of primary hyperparathyroidism. Prompt diagnosis and parathyroidectomy can prevent complications and improve clinical outcomes.

Autoimmune hypocalciuric hypercalcaemia: A diagnostic dilemma

Tahir Omer[1], Ibrahim Suareldahab[2] & Rama Hamed[1]
[1]Northampton General Hospital, Northampton, United Kingdom; [2]Al Neelain University, Al Khurtum, Sudan

Introduction

Hypercalcaemia is a relatively common medical condition affecting around 1% of the general population. Around 90% of the cases are due to either primary hyperparathyroidism (PHPT) or malignancy. Familial hypocalciuric hypercalcaemia (fHH) is a rare autosomal dominant condition that can result in hypercalcaemia. It has an estimated prevalence of1 in 78 000. In most of the cases, fHH is due to a mutation in the calcium-sensing receptor gene (CaSR). Other rare cases of fHH (fHH2 and fHH3) are due to mutations in the GNA11 gene and AP2S1 gene respectively. Very rarely, it can be caused by autoantibodies directed against the CaSR. Differentiating between fHH and PHPT can be difficult in the absence of family history. Normal PTH levels and low Calcium/Creatinine clearance ratio (< 0.01) are in favour of fHH. Resection of the parathyroid tissue might not lead to normalisation of the serum calcium level in fHH. Therefore, reaching an accurate diagnosis is crucial. Herein, we present a patient with hypercalcemia, normal PTH and low urinary Ca:Cr clearance ratio (UCCCR) in the absence of family history and with normal genetic testing. The presence of autoimmune hypocalciuric hypercalcaemia (AHH) was therefore suspected and confirmed. Due to the rarity of the condition, only a few cases have been reported.

Case Report

A 49-year-old lady was referred to the endocrinologist with hypercalcaemia and normal parathyroid hormone. She was symptomatic with fatigue and tiredness. She had a history of kidney stones. Her DEXA scan showed mild degree of osteopaenia. She was thoroughly investigated locally. Her tests showed very low UCCCR (<0.001) on 3 occasions and low 24-hour urinary calcium. An ultrasound scan and SESTAMIBI scan failed to localise any parathyroid abnormality. Genetic testing was negative for CaSR, GNA11 or AP2S1 gene defects. She was considered for exploratory surgery as possible PHPT. She was then referred to us for a second opinion. A repeat urine calcium was very low and she was found to suffer from mild autoimmune hypothyroidism. This raised the possibility of AHH. Anti-parathyroid antibodies were found to be positive. The patient was started on Cinecalcet which has helped reducing her calcium level and improving her symptoms.

Conclusion

This case demonstrates the diagnostic dilemma in hypercalcaemia that may lead a patient to undergo unnecessary invasive surgery. AHH should be suspected in patients with no clear surgical target and low urine CCCR if the genetic testing is negative.

The difficult diagnostic of cystic adenomas of the parathyroid gland

Aiste Cemerkaite & Vita Lizdeniene
Lithuanian University of Health Sciences Kaunas Clinics, Endocrinology, Kaunas, Lithuania

Context

Cystic adenomas of the parathyroid gland are relatively rare, with an estimated incidence of 0.3-1.5% of all parathyroid tumors. These tumors are benign and typically present as a single cyst or multiple small cysts within a solid nodule. Due to their rarity and nonspecific imaging features it may be challenging to diagnose preoperatively. However, the diagnosis is confirmed by fine-needle aspiration (FNA) biopsy and pathological examination of the tissue obtained by FNA.

Case Illiustration

We report the case of a 69-year-old woman admitted to endocrinologist's due to increased sweating and worsening eyesight. The patient had a multifocal goitre that did not require any particular treatment. She was found to have hypercalcemia (2.95 mmol/l; normal: 2.2-2.65 mmol/l), hypercalciuria (10.03 mmol/24 h; normal 0-6.2 mmol/24 h) and elevated PTH (26.4 pmol/l; normal: 1.26-6.74 pmol/l). The plasma phosphorus (0.86 mmol/l; normal: 0.81-1.45 mmol/l), urine phosphorus (30.0 mmol/24 h; normal: 12.9-42 mmol/24 h) and 25-hydroxyvitamin D (76.60 nmol/l; normal: 70-250 nmol/l) were normal. There was no renal failure or osteoporosis. Ultrasonography of the neck revealed a $1.4\times 0.7\times 0.9$ cm cystic mass below the left lobe of the thyroid gland. The nodule found in ectopic thyroid tissue had a mixture of solid and cystic components, this is not a typical feature of a parathyroid gland. SPEC/CT of the neck and mediastinum with 99mTc-MIBI was performed. There was no evidence of accumulation of radiopharmaceutical 99mTc-MIBI, the absence of a parathyroid adenoma was confirmed. As a result of the high previous suspicion of the parathyroid adenoma, it was decided to conduct a fine-needle aspiration of the solid nodule. Cytological and biochemical tests (PTH analysis in rinse material revealed high PTH (210.6 pmol/l)) confirmed parathyroid gland. The multidisciplinary consortium made the decision that surgical treatment is the most appropriate treatment for a parathyroid adenoma. After a parathyroidectomy, histological examination was performed, the diagnosis of a cystic parathyroid adenoma was confirmed. Additionally, post-operative laboratory tests showed normal levels of calcium (2.44 mmol/l) and PTH (2.03 pmol/l) which indicates that surgery was successful.

Discussion

Cystic parathyroid adenomas are rare and have unique characteristics that can make them challenging to diagnose and treat. An experienced endocrine surgeon and multidisciplinary team approach is recommended to manage these cases.

Short-term treatment with 2000IU of cholecalciferol in patients with secondary hyperparathyroidism due to vitamin d insufficiency

Nikolaos Angelopoulos[1], Anastasios Boniakos[2], Spyridon Karras[3], Rodis Paparodis[4,5] & Sarantis Livadas[6]
[1]AHEPA University Hospital, School of Medicine, Academic Department of Nuclear Medicine, Thessaloniki, Greece; [2]Private Practice, Athens, Greece; [3]Medical School, Aristotle University of Thessaloniki, Laboratory of Biological Chemistry, Thessaloniki, Greece; [4]The University of Toledo Health Science Campus, Center for Diabetes and Endocrine Research, Toledo, United States; [5]Endocrinology, Diabetes and Metabolism Clinics, Private Practice, Patras, Greece; [6]Athens Medical Center, Endocrinology, Diabetes and Metabolism Clinics, Athens, Greece

Introduction

Conventional treatment of secondary hyperparathyroidism (SHP) requires supplementation of vitamin d analogues combined with calcium however several studies have reported concerns regarding the safety of calcium supplements particularly in the long term. If vitamin d without concomitant calcium supplementation is sufficient to prompt a fall in the parathyroid hormone (PTH) is still not known with certainty. The purpose of our study was to investigate if vitamin d without calcium effectively suppresses PTH secretion in patients with vitamin d deficiency and a history of gastrointestinal complication in calcium preparations.

Materials and Methods

29 healthy individuals with SHP due to vitamin d insufficiency were enrolled. Treatment with calcium carbonate and vitamin d suggested to all patients while in those with a history of previous side effects due to calcium intake vitamin d only recommended. Group A ($n=16$) received 2000 IU vitamin D (Cholecalciferol), and Group B ($n=13$) received 600 mg calcium carbonate, together with 2000 IU vitamin D, for 60 days. Demographic and laboratory characteristics (serum levels of 25(OH)D, calcium, phosphorous, creatinine, albumin and intact PTH (iPTH) were evaluated at baseline and at the end of the study.

Results

Treatment significantly reduced iPTH and increased 25(OH)D levels in both groups. In vitamin d alone group a significantly increase of phosphorous levels observed. No other significant difference was detected between the two groups.

Conclusion
These preliminary data indicate that 2000IU of daily vitamin d constitute a sufficient alternative and could be preferred particularly when calcium intake may lead to unfavorable side effects or is contradicted.

Brown tumor revealing primary hyperparathyroidism

Chaymaa Alami Hassani[1], Abainou Lahousssaine[2], Ayoub Idrissi[3], Sanae Elhadri[2], Azzelarab Meftah[2,4] & Hicham Baizri[2,4]
[1]CHU SOUSS MASSA AGADIR/ Faculty of Medicine and Pharmacy Ibn Zohr Agadir, Department of Endocrinology Diabetology and Metabolic Diseases, Agadir, Morocco; [2]Military Hospital Avicenne Marrakech, Department of Endocrinology Diabetology and Metabolic Diseases, Marrakech, Morocco; [3]Military Hospital Avicenne Marrakech, Department of Endocrinology Diabetology and Metabolic Diseases, Marrakech, Morocco; [4]Faculty of Medicine and Pharmacy - CADI AYYAD University Marrakech, Marrakech, Morocco

Introduction
Hyperparathyroidism is a frequent endocrinopathy, often diagnosed in the stage of asymptomatic hypercalcemia. The revelation by a bone or renal complication has become increasingly rare dominated by osteoporosis and brown tumors giving a blown aspect of the cortices exposing to pathological fractures. We report 2 cases of primary hyperparathyroidism revealed by a brown tumor and pathological fracture.
Observation 1
This is a 52 year old female patient, followed up for bilateral renal lithiasis for 20 years, admitted for etiological assessment of bone lesions of the pelvic girdle discovered incidentally on a uroscanner, without polyarthralgias, without polyuropolydipsic syndrome nor constipation nor nausea nor vomiting nor fever. The diagnosis of a primary hyperparathyroidism was retained in front of a corrected hypercalcemia to 119 mg/l a hyperparathormonemia to 1200 ng/l and a normal phosphatemia to 25.34 ng/ml, a calciuria of 24 h raised to 268 mg/24 h with localization of a parathyroid adenoma to the ultrasound. Parathyroid scintigraphy with Sestamibi not done due to the patient's lack of financial means.
Observation 2
The patient was 66 years old, without any pathological history, admitted for exploration of a primary hyperparathyroidism revealed by a fracture of the femoral diaphysis on a pathological bone whose anatomopathological examination was in favor of a brown tumor. The biological work-up revealed a corrected hypercalcemia at 140 mg/l, a hyperparathomemia at 1936 ng/ml, a hypophosphatemia at 23.17 mg/l, a 24-hour high calciuria at 246 mg/24 h, and on ultrasound and cervico-thoracic CT scan a parathyroid adenoma of 2.7 cm confirmed by the histological study. The evolution was marked by the installation of the hungry bone syndrome with a good evolution under calcium supplementation.
Conclusion
Brown tumors represent a rare and not exceptional bone complication to be evoked in front of each lytic giant cell lesion and requiring the search for primary hyperparathyroidism given the insidious character of this endocrinopathy while eliminating an underlying malignant process.

Hypocalcemia in a term neonate of a mother with gestational diabetes: A case report

Khaoula Gorgi, Abderrahmane Tadlaoui, Sanae Chakdoufi, Yassine Errahali & Ahmed Anas Guerboub
Mohammed V Military Training Hospital, Endocrinology, Rabat, Morocco

Introduction
Maternal diabetes is described as a risk factor for neonatal hypocalcemia along with maternal vitamin D deficiency or maternal hyperparathyroidism. The frequency of hypocalcemia in a diabetic mother is 20 and 60%, but low in gestational diabetes (GD).
Observation
A 38 year old female patient, with a pregnancy estimated of 35 weeks of gestation, was referred to our department for the management of her gestational diabetes, her cycle was very unbalanced, and her general check-up was without any particularity, especially her phosphocalcic balance. The patient was put on insulin therapy with good evolution, 2 Weeks later; the patient gave birth to a girl with neonatal hypocalcemia.
Discussion and Conclusion
Diabetes is a pathology with fetal and neonatal risk of varying severity .The mechanism of occurrence of neonatal hypocalcemia, its pathophysiology is still unknown today. Studies have established a link between the risk of hypocalcemia in the neonatal period and the maternal glycemic control observed during pregnancy. There is an association between the degree of severity of diabetes and the blood glucose level at birth. The prognosis is better in the case of GDM, especially if it has remained balanced throughout the pregnancy.

Hypercalcemia and confusional syndrome: A case report

Khaoula Gorgi, Mohamed Hamid Abdilahi, Abderrahman Tadlaoui, Yassine Errahali & Ahmed Anas Guerboub
Mohammed V Military Training Hospital, Endocrinology, Rabat, Morocco

Introduction
Severe hypercalcemia is an uncommon but potentially life-threatening condition. Calcium plays a variety of roles and explains the impact of hypercalcemia on the functioning of different organs. We report the case of a patient with severe hypercalcemia revealed by a confusional syndrome.
Observation
A 60 year old male patient, with a medical history of hypertension under treatment, presented a confusional syndrome of progressive onset which worsened towards agitation and disturbance of consciousness hence his admission to the emergency room. The biological assessment was in favor of hypercalcemia at 210 mg/l, a functional renal insufficiency and hyperparathonemia at 2217 pg/ml (33 × the normal range). The patient benefited from rehydration associated with 2 sessions of dialysis due to agitation and worsening of his symptomatology, as well as specific treatments, inhibiting bone resorption. Unfortunately the evolution was marked by the death of the patient.
Discussion and Conclusion
Hypercalcemia is a life-threatening emergency with potentially fatal cardiac, neurological and renal complications. The treatment of acute hypercalcemia will be undertaken in the intensive care unit and includes general measures such as rehydration and diuresis training by diuretics as well as specific treatments, inhibiting bone resorption, biphosphonates associated initially or not with calcitonin.

EP219

Super bone scan: metabolic or secondary origin: Discussion around a clinical case

Imane Boubagura, Neima Hassan, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
University Hospital of Marrakech, Department of Endocrinology, Diabetology and Metabolic Diseases, University Hospital of Marrakech, Marrakech, Morocco

Introduction
– The "super bone scan" is a peculiar condition characterized by extremely high bone uptake compared to soft tissue, with no visualization of renal radioactivity.
– Super bone scan has been described in relation to several conditions such as metastatic disease (prostate/breast cancer), metabolic bone disease (Paget's disease/hyperparathyroidism) and myeloproliferative disorders.
Clinical Case
– A 75 year old man, having as ATCD: a HTA under treatment.
– For one year, he has been suffering from diffuse bone pain, aggravated for the last 3 months, with the onset of FI, evolving in a context of AEG.
– Phosphocalcic assessment revealed: hypercalcemia = 133 phosphoremia = 21, vit D = 24, PTH = 96, elevated PAL and correct renal function.
– The check-up after vit D supplementation: hypercalcemia at 130 and PTH = 71.
– Cervical ultrasound: no abnormalities. Parathyroid cesta-MIBI scan: no argument in favor of a pathological parathyroid gland.
– A whole body scan with technetium-99m methyldiphosphonate (Tc-99m MDP) was performed, showing heterogeneity of global fixation of the radiotracer on the whole axial and peripheral skeleton with an attenuation of the renal shadows evoking the "super bone scan".
– In the sense of bone metastases: RT: asymmetric prostate, firm, bulging on the left side, ultrasound: prostatic hypertrophy at 42 cc heterogeneous seat of calcifications, PSA elevated at 9.8 with a free PSA/total PSA ratio = 0.25 = a prostate biopsy is planned.

Discussion
– The "super bone scan" situations can be related to metabolic pathologies (especially hyperparathyroidism) or secondary: a bone diseases either metastatic (prostate/breast cancer), or myeloproliferative disorders.
– The PTH values in this patient are not comfortable for the diagnosis of hyperparathyroidism (primary/parathyroid carcinoma). And given the context (age, AEG, high PSA), we consider the diagnosis of paraneoplastic hypercalcemia. What about the image of parathyroid fixation on FDG PET? - Considering the high number of false positives on FDG-PET and the low risk of false negatives on cesta-MIBI scintigraphy.
– The most probable diagnosis is considered to be: malignant hypercalcemia in the context of a paraneoplastic syndrome on bone metastases of a prostatic ADK. And that the parathyroid fixation on PET scan is a false positive.
Conclusion
– The "super bone scan" is a peculiar condition characterized by extremely high bone uptake compared to soft tissue, with no visualization of renal radioactivity.
– May be of metabolic or secondary origin.
– The etiological diagnosis must take into account the clinical context and discuss on a case-by-case basis.

EP220

A rare cause of hypocalcaemia: The clues were in the biochemistry

Tanya Chopra[1], Aiman Haddad[1], Elizabeth Hyams[1], Shivani Joshi[1], Catherine Mitchell[2] & Mushtaqur Rahman[1]
[1]Northwick Park Hospital, Department of Diabetes & Endocrinology, London, United Kingdom; [2]Hillingdon Hospital, Department of Diabetes & Endocrinology, London, United Kingdom

Introduction
Pseudohypoparathyroidism (PHP) is a rare cause of hypocalcaemia due to parathyroid hormone (PTH) resistance in the proximal renal tubules. In contrast to PHP type 1A, PHP type 1B is characterised by the absence of the characteristic skeletal abnormalities and is transmitted in an autosomal dominant manner, but in the maternal line. Patients may have resistance to the action of other G-protein signaling hormones, like thyroid stimulating hormone (TSH).
Case Presentation
A 28-year-old male was admitted with intermittent bilateral arm pains, tingling and carpopedal spasms, ongoing for a few years. His calcium was 1.4 mmol/l (2.20-2.60); phosphate, 1.56 mmol/l (0.8-1.5); PTH, 26.3 pmol/l (1.6-6.9) and 25-hydroxy-vitamin D, 24 nmol/l (25-125). Alkaline phosphatase, magnesium, TSH and renal function were normal. There were no phenotypic features of Albright's Hereditary Osteodystrophy (notably normal 4th/5th metacarpals and height). There was no family history of calcium disorders. He reported being treated previously with Alfacalcidol, but had not taken this for years and remained asymptomatic. The hyperphosphataemia in the presence of elevated PTH with normal renal function suggested PTH resistance. His symptoms resolved with Alfacalcidol and calcium supplements. Genetic testing revealed he had pseudohypoparathyroidism type 1B: heterozygous deletion of exons 5-7 of the STX16 gene and complete loss of maternal methylation pattern at the GNAS A/B: TSS-differentiated-methylated region, the latter meaning this was maternally inherited. He had low 24-hour urinary calcium and phosphate: 0.3 mmol/24 hr (2.5-7.5) and 3.4 mmol/24 hr (15-50), respectively. The renal PTH resistance is confined to the proximal tubules with lack of PTH resistance in distal renal tubules or skeleton. This causes reduced urinary calcium and phosphate excretion with preserved skeletal calcium and phosphate mobilisation. This results in partial protection from symptomatic hypocalcaemia and an absence of skeletal abnormality.
Conclusion
PTH resistance should be suspected in patients with chronic hypocalcaemia, hyperphosphataemia, elevated PTH levels and normal renal function, prompting genetic confirmation.

Our experience with the treatment of pseudohypoparathyroidism

Anna Pávaiová, Dušan Pávai & Peter Vanuga
National Institute of Endocrinology and Diabetology, Endocrinology Department, Slovakia

Pseudohypoparathyroidism (PHP) is a group of rare hereditary diseases caused by tissue resistance to parathyroid hormone (PTH), there are two main types I and II. Type I is divided into subtypes. The authors present a case of PHP Ib, with hypocalcemia (level of total calcium 1.41 mmol/l), accidentally detected at childbirth. After the unsuccessful treatment of hypocalcemia, the etiology was considered, but the confirmation of the diagnosis were not adequately tightened. Due to the subjective feeling of palpitations and tremors, she was also examined by a psychiatrist and antipsychotic treatment was started. The level of ionized calcium at the time of treatment initiation was 0.98 (1.03-1.30 mmol/l), total calcium 1.95 (2.18-2.60 mmol/l), parathyroid hormone level was 52.343 (10.5-7.632 pmol/l), the level of phosphorus was 1.360 (0.65-1.61 mmol/l) and the level of vitamin D3 (25-OH) was 33.460 (75-250 nmol/l). Years later, PHP Ib has been genetically proved. By adjusting the proper treatment, including the administration of calcitriol 0.25 ug twice a day, calcium carbonate 1500 mg once a day and chronic treatment, the difficulties subsided. Control level of ionized calcium was 1.16 mmol/l, total calcium was 2.34 mmol/l, and the parathormone level was adjusted to normal 15.762 pmol/l. The effect of PTH on bone was reduced, which is expected to improve the prognosis to the level of the population.
Keywords: hyperphosphatemia, hypocalcemia, parathyroid hormone, pseudohypoparathyroidism.

Femoral fracture revealing primary hyperparathyroidism in a very young patient and multiple lytic bone lesions: A case report

Asmae El Hafiani, Mohamedelhassan Gharbi, Iraqi Hinde, Rifai Kaoutar, Toulali Fatima & Elqandili Hamza
Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction
Primary hyperparathyroidism is the most common endocrinopathy after diabetes and thyroid diseases. Most often, the diagnosis is made at the asymptomatic stage due to the frequent phosphocalcic assessment objectifying hypercalcemia. Much more rarely, primary hyperparathyroidism is diagnosed at the stage of digestive, renal or bone complications. We report the case of a young patient with a femoral fracture that revealed primary hyperparathyroidism.
Observation
A 31-year-old male patient with a history of a left leg fracture at the age of 23 years, admitted to the endocrinology department for the management of acute hypercalcemia at 145 mg/l discovered during a workup for a femoral fracture following a simple fall at home. A CT scan of the pelvis revealed a displaced complex fracture of the left femoral neck, with multiple lytic bone lesions, involving the pelvic girdle and the left femur with cystic density. A complementary thoracic-abdominal-pelvic CT scan showed multiple thoracic-abdominal-pelvic lytic bone lesions. The etiological workup revealed a profile of primary hyperparathyroidism, with a left inferior parathyroid adenoma on topography. The patient underwent stabilization of the fracture site by nailing, followed by adenomectomy with bone biopsy, which revealed lesions consistent with hyperparathyroidism.
Discussion and Conclusion
Primary hyperparathyroidism is the consequence of excessive and inappropriate production of parathyroid hormone. It is often caused by a single or multiple parathyroid adenoma. Its revelation by fracture is very rare as it is the case in our patient. The associated bone lesions are often fibrocystic osteitis lesions due to the hyperactivity of osteoclasts, observed in hyperparathyroidism. Management is based on consolidation of the fracture and removal of the secretory adenoma. Every practitioner should consider the diagnosis of primary hyperparathyroidism at the stage of bone pain before complications development.

Osteoporosis secondary to diabetes mellitus

Siddiqa Soomauroo[1], Raida Ben Salah[1], Faten Haj Kacem Akid[2], Mohamed Abid[2] & Zouheir Bahloul[1]
[1]Hedi Chaker University Hospital, Department of Internal Medicine, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction
Osteoporosis is a generalized skeletal disease that combines a decrease in bone density with changes in bone microarchitecture. The bone is abnormally fragile

and therefore the risk of fracture is high. We report the case of osteoporosis in a young woman secondary to type 1 diabetes mellitus (T1DM).
Case Report
Patient A.M, 26 years old, with a history of polyglandular autoimmune syndrome type 3 since the age of 12, associating T1DM and Hashimoto's thyroiditis, was admitted to hospital for investigation of a spontaneous fracture of the right carpal bone. Bone densitometry (BMD) showed a T score of -3.4 standard deviations (SD) in the spine and -2.6 SD in the femoral neck, confirming the diagnosis of osteoporosis. The etiological investigation was negative. Metabolic, pharmacological, endocrine (hyperthyroidism/hyperparathyroidism), hormonal, deficiency (osteomalacia) and nutritional causes were ruled out and the diagnosis of osteoporosis secondary to diabetes mellitus was retained.
Discussion/Conclusion
Chronic hyperglycaemia adversely affects bone by altering qualitative and quantitative bone formation due to the direct toxic effects of glucose on the osteoblast. In addition, diabetes leads to impaired microcirculation which may interfere with bone repair. Most studies have shown a decrease in BMD in patients with diabetes. Diabetes is therefore associated with an increased risk of fracture through osteoporosis. These findings should be kept in mind for optimal management of our patients with diabetes.

Obesity, as a chronic nutritional disorder, is a high-risk factor for type 2 diabetes, fatty liver and other metabolic diseases. Multiple lncRNAs have been confirmed concerning adipocyte differentiation and thus affect obesity, such as ADINR, Paral1, etc. Previously, we identified a lncRNA named ENST0000052114 (abbreviated to lncRNA52114), highly expressed in human mature adipocytes by differential lncRNA expression profile. Here, we explored the role and mechanism of lncRNA52114 in the differentiation of human preadipocytes from visceral adipose (HPA-vis). Over-expressed or silencing lentiviral vector of lncRNA52114 was constructed. After transfection of precursor cells, the infection efficiency of lentivirus was observed by fluorescence microscope and was verified by qPCR. The classical induction protocol (1-methyl-3-isobutylxanthine, dexamethasone, insulin, and rosiglitazone) was used to induce HPA-vis to mature adipocytes. The morphology and lipid droplet size of adipocytes were detected by oil red O staining, and the content of triglyceride was detected by chemiluminescence method. qPCR and Western Blot were used to detect the mRNA and protein expression levels of adipocyte differentiation (PPARγ, C/EBPα, C/EBPβ, FABP4, etc.). Compared with the control groups, there was no significant change in oil red O staining, triglyceride content, differentiation marker genes expression levels in the lncRNA52114 overexpression groups. On the contrary, the silence of lncRNA52114 expression can significantly inhibit the differentiation rate of HPA-vis compared with the control groups, which is manifested by the decrease of the lipid droplets number and triglyceride content in mature adipocytes. The mRNA and protein expression levels of C/EBPα, C/EBPβ and FABP4 were significantly downregulated in silence group. Fluorescence in situ hybridization (FISH) showed that lncRNA52114 was highly expressed in nucleus and also in cytoplasm. RNA transcriptome sequencing found that the differentially expressed genes were mainly concentrated in the thyroid hormone synthesis pathway (TSHR, GPX3, etc.). Among those genes, TSHR was significantly reduced after lncRNA52114 silencing and closely related to adipocyte differentiation. Overexpression of TSHR on the basis of lncRNA52114 silencing can reverse the effect of its silencing on adipocytes differentiation. CUT&TAG and CUT&RUN showed that lncRNA52114 can decrease the enrichment level of H3K4me3 in TSHR promoter region. LncRNA52114 may influence the differentiation of adipocytes by downregulating the TSHR histone modification in the thyroid hormone synthesis signaling pathway. This study will provide a new theoretical basis and experimental evidence for the study of adipocyte differentiation and a potential target for the prevention and treatment of obesity.

The closest results of the autologous mesenchymal stem cell transplantation in patient with type 1 diabetes mellitus in the honeymoon phase

Olga Ulyanova[1], Manarbek Askarov[2] & Larissa Kozina[3]
[1]National Scientific Medical Center, Endocrine Disturbances Department, Astana, Kazakhstan; [2]National Scientific Medical Center, Stem Cells Technologies Department, Astana, Kazakhstan; [3]National Scientific Medical Center, Central Clinical Laboratory, Astana, Kazakhstan

Background and Aims
The type 1 diabetes mellitus (T1DM) remains one of the main public healthcare problems worldwide. Recent clinical studies have shown a promising stem cell role in the treatment of T1DM. We evaluated the closest therapeutic effect of autologous mesenchymal stem cell transplantation (AMSCT) on carbohydrate metabolism markers in type 1 diabetes mellitus (T1DM) patient in the honeymoon phase.
Materials and Methods
C-peptide (ng/ml), glycated hemoglobin (HbA1C,%), fructosamine (μmol/l), daily insulin dosage (Units/day) were analyzed in the 19-year- old woman (BMI 20.8 kg/m^2) with 7 month history of T1DM with positive islet-cell antibodies (ICA-8.74) before and 6 weeks after AMSCT (cells were obtained from the patients iliac crest and were cultivated for 3 weeks) by intravenous infusion. The quantity of autologous mesenchymal stem cells infused was from $95\text{-}97\times10^6$.
Results
AMSCT 6 weeks after led to increase C-peptide from 0.58 ng/ml to 1.72 ng/ml (normal range: 1.1-4.4 ng/ml), decrease in daily insulin dosage levels from 18 Units/day (0.38 Unit/kg) to 7 Units/day (0.15 Unit/kg) with trend to decrease HbA1c and fructosamine levels, from 8.07% to 7.26% and 320.6 μmol/l to 266.59 μmol/l (normal range: 205.0-285.0 μmol/l), respectively.
Conclusion
The AMSCT in patient with type 1 diabetes mellitus in the honeymoon phase results in an increase in the C-peptide level as well as a decrease of the daily insulin dose, with trends towards a decrease in glycated hemoglobin and fructosamine 6 weeks after transplantation.

Impact of Hybrid Closed-Loop Systems on Diabetes Management Compared to Sensor-Assisted Pump Systems

Anastasia Ntikoudi[1], Eugenia Vlachou[1], Eleni Evangelou[1], Athanasios Tsartsalis[2], John Komninos[2] & George Mastorakos[3]
[1]University of West Attica, Nursing; [2]Naval Hospital of Athens, Endocrinology, Diabetes and Metabolism, Athens, Greece; [3]National and Kapodistrian University of Athens, Athens, Greece

Background and Aim
Over the past years, hybrid closed-loop (HCL) systems have emerged as the state-of-the art treatment of type 1 diabetes (T1D), and there is sufficient evidence to support their safety and value. The aim of this review was to evaluate all the available literature regarding the impact of HCL systems on diabetes management compared to sensor augmented pump (SAP) systems.
Methods
An extensive literature search was conducted through electronic databases (PubMed, Scopus and CINAHL) with the terms 'hybrid closed-loop systems, 'automated insulin dosing systems, 'sensor augmented pump systems' and 'time in range'. Articles published in English, until September 2022, were included; no other criteria on publication dates were set.
Results
A total of 29 studies were included. Eleven studies investigated the effect of the HCL system in adult patients, 7 studies in adult, adolescent, and pediatric patients and 11 studies in pediatric and adolescent patients. The HCL systems used were the Minimed 640G, Minimed 670G, Minimed 780G, Bionic pancreas, Diabeloop, Dana-i and Tandem t: slim. Twenty-seven studies showed statistically significant reduction in mean glucose and a significant increase in the percentage of time within target range in HCL group compared to SAP. In addition, a significant reduction in average HbA1c levels was reported by 14 studies in HCL group compared to the SAP group. Time spent in hyperglycemia and hypoglycemia were significantly reduced in HCL group in 15 studies.
Conclusions
Hybrid closed-loop insulin delivery systems provide better glycemic control and more time in range compared to SAP systems. Therefore, the HCL system represents an important treatment option for patients with T1D.

Disorders of microcirculatory haemostasis in adolescents with tipe 1 diabetes mellitus

Nataliia Nikolaeva, Nina Bolotova & Nataliia Filina
Saratov State Medical University, Saratov, Russia

Microcirculatory disorders play important role in pathogenesis of diabetic vascular complications.
Aim
to study peculiarities of microcirculatory haemostasis (tromboresistance of vessel wall and functional activity of thrombocytes) in adolescents with type 1 diabetes mellitus (T1DM).
Patients and methods
120 adolescents (55 boys, 65 girls) 12–17 y.o. with T1DM were examined. The duration of the disease was: less than 1 year - in 42 patients (HbAc1 7.4 ± 0.5%) – group 1, from 1 to 5 years - in 46 patients (HbAc1 8.3 ± 1.2%) – group 2, more then 5 years - in 32 patients (HbAc1 10.2 ± 1.1%) – group 3. Control group: 110 healthy adolescents 12-17 y.o. The indexes of tromboresistance of vessel wall (antiaggregating, anticoagulating, antifibrinolytic activity) measured by manjetic method. The indexes of trombocyte aggregation (degree, speed and time of aggregation) measured by laser method with different inductors (ADP, adrenalin, kollagen) and intravascular aggregation were evaluated.
Results
tromboresistance of vessel wall was normal in group 1 in comparance of control group ($P < 0.05$). Levels of ADP- and adrenalin-stimulating aggregation, intravascular aggregation of thrombocytes were increased in this group ($P < 0.05$). Tromboresistance of vessel wall was decreased in group 2 ($P < 0.05$). Levels of ADP- and kollagen-stimulating aggregation ($P < 0.05$) and intravascular aggregation ($P < 0.05$) were also increased in group 2. Decrease of aggregation time was revealed in this group ($P < 0.05$). Decrease of tromboresistance of vessel wall ($P < 0.001$), increase of all indexes of functional activity of thrombocytes ($P < 0.05$) and intravascular aggregation ($P < 0.001$) were found in patients of group 3 in comparance of control group.
Conclusions
Microcirculatory disorders in adolescents with T1DM correlated with duration of the disease and may demand treatment.

Importance of MMP-2 and MMP-9 gene polymorphism in the delopment of microvascular complications in type 2 diabetes patients

Marina Andjelic Jelic[1,2], Jelena Stojanovic[1], Miljanka Vuksanovic[1,3], Biljana Jojic[1], Milica Marjanovic Petkovic[1,4], Ana Cvetkov Grujanac[1] & Teodora Beljic Zivkovic[1,3]
[1]Clinical Medical Centre Zvezdara, Department of Endocrinology, Diabetes and Metabolic Diseases, Belgrade, Serbia; [2]Faculty of Dental Medicine University of Belgrade, Belgrade, Serbia; [3]Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [3]Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background
Vascular complications are leading cause of increased morbidity and mortality of diabetic patients. Pathophysiological mechanisms included in the development and progression of diabetic complications are various and lately it has been postulated that matrix metalloproteinases MMP-2 and MMP-9, zinc-dependent endopeptidases through remodeling of extracellular matrix can contribute to the onset and progression of diabetic vascular complications. The aim of our study was to assess whether there is a major difference in single nucleotide polymorphisms in the MMP-2 (at position -1306C > T) and MMP-9 (at position -1562C > T) gene in type 2 diabetic patients and healthy controls and to determine whether there is association of these gene variants with the presence of microvascular complications in diabetic patients.
Methods
Our study included 102 type 2 diabetes patients and control group which comprised 56 healthy controls. All diabetic patients were screened for microvascular diabetes complications. Genotypes were detected by polymerase chain reactions followed by restriction analyses with specific endonucleases (PCR-RFLP) and their frequencies determined.
Results
MMP-2 gene variant -1306C > T showed negative correlation with the presence of T2DM ($P = 0.042$). It was shown that presence of allele -1306C increases the probability of developing type 2 diabetes 2.1 times and that allele -1306 T has protective role regarding type 2 diabetes. MMP-2 variant -1306T showed negative correlation with diabetic polyneuropathy ($P = 0.017$) which means that allele-1306T has protective role regarding diabetic polyneuropathy while presence of allele -1306C increases the probability of developing diabetic polyneuropathy 3.2 fold.
Conclusion
To our knowledge, this is the first study investigating MMP2 and MMP9 genetic variants and all three microvascular complications. Our study showed that MMP-2 gene variant (-1306C) doubles the risk of developing type 2 diabetes and for the first time showed association of this gene variant and presence of diabetic polyneuropathy.

Keywords: diabetes mellitus, matrix metalloproteinase-2 and -9, SNP (single nucleotide polymorphism), microvascular complications, diabetic polyneuropathy.

The role of vitamin D in reducing colorectal cancer risk and progression

Zouhour Hamza[1], Sawsen Feki[1], Yasmine Ben ALI[1], Ikram Ben Amor[2], Olfa Abida[4], Raouia Fakhfakh[1], Hend Hachicha[1], Mohamed Ben Amar[3] & Hatem Masmoudi[1]
[1]Immunology Department, Habib Bourguiba University Hospital, Sfax, Tunisia; [2]Blood Donation Center, Sfax, Tunisia; [3]Surgery Department; Habib Bourguiba University Hospital, Sfax, Tunisia

Introduction
In addition to its role in phosphocalcic metabolism, the vitamin D (vitD) seems to have anti-tumor effects, particularly in colorectal cancer (CRC). The active metabolite of vitD [1,25$(OH)_2D_3$], converted by the enzyme CYP27B1, inhibits proliferation and promotes differentiation of CRC cells which express vitamin D receptor (VDR) via the regulation of a high number of genes. The vitD metabolism seems also to regulate inflammatory processes involved in CRC development and progression, including the $CD4^+$ T cells differentiation and the cytokines production. This study aimed to investigate VitD related parameters and Th17-related parameters in CRC patients in comparison with controls.
Patients and Methods
This is a case-control study including 43 untreated CRC patients and 86 healthy controls. The expression levels of *VDR, CYP27B1* and interleukin 23 receptor (*IL-23R*) genes in peripheral blood mononuclear cells (PBMC) were studied using a quantitative PCR (qPCR). The measurement of circulating levels of VitD (25(OH)D) and IL-17A was performed using ELISA kits.
Results
The mean level of circulating 25(OH)D was significantly lower in CRC patients in comparison with controls (13.77 ± 7.93 vs 21.07 ± 8.79; $P = 0.002$, respectively). A statistically significant association was observed between VitD deficiency (25(OH)D < 20 ng/ml) and risk of CRC (OR = 6.42; IC 95% = 2.64 et 15.61; $P < 0.001$). In contrary, the mean levels of *VDR* and *CYP27B1* gene expression were significantly higher in patients than in controls ($P = 0.002$; $P = 0.047$, respectively). Regarding Th17 axis, the mean level of circulating IL-17A was significantly higher in patients than in controls ($P = 0.009$). The mean level of *IL-23R* gene expression was higher in patients than in controls ($P = 0.1$). The levels of 25(OH)D were inversely correlated with the circulating levels of IL-17A ($r = -0.33$; $P = 0.03$). Furthermore, the circulating levels of IL17A were positively correlated with the gene expression levels of *VDR* and *CYP27B1* ($r = 0.33$; $P = 0.035$ and $r = 0.39$; $P = 0.012$, respectively).
Conclusion
The vitD, by binding to its receptor (VDR), seems to regulate the expression of a high number of genes involved in CRC cell proliferation as well as T helper cell differentiation. Further clinical studies are required to confirm the close interplay between vitD, anti-tumor immunity, and CRC, suggesting a possible role of vitD as a potential agent in CRC prevention and therapy.

The impact of type 2 diabetes on the post-COVID period according to the ACTIV SARS-CoV-2 registry

Alexander Arutyunov[1,2], Iuliia Fedorova[3], Roman Bashkinov[4], Tatiana Batluk[5], Evgenii Melnikov[4], Marina Trubnikova[5] & Elizaveta Gordeychuk[3]
[1]National Institute of Health after academician S.Avdalbekyan, Erevan, Armenia; [2]Eurasian Association of Internal Medicine, "ACTIV SARS-CoV-2" Working Group, Erevan, Armenia; [3]Eurasian Association of Internal Medicine, "ACTIV SARS-CoV-2" Working Group, Moscow, Russia; [4]Eurasian Association of Internal Medicine, "ACTIV SARS-CoV-2"

Working Group, Saint Petersburg, Russia; [5]Eurasian Association of Internal Medicine, "ACTIV SARS-CoV-2" Working Group, Sochi, Russia

Background
SARS-CoV-2 profoundly impacts population health through both acute infection and post-COVID period. Multiple studies make it clear that metabolic diseases can significantly affect the course of COVID-19.
Aim
To study the course of post-COVID period in patients with type 2 diabetes mellitus (DM2).
Methods
The international registry ACTIV SARS-CoV-2 (NCT04492384) was established to study COVID-19 in the Eurasian region. The post-COVID period was assessed based on telephone surveys of the patients 3 months ($n=3083$), 6 months ($n=2485$) and 12 months ($n=1774$) after recovery. DM2 was reported in 14.3% ($n=441$), 15% ($n=373$) and 14.2% ($n=252$) of all respondents, respectively.
Results
One or more complaints/symptoms (general weakness, dyspnea, unstable blood pressure, arrythmia, cough, thoracalgia, arthralgia, olfaction disorders, myalgia, lower limb edema) persisted more often in patients with DM2 compared to patients without DM2 within 12 months after recovery. At the same time, the proportion of patients with complaints/symptoms gradually increased over time (Table 1). Sub-analysis of 1416 patients at 3 months, 1110 patients at 6 months, and 702 patients at 12 months after recovery demonstrated that DM2 was associated with more unscheduled care visits after recovery (Table 2). Finally, mortality was elevated, and the adverse outcome rate was the highest in patients with type 2 diabetes at 12 months after recovery (Table 3).
Conclusion
DM2 in COVID-19 patients contributes to longer persistence of complaints/-symptoms, need for unscheduled medical care, and mortality within 12 months after recovery. These findings call for active monitoring, a more detailed examination, and rehabilitation of patients with DM2 in the post-COVID period.

Neurotropic properties of high- and low-selective sodium-glucose cotransporter type 2 inhibitors in type 2 diabetic patients

Anna Simanenkova[1,2], Oksana Fuks[1], Natalya Timkina[1,2], Polina Tikhomirova[2], Alexandr Gagiev[2], Timur Vlasov[2] & Tatiana Karonova[1,2]
[1]Almazov National Medical Research Centre, Clinical Endocrinology, Saint-Petersburg, Russia; [2]Pavlov First Saint-Petersburg State Medical University, Saint-Petersburg, Russia

Background and Aim
Type 2 diabetes mellitus (DM) treatment guidelines give preference to drugs with proven cardioprotective effect, which include sodium-glucose cotransporter type 2 inhibitors (SGLT-2i) and glucagon-like peptide-1 receptor agonists (GLP-1RA). GLP-1RA are known to reduce the stroke risk. Data on SGLT-2i effect on the brain, in conditions of both acute and chronic cerebrovascular disorders, are less complete. The aim of our study was to evaluate the effect of high-selective SGLT-2i empagliflozin (EMPA) and low-selective SGLT-2i canagliflozin (CANA) on the central nervous system biochemical and functional parameters in type 2 diabetic patients.
Materials and Methods
The study included type 2 DM patients aged 45-75 on metformin monotherapy. The following groups were formed: group 1 ($n=12$) - patients with target glycated hemoglobin (HbA1c) level who did not undergo therapy correction, groups 2 and 3 ($n=14$ and $n=12$, respectively) - patients with HbA1c exceeding target no more than 2.5%. In group 2 EMPA therapy was initiated, in group 3 CANA therapy. Control group ($n=18$) of healthy volunteers was also created. In all groups, the levels of HbA1c, neuron-specific enolase (NSE), neurofilament light chains (NLC) were determined initially, cognitive assessment scales (MOCA, MMSE) were used. In groups 2 and 3 these parameters were also evaluated after 3 and 6 months.
Results
Baseline NSE level in DM patients was higher than in healthy volunteers, regardless of glycemic control (2.76 (2.47; 3.92) ng/ml in the control group, 3.22 (2.61; 4.16) ng/ml in DM with target HbA1c, 3.58 (3.11; 3.73) ng/ml in DM with non-target HbA1c). EMPA addition did not cause changes in NSE, while CANA administration significantly reduced NSE (after 6 months it was 2.73 (2.00; 2.92) ng/ml). The NLC in DM patients with target HbA1c initially did not differ from that in control group (4.5 (3.31; 5.56) and 4.13 (3.31; 5.31) ng/ml, respectively), but was elevated in patients with non-targeted HbA1c (5.25 (3.75; 6.25) ng/ml). Both EMPA and CANA caused this parameter decrease, while CANA effect was more pronounced - NLC after 6 months of EMPA therapy was 4.50 (3.45; 4.50) ng/ml, CANA - 2.00 (1.95; 2.20) ng/ml. DM, even with target HbA1c, led to cognitive deficits when assessed by MOCA and MMSE. EMPA and CANA significantly improved these parameters over time. Negative correlation was found between NLC level and the points in MOCA and MMSE.
Conclusions
DM, even with satisfactory glycemic control, has a negative impact on the brain, which is manifested by neuronal damage markers increase and cognitive dysfunction. High- and low-selective SGLT-2i have a neuroprotective effect, which is probably more pronounced in low-selective CANA.

are limited. The aim of this study was to evaluate BMD in patients with T1DM in relation to changes of glycemic control.
Methods/Design
We studied 118 uncomplicated patients with T1DM (GroupD) (mean age: 30.12 + 8.78years, F/M: 65/53) and 94 healthy controls (GroupC) matched for age, sex and body mass index (BMI). All patients in GroupD were re-examined after 18 months (FU). In both groups, we measured HbA1c and BMD at lumbar spine (LS), total hip (TH) and femoral neck (FN) by dual energy X-ray absorptiometry (DXA). HbA1c changes of $\geq$ 0.5% were considered significant. For BMD changes to be considered significant a minimum change of 3% at LS, 3.3% at TH and 4.7% at FN is needed.
Results
At baseline, in GroupD mean duration of diabetes was 16.16 + 9.56 years, mean HbA1c was 7.94 + 1.37% and absolute values of BMD (g/m^2) were significantly lower at LS, TH and FN compared to GroupC ($P = 0.018$, $P < 0.001$ and $P = 0.007$, respectively). At FU, in GroupD mean HbA1c was 7.93 + 1.59% and BMD changes from the baseline were: at LS: -1.4%, TH: -1% and FN: -2.0%. In FU, males in GroupD appeared to have greater decreases in BMD than females (M: LS: -2.2%, TH: -3.3% and FN: -4.1%. vs F: LS: -0.8%, TH: -0.9% and FN: -0.8%) . There was a significant negative correlation between HbA1c changes and TH BMD changes ($r = -0.233$, $P = 0.02$).
Conclusion
Worsening glycemic control is associated with reduction in BMD in patients T1DM, and it seems that males are more affected than females.

EP233

Metabolically healthy non-alcoholic fatty liver disease and progression of coronary artery calcification: A 15 year longitudinal study

Ji-Eun Jun[1], You-Cheol Hwang[1], You-Bin Lee[2] & Jae Hyeon Kim[2]
[1]Kyung Hee University Hospital at Gangdong, Endocrine & Metabolism, Seoul, South Korea; [2]Samsung Medical Center, Endocrine & Metabolism, Seoul, South Korea

Objective
Non-alcoholic fatty liver disease (NAFLD) is considered as a continuum from obesity and metabolic syndrome (MetS). To investigate the cardiovascular prognosis of metabolically healthy NAFLD, this study aimed to evaluate the association between NAFLD with and without MetS and change in coronary artery calcification (CAC).
Methods
This is a retrospective longitudinal study of 5,117 subjects without cardiovascular disease who participated in a health screening program. Ultrasonographic measurements of fatty liver and multi-detector computed tomography were concurrently performed to determine the CAC score. We classified the subjects into four groups according to NAFLD status and MetS presence: controls neither NAFLD nor MetS, NAFLD without MetS, MetS without NAFLD, and NAFLD with MetS. CAC progression was defined as [$\sqrt{}$CAC score (follow-up) $-$ $\sqrt{}$CAC score (baseline)] $\geq$2.5.
Results
During median follow-up of 5.0 years, CAC progression was detected in 2,125 subjects (41.1%). After adjustment for age, diabetes, hypertension, triglycerides, HDL-cholesterol, use of lipid-lowering drugs, smoking status, and baseline CAC score, the hazard ratios (HRs) for CAC progression comparing controls, those of NAFLD without MetS, MetS without NAFLD, and NAFLD with MetS were 1.21 (95% CI: 1.08–1.35), 1.04 (0.85–1.27) and 1.36 (1.15–1.56), respectively. When NAFLD without MetS were stratified by the severity of ultrasonographic findings, subjects with moderate to severe NAFLD had a higher risk of CAC progression, compared to those without NAFLD or mild NAFLD. The prognostic factors for CAC progression were higher HbA1c, fasting plasma glucose, aspartate transaminase, γ-glutamyltransferase, and baseline CAC score in subjects with metabolically healthy NAFLD.
Conclusions
NAFLD without MetS was significantly associated with an increased risk of CAC progression regardless of other cardiometabolic risk factors. NAFLD without MetS might be considered to have an intermediate metabolic phenotype between healthy individuals and NAFLD patients with MetS.

Influence of metabolic factors on the course of the acute period of COVID-19 in hospitalized patients according to the international registry ACTIV SARS-CoV-2

Alexander Arutyunov[1,2], Elizaveta Gordeychuk[3], Roman Bashkinov[4], Tatiana Batluk[3], Evgenii Melnikov[4] & Marina Trubnikova[5]
[1]National Institute of Health after academician S.Avdalbekyan, Erevan, Armenia; [2]Eurasian Association of Internal Medicine, "ACTIV SARS-CoV-2" Working Group, Erevan, Armenia; [3]Eurasian Association of Internal Medicine, "ACTIV SARS-CoV-2" Working Group, Moscow, Russia; [4]Eurasian Association of Internal Medicine, "ACTIV SARS-CoV-2" Working Group, Saint Petersburg, Russia; [5]Eurasian Association of Internal Medicine, "ACTIV SARS-CoV-2" Working Group, Sochi, Russia

Background
The literature shows that body mass index (BMI) and blood glucose levels can significantly influence the course of infectious diseases. In the light of ongoing SARS-CoV-2 pandemic, its rational treatment and prevention are strategic public health goals.
Aim
To study the relationship between BMI and serum glucose levels during the acute period of COVID-19 in hospitalized patients.
«ACTIV SARS-CoV-2» registry was established to evaluate the course of COVID-19 in the Eurasian region and covered 7 countries. ACTIV (NCT04492384) and ACTIV 2 (NCT04709120) are multicenter non-interventional real-world registries. 6396 subjects from ACTIV and 2968 subjects from ACTIV 2 were included in this study.
Results
Patients with higher serum glucose levels and BMI had significantly more severe acute period of COVID-19, characterized by acute kidney injury (AKI), hyperinflammatory syndrome, increase in C-reactive protein (CRP) above 100 mg/l, or need for targeted therapy (Table 1).Moreover, hyperglycemia at 6.9 (5.6–9.18) mmol/l was significantly ($P < 0.001$) associated with death in the acute period (versus 5.7 (5.0–7.0) mmol/l in the survivors).
Conclusions
Analysis of the ACTIV SARS-CoV-2 registry showed that patients with a more severe course of the acute period of COVID-19 in the form of AKI, "cytokine storm", increase in CRP above 100 mg/l, or need for targeted therapy had higher serum glucose levels and BMI. In addition, hyperglycemia was associated with death during hospitalization for SARS-CoV-2. These findings allow the studied clinical parameters to be used as characteristics of the severe course of the disease.

The role of microbiome features in postprandial blood glucose response in patients with gestational diabetes

Polina Popova[1,2], Eugenii Tikhonov[3,4], Artem Isakov[1], Angelina Eriskovskaya[1], Evgenii Pustozerov[2], Elena Vasukova[2], Aleksandra Tkachuk[2], Anna Anopova[1], Maria Kokina[1],

Table 1 (Abstract EP234). Severity of Acute COVID-19 by Serum Glucose Levels and BMI

Characteristics of acute COVID-19	Metabolic factor	Absent Me (Q1 – Q3)	Present Me (Q1 – Q3)	*P*
AKI	Glycemia, mmol/l	5.8 (5.0–7.0)	6.0 (5.2–8.55)	0.011
	BMI, kg/m^2	27.8 (24.8–31.6)	29.6 (25.1–33.5)	0.018
"Cytokine storm"	Glycemia, mmol/l	5.7 (5.0–6.6)	6.1 (5.2–8.0)	<0.001
	BMI, kg/m^2	27.5 (24.4–31.2)	28.7 (25.6–32.8)	<0.001
CRP above 100 mg/dl	Glycemia, mmol/l	5.4 (4.8–6.7)	6.1 (5.0–8.1)	<0.001
	BMI, kg/m^2	27.7 (24.7–31.7)	28.7 (25.5–32.7)	<0.001
Need for targeted therapy	Glycemia, mmol/l	5.8 (5.0–7.1)	6.3 (5.4–8.0)	<0.001
	BMI, kg/m^2	27.7 (24.7–31.3)	29.7 (26.3–34.2)	<0.001

Background and Aims
The gut microbiome has been shown to differ between healthy individuals and those with diabetes and even in women with gestational diabetes mellitus (GDM). This raises the question of its role in postprandial glycemic response (PPGR). We aimed to evaluate the impact of microbiome features in PPGR in women with GDM and healthy pregnant women.
Methods
We obtained stool samples for 96 pregnant women (65 GDM, 31 control), previously recruited for GEM-GDM study (NCT03610178), who consented to continuous glucose monitoring (CGM) for 7 days (31.5±3.1 weeks) and provided relevant food diaries. After additional filtering for quality diaries and number of food intake records per person, 45 women were selected for the statistical analysis. CGM data were analyzed with records of 720 meals. Stool samples were collected within 1-2 weeks after recruitment (28.8±3.6 weeks).16S rRNA gene sequence analysis was carried out after sequencing on a MiSeq platform. 780 bacterial features were selected after the following filters were applied: by the frequency of occurrence of the feature in the samples (at least three) and by the number of copies of the bacterial feature (at least 20). The Shapley additive explanations method was implemented to evaluate feature importance.
Results
When microbiome data were added to the input parameters of the model, the greatest contribution to PPGR was made by the abundance of bacteria of the genera *Ruminococcus* and *Bacteroides*. Their greater relative abundance was associated with an increase in the peak glycemic level after a meal. The contribution of bacterial traits to the accuracy of PPGR prediction depended on the choice of prediction algorithm and method of diary filtering. Models built with the addition of microbiome data showed better prediction accuracy in cross-validation datasets and on new patient data in predicting peak glycemic levels and 1-hour postprandial glucose levels. Inclusion of the microbiome data slightly increased the accuracy for predicting peak glycemic levels (mean absolute error 0.484 mmol/l vs 0.497 mmol/l for the models with and without microbiome data) and correlation between actual and predicted values ($R=0.718$ vs $R=0.704$) based on the full dataset ($n=96$), but did not change the accuracy in the more strictly filtered dataset ($n=45$).
Conclusions
Bacteria of the genera *Ruminococcus* and *Bacteroides* made the greatest contribution to peak postprandial glycemic level in pregnant women with GDM.

Objectives
To describe modifiable sociodemographic and clinical risk factors predictive of severe hypoglycemia with need for urgent health care in adults with type 1 diabetes (T1DM).
Methods
Multicenter, observational and retrospective study with case-control design.
Cases
T1DM adults with severe hypoglycemia, defined as glycemia <70 mg/dl requiring urgent out-of-hospital health care for its resolution. Data source, geographical and temporal framework: cases selected from the register of care contacts of the Public Emergency Company of Andalusia (PECA) throughout the territorial scope of the Andalusian Public Health System (APHS), during the period 2018-2020.
Controls
Adults with T1DM without a history of severe hypoglycemia. Selected with 1:1 ratio, matched by basic variables: sex, age, reference health area, glycemic monitoring method and insulin administration system (multiple doses/insulin pumps).
Results
A total of 389 participants were included (219 cases and 170 controls) from a total of 16 reference hospitals in Andalusia (Spain). The mean age of the cases was 46.4 years (SD 14.2), with 57.5% male. The most frequent cause of severe hypoglycemia was an error in rapid insulin dosing (33.8%). In 15.6% of the cases, evacuation to a health center was required for resolution. More than one severe hypoglycemia event was recorded during the study period (2018-20) in 35.5%. In 18.9% of cases used interstitial flash glucose monitoring systems at the time of severe hypoglycemia, and 3.8% were users of insulin pumps. Among the psychosocial variables, a higher prevalence of depression (17.7% vs 7.1%, $P=0.007$), physical and/or intellectual disability (9% vs 3%, $P=0.04$) and lack of university or technical education (59.7% vs 36.8%, $P=0.002$) was observed in the group of cases. In relation to the natural history of T1DM, the time of evolution was longer in cases compared to controls (27.9 vs 23 years, $P=0.008$), as well as the prevalence of chronic complications (proliferative retinopathy 16.8% vs 6.3%, $P=0.007$; vascular-cerebral accident 6.2% vs 0.8%, $P=0.01$) and of NO follow-up in endocrinology units (14.2% vs 7%, $P=0.04$). The previous history of severe hypoglycemia was significantly higher in the case group, both in the overall follow-up history and in the last year (respectively: 56.4% vs 16.5%, $P<0.001$; 34.5% vs 1.6%, $P<0.001$). Also higher in cases was the prevalence of nocturnal hypoglycemia (56% vs 26.9%, $P<0.001$) and of inadvertent hypoglycemia (61.6% vs 21.2%, $P<0.001$).
Conclusions
Chronic diabetes-related complications, history of severe hypoglycemia, nocturnal hypoglycemia and inadvertent hypoglycemia, as well as depression, dependency status and low academic education level are risk factors for severe hypoglycemia in T1DM. These variables could be incorporated into strategies for identifying patients at risk and designing specific preventive interventions based on diabetes education.

The influence of advanced glycation end-products (AGEs) on diabetic retinopathy progression

Deimante Kardonaite[1], Rasa Verkauskienė[1], Erika Jurkutė[2], Milda Danelienė[2] & Lina Radzevičienė[1]
[1]Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Department of Endocrinology, Hospital of Lithuanian University of Health Sciences Kaunas Clinics, Kaunas, Lithuania

Background
Diabetes-induced prolonged elevated plasma glucose levels result in the formation and accumulation of complex and heterogeneous groups of compounds - advanced glycation end-products (AGEs). AGEs normally accumulate slowly, but this process occurs at a faster rate in patients with conditions such as diabetes or cardiovascular disease. Accumulation of AGEs increases oxidative stress and induces an inflammatory reaction, which has a significant influence on the exacerbation of diabetic vascular complications. One of the most common complications resulting from uncontrolled diabetes is diabetic retinopathy

(DR). However, it is necessary to clarify the role of AGEs in the pathology of DR to improve the quality of life for diabetic patients.
Aim
The aim of this study was to investigate the relationship between AGEs levels and DR progression.
Materials and Methods
120 patients (age $\geq$18) with type 1 (T1D) and type 2 diabetes (T2D), were enrolled. Patients were divided into 3 groups: no diabetic retinopathy (n=50), non-proliferative diabetic retinopathy (n=49), and proliferative diabetic retinopathy (n=11). AGEs levels in the skin were non-invasively measured with AGE Reader (Diagnoptics B.V., The Netherlands). Data on patients' clinical characteristics were collected from medical records.
Results
The median diabetes duration of the patients was 14.5 years, age – 55 years. The study cohort consisted of 64 (58.2%) women and 46 (41.8%) men. Patients with a longer duration of diabetes had more severe form of diabetic retinopathy ($P<$ 0.001). Age and HbA1c were comparable in groups with different severity of diabetic retinopathy (P=0.320 and P=0.094, respectively). However, the concentration of AGEs was higher in the group of patients with proliferative DR than in patients with non-proliferative DR and patients without DR ($P<$0.05). HbA1c levels were not related to AGEs concentration (P=0.354). AGEs levels increased with age (r=0.420, $P<$0.001) and duration of diabetes (r=0.331, $P<$ 0.001).
Conclusions
AGEs levels in the skin increase with progression of DR. These results support the evidence that AGEs have an important role as a prognostic biomarker for vascular risk assessment.

A simultaneous pancreas-kidney transplantation for type 1 diabetes mellitus after a long-term period of hemodialysis (Clinical case)
Madina Yevloyeva[1], Rustam Salimkhanov[1], Nino Katamadze[1], Anastasia Severina[1], Minara Shamkhalova[1], Natalia Trubitsyna[1] & Yan Moysyuk[2]
[1]Endocrinology Research Center, Moscow, Russia; [2]Moscow Regional Research and Clinical Institute ("MONIKI"), Moscow, Russia

Introduction
Today simultaneous pancreas-kidney transplantation (SPKT) is an effective method of treatment for patients with type 1 diabetes mellitus (T1D) and terminal stage of diabetic nephropathy (DN) on renal replacement therapy by hemodialysis. It solves several problems: reduces the severity of intoxication syndrome, contributes to the achievement of euglycemia in most cases, that allows to delay progression of micro- and macrovascular diabetic complications.
Case Description
A 56-years-old Caucasian woman with T1D, end-stage renal disease (ESRD) underwent successful SPKT in October 2014 after 8 years haemodialysis therapy. T1D was diagnosed 34 years ago. Insulin therapy was initiated immediately, but glycemic compensation hadn't been achived after T1D onset due to lack of constant glycemic self-control (patient had 3 diabetic ketoacidosis, impaired awareness of hypoglycemia). Late diagnosis of DN (macroalbuminuria, uremia, blood pressure over 180/110 mm Hg since 2002) and late nephroprotective therapy prescription led to rapid progression of chronic kidney disease (CKD) to the terminal stage. Nonproliferative and proliferative diabetic retinopathy OS and OD respectively were diagnosed in 2011, neuropathic osteoarthropathy (DNOAP) of the right ankle joint - 2013. During 7 years after transplantation she is still euglycaemic without insulin therapy (glycated hemoglobin 5.7%, C-peptide 1.93 ng/ml) with creatinine of 70-90 µmol/l, estimated glomerular filtration rate 45.8 mL/min (stage 3a normoalbuminuric CKD), normal hemoglobin and blood pressure levels. Continuous glucose monitoring registrated hypoglycemic episodes (2.0 mmol/l). The tertiary hyperparathyroidism (HPT) treatment with cinacalcet stabilized calcium-phosphorus metabolism (corrected calcium for albumin 2.38 mmol/l, phosphate 1.03 mmol/l, parathyroid hormone 107.9 pg/ml, 25(OH)D 41.3 ng/ml), bone densitometry scores: T-score is $-$3.7 at the femoral neck, $-$2.0 L1-L4, -5.5 total radius. Surgical treatment of HPT was recommended. Patient received the standard triple immunosuppressive therapy, now receives double therapy. Despite euglycemia diabetes complications progressed to proliferative retinopathy OU, hemophthalmos OS, bilateral DNOAP in 2021. The patient has cardiovascular complications: cerebrovascular disease, atherosclerosis (stenosis of the right common carotid artery 35%, the right posterior tibial artery – 65%).
Conclusion
SPKT is the best treatment option for patients with T1D and ESRD. Unfortunately, even successful SPKT can't guarantee reverse development of diabetic complications, persisting at the moment of transplantation. The progression of complications may be associated with the continued influence of accumulated "metabolic memory" markers (advanced glycation end products (AGEs), receptor for AGEs, etc.). After transplantation such patients need strict control by nephrologist, endocrinologist, cardiologist, etc. to maintain positive results of euglycaemia and kidney function normalization.

Neutrophil to lymphocyte ratio is associated with diabetic ketoacidosis in type 1 diabetes mellitus
Zouhour Hamza[1], Ameni Jerbi[1], Feten HadjKacem[2], Hend Hachicha[1], Mouna Mnif[2], Sawsan Feki[1], Mohamed Abid[2] & Hatem Masmoudi[1]
[1]Immunology Department, Habib Bourguiba University Hospital, Sfax, Tunisia; [2]Endocrinology Department, Hedi Chaker University Hospital, Sfax, Tunisia

Introduction
Inflammation has been involved in the physiopathology of diabetic ketoacidosis (DKA). Hematological inflammatory markers such as neutrophil-to-lymphocyte ratio (NLR) and white blood cell count (WBC) can serve as predictive markers for a systemic inflammatory response. This study aimed to evaluate hematological inflammatory markers in T1DM patients with DKA and without-DKA in an uninfected state and to determine their role in the prediction of DKA.
Patients and Methods
This is a retrospective preliminary study including a total of 30 T1DM uninfected patients. According to the onset characteristics, fasting blood glucose, ketone bodies, and blood gas analysis results, patients were divided into T1DM patients with DKA (n=7) and without-DKA (n=23) groups. Hematological inflammatory markers including WBC, NLR, PLR (platelet-to-lymphocyte ratio) and PNR (platelet-to-neutrophil ratio) were retrieved from complete blood counts.
Results
The median age of T1DM patients was 24.5 years [14-45]. The mean level of WBC was higher in T1DM patients with DKA than those without-DKA (11881.4$\pm$6971.36 vs 8191.3 $\pm$3210.36; P=0.21). T1DM patients with DKA had significantly higher serum NLR levels than those without DKA (9.71$\pm$ 8.85vs 2.30 $\pm$1.05; P=0.035). NLR was also significantly associated with the occurrence of DKA in T1DM patients (OR=2.18, 95%CI: 1.5–4.4, P=0.034). Furthermore, the levels of NLR were positively correlated with the circulating levels of creatinine (r=0.5; P=0.008) and negatively correlated with the circulating levels of albumin (r=-0.55; P=0.01). The mean level of PNR was significantly lower in patients with DKA than those without DKA (25.99 $\pm$14.96 vs 55.82 $\pm$20.77; P=0.001). The mean level of PLR was higher in patients with DKA than those without DKA (171.6 $\pm$93.54 vs 119.33$\pm$41.59; P=0.19). The ability of WBC, NLR, PLR and PNR in predicting DKA was analyzed using ROC curves. The most influential indicator for DKA patients was NLR (AUC 0.85; 95%CI: 0.7–1;p $<$0.005).The statistical threshold value of the NLR in predicting DKA was 2.05, with a sensitivity of 100% and a specificity of 50%.
Conclusion
Our findings indicate that the levels of WBC, NLR, and PLR were elevated in uninfected T1DM patients with DKA. The involvement of neutrophil-mediated inflammation may contribute to the pathogenesis of DKD in T1DM. Consequently, NLR can serve as a practical and cost-effective predictor for the occurrence of DKA in T1DM patients.

Significance of Determining Inflammatory Markers and Carotid Artery Intima Media Thickness values in the Detection of Coronary Heart Disease in Asymptomatic Patients with Type 2 Diabetes
Gabrijela Malesevic[1], Snjezana Popovic Pejicic[2], Tamara Kovacevic[3], Ljiljana Kos[3], Bojan Stanetic[3], Valentina Soldat Stankovic[1] & Ivona Risovic[1]
[1]University Clinical Centre of the Republic of Srpska, Medical Faculty, University of Banja Luka, Department of Endocrinology, Banja Luka, Bosnia and Herzegovina; [2]Medical Faculty, University of Banja Luka,

Banja Luka, Bosnia and Herzegovina; [3]University Clinical Centre of the Republic of Srpska, Medical Faculty, University of Banja Luka, Department of Cardiology, Banja Luka, Bosnia and Herzegovina

Introduction
Increased levels of high-sensitivity C-reactive protein (hs-CRP) and interleukin 6 (IL-6) accelerates atherosclerosis and occurrence of cardiovascular complications in patients with type 2 diabetes (T2D). Intima-media thickness (IMT) is a surrogate marker of atherosclerosis in patients with T2D.
Aim
The aim of the study was to evaluate the significance of determining inflammatory markers IL-6, hs-CRP and IMT, as atherosclerosis markers, during a screening for presence of Coronary Heart Disease (CHD) in asymptomatic patients with T2D.
Methods
The study included 169 patients with T2D, without any symptoms and signs of CHD. Ergometric testing proved or ruled out the presence of CHD. Carotid ultrasonography was performed and IMT was measured. The levels of hs-CRP and IL-6 were determined by ELISA.
Results
Age, HbA1c, LDL cholesterol and albuminuria values were significant predictors of silent CHD ($P<0.05$). Other analysed risk factors: gender, smoking, duration of T2D, BMI, hypertension, total cholesterol and triglycerides did not show statistical significance in the prediction of CHD. It was proven that there was a greater possibility of the presence of silent CHD in asymptomatic patients with T2D with higher values of IMT($P<0.05$), IL-6 ($P<0.05$) and hs-CRP ($P<0.001$).Keywords: diabetes mellitus, coronary heart disease, inflammatory markers, intima-media complex

Infection among type 2 diabetic hospitalized patients: A 4 year retrospective study

Trigui Souleima, Boubaker Fadia, Houcem Elomma Mrabet, Trimech Oumeyma, Najoua Lassoued, Zantour Baha, Alaya Wafa & Sfar Mohamed Hbib
University Hospital Tahar Sfar, Endocrinology, Mahdia, Tunisia

Background and Aims
Acute and chronic infectious diseases appear to be more prevalent among patients having diabetes mellitus. Infections associated with diabetes could be particularly serious increasing morbimortality and treatment costs. Diabetic patients' predisposition to infections could be explained by the hyperglycemic environment impairing immune function. Other factors my contribute such as degenerative complications, for example autonomic neuropathy could decrease gastrointestinal and urinary motility.
Aim
The aim of this work is to assess the prevalence and type of infectious diseases among a type 2 diabetic hospitalized population.
Materials and Methods
We conducted a retrospective study including all type2 diabetics hospitalized in the Diabetology-Endocrinology department during the period 2018-2021.
Results
A total number of 357 type 2 diabetic patients was hospitalized during the study period. The average age was of 52.58 years [17-84]. A female predominance was noted (65.26%). Diabetic complications were distributed as following: 31.65% of patients had cardiovascular diseases, 33.05% a sensory polyneuritis, 29% a diabetic retinopathy, 10.92% a diabetic nephropathy and 8.68% an autonomic neuropathy. The prevalence of infections was of 26.61% with diabetic infected foot (8.96%) and urinary tract infection (7.5% of patients whose pyelonephritis in 85% of cases) as the main ones. Skin infections were present in 6.7% of cases of which the main was erysipelas (2.5% of all patients). Three patients had mycoses (0.8%) and a similar number had shingle. Measles, anthrax, furunculosis and skin wound infection were present in one case for each (0.44%). Respiratory infections affected 3.08% of patients: pneumonia was diagnosed in 1.96% and tracheobronchitis in 1.12% of the study population. Six patients (1.6%) had dental infections. Two patients (0.56%) had osteoarticular infections. A similar number of patients ($n=2$, 0.56%) had a digestive system infection. Regarding severity, a sepsis was noted in 3 cases (0.8%) (of which 2 urinary tract infections). Infection was the revealing factor of diabetes among 31.42% of the cases of recent diabetes.
Conclusion
Infection could be the first manifestation of diabetes mellitus, therefore patients consulting for acute infections and having risk factors for type 2 diabetes should be screened for hyperglycemia and for other metabolic features. Coexistence of diabetes and infection may precipitate metabolic acute complications, such as hypoglycemia, Ketosis, ketoacidosis and hyperosmolar states. Adopting a healthy life style and having a better glycemic control could reduce diabetes' morbidity including the related one to infections.

Hand grip strength and risk of falls in adults with type 2 diabetes mellitus

Maria Hayon Ponce[1,2], David Blanquez Martinez[3], Beatriz Garcia Fontana[2] & Manuel Muñoz Torres[2]
[1]Hospital Universitario de Ceuta, Endocrinology and Nutrition, Ceuta, Spain; [2]University Hospital Clínico San Cecilio, Bone Metabolic Unit, Endocrinology and Nutrition Division, Granada, Spain; [3]Hospital Universitario de Ceuta, Clinical Pharmacy, Ceuta, Spain

Objective
The objective of our study is to evaluate muscle strength and risk of falls in type 2 diabetes mellitus (DM2) patients
Methods
Observational cross-sectional study. Hand grip strength (HGS) (kg/cm^2) was measured with a Jamar. manual hydraulic dynamometer (5030j1; Jackson, MI).To classify normality, data from the Spanish population were used, establishing the cut-off point at p10. To assess the level of mobility and the risk of falls, the Time Up and Go(TUG) test was carried out. A score of less than 12 seconds was defined as low risk of falling and greater than 12 seconds as high risk of falling.
Results
The study included 60 patients with DM2 (60% men and 40% postmenopausal women). Mean age 66.3 ± 8.3 years. Body mass index (BMI) 30.8 ± 4.6. The mean values for dynamometry were 33.5 ± 22.5 kg in males and 21.5 ± 9.4 kg in women, being 96.6% below the 10th percentile. The prevalence of low muscle strength was analyzed by age group, quartiles of BMI and waist circumference (WC). We observed a progressive increase of low muscle strength with age .The prevalence of low hand grip strength was higher in the first and fourth quartiles of BMI and the fourth quartile of WC. According to the results obtained in the TUG test, 25% of men and 41.7% of women had a high risk of falls. Patients with high risk of falls showed significantly lower hand grip strength values than those with low risk of falls (13.8 ± 7.4 vs 18.7 ± 8.1; $P=0.027$).
Conclusions
HGS and TUG are practical tools for assessment muscle weakness in DM2 patients. Decrease in muscle strength should be recognized as a complication of DM2.

Study on histomorphological features of the brain tissues in animals with experimental diabetes mellitus

Talat Saatov, Gulnora Artykbaeva, Elvira Ibragimova & Tokhir Ishanhodjaev
Institute of Biophysics and Biochemistry under Mirzo Ulugbek National University of Uzbekistan, Lab of Metabolomics, Tashkent, Uzbekistan

For quite a long time, the brain has been considered as an insulin independent organ capable of utilizing glucose without participation of insulin. Today, insulin is thought to be not only a regulator of glucose transport and metabolism, but also as a modulator of some processes, including neuronal excitability, proliferation and differentiation of progenitor cells, synaptic plasticity, memory formation, secreting of neurotransmitters and apoptosis. The work was initiated to comparatively analyze the morphological changes in the hippocampus of rats with experimental diabetes mellitus.
Materials and Methods
We studied the brain material taken from 7 rats with a diabetes mellitus model on a high-calorie diet and from 7 controls on the standard diet. Morphological studies were performed on the hematoxylin and eosin histologically stained specimens. The slices of the brain tissues prepared from the paraffin blocks in compliance with the standard methods were examined.
Results and Discussion
The trans-synaptic degeneration providing transfer of the damage from the damaged neuron to the normal one via a synaptic contact is the common process for neurodegenerative diseases of the central nervous system. Apoptosis is thought to be the main mechanism of the neuronal death taking place in neurodegenerative diseases. The findings from examination of the histological

specimens of tissues from rats with diabetes mellitus demonstrated pronounced atrophy of the nerve tissues as compared to those from the controls. Karyopycnosis of neurons could be seen in the cerebral cortex and in the hippocampus. In some places, neurofibrillary tangles could be seen in the cerebral cortex; there were perivascular edema, erythrostasis and a slight reduction in the neurons in the hippocampal region. In all regions under study, in rats with diabetes mellitus, the pronounced reduction of neurons as compared to the one in the controls could be seen. A reduction in the volume of the cytoplasm and nucleus, the membrane thickening and folding, moderate hyperchromatosis of the nucleus and the cytoplasm shrinking are the morphological signs evidencing the involvement of neurons in the apoptosis. Thus, the findings from the histomorphological studies demonstrated a reduction in the number of neurons and their karyopycnosis in the hippocampal region with the neurodegenerative damages, as well as changes in both composition of neurons and shape of the cell nuclei.

Usability of early treatment intervention using personal continuous glucose monitor in hospitalized patients with type 2 diabetes

Soichi Takeishi & Tatsuo Inoue
Inuyama Chuo General Hospital, Diabetes, Inuyama-City, Japan

It was reported that outpatients with type 1 diabetes using real-time continuous glucose monitoring (rtCGM) reduce HbA1c more than those using self-monitoring of blood glucose (SMBG). However, it is not well known whether inpatients with type 2 diabetes using rtCGM reduce glycemic variability more than those using SMBG. This is a prospective parallel-group comparative study. Sixteen patients with type 2 diabetes hospitalized for diabetes treatment were randomly allocated to 2 groups. In group 1, patients used personal continuous glucose monitor (CGM) [GUARDIAN CONNECT], and drug treatment intervention (DTI) is performed based on the sensor glucose levels (SG) in the rtCGM (CGM group). In group 2, patients used professional CGM (iPro2) and DTI is performed based on the capillary blood glucose levels (BG) measured using "glucometers for SMBG, that were compliant with ISO15197:2013 diagnostic test systems" ("GISO") [ACCU-CHEK Guide] (BGM group). In both groups, CGM was attached on the day of hospitalization (day 1) and used for 6 days. In group 1, all 288 SG were referenced for the intervention in real-time. In group 2, BG referenced for the intervention in real-time were measured at pre- and post- prandial time and bedtime (7 points) on days 2 and 5 and pre-prandial time and bedtime (4 points) on days 3 and 4. We preliminarily analyzed the 24-h SG measured using professional CGM (iPro2) for 150 patients with type 2 diabetes at our hospital to determine the target range for intervention using rtCGM to achieve both time-in-range (70–180 mg/dl) [TIR] $>$ 70% and coefficient of variation [CV] $<$ 36%. From this analysis, we determined the target range to achieve TIR $>$ 70% as "75–160 mg/dl" and that to achieve CV $<$ 36% as "within $\pm$30% of mean glucose levels". In both groups, DTI was performed at evening from day 2 to day 5 and morning from day 3 to day 5 based on the DTI algorithm unified for each CGM group and BGM group, where that determened target range was used. Two patients in the BGM group were excluded from this study because they could not carry out the research protocol (CGM group: $n=8$, BGM group: $n=6$). Patients in the CGM group achieved both TIR $>$ 70% and CV $<$ 36% earlier than those in the BGM group (1.4 days vs 2.7 days; $P=0.03$: Log-rank test). During hospitalization, the DTI with reference to rtCGM may achieve both TIR $>$ 70% and CV $<$ 36% slightly earlier than that with reference to BGM.

Dynamics of C-peptide in patients with type 1 diabetes mellitus on the administration of Tolerogenic Dendritic Cells

Tatsiana Mokhort[1], Alena Mokhort[1], Volha Shyshko[2], Yana Minich[3], Elena Shishko[1], Natalia Antonevich[3], Andrei Hancharou[3] & Volha Lazovtseva[2]
[1]Belarusian State Medical University, Endocrinology, Minsk, Belarus; [2]Minsk City Clinical Endocrinological Center, Minsk, Belarus; [3]The Institute of Biophysics and Cell Engineering of National Academy of Sciences of Belarus, Minsk, Belarus

Introduction
Preserving of C-peptide secretion in type 1 diabetes mellitus (DM1) is an important goal in treatment, as it provides the possibility of optimal compensation. Various approaches are used to achieve this goal. We initiated a study to assess the potential effect of the cell therapy based on autologous Tolerogenic Dendritic Cells on the newly diagnosed DM1 (NCT05207995, ClinicalTrials.gov).
Methods
4 patients who were injected with Tolerogenic Dendritic Cells were given standard breakfast (carbohydrate content of 50 g). Fasting glycemia was determined in patients, the test was performed with fasting glycemia in the range of 3.8–9.0 mmol/l, short-acting insulin was not administered before breakfast. The test was carried out for 2 hours with the determination of the level of C-peptide at 0, 30, 60, 90 and 120 minutes. The levels of C-peptide after food stimulation were studied with the calculation of AUC (area under curve). Determination of the level of C-peptide is carried out by the method of chemiluminescent enzyme immunoassay on the analyzer Cobas E411 by Roche Diagnostics (Germany).
Results
There were no changes in insulin requirements (0.56 ± 0.16 U/kg vs 0.52 ± 0.18 U/kg during therapy), and basal levels of C-peptide (1.05 ± 0.55 ng/ml vs 1.36 ± 0.47 ng/ml during therapy) after the administration of Tolerogenic Dendritic Cells. When assessing stimulated levels of C-peptide, we detected an increase in AUC from 220.7 ± 111.9 ng/ml$\times$h. up to 317.6 ± 103.2 ng/ml$\times$h. Also, during continuous monitoring of glycemia, the time in the target range (TIR) reached the recommended value (more than 70%) and only in one patient the target level was not reached (TIR was 51%).
Conclusion
Short-term use of Tolerogenic Dendritic Cells is accompanied by an increase in the secretion of C-peptide in the process of food intake.

The role and mechanism of peptide MSCP2 in regulating inflammation

Ling Li, Lianghui You & Tianying Zhong
Women's Hospital of Nanjing Medical University (Nanjing Maternity and Child Health Care Hospital), Nanjing, China

Mesenchymal stem cell (MSC), as a significant part of regenerative medicine, has been considered as a promising therapy in several diseases. Recently, the secretion effect of MSCs has been found to play a key role in the regulation of inflammatory. Here, we screened different peptides with high expression abundance by mass spectrometry from the supernatant of human umbilical cord MSCs. Also, we identified a peptide (AQTKRLVGDVLLATAFLSYSGP) named MSC-P2 derived from dynein axonemal heavy chain 5. Thus, we explored the role and potential mechanism of MSC-P2 in regulating inflammation of RAW 264.7 cells. ProtParam tool was used to analyze the physicochemical properties of MSC-P2. The instability index (II) of MSC-P2 is computed to be 20.50, classifying itself as a stable peptide. The aliphatic index is 110.91 and grand average of hydropathicity (GRAVY) is 0.441, proving its hydrophobicity. MSC-P2 entered into the cytoplasm of RAW 264.7 cells in 24 hours by fluorescence microscope. Cell Counting Kit-8 detection showed that MSC-P2 exerted no significant cytotoxicity at the concentration from 1uM to 100 uM. Besides, Real-time PCR showed that the mRNA expression levels of iNOS, TNF-α, and IL-6 were significantly down-regulated in the MSC-P2 group, compared with the control group ($P < 0.05$). Consistently, the protein expression levels of iNOS and TNF-α were significantly reduced in the MSC-P2 group, compared with the control group ($P < 0.05$) by Western blot and immunofluorescence. RNA transcriptome sequencing identified 2028 up-regulated genes and 1819 down-regulated genes in the MSC-P2 group ($|\log_2 FC| > 1$ and FDR < 0.05). KEEG analysis revealed that the down-regulated differentially expressed genes (DEGs) were mainly enriched in the pro-inflammation pathways including cytokine−cytokine receptor interaction, NF−kappa B signaling pathway, and NOD−like receptor signaling pathways. Besides, the up-regulated DEGs were mainly concentrated in metabolic pathways associated with anti-inflammation roles including fatty acid metabolism, biosynthesis of unsaturated fatty acids and PPAR signaling pathway. PPI network of top 30 DEGs was built by using the STRING database and it revealed 40 nodes and 92 edges. Most of these genes involving the network, such as Isg15, Fasn, Psmd11 and Tlr4, have been reported with the roles in the regulation of inflammation. This study will help us better understand the protective functions of the secretome from MSCs. In addition, it will provide an anti-inflammatory peptide, which will become a potential drug for prevention and treatment of inflammatory-related metabolic diseases.

Intake of alpha-lipoic acid (thioctic acid) and insulin autoinmune syndrome. A case report

Leticia Serrano Urzaiz, Pablo Trincado, Patricia De Diego, Wendy Valeria Gonzalez, Macarena Lacarta & Carlos Moreno
Hospital Miguel Servet, Endocrinology and Nutrition, Zaragoza, Spain

A 52-year-old female patient with no previous history of interest, and with no prescribed habitual chronic treatment, was admitted to our hospital to be studied for symptomatic hypoglycemias of one month of evolution. Symptoms consisted of malaise, hunger, tremors and profuse sweating that disappeared with food ingestion. She referred hypoglycemic (up to 40 mg/dl) episodes daily, both in fasting and postprandial periods. She even suffered nocturnal episodes that woke her up. On physical examination the patient showed a good general condition, no abdominal masses were palpable, with neither acanthosis nigricans, abdominal obesity, nor lipodystrophic phenotype. Anthropometrically, she presented a waist circumference of 77 cm, a height of 154 cm, a weight of 54 kg and a BMI of 23. As for family history, one brother had been studied for postprandial hypoglycemia. On admission, blood tests showed a glycemia of 46 mg/dl with insulin 257 µIU/ml, proinsulin 5.3 pmol/l and beta-hydroxybutyrate 0.72 mg/dl. A mixed meal tolerance test was performed, showing hypoglycemia at 240 minutes of 53 mg/dl with insulin levels of 1012 µIU/ml and C-peptide of 1.62 ng/ml. Behind time, in a scheduled fasting test, no sugar levels below 45 mg/dl were evident. Research for hypoglycemic agents in urine was negative. The diagnosis of endogenous hyperinsulinism was therefore made and the study was completed with a thoracoabdominal CT scan and a somatostatin receptor scintigraphy where no focal lesions were observed. The study was completed with an echo endoscopy where two space-occupying lesions were evidenced in the pancreatic body which were punctured by FNA. In the pathological anatomy no neoplastic signs were evident. Positive anti-insulin antibodies were found (86.9% N 0-8.2). Hanging in there about previous treatments, the patient revealed a previous one month- treatment with a multivitamin that contained Lipoic Acid due to a meralgia paresthetica. HLA class II typing showed DRB1*04:03 and DRB1*15 alleles, commonly associated with Hirata disease. This is a common cause of hypoglycemia in Eastern ethnicities but extremely rare in Western populations. It is associated with drugs having a sulfhydryl group such as methimazole and lipoic acid among others. The patient was released with a diet distributed in 6 daily intakes, avoiding prolonged periods of fasting, and rich in complex carbohydrates. In addition, treatment with Diazoxide (50 mg/day) and Acarbose (75 mg/day) was started. These drugs where progressively decreased and in three months the patient gradually improved until all hypoglycemias disappeared.

Predictive factors of obesity among adolescents in the governorate of Sousse, Tunisia

Sawsen Nouira, Ben Fredj Sihem, Rim Ghammem, Zammit Nawel, Maatoug Jihen & Harrabi Imed
Hospital Farhat Hached, Sousse, Tunisia

Introduction
Obesity in youth has become increasingly common. This study aims to determine the predictive factors of obesity in adolescents.
Materials and Methods
This is an analytical cross-sectional study of a representative sample of high school students in the year 2019. Overweight and obesity were defined based on age- and sex-specific body mass index (BMI) z-score cutoffs. Data were analyzed using SPSS 20.0 software.
Results
A total of 1153 adolescents were recruited. The mean age was 17.19 ± 1.14 years with a minimum of 13 years and a maximum of 19 years. The sex-ratio M/F was 0.6. Obesity affected 9.4%, 95% CI [7.9%-11%] of adolescents. Regarding predictive factors, there was a female predominance (69.4%) in the obese group, whereas in the normal weight group, the female sex represented (59.4%), ($P=0.002$). Obesity was more common in adolescents with depression (68%) than in those without depression (31%) ($P<10\text{-}3$). We also noted that the majority (91%) of the obese used social networks versus (8%) who did not have access to these means ($P<10\text{-}3$). We found that (68%) of the obese did not engage in regular physical activity versus (31%) who did practice regular activity ($P=0.012$).
Conclusion
Normalization of body weight before the onset of puberty is very important because adolescents who are obese often maintain their weight until adulthood. In addition, obesity in adolescence is significantly associated with an increased risk of cardiovascular and metabolic diseases, such as type 2 diabetes, in adulthood. This study has identified some predictive factors of obesity in adolescents. The identification of these modifiable factors makes it possible to propose corrective actions to prevent the associated risk.

Impact of maternal obesity on the course and outcome of pregnancies and breastfeeding

Yousra Settai, Bensbaa Salma, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
UHC Ibn Rochd, Endocrinology, Diabetology, Nutrition and Metabolic, Casablanca, Morocco

Introduction
Obesity is a public health problem that also affects pregnant and breastfeeding women. Pre-gestational obesity is deleterious and can lead to several maternal and fetal complications, as well as a delay in the initiation of breastfeeding. The objective of this work is to evaluate the impact of maternal obesity on pregnancy, labor and the quality of breastfeeding.
Material and method
Prospective case-control study conducted at the endocrinology department of the UHC Ibn Rochd Casablanca. The study group included 50 obese parturients, and the control group 50 non-obese parturients. All our patients were followed for a diabetic pregnancy.
Results
The average age of our patients was 31 years (22-42), the average gestational age 27 SA (10-36). The average BMI was 36.2 kg/m^2, with an average pre-gestational BMI of 33.5 kg/m^2. The average weight gain during pregnancy was 15.3 kg. Gestational diabetes predominated at 58%, with 38% of DT2 and 4% of DT1. In the study group, gestational diabetes was diagnosed at the first trimester in 36% of patients. In the obese group, a higher rate of HTAG (42%; $P=0.004$), pre-eclampsia (12%; $P=0.004$), threats of premature delivery (14%, $P=0.005$) were observed., miscarriages and fetal deaths in utero (8%, $P=0.03$). Labor was obstructed in 12% of parturients ($P=0.001$), with a postpartum haemorrhage rate of 4% ($P=0.05$). A macrosomia rate of 24% was objectified in the obese group. Breastfeeding was initiated immediately postpartum in 72% of parturients, with an interruption of breastfeeding at 6 months in 44%. OGTT returned in favor of T2DM in 41.3% of patients whose diabetes was discovered during pregnancy.
Conclusion
Pre-gestational maternal obesity, as well as excessive weight gain during pregnancy, condition the course and outcome of pregnancy, with a higher rate of maternal-fetal complications, the risk of developing type 2 diabetes, as well as early termination of breastfeeding. Hence the importance of making obese patients aware of pre-gestational weight loss, with regular weight monitoring during pregnancy, in order to limit weight gain.

Bilateral Cataracts in a Young Patient with Newly Diagnosed Diabetes: A unique Observation

Benlafqih Maryame, Hind Timihiri, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
Arrazi Hospital, Faculty of Medicine and Pharmacy of Marrakech, Mohammed VI University Hospital, Endocrinology, Marrakech, Morocco

Introduction
Cataracts are an opacification of the crystalline lens, either partial or total, primarily caused by senescence, and rarely of metabolic origin. We present the case of a 24-year-old newly diagnosed with bilateral cataracts.
Case Presentation
E.S., a 24-year-old with newly discovered diabetes on insulin therapy, presented with a sudden and significant decrease in visual acuity. Ophthalmologic examination revealed bilateral cataracts with an inaccessible fundus. The patient was referred to us with an HBA1C of 13% for preoperative management.
Discussion
Diabetes is a metabolic disease that can have ophthalmic complications, particularly retinal and crystalline. Cataracts complicate diabetes in 8.8-22%. The pathophysiology of this cataract would be explained either by hyperglycemia leading to an elevation of glucose and its metabolites in the crystalline lens, the excess of intracellular glucose is unable to be metabolized by hexokinase, is converted into sorbitol and then into fructose. However, sorbitol and fructose do not cross the cell membrane, and accumulate, leading to intracellular hyperosmolarity or disruption of the function of the Na + K + ATPase pump, which can make the crystalline lens more sensitive to oxidative stress.
Conclusion
Cataracts are a rare complication of diabetes, especially in young people with newly diagnosed diabetes, which makes our observation unique.

Newborns's condition and pregnancy outcomes in women with gestational diabetes

Olga Gumeniuk[1], Nataliia Kurmacheva[1], Yuriy Chernenkov[1], Michail Svinarev[1,2], Olga Panina[1] & Larisa Bochkova[1]
[1]Saratov State Medical University, Saratov, Russia; [2]Region Paediatric Hospital, Russia

Gestational diabetes mellitus (GDM) is a carbohydrate intolerance with onset or first recognition occurring during pregnancy. GDM could be risk factor for various maternal fetal complications.
Objective
To study newborns's condition to mothers with GDM and pregnancy outcomes in women with GDM.
Patients and methods
Obstetric and perinatal outcomes were compared in two mother-child groups. Group I consisted of 69 mothers with uncontrolled GSD and their 71 children, group II – 59 women with controlled GSD and 60 of their children. According to the existing criteria, blood plasma glucose values in pregnant women on an empty stomach/before meals/at night <5.1 mmol/l, and 1 hour after meals <7.0 mmol/l were considered normal.
Results
Mothers with uncontrolled GSD had statistically significant higher rates of pre-obesity and obesity before pregnancy (62.3% and 44.1% accordingly; $P<0.05$), chronic gynecological diseases (94.2% and 81.4% accordingly; $P<0.05$), preeclampsia (29.0% and 8.5% accordingly; $P<0.001$) and the threat of termination of pregnancy (40.6% and 20.3% accordingly; $P<0.05$) compared to women with controlled GSD. Group 1 newborns were statistically significant more likely to have complications and diseases of the early neonatal period (50.7% and 26.7% accordingly; $P<0.001$), macrosomia (25.4% and 11.7% accordingly; $P<0.05$), neonatal jaundice (12.7% and 1.7% accordingly; $P<0.05$), cerebral ischemia (46.5% and 23.3% accordingly; $P<0.001$), birth trauma (14.1% and 3.3% accordingly; $P<0.05$). Only children of group I had congenital malformations in 16.9% of cases. The incidence of diabetic fetopathy in group I newborns was almost 2 times higher, but without significant differences (12.7% and 6.7% accordingly, $p>0.05$). The presence of macrosomia and diabetic fetopathy in group II newborns may be associated with late diagnosis of GSD (after 30 weeks of gestation).Conclusion. A significantly higher frequency of adverse perinatal outcomes in newborns, as well as obesity, gynecological diseases and pregnancy complications in women with uncontrolled GSD compared to mothers with controlled GSD and their children was established. To normalize glycemic parameters in pregnant women with GDM and improve obstetric and perinatal outcomes, it is necessary to promptly prescribe rational insulin treatment schemes, if diet therapy is ineffective, and improve the quality of patient follow-up.

Diabetes and survival in patients with squamous cell carcinoma of the upper aerodigestive tract

Mohamed Masmoudi, Chaima Zitouni, Wadii Thabet, Ezer Chebil, Mehdi Hasnaoui & Khelifa Mighri
Taher Sfar Hospital, ENT Department, Mahdia, Tunisia

Introduction
Type 2 diabetes is associated with an increased risk of cancer and with reduced survival in several types of cancer. However, data for upper aerodigestive tract carcinoma are limited.
Objective
Our aim of this report is to study the impact of diabetes on survival among patients with upper aerodigestive tract squamous cell carcinoma.
Material and Methods
A retrospective study of 130 patients treated for upper aerodigestive tract squamous cell carcinoma, between 1992 and 2019. Nasopharyngeal, nasal cavity and paranasal sinus carcinomas are excluded. We used the Kaplan–Meier method to calculate the cumulative proportion surviving. Survival curves were compared by log-rank test ($P<0.05$ for statistical significance). We used the Cox regression model for multivariate analysis.
Results
Our study included 117 men and 13 women. The mean age was 59 years. The tumor sites were: larynx (100 cases), hypopharynx (20 cases), tongue (9 cases) and lip (1 case). Twenty-nine patients (22.3%) had type 2 diabetes mellitus. No patient had type 1 diabetes mellitus. Five-year overall survival was 62.1% for nondiabetic group compared with 55.4% for diabetic group. There was no statistically significant difference between the 2 groups ($P=0.77$). Five-year disease-free survival was 60.8% for nondiabetic group compared with 54.7% for diabetic group, without significant difference ($P=0.63$). Multivariate analysis of overall and disease-free survival did not demonstrate a statistically significant difference between the diabetic and nondiabetic groups ($P=0.2$ for overall survival and $P=0.7$ for disease-free survival).
Conclusion
The impact of diabetes on survival in upper aerodigestive tract squamous cell carcinoma is controversial in the literature. Our results demonstrate that there is not a difference statistically significant in overall or disease-free survival among non-diabetic and type 2 diabetes mellitus patients.

Quality of life in patients with severe complications of diabetic foot syndrome with chronic kidney disease

Khamidulla Shokirov & Telman Kamalov
Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, Tashkent, Uzbekistan

Aim
To evaluate the effect of the terminal stage of CKD on the quality of life (Qol) associated with health in patients with DFS.
Material and Methods
48 patients were examined with DM 2 in the period 2021 -2022 .All observed patients were divided into 2 groups: 1 gr. - 23 patients with DFS, complicated by ulcers, gangrene and amputation and combined with CKD 4-5 stages on hemodialysis. 2 gr - 25 patients with DFS, complicated by gangrene and amputation, without CKD. The control group amounted to 20 healthy persons. The patients were performed biochemical (bilirubin, straight, indirect, lipid spectrum, Alt, Ast, Coagulogram, blood sugar, glycated hemoglobin, urea, creatinine, and instrumental: ECG, MRI of foot, etc. The quality of life was evaluated using the international questionnaire a brief form SF-36.
Results
Both groups consisted of patients with an active form of diabetic foot (ulcer, stacker stop, infection) and were comparable by age and sex. It was found that patients with DFS and tsCKD on hemodialysis have significantly higher levels of creatinine, lower levels of hemoglobin, lower levels of albumin, higher performance of peripheral arteries, and lower neuroarthropathy rates of Charcot than in patients with DFS without tsCKD. In patients with DFS with tsCKD on hemodialysis there is a decrease in the quality of life, manifested by low indicators of both physical (by 49.3%) and psychological (by 50.1%) health components. Patients with DFS without tsCKD have a decrease in the of Qol., manifested by low indicators of both physical (by 27.8%) and psychological (by 34.6%) health components
Conclusions
tsCKD negatively affects physical quality of life to a greater extent than mental, in patients with DFS. 2).

Quality of life in patients with diabetic neurogenic bladder

Faten Haj Kacem Akid, Abdel Mouhaymen Missaoui, Siddiqa Soomauroo, Wafa Belabed, Nabila Rekik Majdoub, Mouna Elleuch & Mohamed Abid
Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Background and Aim
Diabetic neurogenic bladder (DNB) is a frequent complication affecting up to 45% of patients suffering from diabetes mellitus (DM). Our study aims to evaluate the impact of DNB on the quality of life (QoL) in this population.
Patients and Methods
We conducted a descriptive cross-sectional study involving 200 patients with DNB. Their QoL was assessed using the Ditrovie scale.
Results
The mean age was 59.3 ± 10.6 years with a female predominance (55.5%). The average duration of diabetes was 11 ± 7.9 years. Mixed insulin-oral antidiabetic treatment (44.2%) was most often proposed. A glycaemic imbalance was noted in 79.7% of patients with a mean HbA1C of 9.2 ± 2.4%. Microvascular complications related to diabetes were frequent: retinopathy (29.6%), nephropathy (9.5%), and sensory-motor neuropathy (53.5%). Macroangiopathy was reported in 21.6%. Overactive bladder (70.5%) was the most reported urinary

disorder, followed by dysuria (51.5%) and stress urinary incontinence (22.5%). The mean Ditrovie score in our series was 2.52 (range = 1-5). QoL was impaired in 44% of patients who described their experience as "bad" (9.5%), "average" (13%), or "worse" (21.5%). Only 18.2% of the surveyed patients had received consultations for their urinary discomfort. Less than 5% were cured or satisfied with the management.

Discussion

DNB is an autonomous complication that is largely underestimated in clinical practice. Patients presenting DM do not report symptoms unless the urinary discomfort would have a severe impact on daily activities. Thus, screening for these disorders should be done systematically by healthcare providers during diabetes consultations.

Dietary and metabolic factors predictive of pancreatitis occurrence in type 1 diabetes

Abdel Mouhaymen Missaoui, Fatma Mnif, Siddiqa Soomauroo, Mouna Elleuch, Mouna Mnif, Nabila Rekik Majdoub, Dhoha Ben Salah & Mohamed Abid

Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Objective

to analyze the dietary and metabolic factors predictive of the occurrence of pancreatitis in patients with type 1 diabetes mellitus (T1DM).

Patients and Methods

Analytical case-control study of 31 T1DM patients separated into two subgroups: G1 ($n = 10$): T1DM cases with pancreatitis. G2 ($n = 21$): T1DM controls without pancreatitis.

Results

The age at diagnosis of T1DM was comparable between the two groups. A discrete female predominance was noted in G1 (60% vs 38.1%; $p > 0.05$). The mean BMI was higher in G2 (20.7 ± 3.7 vs 22.9 ± 4.2 kg/m^2; $P = 0.839$). Controls had more android fat distribution (25% vs 14.3%; $P > 0.05$). G1 T1DM had a higher calorie diet than G2 (2838.8 ± 889.4 vs 2777.8 ± 872.8 kcal/d; $p > 0.05$) with higher intake of simple sugars (42.33 ± 24.1 vs 33.5 ± 35.2 g/d), calcium (558.3 ± 177.7 vs 519.6 ± 226.6 mg/d) but lower fibre (13.7 ± 3.9 vs 17 ± 6.3 g/d). The markers were similar except for phosphorus, which was significantly higher in G1 (1.13 ± 0.41 vs 1 ± 0.23 mmol/l); $P = 0.037$)The dietary and metabolic factors aggravating the risk of pancreatitis in T1DM were associated with dyslipidemia (OR = 3.3; $P = 0.000$), the presence of a metabolic syndrome (OR = 8.14; $P = 0.000$), pre-existing microangiopathy (OR = 3.84; $P = 0.013$) and iterative diabetic keto-acidosis (OR = 2.96; $P = 0.049$).

Discussion

Prevention and treatment of dyslipidemia and metabolic syndrome are key to reducing the risk of pancreatitis in T1DM. Dietary management and physical activity remain the most effective.

Influence of diabetes mellitus on changes in preperitoneal fat measured by nutritional ultrasound, in a cohort of patients who required intensive care unit (ICU) admittance due to severe covid-19 pneumonia, during a 6-month follow-up program

Víctor José Simón Frapolli[1], Isabel Vegas Aguilar[1], Victoria González Rosa[2], Ana María Sánchez García[3], Francisco José Tinahones Madueño[1] & José Manuel García Almeida[1]

[1]Hospital Universitario Virgen de la Victoria, Endocrinology and Nutrition, Málaga, Spain; [2]Complejo Hospitalario Universitario Insular Materno Infantil, Endocrinology and Nutrition, Las Palmas de Gran Canaria, Spain; [3]Hospital Universitario Virgen de la Victoria, Intensive Care Unit, Málaga, Spain

Introduction and Objectives

Preperitoneal fat is an ectopic visceral adipose tissue with a significant proinflammatory metabolic impact. The objective of this study is to measure preperitoneal fat by nutritional ultrasound at discharge, 3 months and 6 months in a cohort of patients who required admission to the Intensive Care Unit (ICU) due to severe COVID-19 pneumonia, and to analyze the differences based on the presence or not of previous DM.

Material and Method

Complete morphofunctional assessment was performed on 76 patients who were admitted to the ICU due to severe COVID-19 pneumonia, at discharge, 3 months and 6 months. Subsequently, preperitoneal fat measured by nutritional ultrasound was compared between diabetic and non-diabetic patients, using ANOVA for paired data (corrected by the Bonferroni test).

Results

Prospective observational study including 76 patients, 22 diabetics and 54 non-diabetics.

Conclusion

During follow-up, patients without diabetes present a statistically significant decrease in preperitoneal fat, probably related to the resolution of the intercurrent infection (decrease in CRP during follow-up). In contrast, in diabetic patients it remains constant with no differences during follow-up despite the progressive decrease in CRP, which may be related to the chronic metabolic impact produced by DM.

Table 1 Severity of Acute COVID-19 by Serum Glucose Levels and BMI

	Baseline	3 months	6 months	Global *P* (a,b,c)
Preperitoneal fat (non-DM) (cm)	0.856(0.5)	0.671(0.5)	0.469(0.3)	**0.011**(0.056,0.09-2,1.000)
Preperitoneal fat (DM) (cm)	0.503(0.3)	0.469(0.3)	0.538(0.4)	0.859(0.848,0.97-5,1.000)

a = statistical significance baseline-3 months ($P < 0.05$).
b = statistical significance baseline-6 months ($P < 0.05$).
c = statistical significance 3 months-6 months ($P < 0.05$).

Hyperhomocysteinemia in type 2 diabetes, a risk factor for the complications of diabetes?

Elyes Kamoun[1,2], Meriem Yazidi[1,2], Sameh Hadj Taieb[2,3], Nadia Khessairi[1,2], Ibtissem Oueslati[1,2] & Melika Chihaoui[1,2]

[1]Hospital Rabta, Endocrinology Department, Tunis, Tunisia; [2]Faculté de Médecine de Tunis, Tunis, Tunisia; [3]Hospital Rabta, Department of Biology, Tunis, Tunisia

Introduction

Patients with type 2 diabetes mellitus are considered at least at high cardiovascular risk. Cardiovascular risk factors must be regularly screened. Hyperhomocysteinemia is considered as an independent risk factor for atherosclerotic disease and coronary disease in some studies. The aim of our study was to confirm the association between hyperhomocysteinemia and atherosclerotic disease in patients with type 2 diabetes.

Methods

We performed a cross-sectional study including 257 type 2 diabetes mellitus patients. For each patient, we looked for personal history of high blood pressure, the duration of diabetes, its treatment and its complications. HbA1c and homocysteine were measured. Hyperhomocysteinemia was diagnosed when homocystein levels were above 15 µmol/l.

Results

The mean age was 59.8 ± 8 years, with extremes ranging from 32 to 84 years old. Mean duration of diabetes was 10.4 ± 5.3 years, with extremes ranging from 3 to 27 years. Hypertension was present and treated in 61.1% of the patients. Mean HbA1c was 8.7 ± 1.9% with extremes ranging from 5.6% to 15.7%. A macrovascular complication was present in 21.8% of cases, with a coronary disease in 17.9%, a cerebrovascular accident in 5.1% and a peripheral artery disease in 1.9% of cases. A microvascular complication was present in 79.4% of cases, with retinopathy in 23.7%, a nephropathy in 31.2%, and a peripheral neuropathy in 54.5% of cases. Mean homocysteine level was 13.3 ± 5.2µmol/l. A hyperhomocysteinemia was found in 26.5% of patients. Hyperhomocysteinemia

was positively associated with age ($P=0.001$), male gender ($P=0.001$), the presence of a macrovascular complication ($P=0.002$), and of a cerebrovascular accident ($P=0.046$). High blood pressure, coronary disease, peripheral artery disease, retinopathy, nephropathy, peripheral neuropathy and HbA1c level were not associated with hyperhomocysteinemia.
Conclusion
Hyperhomocysteinemia is frequent in type 2 diabetic patients. The association between hyperhomocysteinemia and macrovascular complications in particular cerebrovascular disease makes us consider the impact of homocystein levels on the onset of cardiovascular disease and how it consists as a risk factor to monitor.

Advanced glycation end products association in patients with diabetes mellitus

Erika Jurkutė[1], Lina Radzevičienė[1,2], Rasa Verkauskienė[1,2], Deimantė Kardonaitė[2] & Milda Danelienė[1,2]
[1]Department of Endocrinology Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania

Introduction
Advanced glycation endproducts (AGEs) are sugar-modified products that arise during the non-enzymatic glucose oxidation process. AGEs promote oxidative stress and are associated with poor diabetes mellitus (DM) control, metabolic syndrome, and cardiovascular disease.
Objective
to evaluate AGEs accumulation in the diabetic patients' skin and its relationship with DM type, disease duration, and complications.
Methods
116 patients (19-85 years, 66 females and 50 males) with type 2 (T2DM) and type 1 (T1DM) DM, were enrolled in the study during the 2022 year. AGEs were measured non-invasively using an AGE Reader device (DiagnOptics Technologies B.V., SN 00010604, The Netherlands). Patients filled out questionnaires about diabetes and data on diabetes type, duration, and control were collected from medical records. Patients were divided into groups according to: DM types, disease duration (<15 ($n=61$) and ≥ 15 ($n=54$) years), microvascular DM complications (with ≥ 1 microvascular complication ($n=72$) and without ($n=43$)), macrovascular DM complications (with ≥ 1 complication ($n=24$) and without ($n=92$)).
Results
50 T1DM (30 females and 20 males; age 40 ± 12.4 SD years; DM duration 18.8 ± 0.495 SD years) and 60 T2DM (36 females and 30 males; age 63.4 ± 9.4 SD years; DM duration 11.6 ± 8.4 SD years) participated in the study. A significantly higher mean AGEs concentration was found in T2DM vs T1DM patient group (2.4 ± 0.4 SD vs 2.2 ± 0.5 SD, respectively, $P=0.011$). Also, higher mean levels of AGEs were found in patients with longer duration of DM (≥ 15 years) (2.2 ± 0.4 SD vs 2.4 ± 0.4 SD, respectively, $P=0.047$). No significant difference in AGEs concentration between the groups of patients with and without microvascular complications was found (2.4 ± 0.5 SD vs 2.3 ± 0.4, $P=0.327$). However, a higher mean concentration of AGEs was observed in the group of patients with macrovascular DM complications (2.6 ± 0.4 SD vs 2.3 ± 0.4 SD, respectively, $P=0.002$).
Conclusion
A significantly higher AGEs accumulation was found in patients with T2DM, those with macrovascular complications, and longer than 15 years of disease duration. The presence of microvascular complications was not related to concentration.

COVID-19 infection in lipodystrophy syndromes

Gökçen Güngör Semiz[1], Tevfik Demir[1], Ilgin Yildirim Simsir[2], İsmail Selimoğlu[3], Müge Yılmaz[4], Mehmet Çağrı Ünal[1], Hülya Ellidıkuz[5], Hüseyin Onay[6], Ramazan Gen[7] & Bahri Evren[8]
[1]Dokuz Eylul University, Faculty of Medicine, Internal Medicine, Division of Endocrinology and Metabolism, İzmir, Turkey; [2]Ege University, Faculty of Medicine, Internal Medicine, Division of Endocrinology and Metabolism, İzmir, Turkey; [3]Dokuz Eylul University, Faculty of Medicine, Internal Medicine, İzmir, Turkey; [4]Ege University, Faculty of Medicine, Internal Medicine, İzmir, Turkey; [5]Dokuz Eylul University Institute of Oncology, Department of Preventive Oncology, İzmir, Turkey; [6]Ege University, Faculty of Medicine, Medical Genetics, İzmir, Turkey; [7]Mersin University Faculty of Medicine, Internal Medicine, Division of Endocrinology and Metabolism, Mersin, Turkey; [8]İnönü University Faculty of Medicine, Department of Internal Medicine, Division of Endocrinology and Metabolism, Malatya, Turkey

Purpose
The coronavirus disease 2019 (COVID-19) has a high morbidity and mortality in patients with chronic disorders. This study was aimed at assessing the frequency and outcomes of COVID-19 in patients with lipodystrophy syndrome and investigating the effect of restricted access to the hospital during pandemic on metabolic parameters.
Methods
A survey comprising descriptive questions about the situation of the patients during the COVID-19 pandemic was created and performed by a phone call. Patients were asked if they had COVID-19 so far; if so, the hospitalisation, the need for intensive care and the oxygen requirement, COVID-19 treatment and ongoing findings after COVID-19 infection were questioned. Laboratory data from hospital records were retrospectively analysed, and the results after the COVID-19 period, if any, were obtained from the patients.
Results
A total of 71 patients were included. Patients with lipodystrophy had at least one comorbid disease; diabetes mellitus was the most common (87.1%). Six patients (8.5%) stated that they had COVID-19 infection, of which three were hospitalised and one was followed up in the intensive care unit. No death was reported. Microalbuminuria was significantly worsened in all patients compared to their pre-pandemic status.
Conclusions
Patients with lipodystrophy have a high risk of severe COVID-19 due to their multiple comorbidities. Further studies with larger patient groups are needed to verify these findings. Metabolic parameters of patients with rare diseases were deteriorated during the pandemic.

The course of COVID-19 in lipodystrophic patients

	Yes, *n* (%)	No, *n* (%)
Hospitalisation	3(50)	3 (50)
Intensive care unit	1 (16.7)	5 (83.3)

Relation of HLA system genes in patients with type 1 diabetes and other autoimmune diseases

Ivan Lekić[1,2], Romana Marušić[1,3], Saška Marczi[1,4] & Tatjana Bačun[1,4]
[1]Faculty of Medicine, Osijek, Croatia; [2]Osijek Health Center, Osijek, Croatia; [3]County General Hospital Vukovar hospital and the Croatian Veterans, Vukovar, Croatia; [4]Clinical Medical Center Osijek, Osijek, Croatia

Background
Type 1 diabetes mellitus (T1DM) is caused by destruction of pancreatic beta cells. Children and adolescents with type 1 diabetes have an increased risk of developing other autoimmune diseases, most commonly autoimmune thyroiditis and celiac disease.
Objectives
To examine the frequency of individual human leukocyte antigen (HLA) alleles in people with T1DM and associated autoimmune (AI) diseases of the thyroid, digestive system, and skin, and to examine differences in gender and age at the time of diagnosis.
Subjects and Methods
Subjects were patients referred to the Clinical Institute of Transfusion Medicine for HLA typing. Data were collected in Clinical hospital center Osijek (HLA typing findings, associated autoimmune diseases of the thyroid gland, digestive system, and skin; age and sex).
Results
The study was conducted on 147 subjects with T1DM (51.7% women, 48.3% men). The AI disease of thyroid were most common (24.5%). Distribution of subjects by age groups differs significantly. The most common HLA alleles in men are HLA-DRB1*03, -DQA1*05, -DQB1*02, and in women HLA-DRB1*03, -DQA1*03, -DQB1*03(DQ8). Subjects with T1DM were more likely to have the DRB1*03-DQA1*05-DQB1*02 haplotype, and female subjects with T1DM were more likely to have the DRB1*08-DQA1*03-DQB1*03(DQ8) haplotype. There is a significant difference in the distribution of subjects with respect to the presence of autoimmune AI thyroid disease vs HLA-DRB1*03/*10,-DRB1*03(DQ8); AI of the digestive system disease relative to HLA-DRB1*01; AI skin disease versus HLA-DRB1*01, -DQB1*05.
Conclusion
Age is associated with an earlier diagnosis of T1DM, while gender is not. Individual HLA alleles have been associated with the earlier onset of T1DM and AI disease. The incidence of T1DM in the population is increasing and a proper understanding of the mechanism of occurrence is crucial to better diagnose and prevent the development of complications.

Features of the GCK-MODY and HNF1A-MODY: Dynamic observation data

Alla Ovsyannikova[1], Dinara Ivanoshchuk[1], Elena Shakhtshneider[1], Marina Dudina[1] & Oksana Rymar[1,2]
[1]630089, Research Institute of Internal and Preventive Medicine – Branch of the Institute of Cytology and Genetics, Siberian Branch of Russian Academy of Sciences, Novosibirsk, Russia; [2]630089, Siberian Branch of Russian Academy of Sciences, Novosibirsk, Russia

Diabetes mellitus (DM) type MODY (Maturity Onset Diabetes of the Young) accounts 10% of cases of diabetes with onset before 35 years. The aim was to determine characteristics of the course of the main types of MODY.
Materials and Methods
45 patients aged 18 to 35 years diagnosed with MODY molecular genetic testing (next-generation sequencing technology and direct automated Sanger sequencing) were included: 31 had mutations in the *GCK* gene, 14 - in the *HNF1A* gene, they were under dynamic observation for three years. All patients had at baseline and after three years: clinical examination, biochemical blood test, determination of HbA1c, C-peptide, thyroid status, microalbuminuria. Statistical processing of the results was done using the SPSS 20 program.
Results
The median age of patients with GCK-MODY was 21.5 [18.3; 34.6] years, HNF1A-MODY – 24.4 [19.8; 34.8] years ($P=0.108$). The majority of patients (87.1% and 96.8%) ($P=0.562$) with GCK-MODY had no symptoms of hyperglycemia at baseline and after three years. Hypercholesterolemia (25.8%) and allergic reactions (22.6%) prevailed among comorbidities. Patients with GCK-MODY had normal level of median C-peptide - 0.9 [0.6; 1.1] ng / ml at baseline; 0.8 [0.6; 1.9] ng/ml at 3 years ($P=0.864$), HbA1c targets were achieved (median 6.3 [6.0; 6.9]%; 6.5 [6.1; 7.0]% - after three years ($P=0.130$)). 48.4% achieve normoglycemia with a diet. 57.1% with HNF1A-MODY had symptoms of hyperglycemia at baseline and 14.2% ($P=0.062$) after three years. Hypercholesterolemia (64.3% at baseline; 46.2% after three years) ($P=0.180$) and arterial hypertension (28.6% at baseline and after three years) ($P=1.000$) prevailed among comorbidities. Median of C-peptide - 0.8 [0.6; 1.0] ng / ml at baseline; after three years - 0.6 [0.5; 1.0] ng/ml ($P=0.840$)) was normal; HbA1c levels increased slightly (7.0 [6.6; 7.6]% and 7.2 [6.7; 7.5]% ($P=0.102$)). Most patients achieve normoglycemia with oral antihyperglycemic therapy (42.9% at baseline, 50.0% at three years) ($P=0.668$)).
Conclusions
1. Majority patients with GCK-MODY had an asymptomatic course of the disease with moderate, non-progressive fasting hyperglycemia.2. Majority patients with HNF1A-MODY had stable indicators of carbohydrate metabolism remained during dynamic monitoring but they had poorly metabolic control in comparison with GCK-MODY.Acknowledgements: Abstract was written of the grant of the President of the Russia for state support of young Russian scientists - doctors of sciences MD-3017.2022.3.

EP262

Diabetic health literacy and its association with medication adherence among adult patients with type 2 diabetes mellitus

Meriem Marrakchi[1], Sarra Tira[2] & Mouna Gargoury[3]
[1]Basic Health Center, Carthage, Tunis, Tunisia; [2]Basic Health Center, Marsa, Tunisia; [3]Security forces hospital, Marsa, Tunisia

Introduction
Poor adherence to prescribed diabetic medication is a major contributor to disparities in effective glycemic control among patients with type 2 diabetes mellitus. The purpose of this study was to investigate the association between health literacy level and adherence to diabetic medications among this population.
Methods
A cross-sectional survey enrolled 66 patients medically treated for type 2 diabetes mellitus. Patients with dementia syndromes or impaired cognition were excluded. diabetic medication adherence and health literacy were evaluated respectively by the 6-item Morisky Medication Adherence Scale and the 16-items European Health Literacy Survey Questionnaire (HLS-EU-Q16). Socio-demographic characteristics were assessed during the consultation.
Results
The mean age of patients was 63.35 ± 12.63 years. Adherence scores ranged from 0 to 6 with a mean score of 2 ± 1. Overall, only 16.7% of participants had good adherence levels to diabetic medications. The mean score on the literacy questionnaire was 7 ± 3. Adequate health literacy was associated with a higher adherence score ($P=0.001$) and better glycemic control ($P=0.03$). Internet was reported to be the preferred source of health information by 60% of participants with adequate health literacy. All the participants with inadequate health literacy answered wrong about the doctor's comprehension questions. The low educational level ($P=0.041$), lack of medical and social security ($P<0.01$), and low socioeconomic levels ($P<0.01$) were correlated with inadequate health literacy.
Discussion
In this study, no correlation was found between male sex and adequate health literacy, this finding is different from previous research studies and may be explained by the limited variability in health literacy scores among study participants and the limited number of the population. However, the straight of our study that it is one of the rare studies in our country investigating the association between health literacy and diabetic medication adherence among patients with type 2 diabetes mellitus.
Conclusion
Tailored interventions considering health literacy are needed to support medication adherence in order to improve glycemic outcomes of patients with type 2 diabetes mellitus. Additional studies are needed to identify and prioritize factors targeting an effective adherence intervention for this population.

Insulin resistance in the course of acne

Anna Sadowska-Przytocka[1], Michalina Gruszczyńska[2], Weronika Szybiak[2] & Katarzyna Łącka[3]
[1]Poznan University of Medical Sciences, Dermatology, Poznań, Poland; [2]Poznan University of Medical Sciences, Scientific Section at the Department of Endocrinology, Metabolism and Internal Medicine, Poznań, Poland; [3]Poznan University of Medical Sciences, Endocrinology Metabolism and Internal Medicine, Poznań, Poland

Introduction
Acne vulgaris is a common skin disorder among both adolescents and adults. Its multifactorial pathogenesis may include insulin resistance, especially in cases resistant to classical treatment methods. There are few studies which have already

proved acne vulgaris development in the course of insulin resistance, however, there are more studies necessary in order to include insulin resistance evaluation in classical acne vulgaris diagnosing and treatment.
Objective
To investigate acne vulgaris development in the course of insulin resistance.
Material and Methods
41 acne vulgaris patients and 47 healthy age and BMI-matched controls were involved in the study. Glucose and insulin fasting serum levels were obtained from each participant, later HOMA-IR was calculated and insulin resistance was diagnosed in cases with HOMA-IR value over 2.1.
Results
The mean ± SD glucose fasting serum level was 94.88 ± 7.731 [mg/dl] in study group and 79.51 ± 7.175 [mg/dl] in control group ($P < 0.001$). The mean insulin fasting serum level was 14.47 ± 6.394 [μIU/ml] in study group and 11.83 ± 4.309 [μIU/ml] in control group ($P = 0.059$). Calculated HOMA-IR mean value in study group was 3.4 ± 1.49 and in control group 2.34 ± 0.909 ($P < 0.001$).Out of 41 patients 32 were diagnosed with insulin resistance (78%) and out of 47 controls 26 were diagnosed with IR (55%) ($P = 0.026$).
Conclusions
HOMA-IR values were found to be statistically higher in acne patients compared to healthy controls. Insulin resistance diagnosis was statistically more common among the group of acne patients compared to controls. Insulin resistance might be an independent factor in acne vulgaris development and should be considered in the process of acne diagnosing and treatment.

Prevalence and factors associated with hypoglycaemia in type 1 diabetes

Abir El Amri, Zohra Hadj Ali, Asma Cherni, Malek Bejaoui, Ikram Hmaidi, Hedfi Imene, Chaima Jemai, Yosra Htira & Feika Ben Mami
Institut De Nutrition, Tunis, Tunisia

Introduction
Hypoglycaemia is the most common metabolic complication in type 1 diabetes. Although rarely dangerous, it significantly impairs quality of life. The aim of our study was to determine the prevalence and factors associated with hypoglycaemia in T1DM.
Methods
Descriptive cross-sectional study conducted over 3 months in ward C of the Institute of Nutrition, which included patients with type 1 diabetes.
Results
Fifty-seven patients were included, of whom 31 were women and 26 men. The characteristics of the patients were respectively: age: 32.3 ± 9.6 years, BMI: 23.16 ± 3.1 kg/m^2, HbA1c: 10 ± 2.2%, duration of diabetes: 16.1 ± 8.8 years, duration of insulin therapy > 10 years: 65%. Forty-two patients were on human insulin and 15 patients on insulin analogues. Of these, 78% were on basal/bolus plus. 72% of our patients had at least one episode of hypoglycaemia in the previous 6 months. The frequency of hypoglycaemia was correlated with the length of time the patient had diabetes ($P = 0.02$), the number of insulin injections per day ($P = 0.013$) and with gender, with women having more hypoglycaemia than men ($P = 0.028$). Moreover, the higher the frequency of hypoglycaemia, the higher the HBA1C ($P = 0.031$). However, there was no statistically significant correlation between the prevalence of hypoglycaemia and chronic degenerative complications of diabetes.
Conclusion
In T1DM patients, the predictive factors for hypoglycaemia are: female gender, duration of diabetes, duration of insulin treatment and number of injections.

Mauriac syndrome: A case report

Abir El Amri, Ramla Mizouri, Ines Bani, Rym Ben Othman, Nadia Ben Amor, Faten Mahjoub, Berriche Olfa & Jamoussi Henda
National Institute of Nutrition, Tunis, Tunisia

Introduction
Mauriac syndrome is typically characterised by poor glycaemic control in type 1 diabetics. It is associated with diabetes, hepatomegaly, disturbed liver function and severe staturo-weight delay.
Observation
We report the case of a young type 1 diabetic patient referred to our department for further management of a glycaemic imbalance. The patient was 16 years old, type 1 diabetic for 10 years on insulin analogues, with a history of vitiligo since the age of 5 years, febrile convulsion at the age of 3 years, put on valproic acid for 2 years. The clinical examination showed a delay in growth and development and puberty (< 4 DS, Tanner stage 1), hepatomegaly with a liver arrow at 17 cm. The biological work-up showed an HbA1c of 11%, hepatic cytolysis at 3 times normal with negative hepatitis B and C serology. A strictly normal hormonal work-up including FSH, LH, testosteronemia, cortisol and GH with normal GH stimulation test. Celiac disease serology was negative with no villous atrophy on oesogastroduodenal fibroscopy. Abdominal CT scan showed homogeneous hepatomegaly with regular liver contours. Based on these clinical, biological and radiological arguments, Mauriac syndrome was strongly suspected, hence the indication for a liver biopsy, which was refused by the patient.
Conclusion
Our observation illustrates the importance of evoking Mauriac's syndrome when hepatomegaly with statural delay is discovered in a type 1 diabetic. The diagnosis of certainty is histological and the treatment is based on the control of diabetes.

The clinical and biological factors associated with the use of insulin therapy in women with gestational diabetes

Marwa El Arem[1,2], Kamilia Ounaissa[3], Fatma Boukhayatia[3] & Chiraz Amrouche[3]
[1]University Hospital, Endocrinology, Monastir, Tunisia; [2]Hospital Fatouma Bourguiba, Endocrinology, Monastir, Tunisia; [3]Institut de Nutrition, Hopital du Jour, Tunis, Tunisia

Objective
The objective of our study was to identify maternal and biological factors associated with the use of insulin therapy in patients with GDM.
Methods
Retrospective study including 100 pregnant women followed up for gestational diabetes during the year 2021. Information was collected from medical records and supplemented, if necessary, by telephone interviews with the patients.
Results
The mean age of the patients was 32.7 ± 4years. Half of the population had a first-degree family history of type 2 diabetes and 52% were obese with a mean body mass index of 29 ± 5.5 kg/m^2. The mean gestational age at discovery of GDM was 19.4 ± 7SA. The diagnosis was made on the basis of pathological fasting blood glucose in 67% of cases. Insulin therapy was indicated in 32% of cases. Compared to pregnant women with diabetes controlled by dietary measures alone, insulin-treated patients had higher gestational age and parity, earlier gestational age at discovery of GDM and more frequently had two pathological oral glucose values, but the difference was not significant. In multivariate analysis, the factors significantly associated with the use of insulin therapy were the existence of a first-degree family history of type 2 diabetes, pre-gestational obesity and an HbA1c ≥ 5.5% at the discovery of GDM.
Conclusion
Knowledge of the factors associated with insulin therapy helps to optimise the management of gestational diabetes and thus improve the maternal-fetal prognosis.

Comparison of cardioprotective effects of empagliflozin and vildagliptin

Volha Vasilkova[1], Ivan Pchelin[2] & Tatsiana Mokhort[3]
[1]Gomel State Medical University, Endocrinology, Gomel, Belarus; [2]Saint Petersburg State University, Saint Petersburg, Russia; [3]Belarusian State Medical University, Minsk, Belarus

Background and Aim
To study the cardioprotective effects of empagliflozin and vildagliptin in patients with diabetes type 2.
Method
90 patients with type 2 diabetes were randomized using a random number generator into 3 groups, depending on the antihyperglycemic therapy prescribed for the next 6 months: the group that continued to receive gliclazide and metformin, the group in addition to gliclazide and metformin received vildagliptin at a dose of 100 mg/day, the group in addition to gliclazide and metformin received empaglilflozin at a dose of 25 mg/day.

Results
Empagliflozin therapy was accompanied by regression of the left ventricular mass index (118.00 [116.00; 121.00] g/m^2) vs 121.00 [118.00; 122.00] g/m^2) and a decrease of the natriuretic peptide (proBNP) (23.50 [16.70; 33.30] pg/ml vs 31.00 [24.30; 46.20] pg/ml ($p < 0.05$).
Conclusion
SGLT2 inhibition by empagliflozin has a complex and multifunctional effect on the body that can effectively influence cardiovascular outcomes.

Experience of the transition from pediatrics to adult medicine by young type 1 diabetics

Yousra Settai, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
UHC Ibn Rochd, Endocrinology, Diabetology, Nutrition and Metabolic, Casablanca, Morocco

Introduction
Type 1 diabetes (T1D) is the most common metabolic disease in children and adolescents. The transition of care from pediatrics to adult medicine is a real challenge and can be experienced by patients as a huge struggle.
Objective
The objective of this work is to retrospectively study the experience of transition by young type 1 diabetics, in order to shed light on the factors facilitating or hindering this transition.
Materials and Methods
Retrospective study conducted in the endocrinology and diabetology department of the UHC Ibn Rochd, including 60 T1D patients followed in the young adult consultation, referred from the pediatric diabetology department of Harouchi hospital. These patients answered a questionnaire concerning their experience of this transition.
Result
The average age of our patients was 16 years (14-20), with a female predominance (60%), all were on a basal bolus regimen. The average age of diagnosis of diabetes was 7 years. The average age of transition was 14 years old. The announcement of the transition was made by the pediatrician in all our patients. Regarding the feelings of patients at the time of the announcement, 41.6% were curious, 45% worried, 5% refused the transition, and 8.3% had no opinion. The average HbA1c at the time of transition was 8%. At the first young adult consultation, 70% of patients were accompanied by their mother, 25% by their father, 5% came alone. The establishment of trust with the healthcare team was rapid in 60% of patients. The first hospitalization in adult medicine was for diabetic ketosis in 66% of patients (including 70% on insulin withdrawal), severe hypoglycemia in 5%, and for glycemic imbalance in 29%. The average time between the transition and the first hospitalization was 6 months. Regarding the overall experience of the transition in our patients, it was easy and smooth in 40%, difficult in 45%, while 15% did not realize it.
Conclusion
The transition from pediatrics to adult medicine is a critical period for young people with T1D which can be difficult for some, thus causing a glycemic imbalance, or even acute decompensation of their diabetes. Hence the importance of being aware of the factors hindering this transition in order to make it easier, especially during adolescence.

Pseudohyponatremia caused by hyertriglyceridemia: A case report

Amina Ben Brahim[1], Marrakchi Rim[1], Boudaya Mariem[1], Ben Ayed Assawer[1], Mhadhbi Hayet[1], Jamoussi Kamel[1], Turki Mona[1], Hadj Kacem Faten[2] & Abid Mohamed[2]
[1]Hedi-Chaker University Hospital, Biochemistry Department, Sfax, Tunisia; [2]Hedi-Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Introduction
Serum sodium assay is one of the most commonly performed laboratory tests in a hospital setting. However, in some instances, the reported laboratory sodium results may not reflect the true actual values. Overcorrection of the serum sodium levels in pseudohyponatremia may cause serious complications
Case Presentation
A 31-year-old woman was hospitalized in June 2022 in endocrinology department for asymptomatic hyponatremia. She was followed in endocrinology department since 2014 for hypertriglyceridemia (Familial hyperlipoproteinemia type 4). She has a history of type 1 diabetes treated withi nsulin since 2009 and 3 episodes of acute pancreatitis (type D and E), the last one was in December 2015. Results of Biochemical parameters at admission were as follows: sodium 124 mmol/l, potassium 3.7 mmol/l, chloride 98 mmol/l, triglyceride 20 mmol/l, cholesterol 4.3 mmol/l, glycemia 3.5 mmol/l.His laboratory results obtained with AU 480® Beckman Coulter. Given the high triglyceride level in the sample as a potential cause of pseudohyponatremia, we used a direct ISE (electrode selective of ions) method on ABL80® Radiometer to check sodium concentration and obtained a result of 139 mmol/l in a sample with a sodium of 124 mmol/l by the indirect ISE on AU 480® Beckman Coulter.
Conclusion
Pseudohyponatremia is a measurement artifact when the fraction of solid-phase particles is more than the physiological range like in hyperlipidemia.Clinicians must be aware about the methods involved in the measurement to prevent mismanagement in such conditions. Direct ISE may be an alternate option in these conditions.

Ultrasonographic features of thyroid nodules and thyroid gland in obese patients

Neslihan Çuhacı Seyrek[1], Nurcan Ince[1], Sevgul Faki[2], Husniye Baser[1,3], Abbas Ali Tam[3], Şefika Burçak Polat[1], Oya Topaloglu[1], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Ankara Yıldırım Beyazıt University, Faculty of Medicine, Departments of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara City Hospital, Departments of Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara Yıldırım Beyazıt University, Faculty of Medicine, Ankara, Turkey

Objective
Thyroid nodules are one of the most common thyroid diseases. Ultrasonography is an reliable and the most commonly used imaging method in the evaluation of thyroid nodules with a high sensitivity (Sn) and specificity (Sp). The prevelance of obesity, especially severe obesity, is increasing at an alarming rate in the worldwide. Although obesity and thyroid disorders are related to each other, the pathological relationship between those is not clear. Several studies have revealed that thyroid nodules are associated with adiposity which is assessed by body mass index (BMI). In this study we aimed to evaluate the morphological structure of the thyroid gland and thyroid nodules in obese patients according to the degree of the obesity.
Methods
273 patients with BMI>30 kg/m^2 and applied to our endocrinology outpatient clinic between 2019 and 2022 years for obesity or any other reason and also requested thyroid ultrasonography and thyroid function tests were analyzed retrospectively. The demographic data of the patients (sex, age), thyroid function tests, thyroid ultrasonography features (thyroid gland size, volume, parenchyma structure, and, if any, nodule and nodule features) and also if there is thyroid nodule cytology, were evaluated. According the body mass index patients were divided as class I (BMI;30-34.9 kg/m^2), class II (BMI; 35-39.9 kg/m^2) or class III (BMI; ≥ 40 kg/m^2) obesity.
Results
Total of the 273 patients, 53 (19.4%) were male, 220 (80.6%) were female. 19 (7%) , 60 (22%), and 194 (71%) of the 273 patients had class I, II, and class III obesity, respectively. Ultrasonographically, the thyroid parenchyma was heterogeneous in 221 (92.9%) of the patients. But there was no statistically significant thyroid gland heterogeneity between the groups. Anti thyroglobulin antibody positivity was significantly higher in class III obese patients ($P=0.047$), but no significant difference was found in antiTPO antibody positivity and thyroid function tests between obesity classes. Also there was no significant difference between obesity classes and thyroid nodule features including; echogenicity, structure, halo sign, border regularity, presence of calcification and also thyroid nodule cytology. Conclusıon: Although we could not found a relationship between obesity classes and thyroid function tests and nodule features, most of the obese patients had parenchymal heterogeneity. Considering the increasing incidence of obesity and frequency of thyroid nodules, thyroid ultrasonography will be useful in obese patients.

Prevalence of obesity complications in a group of obese patients undergoing bariatric surgery

Faten Mahjoub, Abir El Amri, Nadia Ben Amor, Ines Bani, Rym Ben Othman, Ramla Mizouri & Jamoussi Henda
National Institute of Nutrition, A, Tunis, Tunisia

Introduction
Obesity is recognized as a continuously growing, global public health problem. It is associated with increased risk of a variety of acute and chronic disorders.
Objective
The aim of our work was to estimate the prevalence of obesity-related complications in a group of patients undergoing sleeve gastrectomy.
Methodology
Retrospective, descriptive study of a group of obese candidates for bariatric surgery recruited from the obesity research unit of the National Institute of Nutrition. All patients underwent a thorough interview, physical examination and biological analysis to rule out secondary obesity and to look for metabolic complications of obesity.
Results
Our study included 40 patients, 7 men and 33 women. The mean age of the patients was 34.6 years [18-57]. The mean BMI was 50.23 ± 8.27 kg/m^2. The mean waist circumference was 137.75 ± 16.09 cm. The prevalence of morbid obesity was 95%. Nearly two thirds of the subjects had a first degree family history of obesity. The prevalence of smoking and alcoholism was 27% and 2.5% respectively. The prevalence of metabolic complications of obesity was 7.5% for hyperuricemia, 37.5% for hypercholesterolemia, 67.5% for hypoHDLemia and 30% for hypertriglyceridemia. Concerning the disorders of carbohydrate tolerance, type 2 diabetes was found in 17.5% of patients, moderate fasting hyperglycaemia in 40% of patients and carbohydrate intolerance in 2 patients. Hypertension was diagnosed in 20% of patients. PCOS and fertility disorders were observed in 18% and 10% of obese women respectively. Digestive complications such as non-alcoholic fatty liver disease, vesicular lithiasis and gastroesophageal reflux were noted in 62.5%, 7.5% and 25% of cases respectively. Bone and joint complications were dominated by gonarthrosis in 57% of patients. obstructive sleep apnea syndrome (OSAS)was noted in 80% of patients with 32% mild, 22% moderate and 25% severe OSAS.
Conclusion
Our work demonstrates a significant prevalence of obesity complications in our population. This justifies the need for early and adequate management of obesity in order to prevent the occurrence of these complications.

Impact of Ramadan fasting on the metabolic profile of obese patients

Imane Hasbi, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
University Hospital Center Ibn Rochd, Endocrinology and Metabolic Diseases, Casablanca, Morocco

Introduction
During Ramadan, patients often have an inappropriate eating behaviors which can have an impact on the metabolic profile, particularly in obese subjects.
Aim
The Aim of the study is to evaluate the effects of Ramadan fasting on the metabolic profile of obese patients.Patients and methods: This is was a prospective study including 109 obese patients with BMI ≥ 30 kg/m^2 aged 19 to 80 years of both sexes followed in the Endocrinology and metabolic diseases department of the IBN Rochd hospital center in Casablanca or seen at the consultation from March to May 2022. The patients were divided into 2 groups (fasting, non-fasting). A clinical and biological evaluation was carried out before and after Ramadan.
Results
The study population consisted of 109 patients, 80.7% were female and 19.2% were male. The average age was 55.92 ± 8.6 years. 87.15% of the patients were diabetic. Comparing the groups studied before and after Ramadan fasting, there was an increase in HbA1C in the non-fasting group (10.4 ± 2.13% against 9.4 ± 1.09%) ($P = 0.01$) compared to the fasting group where HbA1C remained stable (7.4 ± 0.89% vs 7.4 ± 1.82%). A slight decrease in fasting glycemia was objectified in fasting people ($P = 0.001$). Regarding anthropometric parameters, there was a slight weight loss (0.5-1 kg) with a decrease in BMI in the fasting group (33.1 kg/m^2 against 33.8 kg/m^2) ($P = 0.01$). In the fasting group, a slight increase in LDL levels was observed after Ramadan, but there was no significant change in total cholesterol, triglycerides and HDL levels.
Conclusion
This study indicated that Ramadan fasting caused a slight decrease in blood glucose and weight. Although there was a significant reduction in meal frequency, a slight increase in LDL was observed during Ramadan. It appears that the effect of Ramadan fasting on serum lipid levels may be closely related to diet.

DOI: 10.1530/endoabs.90.EP272

Ferrokinetic parameters in patients with diabetes mellitus type 2 and Covid-19

Ina Darashkevich[1], Tatsiana Mokhort[2], Olga Martinkevich[3] & Mikhail Kurbat[4]
[1]Grodno State Medical University, Grodno, Belarus; [2]Belarusian State Medical University, Minsk, Belarus; [3]Grodno University Clinic, Grodno, Belarus

Recent evidence points to a relationship between the severity of Covid-19 infection and iron metabolism. In patients with type 2 diabetes mellitus (DM 2), the prevalence of anemia of chronic diseases exceeds the general population indicators, which may be one of the factors determining the increase in mortality in this category of patients with Covid-19.
Aim
To determine the differences between markers of ferrostatus indicators in patients with DM 2 and Covid-19 depending on the value of blood oxygen saturation (SpO2).
Materials and Methods
The study included 84 patients with Covid-19 and DM 2. The levels of glycated hemoglobin (HbA1c), C-reactive protein (CRP), glomerular filtration rate (eGFR), interleukin6 (IL6), ferritin, serum iron (SI), transferrin, soluble transferrin receptors (STR), parameters of a general blood test were determined; SpO2 was assessed; damage to the lung tissue according to computed tomography scan of the lungs was evaluated. All patients we divided into 2 groups. Group 1 included patients with SpO2 $\geq$ 95%, group 2 - SpO2 $<$ 95%. The comparison groups did not differ in eGFR and HbA1c.
Results
Having analyzed the results of the study the following data were obtained. The data significantly differed between SpO2 values in groups 1 and 2 - 95.0 [95.0; 96.0]% vs 89 [87.0; 91.0]%,($P = 0.003$). Group 2 had the greatest damage to the lung tissue - 67.2 [65.0; 70.0]% vs 48.3 [40.0; 60.0]%, $P = 0.001$, maximum indices of inflammatory markers CRP (74.8 [69.0; 76.0] vs 45.4 [39.0; 53.0] mg/l, $P = 0.023$, IL6 (64.8 [59.0; 72 .0] vs 38. 2 [14.5; 51.0] pg/ml, $p = 0.031$ and minimal hemoglobin values (110 [101.0; 115.0] g/l vs 119 [108.0;121.0] g/l, $P = 0.017$). The ferrokinetic parameters differed significantly between the comparison groups. Ferritin above the acceptable target values was noted in two groups (in group 2-842.0 [663.0; 942.0] ng/ml vs 350.0 [310.0; 393.0] ng/ml, ($P = 0.003$)). The SI in group 2 was 0.6 [0.5; 0.9] vs 1.1 [0.8; 1.3], $P = 0.018$, the value of transferrin in group 2 was 1.3 [1.2; 2.0] vs 2.1 [1.9; 2.8], $P = 0.021$; STR in group 2 - 1.1 [0.8; 1.3] mg/l vs 1.3 [0.9; 1.4] mg/l in group 1, $P = 0.041$.
Conclusions
In the group of patients with type 2 diabetes and Covid-19 with SpO2 $<$89%, the most pronounced disturbances of ferrokinetic parameters were registered, which may be one of the factors determining the more severe course of Covid-19. STR is within the normal range, which indicates the absence of signs of iron deficiency anemia. Probably, there is a redistribution of iron in the body in patients with DM 2 and Covid-19 infection.

New onset diabetes and COVID-19 and: what type?

Gorchene Asma[1], Taieb Ach[1], Jihene Sahli[2], Ben Abdelkarim Asma[1], Nassim Ben Hadj Slama[1], Hamza Elfekih[1], Ghada Saad[1], Molka Chadli Chaieb[1] & Koussay El Euch[1]
[1]Farhat Hached Hospital, Endocrinology Department, Sousse, Tunisia; [2]Farhat Hached Hospital, Community Medecine, Sousse, Tunisia

Introduction
During the COVID-19 pandemic, an increase of new-onset diabetes has been reported in various diabetes centers with many studies speculating an auto-immune-triggering mechanism while other studies hypothesizing an increase of type 2 diabetes (T2D).

Aim
The aim of this study is to compare the type of new-onset diabetes presenting with a diabetic ketoacidosis and its prevalence in the pre-pandemic vs pandemic COVID-19.
Methods
This is a comparative study of patients hospitalized in the diabetology department in the university hospital Farhat Hached of Sousse for a new-onset diabetic ketoacidosis in the pre-pandemic period (between March 2018 until March 2020) (G1) and 203 admitted during the pandemic period (between March 2020 until March 2022 (G2).
Results
A total of 340 patients were hospitalized in the diabetology department in the university hospital Farhat Hached of Sousse for a new-onset diabetic ketoacidosis, with 137 patients admitted in the pre-pandemic period (G1) and 203 admitted during pandemic period (G2). There was no significant difference in the prevalence of type 1 diabetes (T1D) between G1 and G2 as 54 out of 137 patients (39.41%) were T1D in G1 vs 81 out of 201 patients (40.2%) in G2. In the same way, the prevalence of T2D did not differ between the two groups with 83 out of 137 (60.5%) patients were T2D in G1 vs 120 out of 201 (59.1%) patients in G2 ($P=0.871$). Anti-GAD antibodies levels significantly increased during the pandemic period compared with the pre-pandemic period with a median value of 92.5 IQR [22.5-1074] in G1 vs 330 IQR [58.5-1795] in G2 ($P=0.021$). Anti-IA2 antibodies levels significantly increased as well during the pandemic period compared to the pre-pandemic period with a median value of 0 IQR [0-104.75] in G1 vs 93 IQR [0-3571] in G2 ($P=0.009$). No significant difference was found regarding anti-ZNT8 antibodies levels between the two groups ($P=0.475$).
Conclusion
Although the prevalence of T1D does not seem to increase during COVID-19, the increase of anti-GAD and anti-IA2 antibodies levels may reflect an increase in the intensity of auto-immune reaction of T1D during COVID-19.

Stressful war conditions trigger eating disorders and worsen metabolic control in diabetic 2 patients

Fedir Laniush[1], Alina Urbanovych[1] & Solomiia Shykula[2]
[1]Danylo Halytsky Lviv National Medical University, Endocrinology, L'viv, Ukraine; [2]Danylo Halytsky Lviv National Medical University, L'viv, Ukraine

Background and Aims
the war has become a stressful factor for many people in Ukraine. It is known that eating disorders (ED) might be triggered by a great stress. Binge eating disorder (BED) and night eating syndrome (NES) belong to hyperphagic ED mostly affecting those with obesity and diabetes type 2 (DT2). In our study we investigated how the war changed eating behavior and metabolic control in DT2 patients.
Materials and Methods
63 individuals (mean age – 54.1±7.3 years; BMI - 34.8±3.6 kg/m^2) with DT2 and without previous history of BED or NES were recruited into the study. All participants were receiving adequate therapy and did not stop taking antidiabetic medications during study period. They completed Binge eating scale-7 and Night eating questionnaire to diagnose BED and NES respectively. The level of glycated hemoglobin (HbA1c) before the war was checked in electronic healthcare system and measured again during war conditions.
Results
9 participants (14.3%) were screened positive with BED and 7 (11.1) – with NES. The current HbA1c level was significantly higher (7.8% vs 9.1%, $P<0.05$) when comparing with its level before the war. 12 (19%) participants reported about more frequent binge episodes that occur after the end of air raid warning. 5 (7.9%) individuals reported about binge episodes during the electricity blackout.
Conclusion
metabolic control of DT2 depends on a reaction to stressful life conditions. A serious stress factor for initiating BED and NES is war. Binge episodes occur more frequent during stressful events such as air raid warning or blackouts. War conditions require a tight metabolic control and an adequate stress management to avoid decompensation of diabetes and development of ED.

The Mediterranean Diet: Effects on insulin resistance and secretion in subjects with obesity

Annamaria Docimo[1], Ludovica Verde[1], Claudia Vetrani[1], Luigi Barrea[2], Annamaria Colao[1,3] & Giovanna Muscogiuri[1,3]
[1]University of Naples Federico II, Clinical Medicine and Surgery, Section of Endocrinology, Diabetology and Andrology, Naples, Italy; [2]Pegaso Telematic University, Human Sciences, Naples, Italy; [3]University of Naples Federico II, UNESCO Chair for Health Education and Sustainable Development, Naples, Italy

Introduction
A higher adherence (HA) to the Mediterranean Diet (MD) is associated to a lower risk of developing type 2 diabetes (T2DM). However it is less clear if this is caused by a "food cluster" (FC) or a single MD food effect on the insulin-resistance (IR) and/or on the insulin-secretion (IS).
Aim
This study investigated the association between MD adherence, IR and IS, indirectly measured, in subjects affected by obesity without diabetes (SNDO). The secondary aim was to determine if the FC or a single MD food is linked to IR and/or IS.
Methods
Participants underwent to an OGTT and an evaluation of IR (HOMA-IR and ISI) and IS (HOMA-β, OGIS e β-cell function). MD adherence was determinated through the PREDIMED questionnaire (0-5, 6-9, ≥10 for low (LA), intermediate (IA) and HA, respectively).
Results
Sixty-two SNDO were enrolled (9M/53F, 43.7±12 years, BMI 36±6.1 kg/m^2). The 18% of the SNDO had Impaired Fasting Glucose (IFG) whilst the 13% had Impaired Glucose Tolerance (IGT).Despite there were no significant differences in terms of BMI, SNDO with HA showed significantly lower values of HOMA-IR ($P<0.05$) compared to an IA and higher values of ISI ($P<0.05$) compared to a LA. MD adherence was inversely correlated to HOMA-IR (*r*:-0.400; *P*:0.004) and directly correlated with ISI (*r*:0.296, *P*:0.039). Among the MD food, fish was directly related with ISI (*r*:0.394, *P*:0.005) and inversely related with HOMA-IR (e *r*:-0.327, *P*:0.019) (Table 1).
Conclusions
A HA to the MD, and in particular the consumption of fish, is associated to a lower IR in SNDO and this was probably mediated by high content of polyunsaturated fatty acids.

Table 1 Participants' demographic and antropometric parameters and insulin-sensibility and secretion indexes

Parameters	Low adherence (PREDIMED: 0-5) ($n=12$)	Intermediate adherence (PREDIMED: 6-9) ($n=36$)	High adherence (PREDIMED: ≥10) ($n=14$)
Gender (M/F)	4/8	3/33	2/12
Age (Years)	41±14	45±12	45±11
BMI (kg/m^2)	39±7	36±6	35±6
WC (cm)	120±27	113±14	107±13
HOMA-IR	4.1±1.1	5.0±2.9	2.3±0.9‡
HOMA-β	18±5.5	20±5.9	10±4.1
OGIS (ml × min^{-1}× m^{-2})	395±62	406±72	440±52
ISI ((mg/dl)^2/(μU/ml)2) $^{-1/2}$)	2.7±0.9	3.0±2.0	4.5±2.6*
β-cell function (mg/μU)	0.5±0.2	0.6±0.5	0.8±0.3

The data are presented in terms of an average and SD.

Relationship between diabetic microangiopathy and sexual dysfunction in women with type 2 diabetes

Meriem Marrakchi[1], Nesrine Dhieb[2], Kamilia Ounaissa[2], Mehrez Achwak[2], Fatma Boukhayatia[2], Asma Ben Brahim[2], Rim Yahyaoui[2], Haifa Abdelsellem[2] & Chiraz Amrouche[2]
[1]Basic Health Center, Carthage, Tunisia; [2]National Institute of Nutrition, Tunis, Tunisia

Introduction
Female sexual dysfunction (FSD) is a frequent comorbidity in women with type 2 diabetes mellitus (T2DM), and is now increasingly considered a surrogate marker of endothelial dysfunction as well as a sentinel predictor of new-onset macroangiopathic events. Less attention, however, has been directed at the potential association of FSD and microangiopathy in hyperglycemic states.
Methods
We analyzed 30 consecutive female T2DM outpatients in whom FSD was assessed by the Female Sexual Function Index (FSFI) questionnaire. A score of

less than 26.55 characterizes FSD. Participants underwent a comprehensive interview, a complete eye examination and fasting blood tests. Socio-demographic and clinical characteristics were assessed during the consultation.
Results
Mean age and diabetes duration were 42.97 ± 6.6 years and 12.7 ± 6.21 years, respectively.Compared with patients without diabetic microangiopathy, those with any microangiopathy (odds ratio 12.6, $P = 0.007$) had an elevated risk of having sexual dysfunction. Women with diabetic nephropathy (odds ratio: 6, $P = 0.045$) and diabetic neuropathy (odds ratio 4, $P = 0.03$) had sixfold and fourfold increased odds of having sexual dysfunction, respectively, compared with those without diabetic nephropathy and neuropathy. Diabetic retinopathy, irrespective of presence or severity, was not independently associated with FSD ($P = 0.141$).
Conclusion
The presence and severity of diabetic nephropathy and neuropathy but not diabetic retinopathy is independently associated with self-reported female sexual dysfunction.

[1]Complejo Hospitalario Universitario Insular Materno Infantil, Endocrinología y Nutrición, Las Palmas de Gran Canaria, Spain; [2]Hospital Universitario Virgen de la Victoria, Endocrinology and Nutrition, Málaga, Spain; [3]Complejo Hospitalario Universitario Insular Materno Infantil, Hospital Pharmacist, Las Palmas De Gran Canaria, Spain

Introduction
Achieving glycemic goals remains a challenge for many people with T1D despite recent technological advances. Integrated systems and closed loops pumps have shown significant improvements in glycemic control in clinical studies as well as in real life conditions.
Objective
Assess the performance of the systems Tandem Control-IQ and DIABELOOP in people with T1D comparing the glucosa readings before and after having the device for 14 days.
Research Design and Method
Retrospective observational study of 31 adults with long-evolving T1D, carriers of continuous insulin infusion pump (BICI) for at least 10 years and FSL2 to which a Dexcom G6 sensor is implanted and then the handle is closed. 19 patients (10 women) with a mean age of 49 years, and 29 years of evolution of diabetes were carriers of Tandem Control-IQ system and 12 patients (7 women) with a mean age of 46 years and 28 years of evolution of diabetes, carriers of DIABELOOP system (DBL). Both groups had at least 90% of the time in automatic mode. The data were analyzed by student T for paired samples.
Results
Both groups started from a time under the range (TBR) <54 in objective (IQ control 0.3%; DBL 0.9%) and only the IQ control group started from a TBR <70 in objective of 2%, being 4% in the DBL group. At 14 days, improvement was observed in the rest of the glycometric parameters, being significant in the control group IQ the increase of time in range (TIR, 59.9%-69.63%, $P = 0.0014$), the reduction of average glucose (GM 169.5-156, $P = 0.0075$) and the reduction of the glucose management index (IGG 7.8-%7.1%, $P = 0.0052$). Time above range (ART) 180-250 and > 250 was reduced without reaching statistical significance (ART 30.4%-24.4%, $P = 0.07$; ART >250 11.7%-7.7%, $P = 0.058$. The DBL group showed an increase in IRR (64.2%-70.4%), and a reduction in RRT <70 (4%-1.9%), RRT <54 (0.9%-0.3%), ART (30.1%-23.6%), ART >250 (9.2%-7.2%), LD (159-156 mg/), IGG (7.21%-7.08%) and coefficient of variation, being the only one that reached statistical significance (36.2%-30.6%, $P = 0.017$).
Conclusions
In our sample of patients with long-term T1D who had previously carried BICI and FSL2, loop closure was already associated at 2 weeks with an improvement in most of the glycometric parameters. 100% of patients in the Control IQ group achieve a TBR <54. Despite this, less than 45% of patients have all the parameters in objective, so we recommend an evaluation at 14-30 days after the system is installed for an early optimization of results.

Footwear in a population of diabetic patients

Soumaya Elarem[1], Imen Dorgham[1], Aymen Haj Salah[1], Bessem Krifa[1], Nedra Feni[2], Mouna Sghir[1] & Wassia Kessomtini[1]
[1]Taher Sfar Hospital, Physical Medicine and Rehabilitation, Tunisia; [2]Ibn El Jazzar Hospital, Physical Medicine and Rehabilitation, Tunisia

Introduction
Diabetic foot is one of the major complications of diabetes. Footwear has been found to be a precipitating cause of injury leading to lower extremity ulceration and amputation in people with diabetes. The aim of this study was to determine the suitability of footwear in a population of diabetic patients.
Methods
A cross sectional study including 150 patients with diabetes mellitus was conducted. Patients were asked about their follow-up during the previous year. An evaluation of risk of foot ulceration was performed based on the International Working Group on diabetic foot (IWGDF) classification. Podiatric and footwear examination were performed.
Results
The mean evolution of diabetes in these patients was 10.5 ± 7.8 years with a six-month follow-up rate in 66% of cases. Education on glycemic balance, lifestyle and dietary measures was done in 73.3% of cases. While education of podiatric risk of diabetes was only done in 16.7% of patients. Foot examination during the previous year was noted in only 12.7% of cases and 10% had a screening for diabetic neuropathy. Three-quarters of the population (74.7%) had no idea about the impact of diabetes on the foot. Regarding footwear, 89.3% of patients had no idea about the criteria for choosing a good shoe and 80.7% wore inappropriate commercial shoes. Appropriate therapeutic footwear was noted in 18% of patients and even among high-risk patients (grade 2 or grade 3 of IWGDF), only 6.9% wore orthopedic shoes for diabetic feet.
Conclusion
Majority (80.7%) of the participants wore inappropriate footwear and had no idea about the impact of diabetes on the foot. during follow-up, foot examination and patient education on podiatric risk were insufficient.

After-stroke Rehabilitation outcomes of Diabetic patients

Soumaya Elarem[1], Zahra Sfar[1], Aymen Haj Salah[1], Ikram Haddada[1], Nedra Feni[2], Mouna Sghir[1] & Wassia Kessomtini[1]
[1]Taher Sfar Hospital, Physical medicine and Rehabilitation, Mahdia, Tunisia; [2]Ibn El Jazzar Hospital, Physical Medicine and Rehabilitation, Tunisia

Introduction
Stroke is the mean cause of acquired disability in adults. The objective of our study was to describe functional outcomes and complications in diabetic patients after stroke.
Patients and Methods
A descriptive study including diabetic patients followed in rehabilitation departement for vascular hemiplegia. Sociodemographic characteristics, patient history, and stroke history were collected. A functional assessment at 1 year after stroke was collected using the Barthel index, and neuro-orthopedic complications were noted in each patient.
Results
Sixty patients were included in this study. The mean age was 62 ± 12.6 years. At one year of evolution, orthopedic complications such as algodystrophy (22.5%), inferior subluxation of the humeral head (12%), spastic equinus of the feet (65%) were noted in our population. Mean Barthel index score was 45.5 meaning a moderate functional recovery.
Conclusion
Diabetes seems to worsen the long-term functional prognosis of stroke patients. This requires early and multidisciplinary management of patients with vascular hemiplegia to detect complications and improve functional recovery.

Dupuytren's disease in a patient with type 2 diabetes mellitus: A case report

Zineb Ait Si Ali, Rania Dassoufi, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari

Centre Hospitalo-Universitaire Mohammed Vi Marrakech, Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Marrakech, Morocco

Introduction
Dupuytren's disease (DD) corresponds to a chronic palpable thickening of the palmar aponeurosis which leads to different degrees of irreducible flexion of the fingers. It is one of the manifestations of hand syndrome in diabetes mellitus. We highlight through this report the occurrence of DD as a manifestation of diabetic hand syndrome in a patient with type 2 diabetes mellitus.
Observation
A sixty-six year old patient, truck driver, type 2 diabetic for twenty-two years, treated with oral antidiabetics, was admitted for treatment of an aseptic pseudoarthrosis secondary to surgical treatment of traumatic left tibial fracture. Medical history revealed poorly controlled diabetes, polyuro-polydypsia syndrome, and bilateral functional impotence limiting flexion of the first and second fingers. Clinical examination revealed bilateral flexion retraction of the first and second fingers, predominantly in the left hand, associated with palpable thickening of the palmar fascia. The rest of the osteoarticular examination did not reveal any other abnormalities except the fracture site in the left tibial bone. Biologically, the patient had an elevated HbA1c 9.7%, nonproliferative diabetic retinopathy, and chronic kidney disease at the stage of micro albuminuria. The diagnosis of fingers retraction in the context of DD with flexion deformities of the hands secondary to type 2 diabetes was retained. Therapeutic management was based initially on optimising glycaemic control and therapeutic education. Plastic surgery is planned on both hands.
Discussion
DD is a progressive fibrotic disorder of the fascia of the palm and fingers. Nodules and cords fixed to the skin and palmar fascia lead to flexural deformity of the fingers that disable normal movement of the hand, and result in the pathology of Dupuytren contracture. In people with diabetes, It mostly affects the third and fourth fingers, the thumb and the index are rarely involved. Several risk factors have been identified for DD; diabetes, increasing age, male, heavy alcohol consumption and smoking. The prevalence of DD in the diabetic population ranges from 20% to 63% depending on the series, compared to only 13% in the general population. The treatment of DD in diabetic patients does not differ from non-diabetic patients. Good glycaemic control is essential, Treatment can be medical and/or surgical. The decision to treat is guided by the functional discomfort degree.
Conclusion
DD is a fibroproliferative disorder often associated with diabetes and chronic hyperglycaemia. It causes a significant functional handicap requiring a multi-disciplinary management.

« The renal function in patients with severe complications of diabetic foot syndrome with chronic kidney disease

Telman Kamalov & Khamidulla Shokirov
Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, syndrome, Tashkent, Uzbekistan

Aim
To study renal function in patients with severe complications of diabetic foot syndrome (ulcer, gangrene, amputation) associated with chronic kidney disease.
Material and Methods
91 patients with DM 2 were examined. The patients were divided into 4 groups:1 gr. – 25 patients with DFS complicated by ulcer, gangrene and amputation and in combination with CKD 4-5 stages on hemodialysis; 2 gr. – 25 patients with DFS complicated by ulcer, gangrene and amputation in combination with CKD stages 4-5 without hemodialysis; 3 gr - 20 patients with DFS complicated by gangrene and amputation without CKD.;4 gr - 21 patients with DFS, without severe complications, with the initial stage of CKD.Research methods- biochemical (bilirubin, direct, indirect, lipid spectrum, ALT, AST, PTI, coagulogram, blood sugar, glycated hemoglobin, urea, creatinine, GFR, wound pathogens, procalcitonin,interleukin-6,vascular endothelial growth factorVEGF-A and instrumental: ECG, MRI of the feet, Dopplerography of the main vessels of the legs, ultrasound of the internal organs, the fundus.
Results
The highest rates of fasting glycemia were observed in patients of group 2, that is, with DFS and CKD 4-5 stages without hemodialysis. Significantly lower hemoglobin values were also observed in this group of patients ($P<0.001$), glycated hemoglobin significantly higher values of urea, creatinine and GFR ($P<0.001$). All patients had significantly reduced values of HDL ($P<0.001$) and total cholesterol ($P<0.05$).
Conclusion
Biochemical parameters were significantly impaired in patients of group 1, that is, with DFS and CKD 4-5 stages on hemodialysis, which indicates the need for further research in this group of patients.

Prevalence of malnutrition in elderly patients with diabetes mellitus in the hospital settings

Abdel Mouhaymen Missaoui, Nadia Charfi, Siddiqa Soomauroo, Wafa Belabed, Nabila Rekik Majdoub & Mohamed Abid
Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Objective
To estimate the prevalence of malnutrition in elderly patients with diabetes mellitus (DM) in hospital settings.
Patients and Methods
A retrospective descriptive study of 55 patients over 65 years of age who were hospitalized in the Endocrinology Department. The diagnosis of malnutrition was established according to the criteria proposed by the HAS 2021.
Results
The mean age of the elderly included was 71.4 ± 6.6 years with a female prevalence (53.7%). The age category >70 years represented 46.3% of our series. The mean HbA1C level was 11.2 ± 3.2%. Significant glycaemic imbalance (HbA1C >10%) was reported in 77.8% of cases. The majority of patients were on insulin therapy (84.9%). The average weight was 70.6 ± 15.5 kg corresponding to an average BMI of 26.7 ± 5.5 kg/m^2. Among the elderly with diabetes mellitus, 17.8% had a BMI <22. Significant weight loss was noted in 15.9%. The mean albumin level was 33.1 ± 5.8 g/l with hypoalbuminemia (<30 g/l) affecting 48.5% of patients. The overall prevalence of malnutrition was estimated at 37.5%. It was severe in 14.6%.
Discussion
The prevalence of malnutrition is estimated at 4-10% in the family home, 15-38% in institutions, and 30-70% in hospitals depending on the series. The consequences of poor nutrition are numerous and particularly detrimental in the elderly: increased mortality, frequency of complications during hospitalization (infections, bedsores, falls, etc.), and increased hospital expenditure. Nutritional screening is essential for all senior patients with DM, regardless of their caloric intake and BMI.

HPLC-MS/MS in the diagnosis of factitious hypoglycemia: A case report

Marina Yukina, Ekaterina Avsievich, Agunda Sakkaeva, Liliya Usoltseva, Vitaliy Ioutsi & Ekaterina Troshina
Endocrinology Research Centre, Moscow, Russia

Introduction
Artificial hypoglycemia (AH) is the intentional administration of insulin preparations or the use of oral hypoglycemic agents to lower blood glucose levels. It is one of the variants of Munchausen's syndrome. Hypoglycemia in non-diabetic patients is a blood glucose level of less than 3.0 mmol/l. AH among all causes of non-diabetic hypoglycemia (NDH) is approximately 4-11%. Identification of such cases is an urgent problem in the differential diagnosis of NDH, especially when insulin analogues are administered, since such insulin in the blood is not detected by many test systems.
Materials and Methods
A 28-year-old female patient complained of hypoglycemia up to 1.8 mmol/l, severe weakness, trembling in the body, which was stopped by taking fast carbohydrates. From the anamnesis it is known that the patient worked as a nurse, had long periods of disability, her family has patients with diabetes mellitus. The patient has been receiving treatment for conversion disorder for a long time. In 2015, diabetes mellitus (DM) has been diagnosed, but due to frequent hypoglycemic conditions, she received insulin episodically. MODY variants and autoimmune DM are excluded. In May 2022, during examination at the Endocrinological Research Center: HbA1c - 5.7%, C-peptide - 1.57 ng/ml, insulin

- 12.4 μU/ml, OGTT without deviations. A fasting test was initiated, after 42 hours hypoglycemia was recorded: glucose - 2.53 mmol/l, insulin 0.2 μU/ml, C-peptide 0.22 ng/ml. Hypocorticism and non-islet cell tumour hypoglycemia (NICTH) were excluded. Deliberate administration of insulin analogues is suspected. This blood sample was studied by HPLC-MS/MS, insulin Aspart was detected. When discussing the results, the patient denied the administration of insulin preparations. A conversation was held about the need to take drugs only as directed by a doctor and about the potential danger to life with self-treatment. It is recommended to continue the supervision of a psychiatrist.
Conclusion
The HPLC-MS/MS method greatly simplifies the diagnosis of factitious hypoglycemia and allows you to quickly identify not only oral hypoglycemic drugs, but also insulin analogues. In the case of diagnosing hypoinsulinemic hypoglycemia and excluding its more frequent causes (adrenal insufficiency and NICTH), it is advisable to study a hypoglycemic blood sample by HPLC-MS/MS to determine insulin analogues.

Effects of Diabetes on Clinical Outcomes of Psoriatic Patients With Coronary Artery Disease

Lin Zhao, Lin Sun, Yan Zeng & Xianliang Zhou
Fuwai Hospital, National Center for Cardiovascular Disease, Chinese Academy of Medical Sciences and Peking Union Medical College, Cardiology, Beijing, China

Background
Psoriasis is associated with a heightened prevalence of cardiovascular risk factors, including diabetes. However, it is not clear whether diabetes will cause differences on clinical outcomes of psoriatic patients who have already suffered from coronary artery disease.
Methods
We conducted a retrospective cohort study of consecutive psoriatic patients with coronary artery disease between January 2017 and May 2022 in our hospital. The clinical records, laboratory measurements and coronary angiography reports were collected, and comparisons were made between patients with and without diabetes. The Cox regression analysis and Kaplan-Meier survival analysis were used to evaluate the association between diabetes and major adverse cardiovascular events (MACEs).
Results
Of the 307 participants, 147 patients had diabetes. Individuals with diabetes were more prone to be with hypertension ($P=0.045$), history of stroke ($P=0.041$) and peripheral vascular disease ($P=0.043$). The levels of low-density lipoprotein cholesterol ($P=0.039$), uric acid ($P=0.013$) and homocysteine ($P=0.006$) were higher in the non-diabetes group. Patients with diabetes were more likely to have lesions in the right coronary artery than those without diabetes($P=0.03$). After the mean follow-up of 35.32 ± 18.61 months, MACEs were more prone to occur in diabetes group than non-diabetes group (30.0% vs 19.2%, $P=0.032$). Kaplan-Meier estimates showed the same trend. The COX regression analysis showed that diabetes [hazard ratio (HR)$=1.661$, 95% confidence interval (95%CI): 1.025–2.692, $P=0.039$] was positively associated with an increased risk of MACEs. In the subgroup analysis, diabetes was associated with the occurrence of MACEs especially in men ($P=0.008$) and in patients without chronic kidney disease($P=0.021$).
Conclusion
In psoriatic patients with coronary artery disease, patients with diabetes were more likely to have lesions in the right coronary artery and diabetes can independently predict MACEs, especially in men and in patients without chronic kidney disease. To reduce the cardiovascular disease risk associated with diabetes, it is vital to increase awareness of the condition among these patients.

Prediabetes remission after bariatric surgery: A 4-years follow-up study

Marta Borges-Canha[1], Joao Sergio Neves[1], Maria Silva[1], Fernando Mendonça[1], Telma Moreno[1], Sara Ribeiro[1], Catarina Vale[1], Juliana Gonçalves[1], Helena Urbano Ferreira[1], Sara Santos[2], Raquel Calheiros[2], Inês Meira[1], João Menino[1], Vanessa Guerreiro[1], Jorge Pedro[1], Ana Varela[1], Selma Souto[1], Eduardo Lima da Costa[1], Paula Freitas[1], Davide Carvalho[1] & CRIO Group[1]
[1]Centro Hospitalar E Universitário De São João, Porto, Portugal; [2]Instituto Português de Oncologia do Porto Francisco Gentil, EPE, Porto, Portugal

Background
Bariatric surgery leads to weight loss and to cardiometabolic risk improvement. Although prediabetes remission after bariatric surgery is biologically plausible, data on this topic is scarce.
Aim
We aimed to access pre-diabetes remission rate and clinical predictors of remission in a 4 year follow up period.
Methods
Observational longitudinal study including patients with morbid obesity and prediabetes submitted to bariatric surgery in our centre between January 2010 and December 2021. Prediabetes was defined as having baseline glycated haemoglobin (A1c) between 5.7% and 6.4% and absence of anti-diabetic drug treatment. We excluded patients submitted to gastric band surgery, or without A1c at baseline or first year of follow-up. We used logistic regression models to evaluate the association between the predictors and prediabetes remission rate.
Results
A total of 699 patients were included, 84% being female. The population had a mean age of 45.4 ± 10.1 years-old, body mass index of 43.8 ± 5.7 kg/m^2, and median A1c of 5.9 [5.8, 6.1]%. After bariatric surgery, prediabetes remission rate was 82%, 73%, 66%, and 58%, respectively at the 1st, 2nd, 3rd, and 4th years of follow-up. Gastric sleeve (GS) surgery associated to higher prediabetes remission rate than Roux-en-Y gastric bypass (GB) surgery since the 3rd year of follow-up. Men had a higher remission rate than female, except at 2nd year of follow-up. Younger patients presented a higher remission rate comparing to older patients since the 3rd year of follow-up.
Conclusion
Our results show a high prediabetes remission rate after bariatric surgery. The remission rate decreases along the follow-up period, although most of the patients uphold the normoglycemia. Prediabetes remission seems to be more significant in patients submitted to GS, male and younger patients. These results help to fill the gap in knowledge regarding the effect of bariatric surgery in prediabetes.

Insulin therapy in elderly subjects with type 2 diabetes: Evaluation of injection techniques

Fatma Zaouali[1], Najoua Lassoued[2], Zantour Baha[2], Alaya Wafa[2] & Sfar Mohamed Habib[2]
[1]University of Monastir, Family Medicine Department, Monastir, Tunisia; [2]Tahar Sfar University Hospital, Endocrinology Department, Mahdia, Tunisia

Introduction
Allowing to have a good glycemic control, presenting no contraindications and contributing to the optimization of the general and nutritional state, insulin remains a treatment of choice for the diabetic elderly. Proper injection technique is key to achieving and maintaining goal-level diabetes control. The objective of our study was to assess insulin injection techniques in elderly subjects with type 2 diabetes.
Methods
A cross-sectional study on type 2 diabetic insulin dependent elderly recruited from the outpatient endocrinology consultation over a period of 2 months from June 2021 to July 2021.
Results
We recruited 100 patients with a mean age of 70.8 ± 5.8 years and a sex ratio of 0.85. The mean durations of diabetes and insulin therapy were 15.67 ± 6.7 years and 7.69 ± 6 years, respectively. The mean level of HbA1C was 9.85 ± 1.7%. The majority of patients had uncontrolled diabetes (90%). Sixty-seven were on human insulin (67%) and thirty-three patients were on insulin analogues (33%). Pens were the instruments of injection for 33% of patients. The use of long needles of 6- and 8-mm was noted in 68% of patients although 4 mm needles are the recommended safer option. The patients were dependent on a third person to ensure the injection in 24% of cases. Abdomen and Arms were the preferred injection sites (76% and 59%, respectively). No patient used all four injection sites. Vial or cartridge of cloudy insulin was rolled or tipped less than 20 times in 2% and 3%, respectively. Extensive pen needle re-use (10+ times) for 29% of the patients exposed them to both higher intramuscular (IM) injection risk and lipohypertrophy (LH). Pain or Injection site bleeding was reported by 67% and 54% of patients, respectively. Nearly half of elderly diabetics (47%) skipped injections. In one-third of cases, patients had a history of severe hypoglycemia (35%).

Conclusion
According to our results, almost all aspects of insulin injection need to be improved in diabetic elderly subjects. This requires increased surveillance of the elderly, who face greater challenges in the feasibility of adequate injections.

DOI: 10.1530/endoabs.90.EP287

The impact of hybrid closed loop and predictive low-glucose suspend insulin pumps in the management of type 1 diabetes mellitus in children

Irina Bojoga[1,2], Victor Chiper[1], Carina Dumitrescu[1], Andreea Monica Nita[1], Victor-Costin Dumitrache[1], Elisabeta Malinici[1,2], Sorin Ioacara[1,2] & Simona Fica[1,2]
[1]"Elias" University Emergency Hospital, Endocrinology and Diabetes, Bucharest, Romania; [2]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Introduction
Hybrid closed loop (HCL) systems are made up of continuous glucose monitoring (CGM) sensor, an algorithm that receives the readings from the CGM and an insulin pump able to deliver variable insulin doses according to the information received from the other two parts. Predictive low-glucose suspend (PLGS) insulin pump is able to stop the administration of insulin before hypoglycemia occurs. These new technologies are meant to improve the quality of life and help the patient achieve better metabolic control and avoid hypoglycemia.
Materials and Methods
We performed a longitudinal retrospective study and included children with type 1 diabetes mellitus (DM1) that were admitted to our department in order to initiate PLGS or HCL insulin pump therapy. We evaluated the patients at baseline, when the insulin pump was initiated, and at follow-up, after minimum 3 months from baseline. At both moments we assessed the hemoglobin A1c (HbA1c) level and downloaded the Carelink reports that reflected the previous 90 days. The reports were available at baseline and both at follow up in 18 patients and included the parameters time in range (70-180 mg/dl) (TIR), time below range (TBR), time above range (TAR) and coefficient of variations (CV).
Results
35 children were included in the study (65.7% females), and the mean age was 10.6 ± 3.7 years. HCL pump (Medtronic 780G) was initiated in 13 patients, and PLGS insulin pump (Medtronic 640G and 740G) in 22 patients. Mean follow-up time was 8.5 months. At follow-up, all parameters were improved. HbA1c decreased significantly (7 ± 0.9% vs 6.7 ± 0.5%, $P < 0.03$). Reports revealed that TIR increased significantly (69 ± 13.7% vs 76.6 ± 11, $P < 0.001$), with TBR and TAR significantly lower: TBR 5.3 ± 3.4% vs 3.28 ± 1.84%, $P = 0.02$ and TAR: 25.2 ± 15.5% vs 20.1 ± 10.9%, $P = 0.02$. CV also decreased significantly: 37.2 ± 3.6% vs 35.2 ± 4.2%, $P = 0.04$.
Conclusion
In conclusion, HCL and PLGS insulin pumps improve metabolic control in children with DM1 and they help them achieve targets regarding glucose variability and time spent in normoglycemia, therefor avoiding short-term and long-term complications.

EP289

Evaluation of periodontal status in a population of obese patients: about 50 cases

Amine Gueddari, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
UHC Ibn Rochd, Endocrinology and Metabolic Disorders, Casablanca, Morocco

Introduction
The prevalence of obesity has increased dramatically in recent years. It is a risk factor for several chronic health problems. It is also associated with oral disease, particularly periodontal disease. Furthermore, periodontitis could contribute to obesity by inducing chewing disorders. The objective of this study was to determine the relationship between obesity and periodontal status in a group of obese Moroccan patients and to determine the main factors associated with this disease.
Materials and Methods
This is a case-control study conducted at the endocrinology and metabolic diseases department of the UHC Ibn Rochd in Casablanca and at the Ibn Rochd dental consultation and treatment center. It was spread over a year from September 2021 to September 2022.
Results
The prevalence of periodontitis was 98% in obese patients and 72% in the control group. The overall mean age was 37.54 years (± 12.6 years), that of obese patients was 39.18 years (± 12.16 years) and control patients was 35.9 years (± 13.1 years) with a clear female predominance whether in the group of obese patients or control cases. The average body mass index was 30.21 kg/m2 (± 8.4 kg/m^2), that of obese patients was 36.59 kg/m^2 (± 7.28 kg/m^2) with a statistically significant relationship between periodontitis and obesity ($P = 0.001$). Thus, there is a relationship between class 2 of obesity and the prevalence of the disease ($P = 0.014$). The majority of our patients were of low socioeconomic status (60% of cases) with evidence of a significant relationship ($P = 0.05$). Only a third of our population brushed their teeth correctly (31%). In the group of obese patients this percentage was 16%. The association between poor toothbrushing and periodontal disease was significant ($P = 0.04$). The bivariate analysis showed an increased risk of periodontal disease in the event of anterior tooth loss ($P = 0.01$). Receding gingiva was identified in 62% of obese patients and 54% of non-obese patients. The multivariate analysis did not show any statistically significant association between the different variables.
Conclusion
The susceptibility of obese patients compared to people of normal weight to chronic periodontitis prompts a systematic periodontal and dental examination of these patients in order to improve chewing ability. Hence the importance of multi-disciplinary management of these patients.

EP290

Metabolic profile of morbid obesity compared to moderate and severe obesity

Imane Hasbi, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
University Hospital Center Ibn Rochd, Endocrinology and Metabolic Diseases, Casablanca, Morocco

Introduction
The prevalence of obesity is on the rise worldwide, including morbid obesity. It is responsible for many complications: metabolic, cardiovascular, respiratory, osteo-articular and psychiatric.
Aim
The aim of the study is to compare the metabolic profile of patients with morbid obesity (BMI ≥ 40 kg/m^2) with patients with moderate to severe obesity (BMI: 30 to 39.9 kg/m^2).
Patients and methods
This was a retrospective case-control study including 362 obese patients (BMI ≥ 30 kg/m^2).These patients were divided into 2 groups. Group (G1) included 262 patients with a BMI between 30 and 39.9 kg/m^2, and group (G2) included 100 patients with a BMI ≥ 40 kg/m^2.
Results
The average age of our patients was 55.12 years in G1 and 51.28 years in G2.A female predominance is noted in both groups. The average Body Mass Index in G1 was 32.5 kg/m^2 and 43.39 kg/m^2 in G2. Average waist circumference was higher in G2 (132.5 cm vs 108.46 cm). The prevalence of diabetes was 88.93% (G1) and 79% (G2) ($P = 0.2$). The prevalence of dyslipidemia was 74.04% (G1) and 73% (G2) ($P = 0.3$). Hepatic steatosis was present in 6.87% of cases in G1 and in 7% of cases in G2 ($P = 0.2$). Hyperuricemia was present in 13.7% of cases (G1) and in 15% of cases (G2). ($P = 0.2$).
Conclusion
Our study showed that morbid obesity is not significantly correlated with metabolic risk.

Arterial stiffness in patients with type 2 diabetes mellitus at different stages of diabetic nephropathy

Nodira Alikhanova[1], Charos Musakhanova[1], Nozimakhon Nazarova[1], Rifqat Davronov[2], Feruza Takhirova[1], Gulzoda Akramova[1], Lola Abboskhujaeva[1], Shakirova Munavvara[1], Raisa Trigulova[3], Durdona Kayumova[1], Mokhira Aykhodjaeva[1] & Nigora Maksutova[1]
[1]Republican Specialized Scientific and Practical Medical Center of Endocrinology named after academician Y.Kh. Turakulov, Tashkent, Uzbekistan; [2]V.I. Romanovsky Institute of Mathematics, Academy of Sciences, Tashkent, Uzbekistan; [3]Republican Specialized Scientific and Practical Medical Center for Cardiology, Tashkent, Uzbekistan

Background and Aims
Arterial stiffness is associated with increased risk for target organ damage, cardiovascular events and overall mortality in the general population, patients with diabetes mellitus (DM) and patients with chronic kidney disease (CKD) of

all stages. The aim of this study is assessment of pulse wave velocity (PWV) in patients with type 2 diabetes at different stages of diabetic nephropathy and without it.
Materials and Methods
We examined 138 patients with DM type 2 aged 18 to 70 years. We divided the patients into two groups: the control group - patients without CKD and the main group - patients with CKD. The main group was also divided into 5 groups according to CKD stages by KDIGO (2012). In addition to routine tests for the diagnosis of CKD, we performed sphygmography (SphygmoCor XCEL, AtCor). Informed consent was obtaining from each patient prior to the study. To exclude the effect of smoking on arterial stiffness, former and current smokers were excluded from the study.
Results
Patient's average age was 51.6 ± 8.6 years in control group and 60.25 ± 8.05 years in main. The average duration of diabetes was 6.56 ± 4.8 years in control and 12.87 ± 7.34 years in main group. 55% of them were women ($n = 76$) and 45% were men ($n = 62$). Spearman's rank correlation analysis revealed a significant relationship between the PWV and age of the subjects ($r = 0.4$; $P < 0.001$); the duration of diabetes ($r = 0.3$; $P = 0.01$); estimated glomerular filtration rate ($r = 0.4$, $P = 0.004$) (Table 1). When examining subjects by age group, it was found that DM2 patients with CKD of the same age had a higher PWV compared to the control group (Table 2).
Discussion
Diabetic CKD patients present higher arterial stiffness than non-CKD counterparts do. With an increase in the stages of CKD and age, the PWV also increased. These finding suggest that the presence of CKD is another factor further contributing to the adverse profile of the macrocirculation in DM patients.
Keywords: diabetes mellitus, chronic kidney disease, pulse wave velocity, arterial stiffness

Table 1 PWV parameters in DM patients without CKD and in different stages of CKD

Group	$n=$	PWV (m/s)
Control	33	8.39 ± 1.50
CKD 1	24	9.06 ± 2.20
CKD 2	21	9.89 ± 2.67
CKD 3	25	10.14 ± 2.27
CKD 4	15	10.41 ± 2.31
CKD 5	20	10.75 ± 2.34

Table 2 Age dependence of PWV in DM2 patients with and without CKD.

Prevalence of shoulder pain in people with uncontrolled diabetes in the western part of India: A cross-sectional study

Medha Ajit Oak[1] & Bageshree Oak[2]
[1]OAK Hospital and ICON Multispecialty Hospital, Department of Endocrinology, Thane, Mumbai, India; [2]Sree Balaji Medical College and Hospital, Department of Orthopedics, Chennai, India

Introduction
Musculoskeletal disease is one of the common symptoms observed in people with diabetes. Shoulder pain is found to be the most common symptom and can lead to hindrance in daily activities that can directly or indirectly influence the metabolic processes of our body affecting the quality of life. Hence, we studied the prevalence of shoulder pain and its functional limitations among patients with uncontrolled diabetes mellitus (DM).
Materials
This cross-sectional study was conducted in OAK Hospital and ICON Multispecialty Hospital, Dombivali from October 2022 to December 2022. Included all patients with uncontrolled DM (HbA1c > 8.5) who have visited the clinic. Responses were captured via Interviews using a previously validated questionnaire, the American Shoulder and Elbow Surgeons Evaluation Form. Informed consent was obtained from the participants.
Results
A total of 125 patients were included in the study; 72 (57.6%) were females and 130 (42.4%) were males. Around 76 (60.8%) of the patients were aged 41-60 years. The people with T2DM (90.4%) were the majority. The mean HbA1c level was 10.12%. Shoulder pain was present in 45 (36%) patients. Amongst them, 35.5% were between 41 and 60 years and 48.8% were between 61 and 80 years. The mean shoulder pain intensity for all patients was 5.61 ± 3.1. There was a significant correlation ($P < 0.05$) in different age groups.
Conclusions
Shoulder dysfunction with its increased prevalence needs an early diagnosis and management. It is advised to include screening, prevention, and rehabilitation strategies for shoulder dysfunction in diabetic care programs to improve the daily lifestyle of the patients.
Keywords: T2DM, Shoulder Pain, Quality of life.

Precipitating factors and symptoms in patients with diabetic ketoacidosis

Tatjana Bačun[1,2], Željka Dragila[1], Klara Ćosić[1], Ivana Grubešić[1], Ivan Lekić[1,3], Sran Čalošević[4] & Krešimir Šolić[1,5]
[1]Faculty of Medicine, Osijek, Croatia; [2]Clinical Medical Center Osijek, Department of Internal Medicine, Osijek, Croatia; [3]Dom Zdravlja Zagreb - Centar, Zagreb, Croatia; [4]Department of Emergency Medicine Osijek-Baranja County, Osijek, Croatia; [5]Faculty of Electrical Engineering, Computer Science and Information Technology Osijek, Osijek, Croatia

Aim
The aim of the study was to determine the most common precipitating factors and symptoms of diabetic ketoacidosis and whether there is a difference in regard to age, gender and severity of diabetic ketoacidosis.
Patients and Methods
Medical records from 1 January 2017 to 31 December 2019 were reviewed and patients with the diagnosis of diabetic ketoacidosis were selected.
Results
The study included 52 patients. The median age was 34 years (interquartile range 21-56 years). There was no statistically significant difference between male and female gender. The severity of diabetic ketoacidosis was moderate in the majority of cases (65.4%; $P = 0.005$). The most common precipitating factor was infection (61.7%). In patients with moderate diabetic ketoacidosis, respiratory infections were more common, while gastrointestinal infections were more common in severe diabetic ketoacidosis (33% and 25%; $P = 0.03$). Nausea (median age 32 years; $P = 0.004$) and vomiting (median age 31 years; $P = 0.01$) were more common in the younger age groups, while altered mental status was more common in the older age group (median age 61 years; $P = 0.001$).
Conclusion
Infection was the most common precipitating factor. The most common symptoms in the younger age groups were nausea and vomiting and in the older age group altered mental status.
Keywords: diabetes mellitus, diabetic ketoacidosis, infection, nausea, vomiting

Glucose and sodium levels as disease outcome predictors in critically ill patients

Tatjana Bačun[1,2], Željka Dragila[2], Andrea Dorokazi[3], Ivan Lekić[1,4], Damir Mihić[1,2], Domagoj Loinjak[1,2] & Miroslav Šram[2]
[1]Faculty of Medicine, Osijek, Croatia; [2]Clinical Medical Center Osijek, Osijek, Croatia; [3]Poliklinika Slavonija, Osijek, Croatia; [4]Dom Zdravlja Zagreb - Centar, Zagreb, Croatia

Aim
The main aim of this study was to examine the association of glucose and sodium level with diagnosis and disease outcome of critically ill patients.
Patients and Methods
The glucose and sodium concentration of 283 patients admitted in critical condition to the Intensive Care Unit of the Department of Internal Medicine in a period from 1 November 2015 to 28 February 2017 were reviewed.
Results
Most common diagnoses in critically ill patients were acute kidney injury (26.1%) and sepsis (including septic shock) (22.3%). Significantly lower glucose concentration was observed in patients with acute kidney injury ($P = 0.02$), whereas patients in sepsis and septic shock had significantly higher sodium concentration ($P = 0.04$). Higher glucose level was related to higher mortality rate ($P = 0.001$). On the other hand, sodium level was not significantly associated with survival. Higher mortality as well as higher glucose concentration were more common in patients older than 65 years ($P < 0.001$).

Conclusion
This study has shown significantly lower concentrations of glucose in patients with acute kidny injury, whereas in patients older than 65, glucose concentration was significantly higher. Patients in sepsis and in septic shock have shown significantly higher concentrations of sodium. Higher concentration of glucose was connected with higher mortality in elders, where as concentration of sodium did not show connection with morality.

Place of podoscopic examination in diabetic foot
Soumaya Elarem[1], Imen Dorgham[1], Aymen Haj Salah[1], Ikram Haddada[1], Nedra Feni[2], Mouna Sghir[1] & Wassia Kessomtini[1]
[1]Taher Sfar Hospital, Physical Medicine and Rehabilitation, Mahdia, Tunisia; [2]Ibn El Jazzar Hospital, Physical Medicine and Rehabilitation, Kairouan, Tunisia

Introduction
Diabetic foot is a public health problem. It can cause serious complications leading to amputation. Diabetic neuropathy (DN) is the main factor of ulcerations. Plantar hyperpressure is an aggravating factor.
Aim
The aim of our study was to screen for various deformities of the diabetic foot through podoscopic evaluation.
Patients and Methods
We conducted a bicentric cross sectional study over a three month period including diabetic patients. Detail history including socio demographic data, characteristics of diabetes and the follow-up story were collected. Podiatric examination was performed using a tangential lighting podoscope.
Results
We included 150 patients. Their mean age was 56.91 ± 12.6 years with a range of 20 to 86 years. Half of patients were using oral medications, 28% were using insulin therapy and 21.3% were using both oral and insulin therapies. Diabetic neuropathy was found in 32.7% of the population. The podiatric examination revealed plantar hyperkeratosis in 84% of patients, dry skin in 46% and mycotic lesions in 27.3%. Plantar perforation was noted in 2 patients, and toe amputation in 4 patients. The main hyper pressure zone found was regarding the second metatarsal head (52%). Foot orthotics were prescribed in 18% of patients.
Conclusion
Podiatric examination is essential to detect areas with hyper pressure at risk of hyperkerathosis and plantar perforation. It allows preventive measures, including devices to reduce hyperpressure and prevent complications.

Diabetic Ketoacidosis on Orbital Cellulitis with Mucormycosis: A Case Report
Hasna Ouirar, Ikrame Qasdi, Hajar Azagouagh, Amal Riad, Nawal Moussaid, Kaoutar Rifai, Iraqi Hinde & Mohamedelhassan Gharbi
Ibn Sina University Hospital, Endocrinology and Metabolic Diseases, Rabat, Morocco

Introduction
Mucormycosis is a rare, devastating, fungal infection, which disproportionately affects non-controlled diabetic patients, notably during ketoacidosis. It is a potentially lethal disease. The diagnosis and treatment of mucormycosis remain a challenge because of the nonspecific clinical presentation. We discuss the clinical features and management modalities of this case.
Case
We report the observation of a 41 years old male patient, who had had type 1 diabetes mellitus for 21 years under insulin .He consulted the emergency room for diabetic keto-acidosis (DKA) on left unilateral orbital cellulitis of sudden onset. Clinically the patient was febrile with palpebral oedema, chemosis and painful ophthalmoplegia. The initial orbital CT scan was in favor of chandler stage 1 pre-septal cellulitis of the left eye with grade 1 exophthalmos probably of sinus origin. The patient was immediately put on parenteral tri-antibiotherapy with a worsening of the inflammatory signs clinically, biologically and by the extension on the CT scan of the cellulitis in the retro-septal area with ethmoidal and orbital abscesses complicated by septic thrombosis of the cavernous sinus and the internal carotid artery, intracerebral collections an. After mycological sampling of the inner part of the upper eyelid concluded to be *Rhizopus microsporus*.The patient benefited from endo-nasal surgical debridement and effective antic-oagulation associated with liposomal amphotericin B for 10 days and then classical amphotericin B for 2 months. The subsequent evolution was favourable after broad surgical drainage, with disappearance of inflammatory signs, but blindness is definitive.
Discussion and Conclusion
Mucormycosis is a rare fungal infection that should be considered. The diagnosis, often difficult, must be made as early as possible. Poorly controlled diabetes mellitus is one of the main risk factors. The treatment, initiated as a matter of urgency, combines antifungal treatment, surgical debridement and correction of predisposing factors. The vital and functional prognosis remains severe in most cases.

EP297

Prevalence of symptoms and precipitating factors of Diabetic Ketoacidosis in diabetic patients
Ines Mezghani[1], Rim Marrakchi[1], Mohamed Ksentini[1], Mariem Boudaya[1], Kamel Jammoussi[1], Mouna Turki[1], Faten Hadj Kacem[2] & Mohamed Abid[2]
[1]Hedi-Chaker University Hospital of Sfax, Tunisia, Biochemistry Departement, Sfax, Tunisia; [2]Hedi-Chaker University Hospital of Sfax, Tunisia, Endocrinology Departement, Sfax, Tunisia

Background/Aim
Since diabetes is the most common endocrine disorder and the diabetic ketoacidosis (DKA) is considered as a medical emergency, our aim was to determinate the frequency of symptoms and precipitating factors of DKA in type 1 and type 2 diabetes
Methods
This is a retrospective cross-sectional descriptive study concerning all patients hospitalized in the Endocrinology Department for DKA between August 2021 to December 2022.We compared the differences in prevalence, of precipitating factors and clinical presentations between type 1 (T1D) and type 2 (T2D) diabetes.
Results
Out of 30 patients, 19 (63.3%) patients had type 1 diabetes and 11 (36.7%) had type 2 diabetes. The mean age of patients was 26.7 ± 10.4 years (type 1 diabetes 22 ± 6.5 years; type 2 diabetes 34.9 ± 11 years). The most common symptoms of patients were polyuria and polydipsia seen in 56.7% of patients (T1D: 42.1% vs T2D:81.8%) at the first time of their admission. Nausea and vomiting, abdominal pain, fever and dehydration were observed in 43.3% (T1D:47.4% vs T2D:36.4%), in 26.7% (T1D:31.6% vs T2D:18.2%), in 10% (T1D:10.5% vs T2D:9.1%) and in 6.7% (T1D:5.3% vs T2D:9.1%) of patients, respectively. Polyuria and polydipsia were the only symptoms statistically different between the two groups ($P = 0.03$). The most common precipitating factor of DKA was therapy discontinuation seen in 43.3% of patients (T1D:52.6% vs T2D:27.3%). First presentation and infections were observed in 33.4% (T1D:26.3% vs T2D:45.5%) and in 23.3% (T1D:21.1% vs T2D:27.3%) of patients, respectively. The differences in precipitating factors of DKA between the two groups were no significant.
Conclusion
The most common precipitating factor of DKA was therapy discontinuation mainly among T1D. More information about diabetes mellitus among population is necessary to reduce the incidence of DKA.

EP298

MRI for diagnosis of early-stage Charcot foot
Telman Kamalov[1] & Salimjon Tojiboev[2]
[1]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, Republic of Uzbekistan, 100125, Tashkent, Mirzo Ulugbek street, 56, Tashkent, Uzbekistan; [2]Republican Specialized Scientific Practical Medical Center of Endocrinology of Public Health Ministry named by acad. Ya.Kh. Turakulov, Tashkent, Uzbekistan

Purpose
The purpose of the study is to evaluate the results of MRI of studies in patients with the active stage of the Charcot foot.
Material
The material of the study 29 patients (prospectively) were examined with type 2 diabetes with the active stage of the Charcot foot in the period 2021 at the

RSSNPMC of endocrinology, in the department of diabetic foot. The control group amounted to 20 healthy persons.
Background/Aim
Biochemical (bilirubin, straight, indirect, lipid spectrum, ALT, AST, Coagulogram, blood sugar, glycated hemoglobin, urea, creatinine). Instrumental: ECG, MRI, Dopplerography of the main vessels of the legs, ultrasound of internal organs, DEXA, ocular fundus.
Research Results
In the patient's group, 21 men were observed (the average age of 69.6 years) and 8 women (the average age 68, 9 years). The duration of the DM2 was 21/19, respectively.. The duration of the SDS was 9/7 years, respectively. On MRI we found location of bone marrow abnormality (edema shown in fluid sensitive sequences, and reduction of fatty bone marrow shown in T1 sequences). Pattern tends to be periarticular. In all patients were involved several joints and bones (mostly tarso-metatarsal joints and metatarsophalangeal joints).
Conclusions
During early-stage Charcot foot, CT does not play an important role for imaging since bone marrow and soft tissue changes can be better visualized using MRI. CT may be used in later-stage Charcot foot for better visualization of bony proliferations and consolidation. Recognizing this disease in early stages prevents a delayed onset of an appropriate therapy and helps minimizing the disability of these patients.

Mucormycosis Rhinosinusitis in Diabetic patients

Houas Jihene, Lazid Sarra, Ghammam Monia, Ben Arfi Taissir, El Omri Malika, Bellakhdher Mouna, Hasni El Abed Yosra, Meherzi Abir, Kermani Wassim & Abdelkefi Mohamed
ENT Department and Neck Surgery of Farhat Hached Hospital, Sousse, Tunisia

Purpose
Mucormycosis is a rare and potentially fatal invasive fungal infection which usually occurs in diabetic and other immunocompromised patients. This infection is associated with high morbidity and mortality rates. Prompt diagnosis and rapid aggressive surgical debridement and antimycotic therapy are essential for the patient's survival .The purpose of this study was to expose the clinical feature, and to discuss the specificities management of mucormycosis in the setting of diabetes.
Material and Methods
This study was based on retrospective review of six diabetic patients who suffered from mucormycosis rhinisinusitis, over 22 years period (2000-2022).
Result
The mean age was 41 years with male predominance (4 males per 2 females), the average duration of diabetes follow up was over 10 years. We noticed an orbital involvement in one case. Rhinocerebral mucormycosis was diagnosed in one patient. The infection was limited to the rhinosinus space in 4 cases. The causative agent was, exclusively, Rhizopus arrhizus. Paranasal CT scan was performed for all our patients. In all cases, surgical evaluation was immediately performed for debridement of the necrotic tissues, and multiple biopsies were performed for diagnostic purposes. The medical treatment was based in intravenous liposomal amphotericin B. Nephrotoxicity were noted in 2 cases, with hepatic insufficiency in one of them. The main complication was septicaemia, seen in one case, after one week evolution. We noted a complete recovery in 5 cases. Despite an early diagnosis and rapid treatment the course of the disease has been marked by the death of one patient who had a cerebral involvement.
Conclusion
Mucormycosis rhinosinusitis is a disease with a rapid evolution and high morbidity and mortality rates, especially if there is an orbito – cerebral involvement. Therefore, it would be necessary in all diabetic patients, with sinus symptoms, headaches, visual changes, to suspect a mucormycosis, and perform immediately the appropriate surgical and medical management.

Predictive factors of diabetic foot ulcer recurrence

Sara Ragbi, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
UHC Ibn Rochd, Endocrinology and Metabolic Disorders, Casablanca, Morocco

Introduction
Diabetic foot is a major health problem, especially when it is complicated by recurrences. It entails a heavy economic burden for the patient and for the health system. The objective of this work is to study the characteristics of diabetic patients with recurrent foot ulcer as well as the predictive factors of recurrence.
Material and Methods
This study is a retrospective cohort study from January 2020 to May 2022 involving patients hospitalized in our department for diabetic foot ulcer. The analysis was performed using SPSS 21 software.
Results
Out of a total of 175 patients, 64 patients presented a recurrence, i.e. 36.5%. The average age was 59 years with a sex ratio M/F of 1.5. The average duration of diabetes was 18 years. Regarding the characteristics of the patients, 87.5% were type 2 diabetics with an average HbA1c level of 8.9%. Regarding degenerative complications, 85.9% had a diabetic retinopathy and 66.15% presented peripheral neuropathy, while 68.7% had peripheral artery disease. Concerning the ulcers, 48.4% had neuropathic plantar ulcers while 39% had ischemic ulcers. Among the patients, 54.6% presented foot deformities, 18.7% presented a Charcot foot and 20.3% had a history of amputation. The evolution was favorable in 93.7%. Predictive factors of recurrence were age ($P=0.01$), diabetes duration ($P=0.00$), glycemic imbalance ($P=0.00$), microangiopathy mainly diabetic retinopathy ($P=0.00$) and peripheral neuropathy, existence of peripheral artery disease ($P=0.00$) and low socioeconomic status ($P=0.00$). Charcot's foot, foot deformities and previous amputation were also predictive factors.
Conclusion
Recurrences of diabetic foot ulcers are quite common. Reducing them requires action on modifiable predictive factors and this through effective prevention and education.

DOI: 10.1530/endoabs.90.EP300

EP301

Potential risk factors of hypokalemia in patients with diabetic ketoacidosis

Ines Mezghani[1], Marrakchi Rim[1], Gargouri Omar[1], Boudaya Mariem[1], Jammoussi Kamel[1], Turki Mouna[1], Hadj Kacem Faten[2] & Abid Mohamed[2]
[1]Hedi-Chaker University Hospital of Sfax, Biochemistry Departement, Sfax, Tunisia; [2]Hedi-Chaker University Hospital of Sfax, Endocrinology Departement, Sfax, Tunisia

Background/Aim
Diabetic ketoacidosis (DKA) is a life-threatening acute complication of diabetes. Our aim was to study the clinical features of DKA and precipitating factors responsible for DKA in diabetic patients.
Methods
This is a retrospective cross-sectional descriptive study concerning all patients hospitalized in the Endocrinology Department for DKA between August 2021 and December 2021. Initial kalemia levels (k +) on presentation were determinated on AU 680® Beckman Coulter. Hypokalemia was defined using the criteria set forth by the American Diabetes Association (ADA) as measured serum potassium less than 3.3 mmol/l. The common clinical presentations, precipitating factors and the mean of Glycemia between diabetes who presented hypokaliemia (G1) and those with normal k + (G2). The data were analyzed using SPSS25.
Results
Out of 30 patients, 19 (63.3%) patients had type 1 diabetes and 11 (36.7%) had type 2 diabetes. Mean age was 26.7 $\pm$10.4 years. There were12 (40%) males and 18 (60%) females. The mean of BMI was 20.5$\pm$3.4 kg/m^2. The mean potassium level was 3.73 mmol/l (range 2.3 to 5.3; SD +/- 0.72). Among patients, 26.7% (T1D:50% vs T2D:50%), had hypokalaemia (k + < 3.3 mmol/l). The mean age was 26.7 $\pm$10.4 years (type 1 diabetes 22$\pm$6.5 years; type 2 diabetes 34.9$\pm$11 years). The most common symptoms of patients were polyuria and polydipsia seen in 56.7% (G1:37.7% vs G2:63.6%) at the first time of their admission. Nausea and vomiting, abdominal pain, fever and dehydration were observed in 43.3% (G1:75%vs G2:25%), in 26.7% (G1:62.5% vs G2:0%), in 10% (G1:12.5% vs G2:9.1%) and in 6.7% (G1:0% vs G2:9.1%) of patients, respectively. Abdominal pain, nausea and vomiting were the symptoms statistically different between the two groups ($P<0.0001$, $P=0.035$ respectively). The most common precipitating factor of DKA was therapy discontinuation seen in 43.3% of patients (G1:37.5%vs G2:45.5%), first presentation and infections were observed in 33.4% (G1:25%vs G2:36.4%). and in 23.3% (G1:37.5%vs G2:18.2%), of patients, respectively. The differences in precipitating factors of DKA between the two groups were no significant.
Conclusion
Hypokalemia was observed in 26.7% of patients with DKA. Abdominal pain, nausea and vomiting are more frequents in patients who presented hypokaliémia. Further research is needed to better determine the risks and benefits of administering insulin before obtaining serum potassium values.

Assessment of the nutritional status of elderly diabetics

Berriche Olfa, Abir El Amri, Rym Ben Othman, Nadia Ben Amor, Amel Gamoudi, Ramla Mizouri & Jamoussi Henda
National Institute of Nutrition, Tunis, Tunisia

Objectives
The aim of our study was to assess the nutritional status of elderly diabetics.
Methods
This was a descriptive cross-sectional study conducted at the National Institute of Nutrition in Tunis including 40 diabetics aged over 65 years. All patients underwent anthropometric measurements (weight, height, body mass index (BMI)), a biological assessment (fasting blood glucose, glycated haemoglobin (HbA1c)), a dietary survey and an assessment of nutritional status using the Mini Nutritional Assessment MNA questionnaire.
Results
The mean age of the patients was 71.3 ± 5.5 years, the mean HbA1c was $10.32 \pm 2.12\%$. The dietary survey revealed hypocaloric and hypoprotein intake in 25% and 32.5% of patients respectively. The mean BMI was 31.25 ± 5.97 kg/m^2, we found weight loss $>5\%$ in one month and $>10\%$ in 6 months in 10% and 7.5% of patients respectively. Referring to the MNA; almost two thirds of the patients were at risk of malnutrition and 7.5% had a poor nutritional status. Patients with a normal nutritional status according to the MNA had a better glycaemic control than patients with a risk of malnutrition or undernutrition ($HbA1c = 8.97 \pm 1.19\%$ vs $10.9 \pm 2.17\%$, $P = 0.04$). Furthermore, the risk of malnutrition increased significantly with BMI ($P = 0.011$). In contrast, we found no relationship between caloric intake, protein intake and nutritional status according to MNA.
Conclusion
Undernutrition is common in poorly balanced elderly diabetics, justifying a systematic assessment of nutritional status and optimal glycaemic control in these patients.

Indicators of osteocalcin and adiponectin in pregnant women with type 1 diabetes mellitus

Tatsiana Mokhort[1], Tatsiana Skryplionak[2] & Veranika Prylutskaya[3]
[1]Belarusian State Medical University, Endocrinology, Minsk, Belarus; [2]Republic Research and Practical Center «Mother and Child», Minsk, Belarus, Minsk, Belarus; [3]Belarusian State Medical University, Minsk, Belarus

Introduction
The relationship between indicators of carbohydrate, fat and bone metabolism is beyond doubt. It is known that osteocalcin, overcoming the blood-brain barrier, can affect the development of the fetal brain. Adiponectin is currently being considered as a biomarker for pregnancy complications. These facts determined the purpose of the study.
Aim
To study the content of osteocalcin and adiponectin in pregnant women with type 1 diabetes (T1DM).
Materials and Methods
A prospective single-center study was conducted on the basis of the Republican Scientific and Practical Center "Mother and Child" among pregnant women with a full-term pregnancy. We compared 2 groups of pregnant women: group 1 (Gr 1) - pregnant women with T1DM ($n = 37$) and group 2 (Gr 2) - pregnant women without diabetes ($n = 31$) whose levels of osteocalcin and adiponectin in venous blood were determined the day before delivery. Women of both groups were comparable in terms of pregravid body mass index (BMI) ($P = 0.263$), which was in the normal range (BMI <25) and delivery time. Glycated hemoglobin in pregnant Gr 1 was 6.6% (6.0–7.4%).
Results
The level of osteocalcin in Gr1 was 1.04 (0.58–2.49) ng/ml, and in Gr 2 it was 2.05 (0.87–7.64) ng/ml and was statistically significantly less against the background diabetes ($P = 0.013$). The level of adiponectin in Gr1 was 20.59 (12.4–27.07) mcg/ml, and in Gr2 it was 9.7 (9.04–13.35) mcg/ml and was statistically significantly higher ($P < 0.001$) in pregnant women with type 1 diabetes.
Conclusions
In our study, pregnant women with type 1 diabetes had lower levels of osteocalcin than healthy pregnant women, which can be attributed to the effect of hyperglycemia. Higher levels of adiponectin in pregnant women with type 1 diabetes seem to be associated with autoimmune processes, which requires further study.

EP304

Neonatal diabetes mellitus in a patient with a novel heterozygous mutation in GATA6

Elena Sechko, Elizaveta Raykina, Tamara Kuraeva, Dmitry Laptev, Olga Bezlepkina & Valentina Peterkova
Endocrinology Research Centre, Pediatric, Moscow, Russia

Transient neonatal diabetes mellitus (TNDM) occurs in 50-60% of all cases of neonatal diabetes mellitus (NDM). The most common cause of TNDM (70%) is almost invariably associated with defect in chromosome 6 and mutations in the *KCNJ11, ABCC8, INS, NHF1B* etc. genes. TNDM is caused by mutations in the GATA6 gene in rare cases. This gene encodes a transcription factor that is important for the development of the hematopoietic, cardiac and gastrointestinal systems.
Clinical Case
Proband is a female born at 35 week of gestation with intrauterine growth retardation (weight 1580 g (SDS -2.29), length 40 cm (SDS -2.65)) via cesarean section. The proband was fedded using tube feeding in neonatal period. The proband was diagnosed with hyperglycemia 29.6 mmol/l in the neonatal period, insulin therapy was started. Insulin was stopped in 1 month of life. Normoglycemia was observed. Family history of diabetes was negative. The proband was relapse of diabetes in 3 years old after a respiratory infection. She had polyuria, polydipsia and weight loss. HbA1c 11.5%, glycemia 18.6 mmol/l. Insulin (As part, 0.4 U/kg/day) was started. Fasting C-peptide 0.69 ng/ml, stimulated C-peptide in 120 min - 2.32 ng/ml. Specific islet antibodies (GADA, IA2A, IAA, ZnT8A) were negative. Pancreatic hypoplasia was diagnosed due to ultrasound. Genetic test (NGS 27 genes) was performed, no mutations were detected. Proband had extrapancreatic features: moderate growth retardation (growth SDS -1.95), patent ductus arteriosus, mitral valve prolapse, gallbladder agenesis, umbilical hernia, autoimmune thyroiditis. At the age of 8 years (diabetes duration was 5 years) patient was treated fast acting insulin Aspart, 0.7 U/kg/day. HbA1c 5.2%, fasting C-peptide 0.71 ng/ml, stimulated C-peptide in 120 min – 0.9 ng/ml. Whole-exome sequencing revealed novel pathogenic heterozygous mutation c.1302+4 1302+7del in exon 3 of the GATA6 gene, leading to a deletion of 4 nucleotides.
Conclusion
TNDM is rarely caused by mutations in the *GATA6* gene. The development of NDM due to mutations in the *GATA6* gene is probably associated with pancreatic hypoplasia. Diabetes associated with mutations in the *GATA6* gene is progressive. Patients with mutations in the *GATA6* gene have extrapancreatic features (congenital heart defects, gallbladder agenesis, umbilical hernia).

EP305

Study of clinical and laboratory parameters in patients with COVID-19, taking into account the outcome of the disease

Yuliya Dydyshka[1,2], Alla Shepelkevich[1], Mariya Efremava[3], Veranika Lobashova[2] & Elena Brutskaya-Stempkovskaya[3]
[1]Belarusian State Medical University, Endocrinology Department, Minsk, Belarus; [2]Republic Center of Endocrinology and Medical Rehabilitation, Endocrinology Department, Minsk, Belarus; [3]Belarusian State Medical University, Minsk, Belarus

According to modern concepts, stress hyperglycemia and diabetes mellitus (DM) are often found in hospitals and are associated with an increase in complications, length of hospitalization and mortality. The analysis of data on the COVID-19 pandemic indicates a worse prognosis and a high risk of hospital complications in patients with DM.
Aim
The aim of the study was to evaluate clinical and laboratory parameters that can be used to predict an unfavorable outcome of Covid-19.
Materials and Methods
A retrospective analysis of data from of 320 patients with Covid-19 infection, who was treated in the intensive care unit of the infectious Minsk hospital from June 2020 to March 2022, was carried out. The following groups were formed: 224 people with transient hyperglycemia (the main group); 51 patients with DM (comparison group); 45 people without glycemic disorders (control group). Also, patients were divided into subgroups based on the outcome (favorable or unfavorable outcome).
Results and Discussion
The mean age of deceased patients was significantly higher than that of surviving patients (67.0 (59.3; 74.0) years vs 57.0 (47.0; 66.8) years, $P < 0.001$), indicating the fact that the age of the patient is a prognostically unfavorable criterion for the outcome of the disease. Among deceased patients, higher glycemic values were

recorded, mainly in the DM group (20.9 (14.9; 23.9) mmol/l vs 13.4 (10.9; 17.7) mmol/l, $P=0.005$). Patients with an unfavorable outcome had differences in laboratory parameters already on the first day of hospitalization and was characterized by higher values of inflammation indicators (leukocyte level ($P=0.002$), LDH ($P=0.008$), CRP ($P=0.003$), procalcitonin ($P<0.001$), D-dimers ($P<0.001$), as well as greater severity of lymphopenia ($P=0.006$). In patients with an unfavorable outcome, starting from the 4th day of stay in the ICU, a tendency to persistent hyperglycemia was noted. Negative dynamics of glycemia was noted on day 7 in the observation groups, depending on the unfavorable outcome: DM (13.4 (8.1; 19.8) vs10.1 (5.6; 11.9), $P=0.014$), HG (8.7 (7.2; 11.8 6.4 vs (5.7; 7.6), $P=0.017$), control (6.2 (4.0; 7.2) vs 5.3 (5.1; 5.9), $P=0.123$). Moreover, the glucose levels in the DM and HH group increased most significantly on day 7.

Conclusions

Thus, diabetes mellitus and in-hospital hyperglycemia are significant risk factors for the severe course of COVID-19, as well as its poor outcome. From the 4th day patients with an unfavorable outcome showed a tendency to persistent hyperglycemia, which potentially indicates its role as a prognostic parameter.

Maturity Onset Diabetes of the Young (MODY) associated with mutations in the Regulatory factor X6 (RFX6) gene: A case report

Alberto García Piorno, Isabel Losada Gata, Roberto Añez, Alejandra Maricel Rivas Montenegro, Gloria Collado González, Mónica Gómez-Gordo Hernanz & Olga González Albarrán

Gregorio Marañón Hospital, Endocrinology and Nutrition, Madrid, Spain

Introduction

Maturity onset diabetes mellitus of the young (MODY) is a form of monogenic diabetes characterized by pancreatic B-cell dysfunction. The most common subtypes are caused by mutations in the genes encoding glucokinase (GCK) and hepatocyte nuclear factor (HNF1a, HNF4a), although unidentified genes are also involved. Regulatory factor X6 (RFX6) is a transcription factor gene which has an important biological role in B-cell formation and function. Biallelic mutations in RFX6 cause Mitchell–Riley syndrome, characterized by neonatal diabetes, pancreatic hypoplasia, gallbladder agenesis or hypoplasia, and intestinal atresia. Heterozygous RFX6 mutations have been identified in MODY cases.

Case Report

A 19-year-old female, with no past medical history, was referred to the emergency department for diagnostic evaluation of hyperglycemia, which was found in a medical checkup. She had been experiencing symptoms of diabetes mellitus (polyuria, polydipsia and weight loss of 5 kg) over the previous 2 months. Family members, including her sister, mother, and maternal grandfather had a history of diabetes. Her height was 156 cm, and her weight 59 kg, with a body mass index of 26 kg/m^2. Admission laboratory test reports included elevated plasma glucose and HbA1c levels (324 mg/dl and 11.4% respectively); and a diabetes mellitus diagnosis was made. No diabetic ketoacidosis was present. The patient was started on insulin therapy with a total dose of 17 units per day. She was evaluated in the Department of Endocrinology 1 year after the onset of diabetes. She had discontinued insulin therapy and was not receiving further treatment. HbA1c had decreased to 6.5% and her C-peptide level was 1.32 ng/ml. There were no islet cell antibodies (ICA), glutamic acid decarboxylase (GAD) antibodies, or insulinoma-associated (IA-2) autoantibodies found. Genomic sequencing was performed in a panel which included 50 genes associated with monogenic diabetes mellitus. The analysis identified a heterozygous RFX6 mutation (c.541C>T, p.Arg181Trp) in the proband, which carried no pathogenic variants in other tested genes.

Conclusion

We describe a case of MODY due to a heterozygous RFX6 mutation p.Arg181Trp. RFX6 mutations have been associated with non-syndromic MODY with low penetrance and post-pubertal onset. Our report supports the evidence of causal relationship, although further studies are needed to define the association and to determine the appropriate therapeutic approach for these patients.

Factors influencing Tunisian diabetics' knowledge and attitudes: Cross-sectional study

Maali Haoues[1], Chekib Zedini[2], Yosra Hasni[3] & Molka Chadli-Chaieb[3]

[1]Faculty of Medicine Ibn El Jazzar of Sousse, Sousse, Tunisia; [2]Department of Community Medicine, Hospital Farhat Hached, Sousse, Tunisia; [3]Department of Endocrinology and Metabolic Diseases, Hospital Farhat Hached, Sousse, Tunisia

Objective

To determine the factors influencing the level of knowledge and attitudes of diabetics consulting in first and third line in the Sousse region (Tunisia).

Patients and Methods

We undertook a cross-sectional study. Diabetics were included by proportional sampling in 11 basic health centers and six hospital departments and outpatient clinics of the university hospital centers of Sousse. The developed questionnaire was self-administered in Arabic. It included patient demographic characteristics data, diabetes-specific data, the Simplified Diabetes Knowledge Scale to measure knowledge and the Diabetes Attitude Scale-3 to measure attitudes towards diabetes.

Results

We collected 1007 diabetics. Factors influencing the acquisition of a good level of knowledge were high school (adjusted OR = 2.23) or university education (adjusted OR = 3.55), living in an urban area (adjusted OR = 2.49), and stable employment (adjusted OR = 3.04). Type 2 diabetes (adjusted OR = 4.02), insulin therapy (adjusted OR = 4.14), previous therapeutic education sessions (adjusted OR = 1.55), self-monitoring of blood glucose (adjusted OR = 2.67), and regular medical follow-up (adjusted OR = 1.54) also influenced the level of diabetes knowledge. Acceptable glycemic control (adjusted OR = 4.20) was a factor in the development of good attitudes about diabetes.

Discussion

Identification of factors influencing the level of diabetes knowledge and attitudes is an integral part of educational diagnosis. These factors must be taken into account when establishing a personalized therapeutic education program adapted to each patient.

Predictors of the level of knowledge, attitudes and quality of life of tunisian diabetics

Maali Haoues[1], Chekib Zedini[2], Yosra Hasni[3] & Molka Chadli-Chaieb

[1]Faculty of Medicine Ibn El Jazzar of Sousse, Tunisia; [2]Department of Community Medicine, Hospital Farhat Hached, Sousse, Tunisia; [3]Department of Endocrinology and Metabolic Diseases, Hospital Farhat Hached, Sousse, Tunisia

Objective

This study aimed to translate into Arabic and validate the questionnaires "Simplified Diabetes Knowledge Scale" (SDKS), "Diabetes Attitude Scale-3" (DAS-3) and "Diabetes Health Profile-18" (DHP-18) and to study the predictive factors of the level of knowledge, attitudes and quality of life of diabetics in the health region of Sousse.

Population and Methods

A methodological study of psychometric validation was carried out to meet the objective of translation and validation of the questionnaires. A second cross-sectional study was conducted to achieve the main objective of the study. Type 1 and type 2 diabetics from the health region of Sousse, aged 18 years and older and able to read and understand a newspaper in literary Arabic were included. The instrument developed contained a section to collect demographic and clinical data from the patients. Subsequent sections contained the Arabic translated and validated versions of the SDKS, DAS-3 and DHP-18.

Results

Analysis of the responses to the three questionnaires from 333 diabetics produced valid and reliable Arabic versions. One thousand and seven diabetics were collated to study the predictors of the level of knowledge, attitudes and quality of life of diabetics. The level of diabetes knowledge was related to demographic factors: high school (adjusted OR = 2.23) and university education (adjusted OR = 3.55), urban habitat (adjusted OR = 2.49) stable employment (adjusted OR = 3.04) and clinical factors: type 2 diabetes (adjusted OR = 4.02), insulin therapy (adjusted OR = 4.14), prior therapeutic education (adjusted OR = 1.55), self-monitoring of blood glucose (adjusted OR = 2.67), and regular medical follow-up (adjusted OR = 1.54). The development of positive attitudes towards diabetes was related to acceptable glycemic control (adjusted OR = 4.20). The quality of life of diabetics was negatively influenced by age < 40 years (adjusted OR = 2.50), type 1 diabetes (adjusted OR = 1.91), duration of diabetes of more than 10 years (adjusted OR = 1.43) and low level of knowledge about the disease (OR = 1.71).

Conclusion

Valid and reliable Arabic versions of the SDKS, DAS-3, and DHP-18 were produced and are available to caregivers for the assessment of knowledge, attitudes,

and quality of life of diabetics. The identification of factors affecting these parameters can be used as a basis for the development of a therapeutic education program adapted to this population

EP309

Bicycle Exercise and Lifestyle Intervention in Newly Diagnosed Diabetes - An interim analysis of the BELIFE Study

Matthias Hepprich[1,2], Justus Fischer[1], Jonathan Mudry[1], Yoann Aubry[1,3], Beckey Trinh[1,4] & Marc Donath[1]
[1]University Hospital Basel, Endocrinology, Diabetology & Metabolism, Basel, Switzerland; [2]Cantonal Hospital Olten, Clinic of Endocrinology, Diabetes and Metabolic Disorders, Olten, Switzerland; [3]Hopital Du Jura, Endocrinology, Delémont, Switzerland; [4]Rigshospitalet, Centre for Physical Activity Research, København, Denmark

Background/Introduction
Lifestyle adaptations are crucial in the treatment of type 2 diabetes. However, implementation is difficult and patients especially with high glucose levels receive most often medication as first-line treatment instead of intensive lifestyle changes. We hypothesized that a primary lifestyle intervention as first-line treatment for newly diagnosed type 2 diabetes compared to standard of care is didactic, safe and can achieve metabolic control alone.
Methods
62 Adult patients with untreated type 2 diabetes diagnosed within the last 2 years and HbA1c $\geq$ 7.5% will be included in the study if they are clinically stable. After inclusion, patients are randomized to either the intervention group or the control group. Control group receives standard-of-care. Patients in the intervention group are asked to perform a 30-minute bicycle exercise. Clinical parameters are collected and blood analysis is performed throughout the exercise. Afterwards, patients undergo an exercise program along with regular motivational coaching, nutritional and diabetes counseling. HbA1c and glucose are measured after 3 months, to determine whether the intervention was successful. Primary endpoint is achievement of metabolic control, defined as reduction in HbA1c below a certain threshold depending on initial HbA1c, without antidiabetic medication 3 months after study enrollment.
Results
We conducted an interim analysis with 16 patients. Attainment of metabolic control was similar in both groups, with 75% ($n=8$) of patients in the intervention group reaching metabolic control after 3 months, compared to 50% ($n=8$) in the control group ($P=0.6084$). Both groups showed a significant reduction in median HbA1c levels from baseline over 3 months, with a 34.5% reduction from 10.15% to 6.65% in the intervention group ($P=0.0078$) and a 25.9% reduction from 9.85% to 7.30% in the control group ($P=0.0234$). The initial educative bicycle exercise lowered median blood glucose from 12.2 mmol/l to 10.05 mmol/l ($P=0.0078$) after 30 minutes. No significant safety issues were reported.
Conclusion
Data from this interim analysis supports the hypothesis, that intensified lifestyle intervention without anti-diabetic medication is safe and at least as efficient at reducing HbA1c as conventional treatment in patients with new-onset type 2 diabetes, even for patients with severe metabolic decompensation with an HbA1c higher than 10%.

Effectiveness of OneCare digital diabetes IMPACT care program in patients with type 2 diabetes mellitus: An open label randomized controlled trial protocol

Zareen Fatema[1], Shalini Rajesh[2], Preyander Singh Thakur[3], Deepa Kamath[4] & Basavaraj G S[5]
[1]OneCare Diabetes Clinic, Department of Clinical Research, Bengaluru, India; [2]Narayana Institute of Cardiac Sciences, Department of Diabetes and Endocrinology, Bangalore, India; [3]All India Institute of Medical Sciences, Department of Diabetes and Endocrinology, Bilaspur, India; [4]OneCare Diabetes Clinic, Department of Dietetics and Nutrition, Bengaluru, India; [5]Narayana Institute of Cardiac Sciences, Department of Diabetes and Endocrinology, Bengaluru, India

Background
People with Diabetes (PwD) experience many obstacles in diabetes management including, but not limited to lack of motivation, limited knowledge on diabetes self-management and treatment adherence issues. Diabetes mandates regular follow-ups for good glycemic control and manage complications. Internet and smartphones, have revolutionized digital health and hence by employing digital health and technology, better outcomes may be achieved; which is realizable in Indian context with a very high smartphone prevalence adding value to manage the burden of world's second largest population with diabetes. IMPACT program by OneCare is a personalised digital comprehensive care program for PwD providing holistic management of diabetes. Very little scientifically robust data is available for the plethora of available commercial diabetes apps in the country. The objective of OneCare IMPACT trial is to determine the effectiveness of IMPACT program on glycemic variability, glycemic and metabolic parameters, including medicine changes over the standard of care.
Methods/Design
The IMPACT trial is an Indian open label, multi-centre, randomized, controlled study. 120 patients with an established diagnosis of T2DM, aged 18-70 years, having a smartphone access will be randomly assigned to standard care versus IMPACT program over standard care. Blinded CGMs would be applied before and at the end of interventions in both the groups. OneCare program interventions are virtual, coach-interactive sessions delivered over 12 weeks. The interventions will include qualified CDE as health coach, yoga, physical training and emotional wellness sessions, and mobile app to log-in the blood glucose, diet plan/ meal pictures, exercise/step counts, sleep hours. Patients in the control group will receive standard of care, driven by diabetes educators, meted out by the centre. IMPACT is powered to expect an effect size of 0·8 (SD 2·1) mmol/l between two groups. The primary outcome analysis would be CGM metric variations (glycemic variability, time in range and mean amplitude of glucose excursions) . Secondary endpoints include changes in HbA1c, BMI, pulse rate and blood pressure. Change in medicine dosages, laboratory parameters (FPG, PPG, lipid profile, hsCRP) and hypoglycaemic events are further outcome parameters of interest.
Discussion
In light of paucity in studies looking at the efficacy of digital DSME programs in Indian population, the IMPACT trial would substantially contribute to the scientific evaluation of the efficacy of OneCare program in T2DM to provide evidence to encourage the usage. Clinical Trials Registry-India number: CTRI/2022/09/045748.

EP311

Design of a Randomized Withdrawal Period Following Long-Term Administration of Diazoxide Choline Extended-Release Tablets to People with Prader-Willi Syndrome

Evelien Gevers[1] & Anish Bhatnagar[2]
[1]Queen Mary University London, London, United Kingdom; [2]Soleno Therapeutics, Redwood City, United States

Background
PWS is a rare genetic neurodevelopmental disorder characterized by hyperphagia, obesity, hormonal deficiencies, and problem behaviors for which there is no approved treatment. DESTINY PWS (C601) was an international, placebo-controlled, Phase 3 study of DCCR (diazoxide choline) extended-release tablet in participants with PWS, age 4 and older with hyperphagia. C602 is a long-term, open label extension to C601. DCCR administration to participants with PWS in these studies resulted in significant improvements in hyperphagia, behavior, body composition and metabolic markers. Significant improvements in hyperphagia and PWS associated behaviors were observed in a comparison of results from C601 and C602 to data from a cohort of participants in a PWS natural history study.
Objective
In order to further confirm the effects of DCCR administration on hyperphagia and other endpoints in a controlled setting, a randomized withdrawal (RW) period has been initiated for participants enrolled in C602. All have received DCCR for more than 2 years. The goal is to supplement the currently available data with further controlled data to support a regulatory filing. Input into the design, conduct and analysis of the RW period were sought from patients and caregivers, clinicians and from the FDA.
Methods
Participants who are currently enrolled in C602 will be consented to participate in a 16-week RW period and will be randomized 1:1 to DCCR or placebo. Following completion of the RW period, participants will be eligible to enroll in a new open-label study (C614). Participants who do not consent to the RW period will be eligible to enroll in C614 following 16 weeks off treatment. The primary endpoint of the RW period is change from baseline in Hyperphagia Questionnaire for Clinical Trials total score. Secondary endpoints include the Clinical Global Impression of Improvement (CGI-I), and the Clinical Global Impression of

Severity (CGI-S). Each endpoint will be assessed at baseline (except CGI-I which measures improvement from baseline) and at 4, 8, 12 and 16 weeks. Additional endpoints include changes in other PWS-associated behaviors as assessed by the Prader-Willi Syndrome Profile Questionnaire, weight and BMI, a set of CGI-S of various PWS behaviors and assessments by the Caregiver Global Impression of Severity and Change. The Baseline and 16-week visit are in-clinic, all others are telemedicine. Safety monitoring will occur as it was in C602.

DOI: 10.1530/endoabs.90.EP311

EP312

Nutrition risk assessment in patients with Crohn disease

Maha Mtir, Myriam Ayari, Rim Bourguiba, Syrine Bellakhal, Imen Abdelaali, Taieb Jomni & Hedi Douggui
Internal Forces Security La Marsa Hospital, Internal Medicine, Tunis, Tunisia

Background
Malnutrition and weight loss are well-recognized complications of Crohn disease (CD), however nutritional routine assessment is not commonly performed, resulting in under-detection and under-treatment of both malnutrition and nutrient deficiencies. In fact, a number of nutrition screening tools are available including the Nutritional Risk Index (NRI).
Aim
The aim of this study was to investigate the prevalence and the associated factors of malnutrition during CD.
Methods
We conducted a retrospective single-center study, including patients followed for CD over a 7-year period [2014 - 2021]. Clinico-biological data, anthropometric data, disease severity, and long-term outcomes were collected. Malnutrition risk was estimated based on Nutritional Risk Index (NRI) calculated at first presentation with the following formula: NRI = (1.519 × serum albumin (g/L) + 41.7× (present weight/usual weight). Nutrition status of patients was categorized into four groups: NRI score of > 100 was considered in no risk group, 97.5–100 mild risk, 83.5–97.5 moderate risk, and < 83.5 severe risk group.
Results
In total, 50 patients were enrolled with a mean age of 44.3 years [20-82], a median disease duration of 106 months and a sex ratio M/F of 3.16. Based on NRI, 11/50 (22%) patients had normal nutritional status, 27/50 (54%) mild-moderate risk of malnutriton and 12/50 (24%) had severe malnutrition. In the univariate study, severe malnutrition was associated with the presence of anemia ($P=0.002$), thrombocytosis ($P=0.05$), hypocholesterolemia ($P=0.024$), as well as the existence of radiologic sarcopenia ($P=0.05$). This risk was increased by extensive ileal involvement of more than 50 cm ($P=0.014$), the occurrence of complications such as intraabdominal collection ($P=0.001$) and thromboembolic complications ($P=0.05$). Uncontrolled disease in severe relapse was also a factor associated with malnutrition ($P=0.05$). Regarding, patients who underwent surgical treatment, the occurrence of postoperative complications and extensive small bowl resection were factors associated with severe malnutrition with a *P*-value of 0.02 and 0.025 respectively. On multivariate regression analysis, patients developing intra-abdominal abscess were more likely to have malnutrition (OR 10.5 95% CI 2.22-49.51), $P=0.003$).
Conclusion
Patients with malnutrition had more severe course of CD. Nutritional Risk Index is a simple, validated and reproducible tool to identify patients at increased risk of malnutrition allowing adapted nutritional support.

DOI: 10.1530/endoabs.90.EP312

Is the concentration of ghrelin and leptin important for the course of COVID-19 infection?

Justyna Kuliczkowska-Płaksej, Aleksandra Jawiarczyk-Przybyłowska, Aleksandra Zdrojowy-Wełna, Anna Brona & Marek Bolanowski
Wroclaw Medical University, Endocrinology, Diabetes and Isotope Therapy, Wrocław, Poland

Objectives
SARS-Cov2 infection can lead to severe cytokine storm especially in obese patients. It is known that the cytokine storm might lead to severe clinical manifestations or even acute mortality in critically ill patients with COVID-19. Ghrelin as well as leptin can act as the proinflammatory cytokines. The essential question is whether the cytokine storm in COVID-19 patients with obesity is associated with adipokines dysregulation.
Aim
The study aimed to assess ghrelin and leptin concentrations in patients 6 months after the SARS-Cov2 infection in comparison to control group. In addition, selected biochemical, hormonal, anthropometric and densitometric parameters, considering the influence of sex, were also assessed.
Material and Methods
The study group included 53 patients with a history of COVID-19 and 87 healthy subjects in the control group. Leptin and ghrelin concentrations as well as hormonal and biochemical were measured. The bioethics committee of Wroclaw Medical University approved the protocol of the study. All subjects signed informed consent forms in line with the Declaration of Helsinki. The statistical analysis was performed using R for Windows statistical software (version 4.0.4, Vienna, Austria).
Results
A statistically higher ghrelin concentration was observed in the COVID-19 group in comparison to the control group (1190.56 pg/ml vs 901.39 pg/ml, $P=0.003$), with statistically significant impact of the sex on the relationship between COVID-19 and ghrelin concentration which was lower in males. No statistically significant differences in leptin concentration were observed between the groups although in both groups we observed significantly lower leptin level in males ($P=0.033$). Significant negative correlation was observed between ghrelin and testosterone and morning cortisol levels in COVID-19 group. We observed significant correlation between leptin concentration and metabolic parameters as well as CRP levels in both groups.
Conclusions
The higher levels of ghrelin in patients with mild form of SARS-Cov2 infection for up to six months ago might indicate the possible protective role of ghrelin in inflammatory process. In our study leptin levels did not differ between both groups of patients, probably because patients had only slightly increased BMI. We could also suppose that leptin might be involved in the dysregulation of proinflammatory cytokines in obesity, which is the leading cause of high morbidity and mortality in patients with SARS-CoV-2 infection.

The effect of olfactory odour stimulation on serum oxytocin levels and glucose metabolism: Data from the OLFAMET study

Lolita Matiashova[1,2], Anouk Hoogkamer[1], Alexander Komai[1], Chery Kunz[1], Milica Popovic[1], Yanick Spaar[1], Elias Zehnder[1], Judith Minder[1], Nimmy Varghese[3], Antje Welge-Lüssen Lemcke[4], Anne Eckert[2,5] & Katharina Timper[1,6]
[1]University Hospital Basel, Department of Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]University of Basel, Medical Faculty, Basel, Switzerland; [3]University of Basel, Research Platform, Molecular & Cognitive Neuroscience, Division of Neurobiology, Basel, Switzerland; [4]University Hospital Basel, Ear, Nose, Throat Clinic, Basel, Switzerland; [5]Psychiatric University Clinics Basel, Neurobiology Lab for Brain Aging and Mental Health, Basel, Switzerland; [6]University of Basel, Department Biomedicine Basel, Basel, Switzerland

Background
Studies in rodents and non-human primates revealed beneficial effects of oxytocin on systemic metabolism, body weight and food intake. Several rodent studies demonstrated that olfactory stimulation with D-limonene, improves systemic glycemia, reduces food intake and body weight, while olfactory stimulation with the scent of lavender oil had opposite effects. The aim of this study was to investigate if systemic oxytocin levels are affected upon olfactory stimulation with D-limonene and lavender oil, compared to placebo, in obese humans.
Methods
Single-centre, randomized, cross-over trial with $n=$ 40 participants of both genders, age 18-60 years, with a body mass index (BMI) $\geq$ 35 kg/m^2. Only participants with normosmia (as defined by Sniffin' Sticks Test and threshold, discrimination and identification (TDI) score) and absence of co-morbidities were included. Participants were stimulated with D-limonene, lavender oil and placebo (propylene glycol, all from Sigma Aldrich) for 15 minutes in a randomized cross-over fashion and a wash-out period of 1 week between treatments. After olfactory stimulation, participants received a calorie- and carbohydrate-rich mixed meal test, and blood glucose was measured at 0, 5, 15, 30, 60, 90, 120 minutes. Oxytocin levels were measured via an ELISA kit before and directly after olfactory stimulation with the different odours.
Result
The study included 40 subjects (12 males, 28 females) with a median age of 38.5 [28: 50.5] years and a median BMI of 38.1 [36.2: 42.5] kg/m^2. There was no

difference in oxytocin plasma levels before and after olfactory stimulation with D-Limonene or lavender oil vs placebo (delta (Δ) for D-limonene -2.23 [-14.84: 13.64] pq/ml ($P=0.696$), Δ lavender oil 0.35 [-15.33: 16.38] pq/ml ($P=0.804$) and Δ placebo 2.71 [-8.15: 14.29] pq/ml ($P=0.455$). Participants were divided into subgroups by BMI (< 40 kg/m^2 vs ≥ 40 kg/m^2) and further by gender. The only subgroup with an increase in plasma oxytocin were men with a BMI < 40 kg/m^2 upon olfactory stimulation with D-limonene (Δ 14.73 [2.45: 34.04] pq/ml (0.036*)), while neither changes were seen upon lavender oil (Δ - 7.24 [- 18.60: 2.28] pq/ml ($P=0.093$)) or placebo (Δ 3.75 [-10.36: 18.45] pq/ml ($P=0.779$)) nor in the other subgroups.

Conclusion

Acute olfactory stimulation with D-limonene increases plasma oxytocin levels exclusively in men with BMI < 40 kg/m^2. Thus, metabolic effects upon olfactory D-Limonene treatment do not seem to be related to changes in systemic oxytocin.

Levothyroxine dosing following bariatric surgery – A 4-year follow up

Sara Ribeiro[1,2], Bruno A Lima[3], Juliana Gonçalves[1,2], Telma Moreno[1], Helena Urbano Ferreira[1,2], Jorge Pedro[1,2,4], Ana Varela[1,2,4], Davide Carvalho[1,2] & Paula Freitas[1,2,4]

[1]Centro Hospitalar Universitário de São João, Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]Faculty of Medicine of Universidade do Porto, Porto, Portugal; [3]Oficina de Bioestatística, Porto, Portugal; [4]CRIO, Centro de Responsabilidade Integrada de Obesidade, Porto, Portugal

Introduction

The anatomical and physiological changes induced by bariatric surgery (BS) can significantly impact the absorption and pharmacokinetics of orally administered medication. In particular, levothyroxine (LT4) dosage, given its dependence on patient's weight and gastric pH for optimal absorption, is expected to change following BS. However, the literature is not unanimous and there is a void of longer-term studies. We aimed to compare LT4 dosage 4 years following BS, comparing malabsorptive versus restrictive techniques.

Methods

This was a retrospective observational study performed in a single center between 2010 and 2017 that included patients that underwent BS (Roux-en-Y gastric bypass (RYGB) and gastric sleeve (GS) and completed a 4-year follow up. All hypothyroid patients under LT4 ($n=86$, 92% female, age: 48 ± 11 years, BMI: 43.1 ± 4.3 kg/m^2) were selected from a total of 1070 patients (8%). GS was performed in 39 (45.3%) and RYGB in 47 (54.7%). 44 patients had autoimmune thyroiditis (AIT), 33 had thyroid resection, 3 had central hypothyroidism, 6 unclarified etiology.

Results

Four years after surgery, 23 (59%) patients that underwent GS and 22 (46.8%) that underwent RYGB required a lower daily dose of LT4, had to be increased in 6 (15.4%) and 10 (21.3%) and remained unchanged in 10 (25.6%) and 15 (31.9%), respectively. No statistically significant differences were found between types of surgery. For both GS and RYGB we observed statistically reduced values of total daily dose of LT4 at years 1 and 4 when compared to baseline ($P<0.001$), while the average weight-based daily LT4 was significantly increased at years 1 and 4 when compared to baseline (1.31 μg/kg (± 0.55) at baseline, 1.48 μg/kg (± 0.51) at year 1 and 1.42 μg/kg (± 0.55) at year 4 for GS; 1.11 μg/kg (± 0.44) at baseline, 1.47 μg/kg (± 0.55) at year 1 and 1.41 μg/kg (± 0.47), $P<0.001$). In pairwise comparisons, doses at year 1 and 4 are not statistically different. The same pattern was found independently of hypothyroidism etiology.

Conclusion

Our results are consistent with previous work, demonstrating that following BS, individuals with hypothyroidism and obesity frequently require a lower dose of LT4 per body weight. We further demonstrate that this trend is sustained for at least 4 years. Nevertheless, there is variability, with some patients requiring dosage increment or no adjustment, highlighting the importance of tight and individualized monitorization of patients with hypothyroidism after BS.

Pain in lipedema: proposal for clinical evaluation and correlation with clinical aspects, anthropometric measurements and hormonal profile

Laura Patton, Lorenzo Ricolfi & Micaela Bortolon

Istituto San Gregorio, Lymphological Clinic, Valdobbiadene, Italy

Aim

Lipedema is a **painful** fat disorder that affects 11-17% of woman. The diagnosis is based on typical clinical features: bilateral symmetrical disproportionate fatty tissue hypertrophy on the limbs sparing of the hands and feet, feeling of heaviness and tension, easy bruising, transient edema and pain in the affected areas. There are three clinical stages (1, 2 and 3) that refer primarily to appearance of the skin, texture of subdermal tissue and the presence of palpable nodules and fat accumulation. The clinical severity of the disease increases with the stage. The pain is a fundamental diagnostic element but it is not one of the criteria used for staging, it is very variable and a specific and comparable score to quantify it has not yet been validated. The aim of the study was to evaluate the correlation between the pain by pinching the subcutaneous tissue of the lower limbs with clinical history, anthropometric measurement and laboratory tests.

Materials and Methods

70 women with lipedema underwent clinical evaluation and blood tests. we measured the pain by pinching a skin fold in 6 points of the lower limbs applying a scale from 0 to 4 (0= no pain, 4= maximum pain). the total score ranges from 0 to 24.

Results

All patients had pinch pain, with a total score of 12-24 (mean 19.11 ± 3.57). Based on the clinical stage, we found: 37.1% with stage 1, 38.6% with stage 2 and 24.3% with stage 3. Age, years since disease onset and BMI increase progressively with the clinical stages ($P=0.031$, $P=0.005$, $P=0.000$ respectively). There were no significant differences in the pain score between the 3 clinical stages. There are no significant correlations with white blood cell count, CRP, glucose metabolism indices, estradiol, progesterone, androgen, IGF-1, TSH, FT3 and FT4 levels. The pain score does not correlate with age, disease duration, BMI, waist and hip circumference, WHR or with WHrT. The pain score correlates positively with a single anthropometric parameter: the ratio between hip circumference and height.

Conclusion

The clinical staging currently used for lipedema does not correlate with the pain. Pain should be systematically assessed with a specific score and should be included in the criteria for assessment of clinical severity or staging. The ratio between hip circumference and height, as a new anthropometric index, could be an interesting index for the clinical evaluation of the patient affected by lipedema.

Using Morisky scale to measure adherence and factors associated with non-adherence in patients with type 2 diabetes mellitus: A systematic review

Marian Archer[1] & Sofia Llahana[2]

[1]Leyton Healthcare, 4th Floor Oliver Road Polyclinic, London, United Kingdom; [2]City, University of London, Myddelton Street Building, London, United Kingdom

Aim

We conducted a systematic review aiming to:

- Measure self-reported adherence to medication in patients with type 2 diabetes mellitus (T2DM) using the Morisky medication adherence scales (MMAS).
- Identify barriers and facilitators associated with adherence.

Methods

The systematic review was conducted in accordance with the PRISMA Framework and was registered with PROSPERO (CRD42022359969). The Medline, Embase, Emcare and Ovid Nursing database were searched with predefined keywords and search strategy between the period of 2013 and 2022. Studies were included within the current review if they were cross-sectional and used the MMAS to measure adherence to medication in patients with Type 2 Diabetes (T2DM). Double-blinded screening was used to minimise the risk of bias. Inclusion criteria for participants in the studies were: adults $>$ 18 years, diagnosed with T2DM and prescribed anti-glycaemic medications, including insulin. A narrative synthesis was adopted for data analysis to report factors that influenced nonadherence and MMAS adherence scores. Deductive thematic analysis utilising the COM-B Behavioural change model was used to map identified barriers and facilitators to adherence against the Capability, Opportunity and Motivation.

Results

Of the 9,990 returned records, 30 studies from 17 countries and with a total of 8,402 participants across all studies were analysed. Three studies found that $>80\%$ of their participants had high prevalence of adherence; in 15 studies participants reported high level of adherence to medication, in 3 studies participants had medium level and in 12 studies participants had low adherence to medication. The average level of high adherence was 40.93% and low adherence 42.64%, highlighting most study participants had a low level of medication adherence. Most common patient-level barriers to adherence included depression and poor diabetes knowledge, polypharmacy and healthcare related cost.

Conclusions
The MMAS scale is a reliable tool to measure self-reported adherence and yield homogenous results across studies. Adherence to medication remains low. A greater identification of diabetes-related depression, fewer medication, structured diabetes education programmes and a greater awareness of barriers by health care professionals can contribute to effective behavioural changes that could positively influence adherence to medication.

Atezolizumab induced new-onset type 1 diabetes mellitus and thyroiditis

Joaquin de Carlos[1], Lucia Zabalza[2], Javier García Torres[3], Jon Yoldi[4], Nerea Esparza[4] & Juan Zubiria[5]
[1]Hospital de Zumárraga, Endocrinology, Zumarraga, Spain; [2]Hospital Universitario de Navarra, Gatroenterology, Pamplona, Spain; [3]Hospital Universitario de Araba, Endocrinology, Vitoria-Gasteiz, Spain; [4]Hospital Universitario de Navarra, Pamplona, Spain; [5]Clínica Universidad de Navarra, Madrid, Spain

Introduction
Cancer is the result of genetic and epigenetic alterations generating uncontrolled cell growth. These molecular changes maintain an immunosuppressive microenvironment allowing tumor spread. Immune checkpoint inhibitors (ICI) are novel therapeutic strategies in cancer treatment, promoting anti-tumor response by boosting cytotoxic T lymphocytes. Despite their high effectiveness, they can trigger the activation of diverse autoimmune diseases in genetically predisposed individuals. New-onset autoimmune Diabetes Mellitus type 1 (T1D) is an extremely unusual side effect, described in less than 1% of patients.
Materials and Methods
A case report description conducted with the consent of the patient and with provisions of the Declaration of Helsinki.
Results
Here we present a 44-year-old male with a medical history that includes chronic hepatitis C virus infection, and paranoid schizophrenia. No personal or familial diagnosis of diabetes. He had recently been diagnosed with hepatocarcinoma, presenting retroperitoneal and hepatic hilar adenopathy, making the tumor unresectable. After the onset of ICI, he was diagnosed of two PD-L1 inhibitor-induced autoimmune endocrinopathies, presented as diabetic ketoacidosis (DKA) and thyroiditis. After two cycles of atezolizumab and bevacizumab, he consulted the emergency department with abdominal pain and diabetes cardinal features (polyuria, polydipsia, vomiting). Blood tests demonstrated hyperglycemia superior to 800 mg/dl, capillary ketonemia >3 mmol/l, metabolic acidosis (pH 7.24 with HCO3- 14 mEq/l). Subsequent studies detected a low level of C-peptide level 11 pmol/l, and positive glutamic acid decarboxylase and insulinoma-associated antigen-2 antibodies. Thyroid examination was compatible with thyroiditis, showing a high free thyroxine level (1.91 ng/dl) with low thyrotropin (0.08 mIU/l), negative anti-peroxidase, and anti-TSH receptor, and slight positivity of antithyroglobulin antibodies. After reaching metabolic stabilization, treatment with Atezolizumab was restarted, with no further complications.
Conclusion
Monoclonal antibody targeting has become a breakthrough, generating a shift in the treatment of advanced malignancies. These new drugs promote an anti-tumor immune response. Nevertheless, immune checkpoint blockade is associated with a risk for immune-related adverse events in genetically predisposed individuals. T1M related to ICI is a rare condition that presents as a life-threatening emergency and should be recognized and treated early. Blood glucose and Hb1Ac determinations should be performed at periodic visits for detection. There are genetic factors that predispose susceptible individuals, but there is no evidence of studies to be performed before the onset of ICI or preventive strategies.

Leptin reduces the risk of poor glycemic control in type two diabetes mellitus patients on metformin therapy

Mahmoud A. Alfaqih[1], Mukhallad Aljanabi[2], Ebaa Ababneh[2], Mariam Khanfar[2] & Mai Sater[1]
[1]Arabian Gulf University, Medical Biochemistry, Manama, Bahrain; [2]Jordan University of Science and Technology, Physiology and Biochemistry, Irbid, Jordan

Purpose
Type two diabetes mellitus (T2DM) is a chronic disease of debilitating complications. Good glycemic control could delay disease progression and microvascular complications. Nonetheless, some patients cannot maintain glycemic control.
Patients and Methods
We recruited 340 T2DM patients on metformin therapy and categorized them according to their HbA1c levels into patients with good vs poor glycemic control. The levels of serum leptin were measured. Patients were genotyped for the following SNPs in the *LEP* gene (rs7799039, rs2167270 and rs791620).
Results
Serum leptin reduced the risk of poor glycemic control following adjustments with age, gender, BMI, treatment duration and HOMA-IR (OR = 0.984; CI: 0.973 - 0.994; $P=0.002$). The GA genotype of rs2167270 was less frequent in patients with poor glycemic control and reduced its risk in multivariate analysis (OR = 0.428; CI: 0.248 - 0.737; $P=0.002$).
Conclusion
These findings suggest that leptin therapy or strategies that re-sensitize tissues to existing leptin could be utilized for better glycemic control in T2DM patients on metformin.

Implementation of the use of MFG in Antequera Hospital (Spain)

Maria Jose Vallejo Herrera[1], Viyey Kishore Doulatram Gamgaram[1] & Jose Abuin[2]
[1]Hospital Regional Universitario de Málaga, Endocrinology and Nutrition, Málaga, Spain; [2]Hospital Quirón Salud Málaga, Endocrinology and Nutrition, Málaga, Spain

Introduction
Poor metabolic control in type 1 diabetes mellitus (T1DM) is associated with micro and macrovascular complications. The implementation of interstitial glucose monitoring systems has contributed to the improvement of glycemic control in recent years.
Objectives
Our main objective was to analyze the results of implementing flash glucose monitoring (FGM) devices after 1 year, and see if it managed to improve glycemic control in our patients.
Material and Methods
Cross-sectional observational study in people with T1DM, carriers of the FGM devices, with follow-up at Hospital of Antequera (Malaga, Spain) during the first year since the establishment of a specific medical consultation. We collect the HbA1c prior to the start of FGM, HbA1c a year after FGM, average glucose, time in range, and glucose management indicator (GMI). The analysis has been carried out using the JAMOVI program.
Results
154 patients were included, 41.2% women, mean age 40.8 ± 14.7 years, mean evolution time 18.9 ± 11.5 years, 18.9% presented diabetic retinopathy, 15.5% presented diabetic neuropathy, 27% presented high blood presure, 39.2% associated dyslipidemia. The HbA1c prior to the use of FGM is 8.13% and one year after the use of FGM is 7.65% ($P<0.01$). The average glucose from the FGM is 170 ± 47.6 mg/dl, variability 36.6 ± 8.22%, GMI 7.33 ± 1.34%, time-in-range (TIR) 54.8 ± 21.1%, reaching a TIR above 70% in 27.5% of the patients, use of the sensor of 86.2 ± 18.6%.
Conclusions
The use of FGM has improved glycemic control in people with T1DM being followed up at the Endocrinology consultation at the Hospital of Antequera.

Clinical features of the course of various types of diabetes mellitus in young people

Alla Ovsyannikova[1], Marina Dudina[1], Regina Galenok[1] & Oksana Rymar[1,2]
[1]630089, Siberian Branch of Russian Academy of Sciences, Novosibirsk, Russia; [2]630089, Research Institute of Internal and Preventive Medicine – Branch of the Institute of Cytology and Genetics, Siberian Branch of Russian Academy of Sciences, Novosibirsk, Russia

The age group under 45 years is the most difficult to determine the type of diabetes mellitus (DM), it can include type 1 (DM1), type 2 (DM2), MODY and LADA diabetes. Objective of the study: to determine clinical markers for differential diagnosis of types of DM in young patients.

Materials and Methods
202 patients with onset of diabetes aged 18 to 45 years were included: group 1 - 77 patients with MODY, 2 - 83 with DM 2, 3 - 14 with DM 1, 4 - 28 with LADA. The groups were comparable in terms of gender and age. Patients were compared according to aggravated heredity for DM, features of the onset of the disease, comorbid pathologies and baseline anthropometric parameters.
Results
Patients with MODY more often than with DM2, with DM1 and LADA had a burdened heredity for DM (95 and 79%, $P=0.005$, 95 and 29%, $P<0.001$, 95 and 64 $P=0.035$), more often relatives developed DM up to 45 years (70 and 29%, $P<0.001$, 70 and 14%, $P<0.001$) and more than in 3 generations (65 and 28%, $P<0.001$, 65 and 7%, $P<0.001$, 65 and 8%, $P<0.001$, 65 and 15%, $P<0.001$). Patients with DM2 had often than with MODY obesity (34 and 4%, $P<0.001$), diseases of the gastrointestinal tract (25 and 6%, $P=0.001$) and arterial hypertension (14 and 5%, $P=0.044$). Patients with DM1 had more often than in MODY and DM2 symptoms of DM (93 and 23%, $P<0.001$, 93 and 26%, $P<0.001$), weight loss (50 and 3%, $P<0.001$, 50 and 0%, $P<0.001$), ketoacidosis (64% and 1%, $P<0.001$, 64% and 1%, $P<0.001$). In DM1, ketoacidosis was more common than in LADA (64 and 15%, $P=0.013$). In LADA more often in DM2 were symptoms of DM (61 and 26%, $P=0.016$), weight loss (15 and 0%, $P=0.017$) and less often gastrointestinal tract diseases (0 and 25%, $P=0.031$). With LADA more often than with MODY were symptoms of DM (61% and 23%, $P=0.009$), obesity (31% and 4%, $P=0.008$) and thyroid pathology (31% and 9%, $P=0.040$).
Conclusion
Clinical characteristics for differential diagnosis of the type of DM are aggravated heredity for DM, weight of patients; the presence of clinical symptoms, ketoacidosis in the debut; the presence of arterial hypertension, concomitant diseases of the gastrointestinal tract and thyroid gland.Acknowledgements: Abstract was written of the grant of the President of the Russia for state support of young Russian scientists - doctors of sciences MD-3017.2022.3.

Long-term glycaemic follow-up results of hospitalised COVID-19 patients with hyperglycemia

Sinem Geçti, Emre Sedar Saygili & Ersen Karakilic
Canakkale Onsekiz Mart University Faculty of Medicine, Turkey

Introduction and Aims
A higher prevalence of hyperglycemia has been reported in patients affected by coronavirus disease 2019 (COVID-19). Our study aims to retrospectively evaluate the course of hyperglycemia in patients recovering from COVID-19.
Methods
All patients who were hospitalised in Çanakkale Onsekiz Mart University Hospital between March 2020 and March 2022 due to COVID-19 and whose HbA1c values were checked during hospitalisation were examined. Chronic kidney damage, oncological diagnosis, and pregnancy were determined as exclusion criteria. Three hundred twenty-four patients who met the current conditions were included in the study. Patients were followed up 3-12 months after hospitalisation.
Results
A total of 324 patients with a mean age of 67.48 ± 12.36 years, including 151 (46.6%) women, were included in the study. It was determined that 191 (59%) of 324 cases were still alive, and the number of deceased was 133 (41%). Patients with known DM had significantly increased glucose and glycated hemoglobin (HbA1c) values before and during hospitalisation (glucose 167 (IQR: 129-222) vs 225 (IQR: 162-329) mg/dl, $P<0.001$) (HbA1c 7.8 (IQR: 7.0-9.75) vs 8.5 (IQR: 7.3-10.55), $P<0.001$). A significant decrease was observed in glucose and HbA1c values measured during hospitalisation and in the last outpatient clinic controls of known DM patients (glucose 225 (IQR: 162-329) vs 164 (IQR: 126-232) mg/dl, $P<0.001$) (HbA1c 8.5 (IQR: 7.3-10.55) vs 7.9 (IQR: 6.7-9.03), $P<0.001$). When 163 patients from known diabetic patients who came to the outpatient clinic were evaluated, it was observed that the treatment did not change in 83 (50.9%) patients, it was intensified in 67 (41.1%), and the treatment was reduced in 13 (8%). A significant decrease in glucose and HbA1c levels was observed compared to baseline in known diabetic patients who did not change treatment during follow-up (glucose 204 (IQR: 152-303) vs 165 (IQR:117-227) mg/dl, $P=0.001$) (HbA1c 8.35% (IQR: 7.1-10.1) vs 7.8% (IQR: 6.6-8.8), $P=0.001$).
Conclusion
In our study, it was observed that in hospitalised diabetic COVID-19 cases, the level of hyperglycaemia at admission decreased during follow-up. In our patients whose anti-diabetes treatment did not change, regression was observed in hyperglycaemia with the recovery of the infection. Prospective studies of the finding's evaluation will provide more precise evidence.

DOI: 10.1530/endoabs.90.EP322

Programmed cell death-1 inhibitor-induced Type 1 Diabetes Mellitus – an interesting case presenting with diabetic ketoacidosis

Ariana Maia[1], Catarina Cidade Rodrigues[2], Daniela Soares[1], Sílvia Santos Monteiro[1], Maria Teresa Pereira[1], Cláudia Amaral[1] & Maria Helena Cardoso[1]
[1]Hospital Geral de Santo António, Endocrinology, Porto, Portugal; [2]Centro Hospitalar do Tâmega e Sousa, EPE - Hospital de Amarante, Endocrinology, Amarante, Portugal

Introduction
Immunotherapy has demonstrated a key role in the current individualized treatment of multiple neoplasms, with adverse events related to the endocrine. Thyroid dysfunction is the most frequent reported endocrine event during treatment with pembrolizumab, being autoimmune diabetes an extremely rare adverse effect.
Case Report
We present a case of a 72-year-old man with a progressing urothelial bladder carcinoma (stage IIIB), under treatment with pembrolizumab since 2018. He had the diagnosis of primary hypothyroidism four months after starting the treatment, no personal or family history of diabetes mellitus, and his usual fasting plasma glucose levels were 102-113 mg/dl in the last six months. He was admitted in 2022 due to abdominal pain, anorexia, polydipsia, polyuria, nausea and vomiting with one week of evolution after performing contrast-enhanced imaging, with criteria for severe diabetic ketoacidosis (DKA) (pH 7.18, HCO3 2.9 mEq/l, glucose 695 mg/dl, ketonemia 7.3 mmol/l). He was medicated with prednisolone 20 mg/day three days before admission, due to suspected contrast hypersensitivity reaction. During hospitalization, he underwent fluid therapy with KCl supplementation and intravenous insulin infusion, having transitioned to a basal-bolus scheme after DKA resolution, with progressive glycemic stabilization. Further investigation revealed undetectable levels of C-peptide (0.07 ng/ml), HbA1c 9.2% and positive islets autoimmunity (positive anti-IA2 antibodies), which allowed the diagnosis of autoimmune diabetes. The drug was transiently suspended, and the patient resumed treatment after glycemic profile optimization under insulin therapy.
Conclusion
This clinical case highlights the importance of clinical suspicion and glycemic monitoring in addition to thyroid function, as an integral part of treatment protocols in patients on pembrolizumab and other immune checkpoint inhibitors. In the presence of autoimmune diabetes, the need for long-term insulin therapy is invariably necessary, with the possibility of resuming the drug after adequate glycemic stabilization.

Micronutrient deficiencies and functional disorders of postmenopausal diabetic women

Berriche Olfa, Hana Ben Jemâa, Amel Gamoudi, Rym Ben Othman, Nadia Ben Amor & Jamoussi Henda
National Institute of Nutrition, Department A, Tunis, Tunisia

Aim of the study
Functional disorders might be caused by micronutrient deficiencies. The objective of our study is to screen the micronutrient deficiencies of postmenopausal diabetic women and determine their impact on the functional disorders.
Methods
This is a cross-sectional descriptive study made within the National Institute of Nutrition of Tunis, including 55 postmenopausal diabetic women which benefited from a dietary survey. Functional disorders were detected by the Screening of Micronutrient deficiency (DDM) questionnaire that allows to classify these disorders and evaluate the different disruptions.
Key findings and Results
The average age of our patients is of 63.7 ± 6.5 years old. The dietary survey showed an insufficiency intake of vitamins A, D, C, E, B6, B9, and B12 for respectively 35%, 60%, 38%, 49%, 53%, 34% and 52% of cases. Additionally, insufficiencies of magnesium, iron and zinc intake were observed, for respectively, 49%, 40% and 64% of cases. We found negative and statistically

significant correlations between fatigue, mood disorders and vitamin C (r=-0.297, P=0.028), magnesium (r=-0.441, P=0.01), and iron (r=-0.458, P < 0.01), between digestives troubles and fiber intake (r=-0.458, P <0.01), between osteoarticular disorders and degenerative diseases and vitamin A intake (r=-0.422, P=0.01) as well as manganese (r=-0.287, P=0.03), and finally between circulatory system diseases and vitamin C (r=-0.294, P=0.03).
Discussion
A suitable micronutrient approach for each of our patients is mandatory to maintain an optimal health and correct the functional disorders.

Quality of life and associated factors in a Tunisian diabetic population

Eya Safi, Haifa Abdesselem, Syrine Trabelsi, Yesmine Jallouli, Chaima Sdiri, Maryam Cheikhrouhou, Fatma Boukhayatia, Kamilia Ounaissa, Asma Ben Brahim, Rim Yahyaoui & Chiraz Amrouche
National Institute of Nutrition, Outpatient Department and Functional Explorations, Tunis, Tunisia

Objective
Our objective was to assess quality of life (QoL) in a diabetic population and to identify factors associated with its deterioration.
Patients and Methods
This was a cross-sectional study of 100 type 1 or 2 diabetic patients followed up at the outpatient department of the National Institute of Nutrition in Tunis. The QoL was evaluated using the questionnaire "Diabetes Quality of Life" (DQoL) validated in Arabic version. The latter is a score composed of 29 items divided into 3 factors: concern, impact and satisfaction. It is positively correlated with an impaired QoL.
Results
The mean age of the population was 55.9 ± 13 years with a female predominance in 2/3 of the cases (67%). The majority were type 2 diabetics (89%). The age of diabetes was 14.3 ± 9.35 years. Degenerative complications were observed in 61% of the patients. Three quarters (74%) were on insulin therapy. The mean hbA1c was 11.5 ± 1.8% with an out-of-target level in 66% of cases. Diabetic imbalance was mainly due to dietary deviation (89%). Poor adherence to treatment was noted in a quarter of the population (25%). The mean DQoL score was 85.2 ± 13.6. This score was higher in the female population but not significantly so (P=0.31). It was significantly higher in type 2 diabetics compared to type 1 diabetics (P=0.019). Unbalanced diabetes and the presence of degenerative complications were significantly associated with a deterioration of the QoL (P<0.001 and P=0.031 respectively). The DQoL score was also higher in insulin-treated diabetics but not significantly so (P=0.37). Higher education and medication adherence were associated with better QoL (P=0.23 and P<0.001 respectively).
Conclusion
This study demonstrates the impact of several factors, including diabetes imbalance, the presence of degenerative complications, and educational level, on the QoL of diabetic patients. Therefore, the improvement of this parameter requires therapeutic education and a global management of this chronic pathology.

Increased Knowledge and Awareness about Endocrinology and Science-based Careers Amongst School Children through Public Engagement Event

Mirna Elghobashy[1], Shams Ali Baig[1], Fazna Rahman[1], Syeda Sabbah Batool[1], Mukunth Kowsik[1], Josh Banerjee[1], Kushi Kumar[1], Mohammed Faraaz Saiyed[1], Vardhan Venkatesh[1], Pranav Viswanath Iyer[1], SIMBA and CoMICs Team[2] & Punith Kempegowda[2,3]
[1]University of Birmingham Medical School, United Kingdom; [2]Institute of Metabolism and Systems Research, University of Birmingham Medical School, United Kingdom; [3]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom

Background
It is important to engage and encourage young adults from all economic backgrounds to pursue a career in science and medicine to create an equitable society. Several awareness campaigns are currently underway to improve the awareness and knowledge of various metabolic conditions to promote good lifestyle practices in adolescents. However, such opportunities do not seem to reach those from deprived areas. We conducted public engagement events on students' attitudes towards science-related careers and knowledge and perceptions regarding diabetes, polycystic ovary syndrome (PCOS), health technology, and obesity in deprived areas. In this study, we report the impact of such interventions.
Methods
A half-day public engagement event was held in two state secondary schools in deprived areas of Birmingham in July 2022. Students aged 14-16 years were invited to attend the sessions. The event included three pre-recorded lectures on obesity and diabetes, PCOS and health technology. Following the lecture, all participants worked in groups of 5-8 to make posters showcasing what they learned during the session. This was followed by a speed-dating session with professionals in various science fields so students can find out more about how to get into science-related careers. All participating students completed pre- and post-session surveys. Responses were quantitatively analysed using Wilcoxon Signed Rank. Thematic analysis was conducted on the posters to identify themes as understood by students.
Results
Students had an increased understanding of diabetes (+24.5%, P<0.001), obesity (+15.0%, P=0.007), PCOS (+65%, P<0.001) and emotional well-being (+16.2%, P=0.003), and a better understanding of a career as a scientist (+28.4%, P<0.001). Students also had an increased understanding of what a career as a doctor entailed and an increase in the proportion of students who said they would be interested in a career in health science; however, these were not statistically significant (+1.9%, P=0.904 and +4.9%, P=0.519 respectively). The majority of students found interacting with healthcare professionals informative, and 40% of students said they are likely to do further reading regarding healthcare careers. Within the PCOS and diabetes posters, the main themes identified included the pathophysiology, symptoms and management of each condition as well as the differences between type 1 and type 2 diabetes. The overarching themes of the health technology posters were of health technology at an individual level and within the healthcare system.
Conclusions
Public engagement activities can change attitudes towards science-related careers, enhance understanding of medical conditions and perceptions of these conditions in students.

Precipitating factors of diabetic ketoacidosis before and during COVID-19 pandemic

Gorchene Asma[1], Taieb Ach[1], Jihene Sahli[2], Ben Abdelkarim Asma[1], Nassim Ben Hadj Slama[1], Hamza Elfekih[1], Ghada Saad[1], Molka Chadli Chaieb[1] & Koussay El Euch[1]
[1]Farhat Hached Hospital, Endocrinology Department, Sousse, Tunisia; [2]Farhat Hached Hospital, Community Medecine, Sousse, Tunisia

Introduction
COVID-19 has been incriminated directly and indirectly in the increase of patients presenting with diabetic ketoacidosis.
Aim
The aim of this study is to compare diabetic ketoacidosis precipitating factors in the pre-pandemic and during the pandemic.
Methods
This is a retrospective comparative study between patients hospitalized in the diabetology department in the university hospital Farhat Hached of Sousse for diabetic ketoacidosis in the pre-pandemic (between March 2018 until March 2020) (G1) and during pandemic period (between March 2020 until March 2022) (G2).
Results
A total of 340 patients were included in this study, with 137 patients admitted in the pre-pandemic period (G1) and 203 admitted during pandemic period (G2). The overall distribution of diabetic ketoacidosis precipitating factors differed significantly in the pre-pandemic compared to the pandemic period (P=0.028) with a significant increase of psychological stress (31.2% in G2 vs 22.4% in G1 with an adjusted residual (AR) of 1.98) and excessive food intake notably hypertonic drinks (6.5% vs 2.2%, AR=2) at the expense of corticosteroid use as its accountability in precipitating DKA significantly decreased in G2 (1.5% in G2 vs 6.5% in G1, AR=2.2). In contrast, overall infections accountability did not differ between the two groups (28.6% in G2 vs 29.1% in G1, AR=0.1). The same was noticed regarding cardiovascular events. No identifiable precipitating factor was found in 40.3% in G1 vs 31.7% in G2 (AR=1.6). More specifically, infectious precipitating factors had a significantly different distribution between

the two groups ($P<0.001$) with COVID-19 becoming the first infectious precipitating factor of DKA in G2 (37.04% vs 0% in G1, AR = 4.2) with a decrease of pulmonary and other influenza like illness. The accountability of cutaneous, urinary, profound and other specific infections remained the same in the two groups with a respective AR of 1.8, 0.6, and 0.9.
Conclusion
COVID-19-like any other infection- is directly responsible for triggering diabetic ketoacidosis. COVID-19 seems to decompensate diabetes also indirectly through different mechanisms with an increased accountability of psychological stress and excessive food intake as precipitating factors due probably to periods of lockdown and restricted social activities. The accountability of corticosteroid use seems to decline as most of patients in this study who developed COVID-19 had minor symptoms and therefore did not require corticosteroids.

Dynamics of HbA1c and glycemia in OGTT during pregnancy in healthy women

Violeta Mladenovic[1,2], Marija Andjelkovic[2,3], Zoran Gluvic[4,5] & Milena Mitrovic[6,7]
[1]University Clinical Center «Kragujevac», Serbia, Clinic for endocrinology, Diabetes and Metabolic Diseases, Kragujevac, Serbia; [2]Faculty of Medical Sciences, Univeristy of Kragujevac», Serbia, Kragujevac, Serbia; [3]University Clinical Center «Kragujevac», Serbia, Department of Laboratory Diagnostics, Kragujevac, Serbia; [4]Zemun Clinical Hospital Center, Division of Internal Medicine, Dept of Endocrinology, Beograd, Serbia; [5]School of Medicine, University of Belgrade, Serbia, Beograd, Serbia; [6]University Clinical Center Vojvodina, Novi Sad, Serbia, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Novi Sad, Serbia; [7]School of Medicine, University of Novi Sad, Novi Sad, Serbia

Introduction
Some physiological changes in HbA1c during pregnancy should be considered to determine its optimal value for glycemic control. Erythrocytes half-life decreases during pregnancy, which is reflected in a decrease in HbA1c.
Aim
The aim of this study is to analyse HbA1c during pregnancy in healthy population of pregnant woman. Matherial and methods: The study included 77 pregnant women in the first trimester registered in Center for endocrinology UCC Kragujevac that were tested using OGTT, according to ADA criteria: pregestational and gestational diabetic women were excluded, and also determinaning thyroid parameters (fT4, TSH, TPOAb). We analyzed the HbA1c values of 46 healthy pregnant women (without gestational diabetes mellitus and thyroid disorders including autoimmune thyroiditis). The characteristics of the participants were expressed as mean ± standard deviation.
Results
The mean age of 46 healthy pregnant women was 29.4 ± 4.5 years It has been shown that the normal range of HbA1c was 4.97-5.14% in early pregnancy, and 5.09-5.34% in late pregnancy (Table).
Conclusion
This study demonstrates that the reference range of HbA1C in healthy pregnant women during pregnancy was 4.97% to 5.34% in our population.
Keywords: HbA1c, OGTT, pregnancy

HbA1c (%)	1.trimester	2. trimester	3. trimester	After delivery
X ± SD	5.05 ± 0.28	5.03 ± 0.37	5.08 ± 0.13	5.22 ± 0.43

A case series of monogenic diabetes in pregnancy

Sandhi Nyunt[1], Rochan Agha-Jaffar[1], Maud Hardy[2], Simona Racaru[1], Roberto Cunsolo[1], Christina Yu[2], Jayne Terry[2], Shivani Misra[1] & Stephen Robinson[1]
[1]Imperial College Healthcare NHS Trust, Metabolic Medicine, London, United Kingdom; [2]Imperial College Healthcare NHS Trust, Maternal Medicine, United Kingdom

Monogenic diabetes is estimated to account for 1-2% of all diabetes cases diagnosed before the age of 45. It is caused by mutations in genes encoding for beta cell development, function and regulation. We present three cases of monogenic diabetes in pregnancy.
Case 1
Age 30, Para 3, White ethnicity. This individual was screened for a GCK mutation at 18 weeks gestation (third pregnancy) on the basis of family history. She required metformin and insulin to maintain glycaemic control. Fetal birth weight (FBW) measured 3.7 kg at 39 weeks' gestation. Post-partum, the mutation was confirmed in the mother: she has mild persisting fasting hyperglycaemia.
Case 2
Age 40, Para 3, Turkish. This case represents a known homozygous HNF1A mutation. Insulin requirements increased during pregnancy. Delivery was expedited (concerns regarding pre-eclampsia) and her baby measured 2910 g at birth (37 + 2 weeks' gestation).
Case 3
Age 30, Primip, Black African-Caribbean ethnicity, who was diagnosed aged 22 with mitochondrial genetic mutation (m.3243A4 > G) following onset of blackouts and diabetes. Initially she had planned for pre-implantation genetic diagnosis but conceived spontaneously: she continues on her basal bolus regime during pregnancy. Chorionic villus sampling at 11 + 4 weeks detected 43% mitochondrial variant. Plans are in place for neonatal cardiac evaluation. Pregnancy may be challenging for women with diagnosed or undiagnosed monogenic diabetes. Our case series illustrates that monogenic diabetes can present in all ethnicities and that close oversight of glycaemic control and fetal monitoring are imperative. Additional maternal concerns about inheritance in offspring should be addressed with appropriate counselling.

VLCKD: a suitable nutritional approach for subjects with obesity and glucose derangements?

Giovanni Chirico[1], Annamaria Docimo[1], Ludovica Verde[1], Nicola Tecce[1], Annamaria Colao[1,2], Luigi Barrea[3] & Giovanna Muscogiuri[1,2]
[1]University of Naples Federico II, Clinical Medicine and Surgery, Section of Endocrinology, Diabetology and Andrology, Naples, Italy; [2]University of Naples Federico II; [2]UNESCO Chair for Health Education and Sustainable Development, Federico II University, Naples, Italy., Naples, Italy; [3]Pegaso Telematic University, Department of Human Sciences, Pegaso Telematic University, Naples, Italy

Introduction
The VLCKD is an established diet regimen with positive metabolic effects. Based on that, it was hypothesized that VLCKD could also have positive effects on glucose metabolism and insulin resistance, as well as obesity. Specifically, we aimed to investigate the efficacy of VLCKD on glucose metabolism in subjects with obesity compared to Mediterranean Diet.
Methods
In this cross-sectional study anthropometric parameters (weight, height and waist circumference), body composition (by bioimpedance analysis) and biochemistry data (fasting blood glucose, insulin and HbA1c) of subjects with obesity that underwent to VLCKD were collected before and at the end of active phase of the ketogenic protocol. Finally, Homeostasis Model Assessment of Insulin Resistance (HoMA-IR) was calculated.
Results
Fifty subjects with obesity were enrolled of whom 32 reached the end of the active phase of VLCKD (M5/F27, aged 37.33 ± 15.91 years). At the end of the active phase, the average weight loss was nearly 11.8% of initial weight, with significant reduction in BMI (36.90 ± 5.15 kg/m^2 vs 32.53 ± 7.54 kg/m^2, $P=0.001$), waist circumference (106.83 ± 15.8 cm vs 97.05 ± 23.36 cm, $P=0.009$) and fat mass (40.32 ± 6.01% vs 35.15 ± 11.47%, $P=0.008$). No significant changes were found in fat free mass (59.68 ± 6.01% vs 58.28 ± 16.94%, $P=0.641$). We also detected a significant improvement in fasting blood glucose (89.94 ± 11.5 mg/dl vs 82.66 ± 9.4 mg/dl, $P=0.002$) compared to the baseline. Finally, comparison from baseline to the end of active phase of VLCKD of HOMA-IR showed an improving trend in insulin sensitivity although it was not statistically significant ($P=0.127$).
Conclusion
Our results suggest that VLCKD can be a suitable nutritional approach for subjects with obesity and glucose derangements. Indeed, VLCKD allows a faster weight loss compared to other nutritional approaches[1] thus rapidly shortening the history of obesity and thus the obesity-related damage on glucose metabolism.

Finally, the same entity of weight loss is accompanied by a greater improvement of glucose metabolism when it is obtained by VLCKD compared to other nutritional approach such as MD[2-5] and this could be due to VLCKD property to preserve muscle mass, i.e. tissue important for metabolic activities.

Mauriac syndrome: A rare complication of type 1 diabetes mellitus

Hanane Boualam, Sanaa Bammou, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
Mohamed VI University Hospital Center, Department of Endocrinology, Diabetology, Metabolic Diseases Nutrition, Marrakesh, Morocco

Introduction
Mauriac syndrome (MS) is a rare complication of type 1 diabetes mellitus (DM1), characterized by hepatomegaly (hepatic glycogenosis), puberty and growth delay, transaminase elevation and reduction of IGF1 (insulin-like growth factor 1). MS is more common in children and adolescents with poor glycemic control.
Case Report
A 17-years-old Type 1 diabetic boy was admitted for evaluation of growth retardation. He was diagnosed to have T1DM 15 years back. The patient maintained poor glycemic control since childhood, presenting an elevated glycated hemoglobin rate persistently higher than 10% and recurrent episodes of ketosis. Examination showed that height was 131 cm (less than 3rd percentile), weight 28 kg (less than 3rd percentile) and body mass index of 16.3. Tanner stage was G2P1. He had abdominal distension with hepatomegaly. Investigations showed HbA1c 15.2% and IGF-1 65.7 ng/ml. Liver function test showed AST 514 IU/l, ALT 277 IU/l and total bilirubin 3 mg/l. His renal function was normal. Viral hepatitis serologies and autoimmune study were negative. Ultrasound abdomen revealed hepatomegaly with a liver span of 15 cm. A liver biopsy revealed numerous hepatocytes with glycogenated nuclei, abundant cytoplasmic and nuclear glycogen deposits, and moderate portal fibrosis. Based on the clinical history and investigations, the final diagnosis of Mauriac syndrome was made. A stronger multidisciplinary approach (involving endocrinology, nutrition and psychology) was attempted in order to improve glycemic control. He was followed-up for 2 months. He had shown a reduction in hepatomegaly, a normalization of transaminase concentrations with a decrease of HbA1c concentration (from 15.2% to 11%).
Discussion
In poorly controlled DM1 patients, the hyperglycemic periods lead to accumulation of glycogen in the hepatocytes causing hepatomegaly and liver enzyme elevation. It is imperative to exclude other causes of hepatomegaly and elevated transaminase levels, including autoimmune hepatitis, viral hepatitis, hemochromatosis, and Wilson disease. The pathogenesis of growth retardation is not clear but is thought to be multifactorial. Growth failure, delayed puberty and hepatomegaly in Mauriac's syndrome improves with glycemic control.
Conclusion
Although Mauriac syndrome is rare, it should be still considered in Type 1 diabetic children with growth impairment and liver disease. Optimal glycaemic control may play an important role in preventing such an occurrence.

Acute complications in incarcerated diabetics treated seen in the emergency room

Nezha Raki, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
UHC Ibn Rochd, Endocrinology, Diabétology, Nutrition and Metabolic, Casablanca, Morocco

Introduction
The management of a diabetic patient in a prison environment is often delicate, which explains the frequency of acute complications in diabetics during the period of incarceration.
Purpose of the study
Describe acute complications in incarcerated diabetic patients and to describe their management within the endocrinology and metabolic diseases department at the CHU IBN ROCHD in Casablanca.
Method
This is a retrospective descriptive study over a period of 2 years from January 1, 2020 to November 30, 2022, including diabetic patients who consulted for acute complications in the endocrinology department during their period of incarceration.
Results
During this study period, 86 detained diabetics consulted for acute complications. Among them, 6 were female (7%), against 80 male patients (93%). The average age of prisoners was 36, with an age range of 18 to 68. Among the population studied, 83.5% had at least one toxic history (tobacco, alcohol, cannabis and psychotropic drugs), most of the patients, i.e. 78.6%, were type 2 diabetics and 21.4% type 1 diabetics with an average duration of diabetes of 15.4 years, 63% of patients were on insulin therapy while 27.4% were on oral antidiabetics and 9.6% on no treatment. The most common reasons for consultation were diabetic ketosis in 54.6% of cases and major hyperglycemia in 42.3% of cases. Among the causes of decompensation, there was a predominance of respiratory infections (41.6%), urinary infections (28.4%) and diabetic foot (15.3%), discontinuation of treatment in particular insulin therapy in type 1 diabetics was involved in 12.4% of cases. Patient care required either hospitalization for a few days (on average 7 days) in 56.3% of cases, or day hospitalization in 31.5% of cases, while 12.2% of patients required only outpatient care. All patients benefited from therapeutic and nutritional education during the hospitalization period, with follow-up consultation thereafter.
Conclusion
Our study showed the high frequency of diabetes-related complications in people in prison. The development of specialized consultations, in particular by telemedicine, as well as therapeutic education are essential to improve the care of incarcerated diabetic patients.

Sleep quality and glycemic control in type 2 diabetes

Hager Khiari, Faten Mahjoub, Syrine Trabelsi, Nadia Ben Amor, Ramla Mizouri, Rym Ben Othman & Jamoussi Henda
National Institute of Nutrition, Nutrition, Tunisia

Introduction
Sleep is essential for the proper functioning and the well-being of the body. Poor sleep quality has many negative effects on the patient health. The aim of our study was to determine the prevalence of sleep disorders in patients with type 2 diabetes and to identify the associated factors.
Methods
It is a cross-sectional study including 51 patients and conducted in the nutrition department A of the institute of nutrition of Tunis. The patients were enrolled in April 2022.Sleep quality were evaluated by Pittsburgh sleep quality index (PSQI). Poor sleep quality was defined by a score ≥ 5.
Results
The mean age of the patients was 59.1 ± 9.51 years. The mean body mass index (BMI) was 27.83 ± 5.5 kg/m^2 and the mean duration of diabetes was 12.2 ± 10.31 years. The mean PSQI score was 7.4 ± 4.03. Poor sleep quality was reported in 72.5% of cases. More than the half of these patients were women (52.9%). Only fasting plasma glucose (FPG) was significantly associated with poor sleep quality ($P = 0.001$) with a positive correlation between FPG and PSQI score; an increase of 1 g/l caused a 2 points increase of the score. Age, sex, medical history, BMI, duration of diabetes and type of antidiabetic treatment were not associated with poor sleep quality.
Conclusion
Uncontrolled diabetes is a risk factor for sleep disorders. Similarly, poor sleep quality negatively affects diabetes control. Rigorous management is needed to break this vicious circle.

Unwanted pregnancy in diabetic women

Belhadi Leila, Bensbaa Salma, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
University Hospital Center Ibn Rochd, Department of Endocrinology and Metabolic Diseases, Casablanca, Morocco

Introduction
Pregnancy in diabetic women is a high-risk pregnancy whose prognosis is linked to the degree of glycemic control from conception to delivery, however, a diabetic

patient is encouraged to plan her pregnancy. However, many diabetic women find themselves in a situation of unwanted pregnancy and poorly manage their diabetes during pregnancy.
Goals
Study the causes of unwanted pregnancies and their impact on the evolution of diabetic pregnancy.
Materials and Methods
A retrospective descriptive study from January 2016 to December 2022, was conducted in the endocrinology and diabetology department of the IBN ROCHD University Hospital Center in all patients followed for diabetic pregnancy.
Results
Our study included 712 patients followed for diabetic pregnancy, of which 16% of pregnancies were unwanted. In the group of unwanted pregnancies: The most dominant age group was between 25-35 years old with an average age of 32 years, of which 70% were of low socioeconomic level and 55% were multiparous. A glycemic imbalance was objectified in 40% of parturients with an average HbA1C of 9%. The contraceptive methods most used were: 39% of estrogen-progestogens in which 72% of the causes of pregnancy were forgetting to take the pill, 27% were the cessation of contraception by a health professional because of diabetes, 7% under the intrauterine device with poor monitoring, 4% under microprogestogens; and 11% under male condom or withdrawal; while 39% were not under any contraceptive method. Among the parturients, 42% were difficult to balance. The evolution of pregnancy was complicated by preeclampsia in 15% of parturients and macrosomia in 20% of newborns.
Conclusion
Pregnancy in diabetic women requires close glycemic monitoring to ensure perfect glycemic control. Contraception in Morocco is available at the health center, while its use by parturients is still unknown, which leads patients to unwanted pregnancies. Hence the need to educate patients and health professionals on the benefits of effective contraception and good glycemic control in preconception.

EP335

Impact of ramadan on the course of diabetic pregnancy

Belhadi Leila, Bensbaa Salma, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
University Hospital Center Ibn Rochd, Department of Endocrinology and Metabolic Diseases, Casablanca, Morocco

Introduction
Pregnancy is a state of increased insulin resistance and insulin secretion and reduced hepatic extraction of insulin; thus fasting during pregnancy seems to cause a high risk of morbidity and mortality for the fetus and its mother. This group of diabetic patients is exempt from fasting.However, for young patients or not, Ramadan is accompanied by a change in lifestyle in particular a change in eating habits as well as a disruption of the sleep cycle and a decrease in physical activity, directly influencing the glycemic balance during this holy month.
Objective
To assess the impact of lifestyle changes during the month of Ramadan on glycemic control by assessing dietary habits, sleep quality, and physical activity during this month.
Patients and Methods
Prospective cohort study conducted at the Endocrinology-Diabetology Department of the CHU Ibn Rochd – Casablanca, in patients hospitalized or followed in consultation for diabetic pregnancy; carried out during the month of Ramadan 2022.
Results
Our study included 41 patients, of whom 66% had gestational diabetes, 10% were type 1 diabetics, and 24% had type 2 diabetes. The average age of the participants was 30 years and the average age of their pregnancy was 28 weeks. at the time of carrying out the study. 5 patients (12%) decided to fast and the median number of fasting days was 21 days. The total daily caloric intake before the month of Ramadan was 2302 Kcal with an average carbohydrate intake of 41%, 25% lipids, and 20% protein. While during the month of Ramadan, the average caloric intake was 2503 Kcal/d, with an average intake of carbohydrates of 49%, lipids of 32%, and proteins of 14%. Moderate physical activity was practiced in 30% of patients, while 63% of patients were sedentary. Weight gain was noted in 70% of our parturients with an average of 3 kg in 1 month. Sleep quality was impaired in 70% of patients, as was sleep quantity in 90% of parturients with less than 7 hours of continuous sleep.
Conclusion
The Ramadan period has an effect on the diet with an increase in the consumption of fast sugars and lipids as well as a reduction in physical activity and an alteration in the quality and quantity of sleep.

Predictive factors of in-hospital duration of stay in diabetic patients in a medical unit at a university hospital

Houcem Elomma Mrabet, Boubaker Fadia, Yesmine Elloumi, Younes Ayadi, Malak Belkhiri, Alaya Wafa, Zantour Baha & Sfar Mohamed Habib
University Hospital Tahar Sfar, Department of Endocrinology, Mahdia, Tunisia

Background
Patients with diabetes mellitus (DM) have been reported to have longer duration of in-hospital stay (DS). Identifying factors influencing their DS may help in the decision-making process especially in a public health setting.
Aim
We aim to compare DS in patients with and without DM admitted to a medical unit in a university hospital and to determine the predictive factors of DS in patients with DM.
Methods
A cross sectional study was conducted over a 6 months period from March to September 2020. It included patients admitted to the Medicine department at Tahar Sfar university hospital in Mahdia, Tunisia over that period.
Results
One hundred and Fifty patients were admitted during the study, 106 of which (70.6%) were patients with DM. Median DS was 7 [5-10] days, and was shorter in presence of DM (7 [5-8] days vs 10 [6-14] days, $P=0.002$). In diabetic patients, DS was not correlated to age ($P=0.339$) and there was no significant difference in LS according to gender ($P=0.659$). DS was not correlated to weight, Body Mass Index (BMI), or temperature upon admission. DS was longer in patients presenting with concomitant infection (7.5 [6-10.25] vs 7 [5-8] days, $P=0.026$). There was no difference in DS in patients with Type 1 DM and Type2 DM ($P=0.89$). The presence of complication of DM did not impact the DS ($P=0.47$). DS was positively correlated to White blood cells count ($P=0.048$, $r'=0.19$), Neutrophil ($P=0.014$, $r'=0.24$), PTH ($P=0.002$, $r'=0.31$), initial CRP ($P<10\text{-}4$, $r'=0.37$) and early morning cortisol ($P=0.036$, $r'=0.2$) levels. It was also negatively correlated to hemoglobin ($P=0.005$, $r'=-0.28$), HbA1c ($P=0.01$, $r'=-0.25$), measured plasma calcium ($P=0.049$, $r'=-0.21$) and albumin levels ($P=0.02$, $r'=-0.32$).
Conclusion
In our study DS was shorter in diabetic patients. These findings are opposed to previous data (1). In diabetic patients, the presence of infection and elevated inflammatory markers was positively associated to DS, while biological markers of malnutrition were negatively correlated to DS. These results suggest that such biomarkers can be used as part of an individualized decision making when admitting patients with DM.

Issues of diabetes management in resource poor setting

S Pal[1], T Roy[1] & G Kumari[2]
[1]SFCCP, Med, Meerut, India; [2]Tnm Hosp, Mumbai, India

Issues
In developing nations diagnosis of diabetes brings mental-trauma/depression in family. Focused treatment for pediatric age-group is unavailable in developing-countries. 26% of diagnosed diabetics are children's. Adequately trained physicians/Nurses in issues of pediatric-diabetes provide continuity of care, relief from depression and smooth transition from diagnosis to treatment. Qualitative collaborative relationship between these makes diabetics life bearable. Our NGO-project highlights significance of relationship between nurses and diabetic-children in community clinic setup of rural India. For Diabetes, it's assumed that depression is inevitable sequel to diagnosis. Retrospective analysis of past studies shows—counselling improves QOL & attitude towards diabetes-treatment.
Aims
To describe care issues in diabetic-children's. Observe/modify nature of relationship between nurse and child. To evolve comprehensive treatment plan for patients and families.

Methods
A retrospective analysis of data base from 7 rural health-clinics. Specialized therapy/support to pediatric-age-group not available at any centre. Total 117 children's [4-13 years] diagnosed with diabetes. 23 had additional endocrine/-metabolic problems. Nursing/medical care plan analyzed. No specialized trained personal in rural/tribal India. Opinion/needs from patients' families collected on feedback questionnaire. Then we trained 10 nurses & 2 physicians for handling pediatric cases [4 weeks training].
Results
Out of 117, 41 discontinued Rx due to improper counseling/guidance. 3 died. Patient/family's feedback highlights: Better access to newer drugs-delivery-systems, psychosocial support, follow-up-plan. Nurses/physician be sensitized in pediatric care-issues. Main issues of concern were: illness and coping with their feelings. Initial impact of diagnosis and a search for solution? Expectations for future life & its quality? Concerns of cost of RX Availability of proper follow-up centers in rural areas of developing nations.
Conclusion
Multifaceted Relationship between physician/nurse and Diabetics children's is crucial. Follow-up must be given priority. This relationship provides better continuity of treatment. We show concerns/difficulties while working in Asian set-up for paediatric diabetis to international experts/seniors at ece.

EP338

Residual metabolic effect after cessation of liraglutide therapy in patients with type 2 diabetes

Margarita Samsonova & Ekaterina Shestakova
Endocrinology Research Centre, Moscow, Russia

Objective
The aim of our study was to evaluate the possibility of maintaining the metabolic effects of liraglutide 3.0 mg treatment after it's cessation.
Methods
The study included 8 patients with type 2 diabetes (T2D) and obesity who received liraglutide 3.0 mg daily for 9 months. All of them successfully reduced body weight, insulin resistance level (IR), volume of visceral adipose tissue, HbA1c level. After discontinuation of liraglutide in 2019, these patients did not use GLP-1 analog therapy for 3 years. After 3 years patients were assessed for the following: weight, BMI, glucose, insulin, HbA1c, body composition, hyper-insulinemic euglycemic clamp test with M-index evaluation. Results were compared with similar data collected in 2019 before the start of GLP-1 analog therapy (0-month point), 9 months after the start (9-month point), 3 years after cessation (45-month point).
Findings
BMI did not significantly change between 9-month and 45-month points, though the amount of total and visceral fat increased. Cessation of liraglutide 3.0 mg caused HbA1c deterioration, but according to M-index insulin resistance decreased (Table 1). When comparing data at 0-month and 45-month point we still saw the improvement in fasting glycemia and the non-significant reduction of HbA1c (Table 2).

Efficacy of Dapagliflozin in patients with Non-alcoholic Fatty Liver Disease: A Single Center Experience

Fulya Odabaş[1], Gamze Akkus[1], Ferhatcan Pişkin[2], Emre Odabaş[3], Tuğsan Ballı[2], Ümit Karaoğullarından[3] & Tamer Tetiker[1]
[1]Cukurova University Faculty of Medicine, Division of Endocrinology, Adana, Turkey; [2]Cukurova University Faculty of Medicine, Division of Radiology, Adana, Turkey; [3]Cukurova University Faculty of Medicine, Division of Gastroenterology, Adana, Turkey

Aim
Non-alcoholic fatty liver disease (NAFLD) is a common comorbidity with type 2 diabetes and a few agents such as pioglitazone and metformine has been shown to beneficial effects. SGLT-2 inhibitors are used in the treatment in type 2 diabetes (T2D). It has been shown that they can the effectivenes of improve liver function in patients with NAFLD as well as in T2D. In our study we aim to elucidate the effectiveness of SGLT-2 inhibitors as second line treatment for NAFLD patients with T2D by comparing with pioglitazone.
Patients and measurements
NAFLD patients with T2D ($n=34$) who did not use SGLT2 inhibitors (dapagliflozin, empagliflozin) or pioglitazone were enrolled in the current study. Patients were divided into 3 subgroup who were treated with Dapagliflozin 10 mg, empagliflozin 10 mg and pioglitazone 45 mg as a second line treatment of T2D. Before and after the treatment; all biochemical parameters of the patients' were screened as well as the body mass index and waist circumference. Patients were also followed-up the same treatment during the 16 weeks. Screening for NAFLD was performed using MRI-based (3.0 T, Ingenia, Philips Medical Systems, Best, The Netherlands) proton density fat fraction before and after the treatment. All patients were matched in case of baseline body mass index (BMI), gender differences.
Results
At the end of the 16 weeks after the treatment HbA1c levels (%) of the patients treated with Dapagliflozin ($P=0.04$) and Empagliflozin ($P=0.01$) were decreased compared to baseline levels but not pioglitazone ($P=0.108$). While changing of waist circumference of the patients treated with dapagliflozin ($P=0.001$) or empagliflozine ($P=0.008$) were statistically significant, patients with pioglitazone were not significant ($P=0.801$). Baseline hepatic steatosis measurements of the patients' treated with Dapa, Empa and Pio were 0.19 ± 0.09, 0.17 ± 0.07 and 0.14 ± 0.09, respectively. At the end of the study; measurements of patients' were 0.11 ± 0.09 ($P=0.001$), 0.13 ± 0.08 ($P=0.09$) and 0.12 ± 0.14 ($P=0.360$), respectively.
Conclusion
Dapagliflozin may have a beneficial modulatory effect on NAFLD as well as the T2D.

Table 1 Change in baseline and study completion for three group

Group	Dapagliflozin	Empagliflozin	Pioglitazon	Total

Factors associated with poor diabetes control in insulin-requiring elderly subjects

Fatma Zaouali[1], Najoua Lassoued[2], Zantour Baha[2], Alaya Wafa[2] & Sfar Mohamed Habib[2]

[1]University of Monastir, Family Medicine Department, Monastir, Tunisia; [2]Tahar Sfar University Hospital, Endocrinology Department, Mahdia, Tunisia

Introduction
Management of diabetes in older adults is complicated by the many comorbidities that may interfere with the use of certain oral antidiabetic agents, and the associated geriatric syndromes, psychiatric disorders, and high risk of dependence in this age group. The objective of our study was to determine the factors associated with poor diabetes control in insulin-requiring elderly subjects.
Methods
A cross-sectional study on type 2 diabetic insulin dependent elderly recruited from the outpatient endocrinology consultation over a period of 2 months from June 2021 to July 2021.
Results
We recruited 100 patients with a mean age of 70.8 ± 5.8 years and a sex ratio of 0.85. The mean durations of diabetes and insulin therapy were 15.67 ± 6.7 years and 7.69 ± 6 years, respectively. The mean level of HbA1C was 9.85 ± 1.7%. The majority of patients had uncontrolled diabetes (90%). Poor diabetes control was associated with low socioeconomic level (77.8% vs 30%; $P=0.001$), uncontrolled high blood pressure (54.4% vs 20%; $P=0.039$), not removing insulin from refrigerator at least 30 minutes before use (82.2% vs 50%; $P=0.018$), not checking expiry dates of insulin and needles (75.6% vs 40%; $P=0.018$), using long needles (72.2% vs 30%; $P=0.007$), no hand washing before injection (34.4% vs 0%; $P=0.025$), no disinfecting the rubber of the insulin vial or pen cartridge (92.2% vs 70%; $P=0.026$), the incorrect re-suspension technique for cloudy insulin (no rolling or tipping the vial or cartridge of cloudy insulin: 91.1% vs 50%; $P<10^{-3}$ and 92.2% vs 60%; $P=0.02$, respectively), no rotating of the injection site (36.7% vs 0%; $P=0.019$), skiping the injections (51.7% vs 10%; $P=0.012$), bleeding or hematoma at the injection site (57.8% vs 20%; $P=0.023$) and the loss of insulin from the injection site (44.9% vs 10%; $P=0.033$). After multivariate analysis, no rolling and no tipping the vial or cartridge of cloudy insulin were factors independently associated with poor diabetes control (OR = 12.599; 95% CI, 2.5 to 63.35; $P=0.002$ and OR = 10.188; 95% CI, 1.825 to 56.875; $P=0.008$, respectively).
Conclusion
The challenge to overcome in optimizing diabetes management is not a lack of recommendations or scales. However, it is their adoption and implementation by caregivers and patients that dismisses the need for optimal insulin injection technique as a fundamental driver of diabetes control that could turn the game around.

Metformin-Associated Lactic Acidosis: A Case Report
Gökhan Baykal[1], Mehdi Houssein[1], İrem Önal[2], Enes Seyda Şahiner[2], Cemile Bicer[2], Narin Nasiroglu Imga[1], Oya Topaloglu[3], Reyhan Ersoy[3] & Bekir Cakir[3]
[1]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Bilkent City Hospital, Internal Medicine, Ankara, Turkey; [3]Ankara Yıldırım Beyazıt University, Faculty of Medicine, Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara, Turkey

Introduction
Metformin is widely used as the first-line therapy for patients with type 2 diabetes, and its most common adverse effects are gastrointestinal. Metformin-associated lactic acidosis (MALA) is a rare but serious adverse effect in patients with type 2 diabetes or patients who attempt suicide with metformin overdose. Here, we report the case of a 22-year-old woman who developed severe lactic acidosis after high-dose metformin was taken for a suicide attempt.
Case
A 22-year-old woman with anxiety disorder and depression developed life-threatening lactic acidosis after taking high doses of metformin to attempt suicide. The patient received approximately 30 g of metformin. She applied to the emergency department with slurred speech and nausea. In her initial laboratory findings, arterial blood gas pH was 7.41, bicarbonate 14 mmol/l, anion gap 13 mmol/l, lactate 7.5 mmol/l, and creatinine of 1.44 mg/dl. Then she deteriorated and arterial blood gas pH became 6.96, bicarbonate 5.8 mmol/l, anion gap 33 mmol/l, lactate 23.9 mmol/l, and creatinine of 1.99 mg/dl. Renal replacement therapy was initiated. After one dialysis session, her severe acidemia resolved over time. She was discharged from the hospital without any complications. A Naranjo assessment score of 9 was obtained, indicating a probable relationship between the patient's lactic acidosis and her use of the suspect drug.
Conclusion
MALA is a well-known and life-threatening complication of metformin. Vomiting and diarrhea are the first signs of MALA. Even if severe lactic acidosis may not be apparent at first as in our case clinicians should be aware that lactic acidosis may develop. Severe lactic acidosis can be treated with renal replacement therapy because metformin is dialysable.

Case report: Association of Fenugrec and curcuma as a cause of hypoglycémia
Sanaa Bammou, Neima Hassan, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
Mohamed VI University Hospital Center, Department of Endocrinology, Diabetology, Metabolic Diseases Nutrition, Marrakesh, Morocco

Introduction
Research in the past two decades has shown that Fenugrec seeds help to lower blood glucose in patients with diabetes. Its role as an antidiabetic, by reducing fasting blood glucose levels and improved glucose tolerance in human subjects was reported Curcuminoids have been shown to improve insulin resistance, decrease glucose and insulin levels, increase adiponectin release, and reduce the levels of leptin, resistin, interleukin (IL)-6 IL-1b, and tumor necrosis factor-a in patients with type 2 diabetes.
Case Report
A 48 years old patient that have background type 2 of diabete for 19 years and hypertension for 4 years. She is taking fenugrec and curcuma for 3 months, making a periodic hypoglycemia of variable hours estimated 0.30 g/l felt by tremor and sweat, yielding by dates or honey by itself. It should be noted that these hypoglycemia are noticed one week after taking the fenugrec and curcuma and combination and the patient does not report of meal skipping or intense physical activity which may be the cause of the hypoglycemia. Examination revelated normal vital parameters slate stain or melanoderma. Hormonal profile revealed cortisolemie = 16ug/dl. We linked this hypoglycemia to taking the fenugrec and curcuma combination, so the decision was to stop taking these plants and monitor the patient glycemic cycle. The glycemic cycle brought back one week after his hospitalization did not show hypoglycemia.
Discussion
Scientists have demonstrated that the amino acid 4 OH Ile in fenugreek seeds increases glucose induced insulin release in vitro in human and rat pancreatic islet cells, while others showed that fenugreek seed extract phosphorylates a number of proteins, including the insulin receptor, insulin receptor substrate 1 and p85 subunit of PI3 K, in both 3T3 L1 adipocytes and human hepatoma cells, HepG2.The dose of fenugreek seeds given also affect the blood sugar levels and higher dosages do show more hypoglycemic effect as shown in the previous trials. The dose range was wide ranging from 2 to 25 g/day. The studies showed that the use of Curcuma longa or curcumin (in different formulations) showed significant reduction of lipid peroxidation, fasting blood glucose levels, Glycated hemoglobin (HbA1C), triglycerides, total cholesterol, LDL-c, C-Reactive Protein, systolic and diastolic blood pressure.
Conclusion
Curcumin and funugrec are a natural anti-inflammatory and anti-diabetic agent representing a safe and low-cost alternative for this condition's therapeutic approach, although it is still necessary to know its effective dose to avoid hypoglycemia.

The effect of quadriple combination therapy including SGLT-2 inhibitor in type 2 diabetes
Yonghyun Kim, Jeonga Kim & Donghyun Shin
Bundang Jesaeng Hospital, Endocrinology and Metabolism, Seongnam, South Korea

Introduction
Before launching of SGL¬T-2 inhibitor, triple combination of TZD with metformin and DPP¬4 inhibitor was best option for delaying progression of diabetes by improving insulin resistance and secretory dysfunction. SGLT-2

inhibitor can be used as first combination therapy with metformin, but add on to any diabetic combination will be favorable in terms of body weight and cardiovascular risk reduction, especially in long duration of diabetes with relatively high risk of cardiovascular complication. SGLT-2 inhibitor is better than sulfonylurea in preserving beta cell reserve and preventing diabetic complication, so we tried to know the effect of SGLT-2 inhibitor add on to triple combination because there are few studies about those combination therapy excluding sulfonylurea.
Subject and Methods
In 62 patients with relatively long duration of diabetes that did not reach the goal of HbA1c 7.0% with triple combination with metformin, DPP-4 inhibitor and TZD, SGLT-2 inhibitor-10 mg of empagliflozin or usual or half dose dapagliflozin(5mg) was added due to economical cause because add on to TZD or DPP-4 inhibitor is not covered by national insurance in this country. The clinical characteristics and changes of HbA1c by dose of SGLT-2 inhibitor, body weight were assessed.
Results
The mean age was 63.5±9.2 and duration of diabetes was 13.6±6.2 years. The fasting C-peptide was 2.26±1.09 ng/ml and BMI was 27.3±3.7. The mean of 3 months and just before add on HbA1c level was 7.89±1.00%. The HbA1c level was 7.24±0.87% and 7.14±0.71 after 6 and 12 months after add on, so it was lowered by 0.65% and 0.76% each. HbA1c lowering effect was greater in usual dose of dapagliflozin than half dose and 10 mg of empagliflozin (0.86% vs 0.49% and 0.57% at 6 months, 1.12% vs 0.41 and 0.75% at 12 months, $P<0.05$). Body weight was decreased by 1.89±2.82 after 6 months.
Conclusion
SGLT-2 inhibitor including half dose of empagliflozin and dapagliflozin add on to triple combination of TZD with metformin and DPP–4 inhibitor was effective in body weight as well as glucose lowering effect, so quadriple combination therapy except sulfonylurea can be effective in glucose control and preserving beta cell function before initiation of insulin treatment.

Impact of "Taraweeh" prayer on glycemic control in diabetic patients during ramadan

Yousra Settai, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
UHC Ibn Rochd, Endocrinology, Diabetology, Nutrition and Metabolic, Casablanca, Morocco

Introduction
During Ramadan, diabetic patients should be encouraged to maintain normal physical activity. The physical efforts involved in the "Taraweeh" prayers, are considered part of their daily physical activity. Patients are more likely to reach their HbA1c targets and reduce weight when night prayers are performed.
Objectives
The objective of our study was to assess the impact of the "Taraweeh" prayer on glycemic control and weight change, to assess the risk of hypoglycaemia linked to these prayers, and thus to assess the possibility of encluding these prayers into the diabetes care during Ramadan.
Materials and Methods
Prospective case-control study conducted at the Endocrinology-Diabetology Department of the UHC Ibn Rochd – Casablanca, in type 2 diabetic patients. The study group included 100 subjects practicing the "Taraweeh" prayers, and the control group 100 patients not practicing them.
Results
The average age of our patients was 54 years (38-69 years). In pre-Ramadan the average HbA1c was 8.7%, and the average weight 87.4 kg. Among our patients, 83.7% did not practice any physical activity before Ramadan, and 62.5% were fasting. According to the days of prayers performed, the patients in the study group were divided into 3 groups: <10 days (8.4%), 10-20 days (76.6%), $>$ 20 days (15%). Among our participants, 89% walked an average of 5 min to the mosque. On destiny's night, prayers were performed by 86.2% of the patients, with an average of 20 "rakaa". In comparison with the control group, a reduction in HbA1c of 1.8% (0.7-2.3) on average was observed in our patients ($P<0.001$), with an average weight loss of 5.6 kg ($P<0.001$). This is proportional to the number of days of prayers performed, and all the more so in fasting patients. Hypoglycemia was concomitant with prayers in 27.8% of our patients, with a preponderance in patients on insulin or on sulfonylureas, and in particular on destiny's night.
Conclusion
The "Taraweeh" prayers must be included into the daily physical activity of our diabetic patients, allowing them to achieve a better glycemic balance, as well as weight loss at the end of the holy month. Hence the interest of motivating them to this practice during the pre-Ramadan consultation, with caution to avoid hypoglycaemia.

Factors Contributing to Noncompliance With Diabetic Medications in Patients With Type 2 Diabetes Mellitus in India

Bharat Saboo & Shweta Saboo
Prayas Diabetes Center, Indore, India

Background
Type 2 diabetes mellitus (T2DM) is a chronic medical condition characterised by persistently high blood glucose levels. T2DM risk factors include obesity or being overweight, a high BMI, genetics, and certain medical conditions. Medicine adherence is very important for the management of T2DM and if it is not well controlled by lifestyle modification or DM regulatory medications, it can lead to complications. The goal of this study is to identify the factors that contribute to noncompliance with oral diabetes medications in T2DM patients in India.
Methodology
A cross-sectional questionnaire study was conducted on T2DM patients in Central India via a link distributed on social media, and the contributory factors of diabetes medication noncompliance were assessed.
Results
The study included 324 participants in total. In terms of medication adherence, 199 (61.4%) participants were mostly adherent to their medications, 97 (29.93%) were not, and 28 (8.6%) were occasionally adherent. According to participants, the most commonly reported factors contributing to noncompliance with DM medications were forgetfulness, a lack of knowledge about the importance of diabetes control, and medication side effects. Age, marital status, occupation, comorbidities, diagnosis period, and previous complaints of DM complications all had significant associations with DM medication adherence.
Conclusion
The study's findings revealed that adherence to DM medications was suboptimal among T2DM patients in Central India. Several factors were discovered to have an effect on medication adherence in this study. More research is needed to include other factors that may influence adherence, such as patient-provider communication.

Lifestyle in a group of adolescents with type 1 diabetes

Faten Mahjoub[1], Ines Bani[1], Nadia Ben Amor[2], Hana Ben Jemâa[3], Ramla Mizouri[3], Rym Ben Othman[3] & Jamoussi Henda[2]
[1]National Institute of Nutrition and Food Technology, A, Tunis, Tunisia; [2]National Institute of Nutrition and Food Technology, A, Tunisia; [3]National Institute of Nutrition and Food Technology, Tunisia

Introduction
Type 1 diabetes (T1DM) is an autoimmune disease that requires insulin treatment from the time of diagnosis. The evidence about the influence of lifestyle on the course of T1DM is increasing. The aims of our study were to evaluate the lifestyle of a group of boys with type 1 diabetes and to study their glycemic control.Method: This is a descriptive cross-sectional study conducted at the National Institute of Nutrition in Tunis.The level of physical activity (PA) was evaluated using the International Physical Activity Questionnaire (IPAQ). A nutritional survey was done for each patient using the 24-hour recall method. A high-carbohydrate diet was defined as a carbohydrate intake greater than 5 g/Kg of ideal weight/Day.The ideal weight was determined by the CREFF formula. We analyzed the CGM data for each patient and we calculated the coefficient of variability of glucose (CV), mean of glycemic excursions (MAGE) and the mean of daily differences (MODD).

Results
We included 37 boys with type 1 diabetes in our study, with an average age of 17 ± 2 years old. The mean duration of diabetes was 6 ± 4 years. The average body mass index was 19.5 ± 2 kg/m^2; two patients in the study population were overweight. Among our patients, 13.5% had a high level of PA, 48.6% had a medium level and 37.8% had a low level PA. The average total caloric intake was 2432 ± 665 Kcal/d, distributed as follows:2676 ± 300 Kcal/d for patients with high PA, 2440 ± 800 Kcal/d for patients with medium level of PA and 2320 ± 562 Kcal/d for patients with low level PA. The mean carbohydrate intake was 291 ± 145 g/d (46 ± 7% of the total caloric intake). However, 28.6% of patients had a high-carbohydrate diet. In addition the average protein intake was 84 ± 29 g/d (14 ± 4% of the total caloric intake)and the average fat intake was 98.5 ± 31g/d (36 ± 5% of the total caloric intake).The mean glycated hemoglobin level was 9.8 ± 1.8%, only two patients had Hb1Ac ≤7%.Time in range varied between 4 and 88% with an average of 37 ± 18%.Time below range was between 0 and 36% with an average of 6.6 ± 8%.The mean of time within range was 55.9 ± 21%.The average coefficient of variability of glucose, was 40 ± 10%, that of MAGE was 150 ± 45 mg/dl. Moreover the majority of patients (91.9%) had a MAGE > 65 mg/dl. The average MODD was 85 ± 40 mg/dl.
Conclusion
Dietary measures are difficult to apply in adolescents and this can induce poor glycemic control. Nutritional education must be regularly maintained associated to insulin therapy.

"We must always think that there may be something else". Cushing's disease and a rare partial hereditary lipodystrophy type 6 associated with retinos pigmentosis, coexistence of both diseases in a single patient

Pilar Rodriguez[1,2], María Eugenia López Valverde[2] & Diego Jesus Del Can[2]
[1]Hospital Juan Ramón Jiménez, U.G.C. Endocrinology and Nutrition Service, Huelva, Spain; [2]Juan Ramón Jiménez University Hospital, U.G.C. Endocrinology and Nutrition Service, Huelva, Spain

Lipodystrophic syndromes are a heterogeneous group of usually rare disorders, which have in common the selective and irreversible deficiency of adipose tissue in the absence of nutritional deprivation or catabolic state. Clinically, they are characterized by insulin resistance, related to a state of hypoleptinemia, with manifestations such as polycystic ovarian syndrome, type 2 diabetes mellitus, severe hypertriglyceridemia, and steatohepatitis among their most frequent metabolic complications. Within the lipodystrophic syndromes we must differentiate between congenital and acquired and within the congenital, generalized and partial. Partial congenital lipodystrophy has an asymmetric distribution of fat, with loss of adipose tissue in the extremities, predominantly in the lower limbs, thighs, and buttocks, with the consequent accumulation of fat in the neck, chin, and abdominal fat. That is why, among its differential diagnoses, we must include Cushing's syndrome in patients. We present the case of a patient, with Cushingoid phenotype, with diabetes mellitus, severe hypertriglyceridemia and visual disturbances with a diagnosis of retinitis pigmentosa, who presents data of ACTH-dependent biochemical hypercortisolism, confirmed a pituitary macroadenoma on MRI, the patient underwent resection. Transsphenoidal adenoma, confirming the presence of an ACTH-producing pituitary adenoma in the Immunohistochemistry with ACTH + receptors in the tumor. At first, it seemed strange to us to associate retinitis pigmentosa with Cushing's disease, but no reports were found. We request a genetic study of retinitis pigmentosa in our center. We are informed that two important genetic changes have been detected in other genes: A homozygous change in the LIPE gene (c.551C>A (p.S184*). This gene has been associated with autosomal inheritance type 6 partial lipodystrophy recessive. We conclude with a LIPE gene mutation associated with retinitis pigmentosa in a patient with Cushing's adenoma.

Modified Appleby Procedure in the Treatment of Pancreatic Neoplasms

Susana Torres
Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Introduction
Pancreatic neoplasms portray the 12th most prevalent neoplasm worldwide, determining a five-year survival of only 5 to 10% including all stages. Despite tumoral aggressiveness, the modified Appleby procedure can be performed in selected patients, representing a curable alternative in borderline-resectable or locally advanced pancreatic tumors' treatment in the context of a multimodal practice. Objectives: This work aims to review the state of the art regarding the patients who may benefit from resection using the modified Appleby procedure, the pre- and post-operative procedures to increase survival, and the postoperative outcomes.
Materials and Methods
Research was conducted within the PubMed and Embase databases from July 2022 to January 2023, including single or multicenter articles relative to the modified Appleby procedure but comprising a multimodal approach to pancreatic neoplasms and not only the surgical technique, and papers concerning patients over the age of 18 years.
Results
Out of the 373 articles identified and after extracting duplicates, 267 records were accessed for a title and abstract screening. Afterward, by applying the inclusion and exclusion criteria to the remaining articles and conducting a further extensive reading of the remaining articles, 53 papers were included in this review. Secondary terms relevant to this topic were also used, allowing detection of additional research, thus totalizing the 56 publications included.
Discussion
The initial assessment of pancreatic neoplasms' resectability was appraised, as well as the modified Appleby procedure's surgical technical options, its difficulties, morbidity, and mortality. Patients were addressed based on a multimodal strategy to increase survival, therefore neoadjuvant/adjuvant chemotherapy indications and regimens were also discussed.
Conclusion
When applied to borderline resectable and locally advanced pancreatic cancer, the efficacy of the modified Appleby procedure alone is limited, but the combination with neoadjuvant chemotherapy offers the greatest chance of achieving an R0 resection. Many surgical technical options are available, with or without preoperative artery embolization, but the best results published to date were observed when employing robotic surgery with a retroperitoneal-first approach. However, the indication for performing this surgery and all its perioperative components are still a matter of debate.

Keywords: Appleby procedure, pancreatic neoplasms, celiac axis infiltration, preoperative embolization, liver infarction.

Comorbid depression and cardiovascular disorders in patients with type 2 diabetes

Snjezana Popovic Pejicic[1,2], Nina Pejicic[2], Gabrijela Malesevic[1,2] & Valentina Soldat Stankovic[1,2]
[1]University of Banja Luka, Faculty of Medicine, Banja Luka, Bosnia and Herzegovina; [2]University Clinical Centre of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina

Introduction
Depression often occurs as comorbid and concomitant disorder in patients with type 2 diabetes (T2D) complicating the course and outcome of the disease, prolonging the treatment and accelerating complications of diabetes, especialy cardiovascular complications. Numerous researches show significant presence of cardiovascular disorders in depressed patients with T2D that show up several year after first depressive episode. Mortality caused by cardiovascular disorders in depressed patients with T2D is 50% higher than in general population. Comorbid depression and cardiovascular disorders in diabetic patients making worse health condition, increasing suffering, making hard treatment and outcome is not good.
Aim
The goal is to confirm presence of cardiovascular disorders in depressed patients with T2D as the most common comorbid cardiovasvular diseases.
Methods
A retrospective study has been conducted using data from medical history of 274 depressed patients with T2D hospitalized and treated at the Psychiatric Clinic, University Clinical Center of Republic of Srpska.These parameters were assessed: sex, age, number of hospitalizations, marital and employer status, comorbid disease, body mass index, presence of cardiovascular disorders and laboratory tests (glycemia, lipid status and renal function parameters). Data were presented using tables and graphs.

Results
Cardiovascular disorders in patients with T2D comorbidity with depression we found in 126 patients (45.9%), 96 of them were males and 30 females. Hypertension in comorbidity with depression in diabetic patients was diagnosed in 83 patients (65.8%), while comorbid with cardiac disordes was found in 45 patients (35.7%). In the group of depressive diabetics patients with cardiovascular disorders, 65% of them had unsatisfactory level of glycoregulation.
Conclusion
Depression is often accompained by cardiovascular disorders in patients with T2D. It is very important to recognize this comorbidity in order to treat it successfully and to make better treatment's otucome.
Keywords: diabetes mellitus type 2, depression, cardiovascular disorders.

Hepatopathy of Mauriac síndrome: a case report
Antonio Moreno Tirado, Paloma González Lázaro, Maria Zhao Montero Benítez, Pedro Jimenez Torrecilla, Florentino Del Val Zaballos & Amparo Lomas Meneses
Hospital General La Mancha Centro, Alcázar de San Juan, Spain
We report the case of a 34-year-old woman with a personal history of type 1 diabetes mellitus (DM1) since she was 9 years old. Very poor chronic metabolic control stands out despite multiple insulin schemes with multiple complications: nephropathy, retinopathy and peripheral neuropathy. She was admitted to the hospitalization floor due to diabetic ketoacidosis. At admission Hba1c of 15.3%. During admission after treatment with IV insulin, improvement in glycemic control. Nine days after admission, she began with symptoms of edema in all 4 limbs, distension, and abdominal pain. On examination, she presented a height smaller than expected (150 cm), slightly overweight (59 kg) and extensive hepatomegaly. Liver function tests showed an increase in transaminases (GOT 359 IU/l, GPT 210 IU/l) and alkaline phosphatase (190 IU/l). Viral and autoimmune etiology was ruled out. An abdominal ultrasound was performed, showing a large hyperechogenic homogeneous hepatomegaly. It was decided to perform a percutaneous liver biopsy, which revealed a liver parenchyma with preserved architecture, with hepatocytes with large, clear cytoplasm, with a striking membrane and some empty nuclei with a glucogenic appearance. Cytoplasms show intense periodic acid-Schiff (PAS) staining, but PAS-diastase negativity, confirming cytoplasmic glycogen deposition. No reticulin fibrosis, inflammation, or steatosis is observed. The most probable diagnosis is hepatic glycogenesis secondary to diabetes. Six months later, after improvement in glycemic control, with an Hba1c of 6.6%, normalization of transaminase and alkaline phosphatase levels, resolution of hepatomegaly. The Pierre Mauriac syndrome described in the year 1930, is characterized by growth failure, cushingoid appearance, hepatomegaly and hypertransaminasemia, in a patient with chronic uncontrolled DM1. The most common age of presentation is usually in adolescence, although cases have been described in both children and adults. The hallmark of this syndrome is extreme liver enlargement from massive acucumulation of glycogen. The diagnosis of hepatopathy requires high clinical suspicion and the presence of glycogen accumulation must be corroborated with a liver biopsy. The accumulation of glycogen in hepatocytes is partly caused by long periods of hyperglycemia, in which glucose enters the hepatocyte independently of insulin and is converted to glycogen. Mauriac syndrome is currently a rare cause of liver disease, due to improvements in control and treatment of patients with DM1. However, some cases are described in people with complicated social situations or without therapeutic compliance. This is a reversible condition after improvement in glycemic control with adequate insulinization.

Predictive factors of diabetic nephropathy in type 2 diabetics
Sawsen Nouira, Taieb Ach, Asma Ben Abdelkarim, Ghada Saad & Molka Chadli Chaieb
Hospital Farhat Hached, Endocrinology, Sousse, Tunisia

Introduction
Uncontrolled hyperglycemia in diabetes is a common cause of microvascular complications, including diabetic nephropathy (DN). Despite improvements in the management of type 2 diabetes (T2DM), diabetic nephropathy is still associated with high morbidity and mortality. The objective of our study is to evaluate the predictive factors of DN in adults with T2DM in order to prevent its development.
Patients and Methods
A retrospective study, including 300 patients diagnosed with T2DM hospitalized in the endocrinology department of Farhat Hached Hospital in Sousse between 2018 and 2019. DN was defined with a persistent albuminuria (>300 mg/dl) that is confirmed on at least 2 occasions 3-6 months apart. Predictive factors for DN were determined by univariate logistic regression analysis.
Results
It is about 272 patients with a mean age of 58 years. The sex-ratio M/F was 0.7. The mean diabetes duration was 10 ± 8 years (1-44 years). DN was observed in 44% of patients. Approximately 91% of patients who had been diagnosed with DN were aged more than 50 years old ($P<10^{-3}$). DN was more frequent (93%) after 10 years evolution of diabetes ($P<10^{-3}$). Hypertension was present in 55% of patients with DN ($P=10^{-3}$). The mean systolic and diastolic BP were 130 ± 10 mm Hg and 70 mmHg, respectively. The majority of patients with DN (76%) had LDL-C levels above recommended targets ($P<10^{-3}$). The results of our study showed that 65% of patients with DN were not on statin therapy ($P<10^{-3}$). It was found that 69% of patients with DN had simultaneous diabetic retinopathy ($P<10^{-3}$). However, only duration of T2DM ≥ 10 years, age $>$ 50 years, LDL-C levels above recommended targets, no statin therapy and concurrent RD were significant in stepwise logistic regression analysis.
Conclusion
Our study suggests that the development of DN can be prevented by early control of its modifiable predictors such as: LDL-C levels which should be within the recommended targets with statin therapy.

The state of the kidney in patients with type 2 diabetes mellitus post-EVRP
Bakhodir Nigmonov & Shavkat Muminov
Tashkent Pediatric Medical Institute, Therapy, Tashkent, Uzbekistan

Aim
Determine the state of the kidneys by the concentration of blood creatinine in patients with type 2 diabetes in post-EVRP.
Materials and Methods
Patients with type 2 diabetes who underwent EVRP were included in the 1st stage of the study. 2 groups of patients: in whom CI-AKI developed in the post-procedural period (29 patients) and patients with an uncomplicated course of the post-procedural period (27 patients).
Results
In patients with type 2 diabetes in both groups, the initial creatinine concentration significantly exceeded the CG values (90.41 ± 1.85 μmol/l and 96.89 ± 1.40 μmol/l in the CI-AKI+ and CI-AKI- groups, respectively, versus 55.60 ± 2.53 μmol/l in the CG, the reliability of comparison of both groups of DM with CG was $P<0.001$). Moreover, in the CI-AKI- group, the creatinine concentration was slightly higher than in the CI-AKI+ group ($P<0.05$). On the 4th post-procedural day: the relative dynamics in the CI-AKI+ group was 65.06% vs 16.12% in the CI-AKI- group ($P<0.001$ significance of the difference in the relative dynamics between the groups). Subsequently, the creatinine concentration in both groups decreased, reaching the initial values in the CI-AKI+ group by the 10th day after EVRP, and in the CI-AKI- group, by the 6th day of observation and subsequently decreasing significantly below the initial values, which is probably due to both hydrations after EVRP, and the use of antiplatelet therapy, and lifestyle modification.
Conclusion
During the entire post-procedure period of observation in the CI-AKI- group, the blood creatinine concentration remained significantly lower than in the CI-AKI+ group ($P<0.001$ - significant intergroup difference on the 4th day).

Microvascular and macrovascular complications prevalence, mortality rate in type 2 diabetes patients with severe insulin resistance: A case-control study

Diana Simoniene[1], Gabrielė Čypaitė[2] & Emilė Rudminaitė[2]
[1]Lithuanian University of Health Sciences, Endocrinology, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Medical Academy, Kaunas, Lithuania

Some patients with type 2 diabetes mellitus (T2DM) suffer from severe insulin resistance (IR). There is still a shortage of research analyzing these patients. Relation between IR and diabetes complications, risk of mortality has been poorly described in patients with T2DM.

Objective

To evaluate the prevalence of microvascular and macrovascular complications, mortality in type 2 diabetes patients with severe insulin resistance.

Methods

It was a case control study. If T2DM patients received high insulin doses (>1 IU/kg/day) and their HbA1c $\geq 9\%$, they were assigned to the case group ($n=58$). Patients with lower insulin requirements (<1 IU/kg/day) and HbA1c $< 8\%$ were assigned to the control group ($n=62$). Participants of control group were matched by gender and BMI with the case group. Additionally, the insulin resistance was assessed according to validated eGDR (*estimated glucose disposal rate*) and HOMA-IR (*Homeostatic Model Assessment for Insulin Resistance*) mathematical formulae. HOMA-IR ≥ 2.5 indicates IR. eGDR <4 mg/kg/min reffer severe IR. Data was analyzed using SPSS 27.0 software. The level of statistical significance was set as $P<0.05$.

Results

Total of 120 participants were included, data are shown in Table 1.

Conclusions

1. Subjects with severe insulin resistance had higher daily insulin requirement, HOMA-IR value and lower eGDR.
2. The prevalence of microvascular and macrovascular complications, overall mortality in the groups was similar.
3. Diabetic neuropathy tended to be higher in the Case group.

Table 1 Baseline participant characteristics, distribution of micro- and macrovascular complications and mortality rate in the groups

Variable	Control group($n=62$)	Case group($n=58$)	*P* value
Sex, male, (*n* (%)	25 (40.3%)	28 (48.3%)	0.381
Age (years), m±SD	67.85±8.50	61.26±9.47	<0.001
HbA1c (%), m±SD	6.89±0.82	10.36±1.11	<0.001
INS/kg/d, m±SD	0.64±0.21	1.45±0.33	<0.001
HOMA-IR, median [min-max]	5.4 [3.75 - 10.05]	11.2 [6.95 - 48.41]	0.003
eGDR, m±SD	4.29±1.68	1.65±1.28	<0.001
Microvascular complications:			
Diabetic neuropathy, *n* (%)	53 (85.5%)	56 (96.6%)	0.055
Diabetic nephropathy, *n* (%)	15 (24.2%)	15 (25.9%)	0.833
Diabetic retinopathy, *n* (%)	29 (52.7%)	32 (47.3%)	0.831
Macrovascular complications:			
Stroke, *n* (%)	11 (17.7%)	8 (13.8%)	0.554
Myocardial infarction, *n* (%)	11 (17.7%)	15 (25.9%)	0.281
Coronary artery bypass graft surgery, *n* (%)	11 (17.7%)	7 (12.1%)	0.384
Overall mortality, *n* (%)	10 (16.1%)	14 (24.1%)	0.273

Cardiovascular risk factors associated with diabetic nephropathy

Ergita Nelaj, Margarita Gjata, Irida Kecaj & Mihal Tase
University Hospital Center "Mother Teresa", Internal Medicine, Tirana, Albania

Introduction

Diabetes is the leading cause of end-stage renal disease. Renal disease is a cardiovascular morbidity and mortality predictor which is three times more common in diabetic patients with diabetic nephropathy (DN). We aim to describe the factors of cardiovascular risk associated with DN in a group of type 2 diabetes patients.(T2D).

Materials and Methods

It was retrospective and descriptive study including 204 patients with T2D and confirmed DN, hospitalized in the Internal Medicine at UHC "Mother Teresa", between January to December 2021.

Results

There were 97 (47.5%) women and 107 (52.5%) men with mean age was 70.93 $\pm$ 9.64 years. The body mass index was 28.98 $\pm$ 6.24 kg/m^2. The average duration of diabetes was 11.35 $\pm$ 5.32 years. In 87.7% of cases, treatment for diabetes was insulin therapy. Microalbuminuria as incipient nephropathy was present in 104 patients and 100 patients had renal failure with GFR <90 ml/min. High blood pressure was present in 144 patients, 88% of whom were on ACE inhibitors. Other microangyopathic complications were present, such as diabetic retinopathy in 13.7% patients, 6 of which had a proliferative form and peripheral neuropathy in 25% patients. Ischemic heart disease was found in 36.6% of patients and angiopathy of the lower limbs in 11 patients. Hypertriglyceridemia was observed in 97 patients, hypo-HDL-cholesterolemia in 24 patients and hyper LDL-emie in 75 patients. 69.7% of patients had hiperuricemia. We noted a positive correlation between the DN stage and the severe of glycated hemoglobin (P0.002), as well as duration of diabetes. However, no significant correlation has been demonstrated between the micro and macro albuminuria and the triglyceride level, HDL cholesterol and the LDL cholesterol level.

Conclusions

Diabetic nephropathy increases the cardiovascular risk in T2D. Its prevention and management, requires an optimal glycemic and blood pressure control, in order to protect not only the kidney but also to reduce cardiovascular risk and thus to improve the quality of life of diabetics and their prognosis of life.

Effects of hypertension on the degenerative complications of diabetes

Eya Safi, Hajer Moalla, Emna Bornaz, Ben Ali Khaoula, Imen Ouderni, Yosra Htira & Feika Ben Mami
National Institute of Nutrition, C, Tunis, Tunisia

Introduction

High blood pressure and type 2 diabetes are two pathologies that are often closely linked. The objective of our work is to determine the prevalence of hypertension and its effects on degenerative complications in a type 2 diabetic population.

Methods

This is a retrospective study including 147 patients, followed at the Tunis National Institute of Nutrition for type 2 diabetes and comorbidities.

Results

The mean age of the patients was 57.52 $\pm$ 11.96 years with 66.7% women ($n=98$). The duration of diabetes was 11.42 $\pm$ 8.58 years. Average fasting glucose was 13.76 $\pm$ 5.15 mmol/l. Half had retinopathy (52.1%), one-third had neuropathy (33.3%) and 28.3% had diabetic nephropathy. Coronary insufficiency, peripheral artery occlusive disease (PAD) and stroke were found in 15.5%, 6.9%, and 4.8% of cases, respectively. High blood pressure was noted in 60.5% of patients. Its presence was positively correlated with age ($P<0.001$) and the duration of diabetes ($P<0.001$). The average fasting glucose was higher in hypertensive patients, but not significantly so ($P=0.89$). Retinopathy and neuropathy were more noted in the presence of hypertension ($P=0.2$ and $P=0.12$ respectively). The latter was significantly associated with diabetic nephropathy ($P=0.02$). It was also more frequent in the presence of coronary insufficiency ($P=0.002$). Hypertensive diabetics were also at greater risk of developing stroke or PAD ($P=0.2$ and $P=0.7$ respectively).

Conclusion

Hypertension was common and significantly associated with diabetic nephropathy and coronary insufficiency in our sample, hence the need for its early detection.

A Case Report: Why Continuous Glucose Monitoring in Conjunction with the GluCare. Health Care Model is Important in a Patient Newly Diagnosed with Type 2 Diabetes

Cigdem Ozkan, Yousef Said, Milena Caccelli, Begum Demircan, Yasmeen Manea, Joelle Debs, Carolyn Palsky, Ali Hashemi & Ihsan Almarzooqi
Glucare Integrated Diabetes Center, Dubai, United Arab Emirates

Introduction
Hypoglycaemia is one of the most important acute complications of diabetes. The fear of hypoglycaemia has a significant effect on the quality of life of patients and their families. It also remains a major barrier to achieve optimal glycaemic control. The GluCare Health care model is centered on the use of Continuous Metabolic Monitoring (CMM) and behavioural change to address metabolic diseases in a continuous manner. The Glucare program aims to provide continuous patient supervision and support through personalized lifestyle coaching and behavioural change and includes the use of wearables and continuous glucose monitors (CGM).
Case Report
A 42-year-old male patient presented with symptoms of polyuria and polydipsia. He was diagnosed with type 2 Diabetes Mellitus in another center. He had been advised empagliflozin/ metformin and insulin for diabetes management. Patient refused to use insulin and visited our clinic for his long-term treatment plan. His blood glucose: 109 mg/dl, HbA1c was 10%. There was nothing significant in his physical examination. Tirzepatide 2.5 mg/week, Empaglifozin/Metformin twice daily and onboarding into the GluCare platform was advised to him. In his follow up, after 14 days, according to his food logging and CGM data he received feedback from the dietician, diabetes educator and exercise / sleep recommendations from the health coaches. In the third week of his follow up, although it was not expected, he started to observe low blood glucose values in CGM which was also confirmed with a home blood glucose measurement device. Tirzepatide stopped and continued with empagliflozin/ metformin. Patient did not experience hypoglycaemia anymore. During his follow up his time in range was 95% and glucose management indicator was 5.9%.
Discussion/Conclusions
In a conventional healthcare model, patients with diabetes are evaluated episodically with both engagement and data gaps occurring between scheduled patient visits. Diabetic patients, especially those newly diagnosed, can be better managed when using platforms such as GluCare Health which includes the continuous monitoring and engagement of patients by their care team. CMM generates personalized data and is utilized by care teams to provide the necessary insights to help educate patients about their lifestyle choices and behaviour, in addition to evaluating medication choices, in a hyper-personalized manner to avoid non-compliance with treatment. Long term randomized controlled trials needed to evaluate the effect of CGM in conjunction with the GluCare.Health Care Model to prevent acute and long-term complications of diabetes.

EP357

Prevalence and Predictors of Chronic Complications of type 2 Diabetes Mellitus; our experience

Ergita Nelaj, Irida Kecaj & Mihal Tase
University Hospital Center "Mother Teresa", Internal Medicine, Tirana, Albania

The prevalence of type 2 diabetes (T2D) is rapidly increasing. Diabetes is a silent disorder leading to disabling and fatal complications. The long-term complications of diabetes affect almost every system in the body, especially the eyes, kidneys, heart, feet and nerves. Our aim was to examine the global prevalence and major risk factors for microvascular complications among people with T2D hospitalized in Internal Medicine.
Methods
We conducted a retrospective cohort study among patients hospitalized with T2D in one year. We evaluated these patients for microvascular complications, such as nephropathy, retinopathy, neuropathy, as well as for comorbidities.
Results
A total of 204 participants were included in this study. The mean age of participants was 70.93 ± 9.2 years old. 107 (52.5%) male and 97 (47.5%) woman. 13.7% of patients had diabetic retinopathy, 64.7% diabetic nephropathy and 25% diabetic neuropathy. There was a significant statistical relationship between these complications and HbA1C, as well as longer duration of diabetes. The most common concomitant diseases were: hypertension with a prevalence of 94.1%, dyslipidemia with a prevalence of 36.3% and CHD with a prevalence of 36.3%. Regarding the treatment of diabetes, 87.7% of patients were under treatment with insulin therapy and 15.7% with oral antidiabetics.
Conclusion
The prevalence of chronic complications was higher. Longer duration of diabetes, and poor glycemic control were predictors of chronic diabetes complications. Hypertension was the most frequent comorbidity in diabetic patients and the presence of hypertension accelerates the development of microvascular complications. It is important to achieve good glycemic control and manage comorbid diseases, to minimize the risk of chronic diabetes complications.

EP358

Gamma-GT blood levels and chronic complications of type 2 diabetes

Eya Safi, Ramla Mizouri, Ben Ali Khaoula, Zeineb Zemni, Imen Ouderni, Emna Bornaz, Nadia Ben Amor, Rym Ben Othman, Berriche Olfa, Faten Mahjoub & Jamoussi Henda
National Institute of Nutrition, A, Tunis, Tunisia

Objective
Our objective was to determine the relationship between mean blood gamma-GT (GGT) levels and chronic complications of type 2 diabetes.
Patients and Methods
This was a descriptive study including 89 diabetic patients followed at the department A of the National Institute of Nutrition in Tunis.
Results
The mean age was 56.44 ± 13.02 years. The mean GGT level was 54.77 ± 61.13 IU/l. Diabetes was uncontrolled in 93% of cases with a mean HbA1C of 10.7%. Diabetic retinopathy, nephropathy, and neuropathy were noted in 43%, 19%, and 26% of cases, respectively. Macroangiopathic complications were dominated by coronary artery disease (17%). The analytical study showed a statistically significant association between plasma GGT concentration and the presence of diabetic retinopathy ($P = 0.026$). Plasma GGT concentration was also higher in nephropathy and neuropathy ($P = 0.13$ and $P = 0.15$ respectively) but not significantly. Coronary and arterial patients had higher mean GGT ($P = 0.43$ and $P = 0.4$ respectively). The same was true for patients with a history of stroke, and significantly so ($P = 0.017$).
Discussion
GGT would induce an increase in oxidative stress and lipid accumulation in hepatocytes, thus leading to insulin resistance in hepatocytes[1]. It would therefore be a possible biomarker for the detection of diabetic complications.

Severe infections revealing type 2 diabetes: Epidemiological, clinical and therapeutic aspects

Zineb Ait Si Ali, Jaddi Oussama, Ghizlane El Mghari & Nawal El Ansari
Centre Hospitalo-Universitaire Mohammed VI Marrakech, Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Marrakech, Morocco

Introduction
Type 2 diabetes is an important risk factor for all forms of infection. It may be unrecognised for many years, and often revealed by degenerative or infectious complications. The aim of this study is to investigate the epidemiological, clinical and therapeutic aspects of severe infections revealing type 2 diabetes.
Patients and Methods
Retrospective descriptive cross-sectional study of a series of 5 patients with severe infections revealing type 2 diabetes.
Outcomes
The mean age of our patients was 44.8 years [33-49 years], with a 60% female predominance (3/5). The mean hemoglobin A1c at the time of diagnosis was 11.1% [8-14.3%]. Infections were: Kidney abscess, breast abscess, diabetic foot with phlegmon, pyo-pneumothorax, severe pneumonia. Ketoacidosis or ketosis decompensation was associated in 60% (3/5) of cases. The therapeutic management differed according to the type of infection. All patients had broad-spectrum intravenous antibiotic therapy and received insulin therapy. Discussion: Type 2 diabetes can remain silent for many years, often revealed by degenerative or infectious complications. It is an immunocompromising condition that predisposes to infections in all its sites. This appears to be related to deficits in the immune system, particularly changes in innate immunity. Respiratory infections, cutaneous and soft tissue infections, gastrointestinal and genitourinary infections all appear to occur more frequently in people with diabetes. Not only are they more frequent, but these infections seem to have a poorer response to treatment and a more rapid progression to severe forms of infection.
Conclusion
Infections revealing type 2 diabetes are common, and routine screening for diabetes in patients with severe or recurrent infections is necessary.

Hyperglycemia-induced hemichorea in a Diabetic patient with accompanying post stroke seizure: A case report

Christian Yecyecan & Jerome Barrera
Zamboanga Doctor's Hospital, Department of Internal Medicine, Zamboanga, Philippines

Background
Non-ketotic hyperglycemia hemichorea is a movement disorder characterized by irregular, involuntary and abrupt hyperkinetic movements caused by hyperglycemia. The pathophysiology remains unclear however there are several theories on its mechanism. The diagnosis is confirmed by presence of involuntary irregular movements combined with findings of hyperdensities on the basal ganglia in cranial computed tomography scan (CT-scan) or magnetic resonance imaging scan (MRI) .Pharmacologic goals of treatment include control of hyperglycemia and involuntary movements with several medications including anti-psychotics, GABA-receptor agonists, selective serotonin reuptake inhibitors or dopamine-depleting agents.
Case Presentation
A 74-year-old male known diabetic was admitted with complaints of involuntary movements on the left extremities accompanied by right sided facial spasms. The patient presented with elevated blood glucose on admission with a random blood sugar of 439 g/dl and an HbA1c level of 13.2%. He was admitted as a case of a post stroke seizure versus cerebrovascular infarct with poorly controlled Type 2 Diabetes Mellitus. A cranial computed tomography (CT-scan) was done which showed hyperdense lesions on the right caudate head. The post-stroke seizure was also confirmed by the presence of epileptiform discharges from the right frontal region on electroencephalogram (EEG). The patient's treatment focused on blood glucose control and anti-seizure medications. There was resolution of symptoms after blood glucose was controlled.
Conclusion
Nonketotic-Hyperglycemic hemichorea is a rare and poorly understood neurologic complication of Diabetes Mellitus. Control of blood glucose combined with pharmacologic therapy to control involuntary movements remain superior in management of symptoms with good prognosis.

EP361

Shingles manifesting as a vesicular rash only on the foot: A case report

Sameh Bougatf, Zohra Hadj Ali, Imen Hedfi, Chaima Jemai, Yosra Htira & Feika Ben Mami
National Institute of Nutrition, C, Tunis, Tunisia

Background
Shingles is dermatomal vesicular rash secondary to reactivation of latent varicella zoster virus. It is well recognized when it appears on the trunk, neck or face. Herpes zoster can be easily overlooked in case of dermatomal rash in lower extremity.
Observation
A 32-year-old diabetic female was hospitalized for diabetic ketoacidosis. She had trouble walking because of painful rash on the plantar surface of the right foot. She reported the development of a burning pain one day before the eruption. Crops of vesicular rash were present on the plantar surface of the right foot at the initial visit. A sensation of burning pain preceded the onset of the rash. These symptoms led to the diagnosis of herpes zoster. Antiviral local agent of valacyclovir was administered for 7 days. Skin lesions resolved within two week. She recovered from post herpetic neuralgia three months later.
Conclusion
Acute painful limb or new neurological complaint requires a thorough physical examination with skin assessment. Atypical dermatomal skin lesions may appear in second place suggesting the diagnosis of herpetic neuralgia. Apart from trunk, neck or face herpes zoster can manifest as a dermatomal rash in the lower extremity. Fatal consequences can take place if the diagnosis is missed and early treatment isn't instituted.

Predictive factors for the onset of urinary disorders in patients with diabetes mellitus: A case-control study

Faten Haj Kacem Akid , Abdel Mouhaymen Missaoui, Wafa Belabed, Siddiqa Soomauroo, Nabila Rekik Majdoub, Dhoha Ben Salah & Mohamed Abid Hedi
Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Objective
To assess the predictive factors for the occurrence of urinary dysfunction (UD) in patients with diabetes mellitus (DM).
Patients and Methods
Case-control study comparing two groups of patients suffering from DM: G1 ($n=159$) with UD vs G2 ($n=41$) without UD.
Results
G1 patients were older than G2 patients (59.7 ± 10.3 vs 58 ± 12 years) with no significant difference in gender. The duration of diabetes was significantly longer in G1 (11.9 vs 7.7 years; $P=0.03$). G1 patients were significantly more frequently insulin-requiring (62% vs 42.5%; $P=0.025$) but with an obvious delayed switch to insulin than G2 (7.6 vs 2.6 years; $P=0.011$). Mean HbA1C was statistically significantly worse in G1 (9.5% vs 8%; $P=0.01$). Microvascular complications were more reported in G1 ($P=0.021$). Macroangiopathy did not appear to be associated with UD in our series ($P=0.07$). The multivariate analysis identified long-standing diabetes (OR=1.07; $P=0.033$; CI95%=[1.01-1.16]), HbA1C> 7% (OR=0.38; $P=0.045$; CI95%=[0.15-0.57]) and peripheral neuropathy (OR=6.43; $P=0.000$; CI95%=[2.39-17.28]) as independent predictive factors for the development of UD in patients presenting with DM.
Discussion
A preventive strategy against the onset of UD in patients with DM should be considered by acting on modifiable predictive factors. The pillars of this strategy would be earlier detection of diabetes, more effective glycaemic control, timely use of insulin therapy, and delaying the onset of chronic complications.

Microbiocenosis state in patients with type 1 Diabetes Mellitus

Shakhnoza Akhmedova[1], Said Ismailov[1] & Zulaykho Shamansurova[1,2]
[1]Tashkent Pediatric Medical Institute, Endocrinology with Pediatric Endocrinology, Tashkent, Uzbekistan; [2]Institute of Biophysics and Biochemistry, Metabolomics, Tashkent, Uzbekistan

Introduction
Diabetes Mellitus (DM) is one of the Global pandemics despite to new knowledges and methods of prevention and therapy intensively increased among children, adolescents and adults. Many studies shown the role of the gastrointestinal microbiocenosis in the development and clinical future of DM. Gut microbiota produce numerous bioactive molecules, which can act locally and secreted into bloodstream. The aim of our study were evaluation of gut microbiota in children and adolescent with DM1.
Material and Methods
In 54 patients with MD1, 21 boys and 33 girls in age from 6 to 18 years old blood fasting glycemia, HbA1c level were measured; gut microbiome status were estimated by number of E.coli, lactobacillus, staphylococci, mycobacterium in feces using PCR.
Results
Fasting glycemia level in patients were varied between 5.9 and 13.1 and HbA1c level were 12.9 ± 0.3%. Results of studying the violation of gut microbiocenosis in children with type 1 diabetes showed decrease in the total number of anaerobes and active reproduction of aerobes, including opportunistic pathogens. Thus, they had a deficiency in the total number of anaerobes, bifidobacteria and lactobacilli were found in 100% of cases ($P < 0.01$). At the same time, the content of almost all aerobes significantly increases, especially lactose-negative Escherichia coli, fungi of the genus Candida and Proteus - 6.86 ± 0.165; 6.21 ± 0.28; 4.8 ± 0.32 lg CFU/g, respectively. The most characteristic decrease in the number of lactose-positive Escherichia coli to 6.75 ± 0.59 lg CFU/g against the basic increase in the content of lactose-negative Escherichia coli, enterobacteria, staphylococci, fungi of the genus Candida, especially Proteus ($P<0.001$). Dysbiotic changes in most cases were accompanied by the isolation of bacteria of the opportunistic pathogenic group. Intestinal microflora had differences depending on the duration of the disease and dysbiotic changes were more pronounced in those with disease duration more than 6 years, than those with less than 3 years.
Conclusion
Gut microbiocenosis were changed in patients with DM1 where disbiotic changes shown in decreasing of anaerobes and increasing of aerobes, including opportunistic pathogens. Gut microbiome state may reflected on glycemia level and depends from duration of diabetes.

Erectile dysfunction: An early warning sign of urinary disorders in men suffering from diabetes

Faten Haj Kacem Akid, Abdel Mouhaymen Missaoui, Siddiqa Soomauroo, Oumeyma Trimeche, Nabila Rekik Majdoub, Dhoha Ben Salah & Mohamed Abid Hedi
Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Objective
To determine the prevalence and analyze the predictive value of erectile dysfunction (ED) in the occurrence of fictional disorders (MD) in men with diabetes mellitus (DM).
Patients and Methods
Cross-sectional study of 90 men presenting with DM. A comparative analysis was performed between two subgroups: G1 ($n=75$) with MD vs G2 ($n=15$) without MD.
Results
G1 patients were older than G2 (59.7 ± 10.3 vs 58 ± 12 years). The duration of diabetes was significantly longer in G1 (11.9 vs 7.7 years; $P=0.03$). G1 had poorer glycaemic control than G2, as the mean HbA1C was statistically more impaired in G1 (9.5% vs 8%; $P=0.01$). Microvascular complications were more frequent in G1 ($P=0.021$), notably diabetic retinopathy ($P=0.07$), diabetic nephropathy ($P=0.02$), and peripheral neuropathy ($P=0.000$). Diabetic macroangiopathy was not associated with urinary disorders ($P=0.07$). There was a significantly higher prevalence of ED in G1 (23.3%) compared to G2 (7.5%); $P=0.021$. Multi-variate logistic regression confirmed that ED was an independent predictor of MD in men with DM with an Odds Ratio of 3.61 ($P=0.005$; 95% CI=[0.95-13.74]). Discussion: ED and MD are two manifestations of diabetic dysautonomia secondary to alteration of the autonomic nervous system and bladder-sphincter dyssynergia. ED, an earlier condition, should prompt the clinician to screen for and treat possible underlying urinary disorders.

Co-occurrence of diabetic ketoacidosis and acute pancreatitis in patients with type 1 diabetes mellitus: Clinical and biological peculiarities

Abdel Mouhaymen Missaoui, Fatma Mnif, Siddiqa Soomauroo, Mouna Elleuch, Rihab Khochtali, Mouna Mnif, Nabila Rekik Majdoub, Dhoha Ben Salah & Mohamed Abid Hedi
Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Objective
To describe the clinical and biological presentation of acute pancreatitis (AP) and diabetic ketoacidosis (DKA) in type 1 diabetes (T1D).
Patients and Methods
A retrospective descriptive study of 10 T1DM patients with simultaneous DKA and AP.
Results
The mean age at diagnosis of T1DM was 19.7 ± 9.3 years with a female predominance (60%). T1DM was frequently inaugurated by a cardinal syndrome (50%) or spontaneous DKA (20%). In 10%, T1DM was diagnosed at the time of AP. The mixed AP-DKA episode occurred at a mean age of 26.9 ± 14.9 years. A febrile state (30%) with altered general condition (20%) and severe dehydration (10%) was often reported. Respiratory and neurological signs were present in 20%. Digestive signs were prominent, notably epigastralgia (90%), vomiting (50%), and diarrhea (20%). Acetonuria was massive in 50% with mean blood glucose levels of 3.2 ± 1.4 g/l. Metabolic acidosis was noted in all cases with mean pH and bicarbonate values of 7 ± 0.3 and 12.3 ± 8.3 respectively. Functional renal failure complicated the course of 10% of cases. An infectious syndrome accompanied 40% of cases with a mean CRP of 47 ± 72.9 mg/l. The evolution was favorable in all patients after appropriate treatment with an estimated insulin requirement of 0.76 ± 0.3 IU/kg/d.
Discussion
The co-occurrence of DKA and AP in T1DM is a relatively rare but potentially serious event due to the mutually deleterious effects of these two conditions. The outcome of this mixed emergency depends on early diagnosis and prompt intervention.

Diabetic peripheral neuropathy: Prevalence and predictive factors

Lamya Echchad, Kaoutar El Moatamid, Manal Azriouil, Kaoutar Rifai, Hinde Iraqi & Mohamed El Hassan Gharbi
Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction
Diabetic peripheral neuropathy (DPN) is a frequent complication of diabetes mellitus. The aim of our work is to determine the prevalence as well as the predictive factors of this degenerative complication and as a secondary endpoint the evaluation of the risk factors associated with painful diabetic neuropathy.
Methods
